maxilla. Mandibular angle somewhat obtuse, the cleft of the mouth equalling half the width of the gape Uncovered space on chin very narrow, lanceolate. A shallow groove before the vomer. Teeth—visible in the upper jaw. Fins—the first dorsal commences midway between the snout and the base of the caudal, its first two spines, which are not very strong, are of about the same length, and equal the length of head behind the posterior third of the orbit. Second dorsal 1/3 higher than its base is long, its origin is a little posterior to that of the anal. Pectoral as long as the head excluding the snout, and reaching to the eleventh or twelfth scale of the lateral-line, third anal spine 3/7 of the length of the head. Scales—each with distinct longitudinal lines, rather angular and slightly ctenoid, 21 or 22 rows between the snout and base of first dorsal fin; the eleventh and twenty-second scales of the lateral-line correspond to the origin of the first and second dorsal fins: no elongated axillary one, some fine ones over the second dorsal and anal fins. Free portion of the tail at its least depth equals the length of the head behind the middle of the eye. Colours—a golden spot on the upper portion of the opercles, sometimes dark in the axilla, a narrow dark edge to both dorsal fins, most distinct in the second: caudal with a yellowish base and dark extremity.

Habitat.—Seas and estuaries of India: attaining 5 or 6 inches in length. The one figured (life-size) is

from the Hooghly at Calcutta.

6. Mugil belanak, Plate LXXIV, fig. 5.

Bleeker, Java, iv, p. 337; Günther, Catal. iii, p. 427.

B. vi, D. 4 | $\frac{1}{6}$, P. 15, V. 1/5, A. $\frac{3}{9}$, C. 16, L. 1. 34-35, L. tr. 10.

Length of head $5\frac{1}{4}$, of caudal 6, height of body $5\frac{1}{2}$ in the total length. Eyc—with a broad posterior eyelid which reaches half way across the iris, diameter of eye 2/9 of length of head, 1 diameter from end of snout, and 2 apart. Interorbital space slightly convex, and equal to $2\frac{1}{4}$ in the length of the head. Width of the head equals its length behind the middle of the eye, its height equals its width. Preorbital deeply notched, serrated both inferiorly and posteriorly, the end of the maxilla is uncovered. The maxilla remarks a rather and the state of the state acute angle, where they are notched: uncovered space at chin rapidly narrows posteriorly, rounded anteriorly. Upper lip of moderate thickness, its upper portion forms part of the end of the snout. A groove before the vomer. Cleft of mouth equals half of its width. Teeth—distinct in the upper jaw. Fins—dorsal spines strong, the fin arises midway between the end of the snout and the base of the caudal, its second spine the longest and equal to half the height of the body, but 1/4 shorter than the height of the second dorsal fin, which latter commences slightly behind the anterior origin of the anal, both densely scaled. Pectoral as long as the head behind the middle of the eye. Third anal spine equals 1/3 of the length of the head. Scales—18 rows between snout and origin of first dorsal fin: first and second dorsal fins arise respectively above the eleventh and twentieth scales of the lateral-line. No enlarged axillary scale. Free portion of tail equals the length of the head behind the middle of the eye. Colours—silvery, darkest along the back.

Habitat.—Seas of India to the Malay Archipelago. The specimen figured (life-size) is from Bombay.

7. Mugil poicilus, Plate LXXV, fig. 4.

Day, Proc. Zool. Soc. 1865, p. 33, and Fish. Malabar, p. 140, pl. ix. Mugil cunnumboo, Day, Fish. Malabar, p. 141.

B. vi, D. 4 $\left(\frac{1}{8}, P. 15, V. 1/5, A. \frac{3}{9}, C. 14, L. 1. 30.33, L. tr. 10.11, Cæc. pyf. v.$

Length of head $4\frac{3}{4}$ to 5, of pectoral 7, of caudal 5 to $5\frac{1}{2}$, height of body 5 in the total length. Eyewith a moderately broad posterior adipose lid and a narrow anterior one, diameter $3\frac{1}{2}$ to $3\frac{3}{4}$ in length of head, 3/4 of a diameter from end of snout, and $1\frac{1}{2}$ to $1\frac{3}{4}$ apart. Width of the head equals its height, and its length behind the middle of the eyes. Interorbital space nearly flat. The anterior portion of the snout is formed by the upper lip which is thin. The depth of the cleft of the mouth equals half the extent of the gape. Extremity of the maxilla not concealed by the preorbital which is scaled, angularly bent and serrated. Uncovered space on chin, elongated and tongue-shaped. A transverse groove in front of vomer. Teeth—fine ones in the upper jaw, minute in the lower. Fins—the first dorsal commences above the tenth scale of the lateral-line, has from 20 to 22 rows between it and the snout, and is somewhat nearer the base of the caudal than the end of the snout, its spines are strong, as long as the head behind the eyes, and 1/8 higher than the rays of the second dorsal. Second dorsal commences slightly behind the origin of the anal, above the twentieth scale of the lateral-line, and is one-third higher than long at its base. Caudal emarginate. Scales—slightly ctenoid, no elongated one in the axilla, or along the base of the first dorsal fin, fine ones over second dorsal, anal, and caudal fins. The least depth of the free portion of the tail equals the length of the head behind the eyes. Colours—grayish, shot with purple and silver, becoming lighter on the sides and below, each scale has usually a deep central black spot: fins stained with gray.

M. cunnumboo is the same fish, but without the black spots, having instead brownish stripes along each row of scales, it is the adult form, but in some of my specimens two-thirds grown, a very few black spots are

apparent.

Habitat.—Bombay and the Western coast of India, more especially in the cold months. The one figured (life-size) is from Bombay. It attains at least 2 feet in length.

8. Mugil Kelaartii, Plate LXXV, fig. 1.

Günther, Catal. iii, p. 429.

B. vi, D. 4 | $\frac{1}{8}$, P. 15, V. 1/5, A. $\frac{3}{9}$, C. 17, L. 1. 33, L. tr. 10.

Length of head 5, of caudal $5\frac{1}{4}$, height of body $4\frac{1}{2}$ to 5 in the total length. Eye—with a broad posterior adipose lid nearly reaching the pupil, and a narrow anterior one, diameter of eye 1/4 of length of head, nearly 1 diameter from end of snout, and $1\frac{2}{3}$ apart. The width of the head equals its length behind the middle of the eyes, and its height equals its length excluding the snout. Interorbital space convex and its width equals 3/7 of the length of the head. of the length of the head. Profile from occiput to snout rather convex. Preorbital bent, having a slight notch, serrated inferiorly and posteriorly, and leaving the extremity of the bent maxilla visible. Upper lip rather thin, placed obliquely so that it does not form a portion of the anterior edge of the snout. Mandibles meet at a right angle, are notched at their extremity, and have a knob above the symphysis. The extent of the cleft equals half the width of the gape. Uncovered portion of the chin long, narrow, lanceolate, and constricted on either side about its middle. A shallow groove before the vomer. Teeth—minute in the lower jaw. Fins—first dorsal commences midway between the end of the snout and the base of the caudal, its spines are of moderate strength, equal 3/5 of the length of the head, and are nearly as high as the second dorsal. Length of the base of the second dorsal equals 2/3 of its height. Pectoral inserted above the middle of the depth of the body. Anal has its anterior 1/3 in advance of the origin of the second dorsal. Caudal emarginate, its central rays as long as the postorbital portion of the head. Scales—an elongated pointed one in the axilla: 19 rows of scales between the snout and base of the first dorsal fin, the tenth and twentieth of the lateral-line correspond to the origins of the first and second dorsal fins: second dorsal, anal, and caudal densely scaled. Free portion of the tail in its least depth corresponds to the length of the postorbital portion of the head. Colours—silvery, becoming lighter on the sides and beneath, a darkish spot in the axilla: tips of both dorsals and caudal dark.

Habitat.—Seas of India, Philippines. The one figured (life-size) is from Madras.

9. Mugil Jerdoni.

Mugil Sundanensis, Day, Fish. Malabar, p. 138 (not Bleeker). B. vi, D. 4 | $\frac{1}{8}$, P. 16, V. 1/5, A. $\frac{3}{6}$, C. 15, L. 1. 31-32, L. tr. 10.

Length of head 5 to $5\frac{1}{2}$, of caudal 5, height of body 5 in the total length. Eye—with a broad posterior adipose lid almost reaching to the pupil, and a narrow anterior one, diameter $3\frac{1}{2}$ in the length of head, 1/2 a diameter from end of snout, and $1\frac{1}{2}$ diameters apart. Interorbital space slightly convex, and its width equal to 21 in the length of the head. The height of the head equals its length behind the first third of the eye: its width is slightly less. Preorbital strongly bent and serrated, leaving the end of the bent maxilla visible. Mandibles meet at a somewhat obtuse angle, and are notched, the depth of the cleft of the mouth equals half the extent of its gape: uncovered space at chin narrow, rounded anteriorly, pointed posteriorly. Upper lip of moderate thickness, it forms the end of the snout in the median line. A slight groove in front of vomer. Teeth—distinct in the upper jaw. Fins—first dorsal commences slightly nearer to the snout than it does to the base of the caudal fin, its spines are stout, the longest equals 2/3 of the height of the body below them and are slightly higher than the second dorsal. Pectoral inserted above the middle of the depth of the body, and is as long as the head excluding the snout. The anal is of the same height as the second dorsal, its anterior 1/2 is before the origin of that fin, third anal spine from 3/7 to 2/5 of length of head. Scales—18 rows between the snout and base of first dorsal fin, the tenth and nineteenth correspond to the origins of the first and second dorsal fins. No elongated axillary scale: second dorsal, anal, and caudal densely scaled. Free portion of the tail in its least depth equals the length of the postorbital portion of the head. Colours—steel blue along the back, becoming silvery white on the sides and below. Cheeks tinged with yellow, a black spot over the centre of the eye. Both dorsals with their extremities rather stained with gray, caudal and pectoral dark edged: a rather indistinct spot of gray in the axil of the pectoral fin, sometimes a diffused dark-bluish spot on opercle: ventrals and anal white.

I have named this species after the late Dr. Jerdon, who both directly and indirectly assisted in clearing

up many disputed facts in the Ichthyology of India.

This species is near M. Kelaartii, but has a larger eye and a different disposition of its second dorsal and anal fins, &c. M. engeli also appears to closely resemble it, but has an elongated axillary scale, dorsal spines

Habitat.—Seas of India to at least 6 inches in length.

10. Mugil Dussumieri, Plate LXXIV, fig. 4.

Mugil albula? Ham. Buch. Fish. Ganges, pp. 218, 380 (not Bonn.) and M. lævis, MSS. Mugil Dussumieri, Cuv. and Val. xi, p. 147.
Mugil subviridis, Günther, Catal. iii, p. 423, (? Cuv. and Val.)

Mugil nepalensis, Günther, l. c. p. 424.

B. vi, D. 4 | $\frac{1}{8}$, P. 16, V. 1/5, A. $\frac{3}{8}$, C. 15, L. 1. 29-31, L. tr. 12.

Length of head 5 to $5\frac{1}{4}$, of caudal $5\frac{1}{3}$, height of body $4\frac{1}{4}$ to 5 in the total length. Eyes—with a broad posterior and narrow anterior adipose lid, diameter of eye 4 to $4\frac{1}{4}$ in length of head, 3/4 to 1 diameter from end

of snout, and 2 apart. The greatest width of the head equals its height, or its length excluding the snout. The profile from the first dorsal fin to the snout nearly horizontal. Preorbital scaled, bent, emarginate, and denticulated both inferiorly and posteriorly: the end of the maxilla is not concealed. Upper lip moderately thin and forms a portion of the front end of the snout. The mandibles form an obtuse angle, the uncovered space on the chin is lanceolate: gape of mouth twice as broad as the cleft is deep. Teeth-distinct in the upper jaw. Fins—the first dorsal commences midway between the front edge of the eye and the base of the caudal fin, its spines are strong, the first the longest and strongest, equalling the length of the head behind the middle of the eye, and rather higher than the second dorsal. Pectoral inserted above the middle of the depth of the body, as long as the head excluding the snout, and reaching to the seventh scale of the lateral-line. Anal having its anterior half situated before the commencement of the second dorsal, its third spine equals 3/8 of the length of the head, and is 1/4 longer than the second. Caudal emarginate. Scales—their exposed portion angular, no enlarged elongated one in the axilla, but one at the first dorsal and ventral fins: 18 rows of scales between the snout and the base of the first dorsal fin: the ninth and twentieth scales of the lateral-line correspond to the origins of the first and second dorsal fins: second dorsal, anal, and caudal densely scaled. Free portion of the tail in its lowest portion equalling 2/3 of the length Colours—dull greenish superiorly, becoming lighter on the sides and beneath: outer edge of caudal dark.

Hamilton Buchanan has left a MS. figure of this species, which is closely allied to, if not identical with, M. subviridis, C. V.: the latter however has no teeth in the jaws in the typical specimen which is at Paris. Habitat.—Seas of India, entering fresh water. The specimen figured is from the Hooghly at Calcutta.

11. Mugil subviridis.

Cuv. and Val. xi, p. 115; Day, Fish. Malabar, p. 138.

B. vi, D. 4 | $\frac{1}{8}$, P. 16, V. 1/5, A. $\frac{3}{9}$, C. 15, L. 1. 30, L. tr. 11.

Length of head 5, of caudal $6\frac{1}{2}$, height of body $4\frac{3}{4}$ in the total length. Eye—with a broad posterior and narrow anterior adipose lid, diameter of eye 1/4 of length of head, 3/4 of a diameter from end of snout, and $1\frac{3}{4}$ apart. Preorbital strongly bent and serrated, the end of the maxilla visible. Uncovered space below the chin narrow and lanceolate. Teeth—absent. Fins—20 rows of scales between the snout and first dorsal fin. Pectoral reaches to the seventh scale of the lateral-line. Scales—exposed portion angular, tenth and twentieth scales of lateral-line correspond to the origins of first and second dorsal fins. Second dorsal and anal densely scaled. No elongated axillary scale. Colours—as in M. Dussumieri.

Habitat.—The type specimen of Cuv. and Val. described above was from the Ganges.

B. vi, D. 4 | $\frac{1}{8}$, P. 15, V. 1/5, A. $\frac{3}{8}$, C. 15, L. l. 42-44, L. tr. 14.

Length of head $4\frac{1}{2}$ to $4\frac{2}{3}$, of caudal $4\frac{3}{4}$, height of body $5\frac{1}{3}$ to $5\frac{2}{3}$ in the total length. Eyes—with broad anterior and posterior adipose lids, both of which reach the pupil, diameter $4\frac{2}{3}$ in length of head, 1 diameter from end of snout, and $2\frac{1}{3}$ apart. Interorbital space flat and its width equal to half the length of the head: the dorsal profile from the snout to the base of the first dorsal fin is nearly horizontal. The greatest width of the head equals its length behind the middle of the eyes. Preorbital scaled, neither notched nor bent, its lower and posterior edges serrated, the maxilla only visible as a narrow strip or even quite concealed. Upper lip thin, and in the mesial line forms the front end of the snout. The mandibles join at a right angle, are notched at their point of junction and have two small open glands beneath them. Uncovered space on chin rather broad and rounded anteriorly, narrow and lanceolate posteriorly. The extent of the cleft of the mouth is a little more than half the width of its gape. Teeth—distinct in both jaws. Fins—the first and second dorsal fins commence above the twelfth and twenty-fifth scales of the lateral-line. The origin of the first dorsal is midway between the end of the snout and the base of the caudal, its spines are rather strong, the first is as long as the head behind the eye, and slightly exceeds the height of the second dorsal, the extent of the base of which last fin equals three-fourths of its height. Pectoral situated above the middle of the depth of the body, as long as the head behind the eye and extending to the eleventh scale of the lateral-line. Anal arises opposite the second dorsal, is of equal height, but its base is slightly longer, both fins are emarginate. Caudal with pointed lobes. Scales-rounded, a rather large pointed axillary one and another along the base of the first

Digitized by Google

dorsal. About 23 rows of scales between the snout and origin of the first dorsal fin: few or none on Second dorsal and anal fins. Free portion of the tail, in its least depth, equal to $2\frac{1}{3}$ in the length of the head. Colours—grayish along the back, becoming silvery on the sides and beneath, a dark line along each row of scales in the upper half of the body. Cheeks golden. Pectoral fin with an oblique, deep blue band across its base, having its outer third dark with a light margin. Second dorsal and caudal gray: anal yellowish with a dark mark along the court of the court of the same and a light of the same and a proper second dorsal and caudal gray: a dark mark along its centre, and a light edge. Some specimens have a black edge to caudal fin and appear very similar to M. Borbonicus, C. V.,* height of body 43 in the total length.

This species is identical with M. cephalotus, C. V., which was identified with Forskal's M. oeur. I

have obtained it along the Meckran coast.

The season for capturing these fishes along the western coast of India commences about the middle of November, when they swarm close inshore in order to enter estuaries and the mouths of large rivers to deposit their ova, they continue very numerous until about February. Their roes are collected and dried in the sun with or without the use of salt.

Habitat.—Red Sea, seas of India to China and Japan. It attains at least 3 feet in length. The specimen figured (life-size) is from Bombay.

B. No adipose cyclids.

13. Mugil corsula, Plate LXXI, fig. 6.

Ham. Buch. Fish. Ganges, pp. 221, 381, pl. 9, f. 97; Cuv. and Val. xi, p. 119; Bleeker, Beng. en Hind. p. 101; Eyd. and Soul. Voy. Bonite, Zool. i, p. 172, pl. 4, f. 2; Günther, Catal. iii, p. 460. Kakunda, Ooriah; Hurd-wah-re, Punj.; Corsula and In-ge-lee, Beng.; Undala, Hind.; Nga-zen, Burma.

B. vi, D. 4 | $\frac{1}{7 \cdot 8}$, P. 15, V. 1/5, A. $\frac{3}{9}$, C. 15, L. l. 48-52, L. tr. 15, Cæc. pyl. ii.

Length of head $4\frac{1}{4}$ to $4\frac{3}{4}$, of pectoral $5\frac{1}{2}$, of caudal 6, height of body 6 to $6\frac{1}{4}$ in the total length. Eyes—without adipose lids, elevated, their upper margin being above the level of the flat, interorbital space, diameter 1/7 of length of head, 1 diameter from end of snout, and 1 to $1\frac{1}{2}$ apart. Greatest width of the head equals its postorbital length and its height equals a little more. Head depressed, dorsal profile nearly horizontal. Mouth angular, the upper jaw the longer and overhung by the snout. Preorbital not notched, serrated, and does not conceal the end of the maxilla which reaches to below the middle of the eye. Upper lip thick. Teeth—a single row of fine ones in either jaw. Fins—the first dorsal commences above the sixteenth scale of the lateral-line and somewhat nearer to the base of the caudal than the end of the snout, it has about 28 rows of scales between it and the snout, its spines are about 1/2 as long as the head excluding the snout. The second dorsal arises above the thirty-fourth scale of the lateral-line: anal with its first seven rays anterior to the second dorsal. Caudal slightly emarginate. Scales—finely ctenoid, with a slightly raised line along the centre of each: a few on the second dorsal, anal, and caudal fins. No elongated axillary scale. Colours-dull brown superiorly, becoming lighter along the abdomen, dorsal and caudal fins stained with gray. Eyes of a golden colour. Peritoneum black.

These fish swim with their eyes just above the surface of the water, giving the appearance of a number

of tadpoles. Immediately they are disturbed they dive down with great rapidity.

Habitat.—Rivers and estuaries of Bengal and Burma, found far above tidal influence in the fresh water. It attains a foot-and-a-half or more in length, and is excellent eating. The one figured (life-size) is from Calcutta.

14. Mugil Hamiltonii, Plate LXXV, fig. 5.

Day, Proc. Zool. Soc. 1869, p. 614.

B. vi, D. 4 | $\frac{1}{8}$, P. 13, V. 1/5, A. $\frac{3}{9}$, C. 15, L. l. 44, L. tr. 18.

Length of head $4\frac{1}{4}$ to $4\frac{1}{2}$, of caudal 5, height of body $4\frac{1}{4}$ to 5 in the total length. Eyes—without adipose lids, diameter 2/7 to 1/4 of length of head, 1 diameter from end of snout, and $1\frac{1}{3}$ apart. Height of head equals slightly convex, its width equal to one-third of the length of the head. Mouth rather wide, its cleft equal to half its gape, the mandibular angle somewhat obtuse. Lips rather thin, the upper forming the end of the snout: the maxilla bent but not quite concealed by the preorbital, which latter is not notched but strongly denticulated, with from 10 to 16 strong teeth, the five at its posterior edge being almost spinate. The distance between the nostrils equals half a diameter of the orbit. Uncovered space on chin very narrow and lanceolate. Opercle with a strong spine. Tecth—none visible. Fins—the first dorsal arises midway between the anterior edge of the eye and the base of the caudal fin, above the seventeenth scale of the lateral-line, its longest spine equals the distance between the middle of the eye and the end of the opercle: second dorsal as high as the first, it commences over the anterior third of the anal. Pectoral as long as the head excluding the snout. Caudal rather deeply lunated. Scales—no enlarged one in axilla, they are strongly ctenoid, with a raised line along each: 34 rows between the snout and base of first dorsal fin: some large ones along the base of the first dorsal:

* M. Borbonicus, C. V., has L. l. 42, L. tr. 15, the dorsals arise as in M. ocur, but the height of the body is 41 in the total length, and the second dorsal is rather higher than the first.

a few on the vertical fins. The least depth of the free portion of the tail equals half the length of the head. Colours—silvery, shot with gold, of a leaden colour along the upper half of the body.

Habitat.—Rivers of Burma to about 41 inches in length.

15. Mugil seheli.

B. vi, D. 4 | $\frac{1}{8}$, P. 15, V. $\frac{1}{5}$, A. $\frac{3}{9}$, C. 16, L. 1. 42-43, L. tr. 13-14.

Length of head $4\frac{2}{3}$ to 5 ($6\frac{1}{5}$), of caudal $5\frac{1}{2}$, height of body $4\frac{2}{3}$ to $5\frac{1}{2}$ in the total length. Eyes—without adipose lids, diameter $3\frac{1}{2}$ to 4 in the length of head, 1/2 a diameter from end of snout, and $1\frac{1}{2}$ to 2 diameters apart. The width of the head equals its length behind the first third of the eye, its height equals it length excluding the snout. Preorbital scarcely emarginate, denticulated at its extremity: the end of the maxilla visible, sometimes concealed: upper lip forms the end of the snout. Fins—the first dorsal commences midway between the snout and the base of the caudal fin, it is not quite so high as the second, which last is a little lower than the anal. Pectoral nearly as long as the head. Anal commences slightly before the second dorsal. Caudal emarginate. Scales—21 or 22 between the snout and base of first dorsal fin, the twelfth and twentyfourth scales of the lateral-line correspond to the origins of the first and second dorsal fins, soft dorsal and anal scaly. A long axillary scale. Free portion of the tail in its least depth equals 1/2 the length of the head. Colours—silvery, with a bluish-green tinge along the head and back: a black mark in the axilla. Ventrals

Habitat.—From the Red Sea through those of India to the Malay Archipelago. It attains at least a foot in length.

16. Mugil crenilabris.

Forsk. Desc. An. p. 73; Cuv. and Val. xi, p. 123; Rüpp. N. W. Fische, p. 132; Günther, Catal. iii, p. 458; Kner, Novara Fische, p. 228; Klunz. Verh. z. b. Ges. Wien, 1870, p. 826.

B. vi, D. 4 | $\frac{1}{8}$, P. 17, V. 1/5, A. $\frac{3}{9}$, C. 16, L. l. 41, L. tr. 13.

Length of head $4\frac{2}{3}$ to 5, of caudal $5\frac{1}{2}$, height of body $4\frac{2}{3}$ to 5 in the total length. Eyes—without adipose lids, diameter $3\frac{1}{2}$ in length of head, 3/4 of a diameter from end of snout, and $1\frac{3}{4}$ apart. Profile from upper edge of snout to base of first dorsal fin nearly horizontal: snout obtuse, projecting beyond the mouth. Preorbital bent, not notched, serrated posteriorly: the end of the maxilla just visible. Upper lip very thick, forming the end of the snout, and having about five rows of soft tubercles along its lower fourth, the inferior of which are branched at their extremities: lower lip thick, reflected, deficient opposite the notched symphysis, it is thickly studded with tubercles along its upper exposed surface. Mandibles meet at rather an obtuse angle. Free space beneath the chin narrow. Teeth—none visible. Fins—first dorsal commences midway between the front edge of the eye and the base of the caudal fin, its spines are not strong, as long as the postorbital length of the head and 3/4 the height of the second dorsal. The length of the base of the second dorsal equals 2/3 of its height. Pectoral nearly as long as the head, it reaches to the fifteenth scale of the lateral-line and is inserted above the middle of the depth of the body. Anal arises opposite the second dorsal, the length of its base equals 2/3 of its height, which latter equals that of the second dorsal. Caudal deeply forked, its central rays equal the length of the head behind the last third of the eye. Scales—20 rows between the snout and base of the first dorsal: thirteenth and twenty-fourth scales of the lateral-line correspond to the origins of the first and second dorsal fins: second dorsal, anal, and base of caudal scaled. No enlarged axillary scale. Free portion of the tail as long as the head behind the last third of the eye. Colours-greenish-brown along the back, becoming dull white on the sides and below. A black spot superiorly at the base of the pectoral.

Habitat.—Red Sea to the Andamans and Nicobars. I captured one specimen 41 inches in length at the

Andamans.*

17. Mugil cascasia, Plate LXXV, fig. 6.

Ham. Buch. Fish. Ganges, pp. 217, 380; Cuv. and Val. xi, p. 145. Cuck-se or Buah, Punj.

B. vi, D. 4 | $\frac{1}{8}$, P. 15, V. 1/5, A. $\frac{3}{8-9}$, C. 14, L. l. 36-39, L. tr. 16-18, Cec. pyl. ii (short).

Length of head $4\frac{1}{2}$, of caudal $5\frac{1}{2}$ to 6, height of body $4\frac{1}{2}$ to $5\frac{1}{4}$ in the total length. Eyes—without adipose lids, diameter $3\frac{1}{4}$ to 4 in length of head, 3/4 to 1 diameter from end of snout, and $1\frac{1}{4}$ apart. Head flattened superiorly, its greatest width equals its length behind the middle of the eyes, its height equals its length excluding the snout, and the width of the interorbital space $2\frac{1}{2}$ in the length of the head. Mouth wide, its cleft

In my paper on the Fishes of the Andaman islands, P. Z. S. 1870, p. 685, for Mugil macrochilus, Blocker, M. labiosus and M. crenilabris, should be substituted, the remarks respecting them as food belong to M. coruleo maculatus.

Digitized by GOOQ

being only one third of the extent of its gape: the mandibular angle very obtuse. Upper lip placed obliquely so that it does not form a part of the front of the snout. The end of the maxilla is partially concealed by the preorbital, which is large, slightly bent, serrated along its lower margin and with three spinate denticulations at its posterior extremity. Opercle with a strong spine. Uncovered space on chin somewhat lanceolate. Teeth—minute, but present in both jaws. Fins—the first dorsal commences much nearer to the snout than to the base of the caudal fin, its origin is above the seventh scale of the lateral-line, there are 16 rows between it and the snout, its second spine the longest, equalling the length of the head excluding the snout and 1/3 higher than the second dorsal. The second dorsal arises above the twenty-fourth scale of the lateral-line and opposite the anal, the third anal spine equals 3/7 of the length of the head. Pectoral as long as the head excluding the snout, situated in the middle of the depth of the body, and having a short, angular, somewhat large but not elongated axillary scale. Caudal lunated. Scales—very strongly ctenoid, having a slightly raised line along each: a few over the bases of the vertical fins. The least depth of the free portion of the tail equals half the length of the head. Colours—yellowish olive along the top of the head, grayish on the back and upper third of the side, and with many fine black dots, silvery white in its lower two-thirds. Uncovered space on chin, eyes, base of pectoral, and centre of base of caudal, gamboge yellow: cheeks silvery: fins uncoloured.

Habitat.—Upper waters of Ganges and Jumna rivers, and certainly as low down as Patna: also in the Brahmapootra. It does not appear to exceed 4 inches in length, and is considered very bad eating. The

specimen figured (life-size) is from Delhi.

18. Mugil cœruleo-maculatus.

Lacép. v, pp. 385, 389; Cuv. and Val. xi, p. 128; Bleeker, Riouw. p. 484, and Sumatra, ix, p. 5; Günther, Catal. iii, p. 445.

B. vi, D. 4 | $\frac{1}{8}$, P. 17, V. 1/5, A. $\frac{3}{9}$, C. 14, L. 1. 38, L. tr. 12.

Length of head 5 to $5\frac{2}{3}$, of caudal 5, height of body $4\frac{1}{4}$ to $4\frac{2}{3}$ in the total length. Eyes—without adipose lids, diameter 1/4 of length of head, nearly 1 diameter from end of snout, and 2 apart. Interorbital space slightly convex, its width about equalling 1/2 the length of the head. Width of the head equals its length excluding the snout, its height equals its width. Upper lip thick, placed obliquely so that it does not form a part of the front end of the snout. Preorbital not notched, serrated posteriorly, maxilla hidden. Uncovered portion of chin very narrow. Teeth—minute. Fins—first dorsal commences midway between the snout and the base of the caudal, its spines are stout, not quite so high as the second dorsal, but equalling the length of the postorbital portion of the head: second dorsal commences opposite the anal, they are of equal height and scaled. Pectoral as long as the head excluding the snout. Caudal lunated, its central rays more than half the length of the longest outer ones. Scales—cycloid, 21 rows between the snout and base of the first dorsal fin, the twelfth and twenty-fourth of the lateral-line correspond to the origins of the first and second dorsals. An elongated, pointed scale in the axilla. Free portion of the tail in its lowest part equals the postorbital length of the head. Colours—silvery, becoming light on the sides and beneath, a black spot at the upper edge of the base of the pectoral fin.

Habitat.—Mauritius, and from Bombay through the seas of India to the Malay Archipelago. At

the Andamans I have taken it up to 13 inches in length, but it is said to grow very much larger.

19. Mugil amarulus.

Cuv. and Val. xi, p. 133.

B. vi, D. 4 | $\frac{1}{8}$, P. 16, V. 1/5, A. $\frac{3}{8}$, C. 15, L. 1. 36, L. tr. 12.

Length of head $4\frac{1}{4}$, of caudal $4\frac{1}{2}$, height of body $4\frac{1}{4}$ in the total length. Eyes—without adipose lids, diameter 1/4 of length of head, I diameter from end of snout, and $1\frac{1}{4}$ apart. The greatest width of the head equals its length behind the middle of the eyes, and its height equals its length excluding the snout. Preorbital strongly bent and serrated, leaving the end of the maxilla visible: the mandibles form rather an obtuse angle, are notched at their point of junction, and have a distinct knob: the extent of the cleft is 2/5 that of the width of the gape. Upper lip moderately thick, placed obliquely so as not to form end of the snout. Uncovered space below the chin narrow, and constricted in its middle. A groove before the vomer. Teeth—minute in the lower jaw. Fins—dorsal spines weak, the fin commences midway between the front edge of the eye and the base of the caudal fin, the length of the spines equals the extent of the postorbital portion of the head: second dorsal rather higher, whilst the extent of its base equals 2/3 of its height. Pectoral inserted above the middle of the depth of the body, its length equals that of the head excluding the snout. Anal arises slightly in advance of the second dorsal than which it is rather higher, the length of its base equals 3/4 of its height, its third spine is $3\frac{1}{4}$ in the length of the head. Caudal lunated, its central rays equal the postorbital length of the head. Scales—a short pointed one in the axilla, 18 rows between the snout and base of first dorsal fin, the eleventh and twenty-fourth of the lateral-line correspond to the origins of the equals the postorbital length of the head. Colours—bluish superiorly, becoming light on the sides and beneath, a dark spot at the upper edge of base of pectoral fin: cheeks with a golden tinge: caudal with a dark outer edge.

The foregoing description is (with an exception to be noted) from one of C. and V. types (23 inches in length) in the Paris Museum. I obtained a specimen 41 inches long in Sind, which has a spot at the base of the pectoral fin, but the presence or absence of such a mark is not invariable in Mugils. Habitat.—Seas of India to Java.

20. Mugil labiosus.

Cuv. and Val. xi, p. 125; Bleeker, Timor, ii, p. 213, and Sumatra, ix, p. 6; Günther, Catal. iii, p. 454; Klunz. Verh. z. b. Ges. Wien, 1870, p. 830.

B. vi, D. 4 | $\frac{1}{8}$, P. 15, V. $\frac{1}{5}$, A. $\frac{3}{9}$, C. 15, L. l. 36, L. tr. 11-12.

Length of head $4\frac{1}{2}$ to 5, of caudal $5\frac{1}{4}$, height of body $4\frac{1}{3}$ in the total length. Eyes—without adipose lids, diameter 1/3 of length of head, 3/4 of a diameter from end of snout, and $1\frac{1}{2}$ diameters apart. The greatest width of the head equals its length excluding the snout, whilst its height is a little more. Interorbital space flat. Profile from snout to dorsal fin rather steep. Preorbital has a very large and deep notch on its anterior surface, it is as deep as the extremity of the bone is broad; preorbital smooth except its posterior extremity, which is serrated: extremity of the maxilla visible. Free space below the chin long, narrow, lanceolate, and with a row of glands along either side. Upper lip forming the end of the snout, thick and fringed: lower lip also thick and fringed, except opposite the symphysis where it is deficient, these fringes decrease with age. On the lower surface of the head is a triangular scaleless spot, the base formed by the lower jaw, the apex being below the middle of the eyes. Teeth—absent. Fins—the first dorsal commences midway between the hind edge of the eye and the base of the caudal fin, it is rather higher than the second dorsal. Second dorsal commences over the middle of the anal fin. Pectoral reaches to the eleventh scale. Caudal emarginate. Scales—cycloid, densely covering the vertical fins, the twelfth and twenty-fourth scales of the lateral-line correspond to the origins of the first and second dorsal fins: 22 rows between snout and base of first dorsal. Free portion of the tail in its least depth equals the length of the head behind middle of the eyes. Colours-dark gray above, becoming dull white on the sides and beneath: a dark black spot at base of pectoral fin.

The fringes to the lips existing in my small specimen appear to be absent in the adult stage. Habitat.—Specimens from $3\frac{3}{3}$ to $4\frac{3}{4}$ inches in length were taken at the Andamans. It extends from the Red Sea, through those of India to the Malay Archipelago.

21. Mugil Borneensis, Plate LXXVI, fig. 1.

Bleeker, Nat. Tijds. Ned. Ind. ii, 1851, p. 201, and Borneo, xiii, p. 55; Günther, Catal. iii, p. 448. Mugil adustus, Bleeker, l. c. 1853, p. 503.

B. vi, D. 4 | $\frac{1}{8}$, P. 15, V. 1/5, A. $\frac{3}{9}$, C. 17, L. l. 34, L. tr. 11.

Length of head $4\frac{1}{2}$ to $4\frac{2}{3}$, of caudal 5, height of body $4\frac{1}{2}$ to $4\frac{3}{4}$ in the total length. Eyes—without adipose lids, diameter $3\frac{1}{4}$ to 4 in length of head, 3/4 to 1 diameter from end of snout, and $1\frac{1}{2}$ diameters apart. The greatest width of the head equals its length behind the middle of the eye, and its height equals its length excluding the snout. Preorbital scaled, slightly emarginate, serrated inferiorly, posteriorly it is truncated and denticulated: extremity of the maxilla visible. Upper lip moderately thick and forms part of the anterior profile: lower lip not notched above the symphysis but with a tubercle. The mandibles join at rather an acute angle, the extent of the cleft is 4/9 that of the gape: the uncovered space below the chin narrow and lanceolate. A groove before the vomer. Teeth—tine ones in the upper jaw. Fins—the first dorsal commences midway between the front edge of the eye and the base of the caudal fin, it is not quite so high as the second dorsal, its first spine the strongest, as high as the second and equal to the length of the head behind the middle of the eye. Second dorsal commences over the anterior third of the anal, its height nearly double the length of the base. Anal as high as second dorsal, its base much longer, its first-third is anterior to it: in some of Dr. Bleeker's specimens the first two-thirds of the anal is anterior to the origin of the second dorsal. Pectoral as long as the head excluding the snout. Caudal lunated. Scales—with their exposed portion rounded, 21 rows between snout and first dorsal fin: eleventh and twenty-third of lateral-line correspond to the origins of the first and second dorsal fins. A short, scarcely pointed scale in axilla. Second dorsal and anal with fine scales. Free portion of tail equals about half the length of the head. Colours—silvery, both dorsals and caudal with dark outer edges

Habitat.—Seas of India, Calcutta to the Malay Archipelago.

22. Mugil olivaceus.

B. vi, D. 4 | $\frac{1}{8}$, P. 15, V. 1/5, A. $\frac{3}{8}$, C. 17, L. l. 34, L. tr. 11, Cæc. pyl. iv.

Length of head $5\frac{1}{4}$, of caudal 5, height of body $4\frac{2}{3}$ in the total length. Eyes—without adipose lids, diameter 1/4 of length of head, nearly 1 diameter from end of snout, and $1\frac{3}{4}$ apart. The greatest width of the head equals its length without the snout, whilst its height is a little less. Preorbital slightly emarginate, truncated posteriorly, and serrated: the end of the maxilla visible. Upper lip moderately thick and forming end of snout. Depth of the cleft of the mouth equals half the extent of its gape, lower lip notched, and a tubercle above the symphysis of the lower jaw. Uncovered space below the chin rather narrow and lanceolate.

Digitized by Goog

No groove before the vomer. Teeth—in the upper jaw. Fins—spines of first dorsal strong, arising rather nearer the base of the caudal fin than the end of the snout, as high as the second dorsal or the length of the head behind the middle of the eyes. Second dorsal about twice as high as its base is long. Pectoral as long as the head excluding the snout. Anal 3/4 as long as high, with its first 3/4 in advance of the second dorsal, which fin it equals in height. Caudal emarginate. Scales—with their exposed portions forming half an irregular hexagon, 21 rows between the snout and base of dorsal fin, eleventh and twenty-second of the lateral-line correspond to the origins of the first and second dorsal fins. Scales on second dorsal and anal. A short angular one in the axilla. Free portion of tail equals the postorbital length of the head. Colours—olive along the back, lighter on the sides and beneath: a dull blotch in the axilla, second dorsal and caudal dark externally, anal white.

Habitat.—Seas of India, ascending rivers.

23. Mugil Buchanani.

Bleeker, Beng. en Hind. p. 99. Mugil Ceylonensis, Günther, Catal. iii, p. 446.

B. vi, D. 4 | $\frac{1}{8}$, P. 15, V. $\frac{1}{5}$, A. $\frac{3}{9}$, C. 14, L. 1. 34-35, L. tr. 12.

Length of head $4\frac{2}{3}$, of caudal $4\frac{1}{5}$, height of body $4\frac{2}{3}$ in the total length. Eyes—without adipose lids, diameter 1/4 of length of head, 3/4 of a diameter from end of snout: the width of the interorbital space equals 2/5 of the length of the head. Profile from dorsal fin to snout descends in rather a curve: interorbital space slightly convex. Snout obtuse, upper lip thin and forming the end of snout. Preorbital with a slight notch, its extremity rounded and denticulated, end of maxilla concealed. The mandibles form an obtuse angle, the depth of the cleft equalling 1/3 of the extent of the gape. Uncovered space below the chin very narrow. Fins—first dorsal somewhat nearer base of caudal than end of snout, its spines equal the length of the postorbital portion of the head, and are 1/3 shorter than the rays. Second dorsal twice as high as long, it and the anal arise opposite each other and are of equal height. Pectoral inserted above the middle of the depth of the body, it is nearly as long as the head, and reaches the ninth scale of the lateral-line. Caudal deeply forked. Scales—not angular, 19 rows between the snout and base of the first dorsal fin, the eighth and nineteenth scales of the lateral-line correspond to the origins of the first and second dorsal fins. Second dorsal and anal scaled. A short, pointed, axillary scale. Free portion of tail in its least depth equals half the length of the head. Colours—greenish superiorly, becoming silvery on the sides and beneath, a dark spot superiorly at the base of the pectoral fin.

Dr. Bleeker showed me his type of this species which agrees with M. Ceylonensis. Habitat.—East coast of Africa, seas of India, ascending rivers. It attains above a foot in length.

24. Mugil Troschellii.

Bleeker, Nat. Tijds. Ned. Ind. xvi, p. 277, and Sumatra, viii, p. 80; Günther, Catal. iii, p. 448. B. vi, D. 4 | $\frac{1}{8}$, P. 15, V. 1/5, A. $\frac{3}{6}$, C. 15, L. l. 31-33, L. tr. 11, Cec. pyl. iv.

Length of head $4\frac{2}{3}$ to 5, of caudal 5 to $5\frac{1}{3}$, height of body $4\frac{2}{3}$ to 5 in the total length. Eyes—without adipose lids, diameter 2/7 of length of head, nearly 1 diameter from end of snout, and $1\frac{1}{2}$ apart. Interorbital space nearly flat, its width equals $2\frac{1}{4}$ in the length of the head. Height of head equals its length behind the front edge of the pupil of the eye, whilst its width is rather less. Preorbital scaled, emarginate, and strongly serrated along its lower and posterior edges: maxilla bent, and its end uncovered. Upper lip moderately thick and forming the end of the snout. Mandibles meet at an obtuse angle, cleft of the mouth equals 2/5 of the extent of the gape. Uncovered space below the chin narrow, elongated, rounded anteriorly, and constricted along the sides. Teeth—distinct in the upper jaw. Fins—dorsal arises midway between the front edge of the eye and the base of the caudal, its spines are rather strong, equal 3/5 of the length of the head, and are as high as the second dorsal. Second dorsal twice as high as long, emarginate. Pectoral nearly as long as the head excluding the snout. Anal has its anterior third or half in front of the base of the second dorsal, it is 1/4 higher than its base is long, its lower edge emarginate. Caudal lunated. Scales—18 or 19 rows between snout and base of first dorsal fin: ninth and eighteenth scales of the lateral-line correspond to the origins of the first and second dorsal fins. Second dorsal and anal scaled. A short scale in the axilla. Free portion of the tail in its lowest part equals half the length of the head. Colours—silvery, sometimes a darkish spot at the upper edge of the base of the pectoral fin.

Habitat.—Seas of India to the Malay Archipelago.

25. Mugil oligolepis, Plate LXXVI, fig. 2.

Bleeker, Nat. Tijds. Ned. Ind. 1858, p. 275, Act. Soc. Ned. Ind. vi, Borneo, xiii, p. 40; Günther, Catal. iii, p. 449.

B. vi, D. 4 | $\frac{1}{8}$, P. 15, V. 1/5, A. $\frac{8}{9}$, C. 16, L. 1. 26-28, L. tr. 10.

Length of head $4\frac{2}{3}$, of caudal $4\frac{2}{3}$, height of body $3\frac{2}{3}$ in the total length. Eyes—without adipose lids, diameter 2/7 of length of head, 1 diameter from end of snout, and $1\frac{1}{2}$ apart. Interorbital space nearly flat, and its width equal to the length of the postorbital portion of the head. Height of head equals its length excluding the snout, its width a little less. Dorsal profile from above pectoral fin to the snout rather steep. Preorbital

strongly bent, but scarcely notched, it is serrated at its posterior extremity: end of maxilla just visible. Upper lip thin, it forms the end of the snout. Depth of cleft of mouth equal to 1/3 of the width of the gape. Uncovered space below the chin narrow and lanceolate. Teeth—not visible. Fins—the first dorsal commences between the anterior edge of the eye and the base of the caudal fin, its first spine strong and equal to the length of the head excluding the snout, it is rather higher than the second dorsal. Second dorsal 1/3 higher than long, it commences behind the first third of the anal, whilst the latter is higher than the second dorsal. Pectoral as long as head without the snout. Caudal emarginate. Scales-17 rows before the dorsal fin; ninth and seventeenth scales of lateral-line correspond with the origins of the two dorsal fins. No enlarged one in

axilla. Free portion of tail, its least height equals the postorbital portion of head. Colours—silvery.

Habitat.—Seas and estuaries of India to the Malay Archipelago. The specimen figured is from the

Sunderbunds near Calcutta.

Catal. p. 95.

Mugil melanochir, (Kuhl and v. Hass.); Cuv. and Val. xi, p. 143 (young); Bleeker, Borneo, vi, p. 423.

B. vi, D. 4 | $\frac{1}{7-8}$, P. 17, V. 1/5, A. $\frac{3}{8}$, C. 15, L. 1. 26-27, L. tr. 9, Cæc. pyl. x, Vert. 11 | 13.

Length of head $4\frac{2}{3}$ to 5, of caudal 6, height of body 5 to $5\frac{1}{4}$ in the total length. Eyes—without adipose lids, diameter $4\frac{1}{4}$ to $4\frac{1}{2}$ in length of head, 1 to $1\frac{1}{4}$ diameters from end of snout, and 2 apart. The width of the interorbital space equals the length of the postorbital portion of the head. General appearance short and stout with a depressed head. Height of head equals its postorbital length. Snout obtuse, the centre of the upper lip forming the end of the snont: the mandibles form a very obtuse angle: the maxilla reaches to below the front third of the eye. Preorbital bent, not notched, but strongly serrated, the lower extremity of the maxilla visible. Uncovered space on chin narrow and lanceolate. Teeth—fine ones in the upper jaw. Fins—the first dorsal commences midway between the anterior edge of the eye and the base of the caudal fin, its spines are stout, the second the longest and nearly equal to 1/2 the height of the body, but only 2/3 as high as the second dorsal: the origins of the first and second dorsal fins correspond to the eighth and seventeenth scales of the lateral-line. Pectoral as long as the head excluding the snout. Anterior third of anal before the origin of the second dorsal, the two fins of equal height. Caudal slightly emarginate. Scales—some are minutely ctenoid, they are extended over the vertical fins: no distinctly elongated one in the axilla: 15 or 16 rows between snout and base of first dorsal. Lowest depth of free portion of the tail equals the length of the head behind the middle of the eyes. Cæcal appendages bifurcated. Colours—brownish above, becoming dull white below, a dark streak along each row of scales: fins generally deep black.

Habitat.—From the Red Sea, through those of India to the Malay Archipelago, China, and beyond. It ascends rivers during the rainy season as high as the tides reach. It attains a foot or more in length, and is

good eating. The one figured (life-size) is from Bombay.

FAMILY, XXXV—AULOSTOMATEIDÆ, Cantor.

Fistularidæ, pt., Mull,; Aulostomatoidei, pt., Bleeker.

Branchiostegals five to seven: pseudobranchiæ. Gills four. Form of body elongated: the anterior bones of the skull produced, forming a long tube, and having a small mouth at its anterior extremity. Teeth small. Spinous dorsal, when present, formed of isolated spines: soft dorsal and anal of moderate length: ventrals abdominal with six rays, no spine, and separated from the pubic bones which are attached to the humeral arch. Scales small or none, but parts of the skeleton or else dermal productions may be in the form of external plates. Air-vessel large. Pyloric appendages few. Vertebræ numerous.

Dr. Günther observes that in Aulostomateidæ "the ventrals have an abdominal position in consequence of the prolongation of the pubic bones, which are attached to the humeral arch." In the Centriscidae on the contrary we find the "ventral fins truly abdominal, imperfectly developed."

Genus, 1-FISTULARIA, Linnœus.

Solenostomus, sp. Klein and Gronov.; Cannorhynchus, Cantor.

Branchiostegals seven. Mouth slightly cleft. Dorsal and anal fins composed entirely of undivided rays: caudal forked, with one or two of its central rays very elongated and filiform. No scales, but some bony casing behind the head above and below.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Fistularia serrata, D. 13-15, A. 14-15. Immaculate.

1. Fistularia serrata, Plate LXXVI, fig. 3.

Fistularia tabaccaria, White, Voy. Bot. Bay, p. 296, f. 2; Linn. p. 515. Fistularia tabaccaria, var. Bl. viii, p. 130, t. 387, f. 2, 3; Bl. Schn. p. 114; Russell, Fish. Vizag. ii, p. 58, and Goorum, pl. 173.

Fistularia serrata, Cuv. Règ. Anim.: Günther, Catal. iii, p. 533; Kner, Novara Fische, p. 238; Klunz. Verh. z. b. Ges. Wien, 1871, p. 515.

Cannorhynchus immaculatus, Cantor, Catal. p. 211.
Cannorhynchus serratus, Bleeker, Arou. 1873, p. 3, and Fish. Madagascar, p. 74.

B. vii, D. 13-15, P. 13, V. 1/5, A. 14-15, C. 10/1/10.

Length of head 2/5 to the end of tail (excluding the filament). Eyes— $1\frac{1}{2}$ diameters in the postorbital portion of the head. A serrated ridge from the anterior superior angle of the eye to the nostril. Fins—the rays undivided. Colours—brown, dirty white beneath: occasionally light spots on the back and sides.

At the Andaman islands I found this fish frequenting the most muddy localities; it is common at Madras. Dr. Le Vaillant has lately (1874) shown that the elongated central ray from the tail fin of this fish has been employed in the manufacture of the interesting Serranus phaëton, Cuv. and Val. ii, p. 310, pl. 34; Günther, Catal. i, p. 100, distinguished from all others of the genus by the presence of a deeply forked caudal fin, having the middle ray much elongated.

Habitat. - From the East coast of Africa, through the seas of India to the Malay Archipelago, China, and

New Holland.

FAMILY, XXXVI—CENTRISCIDÆ, pt. Bleeker.

Fistularia, pt. Muller: Amphisiloidei, pt. Bleeker.

Branchiostegals three or four: pseudobranchiæ. Gills four. Form of body oblong, or elevated and compressed: the anterior bones of the skull produced, forming a long tube, and having a small mouth at its anterior extremity. Teeth absent. Two dorsal fins, the first short and having one of its spines strong: the soft dorsal and anal of moderate extent: ventrals abdominal, spineless, and rudimentary. Scales, if present, small: the body usually covered with a cuirass or ossifications which are not confluent with one another. Air-vessel large. Pyloric appendages absent. Vertebræ few.

Genus, 1—Amphisile (Klein) Cuv.

Branchiostegals three or four: pseudobranchiæ. Gill-openings of moderate width. Body elongated and strongly compressed. A dorsal cuirass formed by portions of the skeleton. Teeth absent. Two dorsal fins situated fur back: ventrals rudimentary. Air-vessel large. Pyloric appendages absent.

SYNOPSIS OF INDIVIDUAL SPECIES.

B. iii, D. 3 | 10-12, P. 10, V. 3, A. 12, C. 10, Vert 6/14.

Length of head $3\frac{1}{4}$, height of body 7 in the total length. $Eyes-1\frac{1}{2}$ diameters in the postorbital length of the head: interorbital space concave. Body strongly compressed, the head anteriorly ending in a long tubular snout, having a small terminal mouth. The dermal skeleton ends posteriorly in a long spine, close beneath which are the three spines of the first dorsal fin, below these again is the second dorsal, whilst the caudal appears on the lower surface of the body just behind the anal. Pectoral about midway between the end of the snout and the base of the first dorsal spines. Ventrals rudimentary and situated on the cutting abdominal edge below the third rib. Colours—whitish, shot with pink.

Lütken (Ich. Not. 1866) considers Amphisile macrophthalmus, Steind. as a synonym of the A. scutata.

Whilst the A. scutata, Steind. he believes to be A. strigata, Günther.

Habitat.—Seas of India to China. The one figured (life-size) is from Madras, where they are not uncommon.

FAMILY, XXXVII—OPHIOCEPHALIDÆ,* Bleeker.

Labyrinthici, pt. Cuv.

Branchiostegals five: pseudobranchiæ absent. Gills four. Body elongated, subcylindrical anteriorly: head depressed, having superiorly somewhat plate-like scales. Eyes lateral. Gill-openings wide, the membranes of the two sides being connected beneath the isthmus. A cavity exists above and accessory to the true gill cavity, but although some thin bony laminæ are present, no suprabranchial organ is developed. Teeth in the jaws, vomer, and palate, some of which may be conical. A single, long, spineless dorsal fin, and a similarly constructed though shorter anal. Ventrals thoracic (Ophiocephalus) or absent (Channa), when present consisting of six rays, the outer of which is unbranched and sometimes articulated at its extremity. Scales of large, moderate, or small size. Lateral-line abruptly curved or almost interrupted. Air-vessel present. Pyloric appendages, when present, few.

The Ophiocephalide having hollow cavities in their heads, and an amphibious mode of respiration, are able to exist for lengthened periods out of their native element, and can travel some distance over the ground, especially when moist. Jugglers both in India and China exhibit these fishes walking on the land, and children amuse themselves by making them crawl along. "In China they are often carried alive in pails of water and slices are cut for sale as wanted: the fish selling dear whilst it retains life, while what remains after death is considered as of little value."

Owing to the breadth of their bodies, they are able to progress in a serpentine manner, chiefly by means of their pectoral and caudal fins, first one of the former being advanced and then its fellow. They are exceedingly difficult to retain in aquaria, unless the top is covered over, as otherwise they manage to escape and proceed on their travels.

The different species are somewhat difficult to distinguish from one another, owing to their similarity in colour, the change of livery according to age and locality, and the slight variation in the number of fin rays and scales. The young as a rule are of a more or less orange or scarlet colour, and light longitudinal bands appear to be usually restricted to the immature. Those residing in brackish waters have a purplish tinge.

These fishes appear to be monogamous, some breeding in grassy swamps or the edges of tanks: some in wells or stone-margined receptacles for water: and others again in holes in the rivers' banks. The O. striatus in Mysore; is said to construct a nest with its tail amongst the vegetation near the edges of the tanks, whilst it bites off the ends of the weeds which grow in the water. Here the ova are deposited, the male keeping guard, but should he be killed or captured, the vacant post is filled by his partner. When very young the fry of all these species keep with and are defended by their parents, but as soon as they are sufficiently strong to capture prey for themselves, they are driven away to seek their own subsistence: those which are too obstinate to leave, being, it is believed, eaten by their progenitors.

The varieties which live in tanks and swamps delight in residing at their shallow and grassy edges, so that they can take in with ease their modicum of air for the purpose of breathing, or capture any frog that may incautiously venture too close to their lair.

These fishes apear to be well adapted for pisciculture, as some grow to a large size, whilst all are good eating. The smallest, O. guchua, attains about a foot in length and thrives in almost any situation. They are rather voracious, but appear to consider a frog, mouse, or rat as luscious a morsel as a fellow fish. They assist in keeping water pure by destroying either animal or vegetable substances which may come in their way.

As regards the facility with which these fishes may be conveyed long distances alive, good illustrations are afforded by the following occurrences. On July 19th, 1866, I was bringing some of the O. gachua from the plains to the hills, and a cooly accidentally turned one out of the can of water at 5.55 p.m., when the temperature of the air was 69°, it was not discovered until 8.45 p.m., when the fish was found alive and well on the gravel walk outside the house. On another occasion I was conveying nine from Coonoor to Ooty in an earthen vessel of water in which the temperature was 76°; the transit occupied from 12 a.m. to 4.45 p.m. during which period the water experienced a fall of 21°, but the fish were not affected thereby. I carried one of these fish in a wet pocket handkerchief from Kullaar to Wellington, or an ascent of about 5000 feet, which took four hours in accomplishing, and it did not seem much the worse for its trip.

Judging from their habits in an aquarium some of the Ophiocephali prefer dirty to clean water, perhaps for purpose of concealment. When they have stirred up all the sediment and exuded a quantity of mucus they appear to be delighted, their colours become much more vivid, and they ascend to their favourite resort, lying

‡ Colonel Puckle.

^{*} Bloch thus named the genus owing to their heads having a resemblance to those of serpents. Cuvier remarked that if it were possible to admit that anomalous beings existed in nature, there would be none that might more justly be considered such than these fishes.

[†] Hamilton Buchanan, Fishes of Ganges, p. 59.

amongst the vegetation just beneath the surface of the water. As soon as clean water is given them they become excited as if they imagined the time had arrived when they should change their abode.

Amongst the fish which I have personally seen exhumed from the mud, where a tank had dried up, were some Ophiocephali, whilst they are also among the fish recorded by the natives of India as descending with the

downpours of rain.

Geographical distribution.—Fresh-water fishes distributed throughout India, Burma, Ceylon, and the east, from elevated localities, and the most inland districts, to within the influence of the tides. They inhabit both ponds and rivers, and are able to change their place of abode by traversing moist pieces of ground intervening between one piece of water and another. They possess an accessory cavity to the gills, and are able to respire direct from the atmosphere.

Uses.—All these fishes are useful as food, those which inhabit rivers being better flavoured than the others which live in sluggish or stagnant water. Some classes however object to them on account of

the resemblance their heads bear to those of serpents, (see p. 346 ante.).

Genus, 1—Ophiocephalus, Bloch.

Ventral fins present. Pyloric appendages two. Definition otherwise as in the family.

Although I have given nine species of Ophiocephalus as found in India, I am doubtful whether two, viz., O. leucopunctatus* and perhaps O. pseudomarulius might not be considered as varieties of O. marulius.

SYNOPSIS OF SPECIES.

Ophiocephalus marulius, D. 45-55, A. 28-36, L. l. 60-70, L. tr. 41/3 or 51/3. Orange, banded, having white spots and a black light-edged ocellus at root of caudal fin. Throughout India to China.
 Ophiocephalus leucopunctatus, D. 47-53, A. 28-35, L. l. 59-60, L. tr. 13/3 or 53/3. Orange, banded, having

white spots, no caudal occllus. Deccan and sea coasts of India to China.

3. Ophiocephalus pseudomarulius, D. 52, A. 35, L. l. 64, L. tr. 14. Orange, banded, a black spot at base of caudal. India.

4. Ophiocephalus barca, D. 47-52, A. 34-36, L. 1. 60-65, L. tr. 5. Ventral 2/5 of length of pectoral. Dark violet, spotted, as are also the fins. Large rivers of Bengal.

5. Ophiocephalus micropeltes, D. 43-46, A. 27-30, L. 1. 95-110, L. tr. 7/13. Young scarlet with two black bands, adults gray spotted with black. Western coast of India to Siam and the Malay Archipelago.

- 6. Ophiocephalus striatus, D. 37-45, A. 23-26, L. l. 50-57, L. tr. 4 or 54 or 54 or 100. Dark gray, passing in stripes into the white of the abdomen. India to China.
- 7. Ophiocephalus Stewartii, D. 39-40, A. 27, L. 1. 47-50, L. tr. 34. Ventrals 1/3 as long as pectoral.
- Purplish, spotted with black. Cachar and Assam.

 8. Ophiocephalus gachua, D. 32-37, A. 21-23, L. 1. 40-45, L. tr. 3. Ventrals 2/5 as long as pectoral. Pectoral fin banded, vertical fins edged with red. India, Burma, and Andamans.
- 9. Ophiocephalus punctatus, D. 29-32, A. 21-23, L. l. 37-40, L. tr. $^{4-6}_{\overline{\nu}}$. Spotted or banded, vertical fins dark with a light edge. India and Burma.

1. Ophiocephalus marulius, Plate LXXVI, fig. 4 (young).

Ham. Buch. Fish. Ganges, pp. 65, 367, pl. 17, f. 19; Cuv. and Val. vii, p. 432; Bleeker, Beng. en Hind. p. 42; Jerdon, M. J. L. and Sc. 1848, p. 146; Günther, Catal. iii, p. 478; Day, Fishes of Malabar, p. 146.

? Ophiocephalus Theophrasti, Val. in Jacq. Voy. Ind. Or. pl. xiii, f. 1.
Ophiocephalus aurolineatus, Day, Proc. Z. S. 1870, p. 99 (young).
Hoòvina murl, Can.; Pu verarl, Tam.; Pu murl, Hind.; Pula chapa, Tel.; Choaree verarl and Curavu, Mal.; Kubrah, Sawl and Dowlah, Punj.; Nga-yan-dyne, Burm.; Ha-al, Assam.

B. v, D. 45-55, P. 18, V. 6, A. 28-36, C. 14, L. 1. 60-70, L. tr. $\frac{4 - 6 \frac{1}{3}}{3 - 11}$ or $\frac{5 \frac{1}{3} \cdot 6 \frac{1}{3}}{3 - 11}$.

Length of head from 4 to 5, of caudal 6 to $7\frac{1}{2}$, height of body 7 to $7\frac{1}{2}$ in the total length. Eyes diameter 1/7 (1/5 in the young) of length of head, 1 to $1\frac{1}{2}$ diameters from end of snout, and also apart. The greatest width of the head equals 1/2 or 2/3 of its length, and its height equals 1/2 its length excluding the snout. The maxilla extends 1/2 a diameter of the eye behind the orbit. Teeth—in numerous villiform rows in jaws, vomer, and palate, whilst a posterior row of about 12 large conical teeth exists on either ramus of the mandibles. Fins—dorsal and anal somewhat lowest anteriorly. Pectoral rather more than 1/2 as long as the head but not reaching to above origin of anal: ventral 2/3 as long as pectoral. Scales—about ten rows between the orbit and the angle of the preopercle. The plate-like ones on the summit of the head of moderate size: 16 rows between snout and base of dorsal fin: 10 between eye and angle of preopercle. Scales on the head are roughened by raised lines, which surround in an angular course a central spot, on the body the outer edge of the scales are smooth. Lateral-line—first, passes along 16 or 18 rows of scales body the outer edge of the scales are smooth. Lateral-line—first passes along 16 or 18 rows of scales, then descends for two rows, and subsequently passes direct to the centre of the caudal. Colours—vary both with age and the water they reside in. Back grayish green, the immature with a brilliant orange band passing

* See remarks respecting hybrids, p. 364.

Digitized by Google

from the eye to the middle of the caudal fin, but in the more mature there are five or six cloudy bands descending to below the lateral-line: abdomen orange, the bases of each scale darkest: on the posterior third of the body, on the dorsal, anal, and caudal fins are pearly-white spots, and there is generally a large black ocellus at the upper part of the base or first-third of the caudal fin, which latter is gray, ventrals orange.

"In the lower part of the base or inst-third of the caudal in, which latter is gray, ventrals orange.

"In the lower parts of Bengal, the persons dedicated to religion, from some old prejudice, think it unlucky to say that it (O. marulius) is either good or bad." (Ham. Buch.)

"Some of the Karens in Burma regard these fishes with superstitious awe, and abstain from eating them. They have a legend that they were formerly men, changed into fish for their sins, and the Karens of Tavoy say, 'if people eat them, they will be transformed into lions.'" (Mason).

Habitat.—Fresh waters, principally rivers, from Ceylon and India to China: attaining as much as four feet in length. Colonel Puckle observes "that they are very savage, protecting their young with great boldness." They take a live bait pretty well.

2. Ophiocephalus leucopunctatus, Plate LXXVII, fig. 1.

? Ophiocephalus punctatus, Russell, Fish. Vizag. ii, p. 48 (not Bloch), and Sowarah, pl. 173. Ophiocephalus leucopunctatus, Sykes, Trans. Z. S. ii, p. 352, pl. 69, f. 3; Bleeker, Beng. en Hind. p. 42. ? Ophiocephalus sowarah, Cuv. and Val. vii, p. 426; Bleeker, Beng. en Hind. p. 42.

Ophiocephalus grandinosus, Cuv. and Val. vii, p. 434, pl. 203; Bleeker, Beng. en Hind. p. 42; Günther, Catal. iii, p. 478.

B. v, D. 47-53, P. 18, V. 6, A. 28-35, C. 14, L. l. 59-60, L. tr. $\frac{1}{13}$ $\frac{1}{11}$ or $\frac{5-8}{13-11}$.

Length of head 4, of caudal 6, height of body 7 to $7\frac{1}{4}$ in the total length. Eyes—diameter 8 in length of head, $1\frac{1}{3}$ diameters from end of snout, and $1\frac{1}{2}$ to 2 apart. The width of the head equals 4/7 of its length, and its height equals 1/2 its length excluding the snout. The maxilla extends to 1/2 a diameter of the eye behind the orbit. Teeth—about ten conical, widely separated teeth exist in the lower jaw. Fins—dorsal commences over the end of the opercle, it reaches nearly or quite to above the anal: ventral 2/3 as long as the pectoral. Caudal fan-shaped. Scales—as in O. marulius, 16 rows between snout and base of dorsal fin, the plate-like ones on the summit of the head of moderate size: ten rows between eye and angle of preopercle. Colours—back grayish-green, descending in bars on to an orange abdomen: numerous white spots on the body sometimes with a black margin: caudal and posterior portions of the dorsal and anal black, with numerous

white spots.

Whether this fish should be considered more than a local variety of O. marulius may be questioned, both are found along the sea coasts of India, and the former also in the Decean. Dussumier brought it from Malabar, and I found it was not uncommon in Canara, even more so than the O. marulius. In Bengal proper, Burma, and inland districts, except the Deccan, this form, wanting the occllus on the tail, appears to be

I have a stuffed specimen 10 inches long, which appears intermediate between the O. marulius, O. leucopunctatus and O. pseudomarulius, L. l. 64, L. tr. $\frac{6}{14}, \frac{7}{10}$, head $4\frac{1}{3}$, caudal $6\frac{1}{4}$, height of body 6 in the total length. Colours as in O. leucopunctatus except the end of the dorsal fin is coloured as in Ham. Buch. figure of O. wrahl, and the caudal is transversely barred in zigzag lines, leaving an indistinct occllus at the upper edge of its base, it appears to me as if it were a hybrid between O. marulius and O. striatus, and may be O. pseudomarulius.

Habitat.—Coromandel and Western coasts of India, also in some of the rivers of the Deccan: it appears to be found in China.* It attains 3 feet or more in length. The one figured is from a Malabar specimen.

3. Ophiocephalus pseudomarulius.

Günther, Catal. iii, p. 478.

B. v, D. 52, P. 17, V. 6, A. 35, C. 15, L. 1. 64, L. tr. $\frac{6.7}{14\cdot10}$.

Length of head $3\frac{1}{4}$, height of body $4\frac{2}{3}$ in the total length to the base of the caudal fin. + Eyes—diameter 7 in length of head, 1 diameter from end of snout, and $1\frac{3}{4}$ apart. The greatest width of the head equals rather more than 1/2 its length, and its height equals 1/2 of its length excluding the snout. The maxilla reaches to beyond the vertical from the hind edge of the eye. Teeth—an inner row of six or eight rather widely separated conical ones in the lower jaw. Fins-dorsal commences above the base of the pectoral, its posterior rays are the highest, and they exceed those of the anal. Pectoral [1/2 as long as the head: ventral 3/4 of pectoral.] Scales—the plate-like ones on the summit of the head of moderate size, 16 rows between snout and base of dorsal fin: 10 between eye and angle of preopercle: those on the head roughened in lines which externally are parallel with their outer edges, whilst those on the body are roughened in arched ridges which converge to a line along the centre of each, the outer edge of those on the body smooth. Colours—gray superiorly, becoming lighter

· Since the above was written I have seen a fine specimen in the British Museum from the Cauvery River. † The single stuffed specimen in the British Museum being much damaged, the length of the caudal fin (of which not half remains) has been omitted. The pectorals and ventrals are likewise broken, whilst the dorsal and anal are dried down to the body, so that, being unable to count them, Dr. Günther's enumeration has been copied. The proportions within brackets are likewise from Dr. Günther's original description.

Digitized by GO

along the sides and beneath. "A black, white-edged ocellus, superiorly on the basal portion of the caudal fin," Günther, l. c. See remarks under O. leucopunctatus (p. 364).

Habitat.—India, originally received from the East India Museum as O. wrahl.

4. Ophiocephalus barca, Plate LXXVII, fig. 2.

Ham. Buch. Fish. Ganges, pp. 67, 367, pl. 35, f. 20; Cuv. and Val. vii, p. 436; McClell. C. J. N. H. i, p. 427, pl. xi, f. 3; Bleeker, Ben. en Hind. p. 42; Günther, Catal. iii, p. 477.

? Ophiocephalus nigricans, Cuv. and Val. vii, p. 431; Günther, Catal. iii, p. 477.

Bora chung, Russell, J. A. S. of Beng. viii, 1839, p. 551.

Ophiocephalus amphibius, McClell. C. J. N. H. v, p. 275; Bleeker, Beng. en Hind. p. 42.

B. v, D. 47-52, P. 16, V. 1/5, A. 34-36, C. 19, L. l. 60-65, L. tr. $\frac{5-6}{3}$.

Length of head 4 to $4\frac{1}{2}$, of caudal $4\frac{1}{2}$ to $5\frac{1}{2}$, height of body $5\frac{1}{2}$ to $7\frac{1}{2}$ in the total length. Eyes—diameter 7 to $7\frac{1}{2}$ in length of head, from $1\frac{1}{2}$ to 2 diameters from end of snout, and 2 apart. Height of head not so great as its width which equals that of the body, and almost the length of the postorbital portion of the head. The posterior extremity of the maxilla reaches to nearly 1 diameter behind the hind edge of the eye. Teethamongst the small ones are a few widely separated conical ones in an inner row in the lower jaw, two or three large ones on vomer, and a few on the palatines. Fins—dorsal commences above the posterior extremity of the opercle and is almost 3/4 as high as the body. Pectoral does not quite reach to above the commencement of the anal fin, while the ventral is 2/5 of its length. Anal similar to dorsal. Caudal rounded. Scales—plate-liken scales of moderate size on the summit of head, 15 rows between snout and base of dorsal fin, nine rows between any angle of prespected. The contest of the summit of head, 15 rows between snout and base of dorsal fin, nine rows between snout and base of dorsal fin, nine rows between the same of the sa eye and angle of preopercle. The scales are roughened in lines, forming irregular arches and springing from the centre of the base or middle of each scale. Those on the anterior posterior of the body are rather smaller than those in its posterior portion. Colours—dark violet superiorly, becoming dull white shot with purple beneath, the whole of the back and sides covered with large black blotches, some also exist on the dorsal, caudal, and anal fins, each of which have a red edge: pectorals reddish, with numerous black spots.

The type of O. amphibius, l. c. 17 inches long, has a few more scales, L. l. 80, L. tr. 8/17. Length of head 5, height of body 7 in the total length. Eyes—diameter 6 in length of head, 1 diameter from end of snout, and $1\frac{1}{2}$ apart. Otherwise as above. The specimen in the Calcutta Museum is from Bootan.

Habitat.—Large rivers of the Bengal Presidency, portions of the North Western Provinces, and Assam. It attains three feet in length. The specimen figured is 13 inches long, and from Calcutta. "It inhabits perpendicular banks, in holes dug like those of the Martin (Hirundo). In these it lurks, watching for its prey, with its head out." (Ham. Buchanan).

5. Ophiocephalus micropeltes, Plate LXXVII, fig. 4.

(Kuhl. and v. Hass.), Cuv. and Val. vii, p. 427; Blecker, Verh. Bat. Gen. xxxiii, Labyr. p. 12; Günther,

Ophiocephalus serpentinus, Cuv. and Val. vii, p. 420; Griff. in Cuv. An. King. x, pl. 52, f. 2. Ophiocephalus diplogramme, Day, P. Z. S. 1865, p. 36, and Fish. Mal. p. 147, pl. x (young).

B. v, D. 43-46, P. 15, V. 1/5, A. 27-30, C. 15, L. l. 95-110, L. tr. $\frac{7.8}{13-12}$, Vert. 53.

Length of head $3\frac{1}{2}$ to $3\frac{2}{3}$, of caudal $6\frac{1}{2}$ to $7\frac{1}{2}$, height of body 6 to $6\frac{1}{2}$ in the total length. Eyes—diameter $8\frac{1}{2}$ in length of head, (7 in the young), 2 to 3 diameters from end of shout, 2 to $2\frac{1}{4}$ apart. Width of head equals 4/7 of its length, its height equals nearly 1/2 its length. The maxilla reaches to rather behind the hind edge of the eye: lower jaw slightly the longer. Teeth—a widely separated row of conical ones in the lower jaw, vomer, and palatines. Fins—dorsal commences above the last fourth of the opercles, is of equal height to the anal or 1/2 the height of the body. Pectoral reaches to above the commencement of the anal: ventral about half as long as the pectoral, it has a distinct although weak unarticulated spine and five rays. Caudal fan-shaped. Scales—those on the upper surface of the head, although plate-like, are comparatively small, 22 rows between the snout and base of dorsal fin, 16 or 17 between the eye and angle of the preopercle. The scales are roughened in lines which on the head are more or less parallel with the outer margin of each scale, along the body they are arched. Lateral-line—descends gently to a little behind the end of the pectoral fin when it becomes straight. Colours—vary considerably, in the adult grayish-brown, with the head, back, and sides sprinkled with small brown spots. Dorsal fin gray, with three or four narrow dark bands and a white outer edge: anal gray, with a white margin. Caudal gray, spotted with black, and having a narrow white outer edge. In the young, and up to 12 or 14, or even to 18 inches in length, the back is grayish, sides of an orange scarlet: a black band goes through the eye to the upper half of the caudal fin, and a second from the angle of the mouth to its lower half. In some, vertical bars are also present.

The difference in colour in these two varieties makes it almost incredible that they can be the same species, but not only have I examined a large number of specimens from Malabar and Canara, but seen similar instances at Berlin, and the Hague. The change of colour is not simply due to size, the immature livery being

sometimes retained in very large specimens.

Habitat.—Malabar and Western coast of India, Siam to the Malay Archipelago. It attains at least three feet in length. The specimen figured (15 inches long) was from Trichoor in Malabar.

6. Ophiocephalus striatus.

B. v, D. 37-45, P. 17, V. 6, A. 23-26, C. 13, L. 1. 50-57, L. tr. $\frac{4}{9}$ -7 or $\frac{5}{10}$ -8, Vert. 13 | 39

Length of head $3\frac{1}{3}$ to 4, of caudal 6, height of body 6 to 8 times in the total length. Eyes—diameter 1/6 to 1/7 of length of head, 1 diameter from end of snout, and $1\frac{1}{3}$ apart. Greatest width of head 1/2 to 4/9 of its length, its height equals 1/2 its length excluding the snout. Lower jaw the longer: the maxilla reaches to below the hind edge of the eye, or even 1 diameter behind it. Teeth—an inner row of conical ones in the lower jaw, and cardiform ones on the palatines. Fins—the pectoral does not quite reach to above the origin of the anal. Scales—the plate-like ones on the summit of the head large and irregularly shaped, from 18 to 20 rows between the snout and the origin of the dorsal fin: nine rows between the eye and angle of the preopercle. The number of rows between the lateral-line and the dorsal fin appears subject to variation, some from the East Indian Archipelago and Philippines having only L. tr. $\frac{3}{8}$, and fewer rows between the snout and base of the dorsal fin,* have been termed O. vagus, Peters. (Monats. Akad. Berlin, 1868, p. 260.) The scales on the head are roughened in lines parallel to their margins, on the body they are arched towards the centre of each. Lateral-line—curves downwards below the twelfth dorsal ray. Colours—dark grayish or blackish superiorly, becoming dirty-white or yellowish-white beneath: cheeks and lower surface of the mouth streaked and spotted with gray: bands of gray or black from the sides to the abdomen. Some spots and bars at the posterior end of the dorsal fin: ventrals and anal grayish, with some whitish lines or spots along the base of the latter. In the young there is occasionally a large black occllus at the end of the base of the dorsal fin, and the body may be destitute of any marks.

In Burma the Telaings have a ceremony with one of these fish, said to be very efficacious in cases of sickness. The patient promises that either at the present time or subsequent to his recovery he will propitiate the spirit which he has offended. A Nga-yan (Ophiocephalus striatus) is brought, and the sick person has to pass a string through its nostrils in the same way that a cord is passed through the nose of a bullock. A circle is then formed of the relatives, they dance round this fish, which is also dragged after them, and other offerings

Habitat.—Fresh waters throughout the plains of India, Ceylon, Burma, to China and the Philippines, especially delighting in swamps and grassy tanks: they attain 3 feet or more in length. They take a bait very readily, especially a frog, and are said to rise to the salmon fly.

STOMACH AND CECAL APPENDAGES OF Ophiocephalus striatus.

* Since the above was in type I have looked over some of Dr. Bleeker's specimens of O. striatus, they have either three or four entire and two half rows between the lateral-line and base of first dorsal ray. Some of mine from India have the same number, others have even five and six entire and two half rows at the same spot.

7. Ophiocephalus Stewartii, Plate LXXVII, fig. 3.

Ophiocephalus Stewartii, Playfair, P. Z. S. 1867, p. 14, pl. 3. Sen-ga-lee, Assam.

B. v, D. 39-40, P. 17, V. 6, A. 27, C. 14, L. l. 47-50, L. tr. $\frac{4}{9}$ $\frac{1}{5}$.

Length of head 4, of caudal $5\frac{1}{2}$, height of body 7 to 8 in the total length. Eyes—diameter $6\frac{1}{2}$ in length of head, $1\frac{1}{4}$ diameters from end of snout, and 2 apart. The greatest width of the head equals its length behind the eyes, and its height equals 4/9 of its length. The maxilla reaches to rather beyond the hind edge of the eye. Teeth—some conical ones in the lower jaw, also on the vomer and palate. Fins—the dorsal commences over the base of the pectoral fin, is 2/3 as high as the body and higher than the anal. Pectoral as long as the postorbital length of the head, and extends to nearly or quite above the commencement of the anal; ventral about 1/3 as long as pectoral. Scales—the plate-like ones on the upper surface of the head rather large, 13 rows between the snout and the base of the dorsal fin, five between the eye and angle of the preopercle: those on the upper surface of the head roughened by lines almost surrounding a central spot, whilst those on the body are arched. *Colours*—purplish-black superiorly, becoming lighter on the sides and beneath: many of the scales on the body with a round black mark. Fins dark, the pectoral in the young yellow in its lower half with a blue basal spot, external to which it has several vertical black bands, dorsal edged with yellow.

Habitat.—Cachar and Assam, in both running and standing water, to about 10 inches in length. The specimen figured (life-size) is from Assam.

8. Ophiocephalus gachua.

Ophiocephalus kora motta, Russell, Fish. Vizag. ii, p. 49.

Ophiocephalus gachua, Ham. Buch. Fish. Ganges, pp. 68, 367, pl. 21, f. 21; Bleeker, Beng. en Hind. p. 42; Günther, Catal. iii, p. 471; Kner, Novara Fische, p. 233; Day, Fish. Mal. p. 149; Peters. Monats. Akad. Berlin, 1868, p. 262, (var. Malaccensis).

Ophiocephalus cora-mota et fuscus, Cuv. and Val. vii, p. 414; Jerdon, M. J. L. and Sc. 1848, p. 146. Ophiocephalus marginatus, Cuv. and Val. vii, p. 411; Val. in Jacq. Voy. Ind. Ori. pl. 13, f. 2; Jerdon, M. J. L. and Sc. 1848, p. 145.

Ophiocephalus limbatus, Cuv. and Val. vii, pl. 201; Swainson, Fishes, ii, p. 237. Ophiocephalus montanus, McClell. C. J. N. H. ii, p. 583; Bleeker, Beng. en Hind. p. 42.

Ophiocephalus kelaartii, Günther, Catal. iii, p. 472.

Dheri dhok, Hind.; Karavu, Mal.; Para korava, Tam.; Mah korava, Can.; Chenga or Chayung, Ooriah; Doarrah, Punj.; Chen-gah, Assam.

B. v, D. 32-37, P. 15, V. 6, A. 21-23, C. 12, L. l. 40-45, L. tr. $\frac{3-4}{7-6}$.

Length of head $3\frac{1}{2}$ to $4\frac{1}{4}$, of caudal $5\frac{1}{2}$ to 6, height of body 6 in the total length. Eyes—diameter 1/6 of length of head 5_2 to 4_4 , or catcher 5_2 to 6_1 height of body of in the order length. Dissimilar length of head, 1 diameter from end of snout, and from 1_4 to 1_2 apart. The greatest width of the head equals its length behind the eyes, and its height equals 4/9 of its length. The maxilla reaches to below the hind edge of the orbit. Teeth—an inner row of widely separated conical ones in the lower jaw, some also on vomer and palatines. Fins—pectoral as long as the head behind the eyes, ventral 2/5 length of pectoral. Scales—broad and irregular on the summit of the head: four or five rows between the orbit and the angle of the preopercle: 12 between snout and base of dorsal fin. Those on the head roughened by circular lines, which externally are parallel with their outer edge, whilst the lines on the scales of the body are in the form of arches. Lateral-line—bends downwards after proceeding about 12 scales. Colours—differ materially, according to the water in which they reside: usually greenish, lighter beneath: dorsal, caudal, and anal slate-coloured, with an orange margin: pectoral with a black base, transversely barred (except in some Andaman specimens), and having a slight reddish or orange edge. In the young there is often a large ocellus with a light edge on the last five dorsal rays: caudal barred. Occasionally it is spotted with white, or even orange, (O. aurantiacus), Ham. Buch. Fish. Ganges, pp. 69, 368, pl. 23, f. 22.

O. Kelaarti:—Günther divided this Ceylon form from O. gachua, "differing from it by its longer caudal fin," (it is 5\frac{3}{4} in the total length). Dr. Günther (Zool. Record. 1865, p. 194), observed "O. Kelaartii is not the young of O. gachua as suggested": which assertion I think is erroneous.

Hubitat—Freeh waters throughout India Coular Program and the Andrews all the Andrews and the Andrews all the Andrews and the Andrews all the Andrews all

Habitat.—Fresh waters throughout India, Ceylon, Burma, and the Andamans, also near Gwadur on the Meckran coast. This fish is often found thriving at the bottom of wells, and in fact may be taken from the waters of the plains to those in very high elevations. It attains at least 13 inches in length, is very voracious, and may often be captured in little watercourses, into which it has pursued the Haplochili and other small fish.

Ophiocephalus affinis, Günther, Catal. iii, p. 470.

Phool dhok, Hind.: Korava, Tam.: Beli-korava, Canarese: Muttah, Tel.: Gorissa and Gurrie, Ooriah and Assam: Dulloonga, Punj.: Nga-ain, Mugh.: Dhoalee, Sind: Black caboose, of Europeans.

B. v, D. 29-32, P. 17, V. 6, A. 21-23, C. 12, L. l. 37-40, L. tr. 4-5 %

Length of head $3\frac{1}{3}$ to $3\frac{2}{3}$, of caudal $5\frac{1}{4}$ to $6\frac{1}{4}$, height of body $5\frac{1}{2}$ to 7 in the total length. Eyes—diameter 7 to $8\frac{1}{2}$ in length of head, 1 to $1\frac{1}{2}$ diameters from end of snout, and $1\frac{2}{3}$ to 2 apart. The greatest width of the head equals from 3/5 to 4/7 of its length, its height equals half its length. Lower jaw the longer, the maxilla reaches to below or behind the hind edge of the eye. Teeth—a posterior row of four or five conical ones in the lower jaw. Fins—pectoral equals half the length of the head or even more, and reaches to above the origin of the anal: ventral is 3/4 as long as the pectoral. The dorsal is 2/3 the height of the body, and a little higher than the anal. Scales—on the summit of the head large and of irregular shapes: 12 rows between snout and origin of dorsal fine five rows between the eye and the angle of the opercle. Those which are on the top of the origin of dorsal fin: five rows between the eye and the angle of the opercle. Those which are on the top of the head are roughened in lines which are parallel with their outer edges, but on the body they are more horizontal. Lateral-line—with a slight curve above the fourth anal ray. Colours—vary with the water they reside in. Back greenish, becoming yellow on the sides and abdomen, with a dark stripe along the side of the head: several bands from the back pass downwards to the middle of the body. Fins spotted, the caudal and the vertical ones with a narrow light edge, and dark basal band: ventrals white or gray. Some have scattered black spots over the body and head, and this appears most common near the sea, and in the breeding season, whilst they are absent from the young.

Those without spots, but having more or less oblique bands,* sometimes short at other times more continuous, have been termed O. kurrouvei, Lacép. O. Indicus, McClelland, and O. affinis, Günther. Jerdon, l. c.

observed, "I have not seen any spotted in the manner described by authors."

Personally I have found that placing those with spots in an aquarium, these marks have frequently faded away, on the other hand, in some banded ones, spots have appeared subsequent to their confinement in a globe of

water. I have taken females (spotted and unspotted) containing well developed ova.

Habitat.—Fresh-waters, generally in the plains, preferring the stagnant to the running. They attain to about a foot or a little more in length. I found a female, in February, contained upwards of 4,700 large besides some small ova. The one figured (life-size) is from Calcutta, and is of purplish colour, due to the brackish water from which it was taken.

Genus, 2-Channa, Gronovius.

Differs from Ophiocephalus in being deficient in ventral fins, and having no cacal appendages.

Geographical distribution.—Ceylon and China.

It is not uncommon in India to find specimens of Ophiocephalus gachua having a ventral fin deficient, but I have not observed both wanting.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Channa Orientalis, D. 34, A. 22, L. l. 41. Dull green, with spots and a barred pectoral fin. Ceylon.

1. Channa Orientalis, Plate LXXVIII, fig. 2.

Channa, Sp. Gronov. p. 135, t. 9, f. 1. Channa Orientalis, Bl. Schn. p. 496, t. 90, f. 2; Günther, Catal. iii, p. 483. Channa Indica, Gronov. ed. Gray, p. 100.

B. v, D. 34, P. 14, A. 22, C. 14, L. l. 41, L. tr. $\frac{3\frac{1}{4}-\frac{1}{6}}{7}$, Cec. pyl. 0.

Length of head $3\frac{3}{3}$ to $4\frac{1}{3}$, of caudal $5\frac{1}{3}$, height of body $6\frac{1}{2}$ to 8 times in the total length. Eyes—diameter 1/5 of length of head, 1 diameter from end of snout, and $1\frac{1}{2}$ apart. The greatest width of the head equals its length behind the middle of the eyes, and its height equals half its length. The posterior extremity of the maxilla reaches to behind the orbit. Teeth—some enlarged ones in the lower jaw. Fins—the pectoral equals the length of the postorbital portion of the head. Scales—with longitudinal striated and raised lines. Colours—of a dirty greenish superiorly, becoming dull white or brown on the sides and beneath, there appear to be some darkish spots on the body and fins. Pectoral with vertical bars on its basal third.

Habitat.—Fresh-waters of Ceylon. The one figured (life-size) is from the collection in the British

Museum.

^{*} I have specimens of an almost uniform colour.

FAMILY, XXXVIII—LABYRINTHICI, pt., Cuvier.

Anabantidæ, pt., Richardson; Spirobranchidæ, pt., Swainson; Labyrinthibranchii, pt., Owen. Osphromenoidei, Bleeker.

Branchiostegals from four to six: pseudobranchiæ rudimentary or absent. Gills four. Body compressed, oblong, or elevated. Eyes lateral. Gill-opening rather narrow, the membranes united below the isthmus. Above the third or upper portion of the first branchial arch exists a cavity, in which is contained an elaborate apparatus consisting of thin laminæ of bone, covered by a vascular mucous membrane, and which is employed for respiratory purposes.* The number of dorsal and anal spines variable: ventrals thoracic. Scales ctenoid and of moderate size. Lateral-line interrupted or absent. Air-vessel present or absent. Pyloric appendages when present few.

Professor Peters (Monats. Akad. Berlin, 1868, p. 259) includes Ophiocephalidæ and Luciocephalidæ in this Family.

Geographical distribution.—Fresh water and estuary fishes of Asia and South Africa. They are capable of living a considerable period out of their natural element, as they are able to respire atmospheric air, either directly or else in solution in water. They consist of both vegetable and animal feeders, are often domesticated and acclimatized in other countries. When domesticated they are subject to considerable variations in form, also in the number of their spines and rays.

Uses.—All are considered as good for eating, some are even reputed to have medicinal stimulating properties, whilst due to their living long after removal from the water, they are capable of being brought to the markets in a fresh and wholesome condition.

SYNOPSIS OF GENERA.

A. Teeth on the palate.

1. Anabas. Opercles and preorbital serrated: vomerine teeth. India, Burma, Ceylon, and the East.

B. Fixed teeth in the jaws, palate edentulous.

- 2. Polyacanthus. Dorsal and anal spines numerous: ventrals long: caudal rounded. India and Ceylon. 3. Osphromenus. Dorsal spines in varying numbers (2-13), as are also the anal (7-14): outer ventral ray filiform. India, China, and the East.
 - 4. Trichogaster. Ventral fin a single filiform.ray. India.

Genus, 1-Anabas, Cuvier.

Branchiostegals six: pseudobranchiæ absent. Superbranchial organ well-developed.† Branchial arches with toothed tubercles. Mouth rather small. Opercles and preorbital servated. Teeth villiform in jaws and on the anterior and posterior extremities of the vomer: none on the palatines. Dorsal fin single, the spinous portion of greater extent than the soft: anal spines numerous, but less than those of the dorsal. Scales etenoid, rather large. Lateral-line interrupted. Air-vessel bifid posteriorly with either extremity produced. Pyloric appendages few or absent.

Geographical distribution.—Fresh water and estuary fishes. They are found from India to the Malay Archipelago and the Philippine Islands. They are most numerous in the Maritime provinces, and the deltas of the larger rivers.

Uses.—The fishes of this genus rarely exceed eight inches in length, but are highly esteemed as nourishing food, whilst owing to their vitality being very great, they can be conveyed alive for long distances. The boatmen on the Ganges carry them in moist earthern pots, killing and cooking them as required. They are rather voracious fishes, readily taking a worm as a bait.

These fishes have been reputed to climb trees, and Lieutenant Daldorf reported having captured one five feet from the ground, from the cleft of a palmira tree, the leaves of which commence from the bottom of its stem. They migrate during the rainy season from pond to pond: and have also been found estivating during the hot months.

Accidents are constantly occurring, due to native fishermen killing these fishes by breaking their vertebral column by a bite, as is done by sportsmen in Europe by striking their heads against their boot. Whilst the fish is in the fisherman's mouth for this humane purpose (as it is covered by a slimy, slippery secretion), it occasionally slips into his throat, and then owing to its spiny character it cannot be withdrawn without extensive laceration of the patient's mouth. Although the following treatment may appear somewhat disgusting it is

* Observations on this mode of respiration are deferred until the Silurida come under consideration.

† The superbranchial organ consists of thin bony laminæ placed one above the other, decreasing in size superiorly, and increasing in number with age. At first the edges of these laminæ are smooth, but as the fish get older they become undulated.

Digitized by Googl

most successful. Should the fish be still alive cut off the projecting or caudal portion, causing it to die of hæmorrhage. When dead the parts easily reached may be removed, but any force being employed is most injudicious. An elastic catheter, if necessary, may be passed past the fish in order to feed the patient, but the decay of the animal is most rapid, whilst a little smell more or less is immaterial to a native of the East.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Anabas scandens, D. 1.7.18, A. 9.10, L. l. 28-32, L. tr. 15-16, Cac. pyl. 0-3. India and the East.

Undee-collee, Mal.; Pauni-eyri, Tam.; Coi, Beng. Assam. and Ooriah; Nga-pri, Mugh; Nga-byays-ma, Burm.; Kavaya or Kawhy-ya, Sing.

B. vi, D. 15-16, P. 15, V. 1/5, A. 2-19, C. 17, L. l. 28-32, L. tr. 3-4 | 9-10, Vert. 10/16, Cae. pyl. 0-3.

Length of head $3\frac{1}{2}$ to $3\frac{2}{3}$, of caudal $5\frac{1}{3}$ to $6\frac{1}{2}$, height of body 3 to 4 in the total length. Eyes—diameter $4\frac{1}{2}$ to 5 in length of head, 3/4 to 1 diameter from end of snout, and from $1\frac{3}{4}$ to 2 apart. The greatest width of the head nearly equals its height, or its length excluding the snout. Lower jaw slightly the longer, the maxilla reaches to beneath the middle of the orbit. Preorbital strongly denticulated, the anterior four or five denticulations are directed more or less forwards, and the front one is the longest: posterior edge of opercle, also of sub- and inter- opercles strongly spinate, shoulder scale generally with two or three denticulations. Teeth—villiform in the jaws, with the outer row rather the largest; a small patch on the front end of the vomer, which are slightly obtusely conical but small, none on the palatines. Fins—the length of the base of the spinous portion of the dorsal fin is 5/6 of that of the length of its entire base, soft portion higher than the spinous. Scales—three entire and two half rows between the lateral-line and the commencement of the base of the dorsal fin, some over soft dorsal, caudal, anal, and base of pectoral. Lateral-line—interrupted about the seventeenth scale. Cacal appendages—usually three, but I took some specimens in Madras which were destitute of any. Colours—rifle green, becoming lightest on the abdomen. During life there are usually four wide vertical body bands, and a dark stripe from the angle of the mouth to the preopercle. The young have a black blotch on the side of the base of the tail, surrounded by a light, sometimes yellow, ring; usually they have a black spot at the end of the opercle, and sometimes another at the base of the pectoral.

Variety.—I obtained in the Ganjam district a specimen of this fish of an orange colour, which the fishermen asserted was not an uncommon occurrence and not depending solely upon the water the fish resided

in. At the present time, after it has been nearly ten years in spirit, the orange colour is visible.

Anabas oligolepis, Günther (? Bleeker) Catal. iii, p. 376, from Ceylon and India, is considered to differ as having D. 16 8 8, L. l. 27. I have specimens from India which have only 28 large scales along the lateral-line, and two in the Calcutta Museum have D. 18, L. l. 26, and it appears to me that a regular gradation exists from that number to 32.*

This fish being extensively employed for stocking ponds, considerable differences are found as

to its proportions, the Bengal forms as a rule being rather more elongated than those of Madras.

Habitat—Estuaries and fresh waters of India, Ceylon, and Burma, to the Malay Archipelago and Philippines. The one figured is from Calcutta. They attain at least 8½ inches in length. The breeding season is about June and July.

^{*} It is a subject deserving extended investigation, as to how far the number of spines and rays of the dorsal and anal fins differ in each species of Indian fresh water Acanthopterygian fishes. A rather wide latitude exists in Anabas, Polyacanthus, Trichopaster, Osphromenus, and Ophiocephalus, and to a lesser extent in Etroplus. The number of scales along the lateral-line seems also to be subject to variation in Polyacanthus, whilst in Ophiocephalus in some the number appears constant between the lateral-line and first dorsal spine (as O. micropeltes, O. Stewartii, and O. gachua), in others inconstant (as O. marulius, O. leucopunctatus, and O. strictus) O. striatus).

B. Fixed teeth in jaws, palate edentulous.

Genus, 2-Polyacanthus, (Kuhl. and v. Hass.) Cuv. and Val.

Branchiostegals six: pseudobranchiæ glandular or absent. Body oblong, compressed. Mouth, small and but little protractile. Opercles spineless. Teeth small and fixed in the jaws, palate edentulous. Dorsal fin single, the spinous portion of much greater extent than the soft: the anal of a similar description: ventral with one spine and five well-developed rays, some of which are usually elongated. Scales rather large, etenoid. Lateral-line interrupted, and may be partially or even entirely absent. Air-vessel simple. Pyloric appendages, when present, few.

Geographical distribution.—Fresh waters and estuaries along the coasts of India and Ceylon, but usually not far inland. Occasionally, according to Dr. Jerdon, wounds from their spines inflict a most severe burning pain, which lasts for two or three hours.

Uses.—Although their size is minute, the lower classes of the natives employ them for food.

SYNOPSIS OF SPECIES.

1. Polyacanthus cupanus, D. $\frac{4+1}{5-7}$ 6, A. $\frac{4-1}{10-11}$ 6, L. l. 29-32, L. tr. $\frac{4}{7-8}$ 6. Greenish, barred, having a scarlet ventral ray. India.

2. Polyacanthus signatus, D. \(\frac{1}{6}\)-\frac{1}{10}\), A. \(\frac{1}{4}\)-\(\frac{1}{6}\), L. l. 29, L. tr. 4/9. Olive. Ceylon and Java.

1. Polyacanthus cupanus, Plate LXXVIII, fig. 4.

Cuv. and Val. vii, p. 357; Günther, Catal. iii, p. 381; Kner, Novara Fische, p. 218; Day, Fish. of Malabar, p. 134,

Caringanah and Wunnuttee, Mal.: Punnah, Tam.: Ta-but-ti, Can. and Mal.: Heb-bu-ti, Tel.

B. vi, D. $\frac{14-17}{5-7}$, P. 10, V. $\frac{1}{5}$, A. $\frac{16-19}{9-11}$, C. 13, L. l. 29-32, L. tr. $\frac{4}{7-8}$.

Length of head 1/4 to 1/5, of caudal nearly 1/4, height of body 1/4 of the total length. Eyes—diameter 1/4 to 1/5 of length of head, 1 diameter from end of snout and apart. Preorbital serrated. Posterior half, and the angle of the preopercle finely serrated, as are also the sub-opercle and posterior half of the inter-opercle. Teeth—cardiform in jaws, none on vomer or palatines. Fins—dorsal spines not so high as the rays, the soft dorsal and sometimes the anal rather elongated, caudal wedge-shaped. Lateral-line—in the form of a single round hole in each scale, has three entire and two half rows of scales between it and the base of the first dorsal spine, it ceases about the fourteenth scale. Colours—rifle-green, with the prolonged ventral ray scarlet: caudal barred in spots, as is also the dorsal more especially in its soft portion: a round dark spot at the base of the caudal, and numerous small ones on the head. Variety—rose-coloured with two horizontal black bands,* one from above the orbit to the upper part of the caudal fin, the second from the angle of the mouth through the eye to the lower part of the same fin: head and cheeks spotted. The colour reminds one of the young of the Ophiocephalus micropeltes (see page 365), and appears somewhat to resemble P. Deissneri, Bleeker.

Habitat.—Malabar and Coromandel coasts, often found in ditches, paddy fields, and shallow waters,

generally within or not far removed from tidal influence, but I have likewise taken it in the Bowany at Mettapolliam and also along the base of the ghauts in Canara. It lurks under stones, or amongst weeds, and becomes very tame in an aquarium. It grows to about three inches in length.

2. Polyacanthus signatus.

Günther, Catal. iii, p. 379.

B. vi, D. $\frac{16-17}{8-10}$, P. 11, V. 1/5, A. $\frac{14-16}{10-12}$, C. 14, L. l. 29-32, L. tr. 4/9, Vert. 10/16.

Length of head $3\frac{3}{4}$ to $4\frac{1}{4}$, of caudal $3\frac{1}{2}$ to 4, height of body $3\frac{1}{3}$ to $3\frac{1}{2}$ in the total length. Eyes—diameter $4\frac{1}{2}$ to 5 in the length of head, 1 diameter from end of suout, and 1 apart. Lower edge of preorbital very finely serrated: angle of preopercle finely serrated, the other opercles entire. The maxilla reaches to below the front edge or first third of the eye. Teeth—villiform, the outer row in the jaws rather enlarged, some specimens have a caniniform tooth on either side of the middle of the lower jaw. Fins—dorsal spines stout, rather short, increasing in length to the last: soft portions of the dorsal and anal elongated and pointed due to the prolongation of their central rays: outer ventral ray prolonged into two filaments. Caudal with its central rays the longest. Lateral-line—sub-interrupted. Colours—reddish olive in spirit: probably greenish during life: a round blackish spot on the middle of the base of the soft dorsal.

Habitat.—Ceylon and Java, attaining at least 5 inches in length.

Genus, 3—Osphromenus, (Commerson) Lacépède.

Trichopus, Lacép.: Ctenops, McClelland: Trichopsis, Kner.

Branchiostegals, six. Body, moderately elevated, compressed. Opercle without a spine: opercular pieces serrated in the immature. A superbranchial organ. Mouth small, oblique, protractile. Small and fixed teeth in

* These bands appear to be mostly seen in the young in the Canara district, whilst their checks have well marked black spots.

the jaws, none on the palate. One dorsal fin, its spinous portion sometimes in excess (2-14) but generally less in extent than its soft part. Anal spines in varying numbers (5-14). Outer ventral ray long, filiform, the remainder being generally rudimentary. Scales etenoid, and of moderate size. Lateral-line, when present, uninterrupted. Air-vessel present. Pyloric appendages two.

Geographical distribution.—One species has been introduced into India: and another is found in Assam, N.E. Bengal, Sikkim, and Nepal. The imported species, O. olfax, is of excellent flavour, attaining to 20lbs. or upwards in weight, well adapted for pisciculture, and capable of being extensively spread in tropical and extra-tropical regions. It has been naturalized in the Mauritius and Cayenne: in 1864 some were imported into Australia, and in 1866 into Madras and on to the Neilgherry hills. Commerson who observed it in the Mauritius in 1770, states that he never eat any fish more exquisite in flavour whether from the sea or fresh water: he also added that in Batavia the Dutch reared them in large earthen pots, changing the water daily and feeding them on nothing but fresh water plants, especially the Pistia naturs.

General Hardwicke (Zool. Journ. iv, p. 309), gives an account of the breeding of this fish, apparently monogamous: he observes, they commence at six months of age, whilst their fecundity is astonishing. During the breeding season they frequent the sides of tanks, where shelter is afforded them by the grasses and weeds growing in the water. For several days they are very active, passing in and out of their grassy cover, and in some places thickening it, by entangling all trailing shoots, and forming what is generally considered the spot under which the ova are deposited. They continue to watch this place with the greatest vigilance, driving away any interloping fish, and at the end of a mouth numerous fry appear, over which the old gouranties keep watch

-As already observed they are excellent as food, but must not be allowed access to foul substances Lises or they will consume them, and may thus be rendered unwholesome.

SYNOPSIS OF SPECIES.

1. Osphromenus olfux, D. $\frac{11-14}{11-12}$, A. $\frac{0-12}{10-21}$, L. l. 30-38, L. tr. $\frac{5}{13}$, China, fresh waters of the Malay Archipelago, introduced into the Mauritius, Cayenne, and India.

2. Osphromenus nobilis, D. $\frac{5}{7}$, A. $\frac{5}{8}$, A. $\frac{5}{23}$, L. l. 28-31, L. tr. $\frac{6}{12}$. Brown, with three irregularly interrupted silvery longitudinal bands. N.E. portions of Bengal and Assam.

1. Osphromenus olfax, Commerson, Plate LXXIX, fig. 6.

Osphromenus gourami, Lacép. iii, p. 117, pl. iii, f. 2.

Osphromenus gourami, Lacep. III, p. 117, pl. III, 1. 2.
Trichopodus mentum, Lacép. III, p. 125, pl. III, f. 3.
Trichopus gourami and satyrus, Shaw, Zool. iv, pp. 388, 391, pl. 55.
Osphromenus olfax, Hard. Zool. Journ. iv, p. 309, pl. 36; Cuv. and Val. vii, p. 377; Swainson, Fishes, ii, p. 236; Richards. Ich. China, p. 251; Bleeker, Verh. Bat. Gen. xxiii, p. 10; Cantor, Catal. p. 88; Günther, Catal. iii, p. 382; Peters, Monat. Akad. Berlin, 1868, p. 260.
Osphromenus gourami, Cuv. and Val. vii, p. 377, pl. 198 (immature).

B. vi, D. $\frac{11-14}{11-12}$, P. 15, V. 1/5, A. $\frac{6-12}{19-21}$, C. 16, L. l. 30-38, L. tr. $\frac{5}{13}$, Vert. 12/18-19.

Length of head 1/4, caudal 1/5, height of body 1/3 of the total length. Eyes—diameter about 1/4 of length of head, $1\frac{1}{3}$ diameters from end of snout and 2 apart. Body oblong, elevated and compressed, the abdominal profile more convex than the dorsal, and a slight concavity over the orbit. The posterior extremity of the maxilla extends to beneath the anterior edge of the orbit. In the immature the preorbital finely and evenly serrated, as is also the lower margin of the preopercle. Fins-dorsal spines increasing in length and strength to the last, the sixth and seventh rays the longest: first or second analray sometimes produced in the immature: pectoral and caudal rounded: first ventral ray reaches the base of the caudal. Colours—greenish-brown, becoming lighter on the abdomen: four or five vertical bands extend from the back to the abdomen in the immature: a reddish-brown tinge on the lower surface of the head and chest: base of pectoral fin black in the young; where glands open on the head there are black spots or stars.

Habitat.—China, and fresh waters of the Malay Archipelago. Naturalized in Mauritius, Cavenne, Australia, and introduced into some parts of India, viz. near Calcutta, Madras, and the Neilgherries. Attains 20 lbs. or more in weight and is excellent eating when kept in clean water. The specimen figured is one from the Neilgherry hills, and is 111 inches in length.

2. Osphromenus nobilis, Plate LXXVIII, fig. 5.

Ctenops nobilis, McClelland, Cal. Journ. Nat. Hist. v, p. 281, pl. 21, f. 1.

Trichopodus nobilis, Cantor, Malayan Fishes, p. 91. Osphromenus nobilis,* Day, Proc. Zool. Soc. 1869, p. 519.

B. vi, D. $\frac{5-6}{7-8}$, P. 12, V. 1/5, A. $\frac{5}{23-25}$, C. 16, L. l. 28-31, L. tr. 6/12, Cae. pyl. 2.

* Dr. Günther recorded: "Osphromenus. Surgeon Day describes what he states to be the Ctenops nobilis of McClelland." (Zool. Record, 1869, p. 133). The only specimen of this fish which I have seen in any Continental Museum was at Berlin, it had been received in exchange from the British Museum as "Osphromenus olfax, young, India."

Length of head $3\frac{1}{2}$ to 4, of caudal 4 to $4\frac{1}{3}$, height of body 3 to $3\frac{1}{4}$ in the total length. Eyes—diameter $3\frac{1}{2}$ in length of head, $1\frac{1}{4}$ diameters from end of snout, and also apart. Body compressed: head acute, rather depressed, with the lower jaw the longer. The posterior extremity of the intermaxillaries reaches to opposite the front edge of the eye, the maxilla 4/5 of the same distance. Preorbital rather large and coarsely serrated, as is also the lower edge of the preopercle. Teeth—villiform, with some rather enlarged ones in the jaws. Hins—devel small and situated in the posterior third of the length of the length. Posterel rather above. jaws. Fins—dorsal small, and situated in the posterior third of the length of the body. Pectoral rather above half the length of the head. Outer ventral ray prolonged in some specimens. Anal commences from close behind the end of the ventral spine and is continued almost to the caudal, from which it is separated by a notch, its spines increase in length posteriorly. Scales—etenoid, extending over the bases of the vertical fins. Lateral-line—when present in the form of a simple orifice in the centre of each scale: occasionally it becomes more tubular towards the caudal region. An accessory cavity to the gills exists above and behind the branchiæ. Colours—brown, a silvery white band, usually interrupted, passes from the eye to the centre of the base of the caudal fin; a second similar one extends from the pectoral along the side, and a third at the base

of the anal. Sometimes there is a black light-edged occllus at the upper part of the base of the caudal fin.

Habitat.—Rivers of N. E. Bengal and Assam, extending into those of the hills. It attains at least

4 inches in length. The one figured (life-size) was from Assam.

Genus, 4-Trichogaster, Bl. Schn.

Colisa, Cuv. and Val.

Branchiostegals fice, branchial arches with toothed tubercles. Opercle entire: preopercle usually serrated. Cleft of mouth small, jaws little protractile. A single dorsal fin, the spinous portion more developed than the soft: and similar, but of greater extent. Ventral consisting of a single elongated filiform ray. Teeth small in the jaws, vomer and polatines edentulous. Lateral-line, when present, interrupted. Air-vessel divided posteriorly into two portions. Pyloric appendages few. Intestines with many convolutions.

The numbers of the spines and rays in both the dorsal and anal fins are subject to considerable variation in the species of this genus, whilst the character of the caudal is not invariably identical in all specimens of the same species. The sub-opercle may be serrated or entire in the same species. The lateral-line has been said to be present in some, absent in others: on this however undue stress has been laid. In examining 20 well-marked, banded *Trichogaster chuna's*, it was found as follows:—in some anteriorly in the form of wellmarked tubes, or else they were moderately developed: in others the tubes were absent or represented by a circular spot in the centre of the scale. The tube being the most highly developed form, when less so the round orifice which even may be entirely absent, and as all these three varieties are found in *T. chuna*, the

character of the lateral-line can hardly be considered a sufficient diagnostic distinction for species.

Geographical distribution.—Large rivers and waters in their vicinity throughout Sind, the Punjab, N. W. Provinces, Bengal, Assam, and Burma, but appear to be absent in India, south of the Kistna river

throughout the Madras Presidency, along the western coast, and Ceylon.

Although Bloch and Cuv. and Val. remark upon the existence of these fishes at Pondicherry and Tranquebar, I cannot help thinking some error as to locality has been recorded. The late Dr. Jerdon informed me that he had never seen any in southern India, the Madras Museum does not possess any, and I have searched in vain for specimens at the two localities given above, where the native fishermen were

unacquainted with any fishes resembling the coloured drawings of a Trichogaster.

Ham. Buch. distinguishes the following six species of Trichogaster:—colisa, bejeus, cotra, lalius, sota, and chuna. His MS. figure of bejeus is however so similar to his published colisa, as to leave but little doubt that the two are varieties of one species, the former is said to have D. $\frac{1}{8}$, A. $\frac{1}{16}$, the latter to possess D. $\frac{1}{16}$, A. $\frac{1}{17}$. The T. cotra is stated to have D. $\frac{1}{8}$, A. $\frac{1}{16}$, and appears to be the young of the first species. T. lalius seems to be a well marked form, whilst T. sota may be a variety of the black banded T. chana.

SYNOPSIS OF SPECIES.

1. Trichogaster chuna, D. 17-18, A. 17-20. Caudal slightly emarginate. A dark or black band from the eye to the candal fin. Bengal and Assam.

2. Trichogaster labiosus, D. 17, A. 17-18. Lips very thick and covered with papillæ as in Labeo. Soft dorsal clongated and pointed. Eight or ten bands on the sides. Burma.

3. Trichogaster fasciatus, $\frac{1}{9}, \frac{5}{13}, \frac{1}{3}, A$. $\frac{1}{14}, \frac{5}{18}, \frac{1}{9}$. Caudal notched or cut square. Body banded. Large rivers of Sind, India, and Burma, except Madras, south of the Kistna.

4. Trichogaster lalius, D. $\frac{1}{7}, \frac{5}{8}, \frac{1}{7}, A$. $\frac{1}{7}, \frac{7}{3}, \frac{1}{4}$. Vertical fins densely scaled. Vertically banded with scarlet and azure blue bands. Indus, Ganges, and Jumna rivers.

1. Trichogaster chuna, Plate LXXIX, fig. 3.

Trichopodus chuna, Ham. Buch. Fish. Ganges, pp. 121, 372. Colisa chuna, Cuv. and Val. vii, p. 368.

Trichogaster chuna, Day, Proc. Zool. Soc. 1869, p. 520.

Bah-say-lee or Bainsa-saylee, Assam.

B. v, D. $\frac{17-18}{7-8}$, P. 9, V. 1, A. $\frac{17-20}{11-15}$, C. 15, L. 1. 27-29, L. tr. 5/10.

Length of head from $3\frac{1}{2}$ to 4, of candal $4\frac{1}{4}$ to $4\frac{3}{4}$, height of body $2\frac{1}{2}$ to $2\frac{3}{4}$ in the total length. Eyes—diameter $2\frac{3}{4}$ to 3 in length of head, 1/2 to 3/4 of a diameter from end of snout, and 1 apart. Preorbital and lower edge of preopercle serrated. Maxilla reaches to below the front nostril. Profile very slightly concave over orbits: snout obtuse. Fins—dorsal fin commences midway between end of snout and base of first ray, its spines increasing in length to the last, which equals the postorbital length of the head, and is 2/3 as high as the soft dorsal which is longest in its middle. Pectoral as long as the head. The ventral ray reaches to the posterior extremity of the anal. Caudal slightly emarginate. Scales—ctenoid, about 19 rows between first dorsal spine and the snout, they are but slightly extended over the soft portion of the anal fins and form a short sheath for the spines. Lateral-line—present. Colours—of a dull greenish, becoming lighter along the abdomen: a dark, sometimes black, band from the eye along the side to the lower half of the base of the caudal fin. A dark band in the upper third of the dorsal fin, and another on the back along the base of that fin: anal banded similarly to the dorsal, and likewise with a dark band along the bases of its soft portion. Caudal sometimes with a black spot at its base, whilst its last third is rather dark, occasionally with two or three transverse bands.

Out of 20 specimens seven had 18, the remainder 17 dorsal spines: of the anal spines, five had 20, ten had 19, three had 18, and two had 17; those captured nearest the sea had, as a rule, the most spines.

Habitat.—The Brahmapootra from Upper Assam at Debrooghur to the Hooghly at Calcutta. It is

termed "Chuna kholisha at Goalpara," (H. B. MSS.). The Trichopodus sota, H. B. Fishes of Ganges, p. 120, appears to be a variety of this species, and is termed "Bilk songtak and kalak at Goalpara," (H. B. MSS.) Out of 20 specimens the largest is 1.8 inches in length.

2. Trichogaster labiosus, Plate LXXIX, fig. 4.

B. v, D. $\frac{17}{9}$, P. 10, V. 1, A. $\frac{17-18}{18}$, C. 15, L. 1. 30, L. tr. 5-6/12.

Length of head $4\frac{1}{4}$, of caudal $4\frac{1}{3}$, height of body $2\frac{2}{3}$ to $3\frac{1}{4}$ in the total length. Eyes—diameter $3\frac{1}{2}$ in length of head, 1 diameter from end of snout, and $1\frac{1}{2}$ apart. Preorbital denticulated. Preopercle very slightly rounded at its angle, its lower limb rather strongly serrated: sub-opercle when serrated very slightly so. Maxilla reaches to below the anterior nostril. Lips very thick and covered with papillæ (as in Labeo). Teeth—present in the jaws. Fins—dorsal spines increase in length to the last, which is 2/5 of that of the head, soft dorsal pointed, its third to fifth rays being elongated, and from two to three times as long as the last spine. Anal commences below the base of the pectoral, its soft portion elongated, but not to so great an extent as the soft dorsal. Caudal wedge-shaped, the central rays being the longest. Scales—a few over the base of the anterior anal spines, increasing in number posteriorly, whilst the soft portion of the fin is densely scaled: fewer scales on soft dorsal. Colours—greenish superiorly, becoming lighter beneath, from eight to ten obliquely vertical dark bars on the sides. A light yellowish red band proceeds from the eye across the lower jaw behind the lip, whilst posteriorly it has a dark edge. Fins dark, outer edge of anal yellowish-red.

Habitat.—Burma, found in the Irrawaddi at Rangoon, and certainly as high as Mandalay. The specimen

figured (life-size) is from Rangoon.

3. Trichogaster fasciatus, Plate LXXVIII, fig. 6.

Kussuah and Coilia, Ooriah; Ponundi, Tel.; Kun-gee, Punj.; Pich-ru, Sind.; Koh-lee-hona, Assam.; Nga-pin-thick-kouk and Nga-phyin-thaleb, Burm.

B. v, D. $\frac{1.5-1.7}{9-1.3}$, P. 10, V. 1, A. $\frac{1.5-1.8}{14-1.9}$, C. 15, L. l. 29-31, L. tr. $\frac{4\frac{1}{3}-5\frac{1}{4}}{11-1.2}$, Cec. pyl. 2.

Length of head $3\frac{3}{4}$ to $4\frac{1}{4}$, of caudal $4\frac{1}{2}$ to $5\frac{1}{2}$, height of body $2\frac{2}{3}$ to $3\frac{1}{4}$ in the total length. Eyes—diameter $3\frac{1}{4}$ to $3\frac{1}{2}$ in length of head, 3/4 to 1 diameter from end of shout, and $1\frac{1}{2}$ to $1\frac{3}{4}$ apart. Preorbital denticulated in the young, only its lower edge in the middle aged, whilst in the adults it may be entire: lower than the same of the property of o limb of preopercle serrated, and sometimes a few serratures on the sub-opercle. Fins—dorsal spines of moderate strength, the last the longest and equal to the postorbital length of the head, the soft portion in some is rounded, in others more pointed and even 1/4 longer than the last spine, soft anal resembles the soft dorsal: caudal notched or cut square. Scales—there are few on the vertical fins of Assam specimens, more on those from Calcutta or Ganjam. Colours—superiorly greenish, becoming dirty white below: a green spot on either gill cover: eyes red: fourteen or more orange bands descend obliquely downwards and backwards from the back to the abdomen: ventral fin edged with red and variegated with black, green, and white: dorsal and caudal fins spotted with orange. Immature specimens with a black spot at the root of the caudal fin.

The Assam variety has higher dorsal spines and a more pointed soft dorsal and anal fin, which

Habitat.—The Coromandel coast as far south as the river Kistna, the estuaries of the Ganges, Cachar, and Assam, Punjab, N. W. Provinces, and Sind, British and upper Burma: attaining to 5 inches in length.

It is dried in places in India, whilst in Burma it is frequently made into Ngapee.

4. Trichogaster lalius, Plate LXXIX, fig. 5.

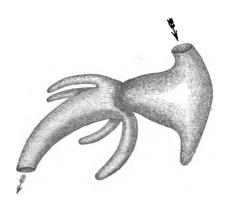

Trichopodus lalius, Ham. Buch. Fish. Ganges, pp. 120, 372. Colisa lalius, Cuv. and Val. vii, p. 366. Colisa unicolor, Cuv. and Val. vii, p. 368. Trichogaster unicolor, Günther, Catal. iii, p. 388. Trichogaster lalius, Day, Proc. Zool. Soc. 1869, p. 520. Kung-gee, Punj.

B. v, D. $\frac{15-16}{7-8}$, P. 10, V. 1, A. $\frac{17-18}{13-14}$, C. 15, L. l. 26-28, L. tr. $\frac{41}{2}$ - $\frac{51}{2}$ /10.

Length of head $3\frac{1}{3}$ to $3\frac{1}{2}$, of caudal $4\frac{1}{2}$ to $5\frac{1}{4}$, height of body $2\frac{1}{3}$ to $2\frac{3}{4}$ in the total length. Eyes—diameter $3\frac{1}{4}$ to $3\frac{1}{2}$ in length of head, 3/4 of a diameter from end of snout, and 1 apart. Profile over eyes rather concave. Preorbital denticulated: lower limb of preopercle serrated, sub-opercle entire. Teeth—present in jaws. Fins—dorsal spines increase in length to the last, the soft dorsal and anal rounded, not produced. Caudal rounded, in large specimens cut square, or even very slightly notched. Scales—covering the soft dorsal, and very densely the soft portion of the anal, they form a high sheath to the anal spines. Colours—vertically banded with scarlet and light blue, half of each scale being of either colour. Dorsal and caudal fins barred in scarlet dots. Anal with a dark band along its base, and a red outer edge.

In the cold season at Calcutta these levely little fishes are often sold alive in bottles of water, and they thrive pretty well in an aquarium. The specimens of *T. unicolor* at Paris appear to belong to this species.

Habitat.—Ganges and Jumna rivers, very common at Calcutta, also in Sind: it attains nearly 2 inches in length. It is termed "Lal kholisha at Goalpara," (H. B. MSS.)

STOMACH AND CECAL APPENDAGES OF Chrysophrys datnia.

The above woodent was accidentally omitted at p. 140, it is intended to show the excal appendages of a specimen (Plate XXXIV, fig. 1) captured at Calcutta. Bleeker, Revis. Sparoids (1876) considers the C. datnia and C. hasta as distinct species, but he appears to have figured the one I have termed C. datnia as hasta, and my C. berda C. hasta as datnia. C. Schlegeli he likewise places as a distinct species, which appears to correspond with C. calamara (variety). Doubtless there are two, perhaps three, closely allied species, however the only form I have taken at Calcutta is that figured, which I think agrees with H. Buchanan's type captured at the

FAMILY, XXXIX—TRACHYPTERIDÆ, pt., Swainson.*

Tænioidei, pt. Cuv.: Gymnetridæ, pt. Swainson.

Branchiostegals six: pseudobranchiæ present. Body elongated, and strongly compressed. Gill openings wide: gills four. Eyes lateral. Cleft of mouth slight. Dentition feeble. A single dorsal fin occupying the whole of the back, having a detached anterior portion, the whole composed of rays that are neither branched nor articulated: anal absent: caudal not in the longitudinal axis of the fish, or else rudimentary: ventrals thoracic. Scales absent. Pyloric appendages numerous. Vertebræ many. Bones soft.

Genus, 1-REGALECUS, Brünn.

Gymnetrus, Bl. Schn.

Definition as in the family, likewise the ventral in the form of a single filament with a dilated extremity.

Caudal fin, if present, minute.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. D. 4-5/320. Silvery. Coromandel coast of India.

1. Regalecus Russellii, Plate LXXIX, fig. 2.

Gymnetrus, Russell, Fish. Vizag. i, p. 28, pl. xl.
Gymnetrus Russellii, Shaw, Zool. iv, p. 195, pl. 28; Cuv. and Val. x, p. 377.
Xiphicthis Russellii, Swains. Fishes ii, p. 46; Jerdon, M. J. L. and Sc. 1851, p. 139 (not synom.)
Regalecus russellii, Günther, Catal. iii, p. 311.

B. v, D. 4-5/320, P. 11, V. 1, C. 4.

Body lanceolate, sword form, smooth, without scales. Mouth small, oblique, jaws extractile, the upper slightly the longer. Teeth—absent. Fins—four or five rays on the head at first distinct, subsequently uniting and forming a long filament: second dorsal extends from the neck to near the caudal fin, the central rays the longest. Pectoral short. Caudal distinct from the dorsal, consisting of four rays united into one filament. Scales—absent. Colours—a pale silver, but the silvering comes off upon handling: dorsal fin with a dark edge.

The fish described and figured by Russell was captured on the outside of the surf at Vizagapatnam, March, 1788, and does not appear to have been subsequently observed.

. Habitat-Vizagapatnam, grows to two feet eight inches in length. The figure is after Russell.

^{*} Swainson, 1839 (Fishes ii, p. 47) instituted this family: Günther, 1861 (Catal. iii, 300) adopted the same name but omitted any reference to Swainson, as a consequence the nomenclature (see Carus and Gerstaecker, Pisces, p. 546), has been erroneously credited to the latter of those two ichthyological authors.

Family, XL—GLYPHIDODONTIDÆ,* Cantor.

Sciænoidei, pt., Cuv.; Labroidei ctenoidei, Müller; Ctenolabridæ, Owen; Pomacentridæ, Günther.

Branchiostegals from five to seven: pseudobranchiæ present. Gills three and a half. Eyes lateral. Body more or less short and compressed, Bones of head variously armed or smooth. Teeth in jaws feeble, palate edentulous: inferior pharyngeal bones coalescing, with or without a median longitudinal suture. Some of the dorsal, anal, and ventral rays unarticulated, forming spines. A single dorsal fin with the spines equal in number to or somewhat less than the rays, very rarely more: the soft anal similar to the soft dorsal, and with two or three spines: ventrals thoracic, with one spine and five rays. Scales ctenoid. Air-vessel present, and destitute of any pneumatic duct. Pyloric appendages few.

Geographical distribution.—Seas of India and tropical seas. A few extending into extra tropical regions.

SYNOPSIS OF GENERA.

1. Amphiprion. Opercles and preorbital serrated or denticulated. Teeth in a single row. Indian Ocean

and beyond.

2. Premnas. Opercles serrated: preorbital armed with one or two spines. Teeth in a single row.

Seas of India to the Malay Archipelago and beyond.

3. Tetradrachmum. Preopercle serrated, and sometimes the preorbital. Teeth in a villiform band. Red Sea, east coast of Africa, seas of India to the Malay Archipelago and beyond.

4. Pomacentrus. Preopercle serrated, and sometimes the preorbital. Teeth in a single row. Red Sea, east coast of Africa, seas of India to the Malay Archipelago and beyond.

5. Glyphidodon. None of the opercles serrated. Teeth in a single row. Red Sea, east coast of Africa, seas of India, to the Malay Archipelago and beyond.

6. Heliastes. None of the opercles serrated. Teeth conical. Tropical seas, also found in the Mediterranean.

Genus, 1-Amphiprion, Bl. Schn.

Coracinus, sp. Gronov.; Prochilus, (Klein), Cuv.

Branchiostegals five: pseudobranchiæ. All the opercles and preorbital are denticulated, the teething on the opercle and subopercle being almost spinate. Teeth in the jaws in one row, conical and small. Scales of moderate or rather small size. Dorsal fin with from 9 to 11 spines: and with two. Lateral-line ceases in a tubular form below the end of the dorsal fin, or is continued lower down in the form of a simple orifice in each scale. Air-vessel present. Pyloric appendages few.

The fishes forming this Genus have as a rule very vivid and decided colouring, vertical bands of a more or less white tint being present in the majority. It appears very probable that some of the species founded on colours, are merely varieties. The caudal fin seems more rounded in the young than in the adults.

Geographical distribution.—Red Sea, east coast of Africa, seas of India to the Malay Archipelago and western portions of the Pacific.

SYNOPSIS OF SPECIES.

1. Amphiprion ephippium, D. $\frac{10^{-11}}{17^{-15}}$, A. $\frac{2}{14^{-15}}$, L. l. 50-55, L. tr. 7/18. Dull yellow, with a dark blotch

on the side. Andamans to the Malay Archipelago and beyond.

2. Amphiprion frenatus, D. \(\frac{10}{16} - \frac{1}{17}\), A. \(\frac{1}{16} - \frac{1}{16}\), A. \(\frac{1}{16} and beyond.

3. Amphiprion Sebæ, D. $\frac{1.0-1}{1.4-1.5}$, A. $\frac{2}{1.2-1.3}$, L. l. 50-55, L. tr. 6/18. Dark, with two white bands, one from nape over opercles, the second from the middle of dorsal fin down the side, it is also continued along the upper third of the soft dorsal. End of free portion of tail and caudal fin yellow. Andamans to the Malay Archipelago and beyond.

4. Amphiprion Clarkii, D. 10, A. 21, L. l. 55, L. tr. 6-7/19. Dark, with three white cross bands: snout, chest, pectoral, and caudal yellow. Ceylon to the Malay Archipelago and beyond.

* Müller separated as Pharyngognathi, the families having the inferior pharyngeal bones combined as in Pomacentrida, Labrida, and Chromides, from the rest of the Acanthopterygians, a division which does not hold good on a more extended investigation. Thus, Genus Gerres was found to have these bones as in the Pharyngognathi, but Kner (Wien. Sitz. Iviii, p. 301) has observed that Gerres macrosoma is an exception, having them separated, and Professor Peters has recorded the same fact in G. plumieri and several East Indian species.

They are coalesced in some of the Gobiida, not so in others.

Digitized by GOOG

- 5. Amphiprion percula, D. 10-11, A. 11-12, L. l. 50-60, L. tr. 7-8/21-23. Yellow, with three white, black-edged cross bands. Pectoral and caudal yellow, with a white edge having a black base. Seas of India to the Malay Archipelago and beyond.
- 6. Amphiprion bifasciatum, D. $\frac{1}{13}$, A. $\frac{2}{12}$, L. l. 50-55, L. tr. 6/19. Dark, with two milk-white cross bands. Caudal with a white upper and lower edge. Andamans to the Malay Archipelago and beyond.

 7. Amphiprion akallopisus, D. $\frac{9}{20}$, A. $\frac{1}{13}$, A. $\frac{2}{13}$, L. l. 60, L. tr. 6/24. Orange, with a blue band from the snout to the dorsal fin: scales on body with a light spot. Andamans to the Malay Archipelago.

1. Amphiprion ephippium, Plate LXXX, fig. 1.

Lutjanus ephippium, Bl. iv, p. 121, t. 201, fig. 2; Lacép. iv, pp. 229, 230.

Amphiprion ephippium, Bl. Schn. p. 200; Cuv. and Val. v, p. 386; Schleg. Overz. Amp. &c. Verh. Nat. Gen. Overz. Bezitt. p. 18; Bleeker, Batoe, p. 321; Günther, Catal. iv, p. 10; Day, Proc. Zool. Soc. 1870, p. 695.

Coracinus insignitus, Gronov. Syst. ed. Gray, p. 57.

B. v, D. $\frac{10-11}{17-18}$, P. 19, V. $\frac{1}{5}$, A. $\frac{2}{14-18}$, C. 15, L, l. 50-55, L. tr. 7/18, Cæc. pyl. 2.

Length of head $3\frac{1}{4}$ to $3\frac{3}{4}$, of caudal $5\frac{1}{4}$ to $5\frac{1}{3}$, height of body $2\frac{1}{3}$ to $2\frac{2}{3}$ in the total length. Eyes—diameter 1/4 of length of head, 1 diameter from end of snout, and $1\frac{1}{4}$ apart. The maxilla reaches to below the first third of the eye. Preopercle serrated, suborbital ring of bones, opercle and sub-opercle denticulated. Fins—dorsal spines of moderate strength, and nearly as high as the rays, there being no notch between the two portions: caudal more rounded in the immature than in the adult. Lateral-line—the tubular portion ceases after passing along about 36 scales, reappearing some rows lower down in the form of a round hole in each scale. Colours-of a dull yellow, with a dark blotch on the side which runs into the general colour, the outer edge of the ventral brown.

Habitat.—Andamans and Nicobars, to the Malay Archipelago and Australia. The specimen, figured life-size, was brought from the Nicobars by the late Dr. Stoliczka.

2. Amphiprion frenatus, Plate LXXX, fig. 2.

Brevoort, Amer. Exp. to China and Japan, p. 263, pl. vi, f. 4; Gill, Proc. Acad. Nat. Sc. Phil. 1860, p. 148.

Amphiprion tricolor, Günther, Catal. iv, p. 8; Castelnau, P, Z. S. Vict. ii, p. 92.

B. v, D. $\frac{10-11}{16-17}$, P. 19, V. 1/5, A. $\frac{9}{14-15}$, C. 15, L. l. 50-55, L. tr. 7/18.

The proportions are as in the last species (A. ephippium). Colours-of a brownish orange hue, becoming lightest on the abdomen and free portion of the tail: a blackish blotch descends from below the last five dorsal spines and first few rays to the middle of the sides. A pearl coloured or bluish band of varying width passes from the nape over the opercles: ventrals externally blackish.

Although I have placed this fish as distinct from A. ephippium, it seems not unlikely that it is merely a variety. Amongst the fishes I took at the Andamans were several of the young having the white ocular band, whilst all the adults were without it, being A. ephippium. Since then I have seen several adults with the light band, but I am not sure whether such may not be the livery of the immature retained in the adult stage.

Hubitat.—Madagascar, Andamans, to the Malay Archipelago, Australia, &c.

3. Amphiprion Sebæ, Plate LXXX, fig. 3.

Seba, iii, p. 70, t. 26, f. 24.

Amphiprion Sebæ, Bleeker, Batav. p. 478; Günther, Catal. iv, p. 4.

Length of head 4 to $4\frac{1}{4}$, of caudal $5\frac{1}{3}$, height of body $2\frac{3}{4}$ to 3 in the total length. Eyes—diameter $3\frac{1}{3}$ in length of head, 1 diameter from end of snout, and also apart. The maxilla reaches to below the front third of the eye. Suborbital ring of bones and preopercle serrated: opercle and sub-opercle denticulated. Fins—dorsal spines of moderate strength, increasing in length to the fourth, which equals about 1/3 of the length of the head, posteriorly they decrease so that the fin is deeply notched, soft dorsal 1/3 higher than the spinous. Caudal cut square, or rather emarginate in the adult. Lateral-line—interrupted after about the thirty-eighth scale. Colours—brownish-black, with two milk-white cross bands, the anterior goes from over the nape to the sub-opercle, touching the orbit anteriorly and covering most of the opercle posteriorly. The second band goes from the three last dorsal spines and four first rays, ending inferiorly a little in front of the vent, superiorly it covers the upper third of the soft dorsal fin: end of free portion of the tail and caudal fin canary-yellow. A young specimen 3/4 of an inch in length had the snout, muzzle, and chest dull yellow, pectoral greenish, its base black.

Habitat.—Andamans to the Malay Archipelago. The specimen figured (life-size) was taken at the

Andamans; both it and another of equal size captured at the same time had D. 11.

Length of head $4\frac{1}{2}$, of caudal $4\frac{1}{2}$ to $4\frac{3}{4}$, height of body $2\frac{1}{2}$ to $2\frac{2}{3}$ in the total length. Eyes—diameter 3 to $3\frac{1}{2}$ in length of head, 1 diameter from end of snout, and $1\frac{1}{4}$ apart. Dorsal profile more convex than the abdominal. Preorbital and suborbital ring of bones denticulated: vertical limb of preopercle likewise serrated: opercle and sub-opercle spinate, also in two distinct patches on the opercle. The maxilla reaches to under the anterior edge of the orbit. Teeth—in a single conical row in both jaws. Fins—dorsal spines strong and lower than the rays, the fin is scarcely notched: caudal lobed, the upper slightly the longer. Scales some over the soft dorsal and anal fins. Lateral-line—tubes cease opposite the posterior extremity of soft dorsal fin. Colours—light brown, with three milk-white cross bands, the first passing from in front of the dorsal fin, over the opercless just touching the posterior edge of the orbit, and is continued on to the interand sub-opercles: the second, commencing at the base of the last five dorsal spines, passes to the front of the base of the anal fin: the third crosses the free portion of the tail. Snout, chest, pectoral, and caudal yellow.

Habitat.—Red Sea, Ceylon, to the Malay Archipelago and beyond.

Ed-ole-jo-do-dah, Andam. or "Turtle's stomach," because they are generally found inside Actiniæ, which

are looked upon as those organs.

B. v, D. $\frac{1.0-11}{14-15}$, P. 17, V. 1/5, A. $\frac{2}{11-12}$, C. 15, L. l. 50-60, L. tr. $\frac{2-8}{21-23}$.

Length of head $3\frac{2}{3}$ to 4, of caudal 4 to $4\frac{2}{3}$, height of body $2\frac{2}{3}$ to 3 in the total length. Eyes—diameter $3\frac{1}{2}$ to 4 in length of head, 1 diameter from end of snout, and also apart. Opercle and subopercle strongly denticulated: suborbital ring of bones spinate. The maxilla reaches to below the front edge of the eye. Fins—dorsal spines strong, the second to the fourth the highest, but not equalling the soft dorsal. Caudal wedge-shaped or rounded. Lateral-line—ceases below about the fourth dorsal ray, and from the thirtieth to thirty-fourth scale. Colours-ground colour bright yellow, with three broad milk-white cross bands having a black edging, the anterior being convex, the convexity being forwards over the hind part of the head. The centre one from the middle of the dorsal fin to the vent, and the posterior one over the free portion of tail. Pectoral and caudal deep yellow or brownish yellow, having a broad white edge which has a narrow black base: dorsal and anal yellow with a white edge having a black base: ventral yellow, with a black extremity. In some specimens the posterior white band on the body is continued along either side of the caudal fin.

Habitat.—Seas of India to the Malay Archipelago and beyond. The specimen figured (life-size) is from the Andamans, where it was taken from inside an Actinia.

6. Amphiprion bifasciatum.

Anthias bifasciatus, Bloch, t. ecexvi, f. 2.

Amphiprion bifasciatus, Bl. Schn. p. 204; Cuv. and Val. v, p. 392; Schleg. Overz. Amp. in Verh. Nat. Gen. Overz. Bezitt. p. 18; Bleeker, Amb. and Ceram. p. 282; Günther, Catal. iv, p. 3.

B. v, D. $\frac{1}{18-15}$, P. 15, V. 1/5, A. $\frac{2}{12-13}$, C. 17, L. l. 50-55, L. tr. 6/19.

Length of head 4 to $4\frac{1}{2}$, of caudal $4\frac{1}{2}$ to 5, height of body $2\frac{1}{4}$ to $2\frac{3}{4}$ in the total length. Eyes—diameter 1/4 of length of head, 1 diameter from end of snout, $1\frac{1}{3}$ apart. Preorbital and preopercle strongly denticulated: preopercle serrated: opercle and subopercle spinate. Lateral-line—tubes cease opposite the middle of the soft dorsal. Colours—brownish-black, with two milk-white cross bands: the anterior from the nape passes

Digitized by GOOQ

over the opercles, just touching the posterior edge of the orbit: the second from the last three spines and first few dorsal rays is continued downward to the middle of the body, and backward to the summit of all the dorsal

rays: caudal black, with a white upper and lower edge.

It is suggested that A. intermedius, Schlegel, is a variety of this species, differing in colour it being brownish, with a curved milk-white band from the nape over the opercle and subopercle: a second from the last few dorsal spines to in front of the base of the anal, it is rather produced superiorly and posteriorly: a third over the free portion of the tail. Fins brownish, edged with black, and tipped with white. In one of the two specimens in the Calcutta Museum, the pectoral has a black extremity with a white edge.

Habitat.—Andamans to the Malay Archipelago and beyond.

7. Amphiprion akallopisus.

Bleeker, Sumatra, ii, p. 281, and Groot Oby. p. 438; Günther, Catal. iv, p. 10.

B. v, D. $\frac{n-1}{2}\frac{n}{0-1}\frac{n}{8}$, P. 19, V. 1/5, A. $\frac{2}{13}\frac{2}{14}$, C. 15, L. 1. 60, L. tr. 6/24.

Length of head $3\frac{1}{2}$ to $4\frac{1}{4}$, of caudal $4\frac{1}{2}$ to $5\frac{1}{2}$, height of body $2\frac{3}{4}$ to 3 in the total length. Eyes—diameter $3\frac{1}{2}$ in the length of head, 1 diameter from end of snout, and also apart. All the opercles and suborbital ring of bones coarsely denticulated. Fins—dorsal spines of moderate strength, short, increasing in length to the fourth, a notch between the spinous and soft portions. Caudal rounded. Colours—orange, brightest on the head, chest and base of caudal fin: a blue band runs from between the orbit to the dorsal fin where it divides into two, half going along either side of the base of the fin. Scales on body with a light spot.

In a specimen 1.5 inches long from the Andamans the preopercle is entire.

Habitat.—Andamans to the Malay Archipelago.

Genus, 2—Premnas, Cuv.

Branchiostegals five or six: pseudobranchiæ. All the opercles serrated: a long strong spine at the posterior edge of the preorbital. Teeth in a single row, conical and small. Dorsal with 9 or 10, anal with 2 spines. Scales of moderate size. The luteral-line ceases below the end of the dorsal fin. An air-vessel. Pyloric appendages three.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Premnas biaculeatus, Bloch, D. $\frac{n-1}{16-18}$, A. $\frac{2}{13-18}$, L. l. 50-60.

Length of head 4, caudal $4\frac{1}{2}$, height of body $2\frac{2}{3}$ in the total length. Eyes—diameter a little above $3\frac{1}{4}$ to 4 in length of head, 1 to $1\frac{1}{4}$ diameters from end of snout, and 1 apart. Preorbital armed with two strong spines, one of which commences opposite the anterior third of the orbit, the largest below its posterior third, the longest reaches the opercle. Preopercle rounded, its vertical border serrated, as is also the lower edge of the subopercle. Fins—fourth dorsal spine longest, and the second of the anal. Lateral-line—ceases in a tubular form opposite the third dorsal ray. Colours—black or chestnut-brown, fins edged with black. A broad white band margined with black passes over the occiput and on to the opercles and subopercle: a second from the three last dorsal spines to in front of the base of the anal: a third over the free portion of the

This fish is said to use Actinia as a hiding place (De Cresp. Proc. Zool. Soc. 1869, p. 248).

The specimen figured (life-size) is from the Malay Archipelago, and for it I am indebted to Professor Schlegel and Dr. Hubrecht of Leyden.

Habitat.—Seas of India to the Malay Archipelago and beyond.

Genus, 3—Tetradrachmum, Cantor.

Dascyllus,* Cuv.

Branchiostegals five: pseudobranchiæ. Preopercle, and occasionally the preorbital are serrated. Teeth villiform in a narrow band, the outer being somewhat the larger. Dorsal with 12 or 13, anal with 2 spines. Scales large or of moderate size. Lateral-line ceases in a tubular form below the soft dorsal, but is continued along the central row of scales as a circular hole in each. Air-vessel large. Pyloric appendages two or three.

• Preoccupied by Latreille (1796), Coleoptera.

SYNOPSIS OF SPECIES.

1. Tetradrachmum marginatum, D. $\frac{1}{14-16}$, A. $\frac{2}{12-15}$, L. l. 25-26, L. tr. 3/12. Bluish, with a dark zone from the front dorsal spines to the ventral fin: scales on head and body with a blue spot. Red Sea, East coast of Africa, seas of India to the Malay Archipelago and beyond.

2. Tetradrachmum aruanum, D. $\frac{12}{12}$, A. $\frac{2}{12}$, L. l. 25-27, L. tr. 3/11. White, with three vertical black bands. Red Sea, East coast of Africa, seas of India to Polynesia.

B. v, D. $\frac{12}{14-16}$, P. 17, V. 1/5, A. $\frac{2}{12-13}$, C. 17, L. 1. 25-26, L. tr. 3/12.

Length of head $3\frac{1}{4}$ to 4, of caudal $3\frac{3}{4}$ to 4, height of body $1\frac{3}{4}$ in the total length. Eyes—diameter $2\frac{1}{4}$ in length of head, 1/2 to 3/4 of a diameter from end of snout, and 1 apart. Body strongly compressed: the profile, omitting the caudal, is nearly orbicular. Preorbital narrow, the suborbital ring and hind edge of preopercle serrated. Fins—dorsal spines from the second to the last of about equal length: caudal slightly emarginate. Colours—Bluish. A dark band passes from in front of and below the first two dorsal spines, through the base of the pectoral to the ventral. Snout dark. Every scale on the head with bright blue spot edged with black, also those on the chest and lower two-bulls of the body: a few on the upper third of the body likewise similarly spotted. Soft dorsal and caudal yellow: spinous dorsal, ventral, and anal black.

A small specimen of this species was dredged off the Andamans by Mr. Wood-Mason. The one figured

was given me for that purpose by Dr. Bleeker.

Habitat.—Red Sea, east coast of Africa, Andamans, to the Malay Archipelago, China, and beyond.

2. Tetradrachmum aruanum, Plate LXXX, fig. 6.

Length of head 4, of pectoral 4, of caudal 41 to 5, height of body 21 in the total length. Eyesdiameter 2/5 of length of head, 1/2 a diameter from end of snout, and 1 apart. The maxilla reaches to below the anterior fourth of the orbit. Preorbital, pre- and sub- opercles serrated. Shoulder-bone also serrated. Fins—third dorsal spine the longest, as is also the second of the anal. Colours—pearl-white, with three vertical black bands, the anterior descending from the three first dorsal spines through the eye over the snout to the under surface of the lower jaw: the second from the sixth to the ninth dorsal spines to the ventral fins, which are black: the third from the base of the soft dorsal to the anal: caudal dark, light posteriorly.

Habitat.—Eastern coast of Africa through the seas of India to Polynesia, &c.: it is numerous at the Andamans, Nicobars and Burmah, but much rarer in Western than in Eastern India.

Genus, 4—Pomacentrus, (Lacép.) Cuv.

Pristotis, Rüpp.: Lepidozygus, Günther.

Branchiostegals four or five: pseudobranchiæ. Preopercle and usually infraorbital ring serrated. Teeth small, compressed: the crowns smooth or emarginated. Dorsal with 12 or 13, and with 2 spines. Scales rather large. Lateral-line ceases below the soft dorsal fin. Air-vessel present. Pyloric appendages few.

Geographical distribution.—Tropical seas of both hemispheres.

SYNOPSIS OF SPECIES.

1. Pomacentrus trilineatus, D. $\frac{1}{16}$, A. $\frac{2}{16}$, L. l. 28, L. tr. 3/9. One or two blue spots on each scale. Three to five blue vertical lines on the forehead. A dark spot on opercles, another across free portion of the tail, a third on the first third of the soft dorsal in the young. Red Sea to the Malay Archipelago and beyond.

2. Pomacentrus trimaculatus, D. $\frac{1}{14}\frac{3}{15}$, A. $\frac{2}{13}\frac{2}{15}$, L. l. 27-28, L. tr. 4/9. Greenish yellow, with the scales on the head spotted with bluish: three black blotches on the back, descending on to the sides. Two blue lines

between the eyes, and a light band over the nape. Andamans to the Malay Archipelago.

3. Pomacentrus bifasciatus, D. \(\frac{13}{14}\), A. \(\frac{13}{12-14}\), L. l. 28, L. tr. 3/9. Yellowish, with two black bands descending from the back to the sides. Andamans and Malay Archipelago.

4. Pomacentrus Bankanensis, D. \(\frac{13}{14}\), A. \(\frac{13}{14-2-16}\), L. l. 26-28, L. tr. 3/9. Two blue lines along forehead, two more through the eye. Scales on body with blue spots. A black white-edged spot from second to sixth dorsal

rays, and usually another across the free portion of the tail. Andamans to the Malay Archipelago.

5. Pomacentrus littoralus, D. $\frac{13}{14}$, A. $\frac{2}{14}$, L. l. 27, L. tr. $3\frac{1}{2}/9$. Olive, with blue spots on the scales. A black spot at commencement of the lateral-line, another at base of pectoral fin, and a third across the free

portion of the tail. Andamans to Australia.

6. Pomacentrus Jerdoni, D. \(\frac{1}{13}\); A. \(\frac{2}{14}\), L. l. 34, L. tr. 5/11. Olivaceous, blue spots on gill-covers and also on scales of sides. A black spot at base of pectoral. Madras.

7. Pomacentrus albefasciatus, D. \(\frac{1}{215}\), A. \(\frac{1}{13}\); A. \(\frac{1}{13}\), L. l. 26, L. tr. 3/9. Olive, bluish spots on head, a broad vertical yellowish band below last dorsal spines, a round black spot edged with white at base of pectoral. Andamans to the Malay Archipelago.

8. Pomacentrus punctatus, D. $\frac{12^{-18}}{13^{-14}}$, A. $\frac{2}{13^{-14}}$, L. l. 27, L. tr. $3\frac{1}{2}/10$. Bluish dots on head and body: a black spot edged anteriorly with white across the base of the last six dorsal rays. Red Sea to the Malay Archipelago.

9. Pomacentrus labiatus, D. $\frac{1}{12}\frac{5}{13}$, A. $\frac{5}{15}\frac{1}{14}$, L. l. 28, L. tr. $3\frac{1}{2}/10\frac{1}{2}$. Lips very thick. Brownish, with dark fins. Blue spots on some of the scales of the head and body. Andamans and Nicobars.

1. Pomacentrus trilineatus.

(Ehrenb.) Cuv. and Val v, p. 428; Günther, Catal. iv, p. 25; Klunz. Fische Roth. Meer. Verh. z. b. Ges. Wien, 1871, p. 522.

Pomacentrus biocellatus, Rüpp. N. W. Fische, p. 127, t. xxxi, f. 3 (young).

B. v, D. $\frac{13}{15}$, P. 17, V. 1/5, A. $\frac{2}{16}$, C. 17, L. l. 28, L, tr. 3/9.

Length of head from 4 to $4\frac{1}{4}$, of caudal $5\frac{1}{3}$, height of body $2\frac{3}{4}$ in the total length. Eyes—diameter $2\frac{3}{4}$ in length of head, 3/4 of a diameter from end of snout, and 1 apart. The greatest depth of the preorbital equals half a diameter of the eye. Suborbital ring of bones below the eye serrated, and two strong denticulations on the first bone. Two opercular spines. Colours—olivaceous: caudal yellow: each scale with one or two blue spots: three to five blue lines on the forehead, the outer of which are continued on to the nape, and sometimes along the base of the dorsal fin. A dark round spot on the opercle: a black spot margined with blue across the free portion of the tail. The immature have a similar spot on the anterior third of the soft dorsal.

Habitat.—Red Sea, East coast of Africa, Andamans, Nicobars, to the Malay Archipelago and beyond.

2. Pomacentrus trimaculatus, Plate LXXX, fig. 10.

Cuv. and Val. v, p. 441; Schlegel, Overz. Amph. in Verh. Nat. Ges. Ned. Ind. Overz. Bezitt, p. 20, t. iv, f. 4; Bleeker, Batav, p. 481; Günther, Catal. iv, p. 19 (not Rüppell, Atl. Fische, p. 39, t. viii, f. 3).

B. v, D. $\frac{1}{14-15}$, P. 17, V. 1/5, A. $\frac{2}{18-16}$, C. 17, L. l. 27-28, L. tr. 4/9.

Length of head $4\frac{1}{2}$ to $4\frac{2}{3}$, of caudal $4\frac{1}{3}$ to $4\frac{2}{3}$, height of body 3 to $3\frac{1}{4}$ in the total length. Eyes—diameter 3 to $3\frac{1}{4}$ in length of head, 1 diameter from end of snout, and also apart. Preorbital entire, the suborbital ring of bones below the eye serrated, as is also the vertical edge of the preopercle. Greatest depth of the preorbital equals rather above 1/2 the diameter of the eye. Fins—the posterior dorsal spines are slightly longer than the middle ones: caudal emarginate. Scales—a row of small ones along the bases of dorsal and anal fins. Colours -greenish-yellow, with three black blotches over the back, the first passing over the head from the origin of the dorsal fin to the snout: the second from between the seventh and tenth dorsal spines descends to below the lateral-line: the third from the middle of the soft dorsal also to below the lateral-line. A light band passes over the nape, and two narrow blue bands go from one orbit to the other, these divide the anterior blotch into three portions. A light blue line along the suborbital ring of bones and spots on the scales covering the cheeks, and at the bases of dorsal and anal fins. Dorsal and caudal with a narrow dark edge, anal with a broad dark outer margin, having one or two narrow blue lines along its base.

Habitat.—Andamans to the Malay Archipelago and beyond. The specimen figured (life-size) is from

the Andamans, where the species is not uncommon.

3. Pomacentrus bifasciatus.

Bleeker, Floris, p. 330; Günther, Catal. iv, p. 18.

B. v, D. $\frac{15}{14}$, P. 17, V. 1/5, A. $\frac{2}{15-14}$, C. 17, L. 1. (25) 28, L. tr. 3/9.

Length of head 4, of caudal 4, height of body $2\frac{2}{3}$ in the total length. Eyes—diameter $2\frac{1}{3}$ in length of head, 2/3 of a diameter from end of snout, and 1 apart. Preorbital and suborbital ring of bones entire, vertical limb of preopercle serrated. Greatest depth of preorbital is not equal to 1/2 a diameter of the eye. Colours yellow, with a curved blue line on the preorbital: a black band from the nape over the opercles, and a second from the last dorsal spines, descending from the fin and going to below the lateral-line. Fins yellow, except a black mark on the dorsal being the commencement of the second band.

I captured a single specimen 1.8 inches in length at the Andamans.

Habitat.—Andamans and Malay Archipelago.

4. Pomacentrus Bankanensis.

Bleeker, Sumatra, iii, p. 513; Günther, Catal. iv, p. 26. Pomacentrus tæniops, Bleeker, Banka, ii, p. 729 (not Cuv. and Val.).

B. v, D. $\frac{13}{14}$, P. 16, V. 1/5, A. $\frac{2}{14-15}$, C. 17, L. l. 26-28, L. tr. 3/9.

Length of head $3\frac{1}{2}$, of caudal $4\frac{1}{2}$, height of body $2\frac{1}{2}$ to $2\frac{3}{4}$ in the total length. Eyes—diameter $2\frac{3}{4}$ in length of head, 1/2 to 3/4 of a diameter from end of snout, and 2/3 to 1 diameter apart. Preorbital narrow, entire: suborbital ring serrated in the adult, entire in the immature: posterior limb of preopercle serrated. Fins—the dorsal spines increase in length posteriorly: caudal slightly emarginate. Colours—brownish, two narrow blue lines along the forehead anteriorly converging on the snout and posteriorly extended on to the back: two more through the eye to the maxilla. A dark blue mark on the opercle: and a line of blue spots along the cheeks below the suborbital ring of bones: each scale with a blue spot, and a black white-edged occllus at the base of the second to the sixth dorsal rays, and sometimes another across the back of the free portion of the tail behind

the base of the dorsal fin. Ventral nearly black.

P. tripunctatus, Cuv. and Val. v, p. 421, a species of which I have not seen the type, appears closely

allied to, if not identical with, the above.

Habitat.—Andamans and Nicobars to the Malay Archipelago and beyond.

5. Pomacentrus littoralus.

(Kuhl. and v. Hass.) Cuv. and Val. v, p. 425; Schlegel, Overz. Amph. &c. in Verh. Nat. Gen. Ned. Overz. Bezitt. p. 20, t. iv, f. 3; Bleeker, Batav. p. 483; Günther, Catal. iv, p. 32.

Pomacentrus pristiger, Cuv. and Val. ix, p. 506.

Pomacentrus hogolenensis, Hombr. and Jacq. Voy. Pôle Sud, Poiss. p. 47, pl. v, f. 3.

Pomacentrus katunko, Bleeker, Timor. p. 169.

B. v, D. $\frac{13}{14}$, P. 18, V. 1/5, A. $\frac{2}{14}$, C. 15, L. 1. 27, L. tr. $3\frac{1}{2}/9$.

Length of head $4\frac{1}{4}$, of caudal $4\frac{1}{4}$, height of body $2\frac{3}{4}$ in the total length. Eyes—diameter $3\frac{1}{2}$ in length of head, I diameter from end of snout, and also apart. Greatest depth of preorbital equals 1/2 the diameter of the eye. Suborbital ring of bones serrated, the anterior denticulation being the strongest: preopercle serrated along its vertical limb. Fins—dorsal spines increase in length posteriorly: caudal with rounded lobes. Colours—olive, with vertical or round bluish spots on the scales. A black spot at the commencement of the lateral-line, another at the base of the pectoral fin, and a third over a free portion of the tail behind the end of the dorsal fin.

Habitat.—Andamans to the Malay Archipelago and Australia.

6. Pomacentrus Jerdoni, Plate LXXX, fig. 7.

Day, Proc. Z. S. 1873, p. 237.

B. iv, D. $\frac{13}{13}$, P. 17, V. $\frac{1}{5}$, A. $\frac{2}{14}$, C. 17, L. l. 34, L. tr. $\frac{5}{11}$.

Length of head 5, of caudal 4 to 4½, height of body $3\frac{3}{4}$ in the total length. Eyes—diameter 1/3 of length of head, 3/4 of a diameter from end of snout, and 1 apart. Preorbital entire, much longer than deep. Preopercle finely serrated on its vertical margin, more coarsely at its angle: opercle with two spines: angle of opercle slightly serrated as well as the contiguous portions of the subopercle: the infraorbital ring narrow, entire, and scaleless. Teeth—compressed into a single row of about thirty. Fins—dorsal spines increase in length posteriorly: soft dorsal and anal pointed: caudal lobes, especially the upper, produced: second anal spine longest and strongest: the ventral reaches the anal: pectoral rounded, as long as the head without the snout. Lateral-line—its tubular portion ceasing below the end of the soft dorsal. Colours—olive, becoming light below: seven rows of light blue snots running across the gill cover one row along the suborbitals and light below: seven rows of light blue spots running across the gill cover, one row along the suborbitals, and one over the snout. A row of light lines along the centre of the scales on the sides. A black spot at the base of the pectoral. Fins dark coloured. Base of caudal and the anal barred with light lines.

The pseudobranchiæ are well developed. This is probably the species mentioned but not named by Dr.

Jerdon (M. J. L. and Sc. 1851, p. 133), and which he obtained at Madras.

ACANTHOPTERYGII.

This fish is very closely allied to P. tapeinosoma, Bleeker, or Lepidozygus tapeinosoma, Günther. Habitat.—Madras, to 5 inches in length.

7. Pomacentrus albofasciatus, Plate LXXX, fig. 9.

Schlegel, Overz. Amph. &c. in Verh. Nat. Gen. Ned. Overz. Bezitt. p. 21; Günther, Catal. iv, p. 19. Pomacentrus leucopleura, Bleeker, Sumatra, iv, p. 85.

B. v, D. $\frac{12-1}{15}$, P. 17, V. $\frac{1}{5}$, A. $\frac{2}{13-14}$, C. 17, L. l. 26, L. tr. 3/9.

Length of head $4\frac{1}{2}$, of caudal $4\frac{2}{3}$, height of body $3\frac{1}{4}$ in the total length. Eyes—diameter $3\frac{1}{3}$ in length of head, 1 diameter from end of snout, and $1\frac{1}{3}$ apart. Preorbital entire, suborbital ring of bones below the eye serrated, as is also the hind edge of preopercle. The greatest depth of the preorbital nearly equals the diameter Colours—dark olive, with bluish spots on the cheeks: a curved blue line below the eye, and a broad vertical yellowish band underneath the last dorsal spines: sometimes a black spot on the base of the last few dorsal rays, and a round one edged white at the base of the pectoral.

Habitat.—Andamans to the Malay Archipelago. The specimen figured (life-size) was brought from the

Nicobars by the late Dr. Stoliczka.

8. Pomacentrus punctatus, Plate LXXX, fig. 8.

Quoy and Gaim. Voy. Uranie. Zool. p. 395, pl. 64, f. 1; Rüpp. Atl. Fische, p. 37; Cuv. and Val. v, p. 429; Blecker, En. Spec. p. 87; Günther, Catal. iv, p. 29; Klunz. Fische, Roth. Meer. Verh. z. b. Ges. Wien, 1871, p. 522.

Pomacentrus cyanospilus, Bleeker, Ceram, ii, p. 709; Günther, Catal. iv, p. 30; Kner, Novara Fische, p. 242. Pomacentrus prosopotænioides, Bleeker, Amb. and Ceram. p. 286.

B. v, D. $\frac{1}{15}$, P. 16, V. $\frac{1}{5}$, A. $\frac{2}{13}$, C. 15, L. 1. 27, L. tr. $\frac{3}{2}$ /10, Cec. pyl. 3.

Length of head $3\frac{1}{4}$ to $3\frac{2}{3}$, of caudal $4\frac{1}{3}$, height of body $2\frac{2}{3}$ in the total length. Eyes—diameter from 3 to $3\frac{1}{3}$ in the length of head, 1 diameter from end of snout, and also apart. Preorbital in the adult nearly as deep as long, and equal to the diameter of the eye: in the immature its depth is not nearly as great. The hind edge of the preorbital, the suborbital ring, and the posterior margin of the preopercle serrated. The maxilla reaches to below the hind nostril. Fins—dorsal spines moderately strong, subequal in height but lower than the soft dorsal which is pointed. Caudal emarginate. Lateral-line—the tubes cease below the last dorsal spine. Colours—grayish-brown, head with irregular bluish-white dots and one on each scale of the body. A black spot, margined anteriorly and superiorly with white, exists across the base of the last six dorsal rays, and is usually also continued on to the back of the free portion of the tail behind the base of the dorsal fin. Occasionally a dark spot in the axil of the pectoral fin.

In Forster's Desc. Anim. (Lichtenstein Ed.) p. 227, Chatodon lividus, Forst. and Bl. Schn. is said to be

identical with Pomacentrus punctatus.

Habitat.—Red Sea, Mauritius to the Andamans, Nicobars and Malay Archipelago. The specimen figured (life-size) is from the Andamans.

9. Pomacentrus labiatus, Plate LXXXI, fig. 2.

B. v, D. $\frac{13}{12-13}$, P. 17, V. $\frac{1}{5}$, A. $\frac{2}{13-14}$, C. 17, L. 1. 28, L. tr. $\frac{31}{2}/10\frac{1}{2}$.

Length of head $3\frac{3}{4}$, of caudal 5, height of body $2\frac{1}{2}$ in the total length. Eyes—diameter 3 to $3\frac{1}{4}$ in length of head, 1 diameter from end of snout, and also apart. Suborbital ring of bones rough, scarcely serrated,* preopercle very finely serrated or even entire: preorbital scaleless, its greatest depth equal to half the diameter of the eye. Maxilla reaches to nearly below the front edge of the eye. Lips very large, thick, covered with papille, and reflected all round the mouth. Teeth—minute, compressed. Fins—dorsal spines of moderate strength, of about equal height, not equalling the soft dorsal which is pointed. Ventral reaches the anal. Upper lobe of caudal usually slightly the longer. Lateral-line—the tubular portion ceases under the commencement of the soft dorsal fin. Colours—brown, lightest on the chest and lower surface of the head: fins black. Blue spots on some of the scales of the head, and usually one on the centre of each scale in the row above the lateral-line.

This species is distinguished from any others recorded from India by its enormously developed lips. Habitat.—Andamans and Nicobars, to $3\frac{1}{2}$ inches in length.

Genus, 5—Glyphidodon, (Lacépède), Cuvier.

Euschistodus, Dischistodus, Hypsipops, Pomatoprion, Microspathodon, Gill.

Branchiostegals five or six: pseudobranchiae. Body short, compressed. Cleft of mouth small. entire, Teeth compressed and in a single row, sometimes the alternate ones being similar. A single dorsal fin with the spines rather more or less, or equal in number to the rays: anal with two spines. Scales of moderate size. The tubular portion of the lateral-line ceases below the end of the dorsal fin, but is continued in the form of minute circular Air-vessel present. Pyloric appendages few.

* This fish in some specimens (always perhaps in the young) has no serrations in the bones of the head, in others the sub-orbital ring is roughened and the preopercle is finely serrated.

SYNOPSIS OF SPECIES.

Glyphidodon sordidus, D. 13/14-16, A. 12-15, L. l. 29, L. tr. 4/12. Preorbital deep. Middle dorsal spines the longest. Five dull bands on the sides, a sixth over the tail. Red Sea to China.
 Glyphidodon leucopleura, D. 13/15, A. 24/14. L. l. 28, L. tr. 4/14. Preorbital deep. Middle dorsal spines the longest. Vertical bands: a deep black blotch over free portion of the tail. Andamans.
 Glyphidodon Cochinensis, D. 13/12-15, A. 10-11, L. l. 28, L. tr. 3/8. All the vertical fins produced. Deep black. Seas of India to the Andamans.

black. Seas of India to the Andamans.

4. Glyphidodon notatus, D. $\frac{1}{13-14}$, A. $\frac{1}{13}$, L. l. 28-30, L. tr. $4\frac{1}{4}/12$. Five narrow white vertical bands.

Andamans.

5. Glyphidodon septemfasciatus, D. $\frac{1}{13}$, A. $\frac{2}{12}$, L. l. 29, L. tr. 3/11. Preorbital deep. Height of body $2\frac{2}{3}$ in the total length. Seven vertical bands. Seas of India to China.

6. Glyphidodon cælestinus, D. $\frac{1}{13}$, A. $\frac{2}{12}$, L. l. 29, L. tr. $4\frac{1}{2}$ /12. Preorbital of moderate depth. Height of body $2\frac{2}{3}$ in the total length. Five vertical black bands. Red Sea to Polynesia.

- 7. Glyphidodon Bengalensis, D. $\frac{1}{12}, \frac{3}{13}$, A. $\frac{1}{12}, \frac{2}{12}$, L. l. 29-30, L. tr. 4/11. Preorbital deep. Height of body $2\frac{1}{2}$ in the total length. Seven vertical bands. Seas of India to the Malay Archipelago and beyond.

 8. Glyphidodon antjerius, D. $\frac{1}{12}, \frac{3}{13}$, A. $\frac{1}{12}, \frac{2}{13}$, L. l. 26-28, L. tr. $\frac{21}{2}$. Colours various. One or two black spots on dorsal fin, usually a blue band along upper portion of body. Red Sea to Malay Archipelago and beyond
- 9. Glyphidodon leucogaster, D. $\frac{1}{12-13}$, A. $\frac{2}{12-13}$, L. 1 26-28, L. tr. 3/12. Upper edge of dorsal and outer two-thirds of anal black, the rest yellow. A black spot at base of pectoral. Red Sea to the Malay Archipelago.

10. Glyphidodon modestus, D. 13, A. 2, L. l. 23-24, L. tr. 21/2/8. Yellowish-olive, vertical fins stained gray externally. Andamans to China.

11. Glyphidodon Sindensis, D. 11/2-12, A. 11/2-13, L. l. 26, L. tr. 31/2/10. Violet, each scale with a blue spot. Soft dorsal, anal, and caudal yellow. Kurrachee in Sind.

Chik-mud-dah Andam: Calamoia nota. Tel.

Chak-mud-dah, Andam.: Calamoia pota, Tel.

B. v, D. $\frac{1}{14-16}$, P. 17, V. 1/5, A. $\frac{2}{12-16}$, C. 15, L. l. 29, L. tr. 4/12, Cec. pyl. 3, Vert. 12/14.

Length of head 4 to $4\frac{1}{4}$, of caudal $4\frac{2}{3}$, height of body $2\frac{1}{4}$ in the total length. Eyes—diameter 4 in length of head, $1\frac{1}{4}$ diameters from end of snout, and $1\frac{1}{3}$ apart. Greatest width of the preorbital, which has an unnotched edge, nearly equals the diameter of the eye, whilst the suborbitals are about half as wide. The profile from the snout to the first dorsal fin ascends abruptly. Teeth—about 36 in the upper jaw, their crowns are notched. Fins—the fifth to the seventh dorsal spines the longest: soft dorsal higher than long: caudal forked. Colours—yellowish-olive, the fins being of a darker colour. Five dull bands, broader than the ground colour, descend from the dorsal fin to the sides, and a sixth, which is nearly black, goes over the free portion of the tail. A black spot at the base of the pectoral. A row of black spots across the nape.

Habitat.—Red Sea, East coast of Africa, seas of India to China. The specimen figured (life-size) was

taken in Sind.

2. Glyphidodon leucopleura, Plate LXXXIII, fig. 4.

B. v, D. $\frac{13}{15}$, P. 17, V. 1/5, A. $\frac{2}{14}$, C. 15, L. 1. 28, L. tr. 4/14.

Length of head $3\frac{1}{2}$, of caudal $4\frac{1}{3}$, height of body $2\frac{2}{3}$ in the total length. Eyes—diameter $2\frac{1}{4}$ in length of head, 1/2 a diameter from end of snout, and 3/4 of a diameter apart. The greatest depth of the preorbital equals 1/3 of the diameter of the orbit, the suborbital ring of bones is very narrow. Teeth—in a single row, small, compressed, and with notched summits. Fins—the third to the sixth dorsal spines considerably longer than the sixth dorsal angular. Caudal slightly lobed, lobes pointed. Scales—superiorly extend forwards a spine of the sixth dorsal spines of the sixth nearly as far as the front edge of the eye, none on the spinous portion of the dorsal fin. Colours—brownish, with a dark, almost black, band from the first half of the dorsal fin descending to the ventral: several narrow white vertical bands from the back to the abdomen. A black spot, edged with white, on the free portion of the tail just behind the end of the dorsal fin and extending upwards on to the bases of the last three dorsal rays. Ventral and anal black. Caudal yellowish, with dark outer edges.

Habitat.—Two specimens, of about the same length, (figured life-size) from the Andamans.

3. Glyphidodon Cochinensis, Plate LXXXI, fig. 1.

Day, Proc. Zool. Soc. 1865, p. 38, and Fish. Malabar, p. 156, pl. xii.

B. v, D. $\frac{15}{12-15}$, P. 15, V. 1/5, A. $\frac{2}{10-11}$, C. 15, L. 1. 28, L. tr. 3/8.

Length of head from $5\frac{1}{2}$ to 6, of caudal $2\frac{1}{2}$ to 3, height of body $3\frac{2}{3}$ in the total length. Eyes—diameter 3 to $3\frac{1}{4}$ in length of head, 3/4 of a diameter from end of snout, and 1 apart. Preorbital narrow, about 1/3 width of orbit, suborbital ring of bones of nearly equal width. Teeth—about 40 in the upper jaw, in a single compressed row, all have their summits notched. Fins—soft portions of dorsal, anal, and caudal lobes much elongated, dorsal spines moderately strong, sub-equal in length from the third. Colours—purplish-black, rather light or at the abdress produce of realty corrections with a lighter times, resternly not so deals are other for lighter on the abdomen, edges of scales sometimes with a lighter tinge: pectoral not so dark as other fins.

Habitat.—Cochin and the Andamans. The one figured (life-size) is from the Andamans.

4. Glyphidodon notatus, Plate LXXXIII, fig. 5.

Day, Proc. Zool. Soc. 1869, p. 521.

B. v, D. $\frac{1}{3-14}$, P. 19, V. 1/5, A. $\frac{2}{13-14}$, C. 17, L. 1. 28-30, L. tr. $4\frac{1}{2}/12$.

Length of head 4 to $4\frac{1}{2}$, of caudal 4 to $4\frac{1}{4}$, height of body $2\frac{1}{3}$ in the total length. Eyes—diameter 3 in the length of the head, 3/4 of a diameter from end of snout, and 1 apart. Greatest depth of the preorbital equals 1/2 the diameter of the eye, the suborbital ring is unnotched and posteriorly decreases rapidly in width. Greatest width of the head equals half its height. Teeth—narrow, compressed. Fins—third to sixth dorsal spines the longest in the fin, rays much longer than the spines: caudal deeply forked. Scales—extend forwards on the summit of the head to opposite the front edge of the eyes. Colours—olive brown, lightest inferiorly, five narrow white bands pass from the back down the sides, the first from the first dorsal spine to the base of the pectoral fin: the second from the third spine to the middle of the ventral: the third from the seventh spine to the commencement of the anal: the fourth from the tenth to the middle of the anal: and the fifth over the free portion of the tail. A black spot at the base of the pectoral: caudal yellowish.

Habitat.—Andamans, to 3½ inches in length.

5. Glyphidodon septemfasciatus, Plate LXXXI, fig. 7.

Cuv. and Val. v, p. 463; Bleeker, Sumatra, i, p. 582; Günther, Catal. iv, p. 40.

B. v, D. $\frac{18}{13}$, P. 17, V. 1/5, A. $\frac{2}{12}$, C. 17, L. 1. 29, L. tr. 3/11.

Length of head $4\frac{1}{4}$, of caudal 5, height of body $2\frac{2}{3}$ in the total length. Eyes—diameter $3\frac{1}{2}$ in length of head, $1\frac{1}{4}$ diameters from end of snout, and $1\frac{2}{3}$ apart. The greatest depth of the preorbital, which is not notched, equals 3/4 of the diameter of the eye: whilst that of the suborbitals (below the eye) equals 2/3. Fins—dorsal spines of moderate strength, the fourth to the sixth being the longest. Soft dorsal angular, the fifth ray being the longest: caudal lobes broad, not very greatly emarginate. Scales—on the head reach to opposite the middle of the eye. Colours—greenish-olive, with seven dark cross bands wider than the ground colour: the first, which is indistinct, from the summit of the head to the preopercle: the second from in front of the dorsal fin to the base of the pectoral: the third, fourth, and fifth from the spinous dorsal: the sixth from below the soft dorsal, and the seventh over the free portion of the tail. Spinous dorsal with a black edge and a yellowish band below it. A black spot at base of pectoral.

Habitat.—Seas of India to China. The specimen figured (life-size) is from Bombay.

Glyphisodon quadrifasciatus, et Waigiensis, Bleeker, Labr. Cten. p. 17, and Batav. p. 484. Apogon quinquevittutus, Blyth, Proc. Asi. Soc. Bengal, 1858, p. 272.

Sparus fasciatus, Gronov. ed. Gray, p. 60.

B. v, D. $\frac{13}{13}$, P. 17, V. $\frac{1}{5}$, A. $\frac{2}{12}$, C. 17, L. l. 29, L. tr. $\frac{41}{2}$ /12.

Length of head $4\frac{1}{2}$, of caudal $4\frac{1}{4}$, height of body $2\frac{3}{4}$ in the total length. Eyes—diameter $3\frac{1}{4}$ to $3\frac{3}{4}$ in length of head, 3/4 of a diameter from end of snout, and 1 apart. The greatest depth of the preorbital equals 2/3 of the diameter of the eye, the suborbital ring very narrow. Teeth—about 40 in the upper jaw, narrow and notched. Fins—dorsal spines increase in length posteriorly, soft dorsal pointed, its fourth and fifth rays being the longest. Caudal deeply forked. Scales—on the head extend forwards to opposite the front edge of the eye. Colours—olive-brown, with five vertical dark cross bands that are narrower than the interspaces between them, the first descends from the first spine to the shoulder: the second from the fourth and fifth spines: the third from the tenth and eleventh: the fourth from the last dorsal spines to the front edge of the anal: and the fifth across the free portion of the tail, being continued on to the last dorsal rays. A dark spot at the base of the pectoral fin. Outer edge of caudal usually black.

Habitat.—From the Red Sea and east coast of Africa, through the seas of India to the Malay Archipelago and Polynesia. The one figured (life-size) was from Bombay.

B. v, D. $\frac{1}{12} \cdot \frac{8}{13}$, P. 17, V. 1/5, A. $\frac{2}{11} \cdot \frac{2}{12}$, C. 15, L. 1. 29-30, L. tr. 4/11.

Length of head $4\frac{1}{4}$, of caudal $4\frac{1}{4}$, height of body $2\frac{1}{2}$ in the total length. Eyes—diameter $3\frac{1}{6}$ in length of head, I diameter from end of snout, and 1½ apart. Profile from snout to base of dorsal fin almost semicircular. Greatest depth of the preorbital equals the diameter of the eye; the suborbital ring, above the angle of the mouth, equals 3/4 of a diameter of the eye. Teeth—in a single compressed row, having the crowns not hed. Fins—the third to the sixth dorsal spines rather longer than the last; soft dorsal angular, the fourth and fifth rays being the longest. Caudal forked, lobes pointed. Scales—on the summit of the head reach forwards to opposite the middle of the eyes. Colours—of a dull greenish-olive, with seven vertical dark bands extending downwards from the back, the first across the head, the second across the neck, four below the dorsal fin and one across the free portion of the tail. A dark edge to spinous dorsal, a dark spot at base of pectoral, and two bands along anal fin.

Habitut.—Seas of India to the Malay Archipelago and beyond. The one figured (life-size) is from the

Andaman islands.

Glyphisodon Rossii, Bleeker, Kokos, p. 48 (most of body markings absent). Glyphisodon Balinensis, Bleeker, Bali, p. 9. Glyphidodon fasciatus, Günther, Catal. iv, p. 51 (blue transverse spot on body).

B. v, D. $\frac{1}{12-13}$, P. 17, V. 1/5, A. $\frac{3}{12-13}$, C. 17, L. l. 26-28, L. tr. $2\frac{1}{2}/9$.

Length of head $4\frac{1}{4}$ to $4\frac{1}{2}$, of caudal 5, height of body $2\frac{2}{3}$ to 3 in the total length. Eyes—diameter 3 to $3\frac{1}{2}$ in length of head, 3/4 to 1 diameter from the end of snout, and 1 apart. Preorbital rather broad, its greatest depth equal to about 1/2 a diameter of the eye: suborbital ring narrow. Teeth—narrow and in two rows. Fins—posterior dorsal spines somewhat the longest: soft dorsal and anal angular. Caudal slightly forked. Scales—on the summit of the head, are continued forwards to opposite the front edge of the eyes. Colours exceedingly various, the markings being partially or entirely absent in some specimens, and that not merely due to age. Cærulean blue above the lateral-line, this colour extending on to some scales along the base of that fin, and ending at the end of the soft dorsal by surrounding one (sometimes two) black blotches, the black blotches on the dorsal fin are sometimes absent. A blue line is generally continued along the supraorbital region, joining another from the opposite side across the snout. A median blue or dark band occasionally is seen along the occiput. Two blue bands along the eye, and one from the eye to the angle of the mouth: another

Digitized by GOOG

along the suborbital ring of bones, and one or two along the cheeks. In some specimens there is a spot of blue on many of the scales of the body.

on many of the scales of the body.

Habitat.—From the Red Sea through those of India to the Malay Archipelago and beyond. The specimens figured (life-size) are from the Andamans.

9. Glyphidodon leucogaster, Plate LXXXI, fig. 3.

Bleeker, Labr. Cten. p. 26; Günther, Catal. iv, p. 46; Klunz. Verh. z. b. Ges. Wien, 1871, p. 523. B. v, D. $\frac{1}{12-13}$, P. 17, V. 1/5, A. $\frac{2}{12}$, C. 17, L. l. 26-28, L. tr. 3/12.

Length of head $4\frac{1}{2}$, of caudal $4\frac{1}{2}$, height of body $2\frac{1}{3}$ in the total length. Eyes—diameter $2\frac{3}{4}$ in length of head, 2/3 of a diameter from end of snout, and $1\frac{1}{4}$ apart. Preorbital with a shallow notch, its greatest width equals nearly 1 diameter of the eye: suborbital ring narrow. Teeth—narrow, about 46 in the upper jaw. Fins—dorsal spines, after the second, subequal in length: soft portion of dorsal rather pointed. Second anal spine as long as the head excluding the snout, the soft portion of the fin rounded. Caudal forked with pointed lobes. Scales—extend forward on the top of the head to the snout, they also cover the preorbital and suborbitals. Colours—olive-brown, becoming lighter on the sides and yellowish on the abdomen. Upper edge of dorsal and outer two-thirds of anal black, the rest of the fin and the ventral yellow. Outer margin of caudal dark. A black spot at base of pectoral fin.

black spot at base of pectoral fin.

Habitat.—Red Sea, East coast of Africa, Nicobars to the Malay Archipelago. The one figured (life-size) is from the latter locality. for it I have to thank Professor Schlegel and Dr. Hubrecht of Leyden.

10. Glyphidodon modestus, Plate LXXXI, fig. 6.

Schleg. Overz. Amphr. &c. in Verh. Nat. Gesch. Ned. Overz. Bezitt. p. 23, t. vi, f. 2; Bleeker, Sumatra, ii, p. 285; Günther, Catal. iv, p. 55; Kner, Novara Fische, p. 246.

B. v, D. $\frac{13}{12}$, P. 18, V. $\frac{1}{5}$, A. $\frac{2}{12}$, C. 15, L. 1. 23-24, L. tr. $\frac{21}{8}$.

Length of head $4\frac{1}{2}$, of caudal 5, height of body $3\frac{1}{3}$ in the total length. Eyes—diameter $2\frac{3}{4}$ to 3 in length of head, 2/3 to 3/4 of a diameter from end of snout, and 1 apart. The greatest depth of the preorbital is a little more than half the diameter of the eye, posteriorly the suborbital ring of bones rapidly narrows. Teeth—compressed, notched at their extremities, and about 36 in the upper jaw. Fins—the dorsal spines gradually increase in length to the last, soft dorsal and anal somewhat rounded, caudal slightly cleft and having rounded lobes. Scales—extend forward on the top of the head to opposite the front edge of the eye: none on the preorbital or suborbital ring of bones. Colours—yellowish-olive, becoming lighter on the sides and beneath: the outer third of dorsal and anal fins grayish: a brownish dot superiorly at the base of the pectoral fin.

Habitat.—Andamans through the seas of India to China. The one figured (life-size) is from the

Andamans.

11. Glyphidodon Sindensis, Plate LXXXII, fig. 2.

Day, Sea Fishery Report, 1873, Appendix, p. cclxiii.

B. v, D. $\frac{13}{11-12}$, P. 19, V. 1/5, A. $\frac{9}{11-13}$, C. 15, L. l. 26, L. tr. $3\frac{1}{2}/10$.

Length of head $3\frac{3}{4}$ to 4, of caudal $4\frac{1}{4}$ to $4\frac{1}{2}$, height of body $2\frac{3}{3}$ to 3 in the total length. Eyes—diameter 3 in length of head, 1/2 a diameter from end of snout, and 1 apart. Preorbital in its widest part not equal to 1/3 of the diameter of the eye, suborbital ring of bones narrow. Teeth—in a narrow row, about 50 in the upper jaw, their summits notched. Fins—dorsal spines increase to the fourth, all the posterior ones about equal: soft dorsal rather produced in its centre: caudal forked, upper lobe the longer, and may be produced, more especially in the young: pectoral rounded, as long as head without the snout: soft dorsal and anal scaled. Scales—on the summit of the head extend forward as far as the snout, also on pre- and sub-orbitals. Colours—deep violet, extending on to the dorsal and anal fins: pectoral hyaline with a dark mark at its base: ventral nearly black: the posterior extremities of the dorsal and caudal canary yellow: all the scales on the upper part of the body and free portion of the tail with a light blue central spot. Some blue lines about the head in the young, which has also the free portion of the tail yellow and the chest light coloured.

has also the free portion of the tail yellow and the chest light coloured.

Habitat.—Numerous in the harbour at Kurrachee in Sind. The one figured (life-size) is from that

locality, where I did not obtain them larger.

Genus, 6-Heliastes, Cuv. and Val.

Furcaria, Poey.

Branchiostegals five: pseudobranchiæ. All the opercles entire. Teeth in the juws conical, in a narrow and irregular row. Scales of moderate size. Dorsal fin with 12 to 14 spines: anal with two. Lateral-line in a tubular form not continued beyond the end of the base of the dorsal fin. Air-vessel present. Pyloric appendages two.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Heliastes lepidurus, D. $\frac{1}{10}$, A. $\frac{1}{10}$, A. $\frac{3}{10}$, L. l. 26-27. Olive, scales with a blue dot. East coast of Africa to the Malay Archipelago and beyond.

1. Heliastes lepidurus, Plate LXXXII, fig. 1.

Heliases lepidurus, Cuv. and Val. v, p. 498; Bleeker, Ich. Sumb. Journ. Ind. Arch. 1848; Günther,

Glyphisodon Bandanensis, Bleeker, Banda, i, p. 248.

Heliases frenatus, Bleeker, Ceram. p. 710 (not Cuv. and Val.). Heliases cæruleus, Bleeker, Kokos, iv, p. 455 (not Cuv. and Val.).

Glyphidodon anabatoides, Day, Proc. Zool. Soc. 1870, p. 696. B. v, D. $\frac{11-12}{10-11}$, P. 15, V. 1/5, A. $\frac{2}{10}$, C. 17, L. l. 26-27, L. tr. $2\frac{1}{2}/9$.

Length of head 4 to $4\frac{1}{4}$, of caudal $4\frac{2}{3}$, height of body $2\frac{2}{4}$ to 3 in the total length. Eyes—diameter 3 in length of head, 3/4 to 1/2 of a diameter from end of snout, and 1 apart. Greatest width of preorbital 1/3 of that of the orbit. Teeth—in a single row. Fins—third to fifth dorsal spines the longest: caudal deeply forked. Scales—on preorbital and suborbitals, they extend on the summit of the head to the snont. Colours—olive, each scale with a blue dot: a blue line from the eye across the preorbital, a blue spot at the commencement of the lateral-line: dorsal dotted with blue, and having a dark edge: anal dotted with yellow and also with a dark margin: caudal with a brownish longitudinal band along either lobe. A dark axillary spot on the pectoral: ventrals green.

I found this fish very abundant about the coral reefs of the Andaman islands. As soon as the water was splashed they appeared to retire for safety to the branching coral where no large fish could follow them, and

they allowed great pieces to be removed from the water without venturing to leave their retreat.

Habitat.—East coast of Africa, Andamans, Malay Archipelago and beyond.

FAMILY, XLI—LABRIDÆ, Cuv.

Labroidei cycloidei, Mull.; Scaroidei, Cantor; Cyclolabridæ, Owen.

Branchiostegals five or six: pseudobranchiæ. Gills three and a half. Body oblong or elongated. Teeth in the jaws, palate edentulous: lower pharyngeal bones anchylosed along the median line into one without any median suture. A single dorsal fin with usually as many or more spines than rays: the anal rays usually similar to those of the dorsal: ventral thoracic, with one spine and five rays. Scales cycloid. Lateral-line complete or interrupted. Air-vessel present. No cœcal sac to the stomach. Pyloric appendages ahaan t.

These fishes appear to be entirely marine and mostly confined to the seas of tropical and temperate regions. Many of them are adorned with gorgeous colours, being generally abundant in the neighbourhood of rocks and coral reefs. Some are provided with excessively strong teeth to enable them to crush the shells of the marine molluscs, and a few have an additional pointed tooth at the angle of the mouth which is supposed to be employed for pressing a shell against the crushing front and lateral teeth.

SYNOPSIS OF GENERA

1. Chærops. Cheeks elevated. Anterior teeth conical and free, the lateral ones more or less confluent ridge. D. $\frac{1}{2}$. Scales large, small ones on cheeks. Lateral-line continuous. Red Sea, through those into a ridge. D. $\frac{13}{20}$. of India to Australia.

2. Cossyphus. Anterior teeth conical and free: a posterior canine. Dorsal fin with twelve (rarely thirteen) spines. Cheeks and opercles scaly, also base of soft dorsal. Lateral-line continuous. Red Sea, throughout those of India to Australia and beyond.

3. Labroides. Anterior teeth forming a pair of curved fangs in either jaw. Dorsal fin with nine spines.

Cheeks and opercles scaly. Lateral-line continuous. Red Sea, seas of India to the Malay Archipelago.

4. Cheilinus. Anterior teeth conical and free. Dorsal fin with nine or ten spines. Cheeks and opercles scaly. Lateral-line interrupted. Red Sea, East coast of Africa, seas of India to China and beyond.

5. Epibulus. Lower jaw produced backwards. Anterior teeth conical and free. Dorsal fin with nine

spines. Cheeks and opercles scaly. Lateral-line interrupted. Seas of India to the Malay Archipelago.
6. Anampses. Two compressed and cutting anterior teeth in either jaw. Dorsal fin with nine spines. Head scaleless. Lateral-line continuous. Red Sea, seas of India to the Malay Archipelago and beyond.

7. Hemigymnus. Anterior teeth free and conical. Dorsal fin with nine spines. Cheeks with a row of a

few small scales. Lateral-line continuous. Red Sea, seas of India to the Malay Archipelago and beyond.

8. Stethojulis. Anterior teeth conical and free: a posterior canine. Dorsal fin with nine spines. Head scaleless. Scales on chest at least as large as those on the body. Lateral-line continuous. Red Sea, seas of India to the Malay Archipelago and beyond.

9. Platyglossus. Anterior teeth conical and neither bent backwards nor outwards: a posterior canine. Dorsal fin with nine spines. Head scaleless. Scales on chest smaller than those on the body. Lateral-line

continuous. Red Sea, seas of India to the Malay Archipelago and beyond.

10. Novacula. Anterior teeth conical and free: no posterior canine. Dorsal fin with nine spines, the two first of which are sometimes semi-detached from the remainder. Head scaleless or with a few rudimentary scales on the cheeks. Lateral-line interrupted. Seas of India, intertropical seas and beyond.

11. Julis. Anterior teeth conical and free: no posterior canine. Dorsal fin with eight spines. Head

scaleless. Lateral-line continuous. Red Sea, seas of India, also tropical and adjacent ones.

12. Gomphosus. Snout produced. Anterior teeth conical and free: no posterior canine. Dorsal fin with eight spines. Head scaleless. Lateral-line continuous. Red Sea, seas of India to the Malay Archipelago and beyond.

13. Cheilio. Body elongated: anterior teeth conical and free: no posterior canine. Dorsal fin with nine spines. Head scaleless, or a few scales on opercle. Lateral-line continuous. Red Sea, seas of India to

the Malay Archipelago and beyond.

14. Coris. Anterior teeth conical and free. Dorsal fin with nine spines. Scales small, none on the head. Lateral-line continuous. Red Sea, seas of India to Australia and beyond: also found in the Mediterranean.

15. Cymolutes. Anterior teeth conical and free: no posterior canine. Dorsal with nine spines. Scales small, none on head.

16. Pseudodax. Anterior teeth broad and with cutting lateral edges. Dorsal with eleven spines.

Scales of moderate size on cheeks and opercles. Lateral-line continuous. Nicobars to the Malay Archipelago and beyond.

17. Scarichthys. Teeth in one row anteriorly soldered together, row in mandibles oblique. Dorsal with nine spines. Scales large, a row on cheek. Lateral-line continuous. Red Sea, seas of India to the Malay Archipelago and beyond.

18. Callyodon. Teeth anteriorly imbricated. Dorsal fin with nine, anal with two spines. Scales large, a single row on cheeks. Lateral-line strongly bent or interrupted. Red Sea, seas of India.

19. Pseudoscarus. Upper jaw slightly projecting beyond the lower. Anterior teeth soldered together in quincuncial order. Dorsal fin with nine, anal with two or three spines. Scales large, two or more rows on the cheeks. Lateral-line continuous. Tropical seas.

Genus, 1—CHEROPS, Rüppell.

Cossyphus, sp. Cuv. and Val.; Choirodon and Cossyphodes, Bleeker; Hypsigenys, Günther.

Branchiostegals five or six: pseudobranchiæ. Body oblong, compressed. Snout obtuse. Preopercle cerrated or entire. The four anterior teeth conical and free, whilst the lateral ones are more or less confluent in an osseous ridge, a posterior canine tooth, occasionally two, may be present; inferior pharyngeal teeth not confluent or pavement-like. A single dorsal fin with more spines (thirteen) than rays (seven): anal with three spines and more rays than the soft dorsal (9-10). Scales large: cheeks high, covered with small scales, which usually are not imbricated: opercles scaled. Vertical fins with scaly bases: no enlarged row at base of caudal. Lateral-line continuous.

Geographical distribution.—From the Red Sea and East coast of Africa through the seas of India to the Malay Archipelago and Australia.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Chærops anchorago, D. 13/7, A. 3/9, L. l. 29-30. Red spots over the cheeks: a white vertical band down the sides from the bases of the fourth to the sixth dorsal spines. Andamans to the Malay Archipelago.

1. Cherops anchorago, Plate LXXXII, fig. 5.

Sparus anchorago, Bloch. v, p. 108, t. 276; Bl. Schn. p. 276. Cossyphus anchorago, Trosch. Wiegm. Arch. 1840, p. 279. Chærops anchorago, Günther, Catal. iv, p. 95.

B. vi, D. $\frac{1}{2}$, P. 15, V. 1/5, A. 3/9, C. 14, L. 1. 29-30, L. tr. $3\frac{1}{2}$ /9.

Length of head $3\frac{1}{3}$ to $3\frac{2}{3}$, of caudal $6\frac{3}{4}$ to 7, height of body $3\frac{1}{4}$ to $3\frac{1}{3}$ in the total length. Eyes—high up, diameter $4\frac{1}{2}$ to 5 in the length of head, 2 diameters from end of snout, and $1\frac{1}{4}$ apart. Profile from eye to snout rather abrupt. Height of head equals its length. Preopercial finely serrated. Teeth—a posterior canine in adults. Scales—on cheeks numerous, but scarcely imbricated. Colours—cheeks brownish, shot with yellow, and covered with scarlet spots. Back brownish, with a white vertical band descending from the bases of about the fourth to the sixth dorsal spines to below the last third of the pectoral: a light band over the free portion of the tail behind the base of the dorsal fin. In some specimens there are two to four wide dark cross bands. Dorsal fin with two dark bands and another descending down the first four rays to the back: posteriorly it is yellow and edged superiorly with orange: the other fins yellowish, a band along the ventral and sometimes a brown base to the pectoral.

Professor Peters Monats, Ak. Wiss. Berlin, 1868, p. 270, observes that this species is identical with C. macrodon, Bleeker, or Labrus macrodontus, Lacép. iii, pp. 451, 522; Cuv. and Val. xiii, p. 98; Cherops meleagris, Rüppell, Verz. Mus. Senck. Fische, p. 20; Cossyphus macrodon, Bleeker, Labr. p. 10; Cherops macrodon, Günther, Catal. iv, p. 94; Kner, Novara Fische, p. 248.

Habitat.—Andamans to the Malay Archipelago. It attains a large size, the one figured is 8.5 inches in

length.

Genus, 2—Cossyphus,* Cuvier and Val.

Harpe, Lepidoplois, and Pimelometopon, Gill.

Branchiostegals six: pseudobranchiæ. Body oblong, compressed. Snout more or less pointed. Preopercle serrated or entire. The four anterior teeth conical and free: the lateral teeth in a single row, whilst a posterior canine is as a rule present: inferior pharyngeal teeth not confluent or pavement-like. A single dorsal fin with more spines (11-13) than rays (9-11): the anal with three spines and more rays (10-14) than the soft dorsal. Scales of moderate size, those on the cheeks and opercles imbricated: the bases of the vertical fins scaled. No enlarged row of scales at the base of the caudal fin. Lateral-line continuous.

Geographical distribution.—Red Sea, East coast of Africa, seas of India to the Malay Archipelago, and nearly all intertropical and adjacent seas.

The colours would seem to be subject to considerable variation in the same species. As a rule we find the dorsal fin has only twelve spines.

* Cossyphus as a Generic name has been frequently employed: by Fabr. in Coleop. 1792; Dumeril in Birds, 1802; Val. in Fishes, 1839; and ten years later by McClelland, who instituted this Generic term for a mutilated specimen of Clarias.

SYNOPSIS OF SPECIES.

1. Cossyphus axillaris, D. 12, A. 3, L. l. 34. Orange red, darkest superiorly, as a rule a black spot at

base of pectoral and on the first few rays of dorsal and anal fins. Madagascar, Mauritius, seas of India.

2. Cossyphus Diana, D. 12/10, A. 10³12, L. l. 32-33. Reddish, three white spots between the lateral-line and base of dorsal fin: a small black spot at end of lateral-line, some dark spots on scales in last portion of the body above the lateral-line. Mozambique, Mauritius, seas of India to the Malay Archipelago.

1. Cossyphus axillaris, Plate LXXXII, fig. 3, (variety.)

Labrus axillaris, Benn. Proc. Zool. Soc. 1831, p. 166.
Cossyphus axillaris, Cuv. and Val. xiii, p. 131, pl. 371; Günther, Catal. iv, p. 103; Klunz. Verh. z. b. Ges. Wien, 1871, p. 549.

Cossyphus Neilli, Day, Proc. Zool. Soc. 1867, p. 560 (variety). Moonjilli, Tamil.

B. vi, D. $\frac{12}{10}$, P. 16, V. 1/5, A. $\frac{3}{12}$, C. 14, L. l. 34, L. tr. 5/12.

Length of head 4, of caudal 7 to 8, height of body $3\frac{1}{3}$ to 4 in the total length. Eyes—diameter 4 to $4\frac{1}{3}$ in length of head, $1\frac{1}{3}$ to $1\frac{2}{3}$ diameters from end of snout, and $1\frac{1}{4}$ apart. The greatest height of the head equals its length behind the posterior nostril. Upper lip thick and with a broad anterior fold. Preopercle finely serrated. Teeth—a posterior canine present. Fins—candal truncated or slightly emarginate. Colours—head and upper two-thirds of the back orange red. Fins yellow, with a black base to the pectoral, and a black blotch on the upper two-thirds of the first few dorsal and anal rays.

Variety.—A. Amongst Sir W. Elliott's drawings is one of this fish, in which the black markings are seen

in the form of deep orange blotches.

Variety.—B. (C. Neilli). A second variety (of which the specimen from which it was figured has been preserved), shows the head and upper two-thirds of the body as far as the middle of the dorsal fin of a deep orange red, as is also the first half of the soft anal, the posterior half of both these fins yellow. Caudal

and free portion of the tail orange scarlet, (not so in my specimens). Pectoral flesh-coloured, lips reddish.

The series appears to conclusively prove that the colours of this species are subject to great variation.

The one figured (life-size) is of the second variety (C. Neilli), and from Madras.

The species adverted to by Jerdon, M. J. L. and Sc. 1851, p. 135, are as follows:—Moonjilli, Tam. is

C. axillaris variety Neilli: Kul moonjilli is C. Diana.

Habitat.-Madagascar, Mauritius, seas of India to New Hebrides.

2. Cossyphus Diana, Plate LXXXVII, fig. 3.

Labrus Diana, Lacép. iii, pp. 451, 522, pl. 32, f. 1.

Cossyphus Diana, Cuv. and Val. xiii, p. 127; Peters. Fische Moss. Pr. Ak. Berl. 1855, p. 451; Bleeker, Sumatra vii, p. 86, and Atl. Ich. i, p. 159, t. 38, fig. 1; Günther, Catal. iv, p. 104; Klunz. Verh. z. b. Ges. Wien, 1871, p. 549.

Labrus leucosticticus, Bennett, Proc. Zool. Soc. 1831, p. 166.

Cossyphus spilotes, Guich. in Maillard, Notes on the Isle of Reunion, App. p. 14.

B. vi, D. $\frac{12}{10}$, P. 16, V. $\frac{1}{5}$, A. $\frac{3}{10-12}$, C. 14, L. l. 32-33, L. tr. $\frac{4}{12}$.

Length of head $3\frac{1}{3}$ to $3\frac{1}{2}$, of caudal 6, height of body $3\frac{1}{2}$ in the total length. Eyes—diameter 1/5 of length of head, 2 diameters from end of snout, and $1\frac{1}{4}$ apart. Snout produced, rather pointed: lips thick and broad: preopercle finely serrated. Teeth—a posterior canine in either jaw. Fins—no elongated ventral ray: caudal truncated. Colours—reddish, three large white spots between the lateral-line and the base of the dorsal fin, two being below the spines and one beneath the rays. Dark spots on the end of the scales from the commencement of the soft dorsal to the caudal above the lateral-line: a black spot at the posterior end of the lateral-line: fins diaphanous.

Some specimens have a white spot before the commencement of the lateral-line. Others show a large

black spot upon the ventral, and two more on the anal fins.

Habitat.—Seas of India: a specimen $5\frac{1}{2}$ inches long exists in the Calcutta Museum, taken in the Indian Ocean. There is also a figure of this species amongst Sir Walter Elliot's drawings, it was captured at Waltair. The one figured (life-size) is from the Malay Archipelago, and for it I am indebted to Dr. Hubrecht of the Leyden Museum.

Genus, 3-LABROIDES, Bleeker.

Diproctacanthus, Bleeker; Fissilabrus, Kner.

Branchiostegals five: pseudobranchiæ. Body oblong, compressed. Gill-membranes attached to the isthmus. Snout pointed, lips prominent, one of them having a notch anteriorly. Preopercle entire. A band of small toeth in the jaws, with a pair of curved canines in either jaw, the upper pair being received between the lower ones when the mouth is closed: a posterior canine tooth: inferior pharyngeal teeth not confluent or pavement-like. A single dorsal fin with usually less spines (9) than rays (9-12); anal with two or three spines, and rays nearly similar to those of the dorsal (9-10). Scales on body of moderate size, they are extended over the opercles, checks and base of the vertical fins: no enlarged row at base of caudal fin. Lateral-line continuous.

Geographical distribution.—Red Sea, seas of India to the Malay Archipelago.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Labroides dimidiatus, D, $\frac{9}{10^{-12}}$, A. $\frac{9}{10}$, L. l. 46-50, L. tr. 4/15. Lips notched. A black band from the eye to the tail, widening posteriorly and covering the caudal fin, except its angles. Red Sea and seas of India to the Malay Archipelago.

1. Labroides dimidiatus, Plate LXXXVII, fig 1.

Labrus latovittatus, Rüpp, N. W. Fische, p. 7, t. ii, f. 2, (not Lacépède). Cossyphus dimidiatus, Cuv. and Val. xiii, p. 136.

Labroides dimidiatus, Günther, Catal. iv, p. 119. Fissilabrus latovittatus, Kner, Char. et Syst. Labr. p. 14.

B. v, D. $\frac{9}{10^{-12}}$, P. 13, V. 1/5, A. $\frac{3}{10}$, C. 14, L. l. 46-50, L. tr. 4/15.

Length of head $3\frac{1}{2}$ to $3\frac{3}{4}$, of caudal 5, height of body $3\frac{1}{2}$ to 4 in the total length. Eyes—diameter 1/4 of length of head, 1 diameter from end of snout, and $1\frac{1}{2}$ apart. Opercles entire. The lips emarginate anteriorly. Height of head equals about $1\frac{3}{4}$ in its length. Fins—third anal spine the longest: cautaquare. Lateral-line—curves opposite the posterior end of the dorsal fin. Colours—nearly white, with a lateral-line when the care to the upper third of the base of the gaudal fin when it heads slightly to reach the black band through the eye to the upper third of the base of the caudal fin when it bends slightly to reach the centre of that fin: a black band along the anal, which passes to the caudal and joins the upper band at the end of that fin: a dark band along the dorsal fin. Two specimens, captured at Waltair, exist in Sir Walter Elliot's collection: the figure is taken from one of them. My Andamanese specimen has twelve dorsal rays, the last being divided into two: it has also two posterior canines in either jaw.

Habitat.—Red Sea, Coromandel coast of India, Andamans to the Malay Archipelago.

Genus, 4—Cheilints, (Lacép.) Cuvier.

Oxycheilinus et Crassilabrus, Gill.

Branchiostegals five. Body oblong, compressed. Preopercle entire. Lower jaw not produced backwards. Teeth in one row, two canines in either jaw, none being directed outwards: no posterior canine: inferior pharyngeal teeth not confluent or pavement-like. A single dorsal fin, the number of spines (9-10), being about equal to the rays (9-11). Anal with three spines, the third being the longest, its rays rather less (8-9) than those of the dorsal. Scales large (20 to 23 in a longitudinal row), two rows on the cheeks, the last three at the base of the caudal fin enlarged. Lateral-line interrupted.

Geographical distribution.—Red Sea, and east coast of Africa through the seas of India to the Malay Archipelago, China, and beyond.

SYNOPSIS OF SPECIES.

1. Cheilinus chlorurus, D. 10, A. 3, L. 1. 22. Caudal trilobed, sometimes rounded in the young. Olive brown, cheeks with yellow spots and streaks. Ventral, anal, and caudal with small yellow dots. Bay of Bengal to Malay Archipelago and beyond.

2. Cheilinus trilobatus, D. $\frac{9}{10}$, A. $\frac{3}{8}$, L. l. 20. Caudal rounded except in the adult, when it is trilobed. Grayish-brown, with red spots and stripes on the head. Seas of India to the Malay Archipelago and beyond.

3. Cheilinus fasciatus, D. $\frac{9}{10}$, A. $\frac{3}{8}$, L. l. 21-23. Yellowish, with six or seven dark vertical bands. Seas of India to the Malay Archipelago and beyond.

1. Cheilinus chlorurus, Plate LXXXII, fig. 6.

Sparus chlorurus, Bloch, v, p. 24, t. 260; Bl. Schn. p. 269; Lacép. iv, pp. 55, 163.

Thalliurus Blochii, Swainson, Fishes, ii, p. 230.

Cheilinus guttatus, Bleeker, Labr. Cycl. p. 36.

Cheilinus decacanthus, Bleeker, Banda, i, p. 256.

B. v, D. 10, P. 11, V. 1/5, A. 8, C. 12, L. 1. 22, L. tr. 2/8.

Length of head $3\frac{3}{4}$, of caudal $4\frac{1}{2}$, height of body 3 in the total length. Eyes—diameter $4\frac{3}{4}$ in the length of head, $1\frac{1}{3}$ diameter from end of snout and also apart. The maxilla reaches to below the front edge of the orbit. Teeth—canines of moderate size. Fins—ventral raches the anal rays: outer caudal rays produced, causing the fin to appear three lobed: sometimes rounded in the young. Lateral-line—tubes much branched. Colours—olive-brown, with round yellow spots on the cheeks, and a streak of the same colour from the eye to

Digitized by GOOG

the angle of the mouth: body sparingly dotted with yellow, a yellow mark covers the last few dorsal rays and is continued on to the back of the free portion of the tail: spinous dorsal olive, with red edges, and spines

with brown dots: soft dorsal reddish: anal, ventral, and caudal with small yellow dots.

In the "Fishes of Zanzibar," the authors observe of Cheilinus punctatus, Bennett, Proc. Zool. Soc. i, p. 167=C. punctulatus, C. V. xiv, p. 87, pl. 396, "this species is yellowly allied to C. chlorurus, Bl., and it may be regarded as the western representative of that fish" (p. 89).

Habitat.—Bay of Bengal to the Malay Archipelago and beyond. The specimen figured is from the Andamans, and is 7.7 inches in length.

2. Cheilinus trilobatus, Plate LXXXII, fig. 4.

Cheilinus trilobatus, Lacép. iii, pp. 529, 537, t. 31, f. 3; Cuv. Règ. An. Poiss. pl. 86, f. 2; Rüpp. Atl. Fische, p. 22; Cuv. and Val. xiv, p. 79; Bleeker, Labr. p. 34, and Atl. Ich. i, p. 66, t. 27, f. 2; Günther, Catal. iv, p. 126; Klunz, Verh. z. b. Ges. Wien, 1871, p. 553.

Cheilinus nebulosus, Richards. Ich. China, p. 261.

Cheilinus tetrazona, Bleeker, Sumatra, ii, p. 293.

B. v, D. $\frac{9}{10}$, P. 12, V. 1/5, A. $\frac{3}{8}$, C. 13, L. 1. 20, L. tr. $2\frac{1}{2}$ /7.

Length of head $3\frac{2}{3}$, of caudal 7, height of body $3\frac{1}{4}$ in the total length. Eyes—diameter $5\frac{1}{4}$ in the length of head, $1\frac{1}{2}$ diameters from the end of snout and also apart. Profile over snout rather concave. The maxilla reaches rather above 1/2 way to below the orbit. Teeth—canines rather small. Fins—ventral does not reach the anal: caudal rounded except in some large specimens, when it is usually trilobed. The figure in Lacépède shows the caudal deeply trilobed. Lateral-line—tubules branched. Colours—grayish-brown, with red spots and narrow stripes on the head, the last being mostly before and below the eyes: some of the scales on the body with red spots. Vertical fins green, dorsal and anal having red margins: a dark spot at the base of the middle dorsal rays, sometimes extending to the posterior one.

In Cuv. and Val. xiv, p. 85, Sparus chlorurus, Bl. is considered identical with this species.

Habitat.—Red Sea, East coast of Africa, Andamans to the Malay Archipelago and beyond. The one figured is 9½ inches long, and from the Andamans. It grows to at least three feet in length.

3. Cheilinus fasciatus, Plate LXXXIV, fig. 1.

Ich. i, p. 67, t. 26, f. 2; Günther, Catal. iv, p. 129; Kner, Novara Fische, p. 251: Klunz. Verh. z. b. Ges. Wien, 1871, p. 555.

B. v, D. $\frac{9}{10}$, P. 12, V. 1/5, A. $\frac{3}{8}$, C. 13, L. l. 21-23, L. tr. 2/7, Vert. 10/13.

Length of head $3\frac{1}{2}$, of caudal $4\frac{2}{3}$, height of body 3 to $3\frac{1}{3}$ in the total length. Eyes—diameter 5 in the length of head, 2 diameters from the end of snout and also apart. The greatest height of the head equals its length. The outer end of the maxilla is curved forwards as a hook-like process into the concavity of which the outer extremity of the premaxillary is received. Fins—ventral rounded, not reaching to the anal: caudal truncated, having its upper and lower rays produced. Lateral-line—tubules unbranched. Colours—yellowish, with six or seven dark or black bands: black spots on the nape, opercles and pectoral region, also some scattered over the body. Caudal with a crescentic vertical black band, and a black posterior edge, a four nearest dark bands between the order back bands are seven of the bely a few narrow dark bands between the two. Dorsal with a light edge having a dark base, some of the body bands are extended on to this fin. A large black blotch on the ventral.

Habitat.—Red Sea, through those of India to the Malay Archipelago and beyond. Bloch's specimen from the Indian Ocean is still preserved in spirit in Berlin. The specimen figured is 8.3 inches in length, and from the Malay Archipelago: I am indebted for it to Dr. Hubrecht of the Leyden Museum.

Genus, 5—Epibulus, Cuvier.

Branchiostegals five. Body oblong, compressed. Preopercle entire. Mouth very protractile, the ascending processes of the premaxillaries, also the mandibles and tympanics, being elongated. Teeth in one row, and two canines in either jaw, but no posterior canine: inferior pharyngeal teeth not confluent or pavement-like. A single dorsal fin with less spines (9) than rays (10): three anal spines, the rays less numerous than those of the dorsal. Scales large, two rows on the cheeks, three enlarged ones at base of caudal fin. Lateral-line interrupted.

Geographical distribution.—Seas of India to the Malay Archipelago

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Epibulus striatus, D. 3, A. 3, L. l. 19, L. tr. 2/7. Vertical narrow white bands. Andamans.

1. Epibulus striatus, Plate LXXXVII, fig. 2 (2).

Day, Proc. Zool. Soc. 1870, p. 697.

B. v, D. $\frac{9}{10}$, P. 11, V. 1/5, A. $\frac{3}{8}$, C. 13, L. 1. 19, L. tr. 2/7.

Length of head above 2/5, of caudal 2/11, height of body 2/5 of the total length. Eyes—diameter 2/7 of length of head, 1 diameter from end of snout and apart. The posterior extremity of the lower jaw extends to below the hind edge of the orbit, and the ascending processes of the premaxillaries to opposite the posterior third of the orbit. Fins—not elongated: the interspinous membrane prolonged beyond the spines of both the dorsal and anal fins. Lateral-line—interrupted opposite the middle of the soft dorsal. Colours—a white line between the orbits, and two more on the head, the first of which runs from the eye to the snout: the second descending from the orbit meets one from the opposite side. Body greenish-brown, with five narrow milk-white vertical bands, the first from the opercles to before the ventral fins, the next from the second dorsal spine to the end of the ventral fin, the third from the centre of the dorsal spines to the base of the anal, the fourth from the end of the dorsal fin to the end of the anal, the fifth round the free portion of the tail. Soft dorsal and termination of the anal white, the remainder of the fins dark coloured.

Habitat.—Andamans, where a single specimen $1\frac{1}{2}$ inches in length was captured, it is figured twice life-size.

Genus, 6-Anampses, Cuvier.

Branchiostegals six: body oblong, compressed. Preopercle entire. Tecth in jaws in one row, the two front ones in each being prominent, directed forwards, and compressed, with cutting edges: no posterior canine tooth: inferior pharyngeal teeth not confluent or pavement-like. A single dorsal fin, the spines (9) being less than the rays (12): anal with three spines, and the same number of rays as the dorsal. Scales from rather large to a medium size: none on the head, no enlarged row at base of caudal fin. Lateral-line continuous.

Geographical distribution.—Red Sea, east coast of Africa, through the seas of India to the Malay Archipelago and beyond.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Anampses caruleo-punctatus, D. $\frac{9}{12}$, A. $\frac{3}{12}$, L. 1. 27, L. tr. 4/10. Blue lines from eyes, body and fins spotted with blue. Andamans to the Malay Archipelago and beyond.

1. Anampses cœruleopunctatus, Plate LXXXVII, fig. 4.

? Anampses diadematus, Rüpp. N. W. Fische, p. 21, t. vi, f. 3; Günther, Catal. iv, p. 137; Klunz. Verh. z. b. Ges. Wien, 1871, p. 533.

Anampses cæruleopunctatus, Rüpp. Atl. Fische, p. 42, t. x, f. 1; Cuv. and Val. xiv, p. 5; Cuv. Règ. Anim. Ill. Poiss. pl. 87, f. 2; Bleeker, Atl. Ich. i, p. 104, t. xxiv, f. 2; Günther, Catal. iv, p. 135; Klunz. Verh. z. b. Ges. Wien, 1871, p. 534.

B. vi, D. $\frac{9}{12}$, P. 12, V. 1/5, A. $\frac{3}{12}$, C. 13, L. l. 27-28, L. tr. 4/18, Vert. 11/15.

Length of head $3\frac{1}{2}$, of caudal 7, height of body 3 in the total length. Eyes—diameter 5 in length of head, $1\frac{1}{2}$ diameters from end of snout, and 2 apart. The height of the head equals its length behind the angle of the mouth. The maxilla reaches half-way to below the orbit. Colours—reddish-brown, several bluish vertical lines radiate from the orbit: each scale on the body with a blue spot surrounded by a dark ring, fins reddish, the dorsal with three rows of blue spots, the anal with two or three, the caudal likewise blue spotted, all these fins with light edges. The spots on the middle of the body are sometimes apt to assume the appearance of vertical lines.

Two specimens to 7 inches in length exist in the Calcutta Museum, being those referred to in the J. A.

Soc. Beng. 1860, as presented by Mrs. Edwards from the Andamans.

Habitat.—Red Sea, east coast of Africa, Mauritius, seas of India to the Malay Archipelago and beyond. I am indebted to Dr. Sauvage and the officials of the Jardin des Plantes in Paris for the specimen figured, it came from the Marquesas.

Genus, 7—Hemigymnus, Günther.

Halichæres, sp. Rüppell: Tautoga, sp. Cuv. and Val.: Erychthys and Hemiulis, Swainson.

Branchiostegals six: body oblong, compressed. Preopercle entire: lips very fleshy. Teeth in a single row, two canines anteriorly in either jaw, the lower ones being received when the mouth is closed between the upper pair: generally a posterior canine: inferior pharyngeal teeth not confluent or pavement-like. A single dorsal fin, with less spines (9) than rays (11): anal with three spines and the same number of rays (11) as the soft dorsal. Scales large, none on the opercles, but a strip of very small ones on the cheek: no enlarged row at base of caudal fin. Lateral-line continuous.

Geographical distribution.—Red Sea, east coast of Africa, seas of India, to the Malay Archipelago and Australia.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Hemigymnus melapterus, D. $\frac{9}{11}$, A. $\frac{3}{11}$, L. l. 29, L. tr. 5/14. Scales dotted with blue. East coast of Africa, seas of India to Australia and beyond.

3 E 2

2. Hemigymnus fasciatus, D. 9/11, A. 3/11, L. l. 28-29. Bluish, with wide vertical bands. Red Sea, seas of India to the Malay Archipelago.

1. Hemigymnus melapterus, Plate LXXXIV, fig. 2.

Labrus melapterus, Bl. t. 285; Bl. Schn. p. 247 (L. melampterus). Tautoga melapterus, Cuv. and Val. xiii, p. 311; Bleeker, Verh. Bat. Gen. xxii, p. 16; Richards. Ann. and Mag. 1843, xi, p. 358.

Hemiulis melapterus, Swainson, Fishes, ii, p. 228.

Hemigymnus melanopterus, Günther, Catal. iv, p. 139; Kner, Novara Fische, p. 253.

Length of head $3\frac{1}{4}$ to $3\frac{1}{2}$, of caudal 6 to $6\frac{3}{4}$, height of body $2\frac{3}{4}$ to $3\frac{1}{4}$ in the total length. Eyes—diameter 4 in the young, to 6 or $6\frac{1}{2}$ in the length of head in the adult, 2 to 3 diameters from end of snout, and $1\frac{1}{4}$ to 2 Lips very thick, the lower one notched in the middle, and each lateral portion pendant like a wattle. Teeth—a posterior canine is usually present but concealed by the skin. Scales—about three rows of very small ones on the cheeks. Colours—bluish, brown above, becoming yellowish beneath: a dark mark behind the orbit: scales dotted with blue: dorsal and anal light at their external third, followed by bluish band, external to which they are darker: caudal dark. In the young, the body behind a line from the commencement of the dorsal to the base of the anal, dark violet, some of the lower scales being blue spotted: anterior to this nearly white beneath, but darker along the top of the head, whilst most of the scales have more or less dark spots.

Habitat.—Zanzibar, Andamans, to the Malay Archipelago and Australia. The one figured is from the

Andamans, where it is very common, and attains a large size.

Length of head $3\frac{2}{3}$ to 4, of caudal 6 to $6\frac{1}{4}$, height of body $3\frac{1}{3}$ to $3\frac{1}{2}$ in the total length. Eyes—diameter 5 to 6 in length of head, nearly 3 diameters from end of snout. Lips very thick, folded; the lower one notched in the centre and pendant like a wattle. Teeth—small ones sometimes present at the angle of the mouth. Fins—caudal truncated. Scales—a band of small ones across the cheeks. Colours—bluish, with broad rivulated red bands on the head, and a brown spot behind the eye: these marks appear to be sometimes absent. Five vertical brownish cross bands, wider than the ground colour, descend from the back to the abdominal surface. Dorsal and anal brownish, the lower with blue spots and a blue edge, having a red band below it: anal with two blue longitudinal bands. Caudal brownish, with a blue vertical band. Pectoral yellowish. Outer two-thirds of ventral dark.

Habitat.—Red Sea, east coast of Africa, seas of India to the Malay Archipelago.

Genus, 8-Stethojulis, Günther.

Julis, sp. Cuv. and Val.

Branchiostegals six: body oblong and compressed. Preopercle entire: no anterior canine teeth; a posterior canine: inferior pharyngeal teeth not confluent or pavement-like. A single dorsal fin with less spines (9) than rays (11): and with three spines and the same number of rays as the soft dorsal. Scales of moderate size: none on the head: no enlarged row at base of caudal fin. Lateral-line continuous.

Geographical distribution.—East coast of Africa, seas of India, to the Malay Archipelago and beyond.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Stethojulis strigiventer, D. $\frac{9}{11}$, A. $\frac{2}{11}$, L. 1. 26-27. A brown white-edged band from the snout to below the eye: lines and dots along the sides. A black spot on last dorsal ray, another generally at the base of the caudal fin. Seas of India to the Malay Archipelago,

1. Stethojulis* strigiventer, Plate LXXXIV, fig. 7.

Julis strigiventer, Bennett, Proc. Zool. Soc. 1832, p. 184; Cuv. and Val. xiii, p. 468; Bleeker, Banda, i, p. 251; Peters, Monats. Ak. Wiss. 1855, p. 434.

Halichæres strigiventer, Kner, Labr. p. 12.

Stethojulis strigiventer, Günther, Annal. and Mag. Nat. Hist. 1861, p. 386, and Catal. iv, p. 140; Bleeker, Atl. Ich. i, p. 135, t. 43, f. 1; Kner, Novara Fische, p. 253.

B. vi, D. $\frac{9}{11}$, P. 15, V. 1/5, A. $\frac{2}{11}$, C. 14, L. l. 26-27, L. tr. 2/9.

Length of head $3\frac{1}{4}$ to $3\frac{3}{4}$, of caudal $5\frac{1}{3}$, height of body 4 to $4\frac{1}{4}$ in the total length. Eyes—diameter 4 to $4\frac{1}{2}$ in the length of head, $1\frac{1}{4}$ to 2 diameters from the end of snout, and $1\frac{1}{4}$ apart. Fins—ventral rather short, caudal rounded. Colours-light brown, becoming yellowish on the abdomen: a brown band having a white lower edge passes from the snout and angle of the mouth below the eye to the opercle: several longitudinal yellow lines and some black dots along the sides, especially in the lower half of the body: a black spot on the last dorsal ray, another at the base of the caudal fin, which last mark is apparently sometimes absent.

In "the Fishes of Zanzibar" a variety is given as follows: "bright green: lower part of the sides with

several pale-green longitudinal lines, on which there are some black dots. A blue, brown-edged band from mouth, below eye, to operculum: sometimes an ocellated spot at the end of the dorsal and on the upper part of the base of the caudal."

Habitat.—From East Africa through the seas of India to the Malay Archipelago and China. It is very abundant at the Nicobars and Andamans, from the latter of which localities the specimen figured was obtained.

Genus, 9—Platyglossus, (Klein), Günther.

Halicheros, sp. Rüppell; Julis; sp. Cuv. and Val.; Macropharyngodon, Güntheria, and Hemitautogu, Bleeker; Chærojulis, Gill.

Body oblong, compressed. Anterior teeth conical, but neither bent outwards nor backwards: a posterior canine: inferior pharyngeal teeth not confluent or pavement-like. A single dorsal fin with less spines (9) than rays (10-14): anal with three spines and about the same number of rays (11-14) as the soft dorsal. Scales rather large: those on the thorax smaller than on the remainder of the body: none on the head (except a few rudimentary ones behind the eye in two or more species), no enlarged row at base of caudal fin. Lateral-line continuous.

Geographical distribution.—Red Sea, seas of India, and generally tropical and adjacent seas.

SYNOPSIS OF SPECIES.

1. Platyglossus notopsis, D. $\frac{9}{13}$, A. $\frac{3}{12}$, L. l. 27-29. Two black spots on dorsal fin, the first between first and second spines, the largest between that and sixth rays. Andamans to the Malay Archipelago.

2. Platyglossus Hyrtlii, D. $\frac{9}{12}$, A. $\frac{3}{12}$, L. l. 27-28. Two brownish-black longitudinal bands.

Andamans to the Malay Archipelago.

- 3. Platyglossus marginatus, D. $\frac{9}{12-13}$, A. $\frac{3}{11}$, L. l. 27. Undulating green streaks edged with blue on head and anterior half body, and streaks on vertical fins. Red Sea, through seas of India to the Malay Archipelago.
- 4. Platyglossus Dussumieri, D. 1/2, A. 1/2, L. l. 28-29. Bluish-green, scales chequered with dull purplish A black spot at base of pectoral. A bluish occllus between fifth and seventh dorsal spines. East coast of Africa, seas of India to the Malay Archipelago and beyond.

5. Platyglossus leparensis, D. $\frac{9}{12}$, A. $\frac{3}{12}$, L. l. 26-28. Brown streak from eye to snout, and a silvery band from eye to tail, with four and five more below it. Two spots on dorsal fin. Andamans to the Malay Archi-

- 6. Platyglossus hortulanus, D. 10 12 A. 3 A. 3 L. l. 28. Broad bluish streaks on the head, and bluish spots on first part of the back. From one to three yellow spots on back below the base of the dorsal fin. Red Sea, seas of India to the Malay Archipelago and beyond.
- Julis Finlaysonii, Cuv. and Val. xiii, p. 471, may be a Stethojulis. The description was made from a drawing executed in Siam by Major Finlayson. The colours are greenish. Commencing at the corner of the mouth and passing below the eye is a light brown lateral band covered with deeper coloured spots. The dorsal light pink, bordered with red, having a red spot at the base of each spine and ray: the anal is figured as similar, but the basal spots are not distinct in Sir W. Elliot's figure. Caudal bluish, with three oblique bands on either lobe. There is also a row of red spots between the lateral band and the back in Sir W. Elliot's figure. Under surface of the head silvery, with a tinge of orange. Amongst Sir W. Elliot's drawings of fishes I found one which agrees with Major Finlayson's, it is marked Julis.

 Habitat.—Siam (not Carlor) is noted at the

Habitat. - Siam (not Ceylon) is noted on the original drawing, and Madras. See Jerdon, M. J. L. and Sc. 1851, p. 135.

7. Platyglossus kawarin, D. 3, A. 3, L. 1. 28-29. Head with blue lines and spots. Each scale below lateral-line with a central rosy spot forming longitudinal bands. A black spot from last dorsal spine to second Andamans to the Malay Archipelago.

8. Platyglossus nebulosus, D. 1, A. 1, L. l. 28. Body with light and dark blotches and spots. Two

black spots on dorsal fin. Red Sea and seas of India to the Malay Archipelago.

9. Platyglossus scapularis, D. $\frac{9}{11}$, A. $\frac{3}{11}$, L. 1. 27. A broad red, blue-edged band from the shoulder to the back of the tail. Red Sea, seas of India to the Malay Archipelago.

10. Platyglossus bimaculatus, D. $\frac{9}{10}$, A. $\frac{3}{11}$, L. 1. 27. Violet bands radiating from the eye. A black white-edged spot under the ninth or tenth scales of the lateral-line. Red Sea, East coast of Africa, seas of India.

1. Platyglossus notopsis, Plate LXXXIV, fig. 4.

Julis notopsis, (Kuhl. and v. Hass.) Bleeker, Sumatra, ii, p. 290.

B. vi, D. $\frac{6}{13}$, P. 13, V. 1/5, A. $\frac{3}{12}$, C. 14, L. l. 27-29, L. tr. 3/11.

Length of head 4 to $4\frac{1}{2}$, of caudal 6 to $6\frac{1}{2}$, height of body $3\frac{1}{2}$ to $3\frac{2}{3}$ in the total length. Eyes—diameter 3½ in length of head, about 1 diameter from end of snout and also apart. Fins—dorsal spines two-thirds the height of the rays: caudal rounded. Colours—purplish-brown, with four or five red longitudinal bands. Two black ocelli on the dorsal fin, largest in the young: the smaller one between the first and second spines: the larger between the third and sixth rays, and being encircled by a light occllus, there are one or two rows of round light spots on the fin posterior to the large black one: caudal with a yellow band at its base, and yellow edges. The young are much darker than the adults, having light longitudinal narrow lines and three white spots on the back, the anterior of which is usually continued on to the dorsal fin between the sixth and seventh spines: the third spot is on the summit of the free portion of the tail.

Habitat.—Andamans to the Malay Archipelago. The one figured is life-size.

2. Platyglossus Hyrtlii, Plate LXXXVIII, fig. 1.

Julis mola, pt. Cantor, Catal. p. 238; Jerdon, M. J. L. and Sc. 1861, p. 135.

Julis (Halichæres) Hyrtlii, Bleeker, Manado, p. 60. Halichæres Hyrtlii, Bleeker, Labr. p. 286, and Atl. Ich. i, p. 121, t. 39, f. 2.

B. vi, D. $\frac{9}{12}$, P. 14, V. 1/5, A. $\frac{3}{12}$, C. 14, L. l. 27-28, L. tr. 2/12.

Length of head $4\frac{1}{3}$ to $4\frac{1}{2}$, of caudal 7, height of body $4\frac{1}{4}$ to 5 in the total length. Eyes—diameter 5 in length of head, nearly 2 diameters from end of snout, and $1\frac{1}{4}$ apart. Fins—caudal rounded. Colours—olive colour along the back, becoming white along the abdomen: two brownish-black longitudinal bands: the superior united on the snout with that of the opposite side, is continued along the side of the base of the dorsal fin: the inferior commencing on the snout passes through the eye to the centre of the base of the caudal fin where it ends in a black spot, in its course it is interrupted on the opercle by a bright red spot. Dorsal fin anteriorly with two, posteriorly with three rows of spots, the reticulations forming which are very distinct between the first and third spines. Caudal similarly reticulated. Pectoral with a dark spot superiorly at its base.

Amongst my Andamanese fish is one of the young of this species 1 inch in length. For the specimen

figured, which is from the Malay Archipelago, I am indebted to Dr. Hubrecht of Leyden.

Habitat.—Andamans to the Malay Archipelago.

3. Platyglossus marginatus, Plate LXXXIV, figs. 5 and 6 (variety.)

B. vi, D. $\frac{9}{12-13}$, P. 13, P. 1/5, A. $\frac{3}{11}$, C. 15, L. 1. 27, L. tr. $3\frac{1}{2}/10$.

Length of head $4\frac{1}{3}$ to $4\frac{2}{3}$, of caudal $6\frac{1}{3}$, height of body $3\frac{1}{2}$ to $3\frac{2}{3}$ in the total length. Eyes—diameter $4\frac{1}{2}$ to 5 in the length of head, $1\frac{2}{3}$ to 2 diameters from end of snout, and $1\frac{1}{3}$ apart. Dorsal profile somewhat concave above the orbits. Fins—caudal slightly rounded. Colours—blackish-green: head and anterior part of the body with undulating grass-green streaks edged with blue. Numerous red blue-edged streaks and spots on

the vertical fins, which have blue margins: a large vertical green crescent-shaped mark covered with light spots on the middle of the caudal fin, basal half of pectoral black. Variety.—A specimen (fig. 6) captured at the Andamans has the marks on the head and body deep brown, whilst the crescentic band on the caudal fin envelopes the whole of it except its outer angles, and instead of its being covered with light spots it has brown undulating vertical bands. The black base to the pectoral is absent.

Habitat. Bod See through the cost of India to the Malay Archicalers. Figure 5 is from a specimen

Habitat.—Red Sea, through the seas of India to the Malay Archipelago. Figure 5 is from a specimen captured in the Malay Archipelago, and for it I am indebted to Dr. Hubrecht, of Leyden. Figure 6 is from the

variety I obtained at the Andamans. Both are life-size.

Length of head 4 to $4\frac{1}{3}$, of caudal $6\frac{1}{2}$, height of body 4 to $4\frac{1}{2}$ in the total length. Eyes—diameter 5 in length of head, $1\frac{1}{3}$ diameters from end of snout, and 1 apart. Fins—dorsal spines slender: first ray of ventral prolonged: caudal rounded. Colours—green, with some irregular violet bands between the eyes, and one from them to the snout: two or three pass over the opercles: back bluish, chequered with dull purplish red. A black spot with a light anterior edge at the base of the pectoral. Dorsal and anal greenish, with an oval yellow spot between the base of each ray, and another near their summits, the soft portions with a broad purplish external margin: a blackish ocellus, with a yellow edge, between its fifth and and seventh spines. Caudal with a broad blue transverse band having red spots, its angles being orange with a red base.

Habitat.—East coast of Africa, seas of India, to the Malay Archipelago and beyond.

5. Platyglossus leparensis, Plate LXXXIV, fig. 3.

Julis (Halichæres) leparensis, Bleeker, Banka, iii, p. 730. Halichæres leparensis, Bleeker, Syn. Labr. p. 287, and Atl. Ich. i, p. 119, t. xlii, f. 5. Platyglossus leparensis, Günther, Catal. iv, p. 156.

Length of head 4, of caudal 6, height of body $4\frac{1}{4}$ to $4\frac{1}{2}$ in the total length. Eyes—diameter $4\frac{1}{2}$ in the length of head, $1\frac{1}{4}$ diameters from end of snout, and 1 apart. Fins—caudal rounded. Colours—a broad brown streak from the eye to the snout, and a brown spot behind the orbit, which is continued, but in a lighter shade, to the tail: four narrow curved yellowish lines on the upper portion of the opercle. Body vertically banded. A narrow silvery line from the eye to the caudal fin, and below it four or five more: many of the scales with brown spots, especially those above the lateral-line. Dorsal fin with one or two rows of light round spots: two black ocelli on the dorsal fin, the anterior between the first two spines, and the posterior between the first two or three rays, occasionally a third posterior one, on the upper third of the base of the caudal fin on the free portion of the tail: caudal fin yellowish red.

Habitat.—Andamans to the Malay Archipelago. The one figured is life-size.

Length of head $3\frac{3}{4}$ to 4, of caudal $6\frac{1}{2}$ to 7, height of body $3\frac{1}{2}$ in the total length. Eyes—diameter 5 in the length of the head, 2 diameters from the end of snout, and $1\frac{1}{2}$ apart. Fins—caudal truncated. Colours yellowish-brown: broad bluish oblique bands on the head, and the anterior portion of the back with bluish spots. One (may be two or three) yellow spot on the back below the fourth dorsal spine, and sometimes a black spot behind it. Oblique brown streaks on the dorsal fins, sometimes enclosing spaces: a black axillary spot, usually another at the upper part of the base of the caudal, on which brown spots, or vertical bands, may be present or absent: anal with longitudinal bands. In young specimens the dark blotch on the back, just behind the anterior light one, is black: whilst below the last dorsal rays and behind the second white spot on the back, a dark mark is rather well developed.

Habitat.—From the Red Sea and east coast of Africa to the Andamans, Malay Archipelago, and

Polynesia. The specimen figured (8.2 inches in length) was from the Andamans.

7. Platyglossus kawarin.

Julis (Halichares) kawarin, Bleeker, Timor, p. 172. Halichares kawarin, Bleeker, Syn. Labr. p. 286, and Atl. Ich. i, p. 121, t. 41, f. 4. Platyglossus kawarin, Günther, Catal. iv, p. 152.

B. vi, D. $\frac{9}{11}$, P. 14, V. 1/5, A. $\frac{3}{11}$, C. 14, L. 1. 28-29.

Length of head $3\frac{1}{2}$ to $3\frac{2}{3}$, of caudal $5\frac{2}{3}$, height of body $3\frac{1}{2}$ in the total length. Eyes—diameter $4\frac{1}{2}$ in the length of head, 2 diameters from the end of snout, and 1 apart. Fins—caudal slightly rounded. Colours—head with a bluish band from the eye to the snout: a second passes from the angle of the mouth along the posterior edge of the orbit to the upper part of the head: a third from the interopercle: a blue blotch on the centre of the opercle, and a wide light-blue band above: some blue spots on the summit of the head. Colours below the lateral-line are blue, each scale having a central rosy spot, forming seven longitudinal bands. Dorsal and anal fins blue, with three rows of round reddish spots, and a black spot on the last dorsal spine and first and second rays: caudal yellowish, with a dark edge.

Habitat.—Andamans to the Malay Archipelago.

8. Platyglossus nebulosus, Plate LXXXV, fig. 2.

Julis nebulosus, Cuv. and Val. xiii, p. 461.

Julis (Halichares) Reichei, Bleeker, Sumatra, i, p. 43.

B. vi, D. $\frac{9}{11}$, P. 14, V. 1/5, A. $\frac{3}{11}$, C. 14, L. 1. 28, L. tr. 3/12.

Length of head $3\frac{3}{4}$, of caudal $5\frac{3}{4}$, height of body $3\frac{3}{4}$ in the total length. Eyes—diameter 4 in the length of head, $1\frac{1}{2}$ diameters from end of snout, and 1 apart. Fins—caudal rounded. Colours—olivaceous: several violet bands on the head, one on the cheek being curved, but not completing a circle: the opercular lobe violet: a dark band passing from it to the tail, in its course it gives off several superior and inferior short processes, between which are silvery spots, and there are more along the base of the dorsal fin: some oblique silvery streaks are covered by the pectoral fin. A minute spot sometimes present between the two first dorsal spines, and a larger one between the first two rays: two or three red ocelli margined with blue between the dorsal spines and oblique violet bands ascending forwards: anal with a band along its centre and ocelli at its base: caudal occasionally with black dots.

Habitat.—Red Seas and seas of India to the Malay Archipelago. For the specimen figured, from the

Malay Archipelago, I am indebted to Dr. Hubrecht of Leyden.

Length of head $3\frac{1}{4}$ to $4\frac{1}{4}$, of caudal 8, height of body $3\frac{3}{4}$ to 4 in the total length. Eyes—diameter $4\frac{1}{2}$ to 5 in the length of head, 2 diameters from end of shout, and $1\frac{1}{4}$ apart. Fins—outer ray of ventral elongated: caudal rounded. Colours—a broad red blue-edged band passes from the shout to the eye: a second irregular one goes obliquely upwards from the eye to the wide lateral band, which, of a brownish violet colour, passes from the shoulder to the back of the tail: a red streak extends from the axilla to the abdomen, many of the scales on the body with blue spots: dorsal and anal margined with a green blue-edged band. Caudal with reddishviolet transverse bands.

The colours in P. Ceylonensis are given thus: "Yellow, head gray rivulated with yellow: a yellow interrupted band along the lateral-line: another lateral band of the same colour, edged with blue, runs along the side and emits numerous short processes towards the belly: an oblique yellow streak across the base of the pectoral to the belly: vertical fins yellow: a band along the base of the dorsal edged with blue inferiorly: an oblique blue streak behind the base of each dorsal ray, a second behind its middle, and a spot of the same colour behind its top: anal fin with two blue bands: caudal with three irregular transverse rivulated blue bands.

Habitat.—Red Sea, East coast of Africa, seas of India to the Malay Archipelago. The specimen figured is from the Andamans, it is 6.8 inches in length.

10. Platyglossus bimaculatus, Plate LXXXV, fig. 5.

B. vi, D. $\frac{9}{10}$, P. 13, V. 1/5, A. $\frac{3}{11}$, C. 14, L. l. 27, L. tr. 4/9.

Length of head 4, of caudal 9, height of body 4 in the total length. Eyes—diameter 5 in length of head, 2 diameters from end of snout, and $1\frac{1}{2}$ apart. Fins—caudal truncated with its outer rays slightly produced. Colours—yellowish, greenish round the lower edge of the eye, with violet-coloured bands radiating from it: a broad dark green band passes from the eye to the base of the caudal, and a row of light spots above it. A triangular black spot, edged with white, exists on the ninth or tenth scales of the lateral-line, and is continued downwards in a more diffused form. Upper edge of dorsal fin yellow, having a narrow, purplish, intramarginal line, its lower two-thirds reddish, with two rows of round bluish spots edged with yellow: a dark wide band along the middle of the anal. Caudal vertically rivulated with green, and having a light edge. This species may be variously coloured: the ocelli on the vertical fins becoming bands and vice versa.

Habitat.—Red Sea, East coast of Africa, and seas of India. The specimen figured is from Madras, and the only one obtained, it is 8 inches in length.

the only one obtained; it is 8 inches in length.*

Genus, 10-Novacula, Cuv. and Val.

Xyrichthys, sp. Cuv. and Val.

Branchiostegals six: body oblong, compressed: the head also compressed, having its upper edge sharp or Anterior teeth conical: no posterior canine: inferior pharyngeal teeth not confluent or pavement-like. Dorsal fin single with less spines (9) than rays (12), the two first dorsal spines sometimes more or less separated from the others. Scales rather large: head may be entirely scaleless, or the cheeks with two or more rows of small ones, no enlarged row at base of candal fin. Lateral-line interrupted.

This Genus has been sub-divided into the following sub-genera:

- 1. The two first dorsal spines more or less separated from the remainder of the fin.
- A. Cheeks without or with merely a few rudimentary scales. Iniistius, Gill.

 - a. Upper edge of the head sharp. Xirichthys, Bleeker.
 b. Upper edge of the head rather obtuse. Novaculichthys, pt. Bleeker.
- B. Checks scaled. Hemipteronotus, Bleeker.

2. No anterior division of the dorsal fin.

- C. Cheeks without or with merely a few rudimentary scales. Xirichthys et Malacocentrus, Gill.
- a. Upper edge of the head sharp. Novacula, Bleeker.
 b. Upper edge of the head rather obtuse. Novaculichthys, pt. Bleeker.
 D. Cheeks with two or three rows of scales. Novaculichthys, pt. Bleeker.
- E. Cheeks scaled.

Geographical distribution.—Red Sca, seas of India, and generally into tropical seas and beyond.

SYNOPSIS OF SPECIES.

1. The two first dorsal spines more or less separated from the remainder of the fin.

*Platyglossus purpureo-lineatus.

Julis purpureo-lineatus, Cuv. and Val. xiii, p. 471.

This species, described from a drawing by Major Finlayson, is thus defined: Colours—green, with violet streaks on the back, on the middle of the body and on the borders of the dorsal and anal fins; pectoral yellow: head yellowish, spotted with violet: the caudal with small red streaks: the base of the dorsal spotted with very vivid red.

Habitat.—Siam, ? Ceylon.

Digitized by GOOG

- A. Cheeks without or with merely a few rudimentary scales.
- 1. Novacula rufa, D. 2 | 1/12, A. 3/12, L. 1. 26. Two rows of minute scales below and behind the eyes. Reddish, caudal with reticulated gray lines. Madras.

B. Cheeks more or less scaled.

2. Novacula pentadactyla, D. 2 | $\frac{7}{12}$, A. $\frac{8}{12}$, L. l. 28. Eight or nine rows of scales descend from the eye to behind the angle of the mouth. Reddish-brown, with a row of spots behind the eye: a dark spot on side:

dorsal and anal fins with oblique blue markings. Bombay to China.

3. Novacula punctulata, D. 2 | $\frac{7}{12}$, A. $\frac{3}{12}$, L. l. 27. Eight rows of scales descend from the eye to behind the angle of the mouth. Reddish-brown, no spots behind the eyes: most of the scales with a red base and blue streak: anterior profile blue. Fins with bluish lines. Seas of India to China.

1. Novacula rufa, Plate LXXXV, fig. 6.

? Xirichthys cyanifrons, Cuv. and Val. xiv, p. 46; Bleeker, Beng. en Hind. p. 54. ? Novacula cyanifrons, Günther, Catal. iv, p. 171. Novacula rufa, Day, Proc Zool. Soc. 1873, p. 238.

B. vi, D. 2 $| \frac{7}{12}$, P. 14, V. 1/5, A. $\frac{3}{12}$, C. 14, L. 1. 26, L. tr. 5/13.

Length of head 2/7, of caudal 1/8, height of body nearly 1/3 of the total length. Eyes—high up, above 2 diameters from end of snout: some small scales behind and below the orbit. Body strongly compressed, dorsal profile nearly vertical: upper and anterior edge of head sharp. Fins—two first dorsal spines produced, and a deep notch in the interspinous membrane between them and the rest of the fin: spines as long as snout. Outer ventral ray produced, the fin reaches 2/3 of the distance to the base of the anal. Colours—rosy, becoming

yellowish on the abdomen: the fins yellowish, except the caudal, which has dark grayish reticulated bands.

Specimens from Pondicherry marked Xirichthys cyanifrons, which I saw in Paris, appeared to be identical with the species described above, with the exception of longer ventrals: they had a few scales as seen in rufa, but some other specimens marked as from Bombay were destitute of these scales. N. Celebica, Bleeker, judging

from the specimen in the British Museum, appears closely allied to this species. Habitat.—Seas of India. The specimen figured (life-size) is from Madras.

2. Novacula pentadactyla.

Coryphana pentadactyla, Linn. Syst. i, p. 446; Bloch, t. 173; Gmel. Linn. p. 1191; Bl. Schn. p. 294.

Hemipteronotus quinque-maculatus Lacép. iii, p. 215. Novacula pentadactyla, Cuv. and Val. xiv, p. 69, pl. 395; Richard. Ich. China, p. 261; Blecker, Bengal en Hind. p. 54, and Celebes, p. 222; Günther, Catal. iv, p. 177.

Novacula sex-maculata, Cuv. and Val. xiv, p. 72.

Hemipteronotus pentadactylus, Bleeker, Labr. p. 294, and Atl. Ich. i, p. 150, t. xxx, f. 4.

B. vi, D. 2 $\left| \frac{7}{12} \right|$, P. 12, V. 1/5, A. $\frac{3}{12}$, C. 12, L. 1. 28.

Length of head 4 to $4\frac{1}{4}$, of caudal $6\frac{1}{3}$ to $6\frac{3}{4}$, height of body $3\frac{3}{3}$ in the total length. Eyes—high up, 1/2 a diameter from the dorsal profile, $4\frac{1}{4}$ diameters in length of head, 2 to $2\frac{1}{4}$ diameters from end of snout. Height of head hardly exceeds its length. Profile from snout to forehead nearly vertical. Preorbital in the adult, equals in height about 2 diameters of the eye. Fins—the first two dorsal spines remote the rest, thin, flexible, longer than those in the remainder of the fin, and with the interspinous membrane cleft almost to its base. Outer ventral ray rather elongated. Caudal rounded. Scales-8 to 9 rows descending from the eye to behind the angle of the mouth. Colours—light reddish-brown, a row of five or six round red spots behind the eye, most of the scales on the body with a red basal spot: a blackish blotch on the side of the body just below the lateral-line above the end of the pectoral fin, and a reddish blotch inferior to the black one. Oblique narrow blue lines on the dorsal fin, two horizontal ones along the anal, and several vertical ones

Hubitat.—From Bombay through the Malay Archipelago to China. A specimen from Bombay exists in the Paris Museum.

3. Novacula punctulata, Plate LXXXVIII, fig. 2.

Cuv. and Val. xiv, p. 73; Günther, Catal. iv, p. 177 (? Bleeker, N. pentadactyla, Labr. p. 22). Xyrichthys cyanifrons, Jerdon, M. J. L. and Sc. 1851, p. 135 (not Cuv. and Val.).

B. vi, D. 2 | $\frac{7}{12}$, P. 11, V. 1/5, A. $\frac{3}{12}$, C. 14, L. l. 27, L. tr. 4/13.

Length of head $4\frac{2}{3}$, of caudal $6\frac{1}{3}$, height of body $4\frac{1}{4}$ in the total length. Eyes—high up, about 3 diameters from the end of snout. Profile from snout to forehead very abrupt. Height of head exceeds its length by one-third. Fins—two first dorsal spines separated by a cleft from the remainder of the fin reaches the anal when laid flat. Caudal rounded. Scales—cheeks covered with about 8 rows. Colours—brownish, with a dark spot on the side above the end of the pectoral fin, most of the scales on the body with a blue spot or streak, and reddish base: anterior profile bluish: fins orange, two blue bands along the dorsal, and three along the anal fins, also numerous oblique grayish bands: vertical blue bands on the caudal.

The specimen is from Sir W. Elliot's collection, it was captured at Madras, April, 1852. The watercolour drawing of it is termed as above by Jerdon. Its native name is given as Chilacka-sani-muyya, Tamil.

In Cuv. and Val. the fins are said to be destitute of marks, but I think there can be little doubt that the

species are identical.

Habitat.—Seas of India to China.

Genus, 11—Julis, sp. Cuv. and Val.

Branchiostegals six: body oblong and compressed: snout not produced. Anterior teeth conical: no posterior canine tooth; inferior pharyngeal teeth not confluent or pavement-like. A single dorsal fin with less spines (8) than rays (11-14): anal with two or three spines and about the same number of rays as the soft dorsal (11-14). Scales large: none on the head: no enlarged row at the base of the caudal fin. Lateral-line continuous.

Geographical distribution.—Red Sea, seas of India, tropical and adjacent seas.

SYNOPSIS OF SPECIES.

1. Julis dorsalis, D. $\frac{8}{18}$, A. $\frac{3}{11}$, L. l. 26-29. Broad red bands radiate from the eye: six vertical black cross bars along the back, and a black spot at base of pectoral fin. A red band along the side. East coast of Africa, seas of India to the Malay Archipelago.

2. Julis lunaris, D. $\frac{1}{13}$, A. $\frac{1}{17}$, L. l. 28. Oblique red bands on head, body green, each scale with a vertical red streak. Red Sea, seas of India to Malay Archipelago.

3. Julis amblycephalus, D. $\frac{3}{13}$, A. $\frac{2}{11}$, L. l. 27. Blue dark-edged lines across the checks, a dark triangular spot at base of pectoral. Ceylon to the Malay Archipelago.

4. Julis Hebraica, D. $\frac{3}{13}$, A. $\frac{1}{11}$, L. l. 27-28. Greenish, scales with a dark vertical mark. Violet bands pass from the eye, and a buff dark-edged cross-band goes from two first dorsal spines to the ventral fin: a dark could be the stream first and third dorsal spines. Red Sea seas of India and beyond

pass from the eye, and a bull dark-edged cross-band goes from two first dorsal spines to the ventral fin: a dark spot between first and third dorsal spines. Red Sea, seas of India, and beyond.

5. Julis purpurea, D. $\frac{8}{13}$, A. $\frac{8}{11}$, L. l. 27-28. Colours vary, usually green or blue, with or without red bands radiating from the eye. Two or three red or violet bands along the side, sometimes joined by cross bands of the same colour. Red Sea, seas of India, to the Malay Archipelago and beyond.

6. Julis Janseni, D. $\frac{8}{13}$, A. $\frac{2}{11}$, L. l. 28. Yellow, with from three to five vertical black bands: a black spot on first two anal rays. Andamans to the Malay Archipelago and beyond.

Length of head $3\frac{2}{3}$, of caudal $5\frac{1}{2}$, height of body $3\frac{2}{3}$ in the total length. Eyes—diameter $4\frac{1}{2}$ to 5 in the length of head, $1\frac{1}{2}$ to 2 diameters from end of snout, and $1\frac{1}{4}$ to $1\frac{1}{2}$ apart. Fins—caudal lobes somewhat produced. Colours—greenish, becoming silvery along the abdomen. Broad red bands radiate from the eyes: six vertical black cross bars along the back, extended on to the middle of the body: a black spot in the axilla: a red band along the side to the tail: usually a black, or a very dark blue band on the dorsal fin, the anal with a black spot anteriorly: caudal with a grayish semilunar band in its last half.

Habitat.—East coast of Africa, seas of India, to the Malay Archipelago and beyond. The specimen figured (life-size) is from the Moluccas, and I am indebted for it to Dr. Hubrecht, of Leyden.

Julis meniscus et Mertensii, Cuv. and Val. xiii, pp. 415, 421. Julis trimaculatus, Rüpp. N. W. Fische, p. 13, young (not Quoy and Gaim.). Chloriothhys lunaris and Hardwickii, Swainson, Fishes, ii, p. 232. Julis Celebicus, Bleeker, Celebes, viii, p. 313 (young).
Julis lutescens (Soland.) Zool. Beech. Voy. Fishes, p. 65, pl. xix, f. 2. B. vi, D. $\frac{8}{13}$, P. 14, V. 1/5, A. $\frac{2}{11}$, C. 14, L. l. 28, L. tr. $2\frac{1}{2}/10$.

Length of head $4\frac{1}{4}$ to $4\frac{1}{2}$, of caudal $4\frac{1}{4}$ to $5\frac{1}{2}$, height of body 4 to $4\frac{1}{2}$ in the total length. Eyes—diameter 5 in the length of head, $1\frac{2}{3}$ diameters from the end of snout, and 1 apart. Fins—caudal deeply lunated in the adult. Colours—head violet, with several oblique reddish bands: body green, each scale with a vertical red streak, forming bands: an oblong reddish-violet spot on the pectoral. Dorsal red, with a blue and yellow margin: anal violet, with a yellow edge: caudal yellow, its base and lobes green. The young have a black spot at the base of the second to the fourth dorsal rays, and some light blotches along the back, also a black spot at the root of the caudal fin.

Habitat.—Red Sea, east coast of Africa, to the Malay Archipelago and beyond. The specimen figured (life-size) is from the Andamans.

3. Julis amblycephalus.

Bleeker, Malang, p. 83, and Atl. Ich. i, p. 90, t. xxxiii, f. 6; Günther, Catal. iv, p. 182.

B. vi, D. $\frac{8}{13}$, P. 14, V. 1/5, A. $\frac{2-3}{11}$, C. 14, L. 1. 27, L. tr. 2/9.

Length of head $4\frac{1}{3}$ to 5, of caudal 6, height of body 5 to $5\frac{1}{3}$ in the total length. Eyes—diameter 3 to $3\frac{1}{3}$ in length of head, $1\frac{1}{3}$ diameters from end of snout, and 1 to $1\frac{1}{4}$ apart. Fins—outer caudal rays produced. Colours—the upper two-thirds of the head and body olive brown, each scale having a vertical streak: the lower third of the body white: a narrow blue dark-edged line passes from the lower angle of the orbit to the axilla: a second across the angle of the preopercle: a broad triangular spot exists in the axil of the pectoral, which fin is yellow with a blackish extremity. Dorsal fin dark anteriorly, becoming a little lighter posteriorly, the soft portion having a narrow white edge: caudal lobes dark olive.

Habitat.—Ceylon to the Malay Archipelago.

4. Julis Hebraica, Plate LXXXVI, fig. 2.

Labrus Hebraicus, Lacép. iii, pp. 455, 526, plate 29, f. 3. ? Labrus argentatus, var. Lacép. iii, pl. 18, f. 1. Julis eingulata, Quoy and Gaim. Voy. Astrol. p. 711, pl. 15, f. 3.

Julis genivitatus, Cuv. and Val. xiii, p. 416; Günther, Catal. iv, pp. 183, 508.

Length of head 4 to $4\frac{1}{4}$, of caudal 5 to 6, height of body 4 to $4\frac{1}{2}$ in the total length. Eyes—diameter 5 to $5\frac{1}{2}$ in the length of head, $1\frac{1}{4}$ to $1\frac{1}{2}$ diameters from end of snout, and 1 apart. Fins—caudal lobes produced in the adult. Colours—in the young (J. hebraica) greenish, each scale having a vertical dark mark. A wide violet dark-edged band passes from the eye downwards, a second backwards to the base of the pectoral, and a third from the upper edge of the eye to the conjunt. A buff-coloured cross band edged with dark passes from third from the upper edge of the eye to the occiput. A buff-coloured cross band edged with dark passes from the two first dorsal spines to behind the ventral fin. Dorsal fin with a dark occllus between its first and third spines: a semilunar vertical band on the middle of the caudal fin. In the adult (J. genivitata) the bands on the head and spots on the scales are apparent, but there is no light cross band. The pectoral has a dark spot, the colour being most intense at the edge of the fin.

Habitat.—Red Sea, east coast of Africa, seas of India and beyond. The specimen figured (life-size) is from the Andaman islands.

B. vi, D. $\frac{8}{13}$, P. 16, V. 1/5, A. $\frac{3}{11}$, C. 14, L. l. 27-28, L. tr. $3-3\frac{1}{2}/10$.

Length of head $3\frac{3}{4}$, of caudal 7, height of body $3\frac{3}{4}$ to $4\frac{1}{4}$ in the total length. Eyes—diameter 5 to $6\frac{1}{4}$ in the length of head, $1\frac{1}{2}$ to $2\frac{1}{2}$ diameters from the end of snout, and $1\frac{3}{4}$ to 2 apart. Teeth—no posterior canine. Fins—caudal lobes produced in the adult. Colours—green or blue, with or without irregular pinkish or red bands radiating from the eye: a red or pink band which often gives off short ones superiorly, passes from the opercle to the caudal fin: a second of a brownish-violet colour goes along the back to the upper margin of the caudal fin: and a third along the abdomen to the lower margin of the caudal; whilst sometimes there is a fourth from the chest to the end of the base of the anal: the rays of the candal fin are green and the membrane red and violet. Dorsal fin green or yellow with a broad pink blue-edged band along its middle, and sometimes having a black spot anteriorly: anal green, with a dark basal band; the posterior half of the pectoral blackish. In the variety umbrostygma the colours are greenish, becoming of a dull white along the lower third of the body. Head with black lines and scattered spots. Two reddish lines along the side of the body which send up vertical processes joining each other. Occiput and body with small vertical brown spots, either in the form of bands or else scattered. Dorsal fin with a black spot between its first and third spines, a sea-green basal band, another in its upper third and the two separated by round reddish spots: anal similarly marked. Caudal with green streaks between the rays. Outer third of the pectoral stained gray. The dorsal and anal fins are occasionally differently coloured, they may have a single green band along their centres: or a red band

having yellow marks above and below, with a brown blue-edged intramarginal band.

Habitat—Red Sea, East coast of Africa, seas of India to the Malay Archipelago, China, and beyond. The specimen figured is 10 inches in length and from the Andamans, the whole of its back above the upper light band is cornlean blue. Amongst Sir W. Elliot's drawings is one of this fish, captured at Waltair, and termed "Chilatrasani, Tel."

6. Julis Jansenii, Plate LXXXVI, fig. 4.

Bleeker, Manado, p. 56, and Atl. Ich. i, p. 91, t. 34, f. 5; Günther, Catal. iv, p. 187.

B. vi, D. $\frac{8}{13}$, P. 15, V. 1/5, A. $\frac{3}{11}$, C. 14, L. l, 28, L. tr. 2/9.

Length of head 4 to $4\frac{1}{2}$, of caudal $5\frac{1}{3}$, height of body $4\frac{1}{3}$ to $4\frac{2}{3}$ in the total length. Eyes—diameter 6 in length of head, $2\frac{1}{4}$ diameters from end of snout, and $1\frac{1}{3}$ apart. Fins—caudal rounded in the young, lobes produced in the adult. Colours—yellow, with from three to five wide black vertical bands going from the back down the sides. In the specimen figured (from the Andamans) the black colour almost hides the yellow ground colour, and both are continued upwards on to the dorsal fin. A violet streak from behind the opercle on to the base of the pectoral fin. Pectoral, ventral, and analy ellowish, the last with a black spot at the outer end of its last two rays.

In the figure in Bleeker's Atlas, there are only three black cross bands on the body, the anterior going over the head and nape to the base of the pectoral: the second from the fourth to sixth dorsal spines to half way down the sides: the third from the summit of all the dorsal rays decreasing in width as it descends to the

base of the last few anal rays, where it expands so as to cover the outer edge of all. Habitat.—Andamans to the Malay Archipelago and beyond.

Genus, 12—Gomphosus, Lacépède.

Branchiostegals six. Body oblong, compressed. Snout produced, tubiform: the opening of the mouth not extending nearly so far backwards as the eyes: preopercle entire. Gill membranes attached to the isthmus. Anterior teeth conical: no posterior canine: inferior pharyngeal teeth not confluent or pavement-like. A single dorsal fin with less spines (8 or 9) than rays (13). Anal with two or three spines and less rays (11) than the soft dorsal. Scales rather large, none on the head: no enlarged row at base of caudal fin, but the base of the dorsal and anal scaly. Lateral-

Geographical distribution .- Red Sea, East coast of Africa, seas of India to the Malay Archipelago and beyond.

SYNOPSIS OF SPECIES.

1. Gomphosus caruleus, D. 8/13, A. 9/13, L. l. 29. Violet with the vertical fins yellow: or vivid green. Seas of India to the Malay Archipelago.

2. Gomphosus pectoralis, D. 8 A. 2-3, L. l. 26. Brownish, each scale with a dark base: caudal with a white posterior edge. Seas of India to the Malay Archipelago.

3. Gomphosus tricolor, D. $\frac{8}{13}$, A. $\frac{2-8}{11}$, L. l. 29. Greenish or brownish, with a wide yellow band on the shoulder to behind the pectoral: pectoral with a bluish vertical band. Ceylon, seas of India to the western Pacific.

B. vi, D. $\frac{8}{13}$, P. 15, V. 1/5, A. $\frac{2-3}{11}$, C. 14, L. l. 26, L. tr. 2/11.

Length of head $2\frac{3}{4}$ to 3, of caudal 8, height of body $4\frac{1}{2}$ to $4\frac{2}{3}$ in the total length. Eyes—diameter 6 to $6\frac{1}{4}$ in the length of head, 3 diameters from end of snout, and 1 apart. Fins—caudal rounded or truncated in the young, having the outer rays slightly produced in the adult. Colours—upper part of head and back reddish brown, becoming lighter on the abdomen: each scale darkest at its base: cheeks pinkish. A dark band from the snout through the eye. Pectorals yellow: vertical fins dark-coloured, becoming deep brown externally, having a very narrow light edge: caudal the same, with a black margin and a rather wider white border: ventrals

whitish, the outer ray brown. A row of round transparent spots along the base of the anal fin.

The fish figured is identical with the type of G. fuscus, C. and V. (L. l. 26), the type specimen of which is in Paris in a good state of preservation. On the bottle is also marked "G. Commersonii, Q. and G." On referring to Voy. Uranie, p. 282, we find "Gomphose Commerson—Gomphosus pectoralis." The figure of

G. varius, Lacépède, agrees fairly well with this species.

Habitat.—Mauritius, Ceylon, Andamans, to the Malay Archipelago. The one figured (life-size) is from the Andamans. My largest specimen is 6.7 inches in length.

3. Gomphosus tricolor.

Quoy and Gaim. Voy. Uranie, p. 280, and Gomphose Lacépède, pl. 55, f. 2; Bleeker, Manad. and Makass. p. 54, and Atl. Ich. i, p. 85, t. xxi, f. 6; Günther, Catal. iv, p. 193.

Gomphosus Cepedianus, Cuv. and Val. xiv, p. 18, pl. 390.

B. vi, D. $\frac{8}{13}$, P. 16, V. 1/5, A. $\frac{9-3}{11}$, C. 14, L. l. 28-29, L. tr. 3/9, Vert. 9/15.

Length of head $3\frac{3}{4}$, of caudal $7\frac{1}{2}$ to 8, height of body $4\frac{1}{4}$ in the total length. Eyes—rather high up, and situated midway between the angle of the mouth and the end of the opercle. Fins—caudal with its outer rays rather produced. Colours—brownish or greenish, with a broad yellow band from the shoulder to behind the base of the pectoral fin. Vertical fins yellow: pectoral brownish, with a dark spot at its base, and a narrow vertical bluish band parallel with its posterior border.

Habitat.—Ceylon, through the seas of India to the Western Pacific.

Genus, 13—Cheilio, (Commerson) Lacépède.

Branchiostegals six: body elongated and nearly cylindrical. Snout somewhat produced: preopercle serrated in the young. Profile to dorsal fin not elevated. Teeth in a single row, the posterior ones in the lower jaw being compressed and small: no posterior canine. Dorsal spines flexible, less (9) in number than the rays (13-14): anal with 3 (or 2) spines and less rays (11-12) than the dorsal. Scales of medium size: head scaleless, except a row of rudimentary ones on the opercle: no enlarged row at base of caudal fin. Lateral-line continuous.

Geographical distribution.—Red Sea, east coast of Africa, seas of India to the Malay Archipelago and beyond.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Cheilio inermis, D. 130-14, A. 312, L. 1. 45-50. Brownish, divided by a brown band from a silvery abdomen. Red Sea, seas of India to the Malay Archipelago and beyond.

B. vi, D. $\frac{9}{13-14}$, P. 12, V. 1/5, A. $\frac{9}{12}$, C. 13, L. l. 45-50, L. tr. 3/17.

Length of head $3\frac{1}{2}$, of caudal $7\frac{1}{2}$, height of body 9 to 10 in the total length. Eyes—diameter 6 in the length of head, $2\frac{2}{3}$ diameters from the end of snout, and 1 apart. The height of the head equals its postorbital length. Fins—caudal rounded. Colours—brownish superiorly, divided by a darker band (passing from below the eye to the middle of the tail) from a silvery white lower surface: there are some black spots along this lateral band. Irregular blue streaks on the head and fin, two or three rows of blue spots on the dorsal. In some the lateral band ceases at the opercles, or is entirely absent. The scales on the body may have blue or brown centres, or dark edges.

Habitut.—Red Sea, east coast of Africa, seas of India to the Malay Archipelago and beyond. The specimen figured (life-size) is from the Malay Archipelago, and for it I am indebted to Dr. Hubrecht,

Genus, 14-Coris, Lacépède.

Hologymnosus et Labrus, sp. Lacép.: Halichæres, sp. Rüppell: Julis, sp. Cuv. and Val.: Pseudocoris, Hemicoris et Ophthalmolepis, Bleeker.

Branchiostegals six: body oblong, compressed. Anterior teeth conical: a posterior canine may be present: inferior pharyngeal teeth not confluent or pavement-like. A single dorsal fin with less spines (9) than rays (11-12): anal with three spines, and about the same number of rays (11-13) as the soft dorsal. Scales rather small, none on the head (except in C. lineolata): no enlarged row at base of caudal fin. Lateral-line continuous.

Geographical distribution.—Fishes belonging to this Genus have a very wide range: not only do they exist in the Red Sea, throughout the seas of India to Australia and Polynesia, but they are likewise found in the Mediterranean and adjacent parts of the Atlantic.

As in other Labroid fishes the colours of those belonging to the genus appear to be subject to considerable differences, this seems to be sometimes due to sex; thus Steindachner has observed that Coris julis is the male

of C. giofredi.

SYNOPSIS OF SPECIES.

1. Coris formosa, D. $\frac{9}{12}$, A. $\frac{3}{12}$, L. l. 74-84. Gray, with blue spots. Blue bands on head: dorsal and anal lineated or spotted with the. East coast of Africa, seas of India to the Malay Archipelago and beyond.

2. Coris aygula, D. $\frac{9}{12}$, A. $\frac{3}{12}$, L. l. 60. Brown or green, with blue spots on head and bands across neck: a dark axillary spot: a pale cross band behind pectoral, and red blotches on back of tail.

Coris pulcherrima, Gunther, Catal. iv, p. 200. Rattoo-girawah, Cingalese.

B. vi, D. $\frac{9}{12}$, P. 14, V. 1/5, A. $\frac{3}{12}$, C. 14, L. l. 74-84, L. tr. 8/35.

Length of head $4\frac{3}{4}$, of caudal $7\frac{1}{2}$, height of body 4 to $4\frac{1}{4}$ in the total length. Eyes—diameter 6 in the length of head, 2 diameters from the end of snout, and $1\frac{1}{3}$ apart. Teeth—a posterior canine at the angle of the mouth, said to be absent in young specimens. Fins—first spine of the dorsal fin elongated, and having a fine termination, the second a little longer than the remaining ones. Caudal rounded. Colours—Bennett describes them as bluish-gray with circular black spots: head yellow, with two oblique blue bands ascending towards the origin of the dorsal, one commencing from the snout and passing through the eye, the other parallel to the first, running below the eye. Dorsal and anal fins brown, the former with a red margin and with two green lines running within the red: black dots between the rays. Anal with a narrow green edge, and a narrow green intermarginal line; a series of green dots within the margin. The inner half of the caudal red, the outer yellowish white. Or the lines on the head may be violet and rather oblique: one ascends from the eye to the dorsal fin: body brownish-violet, covered posteriorly with scattered blue spots becoming disposed more in horizontal rows along the side of the free portion of the tail. Fins yellowish, dorsal and anal having a blue outer edge, and a blue black-edged intramarginal band, blue spots along the bases of the fins. With or without a reddish vertical band on the middle third of the caudal fin.

Dr. Günther considers Swainson's (=Bleeker's) species as distinct from Bennett's, but he merely reproduces Bennett's plate on a smaller scale. Colours alone do not appear sufficient in members of this family on which to found species; experience as has been observed, "must lead us to suppose that many a tropical species introduced into our system will prove to be merely a variety." (Günther, Catal. iv, p. 508). Dr. Günther further observes (Fish. Zanzibar, p. 100), "This species has been observed by Col. Playfair at Zanzibar for the first time since its discovery by Bennett. The specimen agrees as well with Bennett's figure as if the latter had been taken from the former; and Dr. Günther's opinion as to the distinctness of C. formosa, Bleeker, and C. formosa, Bennett, is fully confirmed."

Habitat.—East coast of Africa, Ceylon to the Malay Archipelago and beyond. I am indebted for the specimen figured to Dr. Hubrecht, of Leyden, it came from the Malay Archipelago.

B. vi, D. $\frac{9}{12}$, P. 14, V. 1/5, A. $\frac{3}{12}$, C. 15, L. l. 60, L. tr. 6/28.

Length of head $3\frac{3}{4}$ to 4, of caudal $7\frac{1}{2}$, height of body $3\frac{3}{4}$ to 4 in the total length. Eyes—small in the adult, a prominent knob on the dorsal profile above them. Upper lip broad, with folds, and not continuous with the lower one which is pendant. Teeth—a posterior canine if present small and mostly concealed. Fins—anterior dorsal spines elevated in the adult: ventrals elongated: caudal rounded. Colours—the immature have the head and anterior part of the body olive brown, occasionally with two brown blotches, also small blue spots over the head, and a black spot on the opercle: a black axillary spot, a pale cross band opposite the end of the pectoral, behind which the colours are buff, sometimes with red or brown blotches on the back and free portion of the tail. Vertical fins brown with black spots and white edges, or with a wide yellow margin. The adult darkish or deep green, occasionally two or three red angular bands across the neck: the edges of the preopercle sometimes red, a blue mark on the extremity of the opercle. Sometimes a light vertical band on the body from the last two dorsal spines to the vent. Vertical fins greenish, with a red intermarginal band, and sometimes oblique red blotches along the base.

Habitat.—Red Sea, seas of India, New Hebrides.

Genus, 15—CYMOLUTES, Günther.

Xyrichthys, sp. Cuv. and Val.

Branchiostegals six: body oblong, compressed. Snout rather elevated. Anterior teeth free: no posterior canine. A single dorsal fin with less spines (9) than rays (12-14); anal with two or three spines, and an equal number of rays to the soft dorsal. Scales small, no enlarged row at base of caudal fin. Lateral-line interrupted.

Geographical distribution. —East coast of Africa, seas of India to the Malay Archipelago.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Cymolutes prætextatus, D. $\frac{9}{12}$, A. $\frac{3}{12}$, L. l. 73. Olive or greenish, with a dark band across the shoulder. East coast of Africa, Ceylon, Mauritius, to the Malay Archipelago.

B. vi, D. $\frac{9}{12}$, P. 13, V. 1/5, A. $\frac{3}{12}$, C. 13, L. 1. 73.

Length of head 4 to $4\frac{1}{3}$, of caudal 7 to $7\frac{1}{3}$, height of body $4\frac{1}{3}$ in the total length. Eyes—high up, near dorsal profile, diameter $4\frac{1}{3}$ in the length of the head, 2 diameters from end of snout, and 1 apart. Snout parabolic: lower jaw slightly the longer. The greatest width of the head equals half its height. Colours—greenish, with a dark blue-edged band across the shoulder. Variety—"pale olive: head immaculate: body covered with narrow brown lines, angularly bent, the angle pointing backwards: these are generally darker. on the shoulder. Sometimes a round black spot below the lateral-line, and under the sixth dorsal spine. Dorsal pale violet, with irregular reddish lines and spots: the specimens without the lateral blotch have a deep black margin to the spinous portion. Anal uniform orange or rosy: caudal orange, with yellowish transverse lines: ventrals and pectorals transparent."

Habitat.—East coast of Africa, Ceylon, Mauritius, to the Malay Archipelago. The specimen figured is

from a specimen in the British Museum collection.

Genus, 16-PSEUDODAX, Bleeker.

Odax, sp. Cuv. and Val.

Branchiostegals six. Body oblong, compressed. Upper jaw with one, lower with two, pairs of broad incisors, having cutting lateral edges: teeth in the pharyngeals confluent and pavement-like. A single dorsal fin having nearly the same number of spines (11) as rays (12): anal with three spines and more rays (14) than the second dorsal. Scales of moderate size, extended over the cheeks and opercles: an enlarged row at base of caudal fin. Lateral-line

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Pseudodax Moluccanus, D. 11, A. 3, L. l. 32-33. Brownish red, with a dark spot on each scale of body and opercles. Nicobars to the Malay Archipelago.

1. Pseudodax Moluccanus, Plate LXXXIX, fig. 1.

Odax Moluccanus, Cuv. and Val. xiv, p. 305, pl. 408, fig. 2 (head); Cuv. Règ. Anim. Ill. Poiss. t. 91, f. 3; Bleeker, Manado, p. 64; Kner, Sitz. Wien Acad. 1860, p. 56, t. ii, f. 18 (Pharyngeal apparatus).

B. vi, D. $\frac{11}{12}$, P. 15, V. 1/5, A. $\frac{3}{14}$, C. 14, L. l. 32-33, L. tr. 4/12.

Length of head $4\frac{1}{4}$, of caudal 8, height of body $3\frac{1}{3}$ in the total length. Eyes—diameter $5\frac{1}{2}$ in the length of head, 2 diameters from end of snout, and $1\frac{1}{4}$ apart. Teeth—the outer incisor on either side of symphysis of lower jaw recurved. Colours—back brownish-red, becoming lighter on the abdomen, most of the scales on the body with a dark central spot. Teeth green. Dorsal and anal yellow in their basal portion, the former having black reticulated lines, a dark base, and a blue margin: anal with from two to four dark undulating longitudinal bands and a dark blue-margined outer edge. Pectoral with a dark mark at its base. Caudal brown with a blue posterior edge, some rootical darker bands and the large scales at its base. brown, with a blue posterior edge, some vertical darker bands, and the large scales at its base of a light buff colour.

Habitat.—Nicobars, east coast of Africa, to the Malay Archipelago. The specimen figured (8.2 inches

in length) is from the Malay Archipelago, and for it I am indebted to Dr. Hubrecht, of Leyden.

Genus, 17—Scarichthys, Bleeker.

Body oblong, compressed. Upper lip double in its whole extent. Teeth in one row, anteriorly soldered together, those in the mandibles being in a very oblique row: the inferior pharyngeal toothed plate broader than long. A single dorsal fin with less spines (9) which are flexible, than rays (10): two anal spines and eight rays. Scales large, a single row on the cheeks. Lateral-line entire.

Geographical distribution.—Red Sea east coast of Africa, seas of India, to the Malay Archipelago, and also tropical portion of the Pacific.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Scarichthys caruleopunctatus, D. $\frac{9}{10}$, A. $\frac{2}{8}$, L, l. 24. Head and body with numerous blue dots and spots. Red Sea to the Malay Archipelago.

1. Scaricththys caruleopunctatus, Plate LXXXVII, fig. 5.

Scarus (Calliodon) cœruleopunctatus, Rüpp. N. W. Fische, p. 24, t. vii, f. 3; Cuv. and Val. xiv, p. 262; Bleeker, Banda, iii, p. 110.

Scarichthys caruleopunctatus, Bleeker, Atl. Ich. i, p. 16, t. i, f. 2; Günther, Catal. iv, p. 213; Guichenot, Scarides, Mem. Soc. Imp. Cherbourg, 1865, t. xi, p. 19; Klunz. Verh. z. b. Ges. Wien, 1871, p. 557.

B. v, D. $\frac{9}{10}$, P. 14, V. 1/5, A. $\frac{9}{8}$, C. 13, L. 1. 24.

Length of head $3\frac{3}{4}$ to 4, of caudal $6\frac{1}{4}$, height of body 4 in the total length. Eyes—diameter 5 in the length of head, 2 diameters from end of snout, and $1\frac{1}{4}$ apart. Fins—pectorals short, two-thirds the length of the head: caudal rounded. Scales—may be present or absent from the base of the dorsal fin. Colours—olive brown, the body and caudal fin covered with blue black-edged spots: two or three rows of brown spots on the dorsal, ventral, and anal fins.

The specimen figured is from the Malay Archipelago, and for it I am indebted to Dr. Hubrecht, of Leyden.

"Habitat.—Red Sea, east coast of Africa, through the seas of India, to the Malay Archipelago.

Genus, 18—Callyodon, (Gronov.), Cuv. and Val.

Body oblong, rather compressed. Teeth in both jaws, anteriorly compressed and imbricated, being in one row in the upper and two in the lower jaw, whilst laterally they are soldered into one deep-cutting lamina: the inferior pharyngeals, where the teeth (which are pavement-like) are present, broader than long. Anterior nostril with a barbel-like prolongation. A single dorsal fin with less spines (9) than rays (10): anal with two spines and less rays (8) than the soft dorsal. Scales large: a single row on the cheeks. Lateral-line strongly bent or interrupted below the posterior end of the dorsal fin.

Geographical distribution.—From the Red Sea, through those of India to the Malay Archipelago, and inter-tropical seas generally.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Callyodon viridescens, D. $\frac{9}{10}$, A. $\frac{2}{8}$, L. l. 24. Colours various. Brown or greenish and spotted: pectoral with a black base, and a similar spot between two first dorsal spines. Red Sca, east coast of Africa to the Andamans.

1. Callyodon viridescens, Plate XC, fig. 2.

Rüpp. N. W. Fische, p. 23, t. vii, f. 2; Günther, Catal. iv, p. 214, and Fish. Zanzibar, p. 103; Klunz. Verh. z. b. Ges. Wien, 1871, p. 558.

B. vi, D. $\frac{9}{10}$, P. 13, V. 1/5, A. $\frac{2}{8}$, C. 13, L. 1. 24.

Length of head 3½, height of body 3 in the total length. Eyes—diameter 5 in length of head, 1½ diameters from end of snout. Teeth—no inner row in the upper jaw, but the outer tooth on either side is recurved. Fins—caudal truncated. Scales—lower third of dorsal fin covered by them. Colours—vary considerably, but it appears to have a black base to the pectoral, and a black spot between the first and second dorsal spines. It may be brown, markled and spotted with darker; or green, with black dots on the sides, red streaks on the snout, and oblique brown marks on dorsal and anal fins. Or olive, becoming white below, and nearly every scale with a brick-red centre and white spots. Head and middle of body with scattered red spots having a dark centre. Two or three red lines on head, and a light lateral band from the angle of opercle to root of tail. Reddish-yellow spots on dorsal and caudal fins. Anal with a black edge and two red longitudinal bands that coalesce and enclose round white spots; ventrals white pectorals yellow.

bands that coalesce and enclose round white spots: ventrals white, pectorals yellow.

Habitat.—Red Sea, east coast of Africa to the Andamans. The specimen figured is from a fish in the British Museum collection.

Genus, 19—PSEUDOSCARUS, Bleeker.

Hemistoma, Swainson.

Body oblong, somewhat compressed. The upper jaw projecting beyond the lower: the upper lip double in its whole extent. The anterior teeth soldered together, arranged in quincuncial order: the teeth in the inferior pharyngeal bones pavement-like, and the space they cover longer than broad. A single dorsal fin with less spines which are flexible (9) than rays (10): anal with two spines, and less rays (8-9) than the soft dorsal. Scales large, two or more rows on the cheeks: large ones at base of caudal fin. Lateral-line continuous.

The fishes of this Genus appear to be subject to very great variation in colour, dependant perhaps on age, sex, season, or locality. Dr. Günther observed "their distinctive characters really appear to depend so much on the colours, which rapidly fade after death, that it will always be very difficult to determine preserved and the colours of the colours of the colours. The colours of the colou much on the colours, which rapidly fade after death, that it will always be very difficult to determine preserved specimens," (Catal. iv, p. 217, 1862). He also remarked "by far the greater portion of our knowledge of this genus is due to the labours of Dr. v. Bleeker, who first pointed out the characters by which the species may be determined." Later (Zool. Record, 1866) he observed on the great variation of colours in fish belonging to this Genus, and in recording his own remarks on the Fishes of Zanzibar, he concluded that the three varieties of colours which he has shown in P. Troschelli "would be types of three distinct species according to Bleeker's views," (p. 149.) That colours alone should be considered a sufficient diagnosis of species, is I consider open to very grave doubt.

SYNOPSIS OF SPECIES.

1. Pseudoscarus harid. Caudal lobed. Three rows of scales on cheeks, none on lower preopercular limb. Upper lip broad, snout elongated. A pointed tooth at angle of mouth. Greenish, two red streaks from snout through the eye, and another on lips. Dorsal and anal fins reddish, edged with blue, and with blue bands or spots. Red Sea, seas of India to the Malay Archipelago.

2. Pseudoscarus chrysopoma. Caudal truncated. Three rows of scales on cheeks, the lower covering the inferior limb of preopercle. Upper lip broad. A pointed tooth at angle of mouth. Green, blue lines radiate from the eye and cover the lips. Dorsal and anal rosy, with a narrow band along their bases, and green

edges. Seas of India and Malay Archipelago.

3. Pseudoscarus ghobbam. Caudal truncated. Two rows of scales on cheeks, the lower of which has five scales, and two scales on lower preopercular limb. Upper lip broad, no pointed tooth at angle of mouth (at least in the young). Lips blue, scales on body with blue edges, vertical fins reddish, with blue bases and edges. Red Sca, seas of India, to the Malay Archipelago.

4. Pseudoscarus æruginosus. Caudal truncated. Two rows of scales on cheeks and two scales on the lower preopercular limb. Upper lip broad. A pointed tooth at angle of mouth, present or absent. Olive, with three longitudinal silvery bands below the pectoral fin. Seas of India to the Malay Archipelago.

5. Pseudoscarus rivulatus. Caudal truncated. Two rows of scales on cheeks, the lower of which has six scales, and two scales on the lower preopercular limb. Upper lip broad. Usually a pointed tooth at angle of mouth. Green, each scale with a red base. Dorsal and anal reddish, spotted or banded with green. East

coast of Africa, seas of India, to the Malay Archipelago.
6. Pseudoscarus erythrodon. Caudal rounded. Two rows of scales on cheeks, none on the lower preopercular limb. Upper lip very broad. A pointed tooth at angle of mouth. Purplish, a narrow black edge

to dorsal fin. East coast of Africa, Andamans, to the Malay Archipelago.

7. Pseudoscarus sordidus. Caudal truncated. Two rows of scales on cheeks, none on the lower preopercular limb. Upper lip narrow. A pointed tooth at angle of mouth. Pink, green, or brown, sometimes with green lips and a blue or green band or spots along the dorsal and anal fins. Red Sea, east coast of Africa, to the Malay Archipelago.

1. Pseudoscarus harid.

Scarus harid, Forsk. p. 30; Gmel. Linn. p. 1282; Rüpp. Atl. Fische, p. 80, t. xxi, f. 1; Cuv. and Val. xiv, t. 404 (not description); Jerdon, M. J. L. and Sc. 1851, p. 135; Bleeker, Beng. en Hind. p. 54, Scarus mastax, Rüpp. Atl. Fish. p. 80, t. xxi, f. 2, and N. W. Fische, p. 28; Cuv. and Val. xiv, p. 246; Bleeker, Batav. Nov. Nat. T. Ned. Ind. vi, p. 299.

Petronason longicauda, Swainson, Fishes, ii, p. 226.

Pseudoscarus mastax, Bleeker, Atl. Ich. i, p. 35, t. x, f. 1.

Pseudoscarus harid, Günther, Catal. iv, p. 220; Klunz. Verh. z. b. Ges. Wien, 1861, p. 561.

B. v, D. $\frac{9}{10}$, P. 15, V. 1/5, A. $\frac{3}{9}$, C. 13, L. l. 25, Vert. 11/13.

Length of head 4 to $4\frac{1}{2}$, of caudal 4 to 5, height of body 4 in the total length. Eyes—situated in about the middle of the length of head, and about 4 diameters from the end of the snout, which is produced: upper lip broad. Teeth—a pointed one at the angle. Fins—anterior dorsal spines not so high as the succeeding ones: caudal lobes much produced in adult specimens. Scales—three rows on the cheeks, none on the lower preopercular limb. Colours—olive-green, with two red streaks passing from the forehead through the eye: lips red, and forming a narrow red band that passes towards the base of the pectoral fin: scales on body with a bluish basal spot and red margin. Dorsal and anal fins reddish edged with blue, and having several rows of blue or green spots. Upper rays of pectoral and outer ones of caudal blue, sometimes two vertical blue lines on the caudal. There may also be blue spots on the side above the vent.

Habitat.—Red Sea, east coast of Africa, seas of India, to the Malay Archipelago.

Length of head $3\frac{2}{3}$ to $3\frac{3}{4}$, of caudal $8\frac{1}{4}$ to $8\frac{1}{2}$, height of body $3\frac{1}{4}$ to $3\frac{1}{3}$ in the total length. Eyes—diameter $5\frac{1}{2}$ to 6 in the length of head, $2\frac{1}{3}$ diameters from the end of snout, and 2 apart. Upper lip broad. Teeth—edges crenulated, a pointed tooth at the angle. Fins—dorsal spines subequal in length: caudal truncated, the angles being slightly produced in adults. Scales—three rows of scales on the cheeks, the inferior of which cover the lower limb of the preopercle, the centre row consists of five scales. Colours—green. Upper lip with one, lower with two cross bands, passing into a subtriangular spot between the eye and the angle of the mouth: three short lines radiate from the eye. Scales with a reddish margin. Dorsal and anal fins rosy, with a narrow band along their bases, and green margins: caudal green.

Habitat.—Seas of India and Malay Archipelago.

Length of head $3\frac{1}{2}$ to $3\frac{3}{4}$, of caudal $8\frac{1}{2}$, height of body $3\frac{1}{2}$ to $3\frac{2}{3}$ in the total length. Eyes—diameter $4\frac{3}{4}$ to 5 in the length of head, 13 to 2 diameters from end of snout, and 1 to 11 apart. Upper lip broad and double in its whole extent. Teeth—in jaws of moderate size, some have, others are destitute of a small pointed one at the angle of the upper jaw. Fins—anterior dorsal spine rather shorter than the succeeding ones. Caudal truncated. Scales—two rows on the cheeks, the second of which contains five or six scales, whilst two more scales exist on the lower preopercular limb. Colours—olivaceous, with three longitudinal silvery bands along the abdomen below the pectoral fin.

Habitat.—Madras (from which locality there is a specimen at Paris), Andamans where it is common, to

the Malay Archipelago and beyond.

B. v, D. $\frac{9}{10}$, P. 14-15, V. 1/5, A. $\frac{3}{9}$, C. 13, L. 1. 25.

Length of head $3\frac{3}{4}$, of caudal $7\frac{1}{2}$, height of body $3\frac{1}{3}$ in the total length. Eyes—diameter 6 in length of head, 2 diameters from end of snout and also apart. Upper lip broad. Teeth—each jaw with 2 small ones at Fins—the anterior dorsal spines rather shorter than the succeeding ones: caudal rather truncated. Scales—two rows on the cheeks, and two scales on the lower limb of the preopercle, the lower row on the cheek consisting of six scales. Colours—green, each scale with a reddish base. Snout and cheeks with numerous undulating green lines, its ground colour reddish. A narrow green band along the base and edge of the dorsal fin, with an intermediate row of spots: anal green, becoming lighter towards its margin, which is edged with dark green: caudal with green spots. The specimen figured, variety Russellii, was sea green, each scale, except those on the chest, having a semilunar reddish base equal to about half its width: the scales between the bases of the ventral and anal fins reddish: head rosy: a few short blue lines radiate from the lower edge of the orbit: anteriorly one passes to the upper edge of the lip, which it skirts: another goes to its lower margin, which it encircles. Dorsal fin reddish, superiorly edged with light blue, a row of green spots along its centre, and another at its base: caudal reddish, with four or five vertical bluish-green bands: anal similar to dorsal: pectoral and ventral reddish, the outer ray being blue: eyes hazel.

Habitat.—East coast of Africa, through the seas of India to the Malay Archipelago and beyond. The figure

is from a stuffed specimen (a female, 18 inches long) captured at Madras, July 12th, 1868.

B. v, D. $\frac{9}{10}$, P. 15, V. 1/5, A. $\frac{3}{9}$, C. 13, L. l. 25.

Length of head $3\frac{1}{4}$, of caudal 8, height of body $3\frac{1}{3}$ to $3\frac{1}{2}$ in the total length. Eyes—diameter $4\frac{1}{2}$ to $5\frac{1}{2}$ in the length of the head, $1\frac{1}{2}$ to 2 diameters from the end of snout, and $1\frac{1}{4}$ apart. Upper lip broad. Teeth—free margins with crenulated edges, and in the adult a conical tooth at the angle. Fins—dorsal spines subequal in length. Caudal rounded. Scales—two rows on the cheeks, the lower of which is not extended over the lower limb of the preopercle. Colours—of a purplish brown, the edges of each scale being darker than their centres, the large scales covering the first 2/3 of the caudal fin dull yellowish, a violet tint in the thoracic region where the centres of some of the scales are of a light colour. Snout greenish-yellow. Vertical fins brown, the dorsal with a narrow black outer margin. Pectoral transparent.

Habitat.—East coast of Africa, Andamans to the Malay Archipelago. One specimen 2.7 inches long was

taken at Port Blair.

7. Pseudoscarus sordidus. Scarus sordidus, Forsk. p. 30; Gmel. Linn. p. 1281.

Pseudoscarus Troschelli, Bleeker, Atl. Ich. i, p. 25, t. vii. f. 2; Günther, Catal. iv, p. 237, and Fish. Zanz. p. 168, pl. xiv, f. 1, 3, (? 2).

Pseudoscarus sordidus, Klunz. Verh. z. b. Ges. Wien, 1871, p. 568.

B. v, D. $\frac{9}{10}$, P. 15, V. 1/5, A. $\frac{3}{9}$, C. 13, L. 1. 25.

Length of head $3\frac{1}{3}$ to $3\frac{1}{2}$, of caudal 8 to 9, height of body $3\frac{1}{4}$ to $3\frac{1}{3}$ in the total length. Eyes—from 6 to 8 diameters in the length of head, $2\frac{1}{2}$ to 3 diameters from end of snout and 2 apart. Jaws strong. Lips very narrow. Teeth-strong with their edges crenulated, the upper jaw with a pointed tooth at the angle. Finsdorsal spines subequal in length, caudal truncated or slightly emarginate, and with its outer rays a little produced in adults. Scales—only 2 rows on the cheeks, none on the lower limb of preopercle. Colours—in different specimens differ widely, being pink, green or brown, and variously marked. Some have green lips and horizontal red marks across the cheeks, and the dorsal and anal fins may be with or without a central horizontal band or row of spots.

Habitat.—Red Sea, East coast of Africa, seas of India to the Malay Archipelago.

• In the specimen figured, Pseudoscarus Russellii, and also in two others in my collection I find no teeth at the angle of the month.

FAMILY, XLII—CHROMIDES, Müller.

Branchiostegals five or six: pseudobranchiæ absent. Gills four. Body oblong or elevated. Small teeth in jaws, none on palate: inferior pharyngeal bones triangular with a median longitudinal suture. Dorsal fin single, the spinous portion being usually of greater extent than the soft: anal with three or more spines, its soft portion similar to that of the dorsal. Ventrals thoracic with one spine and five rays. Scales generally ctenoid. Lateral-line more or less interrupted. Air-vessel present. Pyloric appendages, when present, few.

Amongst the many genera into which this family of freshwater fishes is divided only one (*Etroplus*) has been discovered in India, the remainder being from Tropical Africa, and America.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Etroplus. Body elevated. Spinous portion of dorsal fin more developed than the soft. Teeth lobate. Western and Coromandel coasts of India, also Ceylon.

Genus, 1—Etroplus, Cuv. and Val.

Pseudetroplus, Bleeker.

Branchiostegals six: pseudobranchiæ present. Body elevated and compressed. Eyes lateral. Cleft of mouth small. Teeth in two rows (or even three) in the jaws, compressed and lobate at their summits. A single dorsal, the spinous portion being of greater extent (17-22) than the rayed (6-15); anal spines more numerous (12-16) than the rays (6-12). Scales very slightly etenoid, of moderate size, and extended on to the bases of the soft dorsal and anal fins. Lateral-line interrupted or abruptly ceasing. Air-vessel present, large and simple. Pyloric appendages absent.

Geographical distribution.—The fishes of this genus are found from South Canara, southwards along the Malabar coast, in Ceylon, along the Coromandel coast as high as the southern portion of Orissa, whilst inland I have obtained them from Arcot. The E. Suratensis has the most extensive range, occupying the whole of the region adverted to, except inland, as it rarely exists many miles from the sea, but I have taken a few specimens at Vithry in the Wynaad, showing that it may be found in an elevated locality: it extends its range into brackish or even saline water. The E. Canarensis appears to be locally confined to Canara; whilst the E. maculatus extends throughout the region inhabited by the E. Canarensis and E. Suratensis, except that it is not found in Orissa, whilst in Madras its range covers many miles inland. This genus does not approach any known Malayan one, but is intimately connected with a new genus (Paretroplus) of freshwater fishes, that Dr. Bleeker has recently discovered amongst some received from Madagascar, (see Fish. Madagascar, p. 13, t. iv, f. 3.)

SYNOPSIS OF SPECIES.

1. Etroplus Canarensis. D. $^{2}1_{6}^{-2}$, A. $^{1}4_{6}^{-1}$. L. l. 30-31. Yellowish with eight slate coloured, dark, vertical bands. South Canara in fresh water.

2. Etroplus maculatus. D. $\frac{1}{8}$, A. $\frac{1}{8}$, A. $\frac{1}{8}$, L. l. 35. From one to three dark blotches along the sides. Each scale with a golden central spot. Fresh waters along the coasts of South Canara, Malabar, Ceylon, and Madras, whilst inland it is taken at least as far as Arcot.

3. Etroplus Suratensis. D. $\frac{1}{1}, \frac{3}{4}, \frac{1}{4}, \frac{3}{4}, \frac{1}{4}, \frac{2}{4}, \frac{1}{4}, \frac{3}{4}, \frac{1}{4}, \frac{2}{4}, \frac{1}{4}, \frac{3}{4}, \frac{1}{4}, \frac{2}{4}, \frac{1}{4}, \frac{3}{4}, \frac{1}{4}, \frac{2}{4}, \frac{1}{4}, \frac{3}{4}, \frac$

Length of head $3\frac{2}{3}$ to $3\frac{1}{2}$, of caudal 4 to $4\frac{1}{2}$, height of body $2\frac{1}{4}$ to $2\frac{1}{2}$ in the total length. Eyes—diameter 3 to $3\frac{1}{3}$ in the length of head, 1 diameter from end of snout and also apart. Teeth—very distinctly lobate on either side. Fins—dorsal spines moderately strong, increasing in length to the fifth, from whence they continue of about equal length. Soft dorsal and caudal pointed: pectoral reaching to above fourth or

Digitized by Google

fifth anal spines: caudal emarginate. Scales—very finely ctenoid, or more scolloped at their edges. Lateral-line—continued for about 15 to 25 scales, when it either ceases or only exists as small open holes. Colours yellowish-buff with about 8 vertical, blackish, slate-coloured bands, each scale being darkest at its base, and some having a light central yellow spot. Dorsal and caudal dirty greenish: pectoral yellow, with a black base: ventral and anal black.

Habitat.—South Canara, attaining at least 4½ inches in length.

B. vi, D. $\frac{17-80}{8-10}$, P. 14, V. 1/5, A. $\frac{12-15}{8-9}$, C. 16, L. 1. 35, L. tr. 6/19, Vert. 15/13.

Length of head $3\frac{1}{2}$ to $3\frac{2}{3}$, of caudal 4 to $4\frac{1}{2}$, height of body $2\frac{1}{4}$ to $2\frac{1}{2}$ in the total length. Eyes—diameter 3 in length of head, rather above 1 diameter from end of snout and 1 apart. Profile rises abruptly to the dorsal, and is slightly concave between the snout and the upper margin of the orbit: lower profile not quite so convex as the upper. Lower jaw rather the longer: the maxilla extends two-thirds of the distance to the orbit. Teeth—trilobate but not quite touching one another. Fins—dorsal spines strong and occupying elevenfourteenths of the entire fin; interspinous membrane deeply notched and longer than the spines: anal spines strong, and occupying seven-tenths of the base of the entire fin, the rays are the same as in the dorsal. Caudal lunated. Scales—scarcely ctenoid. Colours—yellowish, with a greenish back, and about seventeen horizontal lines of deep golden spots: occasionally there are a few along the dorsal fin, the back, and the abdomen, also on the anal. Between the dorsal spines and rays there are more spots, some being brown, and others yellow. Along the lateral-line there are three black finger-marks, the central being the largest, and darkest: ventral and anal fins stained with deep black. In specimens procured between January and May there is occasionally a reddish tinge at the extremity of the caudal fin, and a leaden or violet hue over the body, whilst the number of golden spots seems to have decreased.

In South Canara, the highest point on the Western coast where I have obtained this species, the formula of the fin rays was as a rule, D. $^{1\frac{9-2}{9}0}$, A. $^{14\frac{-1}{9}15}$. At Madras the formula was usually D. $^{17-18}_{\frac{9}{9}-10}$, A. $^{11\frac{1}{9}12}$. Common along the coasts in every paddy field, tank, or piece of fresh water, and even occasionally found in back-waters. Specimens have been received from Arcot, showing that it exists some distance inland. It is eaten by the natives, but as it rarely, if ever, exceeds three inches in length, it is not employed as food by Europeans. Dr. Jerdon observes, "the eggs are not very numerous and are deposited in the mud at the bottom of the stream, and when hatched both parents guard their young for many days, vigorously attacking any large fish that pass near them." This species does not live long after its removal from water, and is therefore transported with some difficulty. It is very pretty in an aquarium, but exceedingly pugnacious, turning at times almost black with passion, and vigorously biting the nearest fish. It readily takes a worm as a bait.

Habitat.-Fresh waters along the coasts of Mudras, and from South Canara along Malabar, and also found in Ceylon. It is captured at least sixty or eighty miles inland.

B. vi, D. $\frac{18-19}{14-19}$, P. 17, V. 1/5, A. $\frac{12-13}{12-11}$, C. 16, L. 1. 35-40, L. tr. $\frac{51}{2}/17$.

Length of head 4, of caudal about 4, height of body $2\frac{1}{4}$ in the total length, Eyes—diameter from 1/3 to 1/4 of length of head, nearly 2 diameters apart. Profile rises abruptly to the base of the dorsal: lower profile not quite so rounded as the upper. The maxilla extends more than half way to below the orbit: the lower jaw slightly the longer. Teeth—in a single row in each jaw, compressed, and with a small lobe on each side, whilst posterior to them in both jaws are one or two rows very much smaller, but of the same description and separated by a short interspace from the outer row. Fins—dorsal spines strong, the spinous portion occupying seventenths of the length of the base of the fin: the interspinous membrane deeply notched and longer than the spines: the fourth or fifth rays the longest, the last the shortest, being not quite a fourth of the length of the longest ray: the anal spines occupy seven-tenths of the length of the base of the fin, and both spines and rays are the same as in the dorsal. Caudal slightly emarginate. Scales—very slightly ctenoid, extended on to the caudal, and along the base of the dorsal and anal fins. Lateral-line—in upper fourth of body, extending from sixteen to eighteen scales, and ceasing opposite the twelfth or fourteenth dorsal spine, or else continued for about six scales further in the form of a small round hole in each scale. Colours—of a light green, with eight vertical bands, the first passes over the occiput, the last across the base of the caudal, and the other six are intermediate. Most of the scales above the lateral-line have a central white pearly spot, whilst there are some irregular black spots over the abdomen. The dorsal, caudal, ventral and anal are of a dark leaden colour, the pectoral yellowish, with a jet black base. Specimens from the salt water are of a deep purple colour, the bands almost black, and the white spots consequently more distinct. During the monsoon time the colours of this fish are most beautiful, the eight vertical bands are more distinctly marked, the abdomen is nearly white, the back of a deep green, and the round white spot gleams on every scale like a small pearl. Very young fish have a large black occllus, surrounded by a white margin, extending from the fourth to the tenth soft rays of the dorsal fin.

Very common in the pieces of fresh water along the coasts of Malabar and Coromandel as high as Orissa. It is excellent eating, especially when of a large size, and grows to upwards of a foot in length. It takes a bait freely, but is not so easily captured in a net, as it buries itself in the mud or dives beneath the net.

a bait freely, but is not so easily captured in a net, as it buries itself in the mud or dives beneath the net.

This fish termed "Etroplus—," by Jerdon (M. J. L. and Sc. 1851, p. 133) is this species, the figure is amongst Sir W. Elliot's collection of drawings, marked "Kallu sella kas," and also Etroplus maculatus showing Jerdon's mistake in his F. W. Fishes, where he terms E. Suratensis. E. maculatus.

Jerdon's mistake in his F. W. Fishes, where he terms E. Suratensis, E. maculatus.

Habitat.—Fresh and brackish waters along the coasts of Ceylon and India, as far as Orissa. Bloch named his fish received from the missionary John, Suratensis, on the supposition that it came from Surat. It does not appear however to be found in that locality, and more probably John obtained it at his station of Tranquebar where it is common. I have taken it inland in the Wynaad. The specimen figured is 7.5 inches in length.

ORDER, II—ANACANTHINI.

All the rays of the vertical and ventral fins articulated, the latter, when present, being jugular or thoracic. Air-vessel, if existing, not having a pneumatic duct.

The order of spineless fishes, or the Anacanthinini, has been divided into sub-orders.

A. Anacanthini gadoidei, the two sides of the head symmetrical.

B. Anacanthini pleuronectoidei, the two sides of the head apparently unsymmetrical.

SYNOPSIS OF FAMILIES.

A. Anacanthini gadoidei.

I. Gadidæ. Gill-openings wide, the membranes not attached to the isthmus. Ventral with several rays, or if only one, the first dorsal fin in two portions. Caudal free, or if united to vertical fins, the first dorsal in two portions. Rays of second dorsal well developed.

II. Ophidiidæ. Gill openings wide, gill membranes not attached to the isthmus. Ventral when present

rudimentary and jugular. No separate portion of first dorsal fin: caudal usually united to vertical fin.

A. Anacanthini gadoidei.

Family, I—GADIDÆ,* Cuv.

Pseudobranchiæ, when present, glandular and rudimentary. Body more or less elongated. Gillopenings wide: gill membranes, as a rule, not being attached to the isthmus. From one to three dorsal fins, occupying nearly the entire length of the back, the rays of the last being well developed: one or two anal fins: caudal usually free, but sometimes united to the dorsal and anal. The dorsal with a separate anterior portion. Ventrals jugular, consisting of several rays, or should they be reduced to a filament, the dorsal fin is divided into two. Scales cycloid, of moderate or small size. Air-vessel and pyloric appendages usually

Geographical distribution.—The fishes of this family are mostly confined to the sea, and as a rule, of the Arctic and temperate regions. The aberrant form Bregmaceros appears to be their sole representative in India. Recently (Nov. 1871) Dr. Günther has described a fish from Manado (Proc. Zool. Soc. 1871, p. 669) as Pseudophycis peregrinus, observing that it lives at great depths, and "the discovery of this fish is of the greatest interest, inasmuch as it is the first instance of a true Gadoid being found in the East Indian Archivelege Breatheast and the state of this few life." Archipelago, Bregmaceros being a much less typical form of this family.'

SYNOPSIS OF SINGLE GENUS.

1. Bregmaceros. Body fusiform. Two dorsals, the first consisting of an occipital ray: the second and the anal having each a dwarfed central portion. Seas of India to the Philippines.

Genus, 1—Bregmaceros, Thompson.

Calloptilum, Richardson; Asthenurus, Tickell.

Branchiostegals seven: pseudobranchiæ absent.† Body fusiform, posteriorly compressed. Gill-openings very wide, the membranes being separated nearly to the chin, and not attached to the isthmus. Eyes lateral. anterior and oblique. Teeth in jaws minute and moveable, also on vomer, none on palate. Two dorsal fins, the

* Sars observed (Ann. and Mag. Nat. Hist. 1868, ii, p. 389) that Codfish deposit their ova on the surface of the water, where, having floated for sixteen days, the embryo leaves the ovum.

† Present in genus Bathymaster. Cope.

3 н

anterior consisting of an elongated ray arising from the occiput: the second and the anal having each a central dwarfed portion almost forming a distinct fin. Ventrals jugular, consisting of five or six rays, the outer of which are elongated. Scales cycloid, of moderate size. Lateral-line continuous. Air-vessel present. Pyloric appendages few.

Geographical distribution.—These small fishes appear to inhabit the coasts and estuaries of India, China, and the Philippines to New Zealand.

SYNOPSIS OF SPECIES.

1. Bregmaceros atripinnis. D. 1/20 + XV + 22, A. 22 + 10 + 26, L. l. 70, L. tr. 18, Cœc. pyl. 2. Rich

brown, becoming lighter on the abdomen: fins black, except the ventral, which is of a dirty white. Coasts of India, Burma, and the Andamans to New Zealand.

2. Bregmaceros McClelland. D. 1/16 + X + 15, A. 22 + X + 15, L. l. 64, L. tr. 6/8. Silvery: back shaded with green: occiping, upper half of pectoral, and first half of dorsal spotted with black. Coasts of India to China and the Philippines.

1. Bregmaceros atripinnis, Plate XCI, fig. 1.

Asthenurus atripinnis, Tickell, J. A. S. of Beng. 1865, p. 32. pl. i. Bregmaceros atripinnis, Day, Proc. Zool. Soc. 1869, p. 522. ? Calloptilum punctatum, Hutton, Trans. N. Z. Inst. v, p. 267, pl. xi. Bregmaceros punctatum, Gunther, Ann. and Mag. 1876, p. 398.

D. 1/20 + XV + 22, P. 21, V. 6, A. 22 + 10 + 26, C. 17, L. 1. 70, L. tr. 18, Cec pyl. 2.

Length of head $6\frac{1}{8}$ to $6\frac{1}{2}$, of candal 11 to 12, height of body 6 in the total length. Eyes—diameter 2/7 of length of head, I diameter from end of snout and also apart. Lower jaw rather the longer: the maxilla reaches to below the posterior third of the orbit. Gill membranes separated as far forwards as to below the front edge of the eye. Teeth—in jaws, none on palatines. Fins—the first dorsal consists of a single ray, which commences on the summit of the head, and reaches backwards to opposite the posterior extremity of the pectoral. First portion of the second dorsal higher than the body, its intermediate rays very low. Pectoral commences under the throat and is extended as far as the posterior third of the body. The anterior portion of the anal is not quite so high as that of the dorsal. Caudal slightly emarginate. Scales—cycloid, in parallel rows. Lateral-line—absent. Air-vessel—small, present. The caeal appendages are large. Colours—of a rich brown, becoming lighter on the abdomen. Dorsal, pectoral, anal, and caudal fins black: ventrals of a dirty white: the younger the specimen the less dark it is, in the very young there is no black on the fins.

A figure of this species exists amongst Sir W. Elliott's drawings, it is marked "Misalu maya" found at

Waltair, June 27th, 1853.

Habitat.—Bombay, coasts of India, Burma and the Andamans, to New Zealand: attaining at least 5 inches in length. The specimen figured, life-size, is in the Calcutta Museum, it came from Akyab where it was procured by the late Col. Tickell.

2. Bregmaceros McClellandi.

Thompson, Charlest. Mag. Nat. History, 1840, iv, p. 184; Günther, Catal. iv, p. 368; Day, Fishes of Malabar, p. 171.

Calloptilum mirum, Richards. Voy. Sulphur, p. 95, pl. 46, f. 4-7.

B. vii, D. 1/16 + X + 15, P. 25, V. 5-6, A. 22 + X + 15, C. 15, L. 1. 64, L. tr. 6/8.

Length of head 1/7, of caudal 2/11, height of body 1/7 of the total length. Eyes—diameter 2/5 of the length of the head, 1/2 a diameter from end of snout, and 1 apart. Body fusiform, compressed posteriorly. Upper jaw slightly the longer, extending to behind the centre of the orbit. Teeth—in jaws, a few on the vomer, but none on the palatine bones. Fins—the first dorsal arises on the occiput in the form of a slender ray, which is rather longer than the head. The second dorsal commences in the middle third of the total length, its fourth ray the longest and the fin highest in front, each ray is unbranched but articulated, and very slender, the membrane is deeply notched: the succeeding ten rays being very short and slender, appearing almost like a distinct fin: whilst the last fifteen are lengthened and extend nearly to the base of the caudal. The anal is of much the same shape as the second dorsal. The ventral which arises under the throat, consists of six rays, the outer three of which are dilated, compressed, and extended so as to reach as far as about the twenty-first anal ray. Scales—cycloid, small. Lateral-line—continuous. Colours—silvery, the back shaded with green. Occiput

and upper half of pectoral black, the first half of dorsal spotted with black.

Dr. Günther, Ann. and Mag. 1876, p. 398, appears to consider Bregmaceros punctatum, Hutton=to
B. atripinnis, Tickell, as identical with B. Macclellandi, Thomp. which latter however besides differing in the extent of the fin-rays was said to have neither air-vessel nor cæcal appendages, whereas both are present in

B. atripinnis.

Habitat.—The mouths of rivers and coasts of India to China, and the Philippine Islands: said to grow to about three inches in length.

Family, II—OPHIDIIDÆ, Müller.

Pseudobranchiæ present or absent. Body more or less elongated. Gill-openings wide: the gill membranes not attached to the isthmus. Eyes of moderate size, rudimentary or absent. Barbels present or absent. Sometimes canine teeth in the jaws, the vomerine and palatine ones absent or present. Vertical fins usually confluent, without any distinct anterior dorsal or anal. The dorsal occupies the greatest portion of the length of the back. Pectorals may be absent: ventrals when present rudimentary and jugular, except in Brotulophis, where they are situated opposite to the pectorals. Scales present or absent: lateral-line when present may be single, double or interrupted. The vent may be at the throat. Air-vessel usually present. Pyloric appendages, when present, in small numbers.

Geographical distribution.—Fishes of this family are distributed in the seas and estuaries of nearly all parts of the globe.

SYNOPSIS OF GENERA.

Genus, 1-Brotula. Ventrals present and attached to the humeral arch. Indian Ocean to the Malay Archipelago and beyond.

Genus, 2—Anmodytes. No ventral fins, and the vent some distance from the head. Gill-openings wide, the gill membranes not being united.

Genus, 1—Brotula, Cuvier.

Branchiostegals eight. Body elongated, compressed. Eyes of moderate size. Barbels present. Villiform teeth on jaws, vomer, and palatines. Vertical fins confluent: ventrals reduced to a single filament, which is sometimes bifurcated: the fin is attached to the humeral arch. Scales present, minute. Air-vessel large, either rounded posteriorly or with two horns. A single pyloric appendage.

SYNOPSIS OF INDIVIDUAL SPECIES.

Brotula maculata, D. 115, V. 1, A. 107. Six pairs of barbels. Light dirty greenish colour, with a few reddish brown spots about the body and a dark round mark behind the eye. Muzzle and rostral barbels black. Madras.

1. Brotula maculata, Plate XCI, fig. 2.

Day, Proc. Zool. Soc. 1868, p. 196.

B. viii, D. 115, V. 1, A. 107.

Length of head 1/6, of pectoral 1/8, of caudal 1/16, height of body 1/6 of the total length. Eyes diameter 1/3 of length of head, 2/3 of a diameter from end of snout, 1/3 apart. Body eel-like, compressed: the maxilla extends to beneath the centre of the orbit. A strong spine at the opercle: two smaller ones at the angle of the preopercle. Barbels—two on the snout, and two on either side of the upper jaw: three pairs on the lower jaw, making in all six pairs. Teeth—in fine sharp rows, becoming single posteriorly; a small patch on the vomer, and a single row on the palate. Fins—not enveloped in skin: dorsal, caudal, and anal joined. Dorsal commences over the base of the pectoral: ventral two-thirds as long as the head, and reaching beyond the base of the pectoral. Scales—minute, covering body and head. Air-vessel—large, and rounded posteriorly. Colours—of a light dirty greenish-brown, with a few reddish-brown spots about the body, and a round blackish mark behind the eye. Muzzle and barbels of upper jaw blackish. Fins grayish, external portions deep black. Rather closely approaches Brotula ensiformis, Günther, but in that species the snout is longer than the eye, in this one-third shorter. The maxilla in B. maculata does not extend so far backwards as in the former species.

Habitat.—Madras, where the species was captured in November, 1867. The figure is taken from one of the types which are in the British Museum.

Genus, 2—Ammodytes, Artedi.

Bleekeria, Günther.

Branchiostegals six to eight: pseudobranchiæ composed of lamellæ. Body low, elongated, and compressed. Gill-openings very wide, the gill-membranes not being united. Gills four. Eyes of moderate size. Barbels absent. Lower jaw usually prominent. Teeth, when present, minute. A single long dorsal fin, composed of feeble rays. Scales, if present, small, when absent the skin may have longitudinal folds along the abdomen. Lateral-line single. Air-vessel absent. Vent remote from the head.

Digitized by GOO

SYNOPSIS OF INDIVIDUAL SPECIES.

- 1. Ammodytes kallolepis, D. 40, A. 15, L. l. 100, L. tr. 3/14. Longitudinal bands. Madras.
 - 1. Ammodytes kallolepis, Plate XCI, fig. 3.

Ammodytes, —? Jerdon, M. J. L. and Sc. 1851, p. 139. Bleekeria kallolepis, Günther, Catal. iv, p. 387.

B. vi, D. 37-40, A. 14-15, L. l. 100, L. tr. 3/14.

Length of head about 5, of caudal $6\frac{1}{4}$, height of body $10\frac{1}{4}$ in the total length. Eyes—in the commencement of the anterior half of the head, 2 diameters from the end of snout. Head and body compressed. Lower jaw slightly the longer, the upper very protractile, the posterior limb of the premaxillaries reaching to opposite the front edge of the orbit. Teeth—a few fine ones opposite the symphysis in either jaw. Fins—the dorsal commences above the first third of the pectoral, and does not extend to the base of the caudal, it is composed of simple articulated rays, the highest being equal to about half the height of the body. Pectoral as long as the head behind the middle of the eyes. Anal commences below the last two-fifths of the dorsal, its rays being rather higher. Caudal deeply forked. Free portion of the tail nearly twice as long as it is high at its base. Scales—none on the head. Lateral-line—high up. Colours—back and upper two-thirds of body bluish, lineated with about five yellowish horizontal bands, which are as wide as the ground colour. Dorsal fin with a bluish base and yellow bands: anal with a bluish band along its centre: caudal stained gray externally.

Habitat.—Coromandel coast at Waltair and Madras, from which latter locality Dr. Jerdon sent the specimen figured (life-size) to the British Museum. Several coloured drawings of examples of this fish are

amongst Sir Walter Elliot's collection.

B. Anacanthini, Pleuronectoidei.

Structure of head apparently unsymmetrical on the two sides.

Family, III—PLEURONECTIDÆ, Flemming.

Heterosomata, Bonaparte.

Pseudobranchiæ well developed. Gills four. Body strongly compressed, flattened, with one of its sides coloured, the other being destitute of colour, or having merely some spots. Both eyes (except in the very young) placed on the superior or coloured surface, sometimes rudimentary. The two sides of the head not equally developed,* one remaining almost rudimentary. The jaws and dentition may be nearly equally developed on both sides, or more so on the blind than the coloured. A single long dorsal and anal fin. Pectorals, if present, may be rudimentary. Scales present or absent. Lateral-line on the coloured side single, double, or triple, curved or straight. Air-vessel absent.

Geographical distribution.—These fishes are extended to most regions, residing at the bottom of the sea, some ascend rivers. The upper surface is coloured, and as observed by Adams (Voyage of the Samarang), "amongst the coral reefs where the Pleuronectidæ are frequently found, their tails are often ornamented with rather vivid colours, and their upper sides marked with somewhat striking patterns, whereas those that are half buried, are as dull and dingy as the surface is where they are found."

Dr. Sauvage (Comp. Rend. 1872, April), has observed that the various degrees of development of the termination of the vertebral column in the genera Rhombus, Solea, and Pleuronectes, are in accordance with their geological appearance.

SYNOPSIS OF GENERA.

A. Jaws and dentition nearly similar on both sides.

1. Psettodes. Dorsal fin commences on the neck: eye on right or left side.

2. Citharichthys. Dorsal fin commences before the eyes, which are on the left side. Teeth in a single unequal row in the jaws: lateral-line straight.

3. Pseudorhombus. Eyes on right side. Dorsal fin commences before the eyes. Teeth of upper jaw in

two rows. Lateral-line with a strong curve anteriorly.

4. Platophrys. Eyes on left side, Dorsal fin commences before the eyes. Teeth in a single or double Lateral-line with a strong curve anteriorly.

B. Cleft of mouth narrow, and the dentition on the blind side most developed.

5. Solea. Eyes on right side: pectorals, if present, usually rudimentary: vertical fins not confluent. Scales ctenoid.

6. Achirus. Eyes on right side: pectorals, if present, rudimentary: vertical fin not confluent: dorsal and anal rays scaled. Scales cycloid or ctenoid.

7. Synaptura. Eyes on the right side: pectorals, if present, may be rudimentary. Vertical fins confluent. Scales ctenoid or cycloid.

8. Plagusia. Eyes on the left side: pectorals absent: vertical fins confluent. Two or three lateral-lines

on the left side: lips with tentacles. Scales ctenoid or cycloid.

9. Cynoglossus. Eyes on the left side: pectorals absent: vertical fins confluent. Two or three lateral-lines on the left side. Lips without tentacles. Scales ctenoid or cycloid.

Genus, 1—PSETTODES, Bennett.

Sphagomorus, Cope.

Branchiostegals seven. Cleft of mouth deep, the maxilla being about half the length of the head. Gill. membranes scarcely united at the throat: gill-rakers replaced by groups of minute spines. Eyes on the right or left side. Jaws and dentition nearly equally developed on both sides. Two rows of curved, slender, sometimes barbed,

* Hr. Malm (Svensk. Vet. Akad. Handl. vii, No. 4, 1868) has shown that the skull is only apparently asymmetrical. The young Pleuronectoid is obliged, owing to the depth of its body, increased by the development of the vertical fins, to lie on one side when resting on the ground, as the horizontal fins are not sufficiently developed to sustain it in a vertical position. The eye of the "blind" side has a tendency to turn towards the light, in doing so it carries with it the surrounding cartilaginous frame-work of the skull.

† The terms right (dextral) or left (sinistral) are employed in these fishes with respect to the position of the coloured side. To ascertain this the fish is placed with its tail towards the observer, the dorsal fin upwards, the anal downwards.

distant teeth in either jaw, the anterior of the inner row in the mandible being received into a groove anterior to the vomer: teeth present on vomer and palate. Dorsal fin commencing on the nape. Most of the dorsal and anal rays branched. Scales small, ctenoid. Lateral-line gradually descends to the straight portion.

Geographical distribution.—from the west coast of Africa, through the seas of India to the Malay Archipelago and beyond.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Psettodes erumei, D. 47-56, A. 35-41, L. l. 70-75. Either right or left side coloured, and vertically banded or not so.

B. vii, D. 47-56, P. 16, V. 6, A. 35-41, C. 17, L. 1. 70-75.

Length of head $4\frac{1}{6}$, height of body $2\frac{2}{3}$ in the total length. Eyes—diameter 6 in the length of head, and usually divided by a mere ridge, $1\frac{1}{4}$ diameters from end of snout. Lower jaw much the longer: the maxilla 4/5 of the length of the head. Teeth—strong, barbed at their extremities. Fins—most of the dorsal and anal rays branched: central caudal rays rather the longest. Colours—this fish may be coloured on either the left or the right side. Brownish or purplish-black, with the vertical fins edged with white: a lightish band usually present across the free portion of the tail. Cross bands have likewise been observed.

Habitat.—West coast of Africa, seas of India to the Malay Archipelago and China. It attains at least

16 inches in length.

Genus, 2—CITHARICHTHYS, Bleeker.

Psettichthys, Girard.

Gill-membranes broadly united at the throat. Cleft of mouth wide, and equally developed on both sides: the maxilla more than one-third of the length of the head. Eyes on the left side and on the same level. Teeth in jaws in a single row, without canines: none on vomer or palatines. Dorsal fin commences on the snout, and is not confluent with the caudal: its rays simple. Pectorals present. Scales small, deciduous, ctenoid or cycloid. Lateral-line straight.

Geographical distribution.—Madras, tropical parts of Atlantic.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Citharichthys aureus, D. 82, A. 70, L. 1. 83. First dorsal ray elongated. Orange, with dark marks. Madras.

I. Citharichthys aureus, Plate XC, fig. 3.

B. vi, D. 82, P. 10, V. 6, A. 70, C. 15, L. l. 83.

Length of head $4\frac{1}{3}$, height of body $2\frac{3}{4}$ in the total length. Eyes—on the left side, diameter 6 in the length of head, 1 diameter from end of snout, and also apart: the upper not in advance of the lower. Jaws of equal length anteriorly: height of head 1/4 more than its length. The maxilla 2/5 of the length of the head, and reaching to below the front edge of the eyes. Teeth—in a single row in the jaw, no canines: none (?) on the palate. Fins—anterior dorsal spine elongated, commencing on the snout, and being rather longer than the head, the middle dorsal rays are 2/3 of the length of the head. Dorsal and anal not united to the caudal, which is pointed. Two short ventrals not united to anal. Both pectorals present, but short. No pre-anal spine. Lateral-line—two on the coloured side, straight, divided by about 13 rows of scales, which latter are cycloid: fin-rays not scaled. Colours—orange, with two brown blotches on the lateral-line, and some cloudy markings on the body: vertical fin with dark edges.

Habitat.—Madras, where this single specimen was captured. Owing to its small size it is impossible to

say whether it has or has not teeth on the palate.

Genus, 3-Pseudorhombus, Bleeker.

Chænopsetta, Gill.

Branchiostegals six. Cleft of mouth deep, the maxilla being usually nearly half as long as the head.

Gill-membranes united beneath the throat but not attached to the isthmus, Gill-rakers lanceolate. Eyes on the left side without a free orbital edge: interorbital space not concave. Jaws and dentition nearly equally developed on both sides: teeth in both jaws of unequal sizes and in a single row: vomer, palate, and tongue edentulous. Fin rays simple, the dorsal commences on the snout, its rays, and those of the anal, are simple. Scales of moderate size, or rather small, and extended on to the dorsal and anal fins. Lateral-line having a strong curve anteriorly.

Geographical distribution.—East coast of Africa, seas of India to the Malay Archipelago, also to the Pacific coasts of central and south America.

SYNOPSIS OF SPECIES.

1. Pseudorhombus arsius, D. 71-79, A. 54-61, L. l. 75-85. From five to ten pointed teeth in either jaw. Two dark blotches on the straight portion of the lateral-line. East coast of Africa, through seas of India to the Malay Archipelago and Australia.

2. Pseudorhombus Javanicus, D. 69, A. 52-53, L. l. 70-75. From 20 to 30 teeth in either jaw. Three

dark blotches along the straight portion of the lateral-line. Madràs to the Malay Archipelago.

3. Pseudorhombus triocellatus, D. 69, A. 51, L. 1. 65-70. Teeth minute. Three heart-shaped purplish blotches placed in the form of a triangle on the coloured side. Madras to the Malay Archipelago.

Pseudorhombus arsius, Günther, l. c. p. 426.

? Pseudorhombus polyspilus, Bleeker, l. c. p. 7, t. 237, f. 3.

B. vii, D. 71-79, P. 11 or 12, V. 6, A. 54-61, C. 17, L. 1. 75-85.

Length of head $4\frac{1}{4}$ to $4\frac{1}{3}$, of caudal $6\frac{1}{2}$, height of body $2\frac{1}{3}$ to $2\frac{1}{2}$ in the total length. Eyes—diameter 5 in length of head, 1 diameter from end of snout, and closely approximating, being divided by a mere ridge. Lower jaw the longer, the maxilla reaches to below the hind third of the eye. Teeth—from five to eight in the lower jaw on the left side, and six to ten on the right. Fins—dorsal fin not continuous with the caudal, its longest rays are in the last third of the fin, all except the last three or four being unbranched, they slightly project beyond the membrane: the last five anal rays branched, each fin ray has a row of small scales. Pectoral two-thirds of length of head. Caudal wedge-shaped, its central rays being the longest: pre-anal spine when present but slightly apparent. Scales—ctenoid on the left, cycloid on the right side: largest in the posterior portion of the body: some on the maxilla. Lateral-line—smooth, its anterior curve is equal to half its length, the depth between the lateral-line (just beyond its curve) and the dorsal fin equals the distance from the snout to the base of the pectoral. The dorsal branch of the lateral-line goes to the base of the ninth, tenth, or eleventh ray. Free portion of the tail three times as high as long. Gill-rakers 1/2 as long as orbit. Colours—left side reddish-bolw, usually covered with variously sized rings, and often two dark ocelli on the straight portion of the lateral-line.

Dr. Bleeker distinguishes P. Russellii=P. arsius, as having L. l. 85, seven to nine teeth in the left side of the lower jaw, and nine to fourteen on the right: the body (in comparison with P. polyspilus) is said to be more elevated, and the profile from the neck to the dorsal more convex: teeth more numerous: whilst the dorsal branch of the lateral-line commences at the eighth or ninth dorsal ray.

P. polyspilus, L. l. 75 to 80, five to eight teeth on both sides of the lower jaw. Head and body with numerous black spots surrounded by blue. Dorsal branch of the lateral-line commencing below the tenth dorsal ray.

I have examined 16 specimens in my collection taken indiscriminately and with the following results:— 1 Spec. 9.5 in. long. Sind. D. 79, A. 59, L. l. 85, branch from 11th d. ray. Height of body 21 in the total: teeth 5 upper, 8 lower jaw.

Thus I do not find the scales along the lateral-line as a rule so numerous as recorded from the Malayan examples, for out of 16 specimens two had 85, one had 81, three had 80; one had 79, six had 78; one had 76, and two had 74. The dorsal branch of the lateral-line varied from the ninth to the eleventh dorsal ray. The teeth likewise showed great differences in number.

Pleuronectes, Russell, Fish. Vizag. i, p. 58, and Noree nalaka, pl. 75, or Rhombus maculosus, Cuv. Reg.

Anim. and Jerdon, M. J. L. and Sc., is probably this species marked as in pl. 91, f. 5.

P. arsius, H. B., is this species which is not uncommon at Calcutta, and is coloured as figured (MS.) by Hamilton Buchanan.

Pseudorhombus oligodon, Bleeker, is distinguished from this species, more especially by its possessing ctenoid scales on both sides of the body.

Habitat.—From the east coast of Africa, through the seas and estuaries of India, to Australia. It attains at least a foot in length. The specimen figured is 7.4 inches in length, and from the Andamans.

2. Pseudorhombus Javanicus,* Plate XCII, fig. 2.

Rhombus Javanicus, Bleeker, Batav. p. 503.

Pseudorhombus Javanicus, Günther, Catal. iv, p. 427; Bleeker, Atl. Ich. Pleuron. p. 8, t. ecxxii, f. 3.

B. vi, D. 69, P. 10, V. 6, A. 52-53, C. 18, L. l. 70-75.

Length of head $4\frac{1}{4}$, height of body $2\frac{1}{2}$ in the total length. Eyes—diameter $4\frac{1}{4}$ in the length of head, 1 diameter from the end of snout: they are divided by a mere ridge. Lower jaw the longer: the maxilla reaches to below the middle of the eye. Anterior nostril with rather a tubular valve posteriorly. Head as high as long. Teeth—small, sharp, conical, subequal in size, upwards of 30 in either side of upper jaw, and from 22 to 25 on either side of the lower. Fins—anterior dorsal rays not higher than the middle ones, which equal nearly half the length of the head. Pectoral as long as the head behind the middle of the eyes. A well-developed preanal spine. Scales—ctenoid on the coloured, cycloid on the blind side. Lateral-line—with a strong anterior curve: the nuchal branch goes to the tenth dorsal ray. Colours—of a purplish-brown, having three black spots on the lateral-line, surrounded by a row of white dots, or else a light blotch surrounded by a dark ring: the first of these spots is at the commencement of the straight portion of the lateral-line. There are two or the lateral-line are two or the lateral-line. pectoral fin, midway between the lateral-line and the abdominal profile: another above the arch of the lateral-line, and a third between the straight portion of the lateral-line and the back. The whole of the coloured side is more or less covered with dots or dark rings, which are also continued on to the vertical fins.

Bleeker gives D. 73 to 76, A. 54-56, height of body $2\frac{5}{6}$ to $2\frac{9}{3}$ in the total length. Hubitat.—Coromandel coast of India to the Malay Archipelago. The one figured is from Madras.

3. Pseudorhombus triocellatus, Plate XCII, fig. 1.

Pleuronectes triocellatus, Bl. Schn. p. 145.

Pleuronectes, Russell, Fish. Vizag. i, p. 59, and Nooree-nalaka, pl. 76.

Rhombus triocellatus, Bleeker, Beng. en Hind. p. 76.

Pseudorhombus triocellatus, Günther, Catal. iv, p. 428; Kner, Novara Fische, p. 285.

Patné sootong, Tam. (Jerdon).

B. vi, D. 66-69, V. 5, A. 49-51, L. 1. 65-70.

Length of head 41 to 41, height of body 2 in the total length. Eyes—with their anterior margins on nearly the same level, diameter 4 in the length of the head, 1 diameter from the end of snout, and a mere ridge nearly the same level, diameter 4 in the length of the head, I diameter from the end of short, and a mere ridge dividing the two. Lower jaw slightly the longer, the maxilla reaches to below the middle of the eye. Height of head 1/4 more than its length. The maxilla 4/7 of length of head. Posterior nostril patent, anterior more tubular, and with a short barbel-like prolongation. Teeth—minute. Fins—both ventrals present, Anterior dorsal rays elevated, a rather strong preanal spine. Scales—etenoid on coloured, cycloid on the blind side. Lateral-line—height of its curve equals half its length. Colours—of a rich brown, with three large heart-shaped purplish occili, each having a light centre and a yellowish circumference, situated in the form of a triangle, the control of the feel the feel to control one. two anterior on a vertical line slightly anterior to the centre of the total length of the fish, the central one midway between them and the base of the caudal. Vertical fins dusky yellow, covered with irregularly shaped dark blotches: pectoral yellowish, with some fine black spots.

Habitat.—Madras, to the Malay Archipelago. It attains to six or eight inches in length.

^{*} Pseudorhombus (Pleuronectes) nauphela, Ham. Buch. Fish. Ganges, p. 126, is said to have D. 73. A. 55, shaped like the head of a lance. Lives in the Gangetic estuaries, where it attains about 8 inches in length.

Colours—greenish-brown, on which are some scattered black spots. This species I have been unable to recognize, unless it is this fish.

Genus, 4-Platophrys, Swainson.

Bothus, Bp.; Rhomboidichthys, Bleeker.

Branchiostegals six. Cleft of mouth moderate or of small extent, the maxilla being about one-third or less in the length of the head. Eyes on the left side separated by a concave interorbital space of varying extent. Jaws and dentition nearly equally developed on both sides: teeth minute, of an equal size and in a single or double row. Vomerine and palatine teeth, as a rule, absent. The dorsal fin commences on the snout, its rays and those of the anal are simple. Scales ctenoid, and extended on to the dorsal and anal rays. Lateral-line having a strong curve

This genus has been divided into sub-genera as follows:—(1) scales very small, Rhomboidichthys: (2) of moderate size (40 rows in lateral-line) and deciduous, Platophrys: (3) of moderate size and not deciduous, Engyprosopon.

Geographical distribution.—From the Red Sea, through tropical seas to Japan, also in the Mediterranean.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Platophrys pantherinus, D. 85-91, A. 65-70, L. l. 75-85. Upper pectoral rays may be elongated. Purplish, with 3 large spots along the middle of the body, and dark rings scattered over the body and fins. Red Sca, east coast of Africa, Andamans, to the Malay Archipelago and beyond.

1. Platophrys pantherinus, Plate XCII, figs. 3 and 4.

Rhombus pantherinus, Rüpp. Atl. p. 121, t. 31, f. 1, and N. W. Fische, p. 84; Bleeker, Kokos, iii, p. 178. Rhombus pavimanus, Bennett, Proc. Zool. Soc. 1831, p. 168. Rhombus sumatranus, Bleeker, Pleuron. p. 14. Rhomboidichthys leopardinus, Günther, Catal. iv, p. 434 (? female). Rhomboidichthus matherinus, Günther, Catal. iv, p. 436. Kleng, Voh. 5, h. Coo. Wicz. 1871, p. 1871.

Rhomboidichthys pantherinus, Günther, Catal. iv, p. 436; Klunz. Verh. z. b. Ges. Wien, 1871, p. 571. Platophrys pantherinus, Bleeker, Atl. Ich. Pleuron. p. 11, t. 233, f. 3.

B. vi, D. 85-91, P. 10, V. 6, A. 65-70, C. 18, L. 1. 75-85.

Length of head $4\frac{1}{4}$, height of body $2\frac{1}{6}$ in the total length. Eyes—diameter $3\frac{3}{4}$ to 4 in the length of head, 3/4 to 1 diameter from end of snout, and 1 diameter apart: one half of the lower eye anterior to the upper orbit. Lower jaw somewhat the longer: the maxilla reaches to below the first third of the lower orbit, there is a knob on its upper portion, sometimes also one on the orbit. Head one-fourth higher than long. Some have a barbel above the eye, others have none. Teeth—small, in two rows in the maxilla. Fins—anterior dorsal rays not longer than the middle ones, which are nearly half the length of the head. Pectoral not so long as the head, except in the upper elongated rays, which may be present or absent, and are probably distinctive of sex. Colours—of a purplish-brown on the coloured side, with three dark spots along the middle of the body, others variously scattered, also some rings of a dark colour: vertical fins with brown spots and white dots.

Habitat.—Red Sea, east coast of Africa, Andamans to the Malay Archipelago and beyond. The two

figured (life-size) were from Port Blair.

Genus, 5-Solea, Klein.

Cleft of mouth narrow, twisted round to the left side. Eyes on the right side, the upper being partially or entirely in advance of the lower. Nostrils variously formed. Dentition most developed on the blind side, where the teeth in the jaws are in villiform rows, none on vomer or palate. The dorsal fin commences on the snout, and is not confluent with the caudal: pectorals present or absent. Scales small, ctenoid. Lateral-line straight.

This genus has been sub-divided :-

A.—Pectorals developed, Microbuglossus.

a.—Nostrils on blind side not dilated, Solea.

-One of nostrils on blind side dilated and broadly fringed, Pegusa.

B.—Pectorals on both sides rudimentary or small, Buglossus.

Pectorals absent, Aseraggodes.

Geographical distribution.—All tropical as well as temperate seas.

SYNOPSIS OF SPECIES.

A. Pectorals present.

1. Solea heterorhina, D. 87-94, P. 8, A. 78-82, L. l. 105-110. Anterior nostril tubular, longer than the

orbit. Brown, with vertical bands, blotches or spots edged with black. Andamans to the Malay Archipelago.

2. Solea elongata, D. 70-73, P. 9, A. 60-62, L. l. 120. Height of body 3 in the total. Scales strongly ctenoid. Stone colour, with black spots and blotches. Madras.

3. Solea ovata, D. 60-66, P. 9, A. 42-49, L. l. 110. Height of body 2\frac{1}{4} in the total. Scales strongly

ctenoid. Stone colour with black spots and blotches. Coromandel coast of India to China.

3 I

ANACANTHINI.

B. Pectorals absent,

4. Solea Indica, D. 55, A. 44, L. l. 75. Brownish, vertical fins darker. Madras.

A. Pectorals present.

1. Solea heterorhina, Plate XCII, fig. 5.

Solea heterorhinus, Bleeker, Amboina, p. 64, and Atl. Ich. Pleur. p. 17, t. 211, f. 2. Soleichthys heterorhinus, Bleeker, En. Spec. p. 183. Solea heterorhina, Günther, Catal. iv, p. 466.

B. vi, D. 87-94, P. 8, V. 4, A. 78-82, C. 16, L. 1. 105-110.

Length of head $6\frac{1}{2}$ to 7, height of body $3\frac{1}{3}$ to $3\frac{1}{2}$ in the total length. Eyes—close together, the upper slightly in advance of the lower, diameter $4\frac{1}{2}$ in the length of head, and about 1/2 a diameter from the end of the snout. Head 1/3 higher than long. Cleft of the mouth extends to below the first third of the lower orbit. Two nostrils, the posterior just in front of the lower orbit, the anterior a little before it, consisting in the adult, of a long tube which being laid backwards reaches the hind edge of the eyes, it is not so elongated in the young: a short tubular nostril on the blind side. Fins—dorsal and anal rays unbranched. Pectoral on the coloured side short, the two upper rays being considerably longer than the lower ones: on the blind side this fin is rudimentary. Free portion of the tail very short. Scales—feebly etenoid on both sides. Lateral-line—straight and in simple tubes. Colours—of a rich brownish olive, with irregular vertical bands, blotches, and spots edged with black.

Habitat.—Andamans to the Malay Archipelago. The specimen (figured life-size) was from Port Blair, where it was captured by Dr. Dobson.

2. Solea elongata, Plate XC, fig. 4.

B. vi, D. 70-73, P. 9, V. 4, A. 60-62, C. 18, L. 1. 120.

Length of head 54, height of body 3 in the total length. Eyes—upper on the same level anteriorly as the lower, diameter 5 in length of head, 1/2 a diameter apart, and 1 from the end of snout. Upper jaw slightly the longer: numerous short tentacles about the blind side of the head, lips not fringed. Angle of the jaws beneath the anterior third of the lower orbit. Two nostrils, a small one in front of lower eye, and a tubular one anterior to it: that on the blind side concealed. Height of head rather exceeds its length. Fins—dorsal and anal rays unbranched, the highest equals 1/4 of that of the body. Pectoral on the coloured side equals rather above 1/2 length of head, and is much longer than that on the blind side: both ventrals present. Scales—feebly ctenoid on both sides, present on dorsal and anal rays. Colours—of an olive stone-colour, irregularly vertically banded, with black spots and blotches, fins also spotted. Centre of pectoral with a black blotch. Fins also spotted.

This fish is closely allied to $Solea\ ovata$, but has a much lower body and A. 60-62, instead of A. 42-49. Habitat.—Madras, where two specimens were obtained.

3. Solea ovata, Plate XCIII, fig. 1.

Richardson, Ich. China, p. 279; Günther, Catal. iv, p. 472 (not Cantor). Solea ——? Jerdon, Madras, Journal Lit. and Science, 1851, p. 147.

B. vi, D. 60-66, P. 9, V. 5, A. 42-49, C. 12, L. 1. 110.

Length of head 5 to 5½, height of body 2½ in the total length. Eyes—upper one-half in advance of the lower, diameter 5 in the length of head, 3/4 of a diameter apart, and the lower 1½ diameters from the end of snout. Height of head 1/3 more than its length. Upper jaw a little the longer, numerous short tentacles about the blind side of the head, lips not fringed. Angle of the mouth below the middle of the lower orbit. Two nostrils, a small open one just in front of the lower eye, and a tubular one anterior to it: that of the blind side not dilated, concealed. Fins—dorsal and anal rays, except the last few, unbranched, the highest being about 3½ in that of the body, pectoral on the coloured side two thirds as long as the head and half longer than the one on the blind side. Both ventrals present. Scales—strongly etenoid, present on dorsal and anal rays. Colours—of an olive brown, with spots and blotches of black on the coloured side of body and vertical fins. Pectoral deep black in its outer two-thirds, or else with a black blotch.

Solea maculata (Cuvier), Blecker, so named from a Pondicherry specimen, collected by Kuhl and v. Hasselt, is probably this species. Blecker observes that Solea humilis, Cantor=S. ovata (Richards.), Cantor and he places S. maculata as a synomym. S. humilis, Cantor, has L. 1. 95-100.

Cantor and he places S. maculata as a synomym. S. humilis, Cantor, has L. l. 95-100.

Habitat.—Madras to China, the one figured was the largest obtained at Madras, where it is termed Selli-patté according to Jerdon.

B. Pectorals absent.

4. Solea Indica.

Günther, Catal. iv, p. 474.

B. vi, D. 55, V. 4, A. 44, C. 12, L. l. 75.

Length of head 41, height of body 21 in the total length. Eyes—small, the upper slightly in advance of the lower, and 1 diameter apart. Jaws of about equal length. No tentacles on the head. Fins—most of the rays of the vertical fins branched, the highest in the dorsal being two-thirds the length of the head: right ventral slightly longer than the eye, and continuous with the anal. Left pectoral absent. Caudal rounded. Scales—strongly ctenoid. Colours—brownish, the vertical fins being darker.

Habitat.—Madras, from whence the late Dr. T. C. Jerdon sent one specimen (22 lines long) to the

British Museum.

Genus, 6-Achirus, (sp. Lacépède) Cuvier.

Pardachirus, Günther.

Branchiostegals six. Gill-openings narrow, the membranes being broadly united below the throat: gill-rakers rudimentary. Eyes on the right side, the upper in advance of the lower. Mouth narrower on the left side. Teeth minute and only on the blind side. The dorsal fin commences on the snout and ends close to the root of, but is not confluent with, the caudal: each dorsal and anal ray scaly, and generally with a pore at the base of each. Two ventrals, united to the anal. Pectorals absent. Scales small, cycloid or very partially or distinctly ctenoid. Lateral-line straight, on the blind side there are two, the upper commencing at the snout passes along the upper profile

Geographical distribution.—From the Red Sca through the seas of India to the Nicobars and Malay Archipelago.

SYNOPSIS OF SPECIES.

1. Achirus pavoninus, D. 64-70, A. 50-56, L. l. 90-100. Some of the scales on the front of the body and head feebly ctenoid. Grayish-brown, covered with milk-white spots, some of which have a black dot in the centre. Andamans, Malay Archipelago and beyond.

2. Achirus maculatus, D. 56, A. 43, L. l. 65. Scales strongly ctenoid. Spotted with brown. Tranquebar.

1. Achirus pavoninus, Plate XCIII, fig. 2.

Achirus pavoninus, Lacép. iv, pp. 658, 661; Cantor, Catal. p. 225; Bleeker, Verh. Bat. Gen. xxiv, Pleur. p. 18, and Atl. Ich. Pleur. p. 24, t. 241, f. 1; Kaup, Uebers. Solein. Arch. Naturg. xxiv, i, p. 102.

Pleuronectes pavoninus, Shaw, Zool. iv, p. 310.

Achirus maculatus, (Kuhl. and v. Hass.) Bleeker, Pleur. p. 18. Pardachirus pavoninus, Günther, Catal. iv, p. 479. Solea (Pardachirus) pavonina, Steind. Fisch. Sing. 1870, p. 570.

B. vi, D. 64-70, V. (r.) 4 (l.) 5, A. 50-56, C. 15, L. l. 90-100.

Length of head $5\frac{1}{4}$ to $5\frac{2}{3}$, height of body $2\frac{1}{2}$ to 3 in the total length. Eyes—upper slightly in advance of the lower, diameter $5\frac{1}{4}$ in the length of the head, anterior edge of the lower eye $1\frac{1}{2}$ diameters from the end of snout. Angle of mouth below the first third of the lower eye. Numerous and rather long fringes along the edges of both upper and lower jaws, also on the left side of the head. Fins—an open pore at the base of each dorsal and anal ray on the left side. Anterior dorsal and anal rays branched. Scales—ctenoid on the head and anterior portion of the body. Colours—right side grayish-brown, covered with milk-white spots of various shapes and sizes, each having a black outer edge and some a central black dot.

Achirus marmorata, Lacép. is similar but distinguished by having only cycloid scales. It has been

recorded from the Nicobars by Kner.

Habitat.—Andamans to the Malay Archipelago and beyond. The specimen figured (life-size) was from Port Blair.

2. Achirus maculatus.

Pleuronectes maculatus, Bl. Schn. p. 157.

D. 56, V. 6, A. 43, C. 15, L. 1. 65.

Length of head $4\frac{1}{3}$, of caudal $5\frac{2}{4}$, height of body $2\frac{1}{2}$ in the total length. Eyes—rather small, diameter 9 in the length of head, the upper slightly in advance of the lower, and 2/3 of a diameter apart. Height of head 1/4 more than its length. Rostral hook covers the symphysis. Angle of mouth at junction of anterior third of head with the middle third. Lower lip fringed. Being a skin it is impossible to say if there were fringes on the head, or the character of the nostrils. Teeth—minute ones present on the blind side. Fins—dorsal commences on the snout, most of its rays appear to be branched, the highest in the posterior third of the body and equal to 1/3 of the greatest height of the body. Pectorals absent. Both ventrals present, but are distinct from it. Scales—strongly etenoid densely covering the dorsal and analyzes on both sides: a but are distinct from it. Scales—strongly ctenoid, densely covering the dorsal and anal rays on both sides: a pore* at the base of each ray on the blind side. Lateral-line—straight. Colours—slaty-brown on the right side, with numerous dark blotches, and some vertical black lines crossing the lateral-line at a right angle.

Digitized by GOOG

^{*} The skin is so covered with varnish that I am not quite clear on this point, but it appears to me that such are visible.

Head appears to have been marked as in A. pavoninus. Blind side of the body yellowish with scattered

This fish evidently cannot be A. pavoninus, the strongly ctenoid character of its scales more resembles

what is seen in Genus Solea than in Achirus, and it must be closely allied to A. poropterus, Kaup.

Habitat.—Tranquebar, from whence Bloch received the specimen described (6.5 inches in length) and for the opportunity of examining which I am indebted to Professor Peters of Berlin.

Genus, 7—SYNAPTURA, Cantor.

Brachirus, Swains. : Achiroides, Bleeker : Æsopia, Euryglossa, and Eurypleura, Kaup.

Branchiostegals six. Body oblong or oval. Eyes on the right side, the upper in advance of the lower. Cleft of the mouth narrow, twisted round to the left side: the lips fimbriated or entire: minute teeth on the left side only: palate edentulous. One of the nostrils on the blind side dilated in some species, not so in others, whilst amongst the latter both pectorals may be present, the right being somewhat the longer, some of which have the nasal tube small and simple (Synaptura), or bifid (Euryglossa). Secondly, the left pectoral may be longer than the right (Anisochirus). Thirdly, the left pectoral may be rudimentary (Æsopia). Fourthly, both pectorals may be also confluent. Scales ctenoid (cycloid in S. cornuta), small. Lateral-line

Geographical distribution.—From Beloochistan, through the seas of India to the Malay Archipelago and beyond.

SYNOPSIS OF SPECIES.

A. Both pectoral fins present, the right the longer.

1. Synaptura Commersoniana, D. 71-81, A. 61-63, L. l. 155. Two tubular nostrils on the coloured side.

Leaden gray, vertical fins with a white margin. Seas of India to the Malay Archipelago.

2. Synaptura albomaculata, D. 72-74, A. 56-59, L. l. 110-120. Two tubular nostrils on the coloured side, with a short barbel intermediate. Brown, with 5 rows of widely separated white spots. Fins slate-coloured added with white. Song of India edged with white. Seas of India.

3. Synaptura Orientalis, D. 61-65, A. 47-52, L. l. 70-85. Scales on nape not enlarged. Slate-coloured, with black blotches, and fine black vertical lines crossing the lateral-line at right angles. Seas of India to China.

4. Synaptura pan, D. 57, A. 43, L. 1. 80. Scales on nape enlarged. Colours as in S. Orientalis. Estuaries and tidal rivers from Orissa and Bengal to the Malay Archipelago.

B. Left pectoral fin rudimentary.

5. Synaptura multifusciata, D. 93, A. 67, L. l. 110. Nasal tube longer than the diameter of the eye. Head and body with 27 narrow cross-bands. East Indies.
6. Synaptura cornuta, D. 69-75, A. 61-62, L. 1. 90-100. First dorsal ray thickened and prolonged.

Thirteen vertical chestnut bands. Coromandel coast of India.

7. Synaptura zebra, D. 65-74, A. 58-60, L. 1. 90-95. No prolonged dorsal ray. Ten reddish-chestnut vertical bands. Seas of India.

A. Both pectorals present, the right the longer.

Erumi naak, Tam.

B. vi, D. 70-81, P. 9, V. 4, A. 60-63, C. 12, L. 1. 155-160.

Length of head 6 to $6\frac{1}{2}$, height of body $3\frac{2}{3}$ to 4 in the total length. Eyes—the upper almost entirely in advance of the lower, diameter $7\frac{1}{2}$ in the length of the head, nearly 1/2 a diameter apart, and $1\frac{1}{4}$ from the end of snout. Height of head rather more than its length. Upper jaw slightly the longer: angle of the mouth below the middle of the lower eye. Two tubular nostrils in front of the lower eye. Scales—strongly etenoid on the coloured side. Colours—leaden-gray, vertical fins black with a broad white outer edge.

Habitat.—Seas of India to the Malay Archipelago: it attains at least 12 inches in length. It is not

esteemed as food in Madras or along the Malabar Coast.

2. Synaptura albomaculata, Plate XCIII, fig. 5.

Kaup, Wiegm. Arch. 1858, p. 98: Günther, Catal. iv, p. 483. B. vi, D. 72-74, P. 7-8, V. 4, A. 56-59, C. 16, L. 1. 110-120.

Length of head $5\frac{1}{3}$ to 6, height of body $3\frac{1}{3}$ to $3\frac{2}{3}$ in the total length. Eyes—of moderate size, the upper half in advance of the lower. Height of head 1/3 more than its length. Angle of mouth below the hind third of the eye. Lips on coloured side fringed. Two tubular nostrils on the coloured side. Barbels—a short one between the two nostrils. Fins—pectoral on coloured side $2\frac{3}{4}$ in the length of the head, very small on blind side. Scales—ctenoid on coloured, cycloid on blind side. Lateral-line—single on either side. Colours—body brown on the coloured side, with three to five rows of widely separated white dots. Fins slate-coloured edged with white.

Habitat.--Seas of India: attaining at least 12 inches in length. The specimen figured, life-size, was from Madras.

3. Synaptura Orientalis, Plate XCIII, fig. 4, and Plate XCIV, fig. 2.

Sappatee, Mal.

B. vi, D. 62-65, P. 7, V. 5, A. 47-50, C. 16, L. 1. 70-85.

Length of head 5 to $5\frac{1}{6}$, of caudal $8\frac{1}{2}$, height of body $2\frac{1}{3}$ to $2\frac{1}{6}$ in the total length. Eyes—the upper one slightly in advance of the lower, and 2/3 to 1 diameter apart. The upper jaw rather overlapping the lower. No dilated nostril on the blind side: nasal tube on coloured side, simple. Fins—the right pectoral longer than the left, and $2\frac{2}{3}$ to 3 in the length of the head. Dorsal commences on the snout, its rays are branched at their extremities, it extends 2/3 up the length of the caudal. Ventral not adherent to the anal. Scales—ctenoid on both sides. Lips on blind side and head with numerous short cutaneous filaments, some are also present on the coloured side of the body and are generally black. Colours—of a bluish slate colour on the right side, usually with short narrow black vertical bands crossing the lateral line: the body is likewise blotched with darker sometimes as spots, in other instances in bands, occasionally some white marks. Vertical fins dark, outer half of pectoral black. The scales on the head and first-third of the length of this fish are usually smaller than those posterior to them along the lateral line and above and below it.

This fish may be at once distinguished from S. pan, because the latter has an enlarged row of scales over

the nape.

I have to thank Professor Peters of Berlin, for permitting me to examine the type specimen of Pleuronectes

1 have to thank Professor Peters of Berlin, for permitting me to examine the type specimen of Pleuronectes

1 have to thank Professor Peters of Berlin, for permitting me to examine the type specimen of Pleuronectes

The specimens figured are from Canara. Habitat.—Sind, western coast of India, Andamans, China seas. I have a specimen from Singapore, from whence it was brought by the late Dr. Stoliczka.

4. Synaptura pan, Plate XCIII, fig. 3.

Pleuronectes pan, Ham. Buch. Fish. Ganges, pp. 130, 373, pl. 24, f. 42. Brachirus pan, Swainson, Fishes, ii, p. 303; Bleeker, Atl. Ich. Pleur. p. 21, t. 240, f. 1.

Pleuronectes pan, Bleeker, Beng. en Hind. p. 76, and Pleur, p. 30 (not synon).

Synaptura pan, Günther, Catal. iv, p. 481.

B. vi, D. 57-60, P. 7, V. 6, A. 43-45, C. 14, L. 1. 80.

Length of head 5, height of body 21/2 in the total length. Eyes—upper slightly in advance of the lower, diameter 6 in length of head, 2 diameters from the end of snout, and scarcely 1 apart. Height of head 1.4 more than its length. The upper jaw slightly overlaps the lower. The maxilla reaches to below the first third of the eye. Two nostrils, a patent one in front of lower eye, and a tubular one just anterior to it: nostril on blind side concealed. Lower lip slightly fringed on the coloured side. Fins—the posterior dorsal and most of the anal rays branched. Right pectoral $2\frac{1}{3}$ in the length of the head, and much longer than the left, which consists of six rays. Scales—strongly ctenoid on both sides. The scales from above the eye to the nape and in a wide band crossing the nape are much larger than those on the remainder of the body: vertical fins rather densely scaled. Lateral-line—straight. Colours—of a dull red or muddy brown or gray, with irregular vertical block block block and hands, visibly recovered block. irregular vertical black blotches and bands: right pectoral black.

ANACANTHINI.

Bleeker gives L. l. 100, being more than I find in Indian or Burmese examples. Habitat.—estuaries and tidal rivers of Orissa, lower portion of the Ganges, Burmese rivers and Malay Archipelago, attaining about 6 inches in length. The one figured was from Calcutta.

B. Left pectoral fin rudimentary.

5. Synaptura multifasciata.

Æsopia multifasciata, Kaup, Wiegm. Arch. 1858, p. 97. Synaptura multifasciata, Günther, Catal. iv, p. 485.

B. vi, D. 93, P. 7-10, A. 67, L. l. 110.

Length of head 7, height of body 3 in the total length. Eyes—placed close together. Nasal tube longer than the diameter of the eye. Fins—two longest pectoral rays exceed the diameter of the lower eye. Colours—head and body with twenty-seven narrow cross-bands.

Habitat.—East Indies. This fish may be a reversed Solea heterorhina (see p. 426).

6. Synaptura cornuta, Plate XCIV, fig. 4.

Pleuronectes, Russell, Fish. Vizag. i, p. 56, and Jerree-potoo, pl. 72.

Solea cornuta, Cuv. Règ. Anim.

Synaptura potoo, Bleeker, Beng. en Hind. p. 76. Æsopia cornuta, Kaup, Wiegm. Arch. 1858, p. 95; Günther, Catal. iv, p. 487; Day, Proc. Zool. Soc. 1873, p. 238.

B. vi, D. 69-75, P. 17, V. 3-4, A. 61-62, C. 17, L. 1. 90-100.

Length of head 6, height of body $3\frac{1}{3}$ in the total length. Eyes—diameter 4 to $4\frac{1}{2}$ in the length of head, scarcely 1 diameter from end of snout, and placed close together: the upper eye is scarcely, if at all, in advance of the lower. Angle of the mouth below the middle of the eye. A few short filaments along the lower edge of the mandible. A round nostril in front of the lower eye, and anterior to it a tubular one. Teeth—some fine ones on the blind side. Fins—pectoral on the coloured side rather longer than the one on the blind side, but both very short.* First dorsal ray thickened and prolonged, the next few rays lower than the succeeding ones. Scales—cycloid on both sides. Lateral-line—single on both sides. Colours—twelve to thirteen vertical chestnut bands on a light ground colour, the anterior of which is on the snout, they are continued on to the vertical fins. Caudal dark, with white markings, dorsal having a white edge.

Habitat.—Coromandel coast: attaining at least 6 inches in length.

7. Synaptura zebra, Plate XCIV, fig. 3.

Pleuronectes zebra, Bl. t. 187; Gmel. Lin. p. 1226; Bl. Schn. p. 151. Pleuronectes, Russell, Fish. Vizag. i, p. 56, and Jeree-potoo B, pl. 71.

Solea jerreus, Cuv. Règ. Anim.

Brachirus jerreus, Swainson, Fishes, ii, p. 303.

Synaptura jerreus, Bleeker, Beng. en Hind. p. 76; Jerdon, M. J. L. and Sc. 1851, p. 148.

Synaptura quagga, Günther, Catal. iv, p. 485.

Varri amler, Tam.

B. vi, D. 65-74, P. 6, V. 5, A. 58-60, C. 16-18, L. l. 90-95.

Length of head 6, height of body 3 in the total length. Eyes-close together, the anterior third of the upper being in advance of the lower, diameter 41 in the length of head, the lower about 1 diameter from the end of snout. Head 1/4 higher than long. Jaws of about equal length anteriorly. Angle of the mouth below the first third of the lower eye. Two nostrils in front of lower eye, the anterior being tubular. Barbels-in some, not all specimens, there is a barbel above either eye, occasionally it is short, but in some examples it equals the diameter of the eye. Fins—pectorals attached to the gill-covers, the upper two rays on the right side longer than the others: left pectoral rudimentary. Scales—ctenoid. Colours—grayish-brown, with ten reddish-brown vertical bands, commencing on the dorsal and continued on to the anal fin, where they become nearly black: pectoral on the right side nearly black: caudal black, with some irregular white markings towards its edges.

I have convinced myself by examining Bloch's type specimen (most kindly lent to me by Professor Peters) that this is his fish, others have considered a Malay Archipelago or a Chinese fish was intended, and it has been described as having D. 77-89, A. 66-79, C. 13-15, L. l. 125-130 and the same colours as S. zebra, Bl.

Kaup suggested that Synaptura multifusciatus, Japonicus, zebra, and the species here described may be varieties of one species.

Habitat.—Seas of India, including Ceylon and ? Chinese seas: attaining at least 6 inches in length.

* The pectorals were overlooked by Russell.

Genus, 8-Plagusia, pt. Cuvier.

Paraplagusia, Bleeker.

Branchiostegals six. Gill-openings very narrow. Eyes on the left side. Anterior portion of snout prolonged and curving downwards and backwards in the form of a hook which covers the mandible. Mouth rather narrow and unsymmetrical: lips on the coloured side fringed. A single nostril on the left side before the angle of the lower eye, but none in the interorbital space. Vertical fin confluent. Pectorals absent. Scales ctenoid, small. Lateral-line on the coloured side, double or triple.

Geographical distribution.—Red Sea and east coast of Africa, through the seas of India, to the Malay Archipelago and beyond.

SYNOPSIS OF SPECIES.

1. Plagusia marmorata, D. 99-106, A. 75-86, L. l. 90-100. Two lateral-lines on the left-side separated by 16 or 17 rows of scales. East coast of Africa, seas of India, to China.

2. Plagusia bilineata, D. 96-102, A. 70-74, L. l. 84-94. Two lateral-lines on the left side separated by

13 or 14 rows of scales. Red Sea, seas of India, to the Malay Archipelago.

1. Plagusia marmorata, Plate XCV, fig. 1.

Nah-lah-ku, Tamil.

B. vi, D. 99-106, V. 4, A. 75-86, C. 10, L. 1. 90-100.

Length of head $4\frac{1}{4}$ to $4\frac{1}{5}$, height of body $3\frac{2}{3}$ to 4 in the total length. Eyes—small, the upper in advance of the lower, they are placed in the middle of the length of head, nearly I diameter apart. Lips fringed. The rostral hook reaches to some distance beyond the posterior edge of the lower orbit. Angle of mouth below the hind edge of the eye and nearer the hind edge of the opercle than the snout. A tubular nostril in front of lower eye: nostril developed on the blind side. Fins—a single ventral. Scales—ctenoid. Lateral-lines—two on the left side separated by 16 or 17 rows of scales, and one on the right side. Colours—brownish, finely marbled with darker.

Habitat.—East coast of Africa, seas of India to China. The specimen figured was from Madras.

2. Plagusia bilineata.

Pleuronectes bilineatus, Bloch, t. 188; Gmel. Linn. p. 1235; (not Bl. Schn.* p. 158) Russell, Fish. Vizag. i, p. 58, and Jerree-potoo, pl. 74; Bennett, Life of Sir S. Raffles, p. 692.

Plagusia Blochii, Bleeker, Pleur. p. 21, and Nat. Tyds. Ned. Ind. i, p. 411. Paraplagusia marmorata, Bleeker, Atl. Ich. Pleuron. p. 27, t. 244, f. 5.

Aralu, Tamil.

B. vi, D. 96-102, V. 4, A. 70-74, C. 8, L. l. 84-94.

Length of head $4\frac{1}{6}$, height of body $3\frac{2}{3}$ in the total length. Eyes—diameter 8 to 12 in the length of head, 1 diameter apart, the upper in advance of the lower, and the two occupying the middle of the length of the head. Height of head equals 8/9 of its length. Angle of the mouth considerably nearer gill-opening than to the end of the snout, the rostral hook extends to below the hind edge of the lower eye. A single tubular nostril on the coloured side in front of the lower eye and close to the lip. A well-developed tubular nostril on the blind side. Fins—a single ventral attached to the anal. Scales—ctenoid. Lateral-line—two on the coloured side separated by thirteen or fourteen rows of scales: a single lateral-line on the blind side. Colours—opercle tinged with bluish-black: each scale on the body lightest in its centre: fins dull orange.

Habitat.—Red Sea, seas of India to the Malay Archipelago. It attains at least 10 inches in length, and is good eating.

Genus, 9—Cynoglossus, † Hamilton Buchanan.

Cantoria, Arelia, Trulla, Icania, Kaup.

Branchiostegals six. Gill-openings very narrow. Eyes on the left side. Anterior portion of snout prolonged,

* Bl. Schn. says of P. arel, p. 159, "Narium foramine superiore inter oculos minores, quam in bilineato, inferiore ante oculum inferiorem," evidently showing the presence of two nostrils in the species which he described.

† Dr. Günther observes Cynoglossus et Achirus H. B. I am unable to find the former name employed by H. B. except as a

specific term.

and curves downwards and backwards in the form of a hook. Mouth rather narrow and unsymmetrical. Lips not fringed. There may be two nostrils on the coloured side, one of which is in the interorbital space (Arelia); or two nostrils before the lower eye, the inferior of which is broader than the superior one (Cantoria); or only one nostril which is in front of the lower eye (Trulla); or no conspicuous nostril (Icania). Minute teeth on the right side only. Vertical fins confluent: pectorals absent. Scales ctenoid or cycloid. Lateral-line on the coloured side double

Geographical distribution.—Tropical seas, some are found in tidal rivers, and are said to enter fresh-water.

SYNOPSIS OF SPECIES.

A. Three lateral-lines on the coloured side.

- 1. Cynoglossus quinquelineatus, D. 109, A. 91, L. l. 100. An open nostril between the eyes, a tubular one before the lower eye. Scales ctenoid on coloured side only, 17 rows between upper and middle lateral-lines, 15 between middle and lower. Opercle black. Madras.
 - Two lateral-lines on the coloured side: a patent nostril between the eyes, a tubular one before lower orbit.
- 2. Cynoglossus lingua, D. 142-150, A. 105-110, L. l. 100-115, L. tr.* 13. Scales feebly ctenoid, and on the coloured side only: one lateral-line on the blind side. Seas and estuaries of India to the Malay Archipelago and beyond.

 3. Cynoglossus elongatus, D. 137-140, A. 107-110, L. l. 95-110, L. tr. 8. Scales cycloid on both sides.

 One lateral-line on the blind side. Madras, Pinang.

 One lateral-line on the blind side. Madras, Pinang.

 One lateral-line on the blind side. Madras, Pinang.

- 4. Cynoglossus oligolepis, D. 118-129, A. 91-95, L. l. 65-75, L. tr. 8-9. Scales ctenoid on the coloured side only. One lateral-line on the blind side. Seas of India to the Malay Archipelago.
 5. Cynoglossus macrolepidotus, D. 116-118, A. 86-90, L. l. 50-55, L. tr. 6-7. Scales ctenoid on the

- coloured side only. One lateral-line on the blind side. Seas of India to the Malay Archipelago.
 6. Cynoglossus Sindensis, D. 106-116, A. 83, L.1. 108, L. tr. 19-20. Angle of mouth in middle of length of head. Scales etenoid on coloured side only. Two lateral-lines on the blind side. Sind, through seas of India.
- 7. Cynoglossus arel, D. 104-114, A. 85, L. 1. 95, L. tr. 7. Scales etenoid on coloured side only: a single lateral-line on the blind side.
- 8. Cynoglossus dispur, D. 109-112, A. 90-94, L. 1. 110-115, L. tr. 18-19. Angle of mouth in front half of head. Scales ctenoid on coloured side only. Two lateral-lines on the blind side. Seas of India.

 9. Cynoglossus dubius, D. 110, A. 88, L. 1. 21. Scales cycloid on both sides. Two lateral-lines on the
- blind side. Beloochistan and Sind.
- 10. Cynoglossus quadrilineatus, D. 107, A. 80-88, L. l. 14-15. Scales etenoid on the coloured side only. Two lateral-lines on the blind side. Seas of India to the Malay Archipelago.

 11. Cynoglossus brachyrhynchus, D. 106, A. 78, L. l. 90-94, L. tr. 17-18. Scales etenoid on both sides. A single lateral-line on the blind side. Estuaries of Bengal and Burnelline on the Malay Archipelago.

- 12. Cynoglossus Bengalensis, D. 101-103, A. 78-80, L. l. 90-95, L. tr. 13-14. Height of body 3½ to 3½ in the total length. Snout 2/5 of length of head. Scales ctenoid on both sides. A single lateral-line on the blind side. Hooghly at Calcutta.

 13. Cynoglossus Hamiltonii, D. 101, A. 76, L. l. 105, L. tr. 15-16. Scales etenoid on both sides. A single
- lateral-line on the blind side. Hooghly.
- 14. Cynoglossus lida, D. 99-104, A. 75-83, L. 1. 90, L. tr. 13. Height of body 4 to $4\frac{2}{3}$ in the total length. Scales ctenoid on both sides. A single lateral-line on the blind side. Burma to the Malay Archipelago.
- 15. Cynoglossus semifasciatus, D. 98-103, A. 75-80, L. l. 85, L. tr. 12-13. Snout 2/7 of length of head. Scales ctenoid on both sides. A single lateral-line on the blind side. Madras.
- 16. Cynoglossus puncticeps, D. 94-100, A. 74-80, L. l. 95-100, L. tr. 16-17. Snout 1/3 of length of head. Scales ctenoid on both sides. A single lateral-line on the blind side. Seas of India to the Malay Archipelago. 17. Cynoglossus brevis, D. 95, A. 70-75, L. l. 96, L. tr. 17-18. Scales ctenoid on both sides. A single
- lateral-line on the blind side. Hooghly at Calcutta.
- 18. Cynoglossus brevirostris, D. 91, A. 76, L. 1. 78, L. tr. 10. Scales ctenoid on both sides. A single lateral-line on the blind side. Madras.
 - A. Three lateral-lines on the coloured side.
 - 1. Cynoglossus quinquelineatus, Plate XCVIII, fig. 1.

B. vi, D. 109, V. 4, A. 91, C. 13, L. 1. 100.

Length of head $5\frac{1}{3}$, height of body 4 in the total length. Eyes—diameter $9\frac{1}{2}$ in the length of head, about 4 from the end of snout, and 1 apart: the upper slightly in advance of the lower. Height of the head equals its length. The maxilla reaches to rather behind the hind edge of the lower orbit, and is situated rather nearer to the gill-opening than to the end of the snout. Two nostrils, a patent one between the orbits, and a

* By L. tr. is here understood the greatest number of rows of scales between the two lateral-lines on the left or coloured side.

tubular one in front of lower eye: one on the blind side not concealed. Fins—a single ventral adherent to the anal. Scales—ctenoid on coloured, cycloid on blind side. Lateral-lines—three on the coloured side, the upper and middle separated at their greatest distance by seventeen rows of scales, the middle and lower ones by fifteen. Two lateral-lines on the blind side. Colours-brownish, opercles black.

Habitat.—Madras. A single specimen 10 inches long.

Cynoglossus potous, Blecker, Atl. Ich. Pleur. p. 33, t. 241, fig. 4.

Kot-aralu, Tam.

B. vi, D. 142-150, V. 4, A. 105-110, C. 8, L. l. 100-115.

Length of head $4\frac{3}{4}$ to 5 or even $5\frac{1}{2}$, of caudal 16, height of body 6 to $6\frac{1}{3}$ in the total length. Eyesdiameter 12 to 14 in the length of the head, they are situated in about the middle of the length of the head, the upper slightly in advance of the lower, and about 1 diameter apart. The greatest height of the head equals 2/3 of its length. The cleft of the mouth extends to a short distance behind the posterior edge of the eyes: rostral hook reaches to below the front edge or even posterior margin of the eyes: lips not fringed. Two nostrils, a patent one between the eyes and a tubular one over the upper lip. Scales—very feebly ctenoid on the coloured side and only in their centre: cycloid on the uncoloured side. Lateral-lines—two on the left or coloured side, divided at their greatest distance by thirteen rows of scales: on the uncoloured side the lateral-line is very indistinct. Colours—reddish-brown on the coloured side, sometimes with some cloudy markings, generally lineated: opercles nearly black.

This is the largest of the marine and estuary species in India, and the most esteemed for the table. Bleeker gives a few less rays, D. 132-133, A. 102-103, L. l. 90-95. In his paper Beng. en Hind. he, correctly

as I think, identified Ham. Buch. and Russell's fish.

Habitat.—Seas and estuaries of India: attaining at least 18 inches in length. The specimen figured was from Calcutta.

3. Cynoglossus elongatus, Plate XC, fig. 5.

Cynoglossus lingua, Cantor, Catal. p. 233, (not Ham. Buch.)

Cynoglossus elongatus, Günther, Catal. iv, p. 501; Bleeker, Atl. Ich. Pleuron. p. 34.

B. vi, D. 137-140, V. 4, A. 107-110, C. 10, L. 1. 95-110.

Length of head $4\frac{3}{4}$, height of body $6\frac{1}{2}$ in the total length. Eyes—small, the upper in advance of the lower, diameter 11 in the length of head, 4 diameters from end of snout, and placed close together. Height of head 2/3 of its length. Angle of the mouth behind the hind edge of the eye, and nearer the gill-opening than the snout. Lips not fringed. Length of snout $2\frac{1}{3}$ in that of the head. Rostral hook reaches to below the mandibular symphysis. Two nostrils, a patent one between the eyes and a tubular one before the lower orbit. Fins—a single ventral attached to the anal. Günther observes "both ventrals are present?" Scales—cycloid on both sides. Lateral-lines—two on the about the limit of the lateral lines to be sided divided at their greatest distance by eight rows of cyclosus one at the limit of the limit of the lateral lines. rows of scales: one on the blind side. Colours-reddish brown, opercle with a dark band: vertical fins with a

Habitat.—Madras and Pinang. The specimen (figured life-size) was from Madras.

4. Cynoglossus oligolepis, Plate XCV, fig. 4.

Plagusia oligolepis, Bleeker, Java, p. 445.

Arelia oligolepis, Bleeker, En. Spec. p. 185. Cynoglossus oligolepis, Günther, Catal. iv, p. 496; Bleeker, Atl. Ich. Pleur. p. 34, t. 242, f. 5.

B. vi, D. 118-129, V. 4, A. 91-95, C. 12, L. 1. 65-75.

Length of head $4\frac{3}{4}$, height of body $5\frac{1}{4}$ in the total length. Eyes—small, situated just before the middle or in the commencement of the anterior half of the head, the upper being half in advance of the lower, 3,4 of a diameter between the two. Height of head equals 4/5 of its length. A patent nostril between the eyes and a tubular one before the lower eye above the lip. Angle of mouth 1/4 of a diameter of the orbit behind the lower eye. Rostral hook reaches to below the front edge of the lower eye. Lips not fringed. Snout 2/5 of the length of the head. Fins—vertical fins comparatively low: only the left ventral present, and not connected to the commencement of the anal. Scales—ctenoid on the coloured, cycloid on the blind side. Lateral-lines—

Digitized by GOO

two on the left side, separated at their greatest distance by 8 or 9 rows of scales, one on the blind side: 60 rows of scales along the blind side of the body. *Colours*—of a rich brown on the coloured side without any markings. *Habitat.*—Seas of India to the Malay Archipelago.

5. Cynoglossus macrolepidotus, Plate XCVI, fig. 3.

Arelia macrolepidota, Bleeker, En. Spec. p. 184.

Cynoglossus macrolepidotus, Günther, Catal. iv, p. 496; Kner, Novara Fische, p. 294; Bleeker, Atl. Ich. Pleuron. p. 34, t. xi, f. 2.

B. vi, D. 116-118, V. 4, A. 86-90, C. 11, L. 1. 50-55.

Length of head $4\frac{1}{3}$ to $4\frac{2}{3}$, height of body $4\frac{1}{4}$ to $4\frac{3}{4}$ in the total length. Eyes—small, diameter 14 to 15 in the length of head, 4 to $4\frac{1}{4}$ diameters from end of snout and 1 diameter apart. The length of the head a little exceeds it greatest height. Rostral hook short. Lips not fringed. Angle of the mouth in the middle of the length of the head. Two nostrils on coloured side, a patent one between the eyes anteriorly, and a tubular one before the lower orbit. Fins—rays unbranched. Scales—ctenoid on coloured, cycloid on blind side. Lateral-lines—two on right side separated by 6 or 7 rows of scales at their greatest distance asunder, one lateral-line on the blind side. Colours—Brownish, with an ill-defined bluish band along the bases of the dorsal and anal fins: a bluish blotch on opercles.

Habitat.—Seas and coasts of India to the Malay Archipelago. The specimen figured (8.2 inches long) was from Madras.

6. Cynoglossus Sindensis, Plate XC, fig. 6.

B. vi, D. 106-116, V. 4, A. 83, C. 12, L. l. 108.

Length of head 5, height of body $3\frac{3}{4}$ to 4 in the total length. Eyes—upper very slightly or not at all in advance of the lower, diameter $8\frac{1}{2}$ to $9\frac{1}{2}$ in the length of the head, 1 diameter apart, and 4 from the end of snout. Height of head rather exceeds its length. Rostral hook covers the symphysis of the lower jaw, but does not extend to below the front eye. Angle of mouth below the hind edge of the lower eye, and midway between the anterior edge of snout and gill-opening. Two nostrils, a small open one betwen the eyes, and a tubular one before the lower eye. Scales—strongly etenoid on coloured, cycloid on blind side. Lateral-lines—two on either side, those on the coloured side separated by 19 or 20 rows of scales. Colours—dark leaden-brown on the coloured side with a large black blotch on the opercles.

This fish is near C. Borneensis, the latter, however, has only one lateral-line on the blind side. It differs

from C. dispar in the situation of the angle of the mouth, &c.

C. trulla, Cantor, is said to have only a single nostril below the lower eye, and no remark is made respecting the number of lateral-lines on the blind side, but there is "a bony protuberance or spine" below the lower orbit.

Habitat.—From Sind through the seas of India: the largest specimen 18 inches long.

7. Cynoglossus arel, Plate XCVIII, fig. 2.

Pleuronectes arel, Bl. Schn. p. 159.

B. vi, D. 104-114, V. 4, A. 85, C. 12, L. 1. 95.

Length of head 4%, height of body 5 in the total length. Eyes—small, upper half in advance of the lower, 1 diameter apart: both eyes in the anterior half of the head. Height of head 1/4 less than its length. Rostral hook just covers the symphysis of the lower jaw. Angle of mouth upwards of one diameter behind the hind edge of the lower eye, and situated a little behind the middle of the length of the head. Two nostrils, a rather large open one between the eyes, and a tubular one above upper lip. Scales—slightly etenoid on the coloured, cycloid on the blind side. Lateral-lines—two on the coloured side separated by 7 rows of scales, a single lateral-line on the blind side. Colours—brownish on the coloured side without markings.

This cannot be (as suggested by Dr. Günther) Cynoglossus or Arelia kaupii, Blecker, as the latter has

two lateral-lines on either side.

I am indebted to Professor Peters of Berlin for the use of one of Schneider's types, from which the above description and figure are taken.

Habitat.—Tranquebar.

8. Cynoglossus dispar, Plate XCVI, fig. 2.

B. vi, D. 109-112, V. 4, A. 90-94, C. 9, L. 1. 110-115.

Length of head $5\frac{1}{2}$ to $5\frac{3}{4}$, height of body $3\frac{1}{2}$ to $3\frac{3}{4}$ in the total length. Eyes—diameter 9 to 11 in the length of head, 1/2 a diameter apart, and 3 from the end of snout: half of the upper eye being in advance of the lower one. Height of head 1/6 more than its length. Two nostrils, one patent between the eyes, the other tubular before the lower orbit. Lips not fringed, the rostral hook is extended a little distance beyond the mandibular symphysis. Angle of the mouth below the hind edge of the lower orbit, and much nearer the end of snout than the gill opening. Fins—ventral adherent to the anal. Scales—strongly etenoid on the coloured,

cycloid on the blind side: eighteen or nineteen rows between the lateral-lines of the coloured side. Laterallines—two on either side, the upper on the blind side ceasing in about the last fourth of the body. Colours brown, blotched all over with darker marks: fins yellowish, with numerous black spots.

This species differs from C. brachyrhynchus and C. Borneensis, each of which have only one lateral-line

on the blind side.

Habitat.—Bombay, to 141 inches in length, also Madras.

9. Cynoglossus dubius, Plate XCV, fig. 2.

Day, Journ. Linn. Society, 1873, xi, p. 525.

B. vi, D. 110, V. 4, A. 88, C. 12, L. 1. 104.

Length of head 4, height of body 31 in the total length. Eyes—diameter 20 in the length of head, $8\frac{1}{2}$ diameters from end of snout, and 2 apart: the upper very slightly in advance of the lower. Head 1/6 longer than high. Rostral hook just covers the symphysis. The maxilla extends to 1 diameter of the eye behind the lower orbit: angle of the mouth just behind the middle of the length of the head. Fins—highest dorsal and analrays 1/6 of the height of the body. No right ventral, the left attached to the anal. Scales cycloid on both sides. Lateral-lines - two on the coloured side separated at their greatest distance by twenty-one rows of scales: two lateral-lines on the blind side. Colours—brownish, with indistinct blotches on the body.

Habitat.—Sind and Beloochistan: the specimen figured, 20 inches long, was captured at Gwadur.

10. Cynoglossus quadrilineatus.

Achirus bilineatus, Lacép. iv, pp. 659, 663.

Plagusia bilineatas, Rüpp. Atl. Fische, p. 123.
Plagusia puddrilineata, Bleek. Pleuron. p. 21, or Natuurk Tydschr. Nederl. Ind. i, p. 412.
Arelia quadrilineata, Kaup, in Wiegm. Arch. 1858, p. 107.
Cynoglossus quadrilineatus, Günther, Catal. iv, p. 427; Kner, Novara Fische, p. 295; Klunz. Verh. z. b. Ges. Wien, 1871, p. 573.

B. vi, D. 107, V. 4, A. 80-88, C. 12, L. 1. 86.

Length of head 5 to 51, height of body 4 in the total length. Eyes—the upper slightly in advance of the lower, 9 or 10 diameters in the length of head, and 3 to $3\frac{1}{2}$ from the end of snout. The height of the head rather exceeds its length. Rostral hook just covers the symphysis of the lower jaw. The angle of the mouth is in about the middle of the length of the head. Two nostrils, an open one between the orbits, and a tubular one before the lower eye. Fins—a single ventral attached to the anal. Scales—etenoid on the coloured, cycloid on the blind side. Lateral-lines—two on the left side separated by fourteen or fifteen rows of scales: two also on the blind side. Colours—brownish on the left side, a darkish blotch covering the opercles.

Habitat.—Sind, seas of India to the Malay Archipelago.

11. Cynoglossus brachyrhynchus, Plate XCVI, fig. 4.

Plagusia brachyrhynchus, Bleeker, Pleur. p. 24, and Nat. Tyds. Ned. Ind. i, p. 414.

Arelia brachyrhynchus, Bleeker, Enum. Spec. p. 184.

Cynoglossus brachyrhynchus, Günther, Catal. iv, p. 499; Bleeker, Atl. Ich. Pleur. p. 37, t. 243, fig. 4.

B. vi, D. 106, V. 4, A. 78, C. 12, L. 1. 90-94.

Length of head $4\frac{3}{4}$, height of body $3\frac{3}{4}$ to 4 in the total length. Eyes—in the anterior half of the head, the upper slightly in advance of the lower, diameter 13 in the length of head, $4\frac{1}{3}$ diameters from the end of snout, about 1 apart. Head as high as long. Length of the snout equals 1/3 of length of head. Angle of the mouth slightly behind the posterior margin of the lower eye, and rather nearer the snout than the gill-opening. Rostral hook extends to in front of symphysis of the lower jaw. Two nostrils, a patent one between the eyes and a tubular one in front of the lower eye. Fins—no right ventral. Dorsal and anal fin-rays about 1/4 of the height of the body. Scales—ctenoid on both sides. Lateral-lines—two on the coloured side, separated by 17 or 18 rows of scales: a single one on the blind side. Colours—brown, irregularly marbled with darker, the opening side sometimes with a dark blotch.

Habitat.—Calcutta and Moulmein in brackish waters but within tidal reach, to the Malay Archipelago.

The specimen figured (life-size) was from Moulmein.

12. Cynoglossus Bengalensis, Plate XCVII, fig. 4.

Plagusia Bengalensis, Bleeker, Beng. en Hind. p. 152, t. vi, f. 3.

Cynoglossus Bengalensis, Günther, Catal. iv, p. 499.

B. vi, D. 101-103, V. 4, A. 78-80, C. 12, L. 1. 90-95.

Length of head 5, height of body $3\frac{1}{2}$ to $3\frac{3}{4}$ in the total length. Eyes—the upper very slightly in advance of the lower, diameter 10 or 11 in the length of the head, 3 to $3\frac{1}{2}$ diameters from end of snout and 1/2 a diameter apart. Head as high as long. Snout about 2/5 of length of head. Angle of the meuth below the middle or end of the lower orbit. Two nostrils, one patent between the eyes, the other tubular before the lower orbit. Rostral hook just covers symphysis. Fins—highest dorsal rays 4 in the height of the body. A single

Digitized by GOO

ventral attached to the anal. Lateral-lines—two on the coloured side, separated at their greatest distance by 13 or 14 rows of scales: a single lateral-line on the blind side. Scales—ctenoid on both sides. Colours stone colour, marbled with darker.

Habitat.—Hooghly at Calcutta.

In the Sittoung river in Burma is a very similar fish, D. 105, V. 4, A. 68, C. 15, L. 1. 100. Length of head and height of body, each 5 in the total length. Eyes—small, contiguous, snout $2\frac{1}{4}$ in the length of head, angle of mouth nearer snout than gill-opening. Height of head equals its length. Rostral hook reaches to below the middle of the front eye. Fins—ventral not attached to anal. Lateral-lines—2 on coloured side divided by 14 rows of scales, 1 on blind side. Scales-etenoid on both sides. Colours-brown, vertical fins spotted with black and black edged.

13. Cynoglossus Hamiltonii, Plate XCV, fig. 3.

Achirus cynoglossus, Ham. Buch. Fish. Ganges, pp. 132, 373. ? Plagusia cynoglossa, Cantor, Catal. p. 229; Blecker, Beng. en Hind. p. 76. ? Icania cynoglossa, Kaup, Wiegm. Arch. 1858, p. 109.

? Cynoglossus Hamiltonii, Günther, l. c. Catal. iv. p. 504. Cynoglossus Buchanani, Day, Proc. Zool. Soc. 1809, p. 522.

B. vi, D. 101, V. 4, A. 76, C. 10, L. 1. 105.

Length of head $4\frac{1}{4}$, height of body $4\frac{1}{4}$ in the total length. Eyes—close together and small, 15 diameters in the length of head, the upper slightly in advance of the lower. Head slightly longer than high, shout 31 in length of head. Rostral hook does not cover the symphysis. The angle of the mouth is 1 diameter behind the lower eye, and much nearer the snout than the gill-opening. Two nostrils, one between the eyes, and a second tubular one before the lower eye. Fins—longest dorsal rays 1/3 of height of body. Scales—ctenoid on both sides. Lateral-lines—two on the coloured side divided by 15 or 16 rows of scales: a single lateral-line on the blind side. Colours—brown, with some vertical irregular bands of a darker colour and also blotches, fins dark with light edges, each scale with a dark line along its centre.

This species is closely allied to C. brachyrhynchus, which however has rather a shorter head, higher body, whilst the proportions of the head differ, and there are 17 or 18 rows of scales between the lateral-lines on the

coloured side.

Ham. Buchanan's fish of which he has left a figure, "Acheirus kukur jibha" appears to be this species. It is said to have no appreciable nostrils, but Buchanan observes, "I have not been able to observe any nostril, unless it be concealed in a small membrane proceeding from the upper jaw, and below the under eye" (? the tubular nostril): Cantor and Günther likewise observe, no conspicuous nostril, but the specimens of the former author which are now in the British Museum, are dried skins, painted and smothered with varnish. As far as I can judge it is this species which is not uncommon at Calcutta.

Habitat - Hooghly at Calcutta, seas and estuaries of India. It attains about 6 inches in length. The

specimen figured was from Calcutta.

14. Cynoglossus lida, Plate XCVII, fig. 3.

Plagusia lida, Bleeker, p. 413, and Pleur. p. 23.

Arelia lida, Bleeker, En. pisc. p. 184.

Cynoglossus lida, Günther, Catal. iv, p. 498; Bleeker, Atl. Ich. Pleuronec. p. 36, t. 243, f. 2.

B. vi, D. 99-104, V. 4, A. 75-83, C. 12, L. 1. 90.

Length of head 5, height of body 4 to $4\frac{2}{3}$ in the total length. Eyes—diameter about 13 in length of head, 41 diameters from end of snout and nearly 1 apart, the upper eye one half in advance of the lower. Head 1/6 longer than high. Angle of mouth below the hind edge of the lower orbit and midway between snout and gill-opening. Rostral hook just covers symphysis of lower jaw. Two nostrils, a patent one between the eyes and a tubular one before the lower eye. Fins—highest dorsal ray equals one-third of the height of the body. Ventral not united to anal. Scales—ctenoid on both sides. Lateral-lines—two on the coloured side separated at their greatest distance by 13 rows of scales. A single lateral-line on the blind side. Colours—brownish, a dark mark on opercle.

Habitat.—Burma to the Malay Archipelago.

15. Cynoglossus semifasciatus, Plate XCVII, fig. 5.

B. vi, D. 98-103, V. 4, A. 75-80, L. 1. 85.

Length of head $4\frac{2}{3}$, height of body $3\frac{2}{3}$ in the total length. Eyes—close together, the upper scarcely in advance of the lower, 8 diameters in the length of head, and $2\frac{1}{2}$ from end of snout. Head 1/4 longer than high: snout $3\frac{1}{2}$ times in the length of the head. The rostral hook covers the symphysis of the lower jaw, and extends to below the front edge of the upper eye. Angle of the mouth 1 diameter behind the posterior edge of the lower eye and slightly nearer the snout than the gill-opening. Two nostrils, one between the eyes, a tubular one in front of the lower orbit. Fins—highest dorsal rays about 1/5 of the height of the body: a single rentral attached to the eyel. single ventral attached to the anal. Scales—ctenoid on both sides. Lateral-lines—two on the coloured side,

separated at their greatest distance by 12 or 13 rows of scales: a single lateral-line on the blind side. Coloursdeep brown, with vertical incomplete or half bands irregularly disposed. They are extended on to the dorsal and anal fins.

Habitat.—Sea at Madras.

16. Cynoglossus puncticeps, Plate XCVII, fig. 1.

Plagusia puncticeps, Richards. Ich. China, p. 280.
Plagusia Javanica, (K. and v. H.) Bleeker, Pleuron. p. 24, and Nat. Tyds. Ned. Ind. i, p. 414.

Arclia Javanica, Kaup, Uebers, Plagus. Arch. Nat. xxiv, i, p. 108; Bleeker, en Spec. p. 104. Cynoglossus puncticeps, Günther, Catal. iv, p. 500; Kner, Novara Fische, p. 297; Bleeker, Atl. Ich. Pleur. p. 37, t. 246, f. 7.

B. vi, D. 94-100, V. 4, A. 74-80, C. 12, L. 1. 95-100.

Length of head $5\frac{1}{4}$ to $5\frac{2}{3}$, height of body $3\frac{1}{2}$ to 4 in the total length. Eyes—diameter $8\frac{1}{3}$ in the length of head, nearly 3 diameters from the end of snout, and close together: the upper one-half in advance of the lower. Head rather higher than long. The length of the snout equals about 1/3 of that of the head. The angle of the mouth situated below the middle or last third of the eye: the rostral hook covers the mandibular symphysis. Two nostrils, a patent one between the orbits and a tubular one opposite the anterior-inferior angle of the lower eye. Fins—right ventral absent. Dorsal and anal fin-rays low, the highest equalling 1/4 of the height of the body. Scales—ctenoid on both sides. Lateral-lines—two on the coloured side, separated by sixteen or seventeen rows of scales: a single one on the blind side. Colours—on the left side reddish-brown with irregular vertical bands which are continued on to the dorsal and anal fins.

Habitat.—From Sind through the seas of India to the Malay Archipelago and China. The one figured was from Madras.

17. Cynoglossus brevis, Plate XCVII, fig. 2.

Günther, Catal. iv, p. 500.

B. vi, D. 95, V. 4, A. 70-75, C. 12, L. l. 96.

Length of head $5\frac{1}{2}$ to $5\frac{2}{3}$, height of body $3\frac{1}{4}$ to $3\frac{1}{3}$ in the total length. Eyes—situated close together, the upper slightly in advance of the lower, diameter 9 to 10 in length of head, 3 diameters from the end of snout. Head 1/4 higher than long: snout 3 to $3\frac{1}{4}$ in the length of head, the angle of the mouth beneath the middle of the lower eye. Two nostrils, one between the eyes, the other tubular before the lower eye. Rostral hook covers symphysis. Fins—highest dorsal rays 5 in the height of the body, a single ventral attached to the anal. Lateral-lines—two on the coloured side, separated at their greatest distance by seventeen an sighteen rays of scalars a single lateral line on the blind side. States, attention both sides. Colours, of sevents at the sides of the sides. or eighteen rows of scales: a single lateral-line on the blind side. Scales—ctenoid on both sides. Colours—of a rich purplish-brown, with vertical bands extending on to the fins.

Habitat.—Hooghly at Calcutta.

18. Cynoglossus brevirostris, Plate XCVII, fig. 6.

B. vi, D. 91, V. 4, A. 76, C. 13, L. l. 78.

Length of head 5, height of body $4\frac{1}{4}$ in the total length. Eyes—minute, situated rather close together, the upper half in advance of the lower. Head as long as high. Angle of mouth 1 diameter behind the lower eye, and situated nearer the end of the snout than the gill-opening. Rostral hook extends to below the front edge of the upper eye. Snout 3½ in the length of the head. Two nostrils, a patent one between the nostrils and a tubular one before the lower eye. Fins—highest dorsal ray equals 1/4 of the height of the body. Ventral united to the anal. Scales—etenoid on both sides. Lateral-lines—two on the coloured side separated at their greatest distance by ten rows of scales: a single lateral-line on the blind side. Colours-brownish.

Habitat.—Madras, from whence a single specimen (figured life-size) was procured.

Order III—PHYSOSTOMI, Müller.

All the fin rays articulated, with the exception of the first in the dorsal and pectoral, which are frequently more or less ossified. Ventral fins, when present, abdominal and spineless. Air-vessel, if existing, having a pneumatic duct (except in the family Scombresocide).

SYNOPSIS OF FAMILIES AMONGST THE PHYSOSTOMI.

1. Silurida. Sub-opercle absent. Margin of upper jaw formed by the premaxillaries. Skin scaleless

and smooth, or covered with osseous plates or scattered tubercles. Adipose dorsal usually present.

2. Scopelidæ. Pseudobranchiæ well developed. Margin of upper jaw formed by premaxillaries.

Opercular pieces sometimes incomplete. No barbels. Gill-openings very wide. Scales present or absent. Adipose dorsal present.

3. Scombresocide. Pseudobranchiæ glandular. Margin of upper jaw formed by premaxillaries and maxillaries. Lower pharyngeals united. No adipose dorsal. Scales present. Air-vessel, when present, destitute of pneumatic duct.

4. Cyprinodontide. Pseudobranchie absent. Margin of upper jaw formed by premaxillaries. Barbels absent. Teeth in both jaws, in superior and inferior pharyngeals. One spineless dorsal in posterior half of body. Air-vessel simple.

5. Cyprinide. Pseudobranchie, when present, glandular. Margin of the upper jaw formed by the premaxillaries. Opercular pieces complete. Mouth toothless, teeth in lower pharyngeals. Head scaleless,

body scaled or scaleless, never covered by osseous plates. Air-vessel present or absent.

6. Clupeide. Pseudobranchiæ usually well developed. Margin of the upper jaw formed by premaxillaries and maxillaries. Opercular pieces complete. Abdomen usually keeled. No adipose dorsal. Scales on body, none on head. Pyloric appendages numerous.

7. Notopteride. Pseudobranchiæ absent. Margin of upper jaw formed by premaxillaries and maxillaries. Opercular apparatus incomplete: a parieto-mastoid cavity on either side, leading into the interior of the skull. A civele myed dorsal for a long and blood body scaled. Two pyloric appendages

interior of the skull. A single rayed dorsal fin, a long anal. Head and body scaled. Two pyloric appendages.

FAMILY, I—SILURIDÆ.

Margin of the upper jaw formed mainly by the premaxillaries: the maxilla rudimentary, often constituting the base of a barbel: no sub-opercle. Either the rayed or adipose dorsal fins may be present or absent. Skin scaleless, and either smooth or covered with osseous plates, or scattered tubercles. Air-vessel, when present, either free in the abdominal cavity or more or less enclosed in bone, it communicates with the organs of hearing by means of the auditory bones.

The Siluroid, or scalcless fishes, are popularly termed cat-fishes, due to their being provided with a number of feelers or long barbels arranged around the mouth. They mostly prefer muddy to clear water, and the more developed the barbels, the more these fishes appear to be adapted for an inland and muddy fresh-water residence.

The wider and deeper the rivers the more suited they are for the Siluridæ, consequently the larger forms are comparatively rare in the south of India, whilst they abound in the Indus, Jumna, Ganges, Irrawaddi and other Burmese rivers.

Due to their usual resort, these fishes appear to employ their feelers in moving about in muddy places, and consequently have less use for their eyes than forms that reside in clear pieces of water. Thus it is, that the size of the eye as compared with the length of the head is much greater in the young than in the adult. The eye in fact atrophies, it does not increase in size in proportion with the remainder of the head, consequently the length of the specimen must be taken into consideration. Some of these fishes have the skin of the head passing over the eye without any trace of a free orbital margin, but this again may at times be due to age, thus in the young of Macrones chryseus we find no free orbital margin, but one is distinctly present in the adult.

In the genus Arius and some allied forms the males appear to carry the ova in their mouths perhaps until

the young are produced.*

Many of these fishes are credited with causing poisonous wounds, and we frequently find such cases admitted into hospitals. They may be divided into two classes, (1) those in which the wounds are of a distinctly venomous description, (2) those in which their jagged spines occasion intense inflammation often of a dangerous character.

The respiration of these fishes is effected in two ways, and it may be appropriate here to refer to the

amphibious fishes of India, as the Labyrinthici and Ophiocephalidæ.

Respiration in fishes is carried out normally (1) by their using the air which is in solution in the water to oxygenate the blood at their gills, (2) by taking in atmospheric air direct which is employed at a special organ, where it oxygenates the blood, which can be returned for use into the general circulation without its going through the gills, thus constituting true amphibious fishes.

No doubt we observe that fishes which normally oxygenate their blood solely at their gills do rise to the surface in very hot weather, when the water is foul or insufficiently charged with air and take in

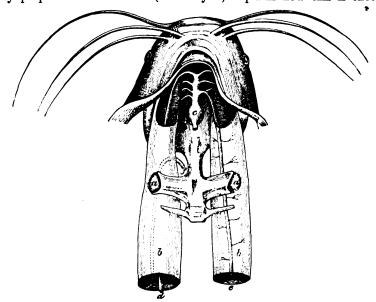

air by the mouth.

Likewise we find that those which mainly take in atmospheric air direct by the mouth may, to a certain

extent, be able to use their gills.

If fishes having these two different modes of respiration are placed in a globe of water, across which a diaphragm of net is inserted below the surface so as to prevent their obtaining access to the atmosphere, those of the first class which oxygenate their blood at the gills are unaffected, whereas those which take in air direct, or amphibious fishes, die, due to blood poisoning.

If we seek for the reason, we find that the amphibious fishes have accessory breathing organs, those of the Ophiocephalidæ and Labyrinthici have been referred to (pp. 362, 369). Amongst the Siluridæ we also find amphibious forms: thus the Clarias has a dendritic apparatus attached to the branchize (Plate CXII, fig. 5a), and the Saccobranchus has a long airt or respiratory sac passing backwards amongst the muscles of the back from behind the gill cavity proper. The woodcut (after Hyrtl) explains how this is effected. The transverse

processes of the first vertebra are dilated to enclose the air-vessel (a) in a bony capsule, from each of these air-vessels there passes a duct which goes to the pharynx, this air-vessel has nothing to do with amphibious respiration, it is the swim-bladder partially enclosed in bone.

The respiratory air-sac (b) passes down amongst the muscles of the back from behind the gills. The blood from the heart goes up the bulbus arteriosus (c) and divides into branches on either side, one of which goes to each respiratory air sac, the anterior on the right, the posterior on the left side. The one on the right (d) goes along the upper wall of the sac, whilst on the left (e) one traverses the lower wall, giving off numerous lateral branches. From this respiratory air-sac the purified blood is returned by a vessel (f) which conveys it direct to the sector. vessel (f) which conveys it direct to the aorta.§

* See remarks under the head of genus Arius.

† See paper on this subject, Proc. Zool. Soc. 1858, p. 274.

† This is not the air-vessel or swim-bladder seen in the majority of Teleosteous fishes, as that also exists more or less enclosed

§ See paper in Journal Linn. Soc. read January 18th, 1877.

It is thus evident that blood can be purified at these respiratory air-sacs, and these fishes can be kept alive hours, and even days, without being in water, thus enabling them to traverse considerable distances where aquatic respiration would be impossible. They are also able when in water, to depurate some of the blood

at the gills, if occasion should necessitate them to do so.

The air-vessel or swim-bladder (not respiratory air-sac) exists in two forms amongst the Siluridæ. In marine ones it is thick and not enclosed in bone, likewise in most of the fresh-water forms it is not enclosed in bone, but as we approach the hills a change occurs, and in most of the genera it possesses an osseous covering. The same character having been considered as valid for sub-dividing the Cyprinide, I have deemed it not inappropriate for similar employment in the Siluridæ.

Geographical distribution.—Fishes of this family are very abundant in the fresh waters of India, likewise in the estuaries and sea; they are not so common however in the clear waters around the Andamans.

Uses .- As a rule (excluding the Pseudeutropius, Callichrous, and Ailia) these Siluroids are more eaten by the poorer than the richer classes, and for two reasons, first, they are forbidden to Jews and Mahomedans,* and secondly, they are very foul feeders. The Saccobranchus and Clarias however are deemed nourishing and often prescribed for patients recovering from illnesses. The air-vessels of the marine forms are collected for export to China, as they afford a coarse isinglass.

SYNOPSIS OF GENERA.

A. Air-vessel not enclosed in bone.

a. An adipose dorsal.

1. Macrones. Gill-openings very wide, the membranes not being confluent with the skin of the isthmus, but overlapping one another, being cleft nearly to the chin. Eves with free orbital margins. Teeth present on the palate. Barbels eight. Dorsal and pectoral spines. Ventral with six, anal with from about eight or nine to twenty or more rays. Throughout most parts of Asia, almost invariably in fresh water.

2. Leiocassis. Gill-openings very wide, the membranes not being confluent with the skin of the isthmus, but overlapping one another, being eleft nearly to the chin. Eyes subcutaneous. Teeth present on the palate. Barbels eight. Dorsal and pectoral spines. Ventral with six, anal with from about 15 to 20 rays. Eastern

Bengal to the Malay Archipelago.

3. Erethistes. Gill-openings narrow, the membranes being confluent with the skin of the isthmus. Mouth narrow. Occipital, scapular, and humeral processes well developed. Eyes subcutaneous. No palatine teeth. Barbels eight. Dorsal and pectoral spines present. Ventral with six, and with about ten rays. Orissa, through Bengal to Burma.

4. Rita. Gill-openings wide, the membranes not being confluent with the skin of the isthmus, and scarcely or not notched. Eyes subcutaneous. Teeth present on the palate. Barbels six or eight. Strong dorsal and pectoral spines. Ventral with seven or eight rays, anal with twelve to thirteen. Throughout Sind and India (except Mysore and Madras) to Burma.

5. Arius. Gill-openings wide, the membranes not being confluent with the skin of the isthmus, and scarcely or not notched. Eyes with free orbital margins. Teeth present or absent on the palate. Barbels six. Dorsal and pectoral spines. Ventral with six, anal with from about fourteen to at least twenty-four rays.

6. Butracocephalus. Gill-openings wide, the membranes not confluent with the skin of the isthmus, but not notched. Eyes with free orbital margins. Teeth present on the palate. Barbels two. Dorsal and pectoral spines. Ventral with six, anal with about twenty rays. Seas and estuaries of India and Burma, to the Malay Archipelago.

7. Ketengus. Gill-openings wide, the membranes not confluent with the skin of the isthmus, but not notched. Eyes with free orbital margins. No teeth on the palate. Barbels six. Dorsal and pectoral spines.

Ventral with six, anal with about twenty rays. Andamans to the Malay Archipelago.

8. Osteogeniosus. Gill-openings very wide, the membranes not being confluent with the skin of the isthmus, but overlapping one another, being notched. Eyes with free orbital margins. Teeth on the palate. Barbels, one pair of semi-osscous maxillary ones. Dorsal and pectoral spines. Ventral with six, anal with from about nineteen to twenty-four rays. Seas and estuaries of India to the Malay Archipelago.

9. Pangasius. Gill-openings wide, the membranes not confluent with the skin of the isthmus, and rather deeply noticed. Eyes with free orbital margins. Teeth present on the palate. Barbels four. Dorsal and pectoral spines. Ventral with six, anal with from about twenty-nine to thirty-nine rays. Large rivers

and estuaries of India and Burma to the Malay Archipelago.

10. Pseudeutropius. Gill-openings wide, the membranes not confluent with the skin of the isthmus and rather deeply notched. Eyes with broad adipose lids. Teeth present on the palate. Barbels eight. Dorsal and pectoral spines. Ventral with six or eight rays: anal with from about twenty-seven to fifty-five rays. Fresh waters of Hindustan to the Malay Archipelago.

* Finding Mahomedans eating the scaleless forms in Sind I enquired the reason, observing that such were forbidden. They told me however that such was not the case, as Mahomed hullaaled fish (cut their throats to prevent the blood being eaten) and those with gill-openings are permitted to "the Faithful."

- 11. Olyra. Gill-openings wide, the membranes not being confluent with the skin of the isthmus. subcutaneous. Teeth on the palate. Barbels eight. Rayed dorsal fin with a short spine: no pectoral spine. Ventral with six, anal with from fifteen to about twenty-three rays. Caudal rounded or lanceolate. Assam to Pegu.
 - b. A single rayed and no adipose dorsal fin.
- 12. Callichrous. Gill-openings wide, the membranes not being confluent with the skin of the isthmus. Cleft of mouth does not extend to the eye. Eyes without free orbital margins. Teeth on the vomer. Barbels two or four. Rayed dorsal fin when present small. A pectoral spine. Ventral with ten or less rays: anal with from about forty-five to ninety-five rays. Fresh waters of India, Ceylon, Burma to the Malay Archipelago and China.

13. Wallago. Gill-openings wide, the membranes not being confluent with the skin of the isthmus. Cleft of mouth deep, extending to behind the eyes. Eyes without free orbital margins. Teeth on the vomer. Barbels four. Rayed dorsal fin short, spineless. A pectoral spine. Ventral with nine or ten rays: anal with sixty-five to ninety-five rays. Fresh waters of India and Burma to the Malay Archipelago.

14. Silurus. Gill-openings wide, the membranes not being confluent with the skin of the isthmus. Eyes with free orbital margins. Teeth on the palate. Barbels four or six. Rayed dorsal fin without spine: no

adipose fin. Pectoral with a spine. Ventral with eight or more rays: anal with from sixty to ninety rays. From eastern Europe, through Turkestan, and some of the higher Indian mountains, to the hill ranges of Burma, the Malay Archipelago, China, and Japan.

c. Two rayed but no adipose dorsal fin.

15. Chaca. Gill-openings narrow, the membrane being confluent with the skin of the isthmus. Mouth

very wide. Eyes rudimentary. No teeth on the palate. Barbels six. Dorsal and pectoral spine. Ventral with six rays: anal divided into two portions. Eastern Bengal, Burma to the Malay Archipelago.

16. Plotosus. Gill-openings wide, the membranes not being confluent with the skin of the isthmus. Eyes with a free orbital margin. Teeth on the palate. Barbels eight. Two rayed dorsal and anal fins: first dorsal and pectoral with a spine. Ventral with about tweethers are second dorsal and anal with numerous rays. and confluent with the caudal. Red Sea, east coast of Africa, seas of India to the Malay Archipelago and Australia.

B. Air-vessel more or less enclosed in bone.

a. No adipose dorsal fin.

17. Clarias. Gill-openings very wide, the membranes not being confluent with the skin of the isthmus and separated to the chin. Eyes with a free orbital margin. Teeth on the palate. Barbels eight. A single elongated rayed dorsal and anal fin: a pectoral spine. Ventral with six rays. A dendritic accessory branchial apparatus attached to some of the branchial arches. Africa and a great portion of Asia, including the Indian

region and the Malay Archipelago to China.

18. Saccobranchus. Gill-openings very wide, the membranes not being confluent with the skin of the isthmus and separated to the chin. Eyes with a free orbital margin. Teeth on the palate. Barbels eight. A short spineless dorsal fin: an elongated anal one (sixty to eighty rays). A strong pectoral spine. Ventral with six rays. An elongated respiratory air-sac, extending backwards amongst the muscles of the back on either side of the neural spines. Sind, India and Ceylon to Burma and Cochin China.

b. An adipose dorsal fin.

19. Silundia. Gill-openings very wide, the membranes not being confluent with the skin of the isthmus and separated to the chin. Eyes with a broad, circular adipose lid and free orbital margin. Teeth on the palate. Barbels two or four. A short dorsal fin having a spine: an elongated anal (forty or fifty rays). A pectoral spine. Ventral with six rays. India and Burma.

20. Ailia. Gill-openings wide, the membranes not being confluent with the skin of the isthmus. Eyes

with a free orbital margin. Teeth on the palate. Barbels eight. No raved dorsal fin. Pectoral with a spine: an elongated anal (sixty to seventy-five rays): a pectoral spine. Ventral with six rays. Sind, the valley of

the Ganges, and Assam.

21. Ailiichthys. Similar to Ailia but destitute of ventral fins. Indus and Punjab rivers, also Ganges and Jumna.

• 22. Eutropiichthys. Gill-openings very wide, the membranes not being confluent with the skin of the isthmus and separated to the chin. Eyes having a broad circular adipose lid. Teeth on the palate. Barbels eight. A short dorsal fin with a spine: a pectoral spine: an elongated anal fin (forty-seven to fifty rays).

Ventral with six rays. Large rivers of India and Burma.

23. Amblyceps. Gill-openings wide, the membranes not being confluent with the skin of the isthmus and notched to the chin. Eyes subcutaneous. No teeth on the palate. Barbels eight. Dorsal fin with one spine and six rays: a small pectoral spine. Anal rather short (eleven to twelve rays). Ventral with six rays.

Valley of Ganges, eastern Bengal to Burma.

24. Sisor. Gill-openings narrow, the membranes being confluent with that of the isthmus. Eyes small. Osseous plates along the back, the adipose fin in the form of a short spine. Teeth absent. Barbels, one maxillary and several mandibular pairs. A short dorsal fin with one spine and six rays: a pectoral

Digitized by GOO

spine. Anal short (six rays). Ventral with seven rays. Upper caudal ray very elongate. Jumna and

25. Gagata. Gill-openings rather narrow, the membranes being confluent with the skin of the isthmus. Eyes subcutaneous. No teeth on the palate. Barbels six or eight. Dorsal with one spine and six rays: a pectoral spine. Anal rather short. Ventral with six rays. Throughout India, (except its southern portion) Assam and Burma.

26. Bagarius. Gill-openings wide, the membranes confluent with the skin of the isthmus. Eyes with free orbital margins. No teeth on the palate. Barbels eight. Dorsal fin with one spine and six rays. A pectoral spine: anal rather short. Ventral with six rays. Throughout large rivers of India and Burma

27. Glyptosternum. Gill-openings wide, the membranes confluent with the skin of the isthmus. Eyes subcutaneous. No teeth on the palate. Barbels eight. Dorsal fin with one spine and six or seven rays. A pectoral spine. Anal short. Ventral with six rays. An adhesive apparatus formed of longitudinal plaits of skin situated on the chest between the bases of the pectoral fins. Hill streams and rapid rivers of the plains of India to the Malay Archipelago.

28. Euclytosternum. As in last Genus but having palatine teeth. Syria, Assam.
29. Pseudecheneis. Gill-openings narrow, not extended on to the lower surface of the head. Eyes small. No teeth on the palate. Barbels eight. Dorsal fin with one spine and six rays: a pectoral spine. Anal rather short (eleven rays). Ventral with six rays. An adhesive apparatus formed of transverse folds of skin situated on the chest between the bases of the pectoral fins. Himalayas at the head waters of the Ganges, also the Kasya hills.

30. Exostoma. Gill-openings narrow, not extending on to the lower surface of the head. Eyes subcutaneous. No teeth on the palate. Barbels six or eight. Dorsal fin with one spine and six rays. Pectoral sub-horizontal with a spine. Anal short. Ventral with six rays. Head waters of Indus along the Himalayas to Assam, Pegu, Tenasserim, and the confines of China.

Genus, 1—Macrones, Dumeril.

Bagrus, pt. Cuv. and Val.; Hypselobagrus, Hemibagrus, Pseudobagrus and Aspidobagrus, Bleeker.

Branchiostegals from six to twelve. Mouth terminal, transverse. Upper jaw generally the longer. Gillopenings wide, the gill-membranes overlapping the isthmus and being separate to the chin. Eyes with free circular lids. Barbels eight, one nasal, one maxillary, and two mandibular pairs. A distinct and separate interneural shield on the nape, closely connected to the basal bone of the dorsal fin: or no such shield. Villiform teeth in the jows, and in a more or less uninterrupted curved band across the palate. Rayed dorsal fin with one spine and seven rays: adipose dorsal of varying length: pectoral with a strong serrated spine: and short or of moderate length: ventral with six rays: caudal forked. Air-vessel of moderate or large size, attached to the under surface of the bodies of the anterior vertebrae. An axillary pore generally present.

These fishes have been divided as follows:

Pseudobagrus. Anal fin with 20 rays or upwards, as M. chryseus.

Hypselobagrus. Adipose dorsal much longer than the anal, as M. cavasius.

Macrones. Adipose dorsal not much longer or shorter than the anal: a separate interneural shield on the nape, as M. seenghala.

Hemibagrus. Adipose dorsal as in Macrones, no separate interneural shield as M. gulio.

As we find the number of rays in the anal fin vary in specimens taken in India from M. Bleckeri with A. 9-10, M. Malabaricus, A. 10-11, M. tengara, A. 11-13, M. gulio, A. 12-15, or in fact a smaller difference in the number of anal rays between the first mentioned with A. 9, and the last with A. 15, than exists between the last (M. gulio) and a species with 20 anal rays I have not employed this arbitrary division of the genus. Whether M. aor or M. seenghala which have a separate interneural shield and an air-vessel with a posterior elongated extremity, should not be separated from the remainder which have no such distinct shield and no prolongation of the air-vessel, may be open to question.

The ova of these fishes are small, consequently very different to what we perceive in their marine

relatives, the Arius and neighbouring Genera.

Geographical distribution.—These fishes extend through most parts of Asia, and are numerous in the fresh waters of India and Ceylon, one species (M. gulio) often being captured in the sea.

Uses.—Employed as food by the poorer natives, but are of inferior quality, being rather insipid.

SYNOPSIS OF SPECIES.

1. Macrones chryseus, A. 26-28. Golden, with a large black shoulder spot. Malabar coast of India.

2. Macrones aor, A. 12-13. Maxillary barbels reach caudal fin. A black spot on adipose dorsal fin. Throughout Sind and India to Burma.

3. Macrones seenghala, A. 11-12. Maxillary barbels reach hind edge of first dorsal fin. Punjab, Sind,

Jumna, Ganges, and Brahmaputra rivers, also Deccan and Kistna river to its termination.

4. Macrones Blythii, A. 12. Maxillary barbels reach front edge of eye. A dark shoulder spot, another on the adipose dorsal, body with indistinct cross bands. Tenasserim provinces.

5. Macrones gulio, A. 12-15. Occipital process half longer than wide at its base, a long interspace

between it and basal bone. Length of base of adipose dorsal equal to half that of the interspace between the two dorsal fins. Coasts, estuaries, and tidal waters, of the whole of India and Burma.

6. Macrones punctatus, A. 11-13. Upper surface of the head almost smooth. Occipital process very narrow, a long interspace between it and basal bone of the dorsal fin. Brown, with some black spots along

the sides. Bowany river at foot of Neilgherry hills.

7. Macrones corsula, A. 11-13. Upper surface of the head roughened. Occipital process short, with a long interspace between it and the basal bone of the dorsal fin. Brown, with some black spots along the sides. From Orissa, through Bengal and Assam.

8. Macrones microphthalmus, A. 12. Occipital process short, with a long interspace between it and the basal bone of the dorsal fin. Dorsal spine smooth, weak, articulated in its upper three-fourths. Burma.

- 9. Macrones cavasius, A. 11-13. Occipital process reaches basal bone. Maxillary barbels reach caudal fin. Adipose dorsal long, commencing just behind the rayed fin. Dorsal spine entire. Silvery, often with a black spot at base of dorsal spine, and fins stained with dark. Sind, throughout India and Assam to Burma.
- 10. Macrones tengara, A. 11-13. Median groove on head reaches base of occipital process, which latter reaches the basal bone of the dorsal fin. Golden, with a black shoulder spot and about five longitudinal dark Northern India and Assam.
- 11. Macrones oculatus, A. 11-13. Eye 3 to 31 in length of head: occipital process reaches basal bone. Maxillary barbels reach middle of anal fin. Base of adipose dorsal as long as that of the rayed fin. Dark

spot anteriorly at base of dorsal fin. Malabar coast and Coimbatore district.

12. Macrones vittatus, A. 9-12. Median groove on head does not reach the base of the occipital process, which latter reaches the basal bone of the dorsal. Sind, India, and Burma.

13. Macrones leucophasis, A. 11-12. Maxillary barbels reach anal fin. Purplish-black, with some white

spots. Burma.

14. Macrones montanus, A. 12. Head 5 in the total length. Median groove on head does not reach

occipital process, which last extends to the basal bone. Maxillary barbels reach anal fin. A dark shoulder mark, a light band along the body, and dark spot at base of caudal. Western ghauts.

15. Macrones keletius, A. 9-10. Head $4\frac{2}{3}$ in the total length. Median groove on head does not reach occipital process, which last does not quite reach the basal bone. Maxillary barbels reach middle of anal fin.

- A large pre-anal papilla. A dark shoulder mark. Coromandel coast.

 16. Macrones Malabaricus, A. 10-11. Head 4\frac{3}{4} to 5\frac{1}{2} in the total length. Median groove on the head does not reach base of occipital process, which last has a long interspace between it and the basal bone. Maxillary barbels reach middle or end of ventral fin. A dark shoulder spot, another at base of caudal fin. Malabar coast and Western ghauts.
- 17. Macrones armatus, A. 11. Head $5\frac{1}{2}$ in the total length. Median groove on the head almost reaches the base of the occipital process, which last reaches the basal bone. Maxillary barbels reach end of ventral fin.
- A dark blotch at base of caudal fin. Malabar and western ghants.

 18. Macrones Bleekeri, A. 9-10. Head 5½ to 5½ in the total length. Median groove on the head reaches the base of the occipital process, which last reaches the basal bone. Maxillary barbels reach the anal fin. Two light longitudinal bands, and sometimes a dark shoulder spot. Indus, Jumna, and upper part of the Ganges rivers, also the Irrawaddi in Burma.

1. Macrones chryseus, Plate XCIX, fig. 3.

Pseudobagrus chryseus, Day, Proc. Zool. Soc. 1865, p. 271, and Fish. Mal. p. 185, pl. xiii, f. 2. Mungil yata, Mal.; Neela katurnee, Hind.

B. x, D. $\frac{1}{7}$ | 0, P. 1/6, V. 6, A. 26-28, C. 17-19.

Length of head 43 to 43, of caudal 5, height of body 5 in the total length. Eyes—diameter 4 to 5 in the length of head, $1\frac{1}{2}$ diameters from the end of snout, and 2 to $2\frac{1}{2}$ apart. Greatest width of the head equals 4/5 of its length. Upper jaw slightly the longer. Width of gape of mouth nearly equal to half the length of the head. Upper surface of head, opercles, and humeral process with smooth ridges. Occipital process twice as long as wide at its base, no interspace between it and the basal bone. The superior longitudinal groove on the head shallow, reaching to opposite the hind edge of the eye. Barbels—the nasal rather above half the length of the head, the maxillary slightly longer: the external mandibular reach the base of the pectoral fin, whilst the internal ones are one-fourth shorter. Teeth—in a narrow uninterrupted semilunar band across the palate. Fins—dorsal spine as long as the head behind the middle of the eyes, strong, with about ten denticulations posteriorly, and three or four anteriorly near its summit, whilst it ends in a soft prolongation: adipose fin short, commencing over the last fourth of the anal. Pectoral reaches the ventral, its spine stronger than that of the dorsal and as long as the head excluding the snout, serrated externally and with 16 or 18 strong teeth internally. Ventral rather above half as long as the pectoral and reaches the anal, the base of which last fin equals the length of the head, it is highest anteriorly. Caudal slightly, or deeply lunated or even forked. Free portion of tail rather higher than long. Colours—back greenish-yellow, sides golden: a large round black mark on the shoulder surrounded by a light yellow ring. Dorsal and anal fins yellowish-orange, stained with deplete at their marging. stained with darker at their margins. Caudal yellow, with a black base and dark edges.

Habitat.—Rivers in Canara and Malabar, preferring the deepest pools, Longest specimen obtained

Digitized by GOO

8 inches, but said to attain to double that size. Wounds from their spines are deemed venomous by the natives.

2. Macrones aor.

Pimelodus aor, Ham. Buch. pp. 205, 379, pl. 20, f. 68.

B. xii, D. $\frac{1}{7}$ | 0, P. 1/9-10, V. 6, A. 12-13 ($\frac{3-4}{9}$), C. 17.

Length of head $4\frac{1}{2}$ to 5, of caudal 4, height of body 6 in the total length. Eyes—transversely oval, diameter 5 to 8 in the length of the head, $2\frac{1}{2}$ to 3 diameters from the end of snout, and $1\frac{2}{3}$ to 2 apart. Snout broad, depressed, the width of the gape being equal from 2/5 to 3/7 of the length of the head, whilst the cleft does not extend half-way to the orbit. The upper jaw the longer. Width of the head is 3/5 of its length, its upper surface rugose in tuberculated ridges. Occipital process does not extend half-way to the basal bone of the dorsal, whilst an intermediate interneural shield exists, and which is usually wider than the occipital process: the width of this bone is subject to great variations, thus in some old specimens it is only twice as long as broad, whilst in others and in some immature it is four times as long as wide. The longitudinal furrow on the head extends to the base of the occipital process. Barbels—the maxillary extend to, or even beyond, the base of the caudal fin: the nasal half-way to the orbit: the outer mandibular ones to the base of the pectoral, and the inner two-thirds of that distance. Teeth—in an uninterrupted semilunar band across the palate. Fins-dorsal spine rather weak, nearly or quite as long as the head (in the young occasionally shorter) finely serrated posteriorly. Pectoral as long as the head excluding the snout, and reaches 4/7 of the distance to the ventral, its spine is stronger than that of the dorsal but shorter, being equal to from 1/2 to 3/5 of the length of the head, it is rugose or finely serrated externally and denticulated internally. The adipose dorsal commences above the last third or end of the ventral, and its base equals about that of the rayed fin or even a little more, whilst the extent of the interspace between the two fins equals half the length of that of the rayed dorsal fin. Ventral arises below the last dorsal rays and does not reach the anal. Caudal with deeply pointed lobes, the three outer rays in the upper lobe being produced. Free portion of the tail rather more than twice as long as high at its base. Air-vessel—large and pyriform. Colours—bluish-leaden superiorly, becoming white beneath: fins yellowish, stained with dark externally in both the dorsal and caudal. A black spot about equal to the diameter of the eye on the soft dorsal on its posterior and inferior portion.

Blyth, Proc. A. S. of Beng. 1858, p. 284, observed of closely allied species that "there is a fourth in the B. aorinus, Jacq. in the others." The latter is not represented to have the conspicuous black spot on the adipose dorsal seen

Habitat.—Throughout Sind and India to Burma, a specimen in Calcutta is 3 feet long.

3. Macrones seenghala, Plate XCIX, fig. 1.

Platystomus seenghala, Sykes, Trans. Zool. Soc. ii, p. 371, pl. 65, f. 2. Bagrus Lamarrii, Cuv. and Val. xiv, p. 407, pl. 415. Bagrus aorellus, Blyth, Proc. A. S. of Bengal, 1858, p. 283. Bagrus seenghala, Jerdon, M. J. L. and Sc. 1849, p. 337. Macrones Lamarrii, Gunther, Catal. v, p. 79. Teng ga-ra, Punj.

B. xii, D. $\frac{1}{7}$ | 0, P. 1/9, V. 6, A. 11-12 $(\frac{9}{8}, \frac{9}{9})$, C. 19-21.

Length of head $4\frac{1}{2}$, of candal $4\frac{1}{2}$, height of body $7\frac{1}{2}$ to 8 in the total length. Eyes—diameter 7 to 8 in the length of head, 2 to $2\frac{1}{2}$ diameters from the end of snout, and $1\frac{1}{2}$ to 2 apart. The greatest width of the head equals 1/2 to 4/9 of its length: snout spatulate: upper jaw rather the longer: the width of the gape equals one-third of the length of the head, its cleft shallow. Upper surface of the head granulated in ridges, its median longitudinal groove reaches the base of the occipital process, which is twice as long as wide at its base, between its posterior extremity and the breal hope of the descel finite a group to intermedial form four between its posterior extremity and the basal bone of the dorsal fin is a separate interneural shield from four times as long as broad in the young, to half that width in the adult. Burbels—the maxillary ones extend to the middle or just beyond the hind margin of the dorsal fin, the nasal to opposite the middle of the orbit, the external mandibular ones to the base of the pectoral, whilst the internal ones are one-third shorter. Teeth—on the palate in an uninterrupted crescentic band. Fins—dorsal one-third to one-half higher than the body, its spine rather weak, anteriorly rugose, indistinctly serrated posteriorly, and as long as the head excluding the snout: length of the base of the adipose dorsal equals or exceeds that of the rayed fin, whilst the intermediate distance is of the same length. Pectoral extends rather above half way to the ventral, its spine is stronger than that of the dorsal and half as long as the head, roughened externally, denticulated internally. Ventral arises behind the vertical from the last dorsal ray and reaches 2/3 of the distance to the anal. Caudal deeply torked, upper lobe the longer. Air-vessel—large, pear-shaped and not enclosed in bone. Colours—brownish along the back, silvery on the sides and beneath, a round black spot at the posterior end of the base of the adipose dorsal fin.

Very closely allied to M. aor, and chiefly distinguished by its much shorter maxillary barbels. Habitat.—The Indus,* salt ranges of the Punjaub, Jumna and Ganges certainly as low as Delhi, also the Deccan, Kistna river to its termination, and Assam. It attains a considerable size.

4. Macrones Blythii.

Batasio affinis, Blyth, J. A. S. of Beng. 1860, p. 190 (not Bagus affinis, Jerdon, 1849.) Macrones affinis, Günther, Catal. v, p. 83; Day, Proc. Zool. Soc. 1873, p. 111.

D. $\frac{1}{7}$ | 0, P. 1/7, V. 6, A. 12 ($\frac{3}{9}$), C. 17.

Length of head nearly 5, of pectoral 6, of caudal 6, height of body 5 in the total length. Eyesdiameter $3\frac{1}{2}$ in the length of head, 1 diameter from end of snout and $1\frac{1}{4}$ apart. Snout projecting. longitudinal groove on head indistinct, but reaching the base of the occipital process, which is narrow, twice as long as wide at its base, and separated from the basal bone of the dorsal fin by an interneural shield. Barbels—the maxillary which are the longest only reach the anterior margin of the orbit. Teeth—in an uninterrupted crescentic band across the palate. Fins—dorsal spine moderately strong, slightly serrated posteriorly in its upper fourth and rather above half the length of the head. Pectoral spine, slightly longer and stronger than that of the dorsal, and denticulated internally. Adipose dorsal commences not far from the hind edge of the first dorsal whilst its base is a little longer than that of the anal. Caudal forked, the lobes of nearly equal length. Calcuts—a dark spot on the shoulder a second on the base of the adipose dorsal first longer with length. Colours—a dark spot on the shoulder, a second on the base of the adipose dorsal fin: body with

Habitat.—Tenasserim provinces from whence one specimen 3.5 inches long was sent to the Calcutta Museum.

B. ix, D. $\frac{1}{7}$ | 0, P. 1/8-9, V. 6. A. 12-15 ($\frac{3-4}{9-11}$), C. 17.

Length of head $4\frac{1}{4}$ to $4\frac{2}{3}$, of caudal $4\frac{1}{2}$, height of body 5 to $5\frac{3}{4}$ in the total length. Eyes—diameter 5 to 6 in the length of head, 11 diameters from the end of snout, and 2 diameters apart. Snout broad and slightly depressed, upper jaw somewhat the longer. Greatest width of head equals its length excluding the snout, and one-fourth broader than high. Upper surface of the head granulated, its median longitudinal groove and one-fourth broader than high. Upper surface of the head granulated, its median longitudinal groove lanceolate, extending to opposite the hind edge of the orbit. Occipital process rounded posteriorly and half longer than wide at its base, a considerable interspace† between it and the basal bone of the dorsal fin. Burbels—nasal shorter than the head, the maxillary reach to the middle or nearly the end of the ventral fin, the external mandibular are longer than the head or than the internal ones. Teeth—in a narrow, uninterrupted crescentic band across the palate. Fins—dorsal spine half as long as the head, strong, anteriorly with one or two teeth at its upper extremity, serrated posteriorly. Anterior rays longer than the spine. Adipose dorsal with a short base equalling about half of the interspace between the two fins. Pectoral does not reach the ventral, its spine is as long as the head excluding the snout, strong, and denticulated internally. Ventral arises on the vertical behind the last dorsal ray and does not reach the anal. Upper caudal lobe the longer, inferior one sometimes rounded. Air-vessel—heart shaped, divided along its centre by a strong partition, having a communicating orifice in its upper back part, whilst the whole has many subdivisions internally. Colours—lurid bluish-brown on the back becoming dull white beneath, fins many subdivisions internally. Colours—lurid bluish-brown on the back becoming dull white beneath, fins especially on their outer halves, usually black: maxillary barbels mostly black, those from fresh waters sometimes have them whitish or white-tipped.

As in the rest of the genus Macrones the ova in this species are small. Some specimens from the Hooghly have 11 branched anal rays, and the maxillary barbels only reach the end of the pectoral fin.

Habitat.—Seas, estuaries, and tidal waters from Sind and Bombay, throughout India and Burma to the Malay Archipelago. There are stuffed specimens in the Calcutta Museum 18 inches in length.

6. Macrones punctatus, Plate C, fig 3.

Bagrus punctatus, Jerdon, M. J. L. and Sc. 1849, p. 339.

[•] Günther records "e. Half grown. Afghanistan. From Mr. Griffith's collection." This may be an error. The specimen was perhaps the one sent, as Pimelodus aor, by McClelland (see Cal. J. N. H. ii. p. 575) to the India Office, and he observed "Pimelodus aor, Buch. has been found also by Griffith to be one of the characteristic fishes of the Indus, as well as of the Ganges above Scharunpore, but disappears in Afghanistan," p. 568.

† This interspace appears to be absent in the immature, but increases with age.

Hemibagrus punctatus, Day, Proc. Zool. Soc. 1867, p. 284. Sholang kelleté, Tam.

B. xi, D. $\frac{1}{7}/0$, P. 1/7, V. 6, A. 11-13 $(\frac{3-4}{8-9})$, C. 17.

Length of head $4\frac{1}{2}$ in the young to 5, of caudal $5\frac{1}{2}$, height of body $6\frac{1}{2}$ in the total length. Eyes—diameter 6 to 7 in the length of head, 2 diameters from end of snout, and $2\frac{1}{2}$ apart. Greatest width of head equals its length behind the nostrils: width of the gape of mouth equals 2/5 of length of head. Upper jaw slightly the longer. Interorbital space rather convex, upper surface of the head and shoulder bones furrowed, but without any tuberculated ridges. Median longitudinal groove very indistinct, lanceolate, and extending almost to the base of the occipital process which is narrow and has an interval equal to twice its length, between it and the basal bone. Barbels—nasal ones reach the hind edge of the orbit, the maxillary the base or middle of the ventral, the external mandibular the base of the pectoral, whilst the internal are one-third shorter. Teeth—on the palate in an uninterrupted crescentic band. Fins—dorsal spine of moderate strength, serrated posteriorly in its upper third, it is 1/2 as long as the head but shorter than the first ray: adipose dorsal with a short base, equalling half the distance of the interspace between it and the first dorsal fin. Pectoral spine longer and stronger than that of the dorsal, equal in length to the head excluding the snout, rugose externally, denticulated internally. Ventrals arise on a vertical line just posterior to the last dorsal ray. Upper caudal lobe the longer. Colours—head and back dark grayish olive, becoming yellow on the abdomen: about ten black, rounded spots, along the lateral-line: fins dusky, except the ventrals which are yellowish.

This fish is evidently very closely allied to M. corsula, but its head is much shorter in the adult, taking for examination specimens of the same size, the upper surface of its head is almost smooth, and its snout is

not so flat.

Habitat.—Bowany river at base of Neilgherry hills, attaining at least 18 inches in length.

7. Macrones corsula, Plate C, fig. 5.

Pimelodus menoda, Ham. Buch. Fish. Ganges, pp. 203, 379. Pimelodus corsula, Ham. Buch. l. c. pl. i, f. 72. Bagrus trachacanthus, Cuv. and Val. xiv, p. 419. Bagrus menoda, Blyth, P. A. S. of Beng. 1858, p. 285. Macrones corsula, Day, Proc. Zool. Soc. 1869, p. 307. Macrones menoda, Lütken, Vid. Medd. 1874, p. 216. Punjah-guggah, Ooriah.

B. x, D. $\frac{1}{7}$ | 0, P. 1/9, V. 6, A. 12-13 ($\frac{3-5}{8}$), C. 17.

Length of head 4 to $4\frac{1}{3}$, of caudal 5 to 6, height of body 6 in the total length. Eyes—diameter $5\frac{3}{4}$ to 7 in the length of head, 2 diameters from the end of snout, and 2 to $2\frac{1}{4}$ apart: interorbital space nearly flat. The greatest width of the head equals its length excluding the snout. Upper jaw the longer. Median longitudinal groove on the head extends to the base of the occipital process in the young, not so far in the adult. Occipital process is very long and narrow, the width of its base being hardly equal to 1/5 of its length, but in old specimens the anterior portion of this bone becomes concealed by skin, and appears to be very short, a very slight interspace exists between it and the basal bone of the dorsal fin. Extent of gape of the mouth equals 3/8 of length of head. Upper surface of the head, opercles, and shoulderbone, roughened by the presence of tubercular ridges. Barbels—the nasal ones extend to below the middle of the orbit: the maxillary ones to nearly or quite the base of the anal: the external mandibular to the base of the pectoral, and the internal to opposite the posterior extremity of the preopercle. Teeth—in an uninterrupted semilunar band across the palate. Fins—dorsal spine slender, serrated posteriorly in its upper half, it is half as long as the head: base of adipose dorsal differs in length, usually as long as, or longer than, that of the rayed fin. Pectoral spine strong, compressed, rugose externally, denticulated along its whole extent internally, it is as long as the head excluding the snout, and slightly longer than that of the dorsal. Ventral half as long as the head, and does not reach the anal: in some specimens the upper caudal lobe is prolonged. Free portion of the tail rather longer than high. Colours—superiorly grayish-brown, inferiorly dull white. Fins grayish, stained with black. Several vertical black spots along the anterior portion of the lateral-line.

I have found 12 to 13 rays in the anal fin in Assam specimens, which are the same number as given by Cuv. and Val. for B. trachacanthus, so I conclude the remark that, the lower caudal lobe is the longer must be a misprint. Blyth observes that it is "a very mucous fish, and those brought to the bazaar are commonly much clotted over with an adhesive clayey mud, as if they had burrowed into it, and they are mostly brought many together expression as if due out from the mud of reads more or less duid up."

brought many together, appearing as if dug out from the mud of ponds more or less dried up."

Habitat.—From Orissa through Bengal and Assam; attaining a foot or more in length.

8. Macrones microphthalmus, Plate C, fig. 4.

Nga-ike, Burmese.

B. x, D. $\frac{1}{7}$ | 0, P. 1/9, V. 6, A. 12 ($\frac{3}{9}$), C. 17.

Length of head 4, of caudal $5\frac{1}{3}$, height of body $6\frac{3}{4}$ in the total length (excluding the filamentous prolongation of the caudal fin). Eyes—diameter 6 in the length of head, 2 diameters from the end of snout,

and $2\frac{1}{2}$ apart. The greatest width of the head equals its length excluding the snout. Upper jaw the longer, and $z_{\overline{z}}$ apart. The greatest winth of the head equals its length excitaing the shout. Upper jaw the longer, shout spatulate. Median longitudinal groove on the head reaches nearly to the base of the occipital process, which latter is pointed, scarcely longer than wide at its base, and with a long interspace between it and the basal bone of the dorsal fin. Upper surface of the head nearly smooth, the few ridges not being tuberculated. Barbels—nasal ones reach the hind third of the eye, maxillary ones the base of the caudal, external mandibular ones the first third of the pectoral, whilst the inner ones are shorter. Teeth—in an uninterrupted semilunar band across the palate. Fins—dorsal as high as the body, its spine very slender, only assect a strict of the caudal causes and articulated in its paper two thirds. Langth of base of adjaces dorsal causals that of the osseous at its base and articulated in its upper two-thirds: length of base of adipose dorsal equals that of the rayed fin, whilst the interspace between the two fins is of the same length. Pectoral as long as the post-orbital portion of the head, its spine moderately strong and 1/2 as long as the head, denticulated internally. Ventral nearly 1/2 as long as head and just extends to the anal. Upper caudal lobe with a filamentous prolongation. Free portion of tail 1/2 longer than high. Colours—of a light brown, shot with purple; fins darkest externally.

This fish is closely allied to M. corsula, but differs in the character of its dorsal spine, the length of its maxillary barbels, the smooth ridges on its head, occipital process, &c.

Habitat.—Burma, along the valley of the Irrawaddi

9. Macrones cavasius, Plate C, fig. 1.

Pimelodus cavasius, Ham. Buch. Fish. Ganges, pp. 213, 379, pl. xi, f. 67.

B. vi, D. $\frac{1}{7}$ | 0, P. 1/8, V. 6, A. 11-13 ($\frac{4}{7-9}$), C. 16.

Length of head 6 to $6\frac{1}{4}$, of candal 6, height of body $5\frac{1}{2}$ in the total length. Eyes—diameter $3\frac{1}{4}$ to $3\frac{1}{2}$ in the length of head, 1 to $1\frac{1}{2}$ diameters from the end of snout, and $1\frac{1}{4}$ apart. The greatest width of the head equals its length excluding the snout. Snout rather obtas, upper jaw a little the longer: width of the gape equals 2/5 of the length of the head, the cleft extends half-way to below the orbit. Upper surface of the head slightly roughened, its median longitudinal groove rather wide and extends to the base of the occipital process, which last is narrow and three or four times as long as wide at its base, and with a shallow groove along its last half or two-thirds: no interspace between its posterior extremity and the basal bone of the dorsal fin. Barbels—the nasal nearly or quite as long as the head, the maxillary extend to beyond the base of the caudal fin, the external mandibular almost to the base of the ventral, whilst the internal are as long as the head. Teeth—on the palate in an uninterrupted crescentic band. Fins—dorsal spine weak, entire, and nearly or quite as long as the head excluding the snout, the fin is rather higher than the body and pointed: the adipose dorsal commences just behind the rayed one, and the length of its base is three times as long. Pectoral spine as long as, but stronger than, the dorsal, smooth externally, denticulated internally. Ventral arises just posterior to the vertical from the last dorsal ray. Caudal pointed, upper lobe the longer. Colours—leaden superiorly, becoming yellowish along the abdomen and cheeks. Maxillary barbels, dorsal and caudal fins dusky: pectoral, ventral, and anal dull white. There is usually a black spot covering the basal bone of the dorsal fin. Occasionally there is a bluish band along the lateral-line.

I have a specimen from Lingasagore with a few serrations posteriorly on the dorsal spine. Habitat.—From Sind, throughout India, Assam, and Burma: attaining at least 18 inches in length.

10. Macrones tengara, Plate CI, fig. 5.

Pimelodus tengara, Ham. Buch. Fish. Ganges, pp. 183, 377, and Pimelodus butasius, pl. 23, f. 60.* Bagrus tengara, Cuv. and Val. xiv, p. 414; Bleeker, Beng. p. 114. Kuttahrah, Hind.: Ting-ga-rah, Assam and Punj.: Karaal, Punj.

B. x, D. $\frac{1}{7}$ | 0, P. 1/8, V. 6, A. 11-13 ($\frac{2}{9}$ - $\frac{3}{10}$), C. 19.

Length of head $4\frac{1}{3}$, of caudal $4\frac{1}{3}$, height of body $4\frac{1}{3}$ in the total length. Eyes—diameter $3\frac{1}{2}$ in the length of head, 3/4 to 1 diameter from the end of snout, and $1\frac{1}{2}$ apart. Greatest width of the head equals its length excluding the snout. Gape of mouth equal to 2/5 of the length of the head. Upper jaw slightly the longer. Median longitudinal groove extends to the base of the occipital process, which latter, (as well as the upper surface of the head), is corrugated and about thrice as long as wide at its base, it reaches the basal bone of the dorsal fin. Barbels—the nasal ones are nearly as long as the head, the maxillary ones reach

* Hamilton Buchanan distinctly figures this species here and not P. batasius, which is said to have its barlels shorter than the head, and which I have copied from his MSS, figure marked P. batasi (see Plate C. fig. 3). His figure Pl. iii, f. 61 is of the common Bengal form, having at least four barbels longer than the head, and cannot be the little up-country species which I have likewise figured: the names seem to have become transposed.

the base of the ventral, the external mandibular the base of the pectoral, whilst the internal are shorter. Teeth—in a narrow uninterrupted band across the palate. Fins—dorsal spine as long as the head excluding the snout, slightly serrated anteriorly in its upper third, and posteriorly in its whole extent: the length of the base of the adipose dorsal 1/3 less than that of the rayed fin, and equals 1/2 the length of the interspace between the two fins, in some specimens, as the one figured, it is much longer. Pectoral spine nearly as long as the head, stronger than that of the dorsal, smooth externally, and with about 13 denticulations internally. Ventrals arise on a vertical line just behind the last dorsal ray. Caudal forked, upper lobe the longer. Colours-brilliant yellow, with a black shoulder spot and about five black longitudinal lines. In some specimens the mandibular barbels are white with a black streak.

In this species the median longitudinal groove extends further backwards to the base of the occipital

process, than in M. vittatus.

In some Punjab specimens (? Pinelodus anisurus, McClelland, Cal. J. N. Hist. ii, p. 583.) the nasal barbels are not so long as the head, whilst the maxillary only reach to the middle of the pectoral fin.

Habitat.—Northern India, the Punjab and Assam; attaining 3 to 4 inches in length. The specimen figured was from Assam.

11. Macrones oculatus, Plate XCVIII, fig. 4.

Bagrus oculatus, Cuv. and Val. xiv, p. 424; Jerdon, M. J. L. and Sc. 1849, p. 339.

B. x, D. $\frac{1}{7}/0$, P. 1/6, V. 6, A. 11-13 $(\frac{3-4}{8-9})$, C. 15. Length of head $5\frac{1}{2}$, of caudal $4\frac{1}{3}$, height of body 5 in the total length. Eyes—diameter 3 to $3\frac{1}{2}$ in the length of head, about 1 diameter from end of snout and also apart. Profile from snout to dorsal fin rather elevated. Greatest width of the head equals its length excluding the snout: upper jaw slightly the longer. Summit of the head rough: median longitudinal groove extends nearly to the base of the occipital process, which last is three times as long as wide at its base, whilst there is no interspace between it and the basal bone of the dorsal fin. Barbels—the nasal half as long as the head, the maxillary reach the middle of the anal fin, the outer mandibular the middle of the pectoral, whilst the inner are rather shorter. Teeth—in an uninterrupted crescentic band across the palate. Fins—dorsal spine of moderate strength, as long as the head excluding the shout, two or three teeth anteriorly, servated posteriorly: the length of the base of the adipose dorsal equals that of the rayed fin, but is about 1/4 less than the interspace between the two fins. Pectoral spine stronger than the dorsal, as long as the head behind the angle of the mouth, and with about 10 very strong teeth internally. Caudal deeply forked, the upper lobe being the longer. Colours-silvery, lightest beneath, a dark spot at the commencement of the base of dorsal fin, which is also black tipped, a darkish band likewise along the middle of the fin.

Habitat.-Malabar coast and the Coimbatore district: it attains 5 or 6 inches in length.

12. Macrones vittatus, Plate XCVIII, fig. 3; and Plate XCIX, fig. 4.

Silurus vittatus, Bloch. t. 371, f. 2; Bl. Sehn. p. 387.

Macrones tengara, Günther, Catal. v, p. 81; Day, Fish. Malabar, p. 189; Peters. Monats. Akad. Berlin, 1868, p. 271; (not Pimelodus tengara, H. B.)

Bagrus affinis, Jerdon, Madr. J. L. and Sc. 1849, p. 338.

Tengra, Beng.: Kuggur, Hind.: Kel-le-tce, Tam.: Sukujellah, Tel.: Kuntiah, Ooriah: Mulleer and Kuggur, Sind.: Sin-go-rah, Assam: Nga-sa-ring, Mugh.: Nya-zin-yine, Burmese.

B. x, D. $\frac{1}{7}/0$, P. 1/9, V. 6, A. 9-12 $(\frac{2-3}{7-9})$, C. 17.

Length of head $4\frac{3}{4}$ to 5, of caudal $5\frac{1}{2}$, height of body 5 in the total length. Eyes—diameter $\frac{1}{4}$ to 6 in the length of head, $1\frac{3}{4}$ to 2 diameters from end of snout, and $1\frac{1}{2}$ to 2 apart. The greatest width of the head equals its length excluding the snout or behind the angle of the mouth, and is very little more than its height, in some specimens there is a considerable rise to base of first dorsal fin. Upper surface of the head roughened in tubercles hardly forming lines, median longitudinal goove reaches to midway behind the hind edge of the eye and the base of the occipital process, which latter is rough, three times as long as wide at its base, and a short (if any) interspace existing between it and the basal bone of the dorsal fin: radiating rough lines on the opercle: shoulder bone with its triangular portion a little longer than wide at its base, and roughened in raised lines. shoulder bone with its triangular portion a little longer than wide at its base, and roughened in raised lines. Barbels—the maxillary reach the ventrals, the nasal the opercle, the external mandibular the first third of the pectoral spine, whilst the internal are shorter. Teeth—in an uninterrupted semilunar band across the palate. Fins—dorsal 2/3 as high as the body, its spine half as long as the head with 2 or 3 teeth anteriorly in the young, whilst it is finely serrated posteriorly: length of the base of the adipose dorsal varies, in some specimens it usually equals that of the interspace between the two fins, and a little more than the length of the rayed fin. Pectoral spine strong, as long as the head excluding the snout, denticulated internally with about 16 coarse teeth. Ventral reaches from 1/2 to 2/3 of the distance to the base of the anal. Upper caudal lobe the longer. Colours—silvery or golden, old specimens at Madras (Pl. xeviii, f. 3) have a light bluish band along the longer. Colours—silvery or golden, old specimens at Madras (Pl. xeviii. f. 3) have a light bluish band along the middle of the side, and a narrow light one above and below it, a dark shoulder spot, and sometimes another near the base of the caudal fin. More to the eastward as Orissa and Bengal (Pl. xcix, f. 4) the colours are more vivid, usually of a golden hue, with a black shoulder spot, a narrow black band along either side of the

lateral-line, a lighter parallel one below, and two wider ones above. Sometimes these fish appear to be dark, with 5 longitudinal silvery bands. Tips of fins usually dark.

Bagrus affinis, Jerdon, is said to differ in its more depressed head, eye, if anything, smaller: dorsal spine

barely notched, pectoral spine with 12 teeth.

This fish is termed "the fiddler" in Mysore: I touched one which was on the wet ground, at which it appeared to become very irate, erecting its dorsal fin and making a noise resembling the buzzing of a bee, evidently a sign of anger. Having put some small carp into an aquarium containing one of these fishes it rushed at a small example, seized it by the middle of its back and shook it like a dog killing a rat, at this time its barbels were stiffened out laterally like a cat's whiskers.

Habitat.—Throughout Sind, the continent of India, Assam, Burma, Siam, also Ceylon: it attains 7 or 8

inches in length.

13. Macrones leucophasis, Plate C, fig. 2.

Bagrus leucophasis, Blyth, Pro. A. S. of Bengal, 1860, p. 148. Macrones leucophasis, Günther, Catal. v, p. 78; Day, Proc. Zool. Soc. 1873, p. 112.

B. xi, D. $\frac{1}{7}$ | 0, P. $\frac{1}{8}$ -10, V. 6, A. 11-12 ($\frac{3}{8}$ - $\frac{3}{9}$), C. 17.

Length of head $4\frac{1}{2}$ to 5, of caudal $3\frac{1}{2}$ to $4\frac{1}{3}$, height of body $4\frac{1}{2}$ in the total length. Eyes—diameters 4 to 5 in the length of the head, $1\frac{1}{2}$ to 2 diameters from the end of snout, and 1 to $1\frac{1}{3}$ apart. The greatest width of the head equals its length behind the nostrils. Snout rounded, the upper jaw slightly the longer. Median longitudinal groove on the head does not quite reach the base of the occipital process, which last is twice as long as wide at its base, whilst between it and the basal bone of the dorsal fin is a pyriform bone about twice as long as wide. Upper surface of the head rather rugose. Barbels—the nasal ones reach to the front edge or the middle of the eye, the maxillary to the anal fin, the external mandibular to the middle of the pectoral, and the internal to the gill-openings. Teeth—in an uninterrupted crescentic band across the palate. Fins—dorsal spine moderately strong, as long as the head posterior to the nostrils or angle of the mouth, finely serrated posteriorly in two and a half times that of the base of the first dorsal. Pectoral spine much stronger than that of the dorsal, than which it is a little shorter, and denticulated internally. Caudal deeply forked, the lobes having filamentous prolongations. Air-vessel—large. Colours—purplish-black over body and fins: some white dots

exist on the body.

Habitat.—Rivers of Burma, attaining a foot or more in length. Major Berdmore sent 4 or 5 specimens from Tenasserim to the Calcutta Museum. The specimen figured (life-size) was from Bassein. The native name Nga-pet-lek and Nga-nouk-thawa signifies "topsy-turvy" as it is believed to swim in that position.

14. Macrones montanus, Plate CI, fig. 4.

Bagrus montanus, Jerdon, M. J. L. and Sc. 1849, p. 337.

B. x, D. $\frac{1}{7}$ | 0, P. 1/6, V. 6, A. 12 $(\frac{3}{9})$, C. 19.

Length of head 5, of caudal 5, height of body 6 in the total length. Eyes—diameters 3½ to 4 in the length of head, rather above 1 diameter from the end of snout, and 1½ apart. A very slight rise in the profile from snout to base of first dorsal fin. Greatest width of the head equals its length behind the angle of the mouth. Upper jaw slightly the longer: the width of the mouth equals 2/5 of the length of the head. Upper surface of the head roughened in granulated lines which extend on to the occipital process. Median longitudinal groove extends to midway between the eye and the base of the occipital process, which last is narrow, about four times as long as wide at its base, and extends to the basal bone of the dorsal fin: opercle with roughened, radiating lines: shoulder bone rather longer than deep at its base and with roughened lines. Barbels—the nasal ones extend to rather behind the hind edge of the eye, the maxillary ones to the anal fin, the external mandibular to the end of the pectoral, whilst the internal are shorter. Teeth—in an uninterrupted crescentic band across the palate. Fins-dorsal nearly as high as the body, its spine rather weak, half as long as the head and posteriorly serrated: length of base of adipose dorsal one-third more than that of rayed fin which equals that of the interspace. Pectoral spine strong, as long as the head excluding the snout, and with about 16 strong denticulations internally. Ventral does not reach anal: upper caudal lobe the longer. Colours-silvery superiorly, with a tinge of yellow on the under surface of the head and along the abdomen, a bluish shoulder spot, and a silvery line along the side ending in a dark spot at the base of the caudal fin,

one or two light bands along the side above the lateral-line: fins tinged with green.

Amongst Sir W. Elliott's figures was one of this species marked by Jerdon "Bagrus ——? Manantoddy," taken in connection with the locality where I procured the fish, leaves but little room to doubt the identity of

the two.

Bagrus agricolus, Jerdon, is said to have, A. 10, and maxillary barbels only reach the ventrals, to be found in the Wynaad, and no other essential differences are pointed out. (Madr. J. L. and Sc. 1849, p. 339). Habitat. Wynaad range of hills, and Manantoddy.

15. Macrones keletius, Plate XCVIII, fig. 3.

Bagrus keletius, Cuv. and Val. xiv. p. 411; Jerdon, M. J. L. and Sc. 1849, p. 337; (not Bleeker). Macrones keletius, Günther (not synon.).

3 м

B. x, D. $\frac{1}{7}$ | 0, P. 1/10, ∇ . 6, A. 9-10 ($\frac{9-3}{7-8}$), C. 17.

Length of head $4\frac{2}{3}$, of caudal 5 to $5\frac{1}{4}$, height of body 6 to $6\frac{1}{4}$ in the total length. Eyes—diameters $4\frac{1}{2}$ in the length of head, $1\frac{1}{3}$ diameters from the end of snout, and 2 apart. The greatest width of the head equals its length excluding the snout. Upper jaw slightly the longer. The upper surface of the head roughened in closely set tubercular lines continued on to the occipital process, opercle likewise striated with similar lines. Median longitudinal groove rather constricted in its centre, it reaches to opposite the hind border of the preopercle. Occipital process narrow, three times as long as wide at its base and does not quite reach the basal bone. Barbels—the nasal reach the opercle, the maxillary the middle of the anal fin, the external mandibular the end of the pectoral spine, whilst the internal are shorter. Humeral process rather short and pointed. Teeth—in an uninterrupted crescentic band across the palate. Fins—dorsal as high as body, its spine with two or three teeth anteriorly near its summit and serrated posteriorly, it equals 3/7 of the length of the head: length of the base of the adipose dorsal equals that of the rayed fin or of the interspace between the two. Pectoral reaches two-thirds of the way to the ventral, its spine is stronger than that of the dorsal and equals the length of the head excluding the snout. The ventral does not reach the anal. Upper caudal lobe the longer. A well marked pre-anal papilla. Colours—silvery along the back, becoming dull white beneath. A dark shoulder spot, a light band along the lateral-line, and a silvery one above and another below it, dorsal and caudal black tipped, anterior half of anal dark.

At the Jardin des Plantes I was allowed to examine one of M. Leschenault's Pondicherry specimens, still

in excellent preservation. The anal papilla is very distinct.

Habitat.—Madras to Pondicherry and inland to Coimbatore, also Ceylon, attaining about 4 inches in length. Jerdon observes that it is also found in Mysore.

16. Macrones Malabaricus, Plate CI, fig. 2.

B. x, D. $\frac{1}{7}$ | 0, P. 1/9, V. 6, A. 10-11 ($\frac{2}{8}$), C. 18.

Length of head $4\frac{7}{4}$ in a Wynaad specimen to $5\frac{1}{2}$, of pectoral 6 to 7, of caudal 5 to 6, height of body 6 to 7 in the total length. Eyes—diameters 4 to $4\frac{1}{2}$ in the length of head, $1\frac{1}{4}$ diameters from the end of snont, and $1\frac{3}{4}$ apart. Scarcely any rise in the dorsal profile from the snout to the base of the dorsal fin. Greatest width of the head equals its length behind the angle of the mouth. Upper surface of the head nearly smooth. Median longitudinal groove extends to midway between hind edge of the eye and the base of the occipital process, which last is about twice as long as wide, whilst there exists a considerable interspace between it and the basal bone of the dorsal fin. The triangular portion of the shoulder-bone curves rather upwards, and is 1/4 longer than deep at its base. Barbels—the masal reach to a little behind the orbit, the maxillary to the middle or end of the ventral fin, the external mandibular to the end of the pectoral, whilst the internal are a little shorter. Teeth—in an uninterrupted crescentic band across the palate Fins—dorsal nearly as high as the body, its spine weak, finely serrated or almost entire posteriorly, and one denticulation anteriorly near its summit, its length equals that of the postorbital portion of the head: length of base of the adipose dorsal 1/3 more than that of the rayed fin, or of the interspace between the two fins. Pectoral spine strong and equal to the length of the head excluding the snout, internally with about eight or ten strong denticulations, whilst it is roughened externally. Upper caudal lobe the longer. Colours—deep leaden, usually with a dark blotch on the shoulder surrounded by a lighter edge, another at the base of the caudal fin: a dark band along the lateral-line, abdomen of a dull white. Fins with minute dark spots, making the upper portion of the dorsal and the lower third of the anal blackish.

Habitat.—Malabar coast of India and the Wynaad, attaining upwards of 6 inches in length. The specimen figured was from south Canara, where it extends inland to the ghauts.

17. Macrones armatus, Plate CI, fig. 3.

Hypselobagrus armatus, Day, Proc. Zool. Soc. 1865, p. 289, and Fish. Malabar, p. 187. Cuaree, Mal.

B. x, D. $\frac{1}{7}$ | 0, P. 1/9, V. 6, A. 11 ($\frac{3}{8}$), C. 17.

Length of head $5\frac{1}{2}$, of caudal $5\frac{1}{2}$, height of body $5\frac{1}{2}$ in the total length. Eyes—diameters 5 in the length of head, $1\frac{1}{4}$ from end of snout, and 2 apart. A considerable rise from the snout to the base of the dorsal fin. The greatest width of the head equals its height or its length excluding the snout. Upper surface of the head roughened, the median longitudinal groove almost reaches the base of the occipital process, which last is about three times as long as wide and reaches the basal bone of the dorsal fin: shoulder-bone roughened in lines and 1/2 longer than deep at its base. Barbels—the nasal nearly reach the opercle, the maxillary the end of ventral fin, the outer mandibular the end of pectoral spine, whilst the internal are shorter. Teeth—in an uninterrupted crescentic band across the palate. Fins—dorsal as high as the body below it, its spine very finely serrated posteriorly or entire, and 4/9 of the length of head: length of base of adipose dorsal exceeds that of the rayed fin or of the interspace between the two. Pectoral spine strong, as long as the head excluding the snout, and having from ten to fourteen strong denticulations internally. Upper caudal lobe the longer. An anal papilla before the fin. Colours—leaden or brown superiorly, lighter

beneath, with or without a brown band along the side, and a dark blotch at the base of the caudal fin. Upper half of dorsal fin darkish, and a dark band along the anal.

This fish is allied to M. Malubaricus, differing in a higher body, more elevated dorsal profile, a higher dorsal fin, and an anal papilla.

Habitat.—Malabar and the Wynaad range of hills.

18. Macrones Bleekeri, Plate CI, fig. 1.

Bagrus keletius, Bleeker, Beng. en Hind. p. 115 (not Cuv. and Val.). ? Bagrus tengara, (var.) Blyth, P. A. S. of Beng. 1860, p. 149. Macrones keletius, Günther, Catal. v, p. 84.

B. x, D. $\frac{1}{7}$ | 0, P. 1/9-10, V. 6, A. 9-10 ($\frac{3}{6-7}$), C. 17.

Length of head $5\frac{1}{4}$ to $5\frac{1}{2}$, of caudal $5\frac{1}{2}$, height of body 5 in the total length. Eyes—diameters $4\frac{1}{2}$ in the length of head, nearly 2 diameters from the end of snout, and $1\frac{1}{2}$ apart. Greatest width of the head equals its length behind the hind nostril, and equals its height. Snout somewhat obtuse. Width of the gape of the mouth nearly equals half the length of the head. Upper surface of head, opercles, occipital bone and humeral process granulated. Median longitudinal groove on the head shallow, and reaching to the base of the occipital process, which is twice as long as broad at its base, and reaches the basal bone of the dorsal fin. Occipital process not grooved, but with ridged lines. Barbels-nasal ones reach the hind edge of the eye, maxillary ones the anal fin, external mandibular ones the base of the pectoral, the internal ones a little shorter. Teeth—on the palate in an uninterrupted semilunar band. Fins—dorsal fin rounded, not so high as the body, the spine smooth and equal to half the length of the head, (in Sind specimens it is slightly serrated posteriorly and I once saw a specimen that had eight branched dorsal rays:) adipose dorsal commences just behind the rayed fin, and the length of its base is twice that of the head. Pectoral spine stronger than that of the dorsal, and as long as the head excluding the snout: denticulated internally. Caudal with pointed lobes, the upper being the longer. Colours—brownish-gray, with two light longitudinal bands, one above the other below the lateral-line, some specimens have a dark shoulder spot and a dark band along the middle of the anal fin. The fins are mostly darkest at their edge. In a specimen from Burma there is a dark spot at the end of the lateral-line and light longitudinal body bands.

Habitat.—Sind, Jumna, upper waters of the Ganges, and Burma, not attaining to a large size. It descends the rivers as low as Bengal.

Genus, 2—Leiocassis, Bleeker.

Rama, Bleeker; Macrones, pt. Günther.

Branchiostegals six. Gill-openings very wide, the membrane not being confluent with the skin of the isthmus, and notched as far as the chin. Mouth of moderate size, anterior, the upper jaw the longer. Nostrils distant one from the other. Eyes subcutaneous. Barbels six, a short maxillary and two mandibular pairs. Teeth villiform in both jaws, and in an uninterrupted band across the palate. One spine and six rays in the first dorsal; adipose fin present, it and the anal of moderate lengths. Ventral with six rays, situated posterior to the base of the dorsal: caudal forked. Air-vessel not enclosed in bone.

Geographical distribution.—Eastern Bengal and Assam to the Malay Archipelago.

SYNOPSIS OF INDIVIDUAL SPECIES

1. Leiocassis rama, A. 16. A dark shoulder mark. Body with short vertical dark marks. Eastern Bengal and Assam.

1. Leiocassis rama, Plate CXIV, fig. 2.

B. vi, D. $\frac{1}{6}$ | 0, P. 1/9, V. 6, A. 16 ($\frac{3}{1.3}$), C. 18.

Length of head 4 to $4\frac{1}{2}$, of caudal $4\frac{1}{2}$, height of body $4\frac{1}{2}$ to 5 in the total length. Eyes—subcutaneous, diameters 3 to $3\frac{1}{4}$ in the length of head, 1 diameter from the end of snout, and also apart. The greatest width of the head equals its length excluding the snout. There is a considerable rise in the dorsal profile to the base of the rayed fin. Upper jaw the longer. Upper surface of the head covered with skin, a rather wide median longitudinal groove which extends up the first third of the occipital process, which is twice as long as wide at its base, and a distinct oval interneural shield exists between it and the basal bone of the dorsal fin. Scapular process well developed: humero-cubital process rather longer than high at its base. Barbels—a short maxillary pair, two pairs behind the symphysis of the lower jaw, Teeth—in an uninterrupted, semicircular villiform band across the palate. Colours-golden, with short, vertical, brown marks and a dark shoulder spot.

Digitized by Google

In Ham. Buch. MSS. P. chandramara is said to be found in the Rangpur district in the Mahánandá and also in the Dinajpur district. In Purniah he records it as termed Thunka-patasi of the Kusi and Khamain at Bholahat. In the "Fishes of the Ganges," he remarks that P. rama is from the Brahmaputra. The fish I have here described from the same locality, appears to be a link between the two forms, as the Assam one is said to have on the nape a large black spot divided into four lobes, and which is not present in my specimens, whilst it is stated to differ from P. chandramara, chiefly in the latter being deficient in this mark. I have referred my specimen to the P. rama, as it came from Assam.

Blyth, who appears to have seen H. B.'s figure of *Pimelodus chandramara*, now missing from the Calcutta series of drawings, observed "B. chandramara is referred to Silundia by Valenciennes, and is described by Hamilton Buchanan to have only two cirri; but his unpublished figure represents six cirri distinctly, and in all this group the minute cirri are discernible with difficulty and are extremely liable to be overlooked.

Habitat.—Eastern Bengal and Assam. The specimen figured (twice life-size) was from Assam. This fish appears not to exceed 2 or 3 inches in length.

Genus, 3—Erethistes, † Mull. and Trosch.

Hara, Blyth.

Head osseous superiorly, somewhat depressed. Mouth small, terminal or sub-inferior, besides the occipital and humero-cubital processes there is a strong scapular one, none of which are covered by skin. Gill-openings narrow, the membranes being confluent with the skin of the isthmus. Eyes small, subcutaneous, not having a free orbital margin. Nostrils close together, separated by a barbel. Barbels eight, the maxillary ones with broad bases. Villiform teeth in the jaws, palate edentulous. First dorsal fin arising anterior to the ventrals, having an osseous, serrated spine and five or six branched rays: adipose dorsal present. Pectoral with a serrated spine. Air-vessel not enclosed in bone.

Geographical distribution.—From the Mahanuddee river in the West to the Salwein in British Burma. This genus extends inland to the Moora river at Bheer Bhoom in Bengal, to Assam (where in the Brahmaputra and waters in its vicinity the finest specimens are procured), and also as high as Mandalay in upper Burma. It has been reported from Chusan by McClelland.

SYNOPSIS OF SPECIES.

- 1. Erethistes hara, D. $\frac{1}{6} \mid 0$, A. 10. Blunt spinate ossicles in the skin. Serrations on outer edge of pectoral spine, directed alternately forwards and backwards. No elongated caudal ray. Bengal, Assam, and Burma.
- 2. Erethistes conta, D. $\frac{1}{6} \mid 0$, A. 10. Skin tuberculated. Serrations on outer edge of pectoral spine directed backwards. Upper caudal ray elongated. Bengal and Burma.

 3. Erethistes Jerdoni, D. $\frac{1}{6} \mid 0$, A. 10. Skin smooth. Serrations on outer edge of pectoral spine directed backwards. Spine elongated. No prolonged caudal ray. Sylhet.

 4. Erethistes elongata, D. $\frac{1}{6} \mid 0$, A. 10. Skin tuberculated. Head $6\frac{1}{2}$ in the total length. Dorsal spine corrected on both edges. Both could be be also at the countered.
- serrated on both edges. Both caudal lobes elongated. Naga hills.
 - 1. Erethistes hara, Plate CII, fig. 1 (adult), fig. 2 (half-grown).

Pimelodus hara, Ham. Buch. Fish. Ganges, pp. 190, 378; Cuv. and Val. xv, p. 152. Erethistes pusillus, Müll. and Trosch. Horæ Ich. 1849, p. 12, t. i, f. 2; Günther, Catal. v. p. 263; Day,

P. A. S. of Beng. 1872, p. 122.

Hara Buchanani, Blyth, P. A. S. of Beng. 1860, p. 152; Günther, Catal. v, p. 189; Day, P. Z. S. 1869, p. 369. Nga-kyouk-pah, Burmese.

D. $\frac{1}{6}$ | 0, P. 1/6, V. 6, A. 10-11 $(\frac{1}{7}^3)$, C. 15.

Length of head 4 to $4\frac{1}{2}$, of candal 5, height of body $4\frac{1}{2}$ to 5 in the total length. Eyes—diameters about 10 in the length of head, situated in the commencement of the hind half of the head, 3 diameters apart. The greatest width of the head equals its length, and one-third or 1/4 more than its height. Upper jaw slightly the longer, the width of the mouth equal to 1/3 of the length of the head. A semilunar subcutaneous bone surrounds the anterior and lower margin of the nasal orifices, which are close together but divided by a barbel. Median longitudinal groove on the head shallow and reaches to opposite the hind edge of the eye. Occipital process from twice in the adult to about three times in the young, as long as wide at its base: humero-cubital process elongated and rugose, having two rounded osseous projections posteriorly: between the humero-cubital and occipital process is a third intermediate one, the scapular, directed somewhat downwards: the basal bone of the dorsal fin considerably dilated externally. Barbels—the nasal ones short, the maxillary ones reach the base of the pectoral fin, the mandibular ones arise on a transverse line, the external reach the gill-openings, whilst the internal are shorter. Teeth—none on the palate. Fins—dorsal spine stout, from 3/4 to nearly as long as the head (in the adult comparatively longest as is also the pectoral spine) serrated posteriorly, and sometimes rugose anteriorly: length of the base of the adipose dorsal 4/7 of that of

^{*} So difficult is it to distinguish the minute barbels in this fish, that I have only been able to do so, by floating the specimens in water over a dark substance † See Proc. Asi. Society of Bengal, 1872, p. 122.

the rayed fin, equalling the length of the interspace between the two fins and 1/3 longer that high. Pectoral spine from as long as, to 1/4 longer than, the head, strong, flattened, denticulated internally and serrated externally, each alternate tooth (in many, especially small, specimens) being directed anteriorly or posteriorly, the fin reaches the ventral, and the latter the anal, this last being highest anteriorly. Caudal forked. Shin—covered with small, pointed elevations, which in the posterior part of the body are arranged in parallel lines, they are also seen on the cheeks. When captured the secretion from each of these orifices forms over them in rounded incrustations, causing the skin to appear tuberculated. Air-vessel—large and not enclosed in bone. Colours—yellowish-brown, banded or blotched with darker: fins with black bands or markings: all the barbels annulated with black.

Hubitat.—Rivers and contiguous pieces of water from Orissa, through Bengal, Assam, and Burma, attaining at least $5\frac{1}{2}$ inches in length. The large specimen figured is from Suddya in Assam, the smaller from a specimen now in the Calcutta Museum. Those from the Naga hills are more deeply coloured, and the under

surface of the chest is covered with the orifice of numerous glands.

2. Erethistes conta, Plate CII, fig. 5.

Pimelodus conta, Ham. Buch. Fish. Ganges, pp. 191, 379; Cuv. and Val. xv. p. 151. Hara filamentosa, Blyth, P. A. S. of Bengal, 1860, p. 152; Günther, Catal. v, p. 189. Hara conta, Günther, l. c.; Day, J. A. S. of Beng. 1870, p. 40, pl. iv, f. 3. Nga-that-to (Upper Burma): Nga-kouk-thwa (Bassein) Burmese.

D. $\frac{1}{6}/0$, P. 1/6, V. 6, A. 11 ($\frac{3}{8}$), C. 17.

Length of head 5, of caudal $4\frac{1}{2}$, height of body $4\frac{1}{4}$ in the total length (excluding the filamentous prolongation of the upper lobe of the caudal fin. Eyes—diameters 8 in the length of the head, slightly behind the middle of the length of the head, and $2\frac{1}{2}$ diameters apart. The greatest width of the head rather less than its length. Upper jaw slightly the longer, median longitudinal groove on the head rather deep and extends to the base of the occipital process, which latter is three times as long as wide at its base: humero-cubital process elongated, rough, and with two rounded osseous projections posteriorly: between the humero-cubital and occipital process is a third intermediate one, the scapular, directed somewhat downwards: basal bone of the dorsal fin not dilated externally. Barbels—the nasal short, the maxillary as long as the head, the mandibular ones, which arise on a transverse line, shorter. Fins—dorsal spine strong, nearly as long as the head, rugose anteriorly, denticulated posteriorly: length of the base of the adipose dorsal equals that of the first dorsal fin, or the interspace between the two fins, it is 1/3 as high as long. Pectoral spine rather shorter than the head, denticulated internally, and with backwardly directed serrations externally. Caudal forked, its upper lobe having a filamentous prolongation. Skin—covered with smooth tubercles, most of which are on a rounded base. Colours— as in E. hara, except that the mandibular barbels do not appear ever to be annulated with black, and sometimes the maxillary ones are even destitute of colour.

Habitat.—Eastern Bengal, Assam, Burma as far as the Tenasserim province, from whence Major Berdmore sent 5 or 6 specimens to the Calcutta Museum. They are found as high as Prome, and I have also

taken them at Bassein.

3. Erethistes Jerdoni, Plate CII, fig. 3.

Day, Journ. As. Soc. of Bengal, 1870, p. 37.

D. $\frac{1}{5}/0$, P. 1/6, V. 6, A. 10, C. 12.

Length of head $3\frac{3}{4}$, of caudal 6, height of body 4 in the total length. Eyes—in the anterior half of the head, 3 diameters from end of snout. Head 1/2 wider than high opposite the opercles. Median longitudinal groove extends nearly to the base of the occipital process where it terminates in a small depression. Occipital process half longer than wide at its base: cubito-humeral process of an elongated triangular shape having two prominent ossicles posterior to it; between these two processes is a third. Barbels—The maxillary reach the gill-opening, the others are shorter. Fins—dorsal spine half as long as the head, it is serrated posteriorly: the length of the base of the adipose dorsal is 2/3 that of the rayed fin. Pectoral spine flattened and rather exceeding the distance between the snout and the base of the dorsal fin, when laid flat it reaches as far as the posterior end of the ventrals, it has 12 strong denticulations internally, 26 smaller ones, directed backwards, externally. Caudal rays elongated. Skin—smooth. Colours—brownish, irregularly banded, barbels annulated with black.

Habitat.—Sylhet district, out of 3 specimens shown me by the late Dr. Jerdon, the largest was only 1.5 inches in length.

4. Erethistes elongata, Plate CII, fig. 4.

Hara elongata, Day, Proc. Zool. Soc. 1871, p. 704.

D. $\frac{1}{6}/0$, P. 1/6, V. 6, A. 10 ($\frac{3}{7}$), C. 17.

Length of head $6\frac{1}{2}$, of caudal 4, height of body 7 in the total length. Eyes—small, situated in the posterior half of the head. Occipital process three times as long as wide at its base. The scapular and cubito-humeral processes well developed, the last having an oval ossicle posterior to it. Fins—dorsal spine stout, as long as the head, anteriorly strongly denticulated, the teeth being directed downwards, also slightly serrated

posteriorly. Pectoral spine one fourth longer than that of the dorsal and serrated on both edges, most strongly Ventral extends two-thirds of the distance to the anal: caudal deeply forked, its outer rays being prolonged. Skin-covered with tubular porcs. Colours- brownish, banded with darker: fins yellow with black bands.

Hubitat.—Naga Hills from whence the single specimen (figured life-size) was procured.

Genus, 4-RITA, Bleeker.

Gogrius, Day.

Branchiostegals eight. Gill-openings with a free posterior edge and not confluent with the skin of the isthmus. Mouth transverse, upper jaw the longer, nostrils on either side sub-contiguous, but the pair on one side widely separated from that on the other. Eyes subcutaneous, without free circular margins. Barbels six, a minute pair at the posterior nostrils, a maxillary and a mandibular pair. Teeth villiform in both jaws or mixed with molarform ones in the mandibles, molarform on the pulate. One strong spine and six rays in first dorsal fin, the adipose and the anal of moderate lengths. Ventral posterior to the base of the dorsal, and having seven or eight rays: caudal forked. Airvessel not enclosed in bone, with or without a posterior prolongation. The ova are much larger than in Macrones, but very much smaller than in Arius and its allies. A strong cubito-humeral process protects the pectoral spine when it is flexed along the side of the body.

Geographical distribution.—Large rivers of Sind, India (except its southern portions) and Burma far

above Mandalay.

Uses—food for the lower classes. It retains life long subsequent to its removal from water, and can be conveyed fresh for long distances.

SYNOPSIS OF SPECIES.

A. Some of the posterior teeth in the lower jaw molarform.

1. Rita Buchanani. Eye, 8 to 10 diameters in length of head. Patches of teeth in palate wide apart. Dorsal spine in the adult as long or longer than the head, entire anteriorly. Indus and affluents, also Jumna, Ganges and Irrawaddi.

2. Rita pavimentata. Eye, 5½ to 6 diameters in length of head. Patches of teeth in palate close together. Dorsal spine as long as head excluding the snout, entire anteriorly. Deccan, throughout Kistna and its

3. Rita chrysca. Eye, 4 diameters in the length of head. Patches of teeth in palate close together in their front halves. Dorsal spine longer than the head, coarsely serrated anteriorly in its whole extent. Orissa.

B. Teeth in lower jaw villiform or cardiform.

Eye, 4; to 5 diameters in length of head. Patches of teeth in palate wide apart. 4. Rita hastata. Dorsal spine as long or longer than the head, serrated anteriorly in its lower third. Deccan, throughout the Kistna and its tributaries.

A. Some of the posterior teeth in the lower jaw molarform.

1. Rita Buchanani, Plate CIII, fig. 1 (semi-adult), 2 (immature), and Plate CIV, fig. 2 (young).

Nga-htway, Burmese.

B. viii, D. $\frac{1}{6}/0$, P. 1/10, V. 8, A. 12-13 ($\frac{4-5}{6}$), C. 19.

Length of head 4 to $4\frac{1}{3}$, of caudal 5, height of body $5\frac{1}{2}$ to 6 in the total length. Eyes—diameters 8 to 10 in the length of head, 3 diameters from the end of snout and 4½ apart. The greatest width of the head equals its length behind the nostrils, whilst its height is a little less. Upper surface of the head covered with skin except a strip anterior to the base of the occipital process, that bone, the scapular and cubito-humeral processes are granulated, the occipital process nearly as long as wide at its base, notched anteriorly to receive the basal bone of the dorsal fin and which is nearly as long as the occipital process. Upper jaw the longer: width of the mouth nearly equals half the length of the head. Cubito-humeral process more pointed in young than in adult specimens and about 3/4 the length of the head. Barbels—the nasal short: the maxillary nearly reach the end of the head, and the mandibular ones almost as far. Teeth—villiform in the upper jaw, also in the anterior portion of the mandible, and in an outer row along either ramus, whilst internally are two or three rows of rounded teeth, the most posterior of which are the largest: in two elliptical patches of rounded ones on the palate, which are wide asunder along the median line but coalesce anteriorly. Fins-dorsal spine very strong and slightly serrated posteriorly in its upper portion, its length varies being shortest in the immature, it is generally as long as the head (except in the young) or even 1/3 longer in adults, especially in those from

* If the specific or even the generic name of Indian fishes given in Owen's Catalogue of specimens in the Museum of the College of Surgeons, or in corresponding advantage.

Techaps however this fish should be named R. ritoides.

† A specimen from Sind 2'8 inches long has the dorsal spine as long as head without the snout, and not reaching the base of the adipose fin.

the Indus: base of adipose fin 1/2 or 2/3 that of the rayed fin, or of the interspace between the two fins. Pectoral spine (except in the very young) somewhat shorter than that of the dorsal and denticulated on both edges. Ventrals arise just behind the vertical from the last dorsal ray. Anal 1/2 higher than its base is long. Colours—lurid green, lightest below, and the hind edge of the dorsal sometimes blackish. Air-vessel—with a thick outer covering, and of an almost quadrangular form, whilst posteriorly it is continued into two horn-like prolongations nearly as long as the abdominal cavity, the right one generally passing over to the left side and curving across the commencement of its fellow, whereas the left one passes backwards, and is then as a proportion of the inferior and the i rule recurved on itself. On the inferior wall being removed a longitudinal median partition is seen in its posterior half, dividing it into two lateral chambers which anteriorly communicate together, whilst posteriorly they are continued down the two horn-like processes.

The type of Arius ritoides, C. V. is still at Paris in good preservation, it is nearly 6 inches in length and appears to be the young of this species, as seen in plate CIII, fig. 2. The dorsal spine reaches the commencement of the adipose fin and is longer than in R. pavimentata, with which species Dr. Günther unites

it, but with a point of doubt.

Habitat.—Indus and affluent rivers, Jumna and Ganges, also the Irrawaddi: attaining at least 4 feet in length. The specimen figured (fig. 1) is 11 inches in length from Calcutta, the second (life-size) is from Lahore. This fish is esteemed as food by the natives, but is a very foul feeder.

2. Rita pavimentata, Plate CIII, fig. 3.

Arius pavimentatus, Val. in Jacq. Voy. Ind. Oriental, Atl. Poiss. pl. 17, f. 23; Cuv. and Val. xv, p. 94. Phractocephalus gogra, Sykes, Trans. Zool. Soc. ii, p. 374, t. 66, f. 1.

Rita pavimentata, Günther, Catal. v, p. 93.

Banki yeddu, Tel.: Pilah-gokundu, Hind.

B. viii, D. $\frac{1}{6}/0$, P. 1/10, V. 8, A. 12-13 $(\frac{4}{8-9})$, C. 17.

Length of head $3\frac{3}{4}$ to 4, of caudal $6\frac{1}{2}$, height of body 6 in the total length. Eyes—covered by skin which however forms a rather free margin along its lower edge: diameters $5\frac{1}{2}$ to 6 in the length of head, 2 to $2\frac{1}{4}$ diameters from the end of snout and $2\frac{1}{2}$ apart. Greatest width of the head equals its length behind the angle of the mouth. Upper jaw the longer, the width of the mouth equals 3/10 of the length of the head. Upper surface of the head and occipital process smooth, being covered by skin. Occipital process rather more than twice as long as wide at its base, it is notched anteriorly to receive the V-shaped basal bone. Scapular process short, the cubito-humeral one pointed, as long as the head behind the middle of the eyes, or even a little longer, and roughened in lines. Barbels—the maxillary do not quite reach the posterior end of the head, the mandibular pair extend a little further: the nasal ones are very short. Teeth—in villiform or cardiform rows in both jaws: the posterior rows in the lower jaw, commencing behind the symphysis, with rounded crowns, their size augmenting laterally. Those in the palate in two semi-elliptical patches of rounded ones which are almost continuous along the median line, the posterior being much the largest. Fins—dorsal spine of moderate strength, as long as the head excluding the snout and finely servated posteriorly in almost its entire extent: length of the base of the adipose 3/4 of that of the rayed fin and nearly equal to the extent of the interspace between the two fins. Pectoral spine stronger and a little longer than that of the dorsal, it is denticulated on both edges, it does not reach so far as the ventral fin. Anal rays appear to be sometimes deficient in number. Colours—of a dull yellowish colour, with dark or even black fins.

A drawing and description of this species exists amongst Sir W. Elliot's collection, the locality is not

given, but it was probably from the Kistna, it is termed "Ghogra."

Habitat.—From Poonah and the rivers in the Deccan and affluents of the Kistna. The specimen figured (life-size) was from Kurnool.

3. Rita chrysea, Plate CIV, fig. 1.

B. viii, D. $\frac{1}{6}$ | 0, P. $\frac{1}{9}$, V. 8, A. 12 $\frac{2}{10}$, C. 18.

Length of head $4\frac{1}{4}$, of caudal $4\frac{1}{3}$, height of body 6 in the total length. Eyes—covered by the skin which however is a little reflected along its lower edge, diameters 4 in the length of the head, $1\frac{1}{4}$ diameters from the end of snout, and 1 apart. The greatest width of the head equals its length excluding the snout, its height is slightly less. Upper jaw the longer, the width of the mouth equals 4/13 of the length of the head. Upper surface of the head mesially and posteriorly, also the occipital and scapular processes, rough. Occipital process as wide at its base as it is long, notched anteriorly to receive the basal bone. Cubito-humeral process as long as the head excluding the snout. Barbels—nasal ones short, the maxillary reach the base of the pectoral fin, the mandibular slightly shorter. Teeth—villiform in both jaws, and two or three of the inner rows in the mandibles with globular crowns: in two patches of globular headed teeth on the palate, these patches converge anteriorly so as to touch one another in their front half. Fins—dorsal spine strong, reaching to about the middle of the adipose fin and nearly 1/2 longer than the head, it is coarsely serrated anteriorly in its whole extent, and very finely serrated posteriorly. Pectoral spine rather longer than the head and denticulated on both sides. Caudal deeply forked. Colours—yellowish, the ends of the fins stained grayish.

This appears to be the only form in India propose larging the derest spine corrected enteriorly.

This appears to be the only form in India proper having the dorsal spine serrated anteriorly in its

Habitat.—Orissa, where the single specimen (figured life-size) was captured.

B. Teeth in both jaws, villiform or cardiform.

1. Rita hastata, Plate CIII, fig. 4.

Rita hastata, Günther, Catal. v, p. 93.

Rita kuturnee, Günther, Catal. v, p. 93.

B. viii, D. $\frac{1}{6}$ | 0, P. 1/10, V. 7-8, A. 13-14 ($\frac{5}{8-9}$), C. 17.

Length of head $4\frac{1}{4}$ to $4\frac{2}{3}$, of caudal 5 to 6, height of body 6 in the total length. Eyes—covered with skin, pupil oval, diameters $4\frac{1}{3}$ to 5 in the length of head, $1\frac{1}{3}$ diameters from the end of snout, and 1 apart. Greatest width of the head equals its length behind the angle of the mouth: upper jaw the longer: the width of the mouth 3/8 of the length of the head. Upper surface of the head (except just anterior to the occipital process) covered with skin, the portion in front of the occipital process and the process itself with roughened lines, the latter half longer than wide at its base, anteriorly emarginate to receive the basal bone of the dorsal fin. Scapular process rough but not elongated. Cubito-humeral process as long as the head, sharply pointed posteriorly, and rugose in lines. Barbels—the maxillary reach the base of the pectoral fin, the mandibular to below the hind edge of the eye: the nasal ones short. Teeth—in villiform or cardiform rows in both jaws: in two elliptical patches on the palate, converging anteriorly, and widely asunder along the median line, they consist of pointed ones anteriorly and more granular ones behind. Fins-dorsal spine of moderate strength, as long as, or even longer than, the head, finely serrated posteriorly in its upper portion, and also anteriorly along its lower third: length of the base of the adipose dorsal 2/3 of that of the rayed fin: pectoral spine stronger and a little longer than that of the dorsal, denticulated on both edges: caudal Colours—brownish along the back, silvery on the sides.

The type specimen of A. hastatus, Val. is about 41 inches in length and may have come from Poona

where it is common, it has villiform teeth in the jaws.

Habitat.—Deccan, Poona, Tamboodra and Kistna rivers.

Genus, 5-Arius, Cuvier and Valenciennes.

Sciades, sp. and Ariodes, Müll. and Trosch.: Hexanematichthys, Guiritinga, Hemiarius, Cephalocassis, Netuma and Pseudarius, Bleeker.

Branchiostegals from five to six. Gill-membranes not confluent with the skin of the isthmus, and scarcely, or not notched. Head osseous superiorly, or covered with very thin skin. Eyes with free orbital margins. Mouth anterior: upper jaw generally the longer. Anterior and posterior nostrils placed close together, the latter being provided with a valve. Barbels six, one maxillary, and two mandibular pairs. Teeth in the jaws villiform: there are nearly* always palatine, and sometimes vomerine ones, these may be villiform or granular. First dorsal with one spine and seven rays: † the adipose of moderate length or short: pectoral spine strong and serrated: ventral with six rays, situated behind the vertical from the posterior margin of the rayed dorsal fin: caudal forked or emarginate. An axillary pore. Air-vessel not enclosed in bone.

Considerable stress has been laid in this genus upon the character of the teeth, and whether they are villiform or granular forms a good method of division. Further sub-divisions, as whether the groups are continuous or not so, appear unadvisable, because in some species the size of the patches of palatine teeth increase with age, thus altering their original conformation, and causing one patch to impinge on its

There is likewise another question as regards the palatine teeth in these fishes, in Arius jatius there are usually two small patches of palatine teeth widely separated along the median line: but in some specimens such are entirely absent as stated by Hamilton Buchanan, and subsequently denied by others. The specimen figured has no trace of palatine teeth. Arius tenuispinis appears to me to be so similar to A. Layardi, Günther, excepting in having no palatine teeth, that I cannot help thinking they are identical, but have no series to confirm or disprove this supposition. Consequently genus $Hemipimelodus, \ddagger$ Blecker, has its representatives in India, but such are either abnormal specimens in which the palatine teeth were absent from birth, or else have become lost due to age. These species would appear to be such as have globular teeth.

The air-vessel is not enclosed in bone, is large, heart-shaped, and internally subdivided into five chambers, which communicate together anteriorly, the front one which is the largest occupies its anterior portion, behind it a median septum divides it down the centre, and lateral partitions subdivide the posterior chambers into four. (see A. gagora, p. 465.)

The breeding of these fishes is peculiar and deserves attention, the eggs of Arius are large, averaging about 0.5 to 0.6 of an inch in diameter and I found many males, also of Osteogeniosus, with from 15 to 20 of them

* Species destitute of palatine teeth belong to genus Hemipimelodus, Bleeker.

† Six in some South American species according to Valenciennes. ‡ Dr. Gunther observes, "In species which have rudimentary vomerine teeth, these are sometimes entirely lost with age."

in their mouths. Some of these eggs were in an early stage of development, others nearly ready to be hatched: whilst in the mouth of one specimen was a hatched fry having the yolk bag still adherent. The eggs filled the cavity of the mouth and extended far back to the branchiæ.

In the female organs of generation the eggs seemed to come to maturity in batches of perhaps 50 at a time. On examining the conformation of the ventral fins, those of the females appeared to be larger than those of the males: the rays were thickened by a deposit of fat, whilst the innermost one had a large similar pad attached to its posterior edge. These fins can be expanded into a cup-like surface, the use of which may be to receive the eggs as extruded, which may be vivified there by the male.

Whether the male carries about these eggs in his mouth until hatched or only removes them when danger is imminent from some spot where he is guarding them is questionable, but in none of the specimens which I examined did I find a trace of food in the intestines of the males which had been engaged in this

interesting occupation.

This has been observed likewise elsewhere by Mr. Boake in Ceylon, and Dr. Hensel has recorded the same of a Brazil species A. Commersonii: Dr. Günther of Arius fissus from Cayenne: and the same facts have been remarked in other Siluroid fishes.

Geographical distribution,—Seas and estuaries of tropical regions, ascending to within the tidal influence or even entering fresh waters. They appear to be almost as unknown in the Red Sea as the Sciænidæ, and probably due to the same cause (see p. 181).

Uses.—As food of an inferior quality. On the Western coast of India they are largely salted and a considerable amount of coarse isinglass is procured for export to China by drying their air-vessels.

SYNOPSIS OF SPECIES.

A. Villiform teeth on the palate.

1. Arius Burmanicus, A. 19-22. Head $3\frac{1}{2}$ to $3\frac{2}{3}$ in the total. Eye, 7 to $8\frac{1}{2}$ in length of head. Mouth

spatulate. One patch of teeth not as large as eye on either side of palate. Burma.

2. Arius nenga, A. 19. Head 4½ in total length. Eye, 6 in length of head. Maxillary barbels reach last third of pectoral fin. Two trangular patches of teeth approximating superiorly. Dorsal spine as long as Dull yellow, fins blackish. Hooghly at Calcutta.

3. Arius calatus, A. 19. Head $4\frac{1}{2}$ to $4\frac{2}{3}$ in the total. Eye, 6 to 9 in the length of head. Maxillary barbels reach middle of pectoral fin. Two somewhat triangular patches of teeth, approximating anteriorly. Dorsal spine about as long as head. Seas of India to the Malay Archipelago.

4. Arius acutirostris, A. 19. Head $3\frac{1}{2}$ in the total. Eye, 7 in the length of head. Snout much produced. Maxillary barbels reach hind edge of eye. Teeth in two obliquely ovate diverging patches. Dorsal spine half

as long as head. Salwein river at Moulmein.

5. Arius Sumatranus, A. 18-19. Head 4½ to 4½. Eye, 5 in the length of head. Maxillary barbels reach end of head. Palatine teeth in two triangular patches diverging posteriorly. Dorsal spine not so long as head.

Seas of India to the Malay Archipelago.

6. Arius venosus, A. 18-19. Head $5\frac{1}{6}$ in the total. Eye, $4\frac{1}{4}$ in the length of head. Maxillary barbels reach base of pectoral fin. Teeth on the palate in patches as large as the eye, of a triangular shape, as broad as long, and directed backwards. Dorsal spine as long as the head behind the angle of the mouth. Nicobars, &c.

- 7. Arius parvipinnis, A. 19. Head $4\frac{3}{4}$ in the total length. Eye, $5\frac{3}{4}$ in the length of head. Maxillary barbels reach the end of the pectoral fin. Palatine teeth in a pear-shaped patch, the small end forwards and converging, widely diverging posteriorly. Dorsal spine nearly as long as the head. Coromandel coast of India.
- 8. Arius subrostratus, A. 17-20. Head $3\frac{1}{3}$ to 4 in the total. Eye, 5 to 6 in the length of head, and $2\frac{1}{3}$ to 3 diameters from end of snout. Maxillary barbels do not quite reach the eye. Teeth on the palate in a patch on either side not longer than the eye, and wide asunder. Dorsal spine rather above half as long as head. Malabar.
- 9. Arius sagor, A. 17-19. Head $4\frac{1}{4}$ to $4\frac{1}{3}$ in the total. Eye, $6\frac{1}{4}$ to 7 in the length of head. Head very broad: basal bone of dorsal fin large and butterfly-shaped. Maxillary barbels reach middle or end of pectoral spine. Teeth in two confluent patches on either side meeting anteriorly. Dorsal spine as long as the head

excluding the snout. Seas and estuaries of India to the Malay Archipelago.

10. Arius sona, A. 17. Head 4 in the total. Eye, 7 to 9 in the length of head. Maxillary barbels reach the end of the head. Palatine teeth on either side in a large triangular patch, emarginate posteriorly, and anteriorly conjoined by a small vomerine patch. Dorsal spine as long as the head excluding the snout.

Seas and estuaries of India and Burma.

11. Arius serratus, A. 16. Head $5\frac{1}{4}$ in the total length. Eye, $4\frac{1}{2}$ in the length of the head. Maxillary barbels reach the middle of the pectoral fin. Teeth on the vomer and palatines in three patches on either side converging in the median line anteriorly. Dorsal spine as long as the head behind the middle of the Sind.

12. Arius thalassinus, A. 15-17. Head $4\frac{1}{2}$ to 5 in the total length. Eye, diameter 5 in the length of the head. Maxillary barbels reach base of pectoral fin. Teeth on vomer and palatines in three patches on either side joining anteriorly in the median line. Dorsal spine nearly or quite as long as the head. Red Sea, seas of India to the Malay Archipelago and beyond.

Digitized by GOO

B. Globular teeth on the palate.

13. Arius Buchanani, A. 22. Head 42 in the total length. Eye, 7 to 81 in the length of head. The

maxillary barbels reach the first third of the pectoral spine. Teeth on the palate in two oval patches placed far back. Dorsal spine as long as the head behind the angle of the mouth. Hooghly and Burmese rivers.

14. Arius falcarius, A. 18-20. Head 4 to 5 in the total length. Eye, $5\frac{1}{2}$ to 6 in the length of head. The maxillary barbels reach end of head. Teeth on palate in two semi-triangular patches, parallel along the median line. Dorsal spine as long as the head excluding the snout. Seas estuaries of India to China.

15. Arius Malabaricus, A. 20. Head $4\frac{1}{4}$ in the total length. Eye, $6\frac{1}{2}$ in the length of head. Gape of mouth 2/5 of length of head. The maxillary barbels as long as the head. Teeth on palate in two oval patches well forwards and clickthy convergent enteriorly. Dorsal spine as long as the head behind the angle of the

well forwards and slightly convergent anteriorly. Dorsal spine as long as the head behind the angle of the mouth. Canara.

16. Arius platystomus, A. 19. Head 4 in the total. Eye, 7 in length of head. Width of gape of mouth 4/7 of the length of head. Maxillary barbels reach just beyond base of the pectoral. Teeth on palate in a pyriform band, placed well forward, slightly converging anteriorly. Dorsal spine as long as the head excluding the snout. Canara.

17. Arius nella, A. 19. Eyes small, in front half of head. Coromandel coast of India.

18. Arius macronotacanthus, A. 18-19. Head 4 to 4th in the total. Eye, 5th to 6 in the length of head. Maxillary barbels reach middle of pectoral spine. Teeth on palate in a pyriform band, placed well forwards, and widely divergent posteriorly. Dorsal spine as long as the head behind the nostrils. India to the Malay Archipelago.

19. Arius gagora, A. 18. Head 4 to $4\frac{1}{4}$ in the total length. Eye, 7 to 8 in the length of head. Maxillary barbels not quite so long as head. Teeth on palate in a large semi-ovate patch on either side nearly parallel with one another. Dorsal spine as long as the post-orbital portion of the head. Seas and estuaries of Orissa and Bengal to Siam.

20. Arius jatius, A. 18. Head $4\frac{1}{4}$ in the total length. Eye, $4\frac{1}{4}$ to 5 in the length of head. Maxillary barbels shorter than the head. Teeth in a small ovate patch posteriorly on either side or else absent. Dorsal spine as long as head excluding the snout. Estuaries and rivers of Bengal and Burma.

21. Arius tenuispinis, A. 18. Head $3\frac{1}{2}$ in the total. Eye, 7 in the length of head. Maxillary barbels as s the head. Teeth on palate absent (? two pear-shaped globular patches normally). Bombay, ? Ceylon. 22. Arius jella, A. 17-18. Head $4\frac{3}{4}$ in the total. Eye, 6 in the length of head. Maxillary barbels long as the head.

nearly as long as the head. Teeth on palate in two convex, oblong, ovate, patches rather convergent behind. Dorsal spine as long as the head excluding the snout.

23. Arius Dussumieri, A. 14-16. Head 4 to $4\frac{1}{2}$ in the total. Eye, $6\frac{1}{2}$ in the length of the head. Maxillary barbels rather longer than the head. Teeth on the palate in two patches on either side. Dorsal spine as long as the head excluding the snout. Malabar and Ceylon.

> A. Villiform teeth on the palate. 1. Arius Burmanicus, Plate CV, fig. 4.

Day, Proc. Zool. Soc. 1869, p. 618.

Nga-young, Burmese.

B. vi, D. $\frac{1}{7}/0$, P. 1/10, V. 6, A. 19-22 $(\frac{4-6}{16}, \frac{1}{16})$, C. 15.

Length of head $3\frac{1}{4}$ to $3\frac{2}{3}$, of caudal 5, height of body 7 in the total length. Eyes—without free orbital edges, diameter 7 to $8\frac{1}{2}$ in the length of head, $2\frac{1}{4}$ to 3 diameters from the end of snout, and $1\frac{1}{2}$ to 2 apart. Head depressed, snout spatulate, upper jaw the longer, the greatest width of head equals 2/5 of its length, whilst its height is less. The median longitudinal groove on the head narrow and does not extend so far as to the base of the occipital process which is keeled and rather wider at its base than it is long, whilst superiorly it reaches a V-shaped basal bone. Upper surface of the head with roughened lines which are closest together at the posterior end of the median groove and on the occipital process. Barbels—short, the maxillary do not quite reach the base of the pectoral fin, the outer mandibular are nearly as long. Teeth-those on the palate villiform in two small, oval, obliquely set, patches (not as large as the eye) and diverging posteriorly. Fins—the dorsal one-half higher than the body, its spine strong, half as long as the head, and serrated anteriorly and posteriorly: base of adjose dorsal about as long as that of the rayed fin. Pectoral spine of equal length, stronger, serrated on both edges. Ventral nearly reaches the anal. Colours—purplish, dashed with copper, becoming dull white on the sides and beneath. Both dorsal fins externally stained with black.

In external appearance this fish strongly resembles Macrones aor

Habitat.—Tidal rivers of Burma as at Bassein and Moulmein. The specimen figured (from Moulmein) is 9 inches in length. It attains at least a foot.

2. Arius nenga, Plate CIV, fig. 3.

Pimelodus nenga, Ham. Buch. Fish. Ganges, pp. 171, 376.

B. vi. D. $\frac{1}{7}/0$, P. 1/10, V. 6, A. 19 $\binom{6}{13}$, C. 17.

Length of head $4\frac{1}{4}$, of caudal 5, height of body 5 in the total length. Eyes—diameters 6 in the length of head, $2\frac{1}{4}$ diameters from the end of snout, and 3 apart. The greatest width of the head exceeds its height by 1/3, and is 1/6 less than its length. Upper jaw the longer, the width of the gape of the mouth equals half the length of the head. The median longitudinal groove on the head is shallow anteriorly but becomes narrow posteriorly and does not quite extend to the base of the occipital process, which latter is keeled, nearly as broad at its base as it is long: lasal bone of dorsal fin narrow and crescent shaped. Upper surface of the head almost as far forwards as the eyes, and the occipital process studded with coarse granules. Barbels—the maxillary pair reach the posterior third of the pectoral fin, whilst the outer mandibular ones are as long as the head. Teethon the palate villiform in two triangular patches, approximating superiorly and parallel along the median line. Fins—dorsal much higher than the body, the dorsal spine strong, as long as the head, and having an elongated soft prolongation, it is granulated anteriorly in its lower half, serrated in its upper, posteriorly it is serrated: base of adipose dorsal nearly as long as that of the rayed fin. Pectoral fin almost reaches the ventral, its spine is nearly as long as the head, rough, granulated externally and denticulated internally. Upper caudal lobe the longer. Colours—of a dull yellow, the fins being externally stained with black.

This species is closely allied to A. cælatus, its maxillary barbel is longer, the dorsal spine more produced,

and its colours different. It may be only a variety.

Habitat.—Hooghly at Calcutta from whence the specimen figured, life-size, was procured. Blyth says it attains 12 or 13 inches in length.

3. Arius cælatus, Plate CV, fig. 5.

Cephalocassis calatus, Bleeker, Ich. Arch. Prod. p. 110.

B. vi, D. $\frac{1}{7}/0$, P. $\frac{1}{9}$, V. 6, A. 19 $(\frac{5-6}{14})$, C. 15.

Length of head $4\frac{1}{3}$ to $4\frac{2}{3}$, of caudal 5 to 6, height of body $6\frac{1}{2}$ in the total length. Eyes—diameters 6 to 9 in the length of the head, 2 to 2½ diameters from the end of snout, and from 3 to 4 apart. Head broader than high, its greatest width being equal to its length posterior to the nostrils, the width of the mouth equals the postorbital length of the head or a little more. Upper jaw the longer, the angle of the mouth does not extend so far posteriorly as to below the orbit. Upper surface of the head and occipital process strongly granulated, the median longitudinal groove narrow and deep posteriorly and does not quite reach the base of the occipital process, which is a little keeled, as broad or slightly broader at its base than it is long, its anterior extremity slightly concave and reaches to the basal bone which is V-shaped and rather narrow. Barbels—the maxillary ones reach the middle of the pectoral fin, whilst the external mandibular ones are one-fifth shorter. Teethvilliform in two somewhat widely separated triangular patches, the vomerine being confluent with the palatine ones. Fins—dorsal spine very strong especially in its lower half, which is granulated both laterally and anteriorly, serrated in its upper portion, also posteriorly in its whole extent, it is nearly or quite as long as the head and has a soft prolongation: base of adipose dorsal shorter than that of the rayed fin, and equals about half of the extent of the interspace between the two fins. Pectoral spine as strong as, but rather shorter than, that of the dorsal, it is granulated externally, serrated internally. Ventral does not reach the anal. Upper caudal lobe sometimes the longer. Colours—bluish along the back and sides, becoming white beneath. Adipose dorsal black, with its inferior and posterior margins yellow. Superior portion of dorsal, the end of the pectoral and ventrals black, as is also the anterior part of the anal.

Arius aquibarbis is said to have A. 22, its outer mandibular barbels as long as the maxillary one, and its caudal lobes 1/4 of the entire length, and coming from Bengal and Rangoon.

Habitat.—From Bombay through the Indian Seas to the Malay Archipelago, it is not uncommon at Calcutta. The specimen figured is 8 inches in length and from Moulmein: it attains a considerable size.

4. Arius acutirostris, Plate CVII, fig. 1.

B. v, D. $\frac{1}{7}$ | 0, P. 1/10, V. 6, A. 19 $(\frac{5}{14})$, C. 17.

Length of head $3\frac{1}{2}$, of caudal 6, height of body 7 in the total length. Eyes—diameters 7 in the length of head, $3\frac{1}{2}$ diameters from the end of snout, and 2 apart. The greatest width of the head equals about half its length, and is one-sixth more than its height. Snout fleshy and elongated, extending some distance beyond the mouth mouth inferior, the extent of its gape equalling one-third of the length of the head. Upper surface of the head granulated, or with roughened lines. Median longitudinal groove on head does not extend to the base of the occipital process which is slightly keeled, rather longer than wide at its base, and reaches the narrow V-shaped basal bone of the dorsal fin. Barbels—short, the maxillary reach beyond the hind edge of the eye: the outer mandibular ones are about one-third of the length of the head, whilst the inner ones are shorter. Teeth—the villiform band in the premaxillaries is about 1/3 as deep as wide: those

Digitized by GOO

on the palate likewise villiform in two somewhat obliquely oval patches diverging anteriorly. Fins-dorsal spine rather strong, half as long as the head and serrated on both sides: the length of the base of the adipose fin equals 2/3 of the length of that of the rayed fin. Pectoral spine of about the same length as that of the dorsal and serrated on both edges, the fin reaches 2/3 of the distance to the ventral, whilst the latter does not extend to the anal. Colours—upper portion of rayed and also of 2/3 of adipose dorsal black: pectoral, ventral, and anal stained gray.

Habitat.—The Salwein river at Moulmein in Burma. It attains a foot or more in length.

5. Arius Sumatranus, Plate CVII, fig. 6.

Bagrus Sumatranus, Bennett, Life of Sir S. Raffles, p. 691. Arius Sumatranus, Günther, Catal. v, p. 162.

B. vi, D. $\frac{1}{7}$ | 0, P. 1/10, V. 6, A. 18-19 $(\frac{5}{13-14})$, C. 17.

Length of head $4\frac{1}{4}$ to $4\frac{1}{2}$, of caudal $5\frac{1}{4}$, height of body $5\frac{1}{2}$ in the total length. Eyes—diameters 5 in the length of head, $1\frac{3}{4}$ diameters from the end of snout, and 2 apart. The greatest width of the head exceeds its height and equals its length behind the angle of the mouth. Upper surface of the head with scattered granulations, which are more lineated on the occipital process. Median longitudinal groove becomes narrow posteriorly, nearly reaching the base of the occipital process, its edges in the last portion of its extent are raised. Occipital process slightly keeled, as broad at its base as it is long: basal-bone crescent shaped and narrow. Barbels—the maxillary ones reach end of the head, the outer mandibular ones the base of the pectoral fin. Teeth—in palate villiform, in two triangular patches diverging posteriorly. Fins—dorsal spine as long as the head behind the angle of the mouth, and serrated on both edges: base of adipose dorsal 2/3 of that of the rayed fin. Pectoral spine as long as the head excluding the snout, externally it is roughened in its lower, serrated in its upper portion, internally it is denticulated, it does not reach the ventral. Ventral reaches 2/3 of the way to the anal. Colours—bluish-green superiorly, becoming lighter on the sides and beneath: edges of fins stained gray, very little black on adipose dorsal.

This fish is closely allied to A. venosus, but has a longer head, &c.

In the type specimen, which is in a very bad state, the cubito-humeral process is larger than in my specimen, and the summit of the head is more granulated, and the palatine group of teeth is divided.

Habitat.—Andamans to the Malay Archipelago.

6. Arius venosus, Plate CVI, fig. 2.

Cuv. and Val. xv, p. 69; Bleeker, Silur. Batav. p. 39, and Atl. Ich. Silur. p. 33, t. 54, f. 1; Günther, Catal. v, p. 159.

Arius læviceps, micruropterygius, manjong, and micronotacanthus, Blecker, Silur. Batav. pp. 36, 38. Cephalocassis venosus, Bleeker, Prod. Silur. p. 113.

B. vi, D. $\frac{1}{7}$ | 0, P. $\frac{1}{10}$, V. 6, A. 18-19 $\binom{5-6}{13}$, C. 17.

Length of head $5\frac{1}{6}$, of caudal 5, height of body 6 in the total length. Eyes—diameters $4\frac{1}{4}$ in the length of head, $1\frac{1}{2}$ diameters from the end of snout, and 2 apart. Snout rather obtuse, and the upper jaw the longer: the width of the gape of the mouth equals 1/2 the length of the head. The greatest width of the head equals its length excluding the snout, and slightly exceeds its height. Upper surface of the head with scattered granulations, which are more numerous on the occipital process. Median longitudinal groove on the head shallow except in its posterior portion, which is narrow and deep as far as the base of the occipital process which is keeled, and as broad at its base as it is long. Basal bone V-shaped, and laterally narrow. Barbels—the maxillary ones extend to the base of the pectoral fin, the outer mandibular ones are shorter. Teeth—villiform on the palate, in two triangular patches, the points of which are directed backwards, the patches are about as large as the eye, as broad as long, and rather approximating anteriorly. Fins—the dorsal as high as the body, its spine rather strong and as long as the head behind the angle of the mouth, anteriorly it is serrated in its upper, granulated in its lower half, posteriorly it is serrated: base of adipose dorsal equals half that of the rayed fin. Pectoral spine as long as that of the dorsal, granulated and serrated externally, denticulated internally. The ventral reaches the anal: upper caudal lobe the longer.

This species differs from A. Sumatranus, more especially in having a comparatively much shorter head. Habitat.—From Burma to the Malay Archipelago. The specimen figured was from the Nicobars.

7. Arius parvipinnis, Plate CXIII, fig. 1.

Silurus, Russell, ii, p. 52, and Chinta jellah, pl. 167.

? Bagrus chinta, Cuv. and Val. xiv, p. 445. ? Arius chinta, Bleeker, Beng. en Hind. p. 56.

B. vi, D. $\frac{1}{7}$ \ 0, P. 1/10, V. 6, A. 19 $(\frac{5}{14})$, C. 18.

Length of head $4\frac{3}{4}$, of caudal $4\frac{1}{4}$, height of body 6 in the total length. Eyes—in anterior half of the head, diameters $5\frac{3}{4}$ in the length of head, $1\frac{2}{3}$ diameters from the end of snout, and 3 apart. Greatest width of the head equals its length behind the nostrils, and exceeds its height by 1/4. Upper jaw somewhat

the longer: the width of the gape of the mouth equals that of the postorbital length of the head. Upper surface of the head and occipital process studded with coarse granulations. Median longitudinal groove on head well marked, lanceolate, its last portion deep and not extending to so far as the base of the groove on head well marked, lanceolate, its last portion deep and not extending to so far as the base of the occipital process, which latter has a granulated keel along its centre, is as long as wide, and reaches a narrow crescentic basal bone. Barbels—the maxillary reach the end of the pectoral fin. Teeth—in two pearshaped crescentic patches of villiform ones, placed well forwards, diverging, and their small end anterior. Fins—dorsal spine strong, laterally roughened, serrated anterior in its upper half, also posteriorly, it is as long as the head behind the angle of the mouth. Pectoral spine stronger, of the same length, and serrated on both edges, it reaches two-thirds of the distance to the ventral: the latter is very small, a little above half as long as the pectoral, and does not reach the anal. Caudal deeply lobed, with its upper one rather produced. Colours—on the upper surface dull leaden, sides and abdomen whitish, adipose dorsal with a black blotch: nectoral ventral and outer half of anal dark blotch: pectoral, ventral, and outer half of anal dark.

The only objection to considering this fish Russell's is, the teeth are villiform, it is evidently closely allied to A. macronotacanthus, which however has large pectoral and ventral fins.

Habitat.—Coromandel coast of India.

8. Arius subrostratus, Plate CVI, fig. 6.

Arius subrostratus, Cuv. and Val. xv, p. 62; Jerdon, M. J. L. and Sc. 1851, p. 146; Bleeker, Beng. en Hind. p. 58; Day, Fish. Malabar, p. 177.

Arius rostratus, Cuv. and Val. l. c. p. 63; Jerdon, l. c. p. 146; Bleeker, Beng. en Hind. p. 56.

B. vi, D. $\frac{1}{7}/0$, P. 1/9, V. 6, A. 17-20 $(\frac{5-6}{12\cdot 14})$, C. 17.

Length of head $3\frac{1}{3}$ to 4, of caudal 6 to 7, height of body 5 in the total length. Eyes—diameters 5 to 6 in the length of head, $2\frac{1}{4}$ to 3 diameters from the end of snout, and 2 to $2\frac{1}{4}$ apart. The greatest width of the head rather exceeds its height and equals 4/7 of its length. Snout elongated and a little depressed, the upper jaw the longer, the width of the gape equals 2/7 of the length of the head, depth of cleft short extending 1/3 of the distance to the orbit, median longitudinal groove on the head shallow, anteriorly becoming narrow, and posteriorly deep, it extends nearly to the base of the occipital process. Upper surface of the head behind the middle of the orbit granulated, as is also the occipital process which is rather wider at its base than it is long, has nearly straight lateral edges, and reaches the narrow basal bone of the dorsal fin. Barbels—short, the maxillary pair do not quite reach the eye, the outer mandibular are still shorter, and the internal the shortest. Teeth—those on the palate villiform, in two small patches wide asunder, on either side of the palate, not longer than the diameter of the eye. Fins-dorsal one-fourth higher than the body, its spine not very strong, rather above half as long as the head, rugose anteriorly, serrated posteriorly: length of the base of the adipose dorsal equals two-thirds of that of the rayed fin. Pectoral scarcely reaches the ventral, its spine is as long as, or a little longer than, that of the dorsal, serrated internally. Ventral reaches the anal, caudal forked. Colours—silvery-leaden colour along the back when fresh, a series of about 15 minutely spotted vertical bands are seen on the body. Fins stained with gray.

In Cuv. and Val. A. rostratus is stated to have the snout more elongated than in A. subrostratus; they

both come from the Malabar coast, and any differences are perhaps due to the age of the specimens. In some young specimens the filamentous prolongation of the dorsal fin reaches almost to the base of the caudal.

Habitat.—Malabar coast of India to a foot in length.

B. vi, D. $\frac{1}{7}/0$, P. 1/10, V. 6, A. 17-19 $(\frac{3-4}{14-15})$, C. 15.

Length of head $4\frac{1}{4}$ to $4\frac{1}{2}$, of caudal 5 to 6, height of body 5 in the total length. Eyes—diameters $6\frac{1}{4}$ to 7 in the length of head, 2 diameters from end of snout, and 3½ apart. Head depressed, much broader than high, its width equalling its length or a little less. Upper jaw the longer, the width of the gape of the mouth equalling 1/2 of the length of the head. The median longitudinal groove on the head shallow, extending to a little behind the posterior edge of the eye. Upper surface of the head granulated in radiating lines. Occipital process one-half wider at its base than it is long, its posterior extremity rounded where it meets the basal bone of the dorsal fin, which is large and somewhat butterfly-shaped. Barbels—the maxillary reach to the middle or end of the pectoral spine, the outer mandibular to its base or middle. Teeth—on the palate in two confluent villiform patches on either side, and meeting in the mesial line, each of these patches has a convex inner edge. Fins—dorsal higher than the body, its spine strong and as long as the head excluding the snout, granulated or serrated anteriorly, serrated posteriorly: the base of the adipose nearly as long as that of the rayed fin. Pectoral spine stronger and as long as that of the dorsal, serrated externally along its outer fourth and

denticulated internally, its outer ray often prolonged. Ventral nearly reaches the anal. Upper caudal lobe the longer. Colours—greenish-brown, becoming lighter on the abdomen, some specimens have narrow vertical bands of spots on the body. Fins tinged with dark.

Bagrus doroides has a few ossified plates along the first portion of its lateral-line.

Habitat.—From Bombay through the seas and estuaries of India to the Malay Archipelago. It is said to be very common at Batavia, where it is largely consumed. The specimen figured is 9 inches in length and from Calcutta: it attains at least 3 feet.

Netuma netuma, Day, Fish. Malabar, p. 175 (not Cuv. and Val.) Arius sona, Day, P. Z. S. 1871, p. 708.

B. vi, D. $\frac{1}{7}/0$, P. 1/12, V. 6, A. 17 ($\frac{6}{17}$), C. 17.

Length of head 4, of caudal 5 to 6, height of body 6 in the total length. Eyes-diameters 7 to 9 in the length of head, $2\frac{1}{2}$ to 3 diameters from the end of snout, and $3\frac{1}{2}$ to $4\frac{1}{2}$ apart. Head one-half broader than high, and almost as wide as long. Upper jaw the longer: the extent of the gape of the mouth equals two-thirds of the length of the head. Median longitudinal groove on the head wide but does not extend so far as the base of the occipital process, the latter being keeled, convex at its posterior extremity where it reaches the basal bone of the dorsal fin which is somewhat narrow, especially in its centre, whilst either side is slightly bent into an S-shaped form. The occipital process is as wide or rather wider at its base than it is long, it, and also the crown of the head from behind the eyes, are granulated, these granulations have somewhat of a radiating direction.

Barbels—the maxillary reach to the end of the head, the outer mandibular ones are shorter. Teeth—on palate villiform, those on the palatines on a large somewhat triangular patch which is emarginate posteriorly, anteriorly two small patches on the vomer connect the two palatine ones together. Fins—dorsal spine strong, granulated anteriorly, serrated posteriorly, and as long as the head excluding the snout, but not so high as the rays which are higher than the body: length of the base of the adipose dorsal equals that of the rayed fin. Pectoral spine stronger and usually slightly shorter than that of the dorsal, rough externally, sometimes even with a few serrations near its tip, serrated internally. Ventrals not reaching the anal. Caudal forked. Colours—brownish above, bluish on the sides where it is glossed with gold, and of a dull white beneath. Fins with a bluish-black tinge. Young specimens are of a brownish colour, superiorly glossed with purplish and yellow, the fins are nearly black.

Blecker, Atl. Ich. Silur. p. 36, considers Arius gagoroides=Pimelodus arius, H. B.=Arius arius, C. V. and Pseudarius arius, Bleeker, whereas I have considered them as four distinct species as follows, Arius gagoroides, C. V.=P. sona, H. B.: Pimelodus arius, H. B. is not Arius arius, C. V. but=Arius Buchanani; Arius arius, C. V.=A. falcarius, Richardson; Pseudarius arius, Bleeker=Arius angulatus, Bleeker, &c.

Habitat.—From Bombay through the seas of India, entering estuaries and tidal rivers. It attains at least three feet in length. The specimen figured is 7.5 inches in length and from Bombay.

11. Arius serratus, Plate XCV, fig. 3.

B. vi, D. $\frac{1}{7}/0$, P. 1/10, V. 6, A. 16 ($\frac{5}{11}$), C. 17.

Length of head $5\frac{1}{4}$, of caudal $4\frac{1}{4}$, height of body $5\frac{3}{4}$ in the total length. Eyes—diameters $4\frac{1}{2}$ in the length of head, $1\frac{1}{4}$ diameters from end of snout and 2 apart. The greatest width of the head equals its length behind the angle of the mouth. Upper jaw the longer, the width of the gape of the mouth equals half the length of the head. Upper surface of the head granulated or with rough lines, most distinct on the occipital process. Median longitudinal groove on the head does not quite reach posteriorly to above the hind edge of the opercle, from it commences a serrated ridge, which is continued along the occipital process. Occipital process with a serrated keel, a little longer than wide at its base. Basal bone narrow and crescent-shaped. Barbels—the maxillary ones reach to the middle of the pectoral fin, the outer mandibular ones to the gill-opening. Teeth-in the palate villiform in 3 distinct patches on either side, the vomerine patch round, small, and with an interspace between the two, and externally there is another rather longer oval patch. Posteriorly the third patch is parallel to the one on the opposite side. Fins—dorsal higher than the body, its spine which is serrated on both edges, is as long as the head behind the middle of the eyes, and has a soft termination: the length of the base of the adipose 1/2 of that of the rayed fin. Pectoral reaches rather above 1/2 way to the ventral, its spine stronger but not quite so long as that of the dorsal, externally it is rough in its lower, serrated in its outer half, internally it is denticulated. Ventral does not reach the anal. Upper caudal lobe the longer. Colours—upper surface of the head copper-coloured shot with gold, sides silvery. Fins yellowish, rayed dorsal stained with dark in its outer half: adipose fin with a black spot: a dark band, edged with white, along the outer half of the anal: either caudal lobe dark at its extremity.

This fish is nearly allied to A. thalassinus, but has much shorter pectoral fins, and longer maxillary

barbels. Whether the serrations along the occipital ridge are merely due to the specimen being young is questionable.

Habitat.—Sind, from whence the single specimen, figured life-size, was brought.

B. vi, D. $\frac{1}{7}$ | 0, P. 1/12, V. 6, A. 15-17 $(\frac{3-5}{12-13})$, C. 17.

Length of head $4\frac{1}{2}$ to 5, of caudal 5, height of body $5\frac{1}{2}$ to 6 in the total length. Eyes—longest diameter obliquely transverse, 5 in the length of the head, $1\frac{1}{4}$ to $1\frac{3}{4}$ diameters from the end of snout, and $2\frac{1}{2}$ to 3 apart. Width of head equals its length behind the angle of the mouth, it is broader than high. Upper surface of the head granulated: the median longitudinal groove, which is narrow posteriorly, extends to opposite the hind edge of the opercle. The occipital process is granulated, keeled, rather longer than wide at its base, it extends to the basal bone of the dorsal fin, which is small and crescentic in shape. Barbels—the maxillary extend nearly or quite to the base of the pectoral fin, the outer mandibular are a little shorter. Teeth—on the palate villiform, those of each side forming a triangle composed of three patches, two in front and a larger one behind (Pl. civ, fig. 4 b). Fins—dorsal spine as long as the head without the snout, or even a little longer, granulated anteriorly (with some serrations in the young), serrated posteriorly: base of adipose dorsal 2/5 of that of the rayed fin. Pectoral spine strong, but a little shorter than that of the dorsal, rough externally, feebly serrated internally: caudal with the upper lobe usually the longer. Colours—silvery, darkest superiorly: the upper half of the adipose dorsal black. In some specimens the dorsal surface is of a rich brown, and each of the granules on the head appears to be tipped with gold. Width of head equals its length behind the angle of the mouth, it is broader than high. Upper surface is of a rich brown, and each of the granules on the head appears to be tipped with gold.

In a stuffed specimen 27 inches in length the snout is much produced, a condition apparently normal in

the adult of this species, the eye is 8 in the length of the head and situated in the commencement of the anterior half of the head. The teeth on the palate form an undivided patch.

Habitat.—From the Red Sea, through those of Africa and India to the Malay Archipelago and beyond, entering tidal rivers. It attains a large size. The specimen figured is 11 inches long, and from the

B. Globular teeth on the palate.

13. Arius Buchanani, Plate CV, fig. 6.

Pimelodus arius, Ham. Buch. Fish. Ganges, pp. 170, 376.

B. vi, D. $\frac{1}{7}$ | 0, P. $\frac{1}{10}$, V. 6, A. 22 $\binom{6}{16}$, C. 17.

Length of head $4\frac{2}{3}$, of caudal $5\frac{1}{2}$, height of body $5\frac{3}{4}$ in the total length. Eyes—diameters $5\frac{1}{2}$ in the length of head, $1\frac{3}{4}$ diameters from end of snout, and $2\frac{1}{4}$ apart. Greatest width of the head equals its length behind the angle of the mouth. Upper jaw the longer, width of the gape of the mouth 3/8 of the length of the head. Median longitudinal groove on the head rather shallow, and does not reach the base of the occipital process. Upper surface of the head lineated in roughened lines, which are rather close together on the occipital process, which latter is scarcely keeled, and as wide at its base as it is long. Opercle higher than wide. Barbels—the maxillary ones reach to the first third of the pectoral fin, the outer mandibular ones almost to its base. Teeth—on the palate in two oval patches, one on either side, each as large as the eye, placed far back and parallel to one another, the teeth have large globular heads. Fins dorsal higher than the body, its spine as long as the head behind the angle of the mouth, anteriorly roughened in its lower two-thirds, and serrated in its upper, posteriorly very feebly serrated: base of the adipose dorsal 3/4 of that of the rayed fin. Pectoral reaches the base of the ventral, the spine is stronger than that of the dorsal but of equal length, it is serrated on both sides. Ventral almost reaches the anal; upper caudal lobe the longer. *Colours*—silvery along the back, lighter on the sides and below, pectoral and dorsal edged posteriorly with blackish: adipose dorsal with a well defined black spot.

Habitat.—Hooghly at Calcutta and Burma. The specimen figured was from the Irrawaddi.

14. Arius falcarius, Plate CVI, fig. 5.

B. vi, D. $\frac{1}{7}$ | 0, P. 1/10, V. 6, A. 18-20 $(\frac{5-6}{13-14})$, C. 17.

Length of head 4 to 5, of caudal 6, height of body $5\frac{1}{4}$ to 6 in the total length. Eyes—diameters $5\frac{1}{2}$ to 6 in the length of head, $2\frac{1}{4}$ diameters from the end of snout, and 3 to $3\frac{1}{2}$ apart. The greatest width of the head equals its length behind the angle of the mouth, and exceeds its height by about one-sixth. Upper jaw the longer, the width of the gape of the mouth equals 3/7 of the length of the head. The median longitudinal groove on the head, which is wide anteriorly, becomes suddenly narrow midway between the front edge of the eye and the hind edge of the opercle, it does not quite reach the base of the occipital process, which is keeled, rather longer than wide at its base, and reaches the basal bone of the dorsal fin which is V-shaped, narrow, and short. Upper surface of the head behind the eyes (except in groove) strongly granulated, as is also the occipital process. Barbels—the maxillary pair, which are black, reach to the hind edge of the head, the outer mandibular ones to the gill-opening, whilst the inner are shorter. Teeth—the villiform band in the premaxillaries four times as long as wide: those on the palate granular anteriorly, becoming globular posteriorly, in two elongated semi-triangular patches, longer than wide, they are parallel to one another along the median line, whilst their external edge is convex, anteriorly they nearly reach the premaxillary teeth. Fins—dorsal higher than the body, its spine usually ending in a soft point, it equals the length of the head excluding the snout, anteriorly it is serrated in its upper, rough in its lower half, it is serrated posteriorly: the base of the adipose fin equals 3/7 of that of the rayed fin. Pectoral spine a little longer than that of the dorsal, serrated externally in its outer half, rough along its lower, whilst internally it is denticulated, it nearly reaches the ventral, whilst the latter extends to the anal or even to as far as the third ray. Colours—bluish-gray superiorly, becoming dull white beneath: fins grayish, dorsal black tipped, a black blotch on the adipose dorsal, and sometimes one on the anal.

Habitat.—Calcutta, seas of India, to China. Very numerous along the Malabar coast.

15. Arius Malabaricus, Plate CVII, fig. 4 (head).

B. vi, D. $\frac{1}{7}$ | 0, P. 1/10, V. 6, A. 20 ($\frac{6}{14}$), C. 17.

Length of head $4\frac{1}{4}$, of caudal $5\frac{1}{2}$, height of body 5 in the total length. Eyes—diameters $6\frac{1}{2}$ in the length of head, $2\frac{1}{2}$ diameters from the end of snout, and $3\frac{1}{2}$ apart. The greatest width of the head equals its length behind the nostrils, it is rather wider than high. Upper jaw the longer, the width of the gape of the mouth equals 2/5 of the length of the head. Upper surface of the head sparingly granulated. The median longitudinal groove on the head commences opposite the hind edge of the eyes, is very narrow and deep, and is continued nearly to the base of the occipital process, which latter is slightly keeled and granulated, as broad at its base as it is long and emarginate posteriorly to receive the V-shaped basal bone of the dorsal fin. Barbels—the maxillary pair black, and as long as the head, the outer mandibular ones rather shorter. Teeth—in the upper jaw 1/4 as wide as long, those on the palate granular and in two elongated oval patches which reach far forwards, are slightly convergent anteriorly, whilst they extend some distance posteriorly. Fins—dorsal spine of moderate strength, as long as the head behind the angle of the mouth, anteriorly granulated in its lower, serrated in its upper portion, posteriorly serrated: base of soft dorsal rather short. Pectoral spine nearly as long as the head, denticulated internally, it extends to below the last dorsal ray. Ventral does not quite reach the anal. Colours—silvery, glossed with gold inferiorly: adipose dorsal with a black spot in its upper half.

The upper surface of the head is entirely destitute of the ridges seen in A. gagora.

Habitat. - Canara.

16. Arius platystomus, Plate CVII, fig. 3.

B. vi, D. $\frac{1}{7}/0$, P. 1/10, V. 6, A. 19 $(\frac{5}{14})$, C. 17.

Length of head 4, of caudal $5\frac{1}{2}$, height of body 5 in the total length. Eyes—diameters 7 in the length of head, 2 diameters from end of snout and 4 apart. The greatest width of the head exceeds its height by 1/3, and is as long as the head without the snout. Upper jaw the longer, the width of the gape of the mouth equals 4/7 of the length of the head. Median longitudinal groove on head becomes narrow posteriorly, where it just reaches the base of the occipital process which is strongly keeled, rather longer than wide at its base, with straight lateral edges, whilst it reaches the basal bone of the dorsal fin which is rather narrow and S-shaped. A very few scattered granulations over the posterior half of the head and the occipital process. Barbels—the maxillary ones reach just beyond the base of the pectoral, the outer mandibular ones are not quite so long. Teeth—the villiform band in the premaxillaries, six times longer than wide: obtusely conical in the palate in a pyriform patch, rather longer than broad, and which is placed well forwards, it is largest anteriorly where they slightly converge together, the interspace equals 2/3 of the diameter of the eye. Fins—the dorsal about as high as the body, its spine as long as the head excluding the snout, anteriorly its upper half is serrated superiorly, its lower roughened, it is serrated posteriorly: the length of the base of the adipose dorsal nearly equals that of the rayed fin. Pectoral spine rather shorter than that of the dorsal, externally serrated in its anterior, rough in its posterior half, internally it is denticulated, it reaches 3/4 of the distance to the ventral. Ventral just reaches the anal. *Colours*—bluish along the back, becoming lighter on the sides and beneath: dorsal, pectoral, and ventral with a slight tinge of gray. No black mark upon the adipose dorsal.

The appearance of this fish, teething, etc. except black spot on adipose dorsal are like Arius falcarius,

Richardson.

Habitat.--Canara.

17. Arius nella.

Silurus, Russell, Fish. Vizag. ii, p. 55, and Nallah jellah. pl. 170. Pimelodus (?) nella, Cuv. and Val. xv, p. 162: Bleeker, Beng. en Hind. p. 58.

D. $\frac{1}{7}/0$, P. 1/10, V. 6, A. 19, C. 19.

Head broad, depressed. Eyes—small, in front half of the head. Teeth—on palate, globular. Barbels—the maxillary reach to the middle of pectoral fin. Fins—caudal sub-lunate. Colours—head and back bluishleaden: belly, throat, and hinder part of the tail, a dull white. The whole travel with small, obscure, the later later than the later t dusky dots. Dorsal, ventral, and anal with blackish margins. Pectoral and caudal glossy with a faint

yellowish tinge.

This fish has been placed by Cuv. and Val. amongst those having no teeth in the palate, it being erroneously observed that in Russell "les détails de sa tête et de ses dentes n'étant pas indiqués." Dr. Günther probably due to this observation places the fish in genus *Hemipimelodus* stated to have "palate edentulous." But Russell observes "teeth, tongue, and palate as in the last," referring to No. 169, we find as I have observed under *Arius jellah*, the teeth are as in No. 168, where they are said to be "sub-granulous" and present on the palate.

Habitat.—Coromandel coast to $9\frac{1}{2}$ inches in length.

18. Arius macronotacanthus, Plate CXIII, fig. 1.

Bleeker, Silur. Batav. p. 32, and Atl. Ich. Silur. p. 32, t. 55; Günther, Catal. v, p. 169. Cephalocassis macronotacanthus, Bleeker, Silur. p. 106. Arius arius, Cantor, Catal. p. 258 (not Pimelodus arius, H. B.)

B. vi, D. $\frac{1}{7}/0$, P. 1/9, V. 6, A. 18-19 $(\frac{6-7}{12-13})$, C. 15.

Length of head 4 to $4\frac{1}{6}$, of caudal $6\frac{1}{2}$, height of body $5\frac{1}{4}$ in the total length. Eyes—diameter $5\frac{1}{4}$ to 6 in the length of head, $1\frac{1}{2}$ diameters from end of shout, and $2\frac{1}{2}$ apart. The width of the head exceeds its height, and equals its length excluding the shout. Extends the gape of the month equals 4/9 of the length of the head. The median longitudinal groove is wide between the eyes, becomes pointed both anteriorly and posteriorly, and does not reach so far as the base of the occipital process, which latter is as wide at its base as it is long, and reaches a narrow V-shaped basal bone. Upper surface of the head granulated in groups, the occipital process densely so in lines. Barbels—the maxillary reach the middle of the pectoral spine, the outer mandibular ones its base. Teeth—on the palate obtusely conical or granular, placed in two pear-shaped patches as long as the eye, the large ends posterior and divergent, anteriorly they are near to the band on the premaxillaries.

Fins—dorsal spine strong, very rugose laterally, as long as the head behind the nostrils, and serrated both anteriorly and posteriorly, it has a soft termination: the length of the base of the adipose equals 2/3 of that of the rayed fin. Pectoral spine as long as the head excluding the snout, roughened and serrated externally, denticulated internally, it reaches 2/3 the distance to the ventral which does not reach the anal. Colours—base of dorsal darkish, a large black blotch on the adipose fin.

This fish appears to be closely allied to A. parvipinnis, but differs in having smaller pectoral and ventral fins, and villiform teeth. In Bleeker's figure he gives villiform teeth, perhaps they become more obtuse with age. If so the two species would correspond, and also with Russell's chinta, the Arius chinta, C. V.

Habitat.—India to Java, Sumatra, and Pinang.

19. Arius gagora, Plate CVII, fig. 2.

Pimelodus gagora, Ham. Buch. Fish. Ganges, pp. 167, 376, pl. 10, f. 54.

Arius gagora, Cuv. and Val. xv, p. 99; Bleeker, Beng. pp. 56, 119; Blyth, P. A. S. of Beng. 1858, p. 285; Günther, Catal. v, p. 168.

Arius macracauthus, Günther, Catal. v, p. 167.

? Arius jatius, Lütken, Vid. Medd. 1874, p. 207.

B. vi, D. $\frac{1}{7}/0$, P. 1/10, V. 6, A. 18 $(\frac{5-6}{13-12})$, C. 17.

Length of head 4 to $4\frac{1}{4}$, of caudal $5\frac{1}{2}$ to $5\frac{2}{3}$, height of body $6\frac{3}{4}$ in the total length. Eyes—diameter 7 to 8 in the length of head, $2\frac{1}{3}$ diameters from the end of snout, and 3 to $3\frac{1}{4}$ apart. Head 1/4 wider than high, its width equals its length excluding the snout. Upper jaw the longer, the width of the gape of the mouth 4/11 of the length of its head. Most of the occipit and the whole of the occipital process granulated. Median longitudinal groove on the head narrow, rather deep, and extending nearly to the base of the occipital process, which latter is keeled, very slightly longer than wide at its base and reaches a narrow V-shaped basal bone. Opercle higher than wide. Barbels—the maxillary ones not quite so long as the head, the outer mandibular reach

Digitized by Google

the gill-opening. Teeth—those on the palate with globular heads, in large semi-ovate patches: considerable variation in size and direction of these patches of teeth exists, as it not unfrequently happens that some are wanting. Fins—dorsal rather higher than the body, the spine of moderate strength, anteriorly serrated in its upper, rough in its lower half, posteriorly serrated, it is as long as the postorbital portion of the head: length of the base of the adipose dorsal 2/3 of that of the rayed fin. Pectoral reaches two-thirds of the distance to the ventral, its spine is rather stronger than that of the dorsal which it equals in length, externally it is serrated, internally denticulated. Ventral does not extend so far as the anal. Upper caudal lobe the longer. Colours-purplish superiorly, becoming dull white beneath, fins externally stained with gray or black, and a blackish spot on the adipose dorsal. Air-vessel—Taylor described the air-vessel of Gagata typus as that of Arius gagora: Owen appears to have followed him, and (Comp. Anat. i, p. 491) observes that amongst fishes this organ is "seldom divided lengthways into two halves as in Arius gagora." "The divided air-bladder of the Arius gagora, in which the divisions are confined to the forepart of the abdomen and are enclosed in osseous cups developed from the anterior trunk vertebra." (See Gagata typus, Bleeker). I have found it in this species as follows: large and somewhat heart-shaped. On removing its lower wall a longitudinal septum is seen in its posterior half but does not exist anteriorly. It has three transverse subdivisions, forming it into five chambers, the anterior of which is nearly half the size of the entire organ, it having no longitudinal septum. The four lateral chambers communicate freely with one another on either side, also anteriorly with the large chamber.

Habitat.—Seas, estuaries and tidal rivers of Orissa and Bengal to Siam. It attains $1\frac{1}{2}$ feet (or according

to Hamilton Buchanan 3 feet) or more in length: it is commonly seen about 8 or 10 inches long. specimen figured (10 inches long) was from Calcutta.

20. Arius jatius, Plate CVI, fig. 4.

Pimelodus jatius, Ham. Buch. Fish. Ganges, pp. 171, 376; Bleeker, Beng. en Hind. p. 58. Arius jatius, Blyth, Proc. As. Soc. Beng. 1860, p. 151. Nga-youn and Nga-yeh, Burmese.

B. vi, D. $\frac{1}{7}$ | 0, P. $\frac{1}{10}$, V. 6, A. 18 $\frac{5}{13}$, C 17.

Length of head $4\frac{1}{4}$, of caudal 5, height of body $5\frac{1}{4}$ in the total length. Eyes—diameter $4\frac{1}{2}$ to 5 in the length of head, 1½ diameters from the end of snout, and 1½ to 2 apart. Height of head nearly equals its width, the latter equals its length excluding the snout. Upper jaw the longer: the extent of the gape of the mouth equals one-third of the length of the head. Summit of the posterior portion of the head sparingly granulated, the occipital process more thickly so. The median longitudinal groove on the head narrow, and continued almost to the base of the occipital process, which latter is keeled, as wide at its base as long, and reaches the narrow V-shaped basal bone of the dorsal fin. Opercle wider than high. Barbels—short, the maxillary pair shorter than the head, the outer mandibular pair just reach the gill-opening. Teeth villiform, in a band six times as long as wide in the premaxillaries: on the palate globular, in a small oval patch posteriorly, scarcely exceeding half the diameter of the eye; they may be entirely absent. Fins—dorsal as high as the body, its spine strong, as long as the head excluding the snout, serrated on both sides: the base of the adipose dorsal 4/5 of that of the rayed fin. Pectoral spine as long as that of the dorsal, serrated externally, denticulated internally, it reaches as far as the ventral fin and the latter the anal. Colours-of a dark bluish along the back, becoming lighter on the sides and beneath. Fins yellowish, lower half of dorsal stained with gray. Upper edge deep black. A deep black spot on the upper half of the adipose fin, caudal edged with black, and anal with a dark spot on its edge near the middle.

This fish is very closely allied to A. gagora, but it has larger eyes, &c. The specimen figured has no

teeth whatever on the palate and is an Hemipimelodus, but having closely compared it with four more

specimens having teeth as described, I feel convinced of their identity.

Habitat.—Estuaries and rivers of Bengal and Burma, ascending far above tidal reach. It attains a foot or more in length.

21. Arius tenuispinis, Plate CVII, fig. 5 (head).

? Arius Layardi, Günther, Ann. and Mag. Nat. Hist. 1866, p. 473, pl. xv.

B. vi, D. $\frac{1}{7}$ | 0, P. $\frac{1}{10}$, V. 6, A. 18 ($\frac{5}{13}$), C. 17.

Length of head $3\frac{1}{2}$, of caudal $4\frac{1}{2}$, height of body $5\frac{1}{2}$ in the total length. Eyes—diameter 7 in the length of head, 21 diameters from end of snout, and 31 apart. The greatest width of the head equals its length excluding the snout. The extent of the gape of the mouth equals one-third of the length of the head. Median longitudinal groove on the head narrow, and does not quite reach the base of the occipital process, which has a slight keel, is a little longer than wide at its base, and rather convex posteriorly where it reaches a narrow and V-shaped basal bone of the dorsal fin. A few granulations on the top of the head, also along the middle of the occipital process. Barbels—the maxillary ones reach the end of the head, the outer mandibular ones are 1/3 shorter. Teeth—none on the palate. Fins—dorsal spine very weak and thin, nearly as long as the head excluding the snout, serrated posterior is base of the adipose equals half that of the rayed dorsal fin. Pectoral spine as long as the dorsal, but slightly stronger, roughened externally, serrated internally. Caudal forked. Colours—silvery along the back, becoming lighter on the sides and beneath.

The single specimen procured was not in a very good state of preservation, it appears to be a distinct *Hemipimelodus*, provided such are not adult specimens of *Arius* which have lost their palatine teeth, or examples in which such teeth were abnormally deficient during the whole of their existence.

Arius Layardi, Günther, from Ceylon, were it not that it has two pear-shaped patches of granular teeth placed far back, agrees with the above, but a series of examples is necessary to prove whether they are

identical or not.

Habitat.—Bombay, (the single specimen obtained 14 inches in length), and perhaps Ceylon.

22. Arius jella, Plate CVI, fig. 3.

Silurus, Russell, ii, p. 54, and Deddi jellah, pl. 169. B. vi, D. $\frac{1}{7}$ | 0, P. $\frac{1}{10}$, V. 6, A. 17-18 ($\frac{4-5}{13}$), C. 19.

Length of head $4\frac{3}{4}$, of caudal $5\frac{1}{2}$, height of dorsal fin $5\frac{1}{3}$, of body $6\frac{3}{4}$ in the total length. Eyes—diameter 6 in the length of head, 2 to $2\frac{1}{2}$ diameters from the end of snout, and 3 apart. Greatest width of the head 1/6 more than its height, and equals its length behind the nostrils. Upper jaw the longer, the extent of the gape of the mouth equals 3/8 of the length of the head. The median longitudinal groove becomes narrow and deep posteriorly, and reaches nearly to the base of the occipital process, which is slightly keeled, has nearly straight sides and is slightly longer than broad, posteriorly it is a little emarginate and reaches the narrow basal bone of the dorsal fin. Most of the occiput and the occipital process are closely granulated. Barbels—the maxillary are nearly as long as the head, the outer mandibular ones almost reach the gill-opening, which the inner are shorter. Teeth—on the palate in two convex, oblong-ovate patches of globular ones, which are rather convergent behind: none on the vomer. Fins-dorsal spine of moderate strength, as long as the head excluding the snout, sometimes with a very long soft termination, slightly serrated anteriorly, or merely rough in large specimens, strongly so posteriorly. Pectoral spine stronger than that of the dorsal and rather longer, roughened and slightly serrated externally, denticulated internally. Base of adipose dorsal slightly shorter than that of the rayed fin. Ventral scarcely reaches the anal. Upper caudal lobe the longer. Colours—grayish-silvery, becoming white on the sides and below. Fins stained gray, with a white outer edge to the anal. Adipose dorsal with a dark blotch.

In Cuv. and Val. it is suggested that Russell's fish is Arius bilineatus, C. V., Bleeker, &c. which has villiform teeth, and this error has been continued subsequently. Russell observes "teeth on the palate as before described in 166." Number 166 is the *Plotosus arab*, which he observes has "teeth in several rows, in the anterior part of the jaws (palate) small, sub-granulous: in the upper jaw very minute," p. 51.

In Cuv. and Val. it is observed that their fish came from Pondicherry, that it much resembles A. gagora, and has A. 18, it is therefore unlikely to be Pinelodus arius, H. B. having A. 22.

Habitat — Coronavald coast of Table. The apprint of form M. 200.

Habitat.—Coromandel coast of India. The specimen figured was from Madras.

23. Arius Dussumieri, Plate CVII, fig. 7.

Cuv. and Val. xv, p. 84; Bleeker, Beng. en Hind. p. 56; Günther, Catal. v, p. 163. ? Arius Belangerii, Cuv. and Val. xv, p. 71; Bleeker, Beng. en Hind. p. 56.

B. vi, D. $\frac{1}{7}$ | 0, P. 1/12, V. 6, A. 14-16 ($\frac{4-5}{10-11}$), C. 17.

Length of head 4 to $4\frac{1}{3}$, of caudal 5, height of body 5 in the total length. Eyes—diameter $6\frac{1}{2}$ in the length of head, $2\frac{1}{3}$ diameters from the end of snout, and 4 apart. Head one-fourth wider than high, its width equals its length excluding the snout, or even behind the angle of the mouth. Upper jaw the longer, the width of the gape of the mouth equals 4/9 of the length of the head. Median longitudinal groove shallow, becoming most distinct posteriorly, where it reaches the base of the occipital process, which is strongly keeled and nearly (or onite) as wide at its base as it is long its lateral address are results the whilst it and the lateral address are results the whilst it and the lateral address are results that whilst it and the lateral address are results that whilst it and the lateral address are results that the lateral address are results that the lateral address are results that the lateral address are results at the lateral address and the lateral address are results at the lateral address are results at the lateral address are results at the lateral address at the lateral address are results at the lateral address are results at the lateral address are results at the lateral address at the lateral address are results at the lateral address at (or quite) as wide at its base as it is long, its lateral edges are nearly straight, whilst it extends to the basal bone which is narrow and S-shaped. A few scattered granulations on the posterior portion of the head, and over the base of the occipital process. Barbels—the maxillary ones reach just beyond the base of the pectoral, the external mandibular are not quite so long. Teeth—obtusely conical on the palate, in four widely separated patches, those on either side of the vomer being smaller than the palatine patches. Fins the dorsal as high as the body, the spine as long as the head excluding the snout, anteriorly in its upper half serrated, in its lower roughened, it is serrated posteriorly: the length of the base of the adipose dorsal equals half of that of the rayed fin. Pectoral spine rather shorter than that of the dorsal, externally it is serrated in its anterior half, rough in its posterior, whilst internally it is serrated, it reaches 2/3 of the way to the ventral. Ventral just reaches the anal. *Colours*—bluish along the back, becoming lighter on the sides and below, fins blackish externally.

In Cuv. and Val. xv, p. 161, is Pimelodus or Hemipimelodus Peronii, marked as from India, but with the further observation that the locality from whence it was procured is not recorded. It has A. 16. Head 5 in the total. The maxillary barbels scarcely extending beyond the opercle. It may be this species from which the palatine teeth are absent. It would seem that absence of palatine teeth is more general in East Indian species

in those forms in which they are normally globular, than those in which they are villiform when present.

Habitat.—Malabar coast of India and Ceylon. Specimen figured 9.8 inches in length and from

Malabar.

Digitized by Google

Genus, 6-BATRACHOCEPHALUS, Bleeker.

Branchiostegals five. Gill-membranes united at the throat, without a notch, not confluent with the skin of the isthmus. Cleft of mouth wide: lower jaw the longer. Eyes with a free circular margin. Nostrils approximating, the posterior provided with a valve. Barbels two, rudimentary, and inserted at the chin. Teeth obtusely conical in either jaw, with an interspace between the outer and the inner rows, in a broad longitudinal band on the palate: none on the vomer. Dorsal fin with one spine and seven rays, inserted anterior to the ventrals: adipose fin short. Anal of moderate length, not confluent with the caudal which is forked. Ventral with six rays, Air-vessel in the abdominal cavity not enclosed by bone. An axillary pore.

Geographical distribution.—From Beloochistan through the seas, estuaries, and tidal rivers of India to the Malay Archipelago and beyond.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Batrachocephalus mino, A. 20. Silvery, darkest along the back and upper lobe of the caudal fin. Seas, estuaries and tidal rivers of India to the Malay Archipelago.

1. Batrachocephalus mino, Plate CVIII, fig. 1.

Length of head $4\frac{1}{2}$, of caudal 5, height of body 6 in the total length. Eyes—diameter 4 in the length of head, 1/2 a diameter from the end of snout, and $1\frac{1}{2}$ apart. The greatest width of the head equals its length behind the middle of the eyes. Gape of mouth wide, the cleft of the mouth reaches to below the centre of the orbit. Occipital process rather longer than wide at its base, it is lineated in roughened lines. Basal-bone crescentic and narrow. Barbels—minute. Teeth—in a broad longitudinal band on the palate. Fins—dorsal spine of moderate strength, as long as the head behind the middle of the eyes: base of the adipose dorsal equal to half that of the rayed fin. Dorsal and pectoral spines serrated on both edges. Upper caudal lobe a little the longer. Calours—silvery, darkest along the back and upper lobe of the caudal fin. little the longer. Colours—silvery, darkest along the back and upper lobe of the caudal fin.

Habitat.—Seas, estuaries and tidal rivers of India and Burma to the Malay Archipelago: the one figured

was from the Irrawaddi. It is not common and held in no esteem as food.

Genus, 7-KETENGUS, Bleeker.

Branchiostegals five. Gill-membranes united, not confluent with the isthmus, but having a free posterior edge, which is notched. Head osseous superiorly. Eyelids with a free circular margin. Cleft of mouth deep: upper jaw the longer. Barbels six, small, no nasal ones. Nostrils approximating, the posterior provided with a valve. A single row of compressed teeth, which are sub-truncated or almost tricuspid in the jaws: palate edentulous. Dorsal fin with one spine and seven rays, inserted anterior to the ventrals: adipose fin short: anal of moderate length and not continuous with the caudal, which latter is forked. Ventral with six rays. Air-vessel not enclosed in bone. An axillary pore.

Geographical distribution.—Andamans to the Malay Archipelago.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Ketengus typus, A, 19-20. Silvery. Andamans to the Malay Archipelago.

1. Ketengus typus, Plate CVIII. fig. 2.

Bleeker, Silur. p. 9, Nat. Tyds. Ned. Ind. i, p. 271, and Atl. Ich. Siluridæ, p. 44, t. 82, f. 1; Günther, Catal. v, p. 177.

Pimelodus pectinidens, Cantor, Catal. p. 261.

B. v, D. $\frac{1}{7}/0$, P. 1/7-8, V. 6, A. 19-20 $(\frac{5-6}{14})$, C. 15.

Length of head $4\frac{3}{4}$, of caudal $5\frac{1}{4}$, height of body $5\frac{1}{4}$ in the total length. Eyes—diameter $5\frac{1}{4}$ in the length of head, $1\frac{1}{4}$ diameters from end of snout, and $2\frac{1}{2}$ apart. The greatest width of the head equals its length excluding the snout. Upper surface of the head, occipital process and basal bone of the dorsal fin densely granulated. The width of the gape of the mouth equals the length of the head excluding the snout. Longitudinal groove along the upper surface of the head deep but narrow, commencing on the snout it is not continued so far as to the base of the occipital process which is as long as wide at its base. Teeth—as defined in the genus. Fins—dorsal spine as long as the head and serrated on both edges: base of the adipose nearly as long as that of the dorsal and serrated on Colours—silvery.

Habitat.—The Andamans to the Malay Archipelago. The specimen figured was from Port Blair.

Genus, 8—OSTEOGENIOSUS, Bleeker.

Branchiostegals five. Gill-membranes united at the throat, emarginate and overlapping the isthmus not being confluent with it: upper surface of the head covered with very thin skin: mouth anterior: upper jaw the longer. Nostrils approximating, the posterior provided with a valve. Barbels, a single pair of semi-osseous maxillary ones. Teeth in the jaws villiform: obtusely conical on the palate, where they form two widely separated patches. Dorsal with one spine and seven rays, inserted anterior to the ventrals: adipose fin short. Anal of moderate length not united with the caudal, which is forked. Ventral with six rays. Air-vessel in the abdominal cavity not enclosed in bone. An axillary pore.

Geographical distribution.—Seas and estuaries of India to the Malay Archipelago, sometimes entering rivers.

Uses.—Eaten by the poorer classes. A coarse isinglass is made from its air-vessel.

SYNOPSIS OF SPECIES.

1. Osteogeniosus militaris, A. 19-22. Length of head $4\frac{1}{4}$ to $4\frac{1}{2}$ in the total length. Greatest width of head equals its length behind the angle of the mouth. Seas of India to the Malay Archipelago.

2. Osteogeniosus sthenocephalus, A. 20. Length of head $4\frac{3}{4}$ in the total length. Greatest width of head equals 1/2 its length. Burma.

Length of head $4\frac{1}{4}$ to $4\frac{1}{2}$, of caudal $7\frac{1}{4}$, height of body $5\frac{1}{4}$ to $6\frac{1}{4}$ in the total length. Eyes—diameter 7 in the length of head, 2 diameters from the end of snout and 4 apart. The greatest width of the head equals its length behind the angle of the mouth: its height 2/3 of its length: the width of the gape of the mouth equals half the length of the head. Occipital process $2\frac{1}{4}$ times as long as wide at its base, and its length equals 1/3 of that of the head. Median longitudinal groove of moderate width not extending so far as the base of the occipital process. Upper surface of the head almost or quite smooth, a few granulations generally present between the posterior end of the median longitudinal groove and the base of the occipital process, which last is roughened in ridges which are sometimes granular: there also usually exists a patch of granulations above the upper edge of the opercle on the head. Barbels—rather longer than the head. Teeth—on the palate in two somewhat crescentic patches converging anteriorly. Fins—dorsal spine as long as the head excluding the snout, serrated in its upper portion anteriorly and in its whole extent posteriorly. Pectoral spine somewhat stronger than that of the dorsal, the fin reaches about half way to the ventral. Anal highest anteriorly where it equals half the length of the head. Colours—silvery, darkin superiorly, fins tinged with red.

Habitat.—Seas, estuaries and tidal rivers of India to the Malay Archipelago. A specimen Calcutta Museum is 14 inches long. The specimen figured was from Bombay and is 8 inches in length. A specimen in the

2. Osteogeniosus sthenocephalus, Plate CVIII, fig. 3.

B. v, D. $\frac{1}{7}$ /0, P. 1/9, V. 6, A. 20 ($\frac{5}{15}$), C. 17.

Length of head $4\frac{3}{4}$, of caudal $5\frac{1}{2}$, height of body $7\frac{1}{2}$ in the total length. Eyes—diameter $6\frac{1}{2}$ in the length of head, 2 diameters from the end of snout, and 3 apart. The greatest width of the head equals half its length: the width of the gape of the mouth equals half the length of the head. Occipital process three times as long as wide at its base, its length equals 1/3 of that of the head. Median longitudinal groove rather wide and does not extend quite to the base of the occipital process. Upper surface of the head with a few granulations between the posterior end of the median grove and the base of the occipital process, which last is reproduced in sides. roughened in ridges. Barbels-as long as the head. Fins-as in the last species, except that the anterior portion of the anal fin is as deep as the head excluding the snout is long. Colours—silvery, darkest superiorly.

This fish differs from the preceding species in having a much narrower head, deeper anal fin, and flatter

snout.

Habitat.—A single specimen captured at Moulmein.

Genus, 9-Pangasius, Cuvier and Valenciennes.

Pseudopangasius and Helicophagas, Bleeker.

Branchiostegals from about seven to twelve. Gill-openings wide, the membranes not confluent with the skin of the isthmus and rather deeply notched. Upper jaw the longer. Eye with a free orbital margin. Nostrils at some

distance apart, both patent, the anterior situated in front of, or on the upper edge of the snout. Four slender barbels, one maxillary and a pair behind the chin. Teeth villiform intermixed with conical ones in the jaws: those in the romer, if present, distinct from those on the palatines. Dorsal fin inserted anterior to ventral and with one spine and seven rays: adipose fin short. Ventral with six rays. Pectoral with a spine. Anal rather elongate (29 to 39 rays), not confluent with the caudal. Air-vessel in the abdominal cavity and not enclosed in bone. One or more axillary pores.

This genus is divided by Bleeker in the following manner:-

A.—Anterior nostril patent and entirely anterior on the snout.

1. Pangasius. Four groups of teeth on the palate, those on the palatines close to the vomerine ones and forming a transverse band.

2. Pseudopangasius. Vomerine teeth forming a broad square patch, those on the palate in an oblong

lateral patch.

B.—Anterior nostril patent on upper edge of the snout.

3. Helicophagus. Teeth on the vomer if present in two small patches. Geographical distribution.—Large rivers and estuaries of India and Burma to the Malay Archipelago.

SYNOPSIS OF INDIVIDUAL SPECIES.

- 1. Pangasius Buchanani, D. ½/0, A. 31-34. Large rivers of India and perhaps Java.
 - 1. Pangasius Buchanani, Plate CVIII, fig. 5.

Pimelodus pangasius, Ham. Buch. Fish Ganges, pp. 163, 378, pl. 38, f. 52.

Pangasius Buchanani, Cuv. and Val. xv, p. 45, pl. 425; Bleeker, Hind. pp. 58 and 118; Blyth, Proc. A. S. of Beng. 1858, p. 286; Günther, Catal. v, p. 62.

? Pangasius djambal, Bleeker, Batav. p. 181, and Atl. Ich. Silur. p. 73, t. 76; Günther, Catal. v, p. 62.

Jellum, Ooriah.

B. ix-x, D $\frac{1}{7}/0$, P. 1/12, V. 6, A. 31-34 ($\frac{4-5}{27-29}$), C. 19.

Length of head $5\frac{1}{4}$ to 6, of caudal 5 to $5\frac{1}{4}$, height of body 4 to 5 in the total length. Eyes—partly on the lower surface of the head, and in the commencement of its anterior half, the width of the interorbital space equalling the length of the head excluding the snout. The greatest width of the head equals its length behind the angle of the mouth. Upper jaw the longer: width of the gape of the mouth equals 3/7 of the length of the head, its cleft reaches to below the hind nostril and is opposite the centre of the front edge of the eye. Upper surface of the head smooth in small specimens, rather lineated in large ones especially along the occipital process which is from $2\frac{1}{2}$ to 3 times as long as wide at its base. Barkels—the maxillary ones reach the base of the pectoral fin: the mandibular ones are half as long as the head. Teeth—on the palate in a crescentic row, the vomerine patches being either distinct from or just confluent with those on the palate. Fins-dorsal spine of moderate strength, as long as the head behind the angle of the mouth, slightly serrated anteriorly, in its entire length pesteriorly. Pectoral spine rather stronger than that of the dorsal, in some specimens of the same length, in others as long as the head, denticulated internally. Caudal deeply forked. Colours—silvery, darkest along the back and glossed with purple on the sides: cheeks and under surface of the head shot with gold. Air-vessel—large, its anterior portion occupies about 1/2 the length of the abdominal cavity, and is then divided by a constriction from the second portion, which is narrowed and divides into two small continuations one of which extends on either side amongst the muscles covering the hæmal spines, as far as to above the middle of the anal fin. The anterior portion of the air-vessel has a large pyramidal and cellular cavity, the base of which is anterior, on either side of this cellular cavity is a pyriform smooth chamber the two communicating anteriorly. The remainder of the air-vessel is cellular or rather furnished with valvular-formed folds.

Habitat.—Large rivers and estuaries of India, Assam, Burma, and perhaps the Malay Archipelago. It attains upwards of 4 feet in length, and is a foul feeder.

Genus, 10—Pseudeutropius,* Bleeker.

Clupisoma, Swainson; Schilbeichthys, Bleeker.

Branchiostegals from six to ten. Gill-openings wide, the membranes not confluent with the skin of the isthmus and rather deeply notched. Body elongated and compressed. Head covered with soft skin. Eyes large, with or without broad adipose lids, and situated behind as well as a little below the angle of the mouth, being usually partly

* Genus Eutropius, Muller and Troschel, is closely allied but has its mandibular barbels of each side placed one behind the other: Dr. Gunther gives as its geographical distribution "Tropical Africa, East Indies." Two of the species he cites belong to Pseudeutropius, the remaining one he describes as new. Eutropius obtusirostris, Gunther Catal. v, p. 53, it seems to be of doubtful East Indian origin: it was purchased in Liverpool, and is as follows:—

1). \(\frac{1}{3} \) | 0.P. 1/8, V. 6, A. 54.

Height of body 4\frac{1}{3} in the total length without the caudal fin: length of head 4\frac{2}{3}. Eyes without adipose lids. Maxillary barbels as long as the head. Dorsal spine 3/4 as long as the head. Vomerme teeth in an uninterrupted transverse band, not confluent with the palatine one. India 3 inches long. This fish appears to me to be probably of African origin.

on the inferior surface of the head. Upper jaw, as a rule, the longer. Nostrils patent, the posterior ones transverse and as near together as they are to the anterior pair. Barbels eight, one nasal pair, one maxillary and two mandibular pairs, these last commencing in a transverse line close to the hind margin of the lower lip. Teeth villiform on the jaws and palate. Dorsal fin short, with one spine and six to eight rays; a very small adipose dorsal which may be absorbed in the adult (Schilbeichthys): pectoral with a serrated spine: anal long, terminating at some distance from a forked caudal. Ventral with from 6 to 8 rays. Air-vessel rather small, somewhat heart-shaped, with a notch at its anterior edge, and closely attached to the front surfaces of the vertebræ. An axillary pore generally present.

Geographical distribution.—Fresh waters of Sind, India, Ceylon, and Burma to the Malay Archipelago, where Bleeker observed it appears to have a single representative.*

Uses—These fishes are all excellent as food, but in some localities are to be avoided as they consume offal.

SYNOPSIS OF SPECIES.

Pseudeutropius goongwaree, A. 54. Nasal barbels reach the dorsal, maxillary barbels the anal fin: the mandibular are about as long as the head. Cleft of mouth to below first third of the eye. Deccan, Bengal, and Burma.

2. Pseudeutropius taakree, A. 43-46. Maxillary barbels reach middle of pectoral fin, the mandibular ones shorter than the head. Deccan, Kistna, and Jumna rivers.

3. Pseudeutropius acutirostris, A. 42-46. Snout projecting, and inferiorly covered with teeth which are entirely in advance of those of the lower jaw. The maxillary barbels reach the anal fin, the mandibular ones are as long as the head. Burma.

4. Pseudeutropius murius, A. 38-43. Maxillary barbels as long as head, the others shorter. Rivers of

India except its more southern portion.

5. Pseudeutropius Sykesii, A. 35-37. Maxillary barbels reach the ventral fin, the mandibular ones as long as the head. Teeth on the palate in two distinct patches.

6. Pseudeutropius atherinoides, A. 33-41. Maxillary barbels reach the anal fin, the mandibular are longer than the head. Dark bands along the body, and a spot at the base of the caudal. India (except the western coast) and Assam.

7. Pseudeutropius garua, A. 29-36. Maxillary barbels reach the ventral fin, the mandibular pairs are about as long as the head. The adipose dorsal fin is absent in adults. Throughout the large rivers of Sind, India, Assam, and Burma.

B. vi, D. $\frac{1}{7}$ | 10, P. $\frac{1}{13}$, V. 6, A. 54 $(\frac{3}{61})$, C. 17.

Length of head 5, of caudal 5, height of body 5 in the total length. Eyes—with a very broad circular adipose lid, situated partially on the lower surface of the head, diameter $2\frac{3}{4}$ in the length of head, 3/4 to 1 diameter from the end of snout, and 1 apart. The median longitudinal groove on the head reaches the base of the occipital process, which latter is narrow, especially at its base. Width of the head rather above 1/2 its length. Upper jaw the longer: width of gape of mouth equals the diameter of the eye: cleft extends to below first third of the eye. Barbels—the nasal pair reach the base of the dorsal fin, the maxillary the anal fin, and the mandibular ones are about as long as the head. Teeth—in a wide pyriform band wider than those in the jaws, the vomerine and palatine groups touching, but the two vomerine patches having a short interspace between them. Fins—dorsal spine somewhat slender, nearly as long as the head and very finely serrated posteriorly. Pectoral spine slightly longer, stronger, and rather strongly denticulated internally. Ventral fin not quite 1/2 as long as the head, and under the centre of the dorsal fin. Caudal forked. Free portion of the tail rather higher at its base than it is long. Colours—silvery, darkest superiorly.

Habitat.—Rivers of the Deccan, Bengal and Burma, attaining about a foot in length. The specimen figured (life-size) was from Kurnool.

2. Pseudeutropius taakree, Plate CIX, fig 4.

Hypophthalmus taakree,† Sykes, T. Z. S. ii, p. 369, t. 64, f. 4. Bagrus taakree, Bleeker, Hind. p. 56; Jerdon, M. J. L. and Sc. 1849, p. 336. Pseudeutropius longimanus, Günther, Catal. v, p. 60. Eutropius taakree, Day, P. Z. S. 1867, p. 564. Pseudeutropius taakree, Day, l. c. 1869, p. 617.

* Dr. Günther (Geolog. Mag. Oct. 1876) determines a fossil fish from Sumatra, deficient of a head, to be a Pseudentrepius. He does not note the position of the barbels!

† For remarks on the specimen of Pseudentropius, Sykes, which formed the type of P. longimanus, Günther, see Preface under the head of Col. Sykes.

B. vi, D. $\frac{1}{6.7}$ | 0, P. 1/10-11, V. 6, A. 43-52 $(\frac{5.4}{4.0.60})$, C. 17.

Length of head 6 to $6\frac{1}{3}$, of caudal 6, height of body 5 to 6 in the total length. Eyes—situated behind the angle of the mouth and partly on the under surface of the head, having broad circular adipose lids, diameter $2\frac{3}{4}$ to 3 in the length of head, 2/3 to 1 diameter from end of snout, and 1 apart. The greatest width of the head equals 1/2 its length, the width of the gape of the mouth 2/5: the cleft of the mouth extends to opposite the middle of the front edge of the eye. Occipital process long and slender, scarcely reaching the basal bone of the dorsal fin. Median longitudinal groove on the head shallow and reaching to the occipital process. Barbels—the nasal half as long as the head, the maxillaries reach the anal, whilst the mandibular ones are a little longer than the head. Teeth—the vomerine and palatine ones in a distinct patch. Fins dorsal spine smooth anteriorly, serrated posteriorly, it is as long as the head without the snout. Pectoral spine stronger, serrated internally and almost as long as the head. Ventral rather above half as long as the head and reaches the anal. Free portion of the tail about as high at its base as it is long. Colours—silvery, with a gloss of green along the back: caudal stained with gray at its edges.

I have obtained in Burmah, as high as Mandalay, specimens which I am unable to separate from this species, except that in some the pectoral spine is slightly shorter, in others the adipose fin is almost or quite

absent.

Habitat.—Poona, the Deccan, the rivers Kistna and Jumna. It attains upwards of a foot and a half in length, and is good eating. The specimen figured (life-size) was from Kurnool.

3. Pseudeutropius acutirostris, Plate CIX, fig. 1.

Day, Proc. Zool. Soc. 1869, p. 618.

? Bagrus exodon, Val. in Bel. Voyage Ind. Or. Zool. p. 385, pl. 4, f. 1; Cuv. and Val. xiv, p. 394; Bleeker, Beng. p. 56.

B. vi, D. $\frac{1}{6}$ | 0, P. 1/7, V. 6, A. 42-46 ($\frac{2}{40-44}$), C. 17.

Length of head $4\frac{2}{3}$ to 5, of caudal 5, height of body 5 in the total length. Eyes—without adipose lids, situated behind the cleft of the mouth, diameter 1/3 of the length of the head, 1 diameter from the end of snout, and also apart. The greatest width of the head equals half its length. Upper surface of the head flat and rugose. Upper jaw elongated, and projecting considerably beyond the lower. The median longitudinal groove on the head reaches the base of the occipital process, which is narrow and 2/7 as wide at its base as it is long. Barbels—the nasal rather longer than the head, the maxillary reach the base of the anal fin, the mandibular ones as long as the head. Teeth—the whole of the under surface of the snout toothed, the premaxillaries being entirely in advance of the lower jaw,* in two minute patches on the vomer, the premaxiliaries being entirely in advance of the lower jaw,* in two minute patches on the vomer, and of the same character on the palatines, which are not continuous with those on the vomer. Fins—dorsal spine as long as the head behind the angle of the mouth, it is finely serrated posteriorly. Pectoral spine strong, rough externally, and with about ten strong teeth internally, it is as long as the head excluding the snout. Ventral arises somewhat behind the base of the dorsal fin: caudal deeply forked. Colours—silvery, a black spot on the occiput, and a black blotch at the base of the dorsal fin.

The snout of this species much resembles that of Arius acutirostris, plate XCVII. The description in

Cuv. and Val. of Bagrus exodon appears to apply to this species, but the figure is very different, whereas it is

said to have come from Bengal.

The common form has no elongation of the snout, although of the same size as the one having such an elongation, but otherwise the same. The eyes as a consequence are $2\frac{1}{2}$ in the length of head, and 1/2 a diameter from the end of snout: one specimen has a long anal papilla. It extends all through the rivers of Burma as far to the east as Moulmein. It is evidently the Burmese representative of P, atherinoides of India. Belangers specimen if from India (not Burma) may have been a specimen of the P, atherinoides with an elongated snout.

Habitat.—The Irrawaddi and other large Burmese rivers. It does not appear to exceed the size of the

specimen figured.

B. v, D. $\frac{1}{7}$ | 0, P. $\frac{1}{10}$, V. 6, A. $\frac{38-43}{35-40}$, C. 17.

^{*} In the variety in which the snout is not clongated, still the premaxillary is entirely in front of the mandibles.

Length of head $5\frac{1}{2}$ to 6, of caudal $5\frac{1}{2}$ to 6, height of body $5\frac{1}{2}$ to 6 in the total length. Eyes—lateral and very slightly on the lower surface of the head: each with a broad, circular, adipose lid, diameter 3 to $3\frac{3}{4}$ in the length of head, 3/4 of a diameter from end of snout, and 1 apart. The greatest width of the head is rather above 2/3 of its length. Jaws compressed, the upper slightly the longer, the cleft reaches nearly or quite to below the front edge of the eye: the width of the gape equals 1/3 of the length of the head. The median longitudinal groove on the head extends to the end of the occipital process which is narrow, short, half as wide at its base as it is long, and with a long interspace between it and the basal bone of the dorsal fin. Barbels—the nasal reach to a short distance behind the posterior edge of the orbit: the maxillary to the base of the pectoral fin, whilst the two mandibular pairs are a little longer than the head. Teeth—on the vomer and palate form an almost uninterrupted semilunar band. Fins—dorsal spine nearly as long as the first ray, it is weak, as long as the head excluding the snout, very finely serrated anteriorly, more coarsely posteriorly. Pectoral spine weak, nearly or quite as long as the head, rough externally, serrated internally. Ventral small, 1/3 as long as the head. Caudal deeply forked. Caudal peduncle as long as deep at its base. Colours—silvery, lightest along the sides and below: dorsal, pectoral and caudal finely darkest at their margins.

In P. megalops, the maxillary barbels extend to beyond the origin of the anal fin, but I do not see any other difference.

Bugrus Buchanani, Val. in Jacq. Voy. Ind. Orient. belongs to this Genus, as I convinced myself on seeing

the type specimen, but my notes on which I have mislaid. I think it was this species but am in doubt. Habitat.—Rivers of Sind, Orissa, the Jumna and rivers of Bengal and Assam, attaining about 6 or 8 inches in length. The figure of this fish is on Plate cviii, fig. 6, not Plate cix, as stated on the last page.

B. viii-ix, D. $\frac{1}{7}$ | 0, P. 1/9, V. 6, A. 35-37 ($\frac{8}{32}$ - $\frac{3}{34}$), C. 17.

Length of head 6, of caudal 6, height of body 6 in the total length. Eyes—diameter 3 to $3\frac{1}{5}$ in the length of head, 1 diameter from the end of snout, and $1\frac{1}{5}$ apart. Head rather higher than wide, its greatest width equals its length excluding the snout. The angle of the mouth is on a level with the lower edge of the orbit. Upper jaw slightly the longer: posteriorly it reaches 2/3 of the distance between the snout and front edge of the orbit. The median longitudinal groove on the upper surface of the head reaches to the base of the occipital process, which latter is narrow. Barbels—the nasal pair reach to the front edge of the orbit, the maxillary pair to the end of the pectoral or middle of the ventral, the mandibular ones are as long as, or a little longer than the head. Teeth—those on the palate in two distinct patches. Fins—dorsal spine slender, as long as the head excluding the snout, and finely serrated posteriorly: adipose fin small. Pectoral spine stronger and slightly longer than that of the dorsal, smooth externally, denticulated internally Pectoral spine stronger and slightly longer than that of the dorsal, smooth externally, denticulated internally with about twenty-two teeth. Ventral commences just behind the vertical from the last dorsal ray: caudal forked, lower lobe slightly the longer. Colours-bluish-silvery along the back, becoming silvery-white on the sides and below. Dorsal and caudal gray, the other fins white.

Habitat.—Western coast of India in fresh-water, it attains about 6 inches in length.

B. vi, D. $\frac{1}{5-6}$ | 0, P. 1/7, V. 6, A. A. 33-41 ($\frac{3}{30-3}$), C. 17.

Length of head 5 to $5\frac{1}{2}$, of caudal 5, height of body $4\frac{1}{2}$ to $5\frac{1}{2}$ in the total length. Eyes—with free orbital margins, no adipose lids, situated partially on the lower surface of the head: diameter $2\frac{1}{2}$ to 3 in the

* Dr. Günther as a Recorder of facts, animadverted on my considering his well-determined! P. Mitchelli, a synonym of P. Sykesii, Jerdon, observing "if he cannot verify his assertion by the examination of the typical specimen, he has no right to exchange the name of a well-determined species for a doubtful one," (Zool. Record. 1865, p. 193). Jerdon had described the species fitteen years before Dr. Günther, and sufficiently well for my recognizing it at a locality where he found it.

Digitized by Google

length of head, and about 1/2 a diameter from the end of snout. The greatest width of the head equals two-thirds of its length. Upper jaw a little the longer. The median longitudinal groove on the head broad, shallow, and reaches to the base of the occipital process, which is four times as long as broad at its base and extends to the basal bone of the dorsal fin. Barbels—the nasal slightly longer than the head, the maxillary reach the base of the anal (in some Madras specimens only to the ventral) fin, the mandibular pair are rather longer than the head. Teeth—in the premaxillaries usually anterior to those in the mandibles: in a narrow point approach to approach the head. narrow, uninterrupted, crescentic band across the palate. Fins—dorsal spine two-thirds as long as the head, anteriorly rugose, finely serrated posteriorly. Pectoral spine rather longer and stronger than that of the dorsal, with about ten denticulations internally. Ventral half as long as the head. Caudal deeply forked. Colours—silvery, greenish along the back, and with three or four bands along the sides formed by black spots. Occiput and anterior portion of dorsal fin dark coloured.

In a specimen from the Deccan a rather elongated anal papilla exists. I have found the number of anal rays in different localities as follows: Sind, 38-39; Punjab, 35-39; Assam (lower) 38, (upper) 41-44; the Sone river, 38-44; Orissa, 38-41; Madras, 35-36. Some of the higher numbers, as at Debrooghur in Upper Assam and a single specimen with 44 anal rays at the Sone river, I have omitted from the above formula.

Habitat.—Throughout Sind, India (excluding the western coast) and Assam; rarely attaining to above 4 or 5 inches in length. P. urua is said to come from rivers and ponds of the northern parts of Bengal.

B. vi, D. $\frac{1}{7}$, P. 1/11, V. 6, A. 29-36 ($\frac{3}{26-33}$), C. 17.

Length of head $5\frac{1}{2}$ to $6\frac{1}{2}$, of caudal $4\frac{1}{2}$, height of body $5\frac{1}{2}$ to 7 in the total length. Eyes—situated partly on the lower surface of the head, having a broad, circular, adipose lid, diameter $3\frac{1}{2}$ to 4 in the length of the head, $1\frac{1}{4}$ diameters from the end of snout, and $2\frac{1}{2}$ apart. The greatest width of the head equals its length excluding the snout. Upper jaw the longer, the width of the gape of the mouth is 2/5 in the length of the head. Occipital process about four times as long as it is wide at its base, and does not quite reach the basal bone. Barbels—nasal from 1/3 to 1/2 as long as the head, the maxillary extend to the middle or end of the ventral fin, the two mandibular ones are about as long as the head. Teeth—in a semilunar band across the palate, those of the vomer contiguous to those of the palatines, and each patch being semicircular internally: sometimes the two vomerine patches have an interspace between them. Fins—dorsal spine rather slender, rugose anteriorly and feebly serrated posteriorly, as long as the head behind the nostrils, whilst the pectoral is of equal length or a little longer, stronger and denticulated internally. The adipose dorsal generally only exists in the immature, and becomes almost imperceptible in the adult: as its non-existence forms the chief distinction of the Ganus Schillighthas from that of Paradleutronian whilst its absorbed in a court of the results of the court of th Genus Schilbichthys from that of Pseudcutropius, whilst its absence is merely the result of age, I have not adopted the former designation. Lower caudal lobe the longer. Air-vessel—small, somewhat heart-shaped, and closely attached to the front surface of the anterior vertebræ. Colours—silvery, fins stained with gray.

Habitat.—Found generally throughout the larger rivers of Sind, India, Assam, and Burma. Attains upwards of two feet in length. The specimen figured (7 inches long) was from Calcutta.

Genus, 11—OLYRA,* McClelland.

Branchiosteus, Gill.

Body elongate and low, the dorsal profile nearly horizontal: head depressed and covered superiorly with soft skin. Gill-openings wide, the gill-membranes not being confluent with the skin of the isthmus, but notched nearly to the chin. Mouth terminal and transverse: jaws of about equal length, or the lower the longer. Nostrils remote from one another, the posterior provided with a barbel. Barbels eight. Eyes small. Villiform teeth in the jaws and on the palate. First dorsal fin without a spine, \(\dagger and with from six to eight rays: adipose dorsal long and low. Anal of moderate length (15 to 23 rays): ventrals inserted below the dorsal and having six rays: caudal rounded or lanceolate. Air-vessel not enclosed in bone. Skin smooth.

Gill subdivided the Genus into (a) those species which have the jaws subequal in length: anal with more than 20 rays: caudal lanceolate (Olyra); (b.) others in which the lower jaw projects: anal with less than 20 rays: caudal rounded (Branchiosteus).

Geographical distribution.—Small fishes from the Khasya hills and British Burma.

* Preoccupied by Linn. in order Gramineæ.
† Dr. Günther observes "dorsal fin short with a spine." McClelland says "no dorsal spine," and I have found none in O. Burmanica.

SYNOPSIS OF SPECIES.

- Olyra longicaudata, D. 7/0, A. 23. Jaws of equal length. Caudal lanceolate. Khasya hills.
 Olyra Burmanica, D. 8/0, A. 16. Jaws of equal length. Caudal lanceolate. Pegu hills.
 Olyra laticeps, D. 6/0, A. 15. Lower jaw the longer. Caudal rounded. Khasya hills.

1. Olyra longicauda.

McClelland, Cal. J. N. H. ii, p. 588, pl. xxi, f. 1; Bleeker, Beng. p. 58; Günther, Catal. v, p. 98. B. vi, D. 7/0, P. 1/6, V. 6, A. 23, C. 12.

Jaws of equal length. Barbels—eight. Fins—pectoral, preceded by a rough spine. The middle rays of the caudal prolonged to a lengthened point. Air-vessel—membraneous, and placed in the anterior part of the abdomen.

Habitat.—Khaysa hills.

2. Olyra Burmanica, Plate CXI, fig. 5.

D. 8/0, P. $\frac{1}{4}$, V. 7, A. 16 $(\frac{3}{13})$, C. 17.

Length of head $7\frac{1}{2}$, of caudal 3, height of body $7\frac{1}{2}$ in the total length. Eyes—small, subcutaneous, and in the anterior half of the head, above the level of the angle of the mouth. Jaws of nearly equal length, head depressed. Nostrils patent, wide apart, the posterior with a barbel in front of it, the anterior just over the snout, but not in front of it. Gill-openings wide, not confluent with the isthmus, and extending laterally to opposite the end of the opercle. Barbels—eight, not dilated at their bases, the maxillary are the longest, almost extending to the base of the ventral fin, the external mandibular as long as the head. Teeth—villiform in both jaws, the outer row slightly the longest; in an uninterrupted horse-shoe shaped band across the palate. Lateralline—present. Skin smooth. Air-vessel—large, thin, and in the abdominal cavity. Fins—dorsal without any spine, its first ray the shortest, it arises opposite the ventral: adipose dorsal very low and long. Pectoral spine rather strong, slightly serrated externally, coarsely so internally, the fin only extends half way to the ventral. The anal rays increase in length to the last. Caudal with its central rays strongest and elongated, making the fin one third of the total length. Colours—dark brown.

Habitat.—Pegue Yomas or Mountains.

3. Olyra laticeps.

McClelland, C. J. N. H. ii, p. 588, pl. xxi, f. 2; Bleeker, Beng. p. 58. Branchiosteus laticeps, Gill, Proc. Boston, Nat. Hist. Soc. 1862, p. 52; Günther, Catal. v, p. 98. B. xiii, D. 6/0, P. $\frac{1}{9}$, V. 7 (6?), A. 15, C. 18.

Eyes—small and vertical. Head much depressed at the snout. Lower jaw longer than the upper. Six or eight slender barbels. Teeth-villiform in the jaws, palate edentulous. Fins-the anal rays gradually increase in length from the commencement of the fin. Caudal entire.

Habitat.—Khasya hills.

Genus, 12—Callichrous, Ham. Buch.

Ompok, Lacép.: Kryptopterus,* Kryptopterichthys, Micronema, Phalacronotus, Hemisilurus, Silurodes, Pseudosilurus, and Silurichthys, Bleeker: Pterocryptis, Peters.

Branchiostegals twelve to fifteen. Gill-openings wide, the membranes not confluent with the skin of the isthmus, ore deeply notched and overlap. Head covered with skin. Cleft of mouth oblique, not extending so far as the front edge of the eyes: the lower jaw the longer. Eyes subcutaneous, situated behind and opposite the angle of the mouth, lateral or sometimes partially on the lower surface of the head. Barbels four or two, one maxillary, and some distance behind the symphysis a mandibular pair, the latter sometimes being rulimentary, or even absent. Nostrils remote from one another. Teeth villiform in the jaws, in an uninterrupted (Silurodes, Bleeker) or interrupted (Callichrous, Bleeker) band on the vomer, none on the palatines. Dorsal fin spineless, short, rudimentary, or absent, when present anterior to the ventrals: no adipose fin. Pectoral with a spine. Anal long, continuous with (Pterocryptis, Peters) or terminating close to the caudal, the latter being forked, emarginate or rounded. Ventral with eight to ten rays. Air-vessel rather small, attached to the lower surfaces of the second to the fourth vertebre, and not enclosed in hone. Air-vessel rather small, attached to the lower surfaces of the second to the fourth vertebræ, and not enclosed in bone. No axillary pore.

* The Genus Kryptopterus, Bleeker (omitting the consideration of the barbels) separates those species wherein the dorsal fin is rudimentary or absent from others in which it is short, being in fact a question of degree. Such being so, I think it preferable not to subdivide them. Pterocryptis, Peters, forms perhaps a more natural genus, the anal being united to the caudal, but such a character has not been deemed of sufficient importance to warrant dividing the species of Goboides (p. 316), or Mastacembelus (p. 339) consequently I have not adopted it here. It is curious that if genus Krytopterus were accepted, Professor Peters' Gangetic species with its rudimentary dorsal fin would pertain to such, whereas my Indus one having that fin more developed would belong to Callichrous. The only example of a Cryptopterus recorded from India, is Professor Peters' fish, this is interesting as it seems a form usually found more to the eastwards. more to the eastwards.

Digitized by Google

Geographical distribution.—Sind, India, Ceylon, Burma, through Siam, to the Malay Archipelago and China.

Uses.—Although rarely exceeding a foot in length, these fishes are excellent as food, and owing to their quality have been termed "Butter-fish" by Europeans in Bengal, and are generally known as "Puffta," Hind.

SYNOPSIS OF SPECIES.

A. Anal fin united to the caudal.

Teeth on the palate in an uninterrupted band.

- 1. Callichrous Gangeticus, D. 2, A. 75. Maxillary barbels not quite so long as the head. Ganges. Vomerine teeth in two separate patches.
- 2. Callichrous Sindensis, D. 4, A. 45. Maxillary barbels reach middle of pectoral fin. Indus in Sind. B. Anal fin distinct from the caudal.
- 3. Callichrous bimaculatus, A. 60-75, V. 8. Maxillary barbels reach ventral fin. Pectoral not so long as head, spine smooth or serrated. Fresh waters of Sind, India, Ceylon, and Burma to the Malay Archipelago and China.
- 4. Callichrous palo, A. 66-71, V. 9-10. Maxillary barbels shorter than the head. Pectoral spine feebly
- serrated. Jumna, Ganges, and Burmese rivers.

 5. Callichrous macrophthalmus, A. 69-73, V. 8. Eyes large. Maxillary barbels reach middle of fish. Pectoral fin reaches fourth or fifth anal ray. Madras, Assam, and Burma.

 6. Callichrous Malabaricus, A. 61-69, V. 8. Maxillary barbels reach anal fin: of a purplish brown
- colour. Malabar coast of India.
 7. Callichrous pabda, A. 54-60, V. 8. Maxillary barbels reach middle or end of pectoral fin. Sind, Punjaub, Gangetic provinces, sub-Himalayan range, Assam and Orissa.

A. Anal fin united to the caudal.

Vomerine teeth in an uninterrupted band.

1. Callichrous Gangeticus.

Pterocryptis Gangetica, Peters, Mon. Berl. Acad. 1861, p. 712. Cryptopterus Gangetica, Günther, Catal. v, p. 44.

B. xii, D. 2, P. 1/12, V. 10, A. 75.

Length of head nearly 1/7, height of body 2/19 of the total length. Maxillary barbels do not quite reach the pectorals, whilst the mandibular ones reach the edge of the gill-membrane. Fins—pectoral spine feebly serrated: anal united with the caudal.

Habitat.—Ganges. I have not procured this species in India, my nearest approach to it being C. Sindensis.

- 2. Vomerine teeth in two separate patches.
- 2. Callichrous Sindensis, Plate CX, fig. 1.

B. xii, D. 4, P. 1/12, V. 8, A. 47 ($\frac{2}{4.5}$), C. 13.

Length of head $4\frac{2}{3}$, of caudal 7, height of body $4\frac{2}{3}$ in the total length. Eyes—diameter $4\frac{1}{3}$ in length of head, 1 diameter from end of snout, and 2 apart. The dorsal profile rather elevated, and a little concave over the orbits. The greatest width of the head equals its height, or its length excluding the snout. Cleft of mouth very oblique, the lower jaw prominent, and the eye situated rather above the angle of the mouth. Barbels—the maxillary ones reach to the middle of the pectoral fin: the mandibular ones are thin and nearly half as long as the head. Teeth—in two small oval patches on the vomer not confluent in the median line. Fins—dorsal narrow at its base. Pectoral spine as long in the head behind the middle of the eyes and finely serrated internally, the fin reaches to nearly above the commencement of the anal. Ventral reaches the first anal ray. Anal united to the caudal. Colours-silvery, with a black spot behind the gill-opening and above the base of the pectoral

fin, body and fins with numerous cloudy dark markings.

Habitat. Sind from the Indus. The single specimen is figured life size.

B. xii, D. 4, P. 1/13, V. 8, A. 60-75 $(\frac{2-3}{58-72})$, C. 17.

Length of head 5 to 7, of caudal $6\frac{2}{3}$ to 7, height of body $5\frac{1}{3}$ to $5\frac{1}{4}$ in the total length. Eyes—situated opposite the angle of the mouth, diameter 4 to 53 in the length of the head, 1 to 13 diameters from the end of shout, and $2\frac{3}{4}$ to $3\frac{2}{3}$ apart. The greatest width of the head equals its length behind the angle of the mouth. The lower jaw very prominent, the width of the gape of the mouth equals the postorbital length of the head or behind the middle of the eyes. Barbels—the maxillary pair reach the middle of the pectoral or the commencement of the anal. Teeth—in two small oval patches, one on either side of the vomer, and not continuous. Fins—dorsal arises in the commencement of the second two-seventh's of the body, it is narrow and two-thirds as high as the body. Pectoral as long as the head behind the angle of the mouth, its spine of moderate strength, as long as the head behind the middle of the eyes or as the postorbital length of the head, and strongly or feebly serrated internally, or even entire. Anal ceases close to, but is not continuous with, the forked caudal. Colours-silvery shot with purple, a black spot on the shoulder behind the gill-opening and above the middle of the pectoral fin. In some specimens this black spot is much better defined than in others. Occasionally the caudal fin is tipped with black.

Hamilton Buchanan observes that Callichrons duda only differs from C. canio in having A. 73, instead of A. 69, in his original report he considered them as one. In those reports C. canio is said to be identical with the "Kanipabda of Goálpárá." The figure of Kanipabda 4 inches in length, and of which Buchanan has left two views, shows the pectoral spine serrated. Now C. canio with a serrated pectoral spine would be the same as C. chechra. This brings us to uniting C. duda with C. canio, and also with C. chechra. In speaking of the Bulaya of Gorakpur or the C. canio, he again observes that this fish is the "Chhotki chekra" of Purniah.

McClelland (Cal. Journ. Nat. Hist. ii, p. 583) under the head of Silurus Indicus, McClell. from Loodianah, remarks that "it is identical with S. canio, S. duda, and S. chechra, Buch. which would seem to be but varieties of a widely diffused and common species."* Subsequently (Cal. Journ. Nat. Hist. iv, p. 403) McClelland remarked "the chechra may however be conceived to be a variety of S. bimaculatus."

Buchanan remarked (Fish. Ganges, p. 151) that Callichrous canio "has a very strong resemblance to Silurus himaculatus of Bloch and of La Concde but the time of its toil for any ablack a singurate to a singurant to the singurant state.

Silurus bimaculatus of Bloch and of La Cepede, but the tips of its tail fin are not black, a circumstance to which Bloch's fish owes its name. Besides, in Bloch's fish the first ray of each pectoral fin is a very strong indented prickle.'

These black marks on fins have little or no signification, especially in a skin, as such may be unnatural, but dark tipped caudal fins are not rare in Madras though uncommon inland. As to the serrated pectoral spine Buchanan himself does not appear whilst in India to have attached a specific value to it, and I now propose to examine whether we are justified in doing so? and whether the C. chechra or C. canio, H. B. are not identical with C. bimaculatus, Bloch?

In Orissa I found the number of anal rays varied from 66 to 74, the length of the head 5½ to 5½ in the total excluding the caudal fin, 50 per cent. had the pectoral spine smooth, 25 per cent. had it finely, whilst in 25 per cent it was coarsely serrated. At the Bowany I took some specimens, probably of S. Mysoricus, C. V., 50 per cent. had the pectoral spine denticulated, 25 per cent. had it very finely serrated, and 25 per cent had it smooth. The length of the head to that of the body averaged $4\frac{3}{4}$ to 5 in Madras: 5 to $5\frac{1}{3}$ in Canara: $5\frac{1}{4}$ to $5\frac{1}{3}$ in Canara: $5\frac{1}{4}$ to 5\frac{3}{4} in the Bowany and also in the Punjab: and $4\frac{3}{3}$ to $5\frac{1}{4}$ in Assam.

The following were the numbers of anal rays. Madras, 60-67; Canara, 67-70; Bowany river, which goes to Mysore, 60-65; Punjab, 68-72; Assam, 73-74. In the Deccan and Sind the numbers ranged from 70-75.

I think it is clear that the character of the pectoral spine, as to whether smooth+ or serrated, is no criterion as to species, and that Callichrous bimaculatus, Bloch, is identical with C. chechra, H. B.

Habitat.—The fresh waters of Sind, and from the Punjab throughout India, Ceylon, and Assam to the Malay Archipelago and beyond. It attains at least a foot-and-a-half in length. Fig. 3 is from a Malabar specimen, $8\frac{1}{3}$ inches long, having its pectoral spine finely serrated internally near its termination. Fig. 4 is from an Assam specimen, $6\cdot2$ inches long, and with its pectoral spine finely serrated internally.

4. Callichrous pabo, Plate CX, fig. 6.

Silurus pabo, Ham. Buch. Fish. Ganges, pp. 153, 375, pl. 22, f. 48; Jerdon, M. J. L. and Sc. 1849,

* In Vol. IV, Cal. J. N. H. pp. 401, 402, McClelland appears to have altered his opinion, and considered a Callichrous from Chusan identical with C. duda, H. B., and C. mysoricus, C. V. † At Trichinopoly I opened eight specimens having entire pectoral spines; all were females, one had 47,844 eggs.

Wallago? pabo, Bleeker, Beng. en Hind. p. 54. Callichrous pabo, Günther, Catal. v, p. 48. Callichrous nigrescens, Day, P. Z. S. 1869, p. 616. B. xii, D. 5, P. 1/14, V. 9-10, A. 66-71 $(\frac{3}{63-68})$, C. 17.

Length of head 5 to $5\frac{1}{4}$, of caudal $8\frac{1}{2}$, height of body 5 to $5\frac{1}{2}$ in the total length. Eyes—diameter 4 to $4\frac{1}{2}$ in the length of head, $1\frac{1}{4}$ diameters from the end of snout, and $2\frac{1}{2}$ apart. The greatest width of the head equals its length behind the middle of the eyes. The lower jaw slightly in advance of the upper: the width of the gape of the mouth equals half the length of the head. Barbels—the maxillary ones reach the hind edge of the eye or a little further; the mandibular ones fine and short. Teeth- in two short transverse patches rather distant from one another in the median line. Fins—the dorsal situated in the commencement of the second-third of the length of the body. Pectoral fin as long as the head behind the angle of the mouth, the spine feebly serrated (entire in Burma) and half as long as the head. Ventral with ten rays in India, nine in Burma. Colours—silvery, with a badly marked shoulder-spot.

I found in Burma a variety of this fish, C. nigrescens, it was clouded all over with fine dark spots, and

had black tips to the caudal lobes, and nine ventral rays.

The only specimen I obtained in India was the one figured from the Jumna. There are several in the Calcutta Museum from the Ganges. The species is not common.

Habitat.—Jumna and Ganges rivers, also Burma. Ham. Buchanan observes that it is termed at Patna, Támbüliyá páptá or Callichrous resembling a betel leaf.

5. Callichrous macrophthalmus, Plate CX, fig. 2 and 3.

Pseudosilurus macrophthalmus, Blyth, Proc. As. Soc. of Beng. 1860, p. 156. Callichrous notatus, Day, P. Z. S. 1869, p. 616.

B. xv, D. 4, P. 1/12-15, V. 8, A. 69-73 $(\frac{2-3}{66-70})$, C. 18.

Length of head $5\frac{1}{2}$ to 6, of caudal 6 to 7, height of body 5 to 6 in the total length. Eyes—diameter $3\frac{3}{4}$ to 4 in the length of head, 1 to $1\frac{1}{2}$ diameters from end of snout, and 2 to $2\frac{1}{4}$ apart. The greatest width of the head equals its length excluding the snout. Cleft of the mouth descends to opposite the upper third of the eye: the width of the gape equals 1/2 to 4/9 of the length of the head. Barbels—the maxillary pair reach to opposite the eighth or tenth anal ray: the mandibular ones are nearly 1/2 the length of the head. Teeth—in a very narrow oblong patch on either side of the vomer, and not continuous in the median line. Fins—the dorsal 1/2 as high as the body, narrow (especially in Madras specimens) and situated in the commencement of the second third of the length of the fish excluding the snout. Ventrals equal 1½ diameters of the eye. Anal not united to the caudal, the latter deeply forked. Colours—silvery, a dark round shoulder-spot over the middle of the pectoral spine, this mark is very indistinct in Madras specimens fig. 3, but exceedingly dark in those

The only objection to uniting the Madras with the Assam and Burmese form is that the former has P. 1/12-13, the latter P. 1/15. The shoulder spot is not so well marked, and the dorsal fin not so developed in the Madras variety.

This fish is closely allied to C. bimaculatus, but has a larger eye, a narrow band of palatine teeth, much longer pectoral fins and maxillary barbels.

The Burmese form C. notatus is more elongated.

Habitat.—Madras, Assam, and Burma. Fig. 2 is from an Assam specimen 10.5 inches in length: fig. 3 (life-size) is from a Madras specimen.

6. Callichrous Malabaricus, Plate CXI, fig. 1.

Silurus Malabaricus, Cuv. and Val. xiv, p. 353; Jerdon, M. J. L. and Sc. 1849, p. 334; Günther, Catal.

B. xv, D. 4, P. 1/13-14, V. 8, A. $61-69 \left(\frac{3}{58-66}\right)$, C. 17.

Length of head 5 to $5\frac{1}{2}$, of caudal 7, height of body 6 in the total length. Eyes—opposite the angle of the mouth, diameter $5\frac{1}{2}$ in the length of head, $1\frac{1}{4}$ diameters from the end of snout, and 3 apart. The greatest width of the head equals its length excluding the snout. Lower jaw strongly prominent. Barbels—the maxillary reach to above the commencement of the anal fin, the mandibular ones are short. Teeth—in an interrupted band across the vomer. Fins—dorsal narrow. Pectoral rounded, as long as the head excluding the snout, its spine strong, nearly 1/2 as long as the head, and rather strongly serrated internally. A notch between the end of the anal and the base of the caudal, the last being deeply forked with the upper lobe the longer. Colours of a deep grayish-brown shot with purple, fin membranes densely spotted with black.

Specimens captured to the South of Canara or in the Cochin district show the most anal rays, a more

elongated body, and longer mandibular barbels.

Habitat. -- Malabar coast of India up to 20 inches in length. The specimen figured (161 inches in length) was from Canara.

7. Callichrous pabda, Plate CXI, figs. 2 and 3.

Callichrous Egertonii, Day, Proc. Zool. Soc. 1871, p. 710.

Pallu, Punj.; Pabda, Beng.

B. xii-xiv, D. 4-5, P. 1/11-13, V. 8, A. 54-60 ($\frac{2}{52-58}$), C. 18.

Length of head 5 to $5\frac{1}{4}$, of caudal 8, height of body 5 to $5\frac{1}{4}$ in the total length. Eyes—diameter 5 in the length of head, $1\frac{1}{4}$ to $1\frac{1}{2}$ diameters from end of snout, and $2\frac{1}{2}$ to 3 apart. The greatest width of the head equals its length excluding the snout. The width of the gape of the mouth equals half the length of the head. Lower jaw very prominent. Barbels—the maxillary reach the middle or end of the pectoral fin, the mandibular to the hind edge of the orbit. Teeth—vomerine ones in two small oval patches, not confluent together. Fins pectoral spine as long as the postorbital portion of the head, or the head behind the middle of the eyes, serrated internally, sometimes rather strongly, at other times feebly, or entirely smooth. Anal not confluent with the caudal. Colours—these vary considerably, usually silvery glossed with gold, having a dark shoulder spot above the middle of the pectoral fin, and usually another close to the base of the tail. In some specimens the body is covered with brownish blotches. At Jubbulpore I took specimens having a dark band along the upper portion of the back, and a second along the lateral-line, leaving a light line from the gill-opening to the upper portion of the condel for of the caudal fin.

My reasons for uniting C. pabda (fig. 2), having a smooth pectoral spine, with C. anastomus (fig. 3), having a serrated one, are as follows:—the proportions and number of rays are the same. Near Bheer Bhoom in the Sone river I took four specimene of C. pabla, three had smooth pectoral spines, the fourth had the pectoral spine on one side feebly serrated. In the Sunderbunds* I found the two sorts together, also in the Brahmaputra, the amount of serrations varying considerably. Towards the Punjab and along the Indus in Sind the serrations become very well developed, and the smooth spined sorts are comparatively rare. It is evident that this condition of the spine is not a sexual one, and no less evident that it is due to some local peculiarity.

Habitat.—Punjab in the affluents of the Indus and along that river to its termination: at Hurdwar where the Ganges emerges from the Himalayas and along its waters in the Gangetic provinces, and Orissa, also from Darjeeling and the Brahmaputra in Assam.

Genus, 13-Wallago, Bleeker.

Branchiostegals from fifteen to twenty-one. Gill-openings wide, the membrane not being confluent with the skin of the isthmus, and being rather deeply notched. Body elongated and compressed, the dorsal profile being nearly straight. Head covered with soft skin. Cleft of mouth deep, extending to below or even behind the eyes. Snout rather produced: lower jaw a little the longer. Nostrils some distance apart, the posterior small and patent, the anterior slightly tubular. Barbels four, one maxillary and one mandibular pairs. Eyes above the level of the angle of the nouth, and not covered with skin. Teeth numerous and cardiform in both jaws, and in an oblique patch on either wide of the remove nous on the mulatines. A short spingless derayl situated above or slightly before the postroless are side of the vomer, none on the palatines. A short spineless dorsal, situated above or slightly before the ventrals; no adipose fin: anal long, terminating near the caudal, which last consists of two rounded lobes. Ventrals with from eight to eleven rays. Air-vessel heart-shaped, situated in the abdomen, and attached to the bodies of the second to the fourth vertebræ: axillary pore, if present, minute.

Geographical distribution.—Fresh waters of India, Burma, and the East Indian Archipelago.

Uses.—Good eating, and thrives well in tanks, especially if they have grassy margins.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Wallago attu, D. 1, A. 86-93. Silvery. India and Burma.

1. Wallago attu, Plate CXI, fig. 4.

Wallagoo attu, Bleeker, Atl. Ich. Silur. p. 79; Günther, Catal. v, p. 36; Day, Fishes of Malabar, p. 193. Wah-lah, Mal. and Tam.; Mul-la and Pi-i-kee and Jer-i-kee, Sind.; Boyari, Beng.

B. xix-xxi, D. 5, P. 1/13-15, V. 8-10, A. 86-93 ($\frac{4}{82-89}$), C. 17, Vert. 13/56.

Length of head 5 to $5\frac{1}{2}$, of caudal 9, height of body $6\frac{1}{2}$ in the total length. Eyes—with free lids, diameter 2/15 of length of head, 2 diameters from end of snout. Width of head rather less than its length, and equals half its height. Snout rather produced. Cleft of mouth extending to about 1 diameter behind the orbit, the lower jaw being slightly the longer. Barbels—the maxillary twice as long as the head, mandibular ones as long as the snout. Teeth—generic. Fins—the dorsal nearly as long as the pectoral, which last equals in length the depth of the cleft of the mouth. Pectoral spine finely serrated internally. And not confluent with the caudal, which last consists of two rounded lobes. Air-vessel—of moderate size, somewhat heart-shaped, situated in the front portion of the abdomen and attached to the autorior vertaker. front portion of the abdomen, and attached to the anterior vertebræ. Colours—uniform, fins sometimes covered with fine dots.

Habitat.—Throughout India, Ceylon and Burma. It attains at least six feet in length, and is good eating, but is a voracious and not very cleanly feeder. A stuffed specimen in Calcutta is 4½ feet long.

Genus, 14—SILURUS, Artedi.

Parasilurus; pt. Bleeker.

Dorsal profile nearly horizontal: head covered with soft skin. Gill-openings wide, the gill-membranes not confluent with the skin of the isthmus, and deeply notched, Mouth transverse. Eyes subcutaneous, situated above the level of the angle of the transversely placed mouth. Nostrils remote from one another. Barbels six (Silurus, Blecker): or four (Parasilurus, Blecker): one pair being maxillary, and one or two pairs mandibular. Teeth cardiform or villiform in the jaws, in one or two transverse bands on the vomer, none on the palatines. One very short and spineless first dorsal fin, but no adipose one: and terminates close to the caudal but is not usually continuous with it: ventrals situated posterior to the dorsal, and consisting of eight or more rays. Air-vessel in the abdominal cavity, not enclosed in bone.

Geographical distribution.—In India and Burma this genus is represented in the ghauts on the Western coast: along the Himalayas from Afghanistan to Darjeeling also in the hills above Akyab and in the Tenasserim provinces to Cochin China and beyond. These fishes, so far as I know, have not been recorded from waters of the plains of India.

SYNOPSIS OF SPECIES.

A. With six barbels (Silurus.)

1. Silurus Wynaadensis, A. 58-62. Vomerine band of teeth interrupted. Leaden, shot with purple. Wynaad hills in Madras.

B. With four barbels (Parasilurus).

2. Silurus Afghana, A. 70-78. Vomerine band of teeth uninterrupted. Purplish brown. Himalayas from Afghanistan to Darjeeling.

3. Silurus Cochinchinensis, A. 62-64. Vomerine band of teeth interrupted. Leaden, shot with purple. Hills above Akyab and Tenasserim, to Cochin China.

A. With six barbels.

1. Silurus Wynaadensis, Plate CXI, fig. 6.

Silurus punctatus, Day, Proc. Zool. Soc. 1868, p. 155 (not Cantor). Silurus Wynaadensis, Day, Proc. Zool. Soc. 1873, p. 237.

B. xii-xiv, D. 5, P. 1/10, V. 8, A. 58-62 ($\frac{2}{56-60}$), C. 19.

Length of head 6 to 7, of caudal 10, height of body 8 to $8\frac{1}{3}$ in the total length. Eyes—small, situated just above the angle of the mouth, from $2\frac{1}{2}$ to 3 diameters from the end of snout, and 5 apart. The greatest width of the head equals its length behind the nostrils, lower jaw slightly the shorter and rather elevated in its centre. Width of the gape of the mouth equals the postorbital length of the head. A row of large open pores along the lower jaw and across the cheeks. Barbels—the maxillary nearly twice as long as the head, the mandibular pair on each side situated one anterior to the other at a distance equalling one diameter of the orbit, both extend nearly to the base of the pectoral fin. Teeth—two oval patches on the vomer divided by a short interspace. Fins—dorsal small, situated anterior to the origin of the ventral. Pectoral with a short but strong spine ending in a soft termination. Ventrals reach the origin of the anal, the latter is divided from the rounded caudal by a notch. Colours—leaden, becoming purplish beneath and covered all over with small black points: some specimens have a dark finger mark on the shoulder.

Habitat.—Wynaad, in a stream about 3000 feet above the level of the sea, where Mr. Burnett obtained them, they are said never to exceed 12 inches in length.

B. With four barbels.

2. Silurus Afghana, Plate CXII, fig. 1.

Günther, Catal. v, p. 34.

Silurus Dukai, Day, Proc. Zool. Soc. 1873, p. 239.

D. 2, P. 1/13-14, V. 10, A. 70-78, C. 19.

Length of head 6 to 62, of caudal 9 to 12, height of body 9 to 12 in the total length. Eyes—small, Length of head 6 to 6½, of caudal 9 to 12, neight of body 9 to 12 in the total length. Eyes—small, situated above and behind the angle of the mouth and in the anterior half of the head: the width of the interorbital space rather exceeds 1/2 the length of the head. Upper jaw slightly the longer. Barbels—four, the maxillary reach the base of the ventral, the single mandibular pair as long as the head. A single row of six widely separated open glands under the mandible. Teeth—in a single uninterrupted horse-shoe shaped band on the vomer. Fins—the pectoral as long as the head behind the eyes, rounded, its spine moderately strong, short, entire, and having a soft termination: dorsal fin rudimentary,* and in the anterior third of the total length excluding the caudal fin: anal and caudal scarcely united. Colours—uniform, purplish-black or brown.

Habitat.—The Himalayas: Griffith sent it from Afghanistan. I received several specimens from Dr.

Duka, who obtained them at Darjeeling, and Jerdon presented some to the British Museum, the largest of which is about 7.2 inches in length, the locality is not stated but they probably came from either the Cashmere or

Assam regions. The specimen figured (life-size) was from Darjeeling.

3. Silurus Cochinchinensis, Plate CXIII, fig. 2.

Cuv. and Val. xiv, p. 352; Günther, Catal. v, p. 34; Day, Proc. Z. S. 1869, p. 583. Silurichthys Berdmorei, Blyth, P. A. S. of Beng. 1860, p. 156.

B. xiv-xv, D. 4, P. 1/11, V. 10, A. 62-64 $(\frac{2}{60-62})$, C. 17

Length of head 6 to $6\frac{1}{2}$, of caudal $7\frac{1}{2}$, height of body $6\frac{1}{2}$ in the total length. Eyes—minute, situated in the commencement of the anterior half of the head, and above the angle of the mouth. Upper jaw slightly the longer. The width of the head equals its length behind the nostrils. Barbels—the maxillary about twice the length of the head, the mandibular pair rather shorter than the head. Teeth—in two oval spots on the vomer divided by a smooth interspace. Fins—dorsal arises anterior to the origin of the ventral. Pectoral with a short but strong and scarcely serrated spine: ventrals extend to the origin of the anal, which last is slightly joined to the caudal, the latter being rounded. Colours—leaden, purplish below, and covered all over with minute black points, which sometimes form an irregular finger mark on the shoulder. Caudal sometimes yellow.

Habitat.—The hill ranges above Akyab, Tenasserim from whence Major Berdmore sent a specimen to the

Calcutta Museum, and Cochin China.

Genus, 15—Chaca, Cuvier and Valenciennes.

Branchiostegals six to eight. Head large, depressed. Gape of mouth very wide: lower jaw prominent. Gill-openings somewhat contracted, the membranes confluent with the skin of the isthmus. Eyes minute and subcutaneous. Barbels six, t one maxillary and two mandibular pairs. Teeth villiform in both jaws, palate edentilous. Two rayed dorsal fins, the first having one strong spine and three or four rays, the second confluent with the caudal. Two rayed anal fins, the first with from eight to ten rays, the second somewhat longer and confluent with the caudal. Ventral with six rays, and situated behind the vertical of the first dorsal. Air-vessel rather large; somewhat cardiorm in shape, concave anteriorly, lying across the bodies of the anterior vertebræ and not enclosed in bone. No axillary pore.

Geographical distribution.-Large rivers of Bengal, Assam, and Burma, and sluggish fresh-waters in their vicinity. It extends as far as the Malay Archipelago.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Chaca lophioides, D. 314 | 19-25, A. 8-10 | 8-12. Brownish, marbled with darker. Ganges, Brahmaputra and Irrawaddi rivers.

1. Chaca lophioides, Plate CXII, fig. 2.

Platystacus chaca, Ham. Buch. Fish. Ganges, pp. 140, 374, pl. 28, f. 43.

Chaca lophioides, Cuv. and Val. xv, p. 445, pl. 451; Val. in Bel. Voy. Ind. Ori. Zool. Poissons, pl. iv, f. 2; Günther, Catal. v, p. 29; Kner, Sitz. Wien, Akad. 1855, xvii, p. 101, t. i, f. 2-6.

In my Darjeeling specimens, which are small, this fin is comparatively larger than those in the British Museum.

† If eight, a nasal pair exists.

Digitized by Google

Chaca buchanani, Günther, Catal. v, p. 29. Coor-cur-riah, Ooriah; Pêmā, Bhagulpur, (Ham. Buch.). B. vi, D. 1/3-4 | 19-25, P. 1/5, V. 6, A. 8-10 | 8-12, C. 11.

Length of head 3, of caudal 6 to 8, height of body 6 in the total length. Eyes—small, in the anterior fourth of the head, the width of the interorbital space equals half the length of the head, and along it runs a deep central groove. Head strongly depressed, its width equals its length behind the angle of the mouth. Mouth very wide. Head and body in specimens from India having short tentacles and a ring of them round the eyes, and several along the edge of the lower jaw, such were not present in a specimen I captured in the Irrawaddi. Fins—Dorsal spines slightly serrated on both sides, pectoral spine serrated internally. A few tentacles along the lateral-line. Colours—brownish, marbled with darker.

In the British Museum Catalogue is "a. Adult: stuffed. Nepal. Presented by B. H. Hodgson, Esq." This locality I think rather doubtful, especially as the sea and estuary Therapon jarbua, Forskal, or T. servus, Bloch, is said to have been received "half-grown: stuffed (Nepal.?) Presented by B. H. Hodgson, Esq." Labels so often become become implaced in Museums or in transit, that without the revidence I am doubtful if this fish can be admitted into the Nepal Fauna. I once examined some of Schlagintweit's specimens in a Museum, and found an Exocutus labelled as from Cashmere!

Ham. Buchanan observes "of all the horrid animals of this tribe the Chaka of this district is the most disagreeable to behold. It has the habit of the fishes called by Lacépède Uranoscope and Cotté, that is, it conceals itself among the mud from which, by its lurid appearance, and a number of loose filamentous substances on its skin, it is scarcely distinguishable, and with an immense open mouth it is ready to seize any small prey that is passing along. In order that it may see what is approaching, the eyes are placed on the crown of the head. All persons turn away from it with loathing."

Habitat.—Brahmaputra, Ganges, and Irrawaddi rivers, also tanks in connection with them: there is a specimen in the Calcutta Museum 5 inches long, said to have come from the "Bay of Bengal." It attains at least 8 inches in length. The one figured (life-size) was from Debrooghur in Assam, taken in February, 1874.

Genus, 16—Plotosus, Lacépède.

Platystachus, Bloch; Copidoglanis, Günther.

Branchiostegals nine to twelve. Gill-openings wide, the membrane not being confluent with the skin of the isthmus, and separated by a deep notch. Head depressed covered with thin skin: gape of mouth transverse. Eyes with a free circular margin. Nostrils remote from one another: the anterior tubular and on the front edge of the snout, the posterior patent. Barbels eight. Teeth conical in the upper, mixed in the lower jaw: molariform on the vomer. Two rayed dorsal fins, the first with one spine and four or five rays: the second many rayed and confluent with the caudal, as is also the anal. A pectoral spine. Ventral fin many rayed (12). Air-vessel of moderate size, and not enclosed in bone. A dendritic post-anal apparatus.

Genus Copidinglanis, Günther, is divided from the foregoing, having the first branchial arch with a free membrane along the hinder edge of its concave side, and head rather depressed. Plotosus having the 'branchial arches without particular cartilaginous posterior processes, and without posterior membrane. Head depressed."

Geographical distribution.—From the east coast of Africa through the seas and estuaries of India and Burma to Polynesia and Australia.

SYNOPSIS OF SPECIES.

- 1. Plotosus canius, D. 3, 2 D + C + A 244-271. Uniform brownish. Coasts and estuaries of India, Burma, and the Straits.
- 2. Plotosus Arab, D. $\frac{1}{4-5}$, 2 D + C + A 169-189. Brown, with two longitudinal white bands. From Red Sea and East coast of Africa to Japan and Polynesia.

B. xi-xiii, D. $\frac{1}{6}$, 2 D + C + A 242-271, P. 1/10-11, V. 12, Vert. 15/65.

Length of head $4\frac{1}{2}$ to $5\frac{1}{2}$, height of body 7 to $7\frac{3}{2}$ in the total length. Eyes—diameter 10 to 11 in the length of the head, the width of the interorbital space $2\frac{1}{2}$ to $2\frac{3}{2}$ in the length of the head. The width of the head equals its length behind the angle of the mouth. Barbels—the masal nearly reach the maxillary the end of the opercle or base of the pectoral, whilst the outer mandibular pair are slightly longer than

the inner ones. Fins-dorsal spine serrated on both edges, and equal to 2/5 of the length of the head, pectoral spine similar and equal to 1/3 of the length of the head. Colours—brown, the vertical fins edged with black.

Plotosus limbatus, C. V. xv, p. 422; Günther, Catal. v, p. 25, is said to differ in its 2 D + C + A=224
rays: its head and also its nasal barbels being a little shorter.

Bleeker observes that the Malays at Batavia believe that the flesh of this fish has emmenagogue

Habitat.—Estuaries of India and Burma to the Malay Archipelago. It attains 3 feet and upwards in length.

Moorghee, Mal.

B. xi, D. $\frac{1}{4-5}$, 2 D + C + A 169-190, P. 1/11, V. 12, Vert. 12/35.

Length of head 5 to $5\frac{1}{2}$, height of body 7 to 8 in the total length. Eyes—diameter 5 to $6\frac{1}{2}$ of, and situated in the middle of the length of head, the width of the interorbital space equals 1/3 of the length of the head. Greatest width of the head equals its length behind the angle of the mouth. Upper jaw slightly the longer, the width of the gape of the mouth equalling 2/5 of the length of the head. Barbels—the nasal reach the hind edge of the eyes, the maxillary 1/2 to 2/3 as long as the head, the mandibular ones are shorter. Fins—dorsal spine rather strong, 1/3 as long as the head and serrated on both sides. Colours—chestnut-brown, with two bluish-white longitudinal bands, the superior proceeding from above the eye along the base of the dorsal fin, the inferior from the maxilla along the middle of the side of the body. Bleeker observes that these bands entirely disappear in adults. Vertical fins with black edges.

Wounds from the pectoral spines of this fish are much dreaded by the natives of India as occasioning

phlegmonous inflammation or even tetanus.

Habitat.—From the Red Sea and East coast of Africa through the seas of India to Japan and Polynesia.

B. Air-vessel more or less enclosed in bone.*

Genus, 17-CLARIAS, Gronovius.

Macropteronotus, Lacépède; Cossyphus and Phagorus, McClelland.

Branchiostegals seven to nine. Gill-openings wide, the membranes not being confluent with the skin of the isthmus, and separated by a deep notch. A dendritic accessory branchial apparatus attached to the convex side of the second, third, and fourth branchial arches is received into a recess above and behind the usual gill-cavity. Head depressed, gape of mouth of moderate extent, anterior and transverse. Eyes small, with a free circular margin. Barbels eight. Teeth villiform in the jaws and in a band across the vomer. Dorsal fin long and spineless, extending from the neck to the caudal, with which it may be continuous: no adipose fin. Ventral with six rays. Pectoral with a spine. Air-vessel small, transverse, lobed, and enclosed in bone.

Mr. Kitchen-Parker, F.R.S. (on the shoulder girdle, Ray Society, 1868, p. 29) observes of the air-vessel and its surroundings in *Clarias*. "The remarkable trumpet-shaped cavities belong to the Atlas and Axis vertebræ, and they are strongly attached to the post-temporals and clavicles at their point of junction: they lodge the lateral cornua of the three lobed air-bladder. These cavities are very imperfect below: but this deficiency is largely appaled to the attached below to the cartesian advanced. deficiency is largely supplemented by a transverse splint on each side, attached, below to the anterior edge of the great cylinder of the atlas. There is a smaller splint in each cavity, and two smaller splints eke

* This provisional subdivision of the Siluroids is adopted merely for the sake of convenience. A considerable number of dissections will be necessary before the grouping of this family can be satisfactorily arranged. In some of those forms in which the air-vessel is partially enclosed in bone such is effected by the auditory ossicles, in others by being enclosed in osseous capsules formed from a vertebra, or ossified to the vertebra. Placing the amphibious Clarias in the same sub-tamily with Plotosus and Chaca, and putting the amphibious Saccobranchus in another sub-family along with the non-amphibious Silurus, Wallago, and Eutropiichthys does not seem natural. I have here followed Bleeker in placing the amphibious Clarias next to the equally amphibious Saccobranchus.

Digitized by Google

out the mouth of each of these trumpets. The large obliquely transverse splints (they are sometimes turned backwards) meet within a line and a half below the centrum of the atlas, between and behind the splints. This and the next centrum are deeply grooved."

Geographical distribution.—Throughout Africa and western Asia to India, Ceylon, Burma, Siam, the Malay Archipelago, Hong-Kong, the Philippines and beyond. These fish being amphibious live for some time after removal from their native element.

Uses.—Considered by the natives of India as exceedingly wholesome and invigorating.

SYNOPSIS OF SPECIES.

a. Vertical fins confluent with the caudal.

1. Clarias jagur, D. 53, A. 50.

b. Vertical fins not united to the caudal.

 Clarias Teysmanni, D. 70-77, A. 53-63. Vomerine teeth obtuse. Ceylon, Java.
 Clarias Dussumieri, D. 69-70, A. 50-59. Pectoral spine externally serrated. Vomerine teeth very obtuse. Malabar, Pondicherry to the Malay Archipelago.
4. Clarias magur, D. 62-76, A. 45-58. Vomerine teeth villiform. India, Burma, and Ceylon to the

Malay Archipelago.

5. Clarias Assamensis, D. 64-68, A. 46-50. Vomerine teeth obtuse and in two pyriform bands. Assam.

A. Vertical fins confluent with the caudal.

1. Clarias jagur.

Macropteronotus jagur, Ham. Buch. Fish. Ganges, pp. 145, 374. Clarias jagur, Cuv. and Val. xv, p. 388; Bleeker, Beng. p. 58.

D. 53, P. 1/7, V. 6, A. 50, C. 14.

"On the crown of the head is one oval cavity." Nasal barbels as long as the head, maxillary slightly longer: the two outer mandibular are a little longer than the inner, and reach to the back of the head. Teeth-it is stated there are none on the palate. Colours-superiorly blackish-green, below whitish, whilst the sides are slightly variegated with clouds. The fins are of the same colour with the parts on which they are inserted.

This fish I have never seen although I have searched for it in numerous places, the nearest approach has been a mutilated C. magur. Hamilton Buchanan does not record where he procured it, and on examining his MSS. list of fishes obtained in each several district, no allusion is made to it, neither is a figure of it amongst his drawings. It is probably therefore an estuary form.

Habitat.—? It is said to be larger than C. magur, attaining a foot-and-a-half in length.

B. Vertical fins not confluent with the caudal.

2. Clarias Teysmanni.

Blecker, Nat. Tyds. Ned. Ind. xiii, p. 344, Prod. Silur. p. 348, and Atl. Ich. Silur. p. 104, t. 99, f. 1; Günther, Catal. v, p. 19.

? Clarias brachysoma, Günther, Catal. v, p. 20.

B. xi, D. 70-77, P. 7-10, V. 6, A. 53-63, C. 17, Vert. 16/41.

Length of head to end of opercle 5 to $5\frac{1}{2}$, height of body $6\frac{1}{2}$ to $7\frac{1}{2}$ in the total length. Eyes—situated in the commencement of the second third of the total length of the head to the end of the occipital process. The greatest width of the head equals its length to hind edge of opercle. Head nearly smooth. Occipital process 2/3 as long as wide at its base. Barbels—the nasal as long as the head, the maxillary reach the end of the pectoral fin, the mandibular ones are shorter. Teeth—those on the vomer somewhat obtuse, forming a crescentic band which in its centre is of about equal width to the premaxillary band. Fins—the pectoral extends nearly to below the origin of the dorsal fin, its spine moderately strong, more than 2/3 the length of the fin, rugose or finely serrated along its outer edge, serrated internally. Caudal free. Colours—brownish.

Amongst the types of C. brachysoma, in the British Museum, the number of anal rays vary from 53 to 60,

the fish appears to me to be similar to C. Teysmanni.

Habitat.—Ceylon and Java.

3. Clarias Dussumieri.

Cuv. and Val. xv, p. 382; Jerdon, M. J. L. and Sc. 1849, p. 342; Day, Fishes of Malabar, p. 197. Clarias melanoderma, Bleeker, Silur. Batav. p. 54, and Prod. Sil. p. 341, and Atl. Ich. Silur. p. 102, t. 97, f. 2; Günther, Catal. v, p. 19.

Clarias (melanosoma) melasoma, Bleeker, Nat. Tyds. Ned. Ind. iii, p. 427.

B. xi, D. 69-70, P. $\frac{1}{8}$, V. 6, A. 50-59, C. 16.

Length of head to end of gill-cover 6, of caudal 9, height of body 82 in the total length. Eyes—in the commencement of the front third of the distance between the end of the occipital process and the snout: the width of the interorbital space equal to 1/2 the length of the head. The greatest width of the head equals its length: its upper surface finely shagreened and covered with skin, on it are two depressions, the anterior which is oblong extends to opposite the front margin of the eyes, the posterior which is oval is midway between the posterior end of the anterior depression and that of the occipital process, which last is scarcely produced and $3\frac{1}{2}$ times as wide at its base as it is long. Barbels—the nasal reach the hind edge of the eye, the maxillary to the base of the pectoral fin, those on the lower jaw are shorter. Teeth—those on the palate with globular heads and in an uninterrupted curved band, which is rather wider than those on the premaxillaries. Fins—pectoral spine rather strong, its length equals 1/2 the distance between the base of the occipital process and the end of the snout, it is rather strongly serrated externally with a few recovered spines peer its extremity more feebly intervally, whilst the length of the few only exceeds 1/2 the few recurved spines near its extremity, more feebly internally, whilst the length of the fin only equals 1/2 the distance between its base and that of the ventral, it does not quite reach to below the origin of the dorsal. Caudal distinct from the other vertical fins.

I only procured one specimen (7 inches long) from the Wynaad in Malabar. Jerdon seems to have obtained it from tanks and ditches in Malabar. The length of the entire head is 1/4 of the total excluding the caudal fin. It appears to agree with Bleeker's Malay form.

Habitat.—Malabar and Pondicherry to the Malay Archipelago.

B. ix, D. 62-76, P. $\frac{1}{8-11}$, V. 6, A. 45-58, C. 15-17.

Length of head to end of gill covers $5\frac{2}{3}$, of caudal $8\frac{3}{4}$, height of body $6\frac{1}{2}$ to $7\frac{1}{2}$ in the total length. Eyes—diameter 8 in the length of the head, 2 to $2\frac{1}{2}$ diameters from the end of snout, the width of the interorbital space equals 1/2 the length of the head. The greatest width of the head equals its length. Upper jaw the longer, the width of the gape of the mouth equals 4/9 of the length of the head. Head shagreened superiorly and covered with fine granules. Two depressions on the head, the anterior oblong and situated so that its first fourth is between the eyes: the posterior oval and placed midway between the posterior extremity of the anterior fossa and the end of the occipital process. Occipital process rounded behind, the width of its base equalling rather above twice in its length. Barbels—the nasal reach the base of the occipital process: the maxillary the base or middle of the pectoral fin, the mandibular ones shorter. Teeth—on the vomer villiform, not so fine as those in the jaws and becoming a little blunted with age, they form an uninterrupted band which in its centre is rather narrower or as wide as the premaxillary band. Fins—pectoral fin reaches to below the commencement of the dorsal, its spine finely serrated* but covered with skin. Hamilton Buchanan observed that its edges were unindented: and in Cuv. and Val. the same fact is recorded of some Bengal specimens. Caudal free. Colours—dingy green or brownish superiorly, becoming lighter beneath: the vertical fins usually with reddish margins.

Habitat.—Fresh and brackish waters of the plains of India, Burma, Ceylon, and the Malay Archipelago. It lives long after its removal from its native element, being amphibious. It attains at least a foot and a half

in length. As food it is deemed highly nourishing.

Clarias Assamensis.

Mah-gur, Assamese.

B. ix, D. 64-68, P. $\frac{1}{8-11}$, V. 6, A. 46-50, C. 14.

Length of head to end of opercle $5\frac{3}{4}$ to $6\frac{1}{4}$, of caudal $8\frac{1}{3}$, height of body $6\frac{1}{3}$ to 7 in the total length. Eyes—in the commencement of the anterior third of the total length of the head, width of the interorbital space equal to 2/5 of the total length of the head. The greatest width of the head equals its length between the

* The outer serration varies considerably, as a rule in Calcutta specimens they are blunt and nodulated, whilst the inner serrature is likewise very feeble. In Burma a minority of the specimens have the outer edge of the pectoral spine serrated, whilst the vomerine teeth are very slightly obtuse.

snout and the hind edge of the opercle: the width of the gape of the mouth equals 1/3 of the total length of the head. Upper surface of the head very finely shagreened and covered with thin skin: two depressions on the head, the anterior oblong and reaching forwards to between the middle of the eyes: the posterior oval and commences midway between the posterior end of the anterior fossa and the end of the occipital process, which latter is rounded, and twice as broad at its base as it is long. Barbels—the nasal reach to the base of the occipital process: the maxillary to the end of the pectoral spine: the mandibular ones are shorter. Teeth—those

on the vomer in two pyriform bands of globular ones, the widest end being internal where it exceeds the width of the premaxillary band. Fins—pectoral reaches to below the commencement of the dorsal fin and 1/2 way to the base of the ventral, its spine strong, 1/3 of the total length of the head, rough externally, serrated internally. Ventral reaches anal. Vertical fins not confluent with the caudal. Colours—greenishbrown, vertical fins edged with red.

This fish appears to take the place of C. magur in Assam, and I have procured it from Goalpara and as

high as Suddya. Its teeth distinguish this from other species or perhaps varieties.

Habitat.—Upper and lower Assam.

Genus, 18-Saccobranchus, Cuvier and Valenciennes.

Heteropneustes, Müller.

Branchiostegals seven. Gill-openings wide, the membranes not being confluent with the skin of the isthmus, and separated by a deep notch. Gill cavity having an accessory posterior sac, which extends backwards on either side of the neural spines amongst the muscles of the abdominal and part of the caudal region. Head depressed, covered with very thin skin: mouth transverse. Eyes with a free circular margin. Barbels eight. Teeth present in the jaws and on the vomer. Dorsal fin short and spineless: ventral with six rays situated under the dorsal. Anal long and confluent with or separated from the caudal by a notch. Air-vessel* placed transversely across the bodies of the anterior vertebra, where it is enclosed by bone, a duct passes upwards from either side of the air-vessel, unites, and opens into the inferior surface of the pharynx.

Geographical distribution.—Fresh waters of India, Ceylon, Burma, and extending to Cochin China, but not found in the Malay Archipelago. Being amphibious (see p. 439) they can live long after their removal from

Uses.—Considered exceedingly wholesome and invigorating by the natives of India, but in some places deemed by the Brahmins to be impure.

SYNOPSIS OF SPECIES.

A. Anal fin united to the caudal.

- 1. Saccobranchus microps, D. 8, A. 70. Eyes small. Ceylon.
 - B. Anal fin separated from the caudal by a notch.
- 2. Saccobranchus fossilis, D. 6-8, A. 60-79. India and Burma.

A. Anal fin united to the caudal.

1. Saccobranchus microps.

Günther, Catal. v, p. 31.

D. 8, P. 1/6, A. 70.

Length of head $7\frac{1}{2}$, height of body 8 in the total length. Eyes—much smaller than in S. fossilis, and less than 1/3 in the length of the snout. Barbels—the nasal ones reach the end of the pectoral: the maxillary the root of the ventral fin. Teeth—the vomerine band is interrupted in its centre. Fins—origin of the dorsal is 2/7 of the length (excluding the caudal fin) from the end of the snout. Pectoral spine feebly serrated, two thirds as long as head. Ventral fin reaching the anal, which last is united with the caudal. Colours - brown.

Habitat.—Ceylon, to 6 inches in length.

- B. Anal fin separated from the caudal by a notch.
- 2. Saccobranchus fossilis, Plate CXIV, fig. 1.

B. vii, D. 6-7, P. 1, V. 6, A. 60-79, C. 19.

Length of head from $5\frac{1}{2}$ to 7, of caudal from about 9 to 14, height of body (greatly depending upon food or season) from 5 to 8 in the total length. The width of the head equals its length, and that of the gape of the mouth $2\frac{1}{4}$ to $2\frac{1}{2}$ in the length of the head. Eyes—from 2 to 3 diameters from end of snout. Barbels—the maxillary extend to the middle of the pectoral, or even the commencement of the ventral fins. Teeth—those on the vomer in a pyriform patch on either side, converging anteriorly, widely divergent posteriorly. Fins—the dorsal commences rather before the anterior third of the body: the ventrals reach to the third or fourth anal ray or just to the origin of that fin.* Pectoral spine serrated internally, also usually with a few serrations externally at its anterior end, it is from two-thirds to three-fourths as long as the head. Anal and caudal separated by a more or less distinct notch. Colours—leaden, sometimes with two longitudinal yellowish bands. The young are occasionally reddish.

Wounds from the pectoral spine of this fish are dreaded in India, as they are reputed to be very poisonous, even occasioning tetanus. As soon as captured, the offensive spine is broken off by blows with a stake, consequently it is difficult to procure a large and perfect specimen. Fishermen dread it so much that they would prefer cutting the meshes of their nets and allowing it to escape than endeavour to remove it uninjured. As food the flesh is esteemed for its invigorating qualities, and tanks are frequently stocked with them during the rainy season. When food is plentiful they fatten well, if the reverse they become lanky, thus altering the comparative height of the body to that of its length.

In a specimen captured at Bezwada, September 12th, 1868, the ova were fully developed: the colour of

the eggs was of a pea-green.

Habitat.—Fresh waters of Sind, India, Ceylon, Burma, and Cochin-China, attaining a foot or more in length.

Genus, 19—SILUNDIA, Cuvier and Valenciennes.

Branchiostegals eleven to twelve. Gill-openings wide, the gill-membranes overlapping but not confluent with the skin of the isthmus. Body elongated and compressed. Head covered with soft skin. Eyes lateral, with narrow adipose lids. Mouth rather wide, not cleft to so far as the eyes, lower jaw the longer. Nostrils, those on either side approximating, the anterior pair in front of the snout and a little external to the posterior pair. A pair of maxillary and sometimes also a pair of mandibular barbels. Villiform teeth in the jaws, and in an uninterrupted band on the palate. First dorsal fin with one spine and seven rays: the adipose short. Anal long (40-50 rays). Ventral with 6 rays, placed below or just behind the adipose dorsal. Air-vessel kidney-shaped, convex anteriorly, lying across the body of an anterior vertebra, from which it is separated by the aorta, having its lateral margins protected by bone. An axillary pore.

Geographical distribution.—Throughout the larger rivers of India and Burma.

SYNOPSIS OF SPECIES.

A. Two pairs of barbels.

1. Silundia Sykesii, A. 44-50. A pair of maxillary and also of mandibular barbels. Rivers of the Deccan to their terminations.

B. One pair of barbels.

- 2. Silundia Gangetica, A. 40-46. A pair of short maxillary barbels. Indus, Ganges, Jumna, and large rivers of Assam and Burma.
 - A. A pair of maxillary and also mandibular barbels.
 - 1. Silundia Sykesii, Plate CXIV, fig. 2.

Day, Journ. Linn. Soc. Zool. xii, 1876, p. 569.

? Ageneiosus Childreni, Sykes, Trans. Zool. Soc. ii, p. 375, t. 66, f. 3. ? Silundia Childreni, Bleeker, Hind. p. 58; Jerdon, M. J. L. and Sc. 1849, p. 340. Wal-la-ke kel-le-tee (slippery siluroid) and Poo-nat-tee, Tam.; Wan-jou, Tel.

B. xii, D. $\frac{1}{7}$ | 0, P. 1/12, V. 6, A. 44-50 $\left(\frac{2-3}{4\cdot 2-4\cdot 7}\right)$, C. 19.

Length of head $5\frac{1}{4}$, of caudal $4\frac{3}{3}$, height of body $5\frac{3}{4}$ in the total length. Eyes—with a narrow, free, adipose lid, diameter $3\frac{1}{2}$ in the length of the head, 1 diameter from the end of snout, and $1\frac{1}{3}$ apart. The greatest width of the head equals its length behind the middle of the eyes: lower jaw the longer, curved upwards in the middle: snout rather broad: the width of the gape of the mouth equals 4/11 of the length of the

* In Assam the ventrals sometimes do not reach the anal fin.

head. Barbels—the maxillary ones reach the opercle or even the base of the pectoral fin: the mandibular ones equal one diameter of the eye in length. Teeth—villiform in the jaws, in a crescentic band across the palate. Fins—dorsal spine weak, roughened anteriorly, finely serrated posteriorly and as long as the head excluding the snout: pectoral spine stronger, as long as the head behind the angle of the mouth, and reaching to above the ventral. Ventral arises behind the vertical from the last dorsal ray, and reaches to the anal. Caudal forked, the lower lobe rather the longer. Free portion of the tail nearly as high as long. Colours—bluish superiorly, becoming white on the sides and beneath, the fins stained externally with gray.

Sykes says his fish is termed *Purree*, Mahr. and *Sillun* in the Deccan, that it is without cirri, and also that the first bony ray is "serrated on the anterior edge," such being also shown in the figure.

The long maxillary barbels of this species serve to distinguish it from S. Gangetica, C.V. Hubitat.—Rivers of the Deccan and the Kistna and Godavery to their terminations.

B. A pair of short maxillary barbels only.

B. xi-xii, D. $\frac{1}{7}$ | 0, P. 1/11-13, V. 6, A. 40-46 ($\frac{4}{36^{4}+4}$), C. 17.

Length of head $5\frac{1}{4}$, of caudal $5\frac{1}{2}$ to 6, height of body 5 to $5\frac{1}{4}$ in the total length. Eyes—with narrow Length of head $5\frac{1}{4}$, of caudal $5\frac{1}{2}$ to 6, height of body 5 to $5\frac{1}{4}$ in the total length. Eyes—with narrow anterior and posterior adipose lids, diameter 4 to $4\frac{1}{2}$ in the length of head, $1\frac{1}{4}$ to $1\frac{1}{2}$ diameters from the end of snout, and 2 apart. The width of the head equals its length excluding the snout, whilst its height is rather less. Lower jaw the longer, snout rather broad, the width of the gape of the mouth exceeding 1/2 the length of the head. Barbels—a pair of minute maxillary but no mandibular ones. Teeth—in the jaws villiform, and in a crescentic band across the palate. Fins—dorsal spine rather weak, as long as the head behind the middle of the eye, anteriorly smooth or rugose, posteriorly finely serrated in its upper portion. Pectoral spine stronger, as long as head without the snout, and serrated internally. Ventral arises under the posterior dorsal rays, and nearly reaches the anal. Air-vessel—small, with its lateral edges protected by a short osseous process from either side of the vertebra, but it cannot be said to be enclosed in bone. The air-vessel itself, when opened, is found to consist of two oval chambers, having a communicating canal, and in the young is almost surrounded by high osseous sides. Colours—bluish along the back, becoming silvery on the sides, fins stained with gray.

by high osseous sides. Colours—bluish along the back, becoming silvery on the sides, fins stained with gray.

Habitat.—Estuaries of India and Burma, ascending high up the larger rivers to nearly their sources. It

attains 6 feet or more in length, and is called "a shark" by the natives. It is very voracious.

Genus, 20—AILIA, Gray.

Branchiostegals eight. Gill-openings wide, the gill-membranes not confluent with the skin of the isthmus. Body elongated and strongly compressed. Head covered with thin skin. Eyes nearly or quite behind the angle of the mouth, and with adipose lids. Upper jaw slightly the longer. Nostrils patent, those on either side approximating, the anterior in front of the snout. Eight barbels. Villiform teeth in the jaws and in two minute patches on the vomer. No anterior,* but a small adipose dorsal fin posteriorly. Pectoral with a spine. Ventral with six rays. Anal long (59-75 rays). Caudal forked. Air-vessel tubiform, lying across the body of an anterior vertebra, from which it is separated by the aorta, whilst externally it is protected by bone. No axillary pore.

Geographical distribution.—Sind, the larger rivers of the Punjab, N. W. Prov. Bengal, Assam and Orissa.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Ailia coila, V. 6, A. 59-75. Silvery, fins usually with dark edges. Indus, Jumna, Ganges, Brahmaputra, and Mahanuddee rivers.

1. Ailia coila, Plate CXIV, fig. 4.

Malapterurus coila, Ham. Buch. Fish. Ganges, pp. 158, 375. Silurus (Acathonotus) Cuvieri, Gray and Hard. Ind. Zool.

Malapterus (Ailia) Bengalensis, Gray and Hard. Ind. Zool.; Swainson, Fishes, ii, p. 307.

Ailia Bengalensis, Gray, Zool. Misc. 1831, p. 8; Cuv. and Val. xv, p. 538; Günther, Catal. v, p. 56. Acanthonotus Hardwickii, Gray, Zool. Misc. 1831, p. 8.

Melapterurus Cuvieri, Swainson, Fishes, ii, p. 307.

* In some specimens there is a small basal bone situated on the back anterior to the vertical from the origin of the ventral fin, otherwise I cannot discover a vestige of the first dorsal fin. However, Dr. Günther has discerned "a small hole in the skin where the dorsal fin ought to have been placed, it is a short distance from the occiput, and a little before the vertical from the ventral fins," Catal. v,

Ailia coila, Bleeker, Beng. p. 54; Blyth, P. A. S. of Beng. 1858, p. 283.

Ailia affinis, Günther, Catal. v, p. 56.

B. viii, P. 1/14, V. 6, A. 59-75, C. 19.

Length of head 6 to 7, of caudal $5\frac{1}{2}$ to 8, height of body $5\frac{1}{4}$ to 6 in the total length. Eyes—diameter $3\frac{1}{2}$ to $3\frac{3}{4}$ in the length of the head, $1\frac{1}{4}$ diameters from the end of snout, and 1 apart. The greatest width of the head equals its length excluding the snout: the width of the gape of the mouth equals 1/3 of the length of the head equals its length excluding the snout: the width of the gape of the mouth equals 1/3 of the length of the head. Upper jaw the longer, and rather overhung by the snout. Cleft of the mouth reaching 1/2 way to the orbit opposite the centre of the eye. Barbels—extend to the first 1/3 or middle of the length of the fish excluding its caudal fin. Teeth—generic. Fins—pectoral spine slender and about as long as the head. Ventral short. Anal with from 59 to 75 rays in my specimens, and most of the intermediate numbers may be found (A. affinis is given A. 60-61: A. Bengalensis, A. 70-72. One of the first specimens I captured at Delhi had A. 67). Caudal forked. In many specimens the neural spines just appear above the skin along the back. Colours—silvery, some of the fins often stained gray at their margins. The caudal, especially in Orissa specimens, is commonly expressed and with block. is commonly orange edged with black.

This fish is excellent eating. There is a figure of it amongst Sir W. Elliot's drawings from the Telugu

country, probably the Kistna.

Habitat.—From the Kistna and Orissa, throughout the Indus, Jumna, and Ganges, after they leave the hills to their termination; also Assam. It attains at least 7 inches in length. Ham. Buch. records it to 8 or 12 inches in length.

Genus, 21—AILIICHTHYS, Day.

Similar to Ailia except that the ventral fins are absent.*

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Ailiichthys punctata, A. 76-90. A black spot at the base of the caudal fin. Indus, rivers of the Punjab and the Jumna.

1. Ailiichthys punctata, Plate CXIV, fig. 5.

Day, Proc. Zool. Soc. 1871, p. 713.

Put-tas-si and Put-tu-ah, Punj.

P. 1/12, A. 76-90, C. 17.

Length of head 6 to 7, of caudal 6, height of body $5\frac{1}{2}$ in the total length. Eyes—situated more than half below the angle of the mouth, being partly on the lower side of the head, diameter 4/11 to 1/3 of length of head, 1/2 to 2/3 of a diameter from end of snout, 1 diameter apart. Body compressed, upper profile of the head slightly concave. Width of the head equals its postorbital length. Width of the gape of the mouth equals 1/3 of the length of the head. Upper jaw somewhat the longer, the cleft of the mouth only extending about half way to the anterior margin of the eye, and to opposite its centre. Barbels—much the same length and extend to the middle of the length of the fish. Teeth—villiform in the jaws. Fins—adipose dorsal minute. Pectoral spine nearly as long as the head: ventrals absent. Caudal forked, lower lobe the longer. Colours silvery, upper surface of head nearly black, a large black spot before the base of the caudal fin.

Habitat.—Jumna below Delhi, also from the Indus in Sind, where I obtained numerous specimens up to

4 inches in length.

Genus, 19—Eutrophichthys, Bleeker.

Branchiostegals eleven. Gill-openings wide, the membranes not being confluent with the skin of the isthmus, but separated by a deep notch. Body and head compressed. Head covered with soft skin. Eyes with broad adipose lids. Cleft of mouth deep, extending to below the eyes: upper jaw slightly the longer. Nostrils wide and patent, the anterior and outer one being at the side of the snout. Eight barbels. Teeth in jaws shurp: and in a broad band across the vomer and palatines. † First dorsal short, having one spine and seven rays: the adipose short. Pectoral

• Professor Troschel (Wiegm. Arch. 1871, pp. 276-280) remarked upon having received a female specimen of the Siluroid Copidoglanis brevidorsalis destitute of a ventral fin, and considered such might be a sexual character. Dr. Günther (Zool. Record, 1871, p. 104) gave his opinion that the apodal specimen was more likely an instance of individual monstrosity, adducing as one reason that he had seen such in Erythrinus, Ophiocephalus, &c. Dr. Günther (Annal, and Mag. Nat. Hist. 1867, xx, p. 308) drew attention to the fact "that in numerous groups of fishes which live in mud, forms occur devoid of or with only rudimentary ventral fins." I have likewise found in Ireland abnormal examples of Gasterosteus pungitius, in which the ventrals were absent. In the case of the fish described above, out of many specimens, the ventral was absent in all. It however becomes a question whether the absence of this fin should be a sufficient characteristic on which to found a Genus. If not, the Genera Channa, Apua, &c. will have likewise to be suppressed.

† Having (Proc. Zool. Soc. 1869, p. 396) drawn attention to the statement in the definition of this Genus, of "no teeth on the palate," in the "Catalogue of Fishes of the British Museum," Dr. Günther (Zool. Record, 1869, p. 134) observed that "having received an example from Colonel Playfair some years ago, the Recorder has found the palatine teeth, which may be distinguished on a very 'superficial examination.'"

Digitized by GOO

with a spine. Ventral with six rays and situated below the rayed dorsal. Anal long (47-50 rays). Caudal forked. Air-vessel tubiform, and as in Ailia. No axillary pore.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Eutropiichthys vacha, D. 1, A, 3,4. Silvery. India and Burma.

1. Eutropiichthys vacha, Plate CXIV, fig. 6.

Pimelodus vacha, Ham. Buch. Fish. Gang. pp. 196, 378, pl. 19, f. 64. Bagrus vacha, Cuv. and Val. xiv, p. 392; Bleeker, Beng. p. 56. Pachypterus punctatus, Swainson, Fisher Gircher, Charles Co. Dec. Barther Co.

Eutropiichthys vacha, (Bleeker), Günther, Catal. v, p. 38; Day, Proc. Zool. Soc. 1869, p. 306.
Butching, Ooriah; Chel-lee, Sind.; Nee-much, N. W. Prov.; Váchá, Beng.; Nga-myenkouban and Katha-boung, Burmese.

B. xi, D. $\frac{1}{7}$ | 0, P. 1/13-16, V. 6, A. $\frac{3-4}{4}$, C. 17.

Length of head $5\frac{1}{2}$ to $5\frac{3}{4}$, of caudal 5, height of body 5 to $5\frac{1}{2}$ in the total length. Eyes—with broad adipose lids, diameter $3\frac{1}{2}$ to $3\frac{3}{4}$ in the length of the head, 1 diameter from the end of snout, and 1 to $1\frac{1}{4}$ apart. Width of the head equals its length behind the middle of the eyes. Cleft of mouth rather oblique, its extent being 1/4 more than the width of the gape: the angle situated under the middle or hind third of the eyes: snout compressed and pointed, the upper jaw being slightly the longer. Barbels—the nasal pair reaching to the hind edge of the head or even slightly further: maxillary ones to the end of preopercie or even as long as the head: the mandibular ones, which arise on a transverse line across the chin, are rather shorter. Teeth-sharp ones in the jaws, in a pyriform band on the palatines, which with those on the vomer form an uninterrupted band, that nearly touches the band on the upper jaw. Fins—dorsal spine thin, serrated posteriorly, and usually as long as the head excluding the snout. Pectoral fin reaches the base of the ventral, its spine is rough externally, serrated internally, and as long as that of the dorsal. Ventral situated under the posterior dorsal rays, and only extends half-way to the anal. Free portion of the tail as high as long.

Colours—silvery, grayish along the back: pectoral and caudal usually edged with black.

Variety Eutropiichthys Burmannicus has A. 5, and its nasal barbels almost reach to the dorsal fin: the maxillary to the middle of the pectoral spine, whilst all the others are longer than the head. The pectoral

spine is serrated externally, and reaches the anal fin.

Habitat.—From the Punjab through the large rivers of Sind, Bengal, Orissa, and variety E. Burmannicus in Burma. It attains upwards of a foot in length. It is good eating,

Genus, 23—Amblyceps, Blyth.

Branchiostegals twelve. Gill-openings wide, the gill-membranes not confluent with the skin of the isthmus, notched as far forwards as the chin. No thoracic adhesive surface. Head covered with soft skin. Eyes small, subcutaneous. Mouth anterior: gape wide. Nostrils close together, the posterior having a barbel. Teeth in juws villiform: palate edentulous. Anterior dorsal fin enveloped in skin, having one spine and six rays. Pectoral with a concealed spine. Ventral with six rays, inserted behind the vertical from the posterior margin of the rayed dorsal. Anal rather short (9 to 12 rays). Caudal forked. Air-vessel almost entirely enclosed in bone. No axillary pore.

Geographical distribution.—Small fishes inhabiting the fresh waters of India and Burma, usually on or near hills. Griffith observes (Cal. Journ. N. Hist. ii, p. 564) respecting certain fish from the Mydan Valley in Afghanistan, "the most remarkable fish is a dark coloured loach-like Silurus, which is not uncommon about Jubraiz."

I have a large series of this fish, and they show such diversities that it appears to me that all are varieties of one species.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Amblyceps mangois, A. 9-12. Maxillary barbels to end of pectoral spine. Himalayas from Nangra and Darjeeling. Jumna and the Behar district, also Burma.

1. Amblyceps mangois, Plate CII, fig. 6, and CXVII, fig. 1.

Pimelodus mangois, Ham. Buch. Fish. Ganges, pp. 199, 379; Bleeker, Beng. p. 58.

Amblyceps mangois, Blyth, P. A. S. of Beng. 1860, p. 153; Günther, Catal. v, p. 190; Day, Proc. Zool. Soc. 1869, p. 524.

Amblyceps cœcutiens, Blyth, P. A. S. of Bengal, 1858, p. 282; Günther, Catal. v, p, 190. Amblyceps tenuispinis, Blyth, l. c. 1860, p. 153; Günther, Catal. v, p. 190. Akysis Kurzii, Day, Proc. Zool. Society, 1871, p. 703. Billi, "a cat," and Sudaal, Punj.

B. xii, D. $\frac{1}{6}$ | 0, P. 1/7, V. 6, A. 9-12 ($\frac{2}{7}$ - $\frac{3}{9}$), C. 19, Vert. 12/23.

Length of head $6\frac{1}{4}$, of caudal 6, height of body 7 to 9 in the total length. Eyes—small, situated in the anterior 2/5 of the head. Mouth wide, lower jaw somewhat the longer. Barbels—nasal as long as the head, and equalling the internal mandibular pair, the maxillary reach the end of the pectoral spine, whilst the outer mandibular ones are not quite so long. Fins—dorsal not so high as the body, and situated in the commencement of the second fifth of its total length, its spine about half as high as its rays, all are partly enveloped in skin, as are also those of the anal. Adipose dorsal low, the length of its base equalling that of the rayed fin, and two-thirds of the interspace between the two fins. Pectoral scarcely extending half way to the base of the ventral, which latter does not reach the anal. Caudal deeply forked, its upper lobe the longer. Caudal peduncle as high as long. Lateral-line—absent. Air-vessel—has a small rounded lobe on either side of the body of the second vertebræ, and all but a small portion of its front surface enclosed in bone. Colours—olive-brown, lightest beneath. In some a dark line commences opposite the opercles, and soon subdivides: one branch going to the centre of the base of the caudal, the other to the base of the anal.

Hamilton Buchanan observes it is found in the Purniah district. A. tenuispinis, Blyth, appears to be the young, Jerdon brought the specimen from Ghazeepore. A. cocutiens, Blyth, came from Pegu and Moulmein. A. Kurzii, Day, appears to be a specimen which has been placed in too strong spirit, which has entirely altered

its appearance, however a figure is given.

Habitat.—I have taken it at Kangra on the Himalayas and received it from Darjeeling. It is found in the Jumna for some considerable distance from the Hills, also through Burma to Moulinein. It does not appear to exceed 5 inches in length. When captured it bites most viciously, and lives for some time after its removal from the water.

Genus, 24—Sisor, Hamilton Buchanan.

Branchiostegals four. Gill-openings narrow and chiefly lateral, the gill-membranes being confluent with the skin of the isthmus. Head and anterior portion of the trunk broad and depressed. Eyes small. Mouth small, transverse, the upper jaw the longer. Nostrils round and approximating, but separated by a valve, they are situated midway between the eye and the end of snout. One maxillary pair of barbels with broad bases, and about five mandibular pairs. Teeth absent. A short dorsal fin destitute of a distinct spine: pectoral with a strong spine. Ventral having seven rays, and situated below the last portion of the dorsal fin. Anal with six rays. Caudal with its upper ray very prolonged. Air-vessel enclosed in a bony capsule. An axillary pore.

Geographical distribution.—Indus and upper portions of the Jumna and Ganges rivers.

SYNOPSIS OF INDIVIDUAL SPECIES.

Sisor rhabdophorus, D. 1/6, A. 6. Indus, Jumna, and Ganges in their upper portions.

Sisor rhabdophorus, Plate CXV, fig. 1, 1a, 1b.

Ham. Buch. Fish. Ganges, pp. 208, 379; Bleeker, Beng. en Hind. p. 60; Gray and Hard. Ill. Ind. Zool.; Swainson, Fishes, ii, p. 305; Günther, Catal. v, p. 262.

Chennuah, Hind.: Kir-ri-dee, Sind.

B. iv, D. 1/6, P. 1/8, V. 7, A. 6 ($\frac{2}{4}$), C. 11.

Length of head $5\frac{1}{2}$, of caudal 11, height of body 11 in the total length excluding the caudal filament, which in some specimens equals the length of the body. Eyes—small, nearer the gill-opening than the end of the snout, pupil transversely oval, with an extensible muscular flap (a part of the iris) on its upper edge as in the Genus Platycephalus (see p. 274). Snout rather pointed. Median longitudinal groove on the head reaches the base of the occipital process. The greatest width of the head equals two-thirds of its length. Numerous rough ridges exist on the head, which is covered by very thin skin. There is a slight interspace between the end of the occipital process and the basal bone of the dorsal fin, which last has an anterior and two lateral processes covered with rough ridges. Mouth small, transverse, inferior, the upper jaw the longer. Barbelsthe maxillary reach the pectoral spine, and are dilated at their bases. From the lower lip there is a sort of flap, having a rather long barbel at either side, which reaches the gill-opening: and two more intermediate but shorter ones: between these flaps are several short barbels on a transverse line across the chin. There are five plates on either side of the base of the dorsal fin, behind which the back has six elevated scale-like plates along the median line, the last forms a spine before the vertical from the anal fin. The last 1/2 of the body is covered by 12 osseous rings, having a superior and on either side a sharp edge as is seen in the pipe-fishes. The lateral-line has also a series of smaller but rough bony plates. Fins—dorsal rather higher than long, its undivided ray weak, finely serrated anteriorly. Pectoral spine compressed, not quite so long as the head, serrated on both edges, but mostly strongly so on the external one. Ventrals arise under the posterior dorsal rays. The anal commences behind the vertical from the spine on the back. Upper caudal ray with a long prolongation. Colours—blackish above, lighter below.

In dissecting a small specimen (the only one I could spare) no air-vessel was apparent in the abdomen, but two long bony capsules were present in the same situation as in the other fishes with an air-vessel thus enclosed, and they also probably contained them.

3 R 2

Habitat.-Sind, Ganges and Jumna rivers in Northern India, Bengal, and Behar, attaining 8 feet or more in length. It is not uncommon at Delhi. It is only eaten by the lowest and poorest classes. It is said to lie under stones when young.

Genus, 25-GAGATA, Bleeker.

Batasio,* pt. Blyth: Callomystax, Günther.

Branchiostegals five to seven. Gill-openings rather narrow, the gill-membranes being confluent with the skin branchiostegats five to seven. Gitt-openings rather narrow, the gitt-memoranes being confinent with the skin of the isthmus. Thorax smooth. Upper surface of the head with sharp longitudinal ridges, and covered by thin skin. Eyes subcutaneous. Snout overhanging the mouth. Nostrils close together, the anterior rounded, the posterior being provided with a valve and usually with a barbel. Barbels eight, one nasal (sometimes rudimentary), one maxillary, and two mandibular pairs arising on a transverse line behind the chin, and usually with stiff bases. Villiform teeth in jaws: palate edentulous. First dorsal with one spine and six or seven rays: adipose of moderate length. Pectoral spine strong. Ventral with six rays situated posterior to the dorsal fin. Anal with a moderate (11-13) number of rays. Candal forked. Air-vessel in two rounded portions, each of which is enclosed in an osseous cup.

Geographical distribution.—Rivers of Sind, India, (except Madras) and Burma.

SYNOPSIS OF SPECIES.

1. Gagata cenia, D. 5, A. 14-16. Six barbels and a rudimentary nasal pair. Copper coloured, with dark blotches and banded fins in the young: dull gray, with black fins in the adult. Indus, Jumna, and Ganges rivers with their affluents, also Orissa, Assam, and Burma.

2. Gagata itchkeca, D. 16, A. 12-14. Eight barbels. Copper coloured, with dark blotches. Deccan.

3. Gagata batasio, D. 17, A. 16. Eight barbels. Body with two dotted stripes. Testa.
4. Gagata tengana, D. 17, A. 14. Eight barbels. A dark blotch above the pectoral fin, another on the crown of the head. Dorsal and caudal dotted, edges nearly black. Assam.

1. Gagata cenia, Plate CXV, figs. 4 (adult), 5 (young).

B. v-vi, D. $\frac{1}{6}/0$, P. $\frac{1}{9}$, V. 6, A. 14-16 $(\frac{3-4}{11-12})$, C. 19.

Length of head $4\frac{1}{2}$ to 5, of caudal $4\frac{1}{2}$ to 5, height of body 5 to 7 in the total length. Eyes—diameter 4 to $4\frac{1}{4}$ in the length of head (3 in the young), 1 to $1\frac{1}{2}$ diameters from the end of snout, and 1 apart. Head 1/4 higher than wide: snout somewhat compressed, overhanging the mouth. The median longitudinal groove on the head deep, and extends to the posterior end of the occipital process, which is narrow and almost touches the basal bone of the dorsal fin. Barbels—nasal rudimentary: the maxillary pair reach to the base of the pectoral spine, or a little more: the two mandibular pairs arise on a transverse line across the chin, the outer are half as long as the head. Fins—the dorsal higher than the body, its two first rays being the longest, spine moderately strong, as long as, to 1/4 longer than, the head: it is serrated anteriorly in its upper fourth in the young. Pectoral reaches to above the ventral, its spine is stronger, longer or shorter than that of the dorsal, it is strongly denticulated internally, serrated externally in its outer fourth. Base of the adipose dorsal as long as that of the rayed fin. Air-vessel—in two lateral portions, enclosed in bony capsules. Colours—dull gray, the outer two-thirds of the pectoral, the outer halves of both dorsals, ventral and anal black: caudal whitish. The young are of a yellowish bronze colour, becoming silvery on the abdomen: they have three dark bands over the head, and four more over the back, descending as low as the lateral-line. Caudal with a semilunar black band, or a black blotch on each lobe: a dark mark across the dorsal fin.

Some small fry from Darjeeling show the lower half of the front surface of the dorsal spine rough. Habitat.—Rivers of Bengal and Orissa, the Jumna, Ganges, and Indus, also Burma. It attains a foot in length. The specimen (fig. 4) was from Calcutta, where it is very common, (fig. 5) is from a Delhi example.

2. Gagata itchkeea, Plate CXV, fig. 6.

Phractocephalus itchkeea, Sykes, Trans. Zool. Soc. ii, p. 373, t. 67, f. 1.

Bagrus itchkeea, Bleeker, Beng. p. 56. Pimelodus itchkeea, Jerdon, M. J. L. and Science, 1849, p. 341.

• Genus Batasio, Blyth, is said to comprise fishes with the barbels shorter than the head and teeth on the palate, examples: Pimelodus batasio, H. B. (the author merely says of the teeth, that those "in both jaws are crowded"), P. tengana, H. B. B. agains, Blyth, P. chandramara, H. B. and P. rama, H. B. The two first probably belong to Genus Gagata, the third to Macrones, and the last

† This alteration with age is very well shown in a series of these fishes, specimens from 2 to 3 inches long have the dorsal spine from 7 to 7½ in the total length: from 3 to 4 inches the spine is 6 to 7: from 4 to 5 inches the spine is 5 to 5½ times: from 5 to 6 inches the spine is 5 to 5½ times.

Macrones itchkeea, Günther, Catal. v, p. 84. Hemipimelodus itchkeea, Day, Journ. Linn. Soc. Zool. xii, p. 571.

D. $\frac{1}{6}$ | 0, P. 1/8, V. 6, A. 12-14 $(\frac{3-4}{9-10})$, C. 19.

Length of head 5, of caudal $4\frac{1}{2}$, height of body 6 in the total length. Eyes—diameter 3 in the length of head, 1 diameter from the end of snout, and also apart. Snout overhanging the mouth. Median longitudinal groove on the head reaching to the base of the occipital process: a lateral process proceeds from the occiput, curving rather outwards and downwards: the process at the shoulder pointed, and as long as the head excluding the snout. Barbels—the nasal reach to the front third of the eye, the maxillary to the middle of the pectoral spine, whilst the two mandibular pairs (which arise on a transverse line behind the lower lip) are longer than the head. Teeth—villiform in jaws: none on the palate. Fins—dorsal spine smooth, as long as the head posterior to the nostrils: pectoral spine equally long and denticulated internally. Air-vessel—in a lobe on either side, bounded superiorly and partly laterally by the auditory ossicles. Colours—yellowish-bronze, becoming silvery on the sides and abdomen: some dark blotches along the back descending to half way down the sides. A black blotch on either lobe of the caudal, and another on the dorsal fin.

Habitat.—Rivers of the Deccan, it appears to be a small species. The one figured (from Poona) was the largest obtained.

3. Gagata batasio, Plate XCIX, fig. 5.

Pimelodus batasio, Ham. Buch. Fish. Ganges, pp. 179, 377.

Bagrus batasio, Cuv. and Val. xiv, p. 425; Bleeker, Beng. p. 56.

Batasio Buchanani, Blyth. P. A. S. of Beng. 1860, p. 150.

Macrones batasio, Günther, Catal. v, p. 83.

D. $\frac{1}{7}$ | 0, P. 1/?, V. 6, A. 16, C. 20.

Head small, as is also the mouth. Eyes—small, and high up. Barbels—eight, shorter than the head. Fins—dorsal spine strong, entire: pectoral spine strong and serrated internally: caudal lobed, Colours—body diaphanous, having along either side two stripes spotted with black.

Judging from the mandibular barbels and general structure of this fish, it would appear to be a Gagata,

whilst it is observed "there is no slit under the throat."

Habitat.—River Testa, attaining 3 inches in length. The figure is reproduced from H. B.'s manuscript drawings at Calcutta, and the description from his work.

4. Gagata tengana.

Pimelodus tengana, Ham. Buch. Fish. Ganges, pp. 176, 377, pl. 39, f. 58. Bagrus tengana, Cuv. and Val. xiv, p. 453; Bleeker, Beng. p. 56. Batasio tengana, Blyth, P. A. S. of Bengal, 1860, p. 150. Macrones tengana, Günther, Catal. v, p. 84.

B. vi, D. $\frac{1}{7}/0$, P. 1/8, V. 6, A. 14 ($\frac{4}{10}$), C. 15.

Length of head 4, of caudal 4, and height of body 4 in the total length. Eyes—of moderate size, situated nearer the snout than to the posterior end of the opercle. Back rather prominent. Width of the head equals its height, or its length excluding the snout. Mouth small, upper jaw slightly the longer. Median longitudinal groove on the head lanceolate and extending to the base of the occipital process which is twice as long as wide at its base, and reaches the basal bone of the dorsal fin. Barbels—the nasal reach the hind edge of the orbit, and all the remainder are shorter than the head. Fins—the first dorsal cut obliquely, its spine smooth. Pectoral spine serrated internally. Colours—body diaphanous, having a gloss of gold on the sides. On the back are many black dots which are collected into a blotch above the pectoral fin, and another exists on the crown of the head. Dorsal and caudal fins dotted, edges nearly black.

This fish, which is found in Assam, agrees with G. cenia except that the nasal barbels are described and shown as being much longer, and the colour differs.

Habitat.—Brahmaputra river to about 3 inches in length.

Genus, 25a-Nangra.

Branchiostegals five or six. Gill-openings rather wide, and not or only slightly adherent to the skin of the isthmus. Thorax smooth. Upper surface of the head with sharp longitudinal ridges and covered by thin skin. Eyes subcutaneous. Snout overhanging the mouth which is transverse. Nostrils close together, the anterior rounded, the posterior with a barbel. Barbels eight, one nasal (which may be rudimentary), one maxillary and two mandibular pairs, the inner of which last are anterior to the external pair. Villiform teeth in jaws, palate edentulous. First dorsal fin with one spine and six to eight rays: adipose of moderate length. A pectoral spine. Ventral with six rays situated posterior to the dorsal. Anal with a moderate number of rays (10-12). Caudal forked. Air-vessel in two rounded portions each of which is enclosed in bone.

Geographical distribution.—Small fishes found in the Indus, Jumna, Ganges, and Bengal rivers.

This genus differs from Gagata in its barbels not being placed in a transverse line behind the chin: and

in its gill-membranes not being confluent with a broad isthmus but rather deeply notched. It is allied in some respects to Macrones, but has no teeth on the palate, whilst its air-vessel is enclosed in bone.

SYNOPSIS OF SPECIES.

 Nangra Buchanani, D. 1/8, A. 10-11. Muddy colour. Indus, Ganges and Jumna river.
 Nangra punctata, D. 1/6, A. 11-12. Coppery, glossed with gold and having black blotches. Sone river at Bheer Bhoom.

3. Nangra viridescens, D. 1, A. 11. Two greenish bands descend from the back. Northern Bengal and the Deccan.

1. Nangra Buchanani, Plate CXIII, fig. 3.

Pimelodus nangra, Ham. Buch. Fish. Ganges, pp. 193, 378, pl. xi, f. 63; Bleeker, Beng. p. 58. Macrones nungra, Day, Proc. Zool. Soc. 1871, p. 288.

D. $\frac{1}{8}/0$, P. 1/9, V. 6, A. 10-11 $(\frac{2}{8}-\frac{3}{9})$, C. 17

Length of head and caudal fin from $4\frac{1}{2}$ to 5, height of body 6 in the total length. Eyes—rather high up, in the anterior half of the head and covered with skin, $1\frac{1}{4}$ diameters from end of shout. The greatest width of the head equals its length excluding the snout. Upper jaw considerably the longer, snout rather depressed, Median longitudinal groove deep, extending to the occipital process up which it is continued, the occipital process 3 times longer than wide at its base and extending to the basal bone of the dorsal fin. Barbels—the nasal longer than the head, the maxillary reach the vent, or even end of anal fin, external mandibular the base of the ventral, and the internal (which arise in front and to inner edge of the external ones) the base of the pectoral. Teeth—none on the palate. Fins—dorsal spine weak and entire, half as long as the head in the very young, longer in larger specimens: the length of the base of the adipose dorsal equals that of the anal, or the interspace between its commencement and the end of the base of the rayed fin: pectoral spine moderately strong, with nine coarse denticulations internally, it is as long as the head without the snout: caudal deeply forked, lobes of equal length and pointed. Air-vessel—in two oval portions, each of which is enclosed in a thin bony capsule which has a round orifice on the outer side. Colours—muddy, with three indistinct vertical greenish half bands.

Habitat.—Ganges, Jumna, and Indus, attaining two inches in length. The specimen figured was from

Delhi.

2. Nangra punctata, Plate CXV. fig. 8.

B. v, D. $\frac{1}{6}/0$, P. 1/8, V. 6, A. 11-12 ($\frac{3-4}{8}$), C. 18.

Length of head 4, of caudal $5\frac{1}{4}$, height of body $6\frac{1}{4}$ in the total length. Eyes—diameter $4\frac{1}{4}$ in the length of head, $1\frac{1}{4}$ diameters from the end of snout, and $1\frac{1}{4}$ apart. The greatest width of the head equals its length behind the angle of the mouth. Snout compressed, overhanging the mouth, which latter is transverse. Gill-openings rather wide, the skin not confluent with that of the isthmus. The median longitudinal groove on the head deep, with raised sides, extending to the base of occipital process, which is four times as long as wide, and almost reaches the basal bone. Osseous processes from back of skull and above base of pectoral fin well developed. Barbels—the maxillary reach the base of the pectoral spine: the mandibular ones are shorter than the head, the internal pair placed anterior to the external pair. The nasal pair are rudimentary or wanting. Teeth—those in the upper jaw placed anterior to the lower jaw. Fins—dorsal spine strong, smooth, half as long as the head. Pectoral spine very strong, as long as the head behind the angle of the mouth, and with about 12 denticulations internally; it is roughened in its lower half externally. Colours—coppery, glossed with gold on the sides: a black blotch on occiput, and three or four along the back descending half way down the A black band on dorsal, and some black markings on the caudal.

This fish in appearance is very similar to the young of Gagata cenia, but may be at once recognized by

the position of the barbels, and broader head.

Habitat.—I captured two specimens of the same size in the Sone river at Bheer Bhoom, in Bengal.

3. Nangra viridescens, Plate CXV, fig. 7.

Pimelodus viridescens, Ham. Buch. Fish. Ganges, pp. 173, 376, pl. xi, f. 56; Bleeker, Bengal, p. 58. Huddah, Hind.

D. $\frac{1}{6}/0$, P. 1/8, V. 6, A. 11 ($\frac{9}{6}$), C. 21.

Length of head 4 to $4\frac{1}{4}$, of caudal 5, height of body 6 in the total length. Eyes—diameter 4 in the length of the head, $1\frac{1}{4}$ diameters from the end of snout, and 1 apart. The greatest width of the head equals its length behind the angle of the mouth. Snout overhanging the mouth, which is transverse. Gill-openings wide, the membranes being notched. Median longitudinal groove on the head deep, having raised edges, and reaching the base of the occipital process, which latter is three times as long as wide, and does not quite reach the basal bone. Osseous processes from occiput and over base of pectoral fin well developed. Barbels—the maxillary reach the root of the pectoral spine: the two inner mandibular ones are anterior to the external pair. Teethnone on the palate. Fins—dorsal spine strong, smooth, and half as long as the head. Pectoral spine strong, externally rough in its lower half, denticulated internally. Colours-glossy greenish-brown on the back, with two very light green bands passing one from the base of either dorsal fin to the middle of the depth of the body. A dark band on the dorsal fin and spots on either lobe of the caudal.

Habitat.—Rivers of Northern Bengal, not uncommon in the Jumna at Delhi, and also found at Poona in

the Deccan.

Genus, 26—BAGARIUS, Bleeker.

Branchiostegals twelve. Gill-membranes not confluent with the skin of the isthmus, having a free posterior edge and notched half way to the chin. Head depressed, its upper surface osseous. Mouth anterior: upper jaw the longer. Eyes with free orbital margins. Nostrils approximating, the posterior provided with a barbel. Barbels eight, one nasal, one maxillary, and two mandibular pairs. Teeth in jaws pointed, and of unequal sizes: palate edentulous. Thorax destitute of any adhesive apparatus. First dorsal fin in advance of the ventrals, having one spine and six rays: adipose fin present. Ventral with six rays. Anal of moderate length. Caudal deeply forked. Air-vessel small, consisting of two rounded portions enclosed in bone. An axillary pore.

The air- or swim-bladder of this fish is present, but small. Taylor (Gleanings in Science, June 1830) remarks that the Bagarius Yarrellii "has also two air-bladders, which closely resemble the former (Saccobranchus fossilis, &c.) in the argentine tendinous texture of the external coat, and in having no communication with each other, or with the alimentary canal. They are situated one on each side of the body, in a deep groove or furrow of the consolidated transverse processes of the cervical vertebræ, and are extremely small in proportion to the bulk of the fish; each of them in an individual weighing 10 lbs., not exceeding a large garden pea in size: they are placed in the middle of the grooves at about an equal distance from the common integument (immediately behind the pectoral fin) and the vertebral column: the space between each of them, and the former, being filled up with adipose substance, whilst that next to the spine is occupied by the Malleus."

Geographical distribution.—Throughout the course of the larger rivers of the Punjab, India, and Burma, and extending to the Malay Archipelago.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Bagarius Yarrellii, D. 1/6, A. 13-15. Gray, banded and clouded with black. India to the Malay Archipelago.

Bagarius Yarrellii, Günther, Catal. v, p. 183.
Boonch or Goonch, Hind. (N. W. P): Goreah, Assam: Rahti jellah, Tel.: Sah-lun, Ooriah.

B. xii, D $\frac{1}{6}/0$, P. 1/12, V. 6, A. 13-15 $(\frac{3}{10-12})$, C. 17.

Length of head $3\frac{3}{4}$, of caudal $4\frac{1}{4}$, height of body 5 in the total length excluding the prolonged caudal Eyes—small, situated in the middle of the length of the head. The greatest width of the head equals from 2/3 of its length in the young to its entire length in the adult, its upper surface is rugose in irregular bands and lines. Upper jaw the longer, the extent of the gape of the mouth equal to 4/7 of the length of the head. Barbels—the maxillary with broad bases and rather longer than the head: the nasal pair short. Teeth sharp, and of unequal sizes in the jaws, an outer widely separated row of larger ones in the mandibles. dorsal spine smooth, with an elongated soft termination, the osseous portion as long as the head excluding the snout: length of the base of the adipose dorsal as long as that of the rayed fin. Pectoral spine stronger, and as long as that of the dorsal, serrated internally, and having a soft prolongation. Caudal deeply forked, its upper lobe prolonged. Skin—somewhat scabrous over the summit of the head, and slightly so on the body. Coloursbody gray or yellowish, with large, irregular, brown or black markings and cross bands. A black base to all the fins, and generally also a dark band.

This fish takes a live-bait, but is difficult to kill, it is sluggish, goes to the bottom, and it generally escapes by destroying the tackle. Mr. Van Cortland, at the end of 1875, angling at the Okla weir, a few miles

below Delhi, killed one which was 5 feet long and weighed 136 lbs.

Habitat.—Large rivers of India and Java, descending to the estuaries. It attains 6 feet or more in length, and is often termed a "fresh-water shark," partly due to its voracity, and partly to its underhung mouth and general ugliness.

Genus, 27—Glyptosternum, McClelland.

Glyptothorax, Blyth.

Branchiostegals from six to about ten. Gill-openings rather wide, gill-membranes confluent with the skin of the isthmus. Head rather depressed and covered with soft skin. Eyes small, subcutaneous. Mouth inferior, transverse, with the upper jaw the longer. Nostrils close together, separated by a barbel. Barbels eight, one maxillary, and two mandibular pairs, the maxillary ones with broad bases. Villiform teeth in the jaws: palate edentulous. Dorsal fin with a spine and six or seven rays: an adipose fin present. Pectoral horizontal, with a strong spine, some of its rays being occasionally plaited inferiorly, and an adhesive apparatus exists between the bases of the two pectoral fins on the chest, composed of longitudinal plaits. Ventral with six rays, situated posterior to the dorsal. Anal with a moderate (9-12) number of rays. Caudal forked. Air-vessel, when present,* in two lateral portions more or less enclosed in bone.

Blyth instituted Glyptothorax for those species having a spine to the dorsal fin, as McClelland in his definition of his Genus observed "spines when present are concealed within the membrane of the fins," and gave as his type Glyptosternum reticulatus, observing "without spines."

Geographical distribution.—These fishes are found along the Himalayas and rivers at their bases from Afghanistan to the extreme east of Assam, also in the Malay Archipelago. They are also present in some rivers in the plains of India, but usually not far removed from hills. They appear especially adapted for strong streams and those of hilly districts.

It is certainly open to question whether some of the following might not more properly be termed varieties than species. Roughness of the external edge of the pectoral spine may certainly exist in species in which it is normally smooth.

SYNOPSIS OF SPECIES.

1. Glyptosternum lonah, A. 11-13. Length of head 5 to $5\frac{1}{4}$ in the total. Maxillary barbels reach pectoral fin. Pectoral spine rough or smooth externally. Dorsal spine smooth. Brown, with black marks. Jumna and the Deccan.

2. Glyptosternum trilineatum, A. 13. Length of head 6 in the total. Maxillary barbels reach the pectoral

Chestnut-brown, with two light longitudinal bands. Nepal and Burma.

3. Glyptosternum conirostre, A. 11-12. Width of head 2/3 of its length. Adhesive apparatus rather elongated and narrow. Maxillary barbels reach middle of pectoral fin. Himalayas from Kangra and Simla.

- 4. Glyptosternum botia, A. 11-12. Pupil of eyes transversely oval. Maxillary barbels reach to below the hind edge of the eye. Skin roughened with small spinate tuberosities. Jumna and rivers of Northern Bengal.
- 5. Glyptosternum telehitta, A. 11. Pupil of eyes circular. Maxillary barbels reach to below the hind edge of eyes. Skin looks as if it had scales imbedded in it. Punjab, N. W. Provinces, Bengal, and Behar.

6. Glyptosternum striatum, A. 11. Head 43 in the total length. Maxillary barbels reach first third of the

pectorals. Khasya hills.

- 7. Glyptosternum Madraspatanum, A. 10-11. Maxillary barbels reach base of pectoral fin. Dorsal spine with serrations on both edges. Bowany river, Madras.
- 8. Glyptosternum pectinopterum, A. 9-11. Width of head nearly equals its length. Maxillary barbel reaches base of pectoral spine. Adhesive apparatus wider than long. Himalayas to Simla and Darjeeling.

 9. Glyptosternum cavia, A. 9. Upper surface of head with elevated spots. Maxillary barbels as long as
- the head. Ramghur district of Bengal.

1. Glyptosternum lonah, Plate CXIII, fig. 5.

Bagrus lonah, Sykes, Trans. Zool. Soc. ii, p. 371. Glyptosternum lonah, Günther, Catal. v, p. 187. Glyptosternum Dekkanense, Günther, Catal. v, p. 187.

D. $\frac{1}{6}/0$, P. 1/9, V. 6, A. 11-13 $(\frac{3-4}{6-10})$, C. 15-17.

Length of head 5 to $5\frac{1}{4}$, of caudal 5, height of body 7 in the total length. Eyes—slightly behind the middle of the length of the head, the width of the interorbital space equals 1/3 to 2/7 of the length of the head. Width of head nearly or quite equals its length: upper surface rough. Width of gape of mouth equals $2\frac{1}{2}$ to 3 in the length of the head. Lips not fringed. Occipital process nearly or quite four times as long as broad. Barbels—the nasal reach half way to the orbit, the maxillary extend to the base or first third of the pectoral, the outer mandibular pair to the gill-opening, whilst the inner are shorter. Fins-dorsal higher than the body, its spine rather slender, enveloped in skin, $1\frac{3}{4}$ to $2\frac{1}{4}$ in the length of the head: adipose dorsal with its base longer than that of the first dorsal, and equal to half the interspace between the two fins. Pectoral spine moderately broad, internally strongly denticulated, externally roughened in some specimens, smooth in others, the fin does not nearly reach the ventral. Caudal forked. Caudal peduncle—twice as long as high in the young, two-thirds

* In G. Madraspatanum I have been unable to find an air-vessel.

in the adult. Colours-yellowish-brown, banded with blackish: fins yellow: dorsal, caudal and anal with black

Thoracic adhesive apparatus rather elongated, reaching to the first third of the pectoral spine, its plaits are scarcely branched.

Habitat.—Deccan, attaining at least 6 inches in length. I have taken this species at Poona, and also in

the head waters of the Jumna.

2. Glyptosternum trilineatum, Plate CXVI, fig. 3.

Glyptothorax trilineatus, Blyth, P. A. S. of Beng. 1860, p. 154. Glyptosternum trilineatum, Günther, Catal. v, p. 185.

D. $\frac{1}{6}/0$, P. $\frac{1}{10}$, V. 6, A. 13 $(\frac{3}{10})$, C. 19.

Length of head 6, of caudal $5\frac{1}{2}$, height of body 6 in the total length. Eyes—small, behind or in the middle of the length of the head. Head about as long as broad and covered with soft skin, snout obtuse. Lips not fringed. Occipital process nearly three times as long as broad. Barbels—the maxillary reach to the end of the head: nasal barbels nearly to the orbit: the external mandibular pair longer than the internal, and reaching to the base of the pectoral fin. Thoracic adhesive apparatus rather large, Teeth—villiform in the jaws, none on the palate. Fins—dorsal fin as high as the body, its spine weak, slightly serrated posteriorly, and its bony portion rather above half the length of the head: adipose dorsal of moderate height, its base being equal to more than that of the first dorsal, and to about half of the distance between the two fins. Pectoral spine rather broad, denticulated internally, smooth externally, reaching two-thirds of the distance to the base of the ventral. Caudal deeply forked. Skin smooth. Caudal peduncte-twice as long as high. Colours-chestnutbrown, with a light streak along the back, another along the lateral-line, and a third near the abdominal margin.

G. gracile, Günther, v, p. 186, from Nepaul differs in having one more anal ray: occipital process a little

narrower: maxillary barbels longer, whilst the pectoral fin reaches the base of the ventral.

The drawing was made from one in the Calcutta Museum taken in Rangoon in 1869. Habitat.—Burma, Tenasserim and Nepaul. It attains 12 inches or more in length.

3. Glyptosternum conirostre, Plate CXVI. fig. 5.

Steindachner, Verh. z. b. Ges. Wien, 1867, p. 16, t. v and vi, figs. 2.

D. $\frac{1}{6}$ | 0, P. 1/9, V. 6, A. 11-12 $(\frac{9}{9-10})$, C. 17.

Length of head $5\frac{1}{4}$, of caudal $5\frac{1}{2}$, height of body $5\frac{1}{2}$ in the total length. Eyes—slightly behind the middle of the length of the head, the width of the interorbital space equals 1/4 of the length of the head. The width of the head equals 2/3 of its length. Upper jaw the longer: the width of the gape of the mouth equals 1/2 of the length of the head. Lips not fringed. Occipital process there times as long as wide. Barbels—the maxillary have broad bases and extend to the middle of the pectoral fin: the nasal, which have a very wide fringe, reach the hind edge of the eye: the outer mandibular, which is also broad, to the gill-opening: whilst the inner are shorter. Teeth—generic. Fins—dorsal as high or rather higher than the body, its spine strong, as long as the head behind the nostrils and smooth, serrated posteriorly in some specimens: length of the base of the adipose dorsal exceeds that of the rayed fin, and equals two-thirds of the extent of the interspace between the two fins. Pectoral reaches nearly to the ventral, its spine strong, as long as that of the dorsal, and having about 13 denticulations internally, it is not striated inferiorly. Ventral does not quite reach the anal. Caudal forked. Adhesive apparatus in the chest rather broad, but posteriorly a large circular smooth space causes it to be semicircular. Caudal peduncle about as high at its base as it is long. Colours-brownish, fins yellow, stained with black.

This fish has a considerable similarity to G. pectinopterum, but possesses a wider mouth, a narrower head,

broader barbels, a higher caudal peduncle, and a more elongated adhesive apparatus.

Habitat.—Himalayan streams, the one figured was from Simla. Specimens from Kangra have the pectoral spine serrated externally.

4. Glyptosternum botia, Plate CXIII, fig. 4.

Pimelodus botius, Ham. Buch. Fish. Ganges, pp. 192, 378; Bleeker, Beng. en Hind. p. 59.

B. vi, D. $\frac{1}{6}/0$, P. 1/8, V. 6, A. 11-12 ($\frac{2}{9-10}$), C. 18.

Length of head $5\frac{1}{2}$, of caudal $4\frac{1}{2}$, height of body $6\frac{1}{2}$ in the total length. Eyes—pupils transversely oval, small, situated in the commencement of the front half of the head: the width of the interorbital space, which is convex, equal to 1/3 of the length of the head. The greatest width of the head equals its length excluding the snout. Upper jaw the longer: the width of the mouth equals 1/3 of the length of the head. Barbels—eight, the maxillary reach to below the hind edge of the eyes, the nasal half way to the orbits, the mandibular pairs are short. Teeth—villiform in the jaws. Fins—dorsal spine smooth, as long as the head excluding the snout: length of the base of the adipose fin equalling one-third of that of the interspace between the two fins. Pectoral reaches two-thirds of the distance to the ventral, its spine is strong, as long as the head excluding the snont, and with about 20 strong teeth internally. Ventral reaches the anal. Caudal deeply

Digitized by GOO

lobed, lobes of equal length. Adhesive apparatus well-marked. Skin—roughened with small spinate tuberosities arranged in longitudinal rows all over the body. Free portion of the tail twice as long as high at its base. Colours—brownish, intermixed with yellow, and blotched with blackish. Fins yellow with black marks and spots.

This fish very closely resembles G. telchitta, but has a more roughened skin, whilst the profile of the eye is transversely oval. Hamilton Buchanan (MSS.) observes of this species in the Rangpur district, "the Bhot Magur of the Dharká if possible is still uglier (than the Erethistes conta). The people of Bhutan are said to be remarkably fond of it from whence its name is derived. The people of Behar will not eat it."

Habitat.—The specimen figured (life size) was from the Jumna. It is common at Delhi. Hamilton

Buchanan observed that it was from the northern rivers of Bengal, and attains 6 inches in length.

5. Glyptosternum telchitta, Plate CXVI, fig. 2.

Pimelodus telchitta, Ham. Buch. Fish. Ganges, pp. 185, 378; Bleeker, Beng. p. 58. Glyptosternum telchitta, Day, Proc. Zool. Soc. 1871, p. 288. Gooacherah, Beng.; Telliah, Hind. (N. W. P.)

B. vi, D. $\frac{1}{6}/0$, P. 1/8, V. 6, A. 11 ($\frac{2}{9}$), C. 17.

Length of head $5\frac{1}{2}$ to $5\frac{3}{4}$, of caudal $5\frac{3}{4}$, height of body $7\frac{1}{2}$ to 8 in the total length. Eyes—small, with a circular profile, situated in the middle of the length or in the commencement of the posterior half of the head: interorbital space flat, its width 3½ to 4 in the length of the head. The greatest width of the head equals 3/4 of its length. Upper jaw the longer, the width of the gape of the mouth equals 1/3 of the length of the head: lips not fringed. Opercle ends posteriorly in an elongated pointed termination: occipital process three times as long as wide at its base. Barbels—the nasal very short, the maxillary ones reach to rather behind the posterior edge of the orbit: the outer mandibular pair reach the gill-opening, the internal are shorter. Teeth—generic. Fins—dorsal nearly as high as the body, its spine which is 4/7 as long as the head, has a soft continuation, it is slightly enveloped in skin and entire: adipose dorsal of moderate height, the extent of its base equalling that of the rayed fin, or 1/2 of that of the interspace between the two fins. Pectoral spine broad, reaching 2/3 of the distance to the base of the ventral, smooth externally, from 13 to 14 teeth internally, and not plaited below. Caudal deeply forked. Thoracic adhesive apparatus rather large, its plaits nearly longitudinal. Skin everwhere covered with small longitudinal elevations like scales imbedded in it. Free portion of the tail twice as long as high at its base. Colours—blackish-brown, fins yellow with black bands: candal blackish, with a yellow edge. Air-vessel—in two rounded lateral portions enclosed in bone. Habitat.—Punjab, N. W. Provinces, Bengal, and Behar. It attains 5 or 6 inches in length.

6. Glyptosternum striatum.

McClelland, Cal. Journ. Nat. Hist. ii, p. 587: Bleeker, Beng. en Hind. p. 58: Günther, Catal. v, p. 188. B. vi, D. $\frac{1}{6}$ | 0, P. 1/11, V. 6, A. 11 ($\frac{2}{9}$), C. 15.

Length of head $4\frac{3}{4}$, of caudal 5, height of body 6 in the total length. Eyes—situated in about the middle of the length of the head, the width of the interorbital space equal to one-third of the length of the head. Head nearly as broad as long. Upper jaw the longer, the width of the gape of the mouth equals half the length of the head. Lips not fringed. Occipital process three times as long as wide at the length of the resulting and the length of the resulting as the length of the resulting as wide at its base. Barbels—the maxillary reach beyond the base of the pectoral fin. Fins—dorsal higher than the body, its spine slender, 1/2 as long as the head and enveloped in skin: length of the base of the adipose dorsal 2/3 of that of the interspace between the two fins. Pectoral spine much stronger than that of the dorsal, with about 20 fine deuticulations internally and striated along its under surface. Free portion of the tail twice as long as high at its base. Colours—uniform brown.

Glyptosternum reticulatus, McClelland, from Afghanistan (Cal. Journ. Nat. Hist.) is said to be closely allied to this species, but to be without spines, and is probably an Exostoma.

Habitat.—Khasya hills in Assam, attaining at least $8\frac{1}{2}$ inches in length.

7. Glyptosternum Madraspatanum, Plate CXVI, fig. 4.

Day, Journal Linnean Society, xi, p. 526.

B. vi, D. $\frac{1}{6}/0$, P. 1/10, V. 6, A. 10-11 $(\frac{2}{8},\frac{3}{9})$, C. 17.

Length of head 5 to $5\frac{1}{4}$, of caudal $4\frac{1}{3}$ to $4\frac{2}{3}$, height of body $6\frac{1}{2}$ in the total length. situated in the middle or the commencement of the posterior half of the head, the distance between the eyes equals 2/7 of the length of the head. The greatest width of the head equals its length behind the front nostrils. Upper surface of the head rather rough, upper jaw the longer: the width of the mouth equals 2/5 of the length of the head: lips not fringed. Occipital process very narrow, four times as long as wide at its base. Bartelsthe maxillary reach the base of the pectoral, the nasal 2/3 to 3/4 of the distance to the orbit: the outer mandibular ones to the gill-openings, whilst the internal are a little shorter. Teeth—generic. Fins—dorsal spine rather strong, not enveloped in skin, serrated posteriorly, and in some specimens anteriorly in its upper third, it is as long as the head behind the angle of the mouth: base of adipose rather longer than that of the rayed dorsal fin. Pectoral almost reaches the ventral, its spine not plaited, moderately strong and 3/4 as long as the head. Caudal peduncle-half as high as long. Skin smooth. Colours-yellowish, with dark bands: fins also yellow, with black bands. Air-vessel—apparently absent.

This species is nearly allied to G. lonah, but amongst other differences its dorsal spine appears to be

always toothed, whereas in all specimens of G. longh that I have seen it is entire.

This species is nearly allied to G. trilineatum, but has a longer head and less anal rays.

Hubitat.—Bowany river at the foot of the Neilgherry hills, where I obtained 16 specimens up to 5 inches in length.

8. Glyptosternum pectinopterum, Plate CXVI, fig 6.

McClelland, Cal. Journ. Nat. Hist. ii, p. 587; Blecker, Beng. en Hind. p. 58; Günther, Catal. v, p. 188. Glyptosternum Stoliczkie, Steind. Verh. z. b. Ges. Wien, 1867, p. 17, t. v and vi, f. 1. Glyptosternum modestum, Day, Proc. Zool. Soc. 1871, p. 714.

Juppah, Punj. (at Chumba): Nung-grare, Punj. at Beeas if small, Kuggar, if large: No-woo, Punj. at

B. x, D. $\frac{1}{6}/0$, P. $\frac{1}{8}$ -9, V. 6, A. 9-11 $\left(\frac{1-2}{6-9}\right)$, C. 17, Vert. 15-17.

Length of head $4\frac{3}{4}$ to $5\frac{1}{4}$, of caudal $5\frac{1}{2}$ to 6, height of body 6 in the total length. Eyes—in the middle of the length of the head, the width of the interorbital space equals $3\frac{3}{4}$ in the length of the head. The width of the head nearly or quite equals its length. Upper jaw the longer, the width of the gape of the mouth $2\frac{3}{4}$ to 3 in the length of the head. Lips not fringed. Occipital process three times as long as wide at its base. Barbels—the maxillary extend nearly to the middle of the pectoral fin: the nasal reach the orbit: the outer mandibular to the base of the pectoral, whilst the inner are rather shorter. Teeth—generic. Fins—dorsal nearly as high as the body, its spine rather slender, and more than 1/2 as long as the head; in many specimens up to three or four inches in length the soft termination of the spine is continuous with it, and on bending it appears as if there were numerous points anteriorly, this appearance is usually lost in the adult fish: base of the adipose dorsal rather longer than that of the rayed fin and equal to 4/5 of the interspace between the two fins. Pectoral extends three-fifths of the distance to the ventral, its spine is flattened, strong, and as long as the head excluding the snout, and having coarse denticulations internally. The outer rays of the ventral and pectoral are plaited inferiorly, this appearance is usually lost in specimens preserved in spirit unless the alcohol was very strong at the commencement. Candal pedancle—one-third to twice as long as high at its base. Adhesive apparatus well marked. Colours—uniform brown, with a yellowish mark along the back, fins yellow, stained with black. Air-vessel—in two lateral portions, partially enclosed in bony capsules formed by a trumpet-shaped process from the anterior vertebra.

G. modestum appears to be the young, it is much wider in the body and the peculiar appearance shown in the termination of the dorsal spine of moderately sized specimens is scarcely perceptible.

Habitat.—Himalayas through the Punjab, and at Kangra, Simla, Darjeeling.

9. Glyptosternum cavia.

Pimelodus cavia, Ham. Buch. Fish. Ganges, pp. 188, 378. Bagarius? cavia, Bleeker, Beng. en Hind. p. 58. Kanya tenggara, Hind.

D. $\frac{1}{6}/0$, P. $\frac{1}{8}$, V. 6, A. 9 (3/6), C. 17.

"It is flattened before, conical behind, and all its upper parts are scabrous from elevated spots." "Head very large, a good deal flattened, blunt, and covered above with bony plates, forming various ridges.' Upper jaw the longer. Barbels—nasal very short, the maxillary as long as the head, the two pairs of mandibular ones shorter. Teeth—none on the palate. Fins—dorsal spine blunt, rough, but not serrated on the anterior surface: adipose fin small and rough: pectoral spine serrated on both edges: lower caudal lobe the longer. Colours—"lurid, and the back is variegated with brown dots, collected into cloud-like marks, while the sides have a gloss like silver, changing into the hue of copper. The abdomen is of a dirty livid appearance. Across the tail are two transverse bars, and on the tail fin a third, all of which have fewer dots than the adjacent parts. The eyes are white."

Hamilton Buchanan (MSS.) observes of this fish in the Ramghur district "the Kanya tengra of the Dharlá is a very ugly little fish, compared by the natives to a crow."

Habitat.—Rivers of Northern Bengal, where it attains about 6 inches in length.

Genus, 28—Euglyptosternum, Bleeker.

Aclyptostenon, Bleeker.

Dorsal profile nearly horizontal, head covered with soft skin. Gill-openings rather wide, the gill-membranes confluent with the skin of the isthmus, Mouth transverse, upper jaw the longer. Eyes small, subcutaneous. Nostrils close together, separated by a barbel. Barbels eight. Teeth villiform in the jaws and on the palate. Dorsal fin with a spine and six rays: an adipose dorsal present. Pectorals horizontal, with an adhesive apparatus on the chest formed

Digitized by GOO

by longitudinal plaits of skin. Anal short (11 to 13 rays) not continuous with the caudal which is forked. Ventrals situated posterior to the dorsal, and consisting of six rays. Air-vessel in two lateral portions, enclosed in bone.

Geographical distribution.—River Coic near Aleppo, Upper Assam, and the Jumna.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Euglyptosternum lineatum, A. 13. Brown, with a narrow light line along the middle of the side. Suddya in Upper Assam; also the river Jumna.

1. Euglyptosternum lineatum, Plate CXVI, fig. 7.

D. $\frac{1}{6}/0$, P. 1/10, V. 6, A. 12-13 $(\frac{3}{9-10})$, C. 17.

Length of head $4\frac{1}{4}$, of caudal $5\frac{2}{3}$ to 6, height of body 6 to 7 in the total length. Eyes—small, situated about 2 diameters behind or else in the middle of the length of the head, the width of the interorbital space 1/4 of the length of the head. Head rather flattened, its greatest width equals its length behind the nostrils. Upper jaw the longer, the width of the gape of the mouth equals half the length of the head. Lips smooth. Occipital process three times as long as wide at its base. Barbels—the nasal nearly reach to the orbit: the maxillary pair are as long as the head, the outer mandibular ones reach the gill-opening, the inner are shorter. Teeth—villiform in the jaws, and in one large patch extending across the palate, and so closely approximating to the premaxillary teeth that they appear like a single large band. Adhesive apparatus on the thorax distinct. Fins-the dorsal as high as the body, its spine strong, entire, and about half the length of the head: adipose dorsal of moderate height, the length of its base equalling that of the rayed fin, or half the interspace between the two fins. Pectoral spine very strong, smooth externally, denticulated internally with about 9 or 10 teeth, and reaching two-thirds of the distance to the base of the ventral. Caudal deeply forked. Skin smooth. Caudal peduncle—twice as long as high. Colours—brown, with a narrow light band along the side.

Habitat.—The specimen figured (life-size) was from the Jumna, I have procured it 12.5 inches in length

near Suddya in Upper Assam.

Genus, 29—Pseudecheneis, Blyth.

Gill-openings small, not extending on to the lower surface of the head, the gill-membranes being attached to a very broad isthmus. Body somewhat elongate: head rather depressed. An adhesive apparatus formed of transverse folds of skin situated on the thorax between the bases of the pectoral fins. Eyes small, subcutaneous, on the upper surface of the head. Mouth transverse, small, inferior. Nostrils on either side approximating, being divided by a barbel. Barbels eight, the maxillary pair with broad bases. Teeth villiform in the jaws, palate edentalous. Dorsal fin with one spine and six rays: the alipose of moderate extent. Pectoral with its inner third vertical, its lower two-thirds horizontal, its spine feebly serrated. Ventral horizontal, having six rays, and situated below the dorsal. Caudal emarginate. Air-vessel in rounded lateral portions enclosed in bone.

This Genus is evidently formed for an existence in rapids.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Pseudecheneis sulcatus, A. 11-13. Black, blotched with yellow, fins with black bands. Darjeeling and Khasya hills.

1. Pseudecheneis sulcatus, Plate CXVI, fig. 1.

Glyptosternum sulcatus, McClelland, Cal. Journ. Nat. Hist. ii, p. 587, pl. vi; Bleeker, Beng. p. 58. Pseudecheneis sulcatus, Blyth, Proc. Asi. Soc. of Beng. 1860, p. 134; Günther, Catal. v, p. 264.

D. $\frac{1}{6}/0$, P. 1/13, V. 6, A. 11-13 ($\frac{2}{7},\frac{4}{9}$), C. 17.

Length of head $7\frac{1}{2}$, of caudal 6, height of body 6 in the total length. Eyes—small, situated midway between the hind edge of the opercle and the nostrils: the width of the interorbital space equals 31 in the length of the head. Lower surface of the head with numerous papille, especially near the symphysis. The width of the head equals its length. Barbels—the maxillary pair with very broad bases, and about 1/3 of the length of the head. Fins—spine of anterior dorsal broad, weak, and with a soft termination, it is crenulated posteriorly: length of the base of the adipose dorsal as long as that of the interspace between the two fins. Pectoral large and extending to above the base or first third of the ventral, its spine is broad, finely ciliated externally in its lower 1/2, crenulated internally, especially in its posterior soft termination. In some specimens the under surface of the pectoral spine and first ventral ray are striated. Caudal emarginate, lower lobe the longer. The thoracic sucker has about 14 transverse folds. The free portion of the tail about three times as long as deep at its base. Colours—blackish, with some large, irregular, yellowish blotches. Fins yellow, with black bands.

Habitat.—Darjeeling and Khasya hills, attaining 7 to 8 inches in length. The specimen figured was from Darjeeling.

Genus, 30—Exostoma, Blyth.

Chimarrichthys, Sauvage.

Gill-openings narrow, the membranes confluent with the skin of a broad isthmus. Head depressed and covered superiorly with soft skin. No thoracic adhesive apparatus. Mouth inferior, with the lips reflected around the whole or most of its circumference, and usually covered with tubercles. Nostrils close together, separated by a barbel. Eight barbels. Teeth in the jaws in several rows: palate edentulous. Anterior dorsal fin with a rudimentary spine and six rays: adipose fin long and low. Pectorals vertical in their upper, horizontal in their lower half, the spine enclosed in skin. Ventral with six rays inserted some distance behind the rayed dorsal, its form as in the pectoral. Candal square, emarginate or forked. Air-vessel enclosed in bone.

This peculiar mountain Genus has its lips adapted for a sucker, the chest likewise appears to form a flat adhesive surface, bounded by the striated rays of the pectoral and ventral fins.

Geographical distribution.—At present there are six species of this Genus known, four of which are included in this work. These fishes extend from the upper waters of the Indus, along the Himalayas, the Mishmee Mountains in East Assam, Tenasserim to Eastern Tibet on the confines of China.

SYNOPSIS OF SPECIES.*

A. Teeth in jaws pointed.

1. Exostoma labiatum. Lower labial fold uninterrupted. The interspace between the first and adipose dorsal fins equals equals 2/3 the length of the latter. Anal commences much nearer the base of the candal than

that of the ventral. Mishmee Mountains.

2. Exostoma Blythii. Lower labial fold interrupted. A short interspace between the dorsal fins. Anal commences in last 1/3 of the distance between ventral and base of caudal. Head waters or affluents of Ganges.

3. Exostoma Berdmorei. Snout more pointed. Caudal forked. Tenasserim.
4. Exostoma Stoliczkæ. Lower labial fold interrupted. Anal commences nearer the base of the ventral than that of the caudal. Pectoral does not extend to the ventral. Upper waters of Indus.

1. Exostoma labiatum.

Glyptosternum labiatus, McClell. C. J. N. H. ii, p. 580.

Exostoma labiatum, Blyth, P. A. S. of B. 1860, p. 155; Günther, Catal. v, p. 265; Day, Proc. Zool. Soc. 1869, p. 525.

D. $\frac{1}{6}/0$, P. $\frac{1}{11}$, V. 6, A. $\frac{1}{5}$, C. 17.

Length of head 1/5, of pectoral 1/5, of caudal 1/5, height of body 1/8 of the total length. Eyes—small, situated in the posterior two-fifths of the head. Mouth small, inferior, transverse: jaws in the form of a double crescent or co-shape. Lips broad, with a median and a lateral lobe on either side,

having a barbel between. Nasal barbels reach the end of the snout: the maxillary extend to the pectoral fin. Fins—as in the preceding species. Caudal slightly forked.

. Colours—uniform. Habitat.—Mishmee Mountains, East Assam.

2. Exostoma Blythii, Plate CXVII, fig. 2.

Day, Proceedings Zoological Society of London, 1869, p. 525.

D. $\frac{1}{6}/0$, P. $\frac{1}{17}$, V. 6, A. 8 ($\frac{2}{6}$), C. 13.

Length of head $4\frac{3}{4}$, of caudal $6\frac{1}{2}$, height of body 5 in the total length. Eyes—small, situated on the upper surface of the head, and the width of the interorbital space nearly equals the length of the snout, which is broad and depressed. Mouth inferior and transverse, saleus behind lower lip interrupted. Gillopenings not continued on to the lower surface of the head. Barbels—the nasal about three times as long as
the orbit: a fleshy appendage to the maxilla having a rudimentary barbel: two pairs behind the lower lip
arising on a transverse line. Teeth—none on the palate. Fins—pectoral sub-horizontal, its rays plaited below:
base of adipose more than twice as long as that of the rayed fin. Dorsal arising slightly in advance of the
ventrals, its spine weak. Ventrals sub-horizontal. Caudal with its outer rays slightly produced, rendering it almost lunated. Air-vessel-small, in two rounded lobes, both enclosed in a bony capsule. Colours-yellowish brown.

* The other two species alluded to are as follows:—
E. Davidi. The interspace between the two dorsal fins equals the length of the latter. Pectoral reaches ventral. Eastern Tibet.

B. Outer row of teeth compressed.

E. Andersonii. Lower labial fold interrupted. Bhamo.

Habitat.—Rivers below Darjeeling. I was given some specimens up to 3; inches long, by Dr. Stoliczka, who obtained them from that locality.

3. Exostoma Berdmorei.

Blyth, P. A. S. of B. 1860, p. 155; Günther, Catal. v, p. 265; Day, Proc. Zool. Soc. 1869, p. 526. D. $\frac{1}{6} \mid 0$, P. $\frac{1}{16}$, V. 6, A. 6, C. 14.

Maxillary barbels reach the base of the pectoral fin. The snout is much more pointed than in the other species. Fins—caudal rather deeply forked. Colours—"dingy olive-brown, with obscure dark broad bands, presenting more or less of a clouded appearance: the fins mostly darker, below pale."

Habitat.—Tenasserim. The typical specimen (4 inches long) in the Calcutta Museum, is in such a very bad state of preservation that I cannot add more to Blyth's description.

4. Exostoma Stoliczkæ, Plate CXVII, fig. 3.

Day, Proceedings Zoological Society, 1876, p. 782.

D. $\frac{1}{6}$ | 0, P. 1/12, V. 6, A. 6, C. 15.

Length of head from 4 in the young* to $5\frac{1}{3}$ in the adult, of caudal 8, height of body $7\frac{1}{4}$ in the total length. Eyes—minute, situated in the middle of the length of the head: the width of the interorbital space equals half the length of the snout, or the distance between the eye and the front nostril. Head depressed, as broad as long, and obtusely rounded. Mouth inferior: lips thick, and studded with small tubercular elevations: the upper and lower lips continuous at the angle of the mouth, but the transverse fold across the lower jaw is interrupted in the middle. Nostrils close together, the anterior round and patent, the posterior tubular; a barbel divides the two nostrils, it is situated on a bridge of skin, below which the two nostrils are continuous. Barbels—the nasal ones reach the hind edge of the eye: the maxillary ones have a broad basal attachment, and reach the root of the pectoral. Of the mandibular barbels the anterior are situated just behind the inner end of the lower labial fold: they are shorter than the outer pair, which latter extend to the gill-opening. Gill-opening situated on the side of the head in front and above the base of the pectoral fin. Teeth—several rows of pointed ones in each jaw, of which the outer is slightly the larger, rather wide apart, and with rather obtuse summits. Fins—the dorsal arises midway between the snout and the commencement of the adipose fin; its greatest height is one-third more than the length of its base: its spine is rudimentary and enveloped in skin. Adipose dorsal very long and low, posteriorly in some instances it is free, in others it almost appears to decrease in height and join the free portion of the tail. Pectoral nearly as long as the head, having its outer half horizontal and its inner vertical: its spine is rudimentary, with a broad, striated, cutaneous covering. Ventral of a similar form to the pectoral; its first and a portion of its second ray also with a striated cutaneous covering: the fin commences on a vertical line falling just behind the base of the dorsal fin: it is rather nearer the snout than the posterior end of the adipose dorsal, and commences midway between the bases of the ventral and caudal fins: it is half higher than long. Caudal cut almost square. Free portion of the tail one-half higher than long. Skin—tuberculated from the head along the lower surface of the body to nearly as far as the bases of the ventrals. Colours—of a dull yellowish green, becoming lightest along the abdomen. Fins yellowish, with dark edges or bands.

Habitat.—Lek or Ladak, and along the head waters of the Indus, attaining about 7 inches in length.

* The remarkable difference in the comparative length of the head to that of the total is shown in the following figures:

3 specimens 4 inches in length. Head 4 to $4\frac{1}{3}$ in the total length. 4 ,, $4\cdot 2$ to $4\cdot 5$, ,, $4\frac{1}{3}$ to $5\frac{1}{4}$,, $4\cdot 2$ to $5\cdot 7$, ,, $5\cdot 1$ to $5\cdot 2$,

Family, II—SCOPELIDÆ, Müller.

Branchiostegals as a rule numerous. Pseudobranchiæ well developed. Gill-openings very wide. Opercular pieces sometimes incomplete. Margin of the upper jaw formed by the premaxillaries. Barbels absent. Two dorsal fins, the posterior being adipose. Scales present or absent. Ova enclosed in sacs in the ovaries and excluded by oviducts. Intestinal canal short. Pyloric appendages, when present, few in number. Air-vessel small or absent.

Geographical distribution.—These fishes, which in many respects are allied to the Siluroids, appear to be distributed throughout tropical, sub-tropical, and temperate seas.

SYNOPSIS OF GENERA.

- Saurus. A single band of palatine teeth. Ventral with eight rays, the inner being the longest.
 Saurida. Two parallel bands of palatine teeth. Ventral with nine rays: the inner not much longer than the outer ones.
- 3. Harpodon. Premaxillaries but no superior maxillaries. Bones of head soft. Ventral with nine rays. Caudal tri-lobed. Thin and deciduous scales present in the last three-fourths of the body.

 4. Scopelus. Bones of head ossified. Scales rather large. Luminous spots along the body.

Genus, 1—Saurus, sp. Cuvier.

Synodus, pt. Gronovius; Laurida, pt. (Aristotle) Swainson.

Branchiostegals from eight to seventeen. Gill-openings very wide, the gill-membranes not attached to the isthmus. Body clongated, subcylindrical: head oblong, muzzle short. Eyes of moderate size, lateral. Gape of mouth wide, cleft very deep: edge of the upper jaw entirely formed by long and thin premaxillaries: the maxillary likewise elongated, and adherent to the premaxillaries. Teeth numerous, pointed, some are elongated, slender, and can be laid downwards and inwards: they exist on the jaws, tongue and palatine bones, a single band being on the palate and usually none or only a few on the vomer. First dorsal with a moderate number of rays, situated nearly in the middle of the length of the fish: adipose fin small. Ventral with eight rays, the internal ones being the longest: it is inserted anterior to the origin of the dorsal and not far behind the pectorals, which are short: anal of moderate length or short. Caudal forked. Scales of moderate size. Lateral-line entire. Pyloric appendages few.

Geographical distribution.—Tropical portions of the Atlantic and Pacific Oceans; Mediterranean.

SYNOPSIS OF SPECIES.

- 1. Saurus Iudicus, D. 13/0, A. 9, L. l. 55-57, L. tr. $3\frac{1}{2}/7$. Head pointed. Madras.

 2. Saurus myops, D. 12-13/0, A. 16-17, L. l. 52-56, L. tr. $3\frac{1}{2}/7$. Snout obtuse. A black shoulder spot. Longitudinal lines along the body. Seas of India and tropical portions of the Atlantic and Pacific Oceans.
 - 1. Saurus Indicus, Plate CXVII, fig. 4.

Day, Journal of Linnean Society, Zoology, xi, 1873, p. 526.

B. xv, D. 13/0, P. 14, V. 8, A. 9, C. 19, L. 1. 55-57, L. tr. $3\frac{1}{2}$ /7.

Length of head $4\frac{1}{2}$, of caudal $7\frac{1}{4}$, height of body $7\frac{1}{2}$ to 8 in the total length. Eyes—without adipose lids, diameter 53 in the length of head, rather more than I diameter from the end of snout, and nearly 1 apart : the width of the snout at its base equals its length. Greatest width of the head not quite 1/2 its length. Inter-orbital space somewhat concave. Upper jaw slightly the longer. Cleft of mouth extending to far behind the eyes. The hinder portion of the frontal and occipital bones on the summit of the head corrugated. Teeth—the inner row in the jaws the longest, some in the mandible barbed. Five rows of large teeth on the tongue. A single band on the palatines of which the inner row is much the largest. Fins—dorsal about as long as high. Pectoral reaches to the tenth scale of the lateral-line. Inner ventral rays the longest, the fin reaches nearly half way to the base of the anal. Caudal deeply forked. Scales—17 rows between occiput and base of dorsal fin. Those along the lateral-line rather raised, but not distinctly keeled. Colours—brownish in the upper twothirds, dirty white beneath. Numerous bluish irregular spots or blotches along the back and sides, in places almost forming horizontal bands. Dorsal and caudal white, with grayish spots, forming irregular horizontal

Habitat.—Madras to 7 inches in length.

Length of head $4\frac{1}{4}$, of caudal $6\frac{1}{2}$ to 7, height of body 6 in the total length. Eyes—without adipose lids, diameter 1/6 of length of head, 1/2 to 3/4 of a diameter apart, and also from the end of snout. Dorsal profile nearly horizontal: greatest width of head equals half its length. Cleft of mouth extending to at least two diameters behind the orbit: jaws of about equal length anteriorly. Interorbital space deeply concave: summit of head corrugated except the interorbital furrow. Teeth—pointed, two rows in the upper, three in the lower jaw, the inner being the longest. A single two-rowed band on the palate. Tongue likewise toothed. Finsfirst dorsal rather highest anteriorly, nearly square, commences midway between the snout and the second dorsal, its first two rays unbranched: second dorsal very small: pectoral small and rounded at its extremity: ventral sub-horizontal, with its inner rays the longest, it is as long as the head. Caudal forked, with its lower lobe the longer. Scales—arranged in horizontal rows which are rather undulating above the lateral-line: six transverse rows on cheek: none on summit of head or on lower jaw. Lateral-line-slightly raised in single tubes, with a small elevation on either side. Colours—upper half of body of a golden colour, with four longitudinal blue lines having black edges, and nearly as wide as the ground colour. A black spot at shoulder. Abdominal surface silvery. Dorsal fin with three rows of yellow spots: a yellow band along the middle of the pectoral: outer half of anal yellow.

Habitat.—Seas of India to the Malay Archipelago and the tropical portions of the Atlantic and Pacific

Oceans. The specimen figured was from Madras.

Genus, 2-SAURIDA, Cuv.

Synodus, pt. Gronovius; Laurida, pt. (Artedi) Swainson.

Differs from Saurus as follows:—Teeth cardiform, the inner ones being the longest and slender, all can be laid downwards and inwards, they exist on the jaws, tongue, and palatine bones: those on the palate are in two parallel bands on either side, the inner being the shorter. Ventral fin with nine rays, the inner not much longer than the outer ones. Pectoral short or of moderate length.

SYNOPSIS OF SPECIES.

1. Saurida tumbil, D. 11-13/0, A. 10-11, L. l. 53-64, L. tr. 4½/7. From the Red Sea through the seas of India to China and Japan.

2. Saurida nebulosa, D. 10-11/0, A. 9, L. l. 50-52, L. tr. $3\frac{1}{2}/7$. East coast of Africa, seas of India to the Malay Archipelago and beyond.

B. xiii-xvi, D. 11-13/0, P. 14-15, V. 9, A. 10-11, C. 19, L. l. 53-64, L. tr. $4\frac{1}{2}$ /7, Vert. 53.

Length of head $4\frac{1}{2}$ to $5\frac{1}{3}$, of caudal $5\frac{1}{2}$ to 6, height of body $7\frac{1}{2}$ to 8 in the total length. Eyes—with broad adipose lids, diameter 5 in the length of head, $1\frac{1}{4}$ diameters from the end of snout, and the same apart. Cleft of mouth extending to $1\frac{1}{4}$ diameters behind the orbit. Teeth—several rows of card-like teeth in the upper jaw, the internal the largest, and the external smallest: the surface of the premaxillaries on which they are placed is bevilled off, so as to look outwards. The teeth on the mandibles are of the same character, the largest rows internal and smallest external: they are more numerous than in the upper jaw, and placed on a surface looking upwards and outwards. Teeth on palate in two distinct parallel patches, the external row in each of which is the largest, whilst the inner is only one-third the length of the outer row: a small round patch of teeth generally on the vomer, and small ones on the tongue. Fins-first dorsal in the centre of the body: the adipose dorsal is situated over the last two anal rays. Caudal deeply forked. Scales—over the body and head, with some on the base of the caudal fin. Lateral-line—the keel is most developed in the posterior third of the body. Colours—brownish-gray along the back, becoming white beneath, the whole having yellow reflections. In some the dorsal and upper half of the caudal fins are barred in spots. In others (as the one figured) there are no spots, and the middle of the pectoral and ventral are spots, and the middle of the pectoral and ventral are limited.

Habitat.—From the Red Sea through the seas of India to the Malay Archipelago, China and Japan. As food it is rather dry and insipid. The specimen figured (from Madras) is 8 inches in length.

2. Saurida nebulosa.

Saurus à bandes et taches, Liénard, Dixième, Rapp. Maur. Hist. Nat. Soc. 1839, p. 41.

Saurus à bandes et taches, Liénard, Dixième, Rapp. Maur. Hist. Nat. Soc. 1839, p. 41.

Sauruda nebulosa, Cuv. and Val. xxii, p. 504, t. 648; Bleeker, Moluc. p. 292, Chiroc. p. 30, and Atl. Ich. vi, p. 156, Sauruda, t. i, f. 1; Günther, Catal. v, p. 399; Kner, Novara Fische, p. 316; Klunz. Verh. z. b. Ges. Wien, 1871, p. 591.

B. xii-xiii, D. 10-11/0, P. 12-13, V. 9, A. 9-10, C. 19, L. 1. 50-52, L. tr. $3\frac{1}{2}/6$.

Length of head $4\frac{3}{5}$ to $5\frac{1}{5}$, of caudal $6\frac{1}{4}$, height of body $6\frac{1}{2}$ to 9 in the total length. Eyes—diameter 4 to $5\frac{1}{2}$ in the length of the head, rather above 1 diameter from end of snout, and 3/4 to 1 diameter apart. Jaws anteriorly of the same length: snout somewhat pointed, the maxilla extends nearly to the angle of the preopercle. Teeth—thin and pointed, in several rows in the jaws, the outer being the longer, and moveable: none on the vomer: in two bands on the palate, the outer twice as long as the inner. Fins-dorsal higher than long, situated midway between the anterior end of the snout and the base of the caudal fin. Pectoral reaches to the ninth scale of the lateral-line. Ventral as long as the head excluding the snout. Scales—forming a slight ridge in the last portion of the lateral-line. Colours—brownish, becoming lightest below: a series of bars or blotches along the middle of the sides: fins barred.

Bleeker observes that in specimens from the Malay Archipelago none had vomerine teeth, whereas such

were constant in S. tumbil.

Habitat.—From the Red Sea, Madagascar, and the coasts of Zanzibar, to the Mauritius, through the seas of India to the Malay Archipelago and beyond.

Genus, 3—HARPODON, Lesueur.

Triurus, Swainson: Sauridichthys, Bleeker.

Branchiostegals from twenty-three to twenty-five. Gill-openings wide. Body elongated and compressed. Eyes small. Snout short, bones of head soft and partly modified into wide muciferous channels. Cleft of mouth deep: margin of the upper jaw formed by the premaxillaries which are thin and tapering: maxillaries absent. Teeth cardiform, recurved and of unequal size, the largest being on the mandibles and barbed. Teeth exist on the premaxillaries, mandibles, palatines, the tongue and hyoid bone, those on the palatines are large and can be laid downwards. Dorsal fin in the middle of the length of the body, with a moderate number of rays: adipose fin small. Pectorals and ventrals long, the latter with nine rays, and inserted below the anterior dorsal ones, at some distance behind the pectorals. Anal of moderate length. Caudal tri-lobed. Scales thin and deciduous, none on the anterior portion of the body. Air-vessel absent. Pyloric appendages sixteen.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Harpodon nehereus. D. 12-13/0, A. 13-15. No scales (except along the lateral-line) anterior to the dorsal and ventral fins. Caudal tri-lobed. From Zanzibar through the seas of India to China.

B. xxiii-xxvi, D. 12-13 | 0, P. 11-12, V. 9, A. 13-15, C. 19, Vert. 38, Cec. pyl. 16 (22).

Length of head $5\frac{1}{2}$ to 6, of caudal 6, height of body $6\frac{1}{2}$ to $7\frac{1}{3}$ in the total length. Eyes—diameter 1/16of the length of the head, 2 diameters from the end of snout, and 4 apart. Body compressed, snout short and obtuse. Lower jaw the longer, the cleft of the mouth almost reaches the preopercular angle. Opercular pieces diaphanous and apparently more or less blended together. Teeth—recurved and erectile. Those of the jaws and some on the relative to the preopercular angle. and some on the palatines have a single barb at the posterior margin of the point, a few of the former are arrow-shaped. In both jaws appear three series of somewhat distant teeth: the external consists of excessively minute ones, the second of longer, and the internal series the longest. Those of the lower jaw are longer than those of the appearance o longer than those of the upper, particularly three or four on each side of the symphysis. The pharyngeals and palatals contain two rows. The fourth anterior tooth of each palatal is very long. Fine teeth on the tongue, hyoid bone and the upper margin of the branchial arches. Fins—the first dorsal is situated midway between the snout and the root of the caudal: the ventral opposite the dorsal, midway between the snout and the last ray of the anal: the first anal ray midway between the last ray of the dorsal and the root of the caudal: the adipose dorsal opposite the posterior third of the anal. The point of the ventral reaches to the middle of the anal, a long thin elongated scale is situated at its base. The adipose dorsal is rather large. The caudal anal, a long thin elongated scale is situated at its base. divided into three pointed lobes, of which the centre is rather the shortest. The pectorals are falciform, and in the young reach to the last dorsal ray, but become shorter with age. Scales—commence opposite the origin of the dorsal fin, all are diaphanous, and can with but difficulty be distinguished in the fresh fish. Lateral-linerather nearer to the back than to the abdomen: it is slightly keeled with about forty fine rectangular membranous pieces, covered with scales like the rest on the body. Intestines the length of the abdominal cavity being destitute of any convolutions. Colours—head, back, and sides semi-transparent like gelatine, lightgrayish, with minute starlike black or brownish dots: anterior part of the abdomen pale, silvery-bluish: rest grayish-white: cheeks and opercles pale silvery-bluish, dotted like the body: fins transparent, coloured like the body, but more closely dotted, as to appear grayish and black at their extremities, in some specimens the fins are black. Iris golden.

This fish is highly esteemed as food, whether fresh or salted, in the latter form it is extensively employed

as a relish with curries, and is known as the Bombay duck.

Habitat.—From Zanzibar to China, seas and estuaries of India, most common at Bombay but decreasing in numbers down the Malabar coast. It is not very common at Madras but augments in numbers up the Coromandel Coast, being very abundant in the rivers and estuaries of Bengal and Burmah. Bleeker observes that it appears to be very abundant in the straits of Malacca, more rare at Java, and uncommon at Batavia. It attains at least 16 inches in length. The specimen figured (life-size) was from Bombay.

Genus, 4-Scopelus,* Cuvier.

Myctophum (Nyctophus), Lampanyctus, Cocco: Alysia, Lowe: Neoscopelus, Johnson: Ceratoscopelus, Dasyscopelus, Günther.

Branchiostegals eight to ten. Gill-openings very wide. Body oblong and compressed. Eyes large: sometimes a supraorbital spine. Snout short. Bones of head thin, but osseous. Cleft of mouth very deep: premaxillaries long and tapering: maxillaries well-developed. Teeth villiform in both jaws, on the palatines, pterygoids, and on the tonque: usually absent from the vomer except in some large specimens. Rayed dorsal fin in about the middle of the length of the body: a small adipose one likewise present. Pectoral well-developed, as is also the ventral which has eight rays. Anal rather long. Caudal forked. Scales large, smooth, or with rough edges, or even minute spines. Air-vessel small. Pyloric appendages few.

* The following sub-divisions of the Genus have been adopted :-

sub-divisions of the Genus have been adopted:—
A. The number of dorsal rays more than those of the anal.
1. Scales of lateral-line enlarged.
2. , scarcely, if at all, enlarged. Notoscopelus.
B. The number of dorsal rays, less than, or equal to, those of the anal.
1. Eye one-third or more in length of head. No supraorbital spine.
a. Scales smooth, Myctophum. b. Scales with rough edges, Dasyscopelus.
2. Eye large: a supraorbital spine. Ceratoscopelus.
3. Eyes less than 1/3 of length of head.
a. Scales smooth: those of lateral-line enlarged. Alysia.
b. Scales smooth: of unequal sizes. Lampanyctus.
c. Scales with minute spines. Neoscopelus.

c. Scales with minute spines. Neoscopelus.

These fishes have a row of luminous spots along the lower portion of the body, sometimes they are also present on the head, snout and back of tail, whilst a few may exist on the sides.

Geographical distribution.—Temperate and tropical seas.

SYNOPSIS OF INDIVIDUAL SPECIES.

- Scopelus Indicus, D. 10/0, A. 18, L. 1. 43, L. tr. 3½/5. No supraorbital spine. Scales smooth. India.
 Scopelus Indicus, Plate CXVIII, fig. 2.
- D. 10/0, P. 14, V. 8, A. 18, L. 1. 43, L. tr. 3½/5.

Length of head 5, of caudal $6\frac{1}{2}$, height of body $4\frac{1}{2}$ in the total length. Eyes—diameter $2\frac{1}{2}$ in the length of head, 1/4 of a diameter from the end of snout, and also apart. No spine above the orbit. Cleft of mouth reaches almost to the preopercular angle. Fins—the dorsal is situated midway between the base of the caudal fin and the front edge of the eye, it is not quite so high as the body below it. Pectoral reaches the middle of the ventral, whilst the ventral nearly extends to the anal. Caudal slightly forked. Scales—smooth, the row beneath the lateral-line is much larger than the others. Colours—of a deep metallic blue in the upper portion of the body, becoming lighter on the sides and beneath. A line of round golden spots along the lower edge of the abdomen, and a few larger ones scattered over the sides.

In general appearance this species much resembles Scopelus spinosus, Steind. Sitz. Akad. Wiss. 1867,

p. 11, t. iii, f. 4, but its scales are entirely smooth.

Habitat.—A single specimen, now in a bad state, was collected by Sir Walter Elliot at Vizagapatam. It would belong to sub-genus Myctophum.

FAMILY—SALMONIDÆ.

Pseudobranchiæ present. Margin of the upper jaw formed by the premaxillaries and maxillaries. No barbels. A single rayed and posteriorly an adipose dorsal fin. Pyloric appendages usually present and mostly numerous Body scaled, head scaleless. Air-vessel large, simple, and with a pneumatic duct. The ova pass into the cavity of the abdomen before being excluded.

Were this work strictly limited to the indigenous Fishes of India, the Family of Salmonidæ should be omitted, as the Hindoo Koosh is the nearest locality to Hindustan, where they are found.* But as the Salmo Leveneusis and the cyprinoid Tinca vulgaris have been introduced into the waters of the Neilgherry hills, where they appear to be thriving in a wild state, I have considered it better to record them, in order to prevent misconception as to how they came there, when they shall be rediscovered at a future date.

In introducing exotic fishes, one of the first considerations must necessarily be to ascertain whether any representatives of the Family are normally resident in the region it is desired to stock? If such do exist, the question arises, are they a thriving or a diminutive race? It has been maintained that if the latter, the chances of success are too small to render the attempt worth making, as the region is unsuited for their

India, however, is peculiarly situated. Doubtless at a remote period the continent to the south of the Ganges was divided by the sea from the Himalayas, and therefore the entire absence of fresh-water Salmonidæ cannot be looked upon in either a favourable or an unfavourable aspect. I suggested to the Governor of Madras, Sir William Denison, introducing trout into the waters of the Neilgherry hills by means of their ova transported from Europe in ice. My attempt failed.† Wise after the event and may-be not anticipating that it would be renewed, Dr. Güncher chronicled my failure, remarking as "has been foreseen by all acquainted in the control of with the nature of Salmonoid fishes.":

Since then I have had no further opportunity to carry out my experiment, but the late Mr. McIvor, of the Government Gardens at Ootacamund, who assisted me in my endeavour, was so sanguine of eventual success, that he resolved to try and bring out from Loch Leven some live fish. Always ready with an expedient to meet changing circumstances he succeeded in introducing trout, tench, gold carp and eels into the

My figure is from a trout bred in a wild state, and captured on the Koondahs in 1876. For it I am indebted to T. Sullivan Thomas, Esq., of the Madras Civil Service, who received it from Mr. McIvor. Whether the success will continue must depend on two causes, the first climatic, the second whether the breed will be exterminated by man.

Genus, 1-SALMO.

Definition as in the family: pyloric appendages numerous.

Salmo levenensis, Plate CXVIII, fig. 3.

Walker: Yarrell: Günther: Day, Journal Linn. Society, xii, p. 567.

This species is too well known to need description.

Colours-twelve vertical bands demonstrating its being a young fish. The spots which are now black were originally red. The nature of the water and the soil through which it flows exercise great influence on the colour of fishes, and this specimen was bred in a clear hill stream. In Loch Leven, according to Mr. Pennell, the trout have no red spots.

Habitat.—Neilgherry hills, introduced from Loch Leven.

* Salmo Orientalis, McClelland, or S. Oxianus, Kessler.
† Proceedings Zoological Society, 1867, p. 281.
† Zoological Record, 1867, p. 131.

Family, III—SCOMBRESOCIDÆ.

Pharyngognathi malacopterygii, Müller.

Pseudobranchiæ concealed, glandular. Margin of the upper jaw formed, mesially by the premaxillaries, laterally by the maxillaries. Barbels present or absent. Lower pharyngeals united into a single bone. Dorsal fin rayed, with or without finlets posterior to it, situated opposite the anal, and in the caudal portion of the vertebral column: no adipose dorsal. Scales present, frequently a keeled row along either side of the free portion of the tail. Air-vessel generally present, sometimes cellular, and destitute of a pneumatic duct. Stomach and intestines in one straight undivided tube. Pyloric appendages absent.

SYNOPSIS OF GENERA.

1. Belone. Both jaws elongated into a beak. No finlets.

2. Hemirhamphus. Upper jaw short, the lower elongated into a beak.

3. Exocetus. Jaws short: pectoral fins elongated into organs for flying.

Genus, 1—Belone, Cuvier.

Mastacembelus, (Klein), Bleeker: Rhamphistoma, Raf.: Tylosurus, Cocco: Potamorrhaphis, Günther.

Branchiostegals rather numerous. Gill-openings wide. Body elongated, sub-cylindrical or compressed. Eyes lateral. The jaws prolonged into a beak, the upper of which is formed by the premaxillaries. Fine teeth, or rugosities in both jaws, with a single row of long, widely-set conical ones: palute toothed or toothless. The anterior dorsal rays may or may not be elevated, forming a lobe to the fin, whilst the middle and posterior ones may be short or elongated: no finlets: caudal usually forked. Scales small. Lateral-line on free portion of tail, with or without a keel.

Uses.—These Gar-fish are but indifferent as food, whilst their bones are green, as observed in the European forms. They are very destructive amongst young and small fishes.

In very young specimens the jaws are said not to be prolonged, and as age increases the mandibles are considerably advanced before the premaxillaries. Distinct varieties appear to be present in some species, as Belone cancila, some of the inland forms of which have an elevation along the back.

It has been observed that one might form Genera on some of the following characters:-on the comparative lengths and formation of the dorsal and anal fins: or whether the caudal is truncated, rounded, or forked: if the free portion of the tail is depressed: if a keel exists or is absent,

SYNOPSIS OF SPECIES.

1. Anterior dorsal rays elevated, forming a lobe.

a. Caudal forked.

1. Belone melanostigma, D. 24-26, A. 25-27. Length of head 4½ in the total. No teeth on vomer. From

one to seven dark blotches along the side. Red Sea, those of India to the Malay Archipelago.

2. Belone annulata, D. 22-24, A. 20-22. Length of head $3\frac{2}{3}$ in the total. Eyes $2\frac{1}{3}$ in postorbital length of the head. No vomerine teeth. Red Sea, those of India to the Malay Archipelago.

3. Belone choram, D. 22-23, A. 19-20. Length of head $3\frac{1}{3}$ to $3\frac{1}{3}$ in the total. No teeth on vomer. Eye equals half of postorbital length of the head. No vomerine teeth. Red Sea, those of India to the Malay Archipelago. pelago.

b. Caudal truncated or rounded.

4. Belone leiurus, D. 19, A. 22-24. Length of head about 3 in the total. No teeth on vomer. Seas of India to the Malay Archipelago.

5. Belone cancila, D. 15-18, A. 16-18. Length of head $2\frac{2}{3}$ to $2\frac{3}{4}$ in the total. No teeth on the vomer.

Fresh waters of Sind, India, Ceylon and Burma.

6. Belone strongylurus, D. 13-15, A. 16-18. Length of head $2\frac{2}{3}$ to 3 in the total. No teeth on the vomer. A black spot on the caudal fin. Seas and coasts of India to the Malay Archipelago and beyond.

1. Belone melanostigma.

B. xiii-xiv, D. 24-26, P. 14, V. 6, A. 25-27, C. 15.

Length of head 42, of caudal 11, height of body 14 in the total length. Eyes—diameter equals the width of the interorbital space, and 2/5 of that of the postorbital portion of the head. A wide median groove along the summit of the head: superciliary region slightly striated longitudinally. Maxillary nearly concealed by the preorbital. Tongue without asperities. Teeth—none on the vomer: those in the jaws strong. Fins—the anterior dorsal rays from the second to the fourth produced, rendering the fin falciform: the anal commences rather in advance of the dorsal, and is of the same shape: pectoral as long as the head behind the anterior nostril, and when laid forwards reaches the anterior edge of the orbit. Ventral fin situated midway between the posterior margin of the eye and the end of the base of the anal: caudal forked. Free portion of tail somewhat compressed. Lateral-line—not forming a keel. Scales—minute. Colours—pectoral nearly black externally: from one to seven large black blotches along the side, which appear to be occasionally absent in the females.

Habitat.—Red Sea to the Malay Archipelago. A fine specimen 35 inches long, captured off the coast, exists in the Madras Museum. I obtained, in Bombay, both in November and February, some fine female specimens full of roe, unfortunately I was unable to preserve them.

B. xii-xv, D. 22-24, P. 12-15, V. 6, A. 20-22, C. 15.

Length of head $3\frac{2}{3}$, of candal 9 to 10, height of body 13 to 20 in the total length. Width of body equals its height. Eyes—diameter 2½ in the postorbital length of the head, and 2/3 of a diameter apart. Interorbital groove broad and shallow, striated along its anterior portion. Base of premaxillaries depressed and almost concealing the maxilla. Teeth—strong, none on the vomer. Tongue covered with tubercular asperities. Fins—dorsal situated in the last third of the distance between the head and base of caudal fin, elevated in front, and its middle and last rays also rather elongated. Pectoral rather longer than the body is high. Ventral situated midway between the front edge of the eye and the base of the caudal. Anal commences very slightly in advance of the dorsal, and is of somewhat similar shape. Caudal lobed, lower lobe the longer. Scales-thin and small (350 rows, Blecker), some present on the preopercle. Free portion of the tail tetrahedral, rather higher than broad. Lateral-line-forming a badly developed keel on the side of the free portion of the tail. Colours—upper surface of the head and back green, with steel-blue reflections minutely dotted with black, fading into silvery-white on the abdomen. The side of the upper jaw of a dark olive, of the lower silvery. A black line passes from the upper third of the angle of the mouth along the base of the teeth. Cheeks and opercles silvery. Membranes of the dorsal, caudal, and pectoral fins of a light greenish-gray, minutely dotted with black, especially at their margins. Anal and ventral anteriorly white, dotted with black. Iris silvery, the margin of the orbit black. In young specimens the colours vary, the upper surface is more of a yellowish-green, there is a large black spot on the opercle, and the lower jaw is also black: a narrow silvery greenish band passes longitudinally above the lateral-line. The upper portion of the dorsal is black, and the centre of the caudal is stained blackish.

Russell's figure appears to represent either B. choram or B. annulata, both of which are found on the Coromandel coast of India. Bleeker considers it to be Belone or Mastacembelus melanotus, Bleeker.

Habitat.—Red Sea, seas and estuaries of India, Malay Archipelago, China, and North Australia. Grows to at least 2 feet in length.

B. x, D. 22-23, P. 14, V. 6, A. 19-20, C. 18.

Length of head $3\frac{1}{3}$ to $3\frac{1}{2}$, of caudal 9, height of body 12 to 14 in the total length. Eyes—diameter 2 in Length of head $3\frac{1}{3}$ to $3\frac{1}{2}$, of caudal 9, height of body 12 to 14 in the total length. Eyes—diameter 2 in the postorbital length of the head, and from $1\frac{1}{4}$ to $1\frac{1}{2}$ diameters apart. A wide shallow groove exists along the summit of the head, superciliary region striated, maxilla concealed by the preorbital. The height of the head equals half its length behind the front edge of the eyes. Teeth—none on the vomer. Fins—dorsal commences in the posterior 1/3 of the length of the body, its hind rays reach nearly or quite the base of the caudal. Pectoral as long as the head behind the middle of the eyes. Ventral inserted midway between the front edge of the eye and the base of the caudal fin. Anal of the same character as the dorsal. Caudal forked, lower lobe the longer. Free portion of tail nearly as wide as high. Scales—absent from the opercles, some on groove on head. 25 rows between the lateral-line and the base of the dorsal fin. Lateral-line—forming a narrow keel along the side of the free portion of the tail. Colours—bluish-green superiorly, becoming lighter below: a silvery stripe along the side: hower edge of dorsal and pectoral fins usually black. below: a silvery stripe along the side: upper edge of dorsal and pectoral fins usually black.

Habitat.—From the Red Sea and East coast of Africa, through the seas of India to the Malay Archi-

4. Belone leiurus.

B. x, D. 19, P. 11, V. 7, A. 22-24, C. 17.

Length of head 3 to $3\frac{1}{5}$, of caudal 15, height of body 14 in the total length. Eyes—3 diameters in the postorbital length of the head, $1\frac{1}{4}$ apart. A wide shallow groove on the head, broadest anteriorly. Superciliary and parietal regions striated. Teeth—vomerine ones absent: tongue smooth. Fins—ventral arises midway between the posterior margin of the preopercle and the base of the caudal fin: pectoral nearly as long as the postorbital portion of the head, and one-third longer than the body is high: dorsal commences considerably behind the anal, its anterior rays the highest: upper surface of the fin concave. Anterior anal rays the longest: fin inferiorly concave: its last ray, when laid flat, extends one-third of distance to the base of the caudal which is rounded. Scales—small over body and cheeks: 12 rows between the lateral-line and base of the dorsal fin. Free portion of tail compressed, higher than wide, without any distinct lateral keel. Colours—bluish-green, becoming light on the sides and beneath, with a silvery lateral band: the posterior half of the pectoral dark, as is also the lower half of the caudal fin.

Habitat.—Seas of India to the Malay Archipelago.

5. Belone cancila, Plate CXVIII, fig. 5.

Esox cancila, Ham. Buch. Fish. Ganges, pp. 213, 380, pl. 27, f. 70.

Belone Graii, Sykes, Trans. Zool. Soc. 1841, p. 367, t. 63, f. 4; Bleeker, Beng. p. 72; Jerdon, Madras J. L. and Sc. 1849, p. 345.

Belone cancila, Cuv. and Val. xviii, p. 455; Bleeker, Verh. Bat. Gen. xxv, p. 145; Day, Fish. Malabar, p. 166; Günther, Catal. vi, p. 253.

B. x, D. 15-18 $(\frac{2-3}{3-15})$, P. 11, V. 6, A. 16-18 $(\frac{2-3}{1-16})$, C. 15.

Length of head $2\frac{2}{3}$ to $2\frac{3}{4}$, of pectoral 12, of caudal 10, height of body 8 to 12 in the total length. Eyes— 3 to 3 diameters from the hind edge of the opercle, and 1 apart. A deep longitudinal groove along the upper surface of the head. Lower jaw the longer: the maxilla, which is partially concealed by the preorbital, reaches to beneath the first-third of the eye. Supraorbital margin smooth: preopercic rather broader than high. Teeth—a row of large, sharp, widely separated ones in both jaws, with an external row of numerous fine ones, none on the vomer. Fins—dorsal commences opposite the anal, and is rather more than, or else twice as far from the anterior extremity of the orbit as it is from the posterior extremity of the tail. Pectoral equals half the distance of the head behind the front edge of the eye. Ventral is inserted rather nearer the base of the caudal than the hind edge of the eye. Caudal slightly emarginate. The last dorsal and anal rays not elongated. Scales - small over the body and in irregular rows, some over front end of groove on head, also on sides of head except opercles. About 30 rows between the commencement of the dorsal fin and the lateral-line in Punjab, Assam, Burmese, and Orissa specimens, about 25 in those from lower Bengal, and 20 to 22 in those from Madras and the Malabar coast. Free portion of the tail compressed, higher than thick. Colours—greenishgray superiorly, becoming whitish along the abdomen: a silvery streak having a dark margin extends along the body from opposite the orbit to the centre of base of caudal fin. The whole upper two-thirds of the body is closely marked with fine black spots; while there are from 4 to 5 larger blotches along the side between the bases of the pectoral and anal fins, these are absent in the young. Dorsal and caudal posteriorly tipped darker: anal whitish with a grayish margin. Eyes golden.

There is a variety at Hurdwah and in the central Provinces, having a hump along the first part of its

back, sometimes continued as an elevated ridge as far as the origin of the dorsal fin.

Habitat.—Fresh waters of Sind, India, and Ceylon, also through Burma.* It attains at least 12 inches in length.

B. xii, D. 13-15, P. 11, V. 6, A. 16-18, C. 15.

Length of head 2\frac{2}{3} to 3, of caudal 10, height of body 13 to 14 in the total length. Eyes—diameter 3\frac{1}{3} in the postorbital length of the head, 1 to $1\frac{1}{4}$ apart. A shallow median groove along the head, the superciliary region scarcely striated. One-third of the maxillary concealed by the preorbital. Preopercle wide: opercle rounded posteriorly. Teeth—in the jaws widely separated, sharp, straight, not very large. Vomerine teeth absent. Fins—ventral arises midway between the orbit and the base of the caudal fin: anal in the last third of body, its first 4 rays in advance of the dorsal, which last is highest in front, with the upper margin concave, its posterior rays do not extend nearly to the root of the caudal fin: anal of the same shape. Pectoral nearly as long as the postorbital portion of the head. Caudal rounded. Scales - small, on the opercles and groove on the head: 11 transverse rows between the lateral-line and base of the anterior rays of the dorsal fin. line-double. The free portion of the tail compressed, much deeper than wide and without any distinct lateral keel. Colours-summit of head and back yellowish-green, with minute brown dots, fading into silvery on the sides, and white on the abdomen. Cheeks and opercles silvery. A deep blue longitudinal band, bordered beneath by another broader one of silver, passes along the posterior half of the sides. Dorsal with a little orange along its upper edge, it and sometimes the anal bright yellow, and the rays dotted with brown. Pectoral and ventral diaphanous, the latter occasionally with a black spot at the base. Caudal yellowish or greenish, minutely dotted with black, and having a round bluish-black spot in the centre near the root. Iris silvery: upper surface of eye bluish-black.

Dr. Günther considers that B. strongylurus "is very closely allied to B. caudimaculata, but has always

the head shorter and the eye comparatively smaller."

Hubitat.—Seas and coasts of India and Burma to the Malay Archipelago. Sometimes it is taken in estuaries and tidal rivers, it is not uncommon at Calcutta. It attains 2 feet or more in length.

Genus, 2—Hemirhamphus, + Cuv.

Hyporhamphus, Euleptorhamphus, Zenarchopterus, and Oxyporhamphus, Gill.: Dermatogenys (K. and v. Hass.), Peters: Hemirhamphodon, Bleeker: Arhamphus, Günther.

 ${\it Parl\,\, kollarchee},\, {
m Tamil}.$

Branchiostegals rather numerous. Gill-openings wide. Body sub-cylindrical and elongated. Eyes lateral. Upper jaw, which is formed by the premaxillaries, is short and more or less triangular in form: whilst the lower jaw, in the mature, is elongated far beyond the upper. A nasal barbel usually present. Teeth villiform in both jaws. The number of dorsal and anal rays may be about equal, or either may be in excess of the other. The dorsal fin may commence anterior to, above, or behind the origin of the anal: no finlets posterior to the dorsal fin. Pectoral may or may not be prolonged: caudal mostly forked or emarginate, sometimes rounded. Scales of moderate, or large, size: uir-vessel large, occasionally cellular. Dorsal and anal rays may be modified. Some species are viviparous. No pyloric appendages.

During the cold season of the year the roes of these fishes are largely collected on the Malabar coast of India, where they are esteemed a great delicacy.

* It has been brought from Ta young by Dr. J. Anderson.

† The Hemirhamphine have been thus sub-divided (see Bleeker's Atlas, vi, p. 51.)

I.—The portion of the lower jaw (beak) anterior to the conjoined premaxillaries, smooth and edentulous.

Beak rudimentary, not longer than the upper jaw. Caudal lobed, as Oxyporhamphus=Arrhamphus.

Beak much longer than the upper jaw. The dorsal fin commencing above or anterior to the anal. as 1. Hemirhamphus=Hyporhamphus. Body moderately clongate. Teeth in the jaws tricuspidate or conical. Caudal bilobed. 2. Euleptorhamphus. Body very clongate. Teeth in premaxillaries simple: tricuspidate in the lower jaw. Dorsal commencing above or anterior to the anal. Caudal bilobed. 3. Zenarchopterus. Body moderately clongate. Conical teeth in the jaws. Dorsal commencing above or anterior to the anal. Caudal not emarginate. The males may have one or more dorsal, or anal rays modified 4. Dermogenys. Body moderately clongate. Dorsal considerably shorter, and commencing far behind the origin of the anal. Caudal rounded. Teeth conical.

II.—The portion of the lower jaw (beak) anterior to the conjoined premaxillaries, toothed.

6. Hemirham phodon. Body moderately clongated. Dorsal fin commencing far before the anal, and twice as long as it. Caudal rounded. Teeth conical.

In counting the scales of species of Hemirhamphi and Exoceti, those which exist in a straight line between the head and base of the caudal fin are enumerated and not those along the lateral-line, consequently the letters L. r. or lateral rows are employed. Deformed specimens are frequently met with in which the beak has been injured. Bleeker observes, "the length of the lower jaw in the *Hemirhamphi* often varies considerably in the same species." It has yet to be proved whether the teeth in some species may not vary with age.

SYNOPSIS OF SPECIES.

A.—Pectorals long.

1. Hemirhamphus longirostris, D. 21-22, A. 18-20. A silvery band. Coromandel coast of India.

B.—Pectorals short.

2. Hemirhamphus leucopterus, D. 18 (16), A. 15 (14). Beak 41 in the total length. Ventral in last

third of distance between eye and base of caudal fin. No scales on dorsal or anal fins. Bombay.

3. Hemirhamphus Cantori, D. 15-16, A. 15, L. r. 62. Beak 33 in the total. Ventral fin inserted in the commencement of the last third of the distance between the front edge of the premaxillaries and base of

caudal fin. Some scales on anal fin. Seas of India to the Malay Archipelago and China.

4. Hemirhamphus xanthopterus, D. 14-15, A. 16-17, L. r. 56-58. Beak red tipped and 7 to 7½ in the total length. Ventrals inserted midway between hind edge of eye and base of caudal fin. Very few, if any, scales on dorsal or anal fins. Malabar coast of India.

5. Hemirhamphus unifasciatus, D. 15-16, A. 15-17, L. r. 52-58. Beak 63 in the total length. Ventral inserted midway between front edge of eye and base of caudal fin. Seas of India to the Malay Archipelago and beyond.

6. Hemirhamphus Reynaldi, D. 14-15, A. 14-15, L. r. 52-54. Beak $6\frac{1}{3}$ in the total length. Eye equal to length of postorbital portion of the head. Ventral inserted rather nearer base of caudal than that of pectoral. East coast of Africa, seas of India to the Malay Archipelago.

7. Hemirhamphus Georgii, D. 14-15, A. 13-14, L. r. 58. Beak $4\frac{2}{3}$ to $4\frac{3}{4}$ in the total length. Ventral inserted in last third of distance between angle of mouth and base of caudal fin. No scales on dorsal or anal

Seas of India to the Malay Archipelago.

8. Hemirhamphus far, D. 13-14, A. 10-12, L. r. 50-54. Beak 5 to 55 in the total length. Ventral inserted in last third of the distance between the middle of the eye and base of the caudal fin. A few scales on dorsal and anal fins. Four dark vertical blotches along the side. Red Sea, East coast of Africa, seas of India to the Malay Archipelago and beyond.

9. Hemirhamphus limbatus, D. 13-14, A. 13-15, L. r. 50-52. Beak $6\frac{1}{3}$ to $6\frac{1}{2}$ in the total. Ventral inserted

midway between eye and base of caudal. Seas of India to Burma.

10. Hemirhamphus Buffonis, D. 14, A. 10-12, L. r. 42. Beak 3 to 3 in the total length. Some of the vertical rays modified. Ventral inserted in the last third of the distance between the eye and base of the

caudal fin, which is rounded. Seas of India to the Malay Archipelago.

11. Hemirhamphus ectunctio, D. 13-14, A. 10-12, L. r. 46-48. Beak 5½ in the total length. Ventral inserted in last third of distance between eye and base of the caudal fin, which latter is rounded. End of

upper jaw white. From the Hooghly to the Malay Archipelago.

12. Hemirhamphus dispar, D. 11-12, A. 11-12, L. r. 40. Beak 4½ in the total. Ventral inserted in the last third of the distance between the end of the upper jaw and base of caudal fin, which latter is rounded. Some of the anal rays modified. Seas of India to the Malay Archipelago.

13. Hemirhamphus brachynopterus, D. 9, A. 15. Beak 43 in the total. Caudal rounded. Hooghly.

1. Hemirhamphus longirostris.

Esox, Russell, Fish. Vizag. ii, p. 62, and Kuddera, C, plate 178. Hemirhamphus longirostris, Cuv. Reg. Anim.; Cuv. and Val. xix, p. 52; Günther, Catal. vi, p. 276. D. 21-22, P. 8, V. 6, A. 18-20, C. 26.

Length of head 3, of beak $4\frac{1}{2}$, of caudal $10\frac{1}{2}$, height of body 18 in the total length. Eyes—diameter $1\frac{1}{3}$ in the postorbital length of the head, and nearly 1 apart. Body narrow and compressed. Preorbital rather longer than high. Upper jaw convex in both directions and 1/4 wider at its base than it is long. Teeth—small, and numerous. Fins*—dorsal, anteriorly much elevated, it commences somewhat anterior to the origin of the anal. Pectoral $3\frac{2}{3}$ in the length of the body, its upper ray broad and compressed. Ventrals very small, 1/6 the length of the pectoral. Caudal deeply forked, lower lobe the longer. Colours—a silvery lateral band, the fins with dark outer margins.

Habitat.—Coromandel coast of India. It attains to at least 10.5 inches in length.

* In the type specimen at Paris the fins are now much injured, whilst the scales cannot be counted. In Russell's figure the ventrals are shown as inserted midway between the bases of the pectoral and caudal fins.

Digitized by GOO

2. Hemirhamphus leucopterus.

Cuvier and Valenciennes, xix, p. 48.

D. 18 (16), P. 11, V. 6, A. 15 (14), C. 14.

Length of head $2\frac{1}{2}$, of beak $4\frac{1}{2}$, of candal 9, height of body 12 in the total length. Eyes—diameter $1\frac{1}{3}$ in the postorbital length of the head, $1\frac{1}{4}$ diameters apart. Preorbital longer than high. Upper jaw slightly wider at its base than it is long, keeled, not scaled: no barbels. Fins—anal commences under the third dorsal ray. Ventral inserted in the commencement of the last third of the distance between the eye and base of the caudal fin. Lower lobe of caudal the longer, the central rays twice as long as the eye. Scales—none on dorsal or anal fins. Colours—a silvery lateral band: fins colourless: beak black.

Dussumier's specimen from which the foregoing description of *H. leucopterus* is drawn up, is not in a good state, some of the rays are broken and it is partly denuded of scales. It was said to be distinguished from *H. zanthopterus* by a much narrower head, a more slender and longer beak, and lower dorsal and anal fins.

Habitat. - Bombay.

B. xiv, D. 15-16, P. 10-12, V. 6, A. 15, C. 16, L. r. 62.

Length of head $2\frac{1}{3}$, of beak $3\frac{2}{3}$, of caudal 7, height of body 12 to 13 in the total length. Eyes—diameter $1\frac{2}{3}$ in the postorbital length of the head and $1\frac{1}{3}$ apart. Body compressed. Upper jaw pointed, 1/3 longer than wide and rather convex. Height of head equals its length behind the front 1/3 of the eye, and exceeds its width: no barbels. Teeth—one or two rows of (comparatively large) tricuspid ones in both jaws. Fins—dorsal fin commences anterior to the anal, its last rays when laid flat reach the base of the caudal. Pectoral rather longer than the head behind the front edge of the eye. Ventral inserted in the commencement of the last third of the distance between the front end or middle of the premaxillaries and the base of the caudal fin, which latter is forked, its lower lobe the longer, the central caudal rays equal the postorbital length of the head. Scales—none on dorsal fin but some on the anal: 6 rows between the lateral-line and base of dorsal fin. Colours—greenish-blue superiorly, having a burnished silvery stripe along the sides, which posteriorly is broader than a scale.

This is perhaps H. Russelli, C. V., which has D. 17, the beak flattened and nearly 1/4 of the total length.

Cantor's species has the beak 1/6 of the total length, and cannot be the same as C. V.'s fish.

H. Georgii, Cantor, Catal. p. 248; Bleeker, Scomb. p. 45; Günther, Catal. vi, p. 264, differs in the anal fin being scaleless, but the specimens are young and in a bad state of preservation.

Habitat.—Bombay, Malabar, Madras and seas of India to the Malay Archipelago and China.

4. Hemirhamphus xanthopterus, Plate CXIX, fig. 2.

Cuv. and Val. xix, p. 47; Day, Fishes of Malabar, p. 168.

B. xii, D. 14-15, P. 13, V. 6, A. 16-17, C. 15, L. r. 56-58.

Length of head $3\frac{1}{2}$ to $3\frac{1}{3}$, of beak 7 to $7\frac{1}{2}$, of caudal $7\frac{1}{4}$, height of body 12 in the total length. Eyes—diameter $1\frac{1}{3}$ in the postorbital length of the head, and 3/4 to 1 diameter apart. Preorbital rather longer than high. Upper jaw rather longer than wide at its base. No barbels. Teeth—many rows of minute tricuspidate ones in both jaws. Fins—anal commences opposite the dorsal, the anterior portion of both rather elevated. Pectoral reaches the middle of the eyes. Ventral inserted midway between the hind edge of the eye and the base of the caudal. Lower caudal lobe the longer, its central rays as long as the postorbital portion of the head. Scales—with some circular lines on each parallel with the outer margin, so that the edges appear rather raised; none on dorsal or anal fins, or a few very fine ones on their anterior portion: 7 rows between lateral-line and base of dorsal fin. Colours—a brilliant lateral band 2/3 as wide as a scale in its widest part. End of beak coral red.

This fish is very similar to H. Gamaidi, but has a longer triangular upper jaw and more scales. H. Reynaldi has its ventral in a different situation. H. unifasciatus has its dorsal and anal fins scaled.

Habitat.-Malabar coast of India.

5. Hemirhamphus unifasciatus.

Ranzani, Nov. Comm. Acad. Sc. Inst. Bonon. v, 1842, p. 326, t. 25; Günther, Catal. vi, p. 262; Bleeker, Atl. Ich. vi, p. 59.

Hemirhamphus Richardi, Cuv. and Val. xix, p. 26.

Hemirhamphus tricuspidatus, Gill, Proc. Acad. Nat. Sc. Phil. 1859, p. 131. Hemirhamphus neglectus, Bleeker, Nat. Tyds. Dierk. iii, p. 157, and Atl. Ich. Scomb. t. viii, fig. 5. B. x, D. 15-16, P. 12, V. 6, A. 15-17, C. 16, L. 1. 52-58.

Length of head $3\frac{1}{4}$, of beak $6\frac{3}{4}$, of caudal $7\frac{1}{2}$, height of body $11\frac{1}{2}$ in the total length. Eyes—diameter 1½ in the postorbital length of the head, and $1\frac{1}{4}$ apart. The height of the head equals its length behind the middle of the eyes. Teeth—many fine ones in both jaws. Fins—pectoral when laid forwards reaches the front edge of the eye. Dorsal commences in the last fourth of the distance between the angle of the mouth and base of the caudal fin. Ventral inserted midway between the base of the caudal fin and the front edge of the eye. Caudal forked, lower lobe the longer, the length of the central rays $1\frac{1}{3}$ diameters of the eye. Scalespresent on dorsal and anal fins: $5\frac{1}{2}$ to 6 rows between the base of the dorsal fin and the lateral-line. Colours bluish, with a rather narrow silvery band.

Habitat.—Malabar, Andamans, to the Malay Archipelago and beyond.

6. Hemirhamphus Reynaldi.

Cuv. and Val. xix, p. 39; Day, Fish. Malabar, p. 167.

Hemirhamphus Dussumieri, (not Cuv. and Val. xix, p. 33) Bleeker, Snoek, p. 18, Revis. Hemirh. p. 150, and Atl. Ich. vi, p. 56, Scomb. t. vii, f. 3; Günther, Catal. vi, p. 266; Kner, Novara Fische, p. 322.

B. xiii-xiv, D. 14-15 (16), P. 11, V. 6, A. 14-15 (17), C. 15, L. r. 52-54.

Length of head $3\frac{1}{3}$, of beak $6\frac{1}{3}$, of caudal $6\frac{1}{3}$, height of body 11 to 13 in the total length. Eyesdiameter equals the postorbital length of the head, and also the width of the interorbital space. Preorbital rather longer than high. Upper jaw keeled, scaled, rather broader at its base than it is long. No barbels. rather longer than high. Upper jaw keeled, scaled, rather broader at its base than it is long. Body nearly as wide as high. Teeth—numerous fine rows of tricuspid ones in the jaws. Fins—anal commences below the third or fourth dorsal ray. Pectoral reaches as far forwards as the middle or front margin of the eye. Ventral commences rather nearer the base of the caudal than that of the pectoral, or else midway. Caudal deeply forked, lower lobe the longer, its central rays as long as the eye. Scales—none on dorsal or anal fins.

Colours—a silvery lateral band: upper edge of dorsal blackish.

The type of II. Reynaldi, C. V. brought by Reynald from Trincomalce is still in Paris, and it seems to be this species. H. Dussumieri, Bleeker and Günther, appears to have the eye too large, whilst the beak

scarcely agrees with C. V. description.

Klunzinger, Fische d. R. M. Verh. z. b. Ges. Wien, 1871, p. 584, describes another species as H. Dussumieri, C. V., D. 14-15, A. 14-15, L. l. 52-54. Length of head 3, height of body (10½) 14, of beak 5, of caudal fin 8 in the total length. $Eyes-7\frac{1}{2}$ in length of head, and $1\frac{2}{3}$ in postorbital length. Body quadrilateral or rather higher than broad. Teeth—tricuspid. Pectoral twice as long as ventral, but does not quite equal height of body. Ventral inserted between base or last third or fourth of pectoral and base of caudal. Lower caudal lobe somewhat the longer, its middle rays shorter than the eye. Scales—sometimes numerous on dorsal and anal fins.

Habitat.—East coast of Africa, Seas of India to the Malay Archipelago.

7. Hemirhamphus Georgii, Plate CXX, fig. 2.

Cuv. and Val. xix, p. 37, pl. 555 (not Cantor, Catal. p. 248: Jerdon, M. J. L. and Sc. 1851, p. 147; Günther, Catal. vi, p. 264; Bleeker, Atl. Ich. vi, p. 54; Kner, Novara Fische, p. 323).

Hemirhamphus marginatus, Bleeker, Ned. Tyds. Dierk. iii, p. 148, and Atl. Ich. vi, p. 54, Scom. t. viii, f. 4; Günther, Catal. vi, p. 470 (? Esox marginatus, Forsk. &c.)

Hemirhamphus plumatus, Blyth. Proc. As. Soc. of Bengal, 1858, p. 288.

B. xii, D. 14-15 (16-17), P. 11, V. 6, A. 13-14, C. 16, L. l. 54-58.

Length of head $2\frac{3}{4}$, of beak $4\frac{2}{3}$ to 5, of caudal $7\frac{1}{8}$ to 8, height of body 10 to 13 in the total length. Eyes—diameter $1\frac{1}{2}$ to $1\frac{2}{3}$ in the postorbital length of the head, $1\frac{1}{4}$ diameters apart. The height of the head equals its length behind the middle of the eyes. Upper jaw about equalling one diameter of the eye in length, rather pointed and a little longer than wide at its base, convex, scarcely keeled and not scaled. Preorbital slightly longer than high. Teeth—in few rows in both jaws, most are pointed, but there are a few tricuspidate ones intermixed. Fins—dorsal commences in the last fourth of the distance between the front edge of the eye and the base of the caudal fin and a little anterior to the anal. Pectoral reaches the middle of the eye. Ventral inserted in the commencement of the last third of the distance between the angle of the mouth and the base of the caudal fin. Length of base of anal 2/3 that of the dorsal. Caudal deeply forked, its central rays as long as about one diameter of the eye. Scales—none on dorsal or anal fins: 5 rows between lateral-line and base of dorsal fin. Colours—a broad silvery stripe which below the dorsal fin is rather wider than a scale. Fringe on lower jaw black.

The artist has shown the depth of the body as too great in Plate exx, f. 2.

Dussumier's specimen of H. Georgii, from Mahé, 111 inches long, is still preserved at Paris: it has D. 15, A. 14, L. r. 58. M. Leschenault's specimen of H. brevirostris, C. V. at Paris, is in a bad state. Length of head 3, of beak $4\frac{1}{4}$, of caudal $10\frac{1}{2}$, height of body 18 in the total length. Eyes—diameter $1\frac{1}{3}$ in the postorbital length of the head, and nearly 1 apart. Preorbital rather longer than high. Upper jaw convex in both directions, 1/4 wider at its base than it is long. Fins—anal commences slightly behind the dorsal.

Klunzinger observes that H. marginatus. Forsk., has D. 13, A. 12, length of head 3, beak 5 in the total length: and fine deciduous scales on the dorsal and anal fins and is the same as Russell's figure. Habitat.—Seas of India to the Malay Archipelago.

8. Hemirhamphus far, Plate CXX, fig. 3.

Esox far, Forsk. Descrip. Anim. No. 98.

Esox marginatus, var. Bl. Schn. p. 393. Hemirhamphus far, Rüpp. N. W. Fische, p. 74; Peters, Monats. Berlin Acad. 1855, p. 428; Bleeker, en Pisc. p. 157, Revis. Hemir. p. 146, and Atl. Ich. vi, p. 54; Klunz. Verh. z. b. Ges. Wien, 1871, p. 582.

Hemirhamphus Commersonii, Cuv. Rég. Anim.; Cuv. and Val. xix, p. 28; Blecker, Snock, p. 17, and Atl. Ich. Scomb. t. vi, fig. 3; Günther, Catal. vi, p. 271.

B. xii-xiv, D. 13-14, P. 12, V. 6, A. 10-12, C. 15, L. l. 50-54, Vert. 38/16.

Length of head 24 to 3, of beak 5 to 55, of caudal 51 to 6, height of body 81 to 12 in the total length. Eyes—diameter $1\frac{1}{2}$ in the postorbital length of the head, and 1 apart. Greatest width of body 1/2 to 2/3 of its height. Triangular portion of upper jaw much wider than long. Teeth—small, tricuspidate. Fins—dorsal commences considerably in advance of the anal. Pectoral reaches the front edge of the eye. Ventral inserted in the last third of the distance between the middle of the eye and the base of the caudal fin. as long as dorsal. Caudal deeply forked, lower lobe the longer, central rays equal to about 1 diameter of the eye. Scales—a few on the front portion of the dorsal and anal fins. Colours—back dark bluish-green: a silvery

lateral band, and four dark blotches or spots along the sides. Air-vessel—cellular.

Habitat.—Red Sea and East coast of Africa, through the seas of India to the Malay Archipelago and beyond. The specimen figured was from Madras. It is said to attain 15 inches in length.

9. Hemirhamphus limbatus, Plate CXIX, fig. 3.

Esox angulatus, Ham. Buch. MSS. c. fig.

Hemirhamphus limbatus, Cuv. and Val. xix, p. 44; Günther, Catal. vi, p. 272. Hemirhamphus brachynopterus, Blyth, P. A. S. of Beng. 1858, p. 288 (not Bleeker).

Gongaturi, Ooriah.

B. x, D. 13-14, P. 10, V. 6, A. 13-15, C. 14, L. r. 50-52.

Length of head 3_6^1 to 3_4^1 , of beak 6_3^1 to 6_2^1 , of candal 7, height of body 9 to 10 in the total length. Eyes—diameter 1_3^1 to 1_3^2 in the postorbital portion of the head, nearly 1 diameter apart. Preorbital 3/4 as long as the eye, and longer than high. Width of body 2/3 of its height. The height of the body equals its length behind the middle of the eyes, and its width equals its postorbital length. Upper jaw short, 1/2 wider at its base than it is long, and keeled along the mesial line. Teeth—minute, in many rows in both jaws and tricuspidate. Fins-dorsal commences very slightly in advance of the anal, both fins having their outer edges concave. Pectoral reaches forward to the front edge of the eyes. Ventral inserted about midway between the eye (sometimes rather nearer the candal) and base of caudal. Base of anal slightly shorter than that of the dorsal. Caudal lobed, the lower the longer, the central rays equalling 1½ diameters of the orbit in length. Scales—5 rows between the base of the dorsal and the lateral-line. None on dorsal or anal fins, unless a few fine ones over their first portions. Colours—a brilliant silvery lateral band, which posteriorly becomes as broad as one scale. Dorsal, anal, and extremity of caudal sometimes stained blackish.

The foregoing is identical with the specimen of H. limbatus, Cuv. and Val. (6 inches long) brought from Pondicherry by M. Leschenault, and still in the Museum at the Jardin des Plantes at Paris. Cantor's specimens

of H. tridentifer are skins* in a very bad state, and probably H. Gamaidi, C. V.

Habitat.—This is by far the most common species off the Coromandel coast of India, and extends to Burma: it is also found, but more rarely, on the Malabar coast. It ascends tidal rivers, and may be captured in fresh waters.

10. Hemirhamphus Buffonis, Plate CXIX, fig. 4.

Cuv. and Val. xix, p. 48; Bleeker, Nat. Tyds. Ned. Ind. iii, p. 711; Günther, Catal. vi, p. 273. Hemirhamphus striga, Blyth, Pro. Asiatic Soc. of Beng. 1858, p. 288, (not C. V.) Zenarchopterus Buffoni, Blecker, Revis. Hemir. p. 162, Atl. Ich. vi, p. 62, and Scomb. t. vii, f. 4.

Hemirhamphus cirrhatus, Day, Proc. Zool. Soc. 1873, p. 709.

Koo-door-rock-o-dah, Andamanese.

B. xi, D. 14, P. 10, V. 6, A. 10-12, C. 13, L. r. 42.

Length of head $2\frac{1}{9}$ to $2\frac{1}{2}$, of caudal 9, of beak $3\frac{1}{9}$ to $3\frac{1}{2}$, height of body $8\frac{1}{2}$ to 9 in the total length. Eyes—diameter $1\frac{1}{2}$ in the postorbital extent of the head, $1\frac{1}{4}$ apart. Upper jaw 1/4 wider at its base than it is

* Cantor's types (skins) are as follows:—No. 1, Length to base of tail 4.8 inches, of base of dorsal fin 0.5½ inches, beak 6½ in the total length. No. 2, 5.8 inches to base of tail, of base of dorsal fin 0.7½ inches, beak 6½ in the total

Günther's specimen in spirit is 5.8 inches to base of tail, of base of dorsal fin 0.74, of base of anal 0.7 inches.

long. A barbel at the posterior nostril 1/2 the length of the eye. Teeth—conical in both jaws. Fins—dorsal with a rather oblique upper edge. Pectoral, if turned forwards, reaches the middle or the front edge of the eye. Ventral small, inserted in the commencement of the last third of the distance between the eye and base of the caudal fin. Anal commences under the third or fourth dorsal ray, and the length of its base is from 1/2 to 1/3 as long, some of its rays are sometimes thickened. Caudal rounded, its lower rays very slightly produced. Scales—on upper jaw, none on the vertical fins. Colours—a narrow silvery streak along the side which below the base of the dorsal fin becomes nearly one-third as wide as a scale is deep: upper half of dorsal black.

Habitat.—Bombay, Hooghly, Andamans, waters of the Malay Archipelago and perhaps China.

ascends tidal rivers for some distance. It attains at least 8 inches in length.

11. Hemirhamphus ectunctio, Plate CXIX, fig. 6.

Esox ectuactio, Ham. Buch. Fish. Ganges, pp. 212, 380.

Hemirhamphus amblyurus, Bleeker, Snoek. p. 16; Günther, Catal. vi, p. 273. Hemirhamphus Borneensis, Bleeker, l. c. p. 25.

Hemirhamphus ectuactio, Bleeker, Beng. p. 14; Blyth, Pro. Asi. Soc. of Beng. 1858, p. 287. Hemirhamphus Bleekeri, Kner, Sitz. Akad. Wiss. Wien. 1860, p. 539, f. 4 (male.)

Hemirhamphus neglectus, Day, Proc. Zool. Soc. 1869, p. 526.

Zenarchopterus amblyurus, Bleeker, Ned. Tyds. Dierk. iii, p. 160, and Atl. Ich. vi, p. 61, Scom. t. iv, f. 1.

Nga-phoung-yo, Burmese.

B. x, D. 13-14, P. 9, V. 6, A. 10-12, C. 15, L. l. 46-48.

Length of head $2\frac{1}{2}$ to $2\frac{3}{4}$, of beak $5\frac{1}{2}$, of caudal 8 to 9, height of body 11 in the total length. Eyes— $2\frac{1}{4}$ to $2\frac{1}{2}$ diameters in the postorbital length of the head, and $1\frac{1}{4}$ apart. Head and body compressed: height of head equals its postorbital length. Upper jaw twice as long as broad at its base. Upper surface of the head flat. A short barbel, which is sometimes absent, at the nostril. Teeth—in jaws fine and conical. Fins the dorsal commences somewhat anterior to the anal. Pectoral if laid forwards reaches the hind edge of the Ventral inserted in the commencement of the last third of the distance between the eye and base of the caudal fin: it reaches 1/2 way to the anal. Anal rays thickened in the male. Caudal rounded. Scales—on upper jaw, none on vertical fins. Colours—of a dull greenish brown, with a narrow and indistinct lateral band: end of upper jaw milk white.

It is curious to observe these fish in tidal rivers, they swim near the surface, with their milk-white

upper jaw generally visible.

Habitat.—Hooghly, tidal stream at Akyab, Burma, Siam, and to the Malay Archipelago. It attains at least 6 inches in length.

12. Hemirhamphus dispar, Plate CXIX, fig. 5.

Cuv. and Val. xix, p. 58, p. 558; Bleeker, Nat. Tyds. Ned. Ind. vi, p. 498; Günther, Catal. vi, p. 274; Peters, A. Ak. Berl. 1871, p. 32

Zenarchopterus dispar, Gill, Pro. Acad. Nat. Sc. Phil. 1863, p. 273; Bleeker, Revis. Hemir. p. 164, Atl. Ich. vi, p. 63, and Scomb. t. vii, f. 4.

B. x-xi, D. 11-12, P. 10, V. 6, A. 11-12, C. 15, L. 1. 40.

Length of entire head $2\frac{1}{3}$ to $2\frac{1}{2}$, of beak $4\frac{1}{4}$, of caudal 9, height of body 11 in the total length. Eyes—diameter $1\frac{1}{3}$ in the postorbital length of the head, and $1\frac{2}{3}$ apart. Upper jaw as broad at its base as it is long. A nasal barbel 2/3 as long as the eye. Fins—dorsal commences about 3 rays anterior to the origin of the anal, one of its rays may be modified. Pectoral as long as the head behind the front edge of the eye. Ventral inserted in the commencement of the last third of the distance between the end of the upper jaw and the base of the caudal fin. Anal with some of its rays, especially the sixth and sometimes the seventh, much thickened and elongated. Caudal cut square or slightly rounded. Scales—none on dorsal or anal fins: present on upper jaw. Colours—a silvery band along the side.

Habitat.—Seas of India to the Malay Archipelago and beyond. Common at the Andamans in protected

bays.

13. Hemirhamphus brachynopterus.

Bleeker, Beng. en Hind. p. 146; Günther, Catal. vi, p. 275.

Length of head $3\frac{1}{4}$, of beak $4\frac{9}{3}$, of caudal 8, height of body 12 in the length of the body. Eyes— 2 diameters in the postorbital length of the head, rather above 1 apart. Body elongated and compressed, a little higher than wide. Upper jaw rather wider than long, its length not equalling one diameter of the orbit. Upper surface of head flat. Fins—first ray of the dorsal over the fifth of the anal, length of the base of the anal not quite twice as long as that of the dorsal. Anal not lower than the body, its inferior edge concave. Caudal rounded.

. Habitat.—River Hooghly, from whence Dr. Bleeker received a single small specimen, which unfortunately is now in such a bad state that I cannot add anything to the above description.

Genus, 3-Exocetus, Artedi.

Cypsilurus, Swains.: Halocypselus, Weinland.: Parexocotus, Bleeker.

Body moderately oblong. Gill-openings very wide. Jaws short: the premaxillaries and maxillaries separate. Mandible in some species with a tubercular prolongation. Barbels present or absent. Teeth, when present, minute and rudimentary. Pectorals elongated, used as an organ for flying: the dorsal fin may be much or only moderately elevated: ventrals long, short, or of moderate length. Air-vessel large. Pyloric appendages absent.

Genus Parexocatus, Bleeker, was instituted for the reception of those species (as E. mento, C.V.) which have no barbels, but the lower jaw with a short tubercular prolongation as if an indication of an aborted attempt at the elongation seen in Hemirhamphi. Teeth in both jaws, vomer, palatines, tongue and pterygoids.

As many species of flying-fish are only known from young specimens, the size of the eye, and the length of the fins as given in descriptions must be accepted with a reservation, in fact it is necessary that the length of the specimen should be recorded. Barbels in some species may be an indication that the fish is immature, so may likewise vertical bands* on the body.

Geographical distribution.—Seas of temperate and tropical regions.

SYNOPSIS OF SPECIES.

1. Exocatus micropterus, D. 15-16, A. 14-15, L. 1. 50. A pair of barbels. Vertical fins low. Ventral midway between bases of pectoral and caudal fins. Malabar to the Malay Archipelago.

2. Exocatus pacilopterus, D. 12-14, A. 9-10, L. 1. 54. Pectoral reaching base of caudal. Ventral long, it arises between head and base of caudal. Pectoral with black blotches. Seas of India to the Malay Archipelago. pelago.

3. Exocortus evolans, D. 12-14, A. 13-15, L. l. 40-42. Pectoral reaches the base of the caudal. Ventral short, inserted nearer snout than base of the caudal. Tropical and intra-tropical seas.

4. Exocortus furcatus, D. 13, A. 9-10. A pair of barbels at symphysis. Ventral inserted nearer caudal than front end of snout. Indian and Atlantic Oceans.

5. Exocatus Bahiensis, D. 12-13, A. 9-10, L. l. 50. Ventral inserted midway between snout and posterior

end of upper caudal lobe. Red Sea to the Malay Archipelago and beyond.

6. Exocortus mento, D. 10-11, A. 10-11, L. 1. 44. Lower jaw slightly produced at the symphysis. Ventral inserted midway between the front edge of eye and base of caudal fin. East coast of Africa, seas of India to the Malay Archipelago.

1. Exocœtus micropterus.

Cuv. and Val. xix, p. 127, pl. 563; Bleeker, Amb. p. 63, and Atl. Ich. vi, p. 77; Günther, Catal. vi, p. 279.

Cypsiluri micropteri, Bleeker, Exocot. p.128, and Atl. Ich. vi, Scomb. t. iii, f. 1.

B. xiii, D. 15-16, P. 11-12, V. 6, A. 14-15, C. 15, L. 1. 50.

Length of head $5\frac{1}{3}$, of caudal 5, height of body $7\frac{1}{4}$ in the total length. Eyes—diameter $3\frac{2}{3}$ in the length of the head, nearly 1 diameter from the end of snout. A pair of short barbels under the symphysis of the lower jaw, which is prominent. Fins—the dorsal commences a little anterior to the anal, and in the last fourth of the body, its rays are not prolonged, the highest scarcely exceeding 13 diameters of the orbit: upper edge of the fin rather convex. Pectoral not reaching so far as to the ventral, the latter, which is inserted midway between the base of the pectoral and caudal, not extending to the anal. Anal of the same shape as the dorsal. Lower caudal lobe the longer. Colours—bluish above: silvery on the sides and beneath: fins dark.

Habitat.—Malabar to the Malay Archipelago.

2. Exocœtus pœcilopterus, Plate CXX, fig. 4.

Cuv. and Val. xix, p. 112, p. 561; Günther, Catal. vi, p. 291; Bleeker, Atl. Ich. vi, p. 74, and Scomb. t. v, f. 5.

Parravay-kolah, Tamil.

D. 12-14, P. 14, V. 6, A. 9-10, C. 15, L. 1. 54.

Length of head 5 to $5\frac{1}{3}$, of caudal $4\frac{3}{4}$ to $5\frac{1}{3}$, height of body $6\frac{1}{2}$ in the total length. Eyes—diameter $2\frac{3}{4}$ to 3 in the length of head, $\frac{1}{2}$ a diameter from end of snout, and 1 apart. The greatest height of the head equals its length excluding the snout, upper surface of the head roughened. Lower jaw the longer. Barbels—absent. Fins—dorsal commences some way in front of the anal, the height of its anterior rays 1/10 of the total length, the distance between the first dorsal ray and the base of caudal fin rather exceeds the length of the head, 30-32 scales between occiput and origin of the dorsal fin: ventral arises somewhat nearer the base of the caudal than

* Vertical bands in Hemirhamphi, and many of the Scombresocidæ, &c., are usually a sign that the species is immature.

to the hind edge of the head, and reaches to the end of the base of the root of the anal: the pectoral reaches as far as the end of the dorsal. Scales—7 rows between the base of the dorsal fin and the lateral-line. Colours bluish along the back, becoming silvery on the sides and beneath. Pectoral with many rounded and oval spots, sometimes transversely arranged in bands, in others irregularly placed. Out of 3 specimens up to 13 inches in length, taken together at Madras, two had black spots upon the dorsal fin: ventral white or with spots.

Habitat.—Seas of India to the Malay Archipelago. The specimen figured (2/3 life-size) was from

Madras.

3. Exocœtus evolans, Plate CXX, fig. 5.

Lin. Syst. Nat. i, p. 521; Linn. Gmel. p. 1400; Bloch, t. 398; Bl. Schn. p. 430, t. 84; Cuv. and Val. xix, p. 138; Gronov. ed. Gray, p. 145; Bleeker, Cape of Good Hope, p. 76, and Atl. Ich. vi, p. 69; Yarrell, Brit. Fishes, 3rd Ed. i, p. 474; Günther, Catal. vi, p. 282; Kner, Novara Fische, p. 326.

Exocatus volitans, Lacépède, v, p. 401, t. xii, f. 2; Pennant, Brit. Zool. p. 441, t. 78; Donov. Brit. Fish.

ii, p. 31; Brown, Phil. Trans. lxviii, p. 790, pl. 12; Yarrell, Brit. Fish. 2nd Ed. i, p. 453; Benn. Whaling

Voyage, ii, p. 284.

Exocætus splendens, Clarck, Abel, Journ. China, 1818, p. 4 (apud Günther).

Exocætus volans, (Solander), Richardson, Ich. China, p. 264.

D. 12-14, P. 14, V. 6, A. 13-15, C. 17, L. 1. 40-42, Vert. 25/19.

Length of head 5, of caudal 5, height of body 6 in the total length. Eyes—diameter $3\frac{1}{2}$ in the length of head, 3/4 of a diameter from the end of snout, and 1 apart. Interorbital space flat. The greatest height of the head equals its length anterior to the hind edge of the preopercle. Snout obtuse when the mouth is closed, rendering the two profiles equally convex. Fins—anterior dorsal rays not half so long as the head, the fin arises above or slightly in advance of the origin of the anal. Pectoral reaches to the base of the caudal. Ventral short, about 1/2 as long as the head, reaching 1/2 way to the base of the anal. Caudal lobed, the lower much the longer. Scales—6½ rows between the origin of the dorsal fin and the lateral-line. Colours—

bluish along the back, becoming lighter on the sides and beneath. Pectoral gray or black and with a light edge.

Dr. Günther, Catal. vi, p. 283, has separated from this species as *E. obtusirostris*, a form from tropical and subtropical seas which "has the snout shorter and the head more elevated," one more abdominal vertebra

and 7 rows of scales above the lateral-line.

Habitat.—Indian and tropical and sub-tropical seas, attaining at least 9 inches in length. The specimen figured (life-size) was from Bombay, it appears to be numerous at the Andamans.

4. Exocotus furcatus.

Mitchell, Lit. and Phil. Trans. New York, i, p. 449, pl. v, f. 2; Günther, Catal. vi, p. 286.

D. 13, P. 13, V. 6, A. 9-10.

A pair of barbels at the symphysis of the lower jaw. Fins—dorsal moderately high, but its longest rays do not extend to the caudal. The ventrals reach the root of the caudal, and the pectorals nearly as far: the former fin arises slightly nearer the base of the caudal than to the anterior extremity of the snout. Coloursthe posterior part of the ventrals and the lower part of the anal black. Young with three broad vertical bands across the anterior half of the abdomen: opercles and pectorals marbled with black: lower caudal lobe with three dark cross bands (Günther).

Habitat.—Indian and Atlantic Oceans. A small specimen, $2\frac{1}{2}$ inches in length, is in the British Museum, and reputed to have been brought from India.

5. Exocotus Bahiensis, Plate CXXI, fig. 10.

Ranz. Nov. Com. Acad. Sc. Inst. Bonon. v, 1842, p. 362, t. 38; Günther, Catal. vi, p. 293; Bleeker, Atl. Ich. vi, p. 71; Klunz. Verh. z. b. Ges. Wien, 1871, p. 585.

Exocætus vermiculatus, Poey, Mem. Cuba, ii, p. 300. Exocætus albidactylus, Gill, Proceed. Acad. Nat. Sc. Phil. 1863, p. 167.

Exocætus spilonopterus, Bleeker, Exoc. p. 113, and Atl. Ich. Scomb. t. iii, f. 2.

B. xi, D. 12-13, P. 15, V. 8, A. 9-10, C. 19, L. 1. 50.

Length of head 51, of caudal 41, height of body 61 in the total length. Eyes—diameter 1/3 of length of head, nearly 2/3 of a diameter from end of snout, and $1\frac{1}{4}$ apart. Interorbital space nearly flat. Barbelsabsent. Tecth—rudimentary. Fins—dorsal commences between the front edge of the eye and the posterior extremity of the lower lobe of the caudal fin, its anterior rays 1/2 as long as the head. Ventral arises midway between front end of snout and end of upper candal lobe, it reaches to the centre of the base of the anal. Pectorals reach to the end of the base of the dorsal. Anal commences below the last third of the dorsal fin. Colours—Dorsal sometimes with a dark mark on its summit: the pectoral darker than the remainder of the fins, and sometimes nearly black in its last third.

Habitat.—Red Sea, seas of India to the Malay Archipelago and beyond. The specimen figured (life-size)

came on board one of the P. and O. steamers in the Red Sea.

6. Exocœtus mento, Plate CXXXI, fig. 9.

Cuv. and Val. xix, p. 124; Bleeker, Snoek. p. 21; Günther, Catal. vi, p. 281. Parexocotus mento, Bleeker, Exoc. p. 126, and Atl. Ich. vi, p. 77, Scombres, t. v, f. 6.

B. xi, D. 10-11, P. 13, V. 6, A. 10-11, C. 17, L. 1. 44, L. tr. 6/2.

Length of head $4\frac{3}{4}$, of caudal 5, height of body $5\frac{1}{4}$ in the total length. Eyes—diameter $2\frac{3}{3}$ to 3 in the length of the head, about 1/2 a diameter from end of snout, and about 1 diameter from the hind edge of the opercle. Lower jaw a little the longer, slightly produced in the form of a tubercle at the symphysis: interorbital space smooth, with two grooves which diverge from the snout towards the occiput, ceasing opposite the middle of the orbit. No barbels. Teeth—villiform in both jaws, in several rows in the upper, only one in the lower: a large patch of villiform teeth in vomer, and also on the palatines. Fins—dorsal fin elevated as high as the body, and its membrane deeply cleft: 17 to 18 rows of scales between the occiput and origin of this fin, which commences opposite to or slightly before, the first anal ray. Ventrals in some specimens reaching to the anus, in others to the anal fin: the fin arises midway between the anterior edge of the orbit and the base of the caudal fin. Pectoral reaching to opposite the middle or end of the dorsal. Ventral does not quite reach the anal. Lower caudal lobe the longer. Scales—35 to 38 rows between posterior edge of head and base of caudal fin. Colours—bluish, becoming silvery along the abdomen: dorsal fin black: upper half of pectoral black, having a white edge: ventral white: anal white with a dark mark along its base: upper lobe of caudal white with a black bar along its base: lower lobe grayish.

Habitat.—Red Sea, East coast of Africa, seas of India to the Malay Archipelago. In the cold season it

is occasionally numerous at Madras, but I never obtained it above 4.3 inches in length.

FAMILY, IV—CYPRINODONTIDÆ.

Branchiostegals from four to six: pseudobranchiæ absent. Eyes lateral. Margin of the upper jaw formed solely by the premaxillaries. Barbels absent. Teeth in both jaws, also in the superior and inferior pharyngeal bones. A single spineless dorsal fin situated in the posterior half of the body. Scales on head and body. Stomach without any blind sac. No pyloric appendages. Air-vessel simple, and destitute of a pneumatic duct.

This family has been sub-divided into: -Cyprinodontidæ carnivoræ having united mandibles and short intestines; and C. limnophagæ having separated mandibles and long intestines.

SYNOPSIS OF GENERA

Cyprinodon. Mandibular bones united. Teeth in a single row.
 Haplochilus. Mandibular bones united. Teeth in narrow bands. Anal fin more or less elongated.

Genus, 1—CYPRINODON, Lacépède.

Lebias, Cuvier: Aphanius, Nardo: Micromugil, Gulia.

Gape of mouth small: mandibles short and united at the symphysis. Teeth of moderate size, in a single compressed row, and notched at their summits. Origin of dorsal fin anterior to that of the anal, and largest in the male sex. Scales rather large. The colour of the sexes often different. Intestines of moderate length or rather short.

Geographical distribution.—Southern Europe, North Africa, Syria, Persia, along the shores of the Red Sea to Cutch.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Cyprinodon dispar, D. 9, A. 10, L. 1. 25-27, L. tr. 8. Grayish: the caudal fin in the males with dark semilunar vertical bands: narrow vertical bands on the body in the female. Cutch.

1. Cyprinodon dispar, Plate CXXI, fig. 1 (male), 2 (female).

Lebias dispar, Rüppell, Atl. Fische, p. 66, t. 18, f. 1 (male), 2 (female).

Cyprinodon lunatus, Cuv. and Val. xviii, p. 161.
Cyprinodon hummonia, Richardson, P. Z. S. 1856, p. 371 (not Cuv. and Val.)
Cyprinodon dispar, Günther, Catal. vi, p. 303 (not P. Z. S. 1859, p. 470); Klunz. Verh. z. b. Ges. Wien, 1871, p. 587.

Cyprinodon Stoliczkanus, Day, Journ. As. Soc. of Beng. 1872, p. 258.

B. iii, D. 9, P. 17, V. 7, A. 10, C. 15, L. 1. 25-27, L. tr. 8.

Length of head $3\frac{3}{4}$ to 4, of caudal 5 to $5\frac{1}{2}$, height of body $3\frac{3}{4}$ to 4 in the total length. Eyes—diameter $3\frac{1}{4}$ in the length of the head, nearly 1 diameter from the end of snout, and $1\frac{1}{2}$ apart. Lower jaw somewhat the longer, the maxilla does not reach to below the front edge of the eye. Teeth—in a single tricuspid row in both jaws. Fins-dorsal elevated in the male, it commences midway between the middle of the eye and the base of the caudal fin, and above the tenth scale: whereas in the female it is not elevated and commences midway between the opercle and base of the caudal. Ventral is also elongated in the males but not in the females. Caudal lunate. Colours—Male: greenish-yellow reticulated with darker, a small dark shoulder spot. Dorsal fin spotted, anal more sparingly so. Caudal yellowish, with a wide crescentic black band, having a white edge in its last half: another narrow one between it and the root of the caudal which is also dark. Female: silvery, with from seven to nine narrow vertical bands.

Ova very large, almost equalling the diameter of the eye. Length of the intestinal canal about three

times that of the abdomen.

Habitat.—Abyssinia, Palestine, shores of the Red Sea, and common in Cutch, from whence Dr. Stoliczka brought 28 specimens.

Genus, 2-Haplochilus, McClelland.

Aplocheilus, McClelland: Panchax, Cuv. and Val.: Zygonectes, Agassiz: Micristius, Gill.

Branchiostegals from five to six. Body somewhat elongated and compressed. Upper surface of head and nape broad and depressed. Mandibular bones united at the symphysis. Teeth villiform in the jaws, present or absent on the palate. Dorsal fin short, commencing behind the origin of the anal, which latter has an elongated base. Scales cycloid and of medium size. Lateral-line absent. Intestinal canal of moderate length.

Bleeker restricts genus Panchax to those species possessing palatine teeth: and Haplochilus to those

destitute of such. Dr. Günther replies, "in one out of three specimens they are entirely absent." This latter

statement is not in accordance with my numerous examples which show no such variation.

Geographical distribution.—India to the Malay Archipelago and beyond, Tropical Africa, Madagascar and Islands in the Indian Ocean, also temperate and tropical America. In India these fishes are mostly found in the neighbourhood of the sea or tidal rivers, more rarely very far inland.*

SYNOPSIS OF SPECIES.

- 1. Haplochilus melastigma, A. 20-24. Height of body 33 to 4 in the total. No teeth on vomer. India and Burma.
- 2. Haplochilus rubrostigma, A. 17-18, L. 1. 33. Teeth on vomer. A prolonged ventral ray. Anal fin highest posteriorly. Spotted with red. Malabar and Madras.

 3. Haplochilus lineatus, A. 15-17, L. 1. 32-34. Teeth on vomer. A prolonged ventral ray. Anal fin of

nearly even height. Vertical black bands. Malabar and Ceylon.

4. Haplochilus panchax, A. 15-17, L. 1. 31-34. Teeth on vomer. No prolonged ventral ray. Orissa, Bengal, Burma, and Andamans to the Malay Archipelago.

1. Haplochilus melastigma, Plate CXXI, fig. 4.

Aplocheilus melastigma, McClelland, Ind. Cyp. pp. 301, 427, pl. 42, f. 3, and pl. 35, f. 4 (from H. B. MSS.)

Aplocheilus McClellandi, Bleeker, Cyprin. p. 487. Aplocheilus Carnaticus, Jerdon, M. J. L. and Sc. 1849, p. 331.

Panchax cyanophthalmus, Blyth, Journ. As. Soc. of Beng. xxvii, 1858, p. 288, and 1860, p. 111. Haplochilus cyanophthalmus, Günther, Catal. vi, p. 312.

Haplochilus argenteus, Day, Proc. Zool. Soc. 1867, p. 706.

B. iv, D. 6-7, P. 15, V. 6, A. 20-24, C. 15, L. 1. 27, L. tr. 9-11.

Length of head $4\frac{1}{4}$, of caudal $4\frac{1}{2}$, height of body $3\frac{1}{4}$ to 4 in the total length. Eyes—diameter 3 in the length of head, I diameter from end of snout, and also apart. Lower jaw slightly the longer, the maxilla does not quite reach to below the front edge of the eye. Teeth—minute, none on the palate. Fins—dorsal inserted above the last fourth of the anal. Pectoral as long as the head. Ventral small, without any prolonged ray. Anal with in some (not all) examples its rays prolonged in a filiform manner beyond the membrane. Caudal rounded. Colours-of a dull green along the back becoming of a dull white on the abdomen, outer portion of anal rays white edged. A narrow dark line along the middle of the side terminating in a dull spot at the centre of the base of the caudal fin.

Pacilia latipes, Schleg. Fauna Japon. p. 224, pl. cii, f. 5, appears very similar, but the caudal fin is given as emarginate, and the booy is lower.

Habitat.—Wynaad, and Madras Presidency, Orissa, Lower Bengal and Burma. It attains about 11/2 inches in length.

2. Haplochilus rubrostigma, Plate CXXI, fig. 5.

Aplocheilus rubrostigma, Jerdon, M. J. Lit. and Sc. 1849, p. 331.

? Aplocheilus affinis, Jerdon, l. c.

Panchax rubrostigma, Day, Proc. Zool. Soc. 1867, p. 706.

B. iv, D. 8, P. 15, V. 6, A. 17-18, C. 15, L. 1. 33, L. tr. 9.

Length of head $4\frac{5}{4}$, of caudal $5\frac{1}{2}$, height of body $5\frac{1}{2}$ in the total length. Eyes—diameter $3\frac{1}{4}$ in the length of head, $1\frac{1}{4}$ diameters from the end of snout, and $1\frac{1}{2}$ apart. Jaws of about the same length, the maxilla reaches to below the first third of the eye. Teeth—outer row in both jaws much enlarged, and recurved. Fins—dorsal inserted above the last few anal rays. Pectoral not quite so long as the head. Ventral with its second ray elongated and reaching to the middle of the anal fin. Anal much lowest anteriorly and increasing in length to the last ray. Central caudal rays rather prolonged. Colours—a silver occipital spot. Body reddish-brown superiorly, becoming yellowish on the sides and beneath. Each scale along the side with a central red spot. A row, sometimes two, of red spots along the base of the anal fin, some on the dorsal, and a few dark spots on the caudal.

Jerdon observes that *H. affinis* is very similar to *H. rubrostigma*, but "differs in the dorsal and caudal being nearly colourless, unspotted: and the anal being unspotted, orange. Having 16 anal rays instead of 14, being at the same time of less extent, body also not spotted. About 1.5 inches in length. Found in the same localities as H. rubrostigma."

Habitat.—Malabar coast of India, and the lower portion of the Coromandel coast. It attains to at least

3 inches in length.

3. Haplochilus lineatus, Plate CXXI, fig. 6.

Panchax lineatum, Cuv. and Val. xviii, p. 381; Bleeker, Beng. p. 72; Day, Fish. Malabar, p. 221.

* These fishes are termed Kud-di-an in Canarese: a white occipital spot is almost invariably present.

Aplocheilus vittatus, Jerdon, M. J. L. and Sc. 1849, p. 330.

B. v-vi, D. 8-9, P. 15, V. 6, A. 15-17, C. 19, L. 1. 32-34, L. tr. 9.

Length of head $4\frac{1}{4}$, of caudal $4\frac{1}{3}$, height of body 5 to $5\frac{1}{4}$ in the total length. Eyes—diameter $3\frac{1}{2}$ in the length of head, $1\frac{1}{3}$ diameters from the end of snout, and $1\frac{1}{2}$ apart. Jaws of about the same length anteriorly, the maxilla reaches to below the first third of the eye. Teeth—outer row in lower jaw, the outer and innermost row in the upper jaw rather enlarged, and in a single row across the palate. Fins—dorsal inserted above the last few anal rays: pectoral nearly as long as the head. Second ventral ray elongated reaching to nearly the middle of the anal fin: anal high, the last rays about the same length as the anterior ones: central caudal rays rather prolonged. Colours—vary with the seasons and sex. Greenish with a gloss of purple on the cheek and along the abdominal surface. A golden green spot in the centre of each scale and also on the eye. Eight to ten vertical black bands pass down the sides to the abdomen. A black spot at the base of the dorsal, it, the caudal, and posterior half of the anal, with black or green spots, in some these fins are tipped with orange, in others they are darkish. In a Ceylon specimen in the British Museum (marked H. panchax) there are dark blotches and not distinct bars as seen in Malabar.

Habitat.—This species is found in Coorg and the Wynaad, down the Malabar coast and Ceylon. It attains 4 inches in length, and on the Western coast of India, is common in rivers, tanks, and paddy fields, and even I have specimens as small as 12 inches in length, the bands are well marked, also the elongated ventral ray, whilst the caudal is much prolonged, and the height of the fish is 6 in the total length.

4. Haplochilus panchax, Plate CXXI, fig. 3.

Panchax Kuhlii, Cuv. and Val. xviii, p. 384.

Panchax panchax, Cantor, Catal. p. 252.

Panchax melanopterus, Blecker, Oost Java, p. 23, Snock, p. 23, and Beng. p. 144. Haplochilus panchax, Günther, Catal. vi, p, 311.

Pang-chax, Beng.: Kanakuri and Bor-ro-guddi, Ooriah: Nga-saki, Mugh.: Cho-to-dah, Andamanese.

B. v-vi, D. 7-11, P. 15, V. 6, A. 15-17, C. 13, L. l. 31-34, L. tr. 9-10.

Length of head 4 to $4\frac{1}{3}$, of caudal 6, height of body $4\frac{3}{4}$ to 5 in the total length. Eyes—diameter $3\frac{1}{3}$ in the length of head, 1 diameter from the end of snout, and $1\frac{1}{2}$ apart. Lower jaw rather the longer; the maxilla reaches to below the first third of the eye. Teeth—with an enlarged outer row in the upper jaw: in a broad band on the vomer. Fins—dorsal inserted above the last anal rays. In Calcutta specimens it has 7 or 8, rarely more, rays: in those from the Andamans up to 11. Pectoral nearly as long as the head. Ventral small and without any elongated ray. Anal nearly square. Caudal rounded. Colours—A white occipital spot. Upper surface greenish, becoming dull white on the sides and beneath. Fins yellowish, the lower third of dorsal covered with a large black spot. Dorsal, caudal, and anal margined with orange.

Ova very large.

A variety exists on the Sind hills, and in Cutch which has less scales (28) along the lateral-line, and numerous silvery spots along the sides, and a black spot behind the eye, the dorsal and anal fins are likewise more elongated.

Habitat.—From Orissa, through the lower province of Bengal, Burma, Siam to the Malay Archipelago, also the Andamans. (? Also Sind hills.) It attains at least $3\frac{1}{2}$ inches in length.

FAMILY, V—CYPRINIDÆ.

Branchiostegals three: pseudobranchiæ generally present. Body oblong or elongated: abdomen usually rounded, but, if compressed and cutting, destitute of ossicles. Margin of the upper jaw formed by the pre-maxillaries. Opercles in four pieces. Mouth toothless, but from one to three rows of teeth in the inferior pharyngeal bones, which latter are strong, free, and parallel to the branchial arches. A single, rayed dorsal fin. Head scaleless,* body scaled or scaleless, never covered by osseous plates. No "cul de sac" to the stomach, nor pyloric appendages. Air-vessel, if present, large; it may be divided by a constriction into an anterior and posterior portion, neither of which are enclosed by bone (Cyprininæ); or into two lateral portions, partially or entirely enclosed in a bony capsule, (Cobitidinæ).

Geographical distribution.—Carps are found in the fresh waters of the Old World and North America.

The family of carps (Cyprinidae) are well represented amongst the piscine inhabitants of the fresh waters and estuaries of India, Ceylon, and Burma, as they and the Siluridae compose the great mass of fish residing there, especially if we do not include the migratory Clupeidae.

Whereas siluroids as a rule appear to prefer muddy water, carps seem to thrive better in those which are clear, still many species of this family obtain their subsistence in dirty waters, for which purpose their burbels may prove of considerable assistance.

There are few members of this family which are such foul feeders as the Siluroids, consequently Carps may be deemed more wholesome and would be greatly preferable, were it not for the numerous bones with which they are provided. Natives however do not seem to much object to this, and as these fish are very abundant in places, they enter largely into the diet of the indigenous population.

Indian carps do not appear to restrict themselves so much to a vegetable diet as do those in Europe, for in the Tropics an eternal and destructive war is constantly being carried on between the different races of the animal kingdom. Those which prey upon their neighbours, as might be anticipated, are largely represented: whilst amongst those that were apparently produced to be preyed upon, it is mostly only the most prolific which have survived.

In the sub-family Cyprinine, as existing in Asia, considerable difficulty arises in selecting a division into groups.

In forming such, a very distinctive characteristic may be found by observing whether the scaled edge or margin of the abdomen is rounded or cutting, for in the majority of the Indian Cyprininæ the abdominal edge is rounded or smooth, even when somewhat compressed: whilst in a few genera the abdominal edge posterior to the ventral fin is compressed, cutting, and may even be serrated, as in the Clupeidæ: this trenchant edge is in some continued from in front of the ventral fins along the thorax.

Irrespective of the above, there are many other characters which might be employed for forming sub-groups and genera. In some, however, which might at first appear suitable for such purposes, one fails to attach that significance to their presence when large numbers of species come under review, showing the existence of connecting links. Some of these characters may be external, others are internal.

The mouth is variously formed; it may be transverse and inferior, with or without a sucker, the latter being present either on the lower lip or existing on both; or it may be narrow, of medium size, or wide: anterior, and either antero-lateral or oblique. The lower jaw again may be prominent, sharp or rounded, shorter than the upper, or sometimes having a knob at the symphysis; a moveable articulation may exist there, or there may be lateral prominences on the mandibles.

The lips may be exceedingly, moderately, or but slightly developed, sometimes absent from one of the jaws, closely investing both, or reflected from off one, or either. There may be an uninterrupted labial fold across the mandible, or portions of the lip may be much developed, fringed, or crenulated. In some genera, a horny or cartilaginous covering to one or both lips is invariably or generally present, especially in forms from the Hills.

The existence of a transverse groove across the snout can scarcely be distinctive of a species, much less of a Genus. Thus in *Discognathus lamta* we find examples with rounded and smooth snouts, and all intermediate forms to such as the one figured Plate exxii, f. 1. The same may be seen in *Labeo nukta* and several fishes of that Genus, and even in some species of *Barbus*, as *B. dorsalis*. The nearer the hills the more is this groove developed.

* Genus Legtobotia, Bleeker, from China forms an exception, its preopercular region having some rows of small scales.

The existence, number or absence of barbels has been considered by some authors to be a reason for constituting genera, but such is not generally held to be valid. These appendages, more especially when the fish are not kept in a state of domestication, or confinement, but left in natural situations, appear to be pretty constant, and though not in themselves cause enough for defining a Genus, are frequently sufficiently well marked for the purpose of forming sub-genera, good examples of which may be seen in the Genus Barbus, or Barilius. On the other hand, in some species these appendages may be abnormally absent, as in the Danio, consequently sub-divisions of the Genus founded solely on this character would lead to erroneous results.

The position of the fins indicate sub-divisions which may be used in the primary groups, and have for convenience sake been adopted as follows:—

- a. Dorsal fin commencing nearly opposite the ventrals, the anal being short.
- b. Dorsal fin commencing very distinctly posterior to the ventrals, but not extending to above the anal, which last is short, or of moderate length.
- c. Dorsal fin commencing in the interspace between the ventral and anal, or over the latter, and generally extending to above it: whilst the anal is of moderate length or elongated.

The character of the dorsal fin is likewise important, but its length alone, or rather the number of its rays, appears insufficient for the purpose of defining a Genus, much less a sub-division of a group. When an uninterrupted series extends from a few rays to a large number, and no other sufficient difference exists, such divisions cannot be considered natural ones: and if artificial, they can never form the basis of a scientific classification.

The last undivided dorsal ray is variously formed, being articulated or osseous, which latter may be smooth or denticulated, but all these varieties may be found in a single Genus, as Barbus. The anal fin sometimes shows peculiarities, as in the Barbus apogon, C. and V., where the undivided rays are spinate.

Scales, simply as regards their size, unless conjoined to other characteristics, cannot by themselves be taken as a reason for making Genera, because large, moderate, and small-sized scales are all occasionally found represented in a single Genus. But certain modifications may exist, as in the mountain barbels, Schizothoracinæ, where a row of tiled scales encloses the excretory outlets and base of the anal fin; or portions of the body may be naturally left scaleless.

The lateral-line has been employed as one of the signs for the formation of groups, according to its position, as along the middle of the side, or near the abdominal edge; a plan I have not adopted, because its complete existence in some species seems of but little importance: thus in the Genera Barbus, or Barilius, it may be present, or partially absent, sometimes ceasing after proceeding along a very few rows of scales.

As to the internal characters, the skeleton forms one of the most important features, respecting which much still remains to be investigated in the Indian carps, and the same remarks apply to the internal organs.

The pharyngeal teeth are in from one to three series, but these numbers alone do not always suffice for the definition of even Genera: thus in the *Chelas* some have them in two and others in three rows. Even the form of those teeth is not invariably similar in all the species of the same Genus: thus in the *Rohtee microlepis*, Blyth, these teeth have serrations on their edges, and the two largest of the anterior row are molariform, whereas crooked and pointed ones are the rule in the Genus. Likewise the teeth are deciduous, being constantly shed and replaced: they may become blunted with age, although they had at first been sharp and pointed.

I have not retained the sub-family, *Homalopterina*, or carps destitute of an air-vessel, because *Psilorhynchus* links it very naturally with *Discognathus*. In short most of the distinctive characters consist of possessing a single row of pharyngeal teeth and the absence of the air-vessel. In many fishes these however are deemed insufficient on which even to characterize genera. *Homaloptera* leads very naturally from some of the mountain siluroids to the true carps on one hand, and to the Loaches on the other.

A. Abdomen rounded, not trenchant.

A.—Dorsal fin commencing nearly opposite the ventrals. Anal short (5 to 7 branched rays.)

Genus, 1-Homaloptera, v. Hasselt.

Balitora, Gray: Platycara, McClelland.

Head and anterior part of body depressed: snout more or less spatulate. Mouth small, inferior, with two pairs of rostral barbels, and one at either angle of the mouth. Pharyngeal teeth small, from 5 to 16 in one row. Pectoral and ventral fins with many rays, the outer of which are simple. Dorsal short, situated opposite to the ventrals: anal likewise short.

Geographical distribution.—Through some of the hilly districts of the Himalayas to the Wynaad and Bowany river in the Madras Presidency: also found in the fresh waters of Java and Sumatra.

SYNOPSIS OF SPECIES.

1. Homaloptera Brucei, D. 3/8, A. 2/5, L. 1. 70. Lower caudal lobe the longer. Brown blotched with a darker tinge. Himalayas and South India.

- 2. Homaloptera maculata, D. 10, A. 2/5, L. l. 78. Boutan and Khasia Hills, also southern India.
- 2. Homaloptera bilineata, D. 9, A. 6. Horizontal bands. Tenasserim Provinces.

1. Homaloptera Brucei, Plate CXXII, fig. 1.

Balitora Brucei, Gray and Hard., Ind. Zool.; McClelland, Ind. Cyp., p. 299, 428, pl. 49, fig. 1. (From Gray and Hard.); Cuv. and Val. xviii, p. 101.

Platycara australis, Jerdon, M. J. L. and Sc. 1849, p. 333.

Cul-cundee, Tamil. "Stone Carp."

B. iii, D. $11(\frac{3}{8})$, P. 21, V. 11, A. $7(\frac{2}{5})$, C. 17, L. 1. 70, L. tr. 10/7.

Length of head $6\frac{1}{2}$, of caudal 5 in the total length, $Eyes-2\frac{1}{2}$ diameters from end of snout, 1 diameter from end of opercle. Snout broad and depressed, with sharp margins: rostral and maxillary barbels small. Teeth-pharyngeal, conical, 15, in one row. Fins-pectoral nearly reaches the ventral, its anterior nine rays are unbranched, as are also the first two of the ventral. Lower caudal lobe much the longer. Scales—absent from chest and as far as the posterior margin of the base of the ventrals. Colours—dark brown with darker blotches: caudal banded.

Habitat.—Wynaad and Bowany rivers in Madras, Himalayas from about Darjeeling through Boutan, Assam, and the Khasia Hills.

2. Homaloptera maculata, Plate CXXII, fig. 2.

Balitora maculata, Gray and Hard. Ind. Zool.; Cuv. and Val. xviii, p. 102. Platycara maculata, McClell. Ind. Cyp. pp. 299, 427, pl. 49, fig. 2 (from Gray and Hard.) Platycara anisura, McClell. Cal. Journ. Nat. Hist. ii, p. 587, pl. 16, fig. 1.

Homaloptera maculata, Günther, Catal. vii, p. 340.

B. iii, D. $10(\frac{2}{8})$, P. 19, V. 9, A. $7(\frac{2}{5})$, C. 17, L. l. 70.

Length of head $5\frac{3}{4}$ to 6, of caudal 6, height of body 7 in the total length. Eyes—directed upwards and outwards, diameter 1/5 of length of head, 3 diameters from end of snout, 2 diameters apart. Interorbital space convex. Snout broad, depressed: lips fringed. Rostral barbels short, their length equalling about 2/3 of the diameter of the orbit, the pair at the angle of the mouth thicker and slightly longer. Teeth—pharyngeal, 5, in one row. Fins—dorsal arising rather nearer the end of snout than the base of caudal. Pectoral nearly reaching the ventral, its outer 8 rays unbranched Two outer ventral rays simple. Caudal lobed in its posterior third. Scales—cycloid. Lateral-line—complete. Colours—dull olive, becoming yellowish beneath. Large brown blotches on the body. Dorsal in with three rows of dull spots: pectoral and ventral with three or four, anal with two, caudal with three irregular bands, and black tips.

Habitat.—Wynaad, the Bowany river, also the Himalayas. The specimen figured (from the Wynaad)

is a male.

3. Homaloptera bilineata, Plate CXXI, fig. 8.

? Cyprinus sucatio, Ham. Buch. Fish. Ganges, pp. 347, 393; Cuv. and Val. xvi, p. 448. ? Psilorhynchus sucatio, McClelland, Ind. Cyp. pp. 300, 429, pl. l. f. 1, (from H. B.'s MS.); Günther, Catal. vii, p. 343.

Homaloptera bilineata, Blyth, Proc. Asi. Soc. of Beng. 1860, p. 172.

Nemacheilus serpentarius, Day, Proc. Zool. Soc. 1869, p. 551.

B. iii, D. $10(\frac{3}{5})$, P. 17, V. 9, A. $7(\frac{2}{5})$, C. 19, L. l. 64, L. tr. 12/17.

Length of head 1/5, of caudal 1/5, height of body nearly 1/5 of the total length. Eyes—small, behind the middle of the length of the head, about 4 diameters from end of snout, and 3 diameters apart. Snout pointed. Upper lip fimbriated. Barbels—short, six in number, the maxillary pair the longest. Fins—dorsal arises slightly in advance of the ventrals, and midway between the snout and the base of the caudal fin, its upper margin straight. Pectoral, having its five outer rays unbranched, reaches two-thirds of the distance to the ventral, and the latter above half-way to the anal. Caudal deeply emarginate, its lobes pointed. Scales—smooth, with a raised keel along their centres, and increasing in size in the last half of the body. Lateral-line-complete. Colours-brownish, with a wide dark chestnut band passing from the snout through the Air-vessel—absent. orbit to the base of the dorsal fin, which last has a black centre. Caudal deep brown with white margins. A black bar across the base of the ventrals.

This species appears closely allied to Buchanan's fish from the rivers of Northern Bengal, which however is said to have the snout much longer than the remainder of the head. The eyes are represented as large, but only stated to be far back and globular. Fins—dorsal high, anteriorly with a very oblique upper margin. Colours—superiorly greenish, with scattered dots: sides clouded: abdomen whitish. Fins dotted.

Habitat.—Three specimens are in the Calcutta Museum, from the Tenasserim provinces.

Genus, 2—PSILORHYNCHUS, McClelland.

Back somewhat elevated, head moderately depressed: snout more or less spatulate. Mouth small, transverse, inferior. Lips entire, not continuous, reflected from off both jaws, and studded with glands. Barbels absent. Dorsal fin with few rays, commencing opposite the ventrals. Pectorals horizontal, with their outer rays unbranched. Anal short. Scales of moderate size, none on the chest. Lateral-line complete, continued direct to the centre of the base of the caudal fin. Air-vessel present.

This Genus, as illustrated by the single example described, is a connecting link between Homaloptera and Discognathus.

Geographical distribution.—Hill streams and rivers in Bengal and Assam.

SYNOPSIS OF INDIVIDUAL SPECIES.

- 1. Psilorhynchus balitora, D. 9-10, A. 7, L. 1. 33. Reddish-brown, irregularly marked with black. N. E. Bengal and Assam.
 - 1. Psilorhynchus balitora, Plate CXXI, fig. 7; and Plate CXXII, fig. 3.

Cyprinus balitora, Ham. Buch. Fishes of Ganges, pp. 348, 394; Cuv. and Val. Hist. Nat. des Poissons, xvi, p. 451.

Psilorhynchus variegatus, McClelland, Ind. Cyp. pp. 300, 430, pl. 50, f. 2 (from H. B.'s MSS.).
Psilorhynchus balitora, Günther, Catal. vii, p. 343; Day, Jour. As. Society of Bengal, 1871, p. 106,

B. iii, D. 9-10 $(\frac{7}{7}, \frac{2}{8})$, P. 17, V. 9, A. 7 $(\frac{2}{5})$, C. 18, L. 1. 35, L. tr. $4\frac{1}{2}/4\frac{1}{2}$.

Length of head $5\frac{1}{4}$, of caudal 5, height of body 5 in the total length. Eyes—diameter $4\frac{1}{4}$ in the length of head, $1\frac{1}{4}$ diameters from end of snout, and also apart. Head rounded, somewhat depressed. A deep cleft extending from the snout to the angle of the mouth. Lips rather thick and reflected from off either jaw. The jaws have sharp edges, but are destitute of any horny covering. Edges of lips not fringed, their surface covered with round hard pores. Some fine pores also on the cheeks and snout. Fins-dorsal commences in advance of the ventrals: pectorals and ventrals nearly horizontal, the outer seven rays of the former and two of the latter unbranched: caudal forked. $Scales-2\frac{1}{2}$ rows between the lateral-line and base of the ventral fin. Air-vessel—rather large, divided by a constriction into an anterior and posterior portion, and not enclosed by bone. Colours—reddish-brown, with irregular black blotches forming badly defined bands, in places passing over the back. Three bars on the caudal and some black on the anterior half of the dorsal.

Habitat.—Hill streams and rapids in N. E. Bengal and Assam.

Genus, 3-Discognathus, Heckel.

Garra, Ham. Buch.: Platycara, McClelland: Discognathichthys et Lissorhynchus, Bleeker: Mayou, Day.

Body elongated, subcylindrical. Mouth transverse, semicircular, and inferior; upper and lower lips continuous: no lateral lobes to snout, which projects beyond the mouth. A suctorial disk on the chin, formed on the lower lip, upper lip fringed. Barbels four (Garra, Ham. Buch.) or one pair only at each angle of the mouth (Discognathus, Heckel). Pharyngeal teeth uncinate and in three closely approximating rows, 2, 4, 5-5, 4, 2, or 5, 3, 1-1, 3, 5. Dorsal fin with few rays, commencing slightly in advance of the ventrals, its base scaleless: pectoral horizontal: anal short. Scales of moderate size, no enlarged anal row. Lateral-line continued to the centre of the base of the caudal fin. Gill-rakers few, short, and widely set. Air-vessel small.

Geographical distribution.—Rivers, more especially mountain streams, of Asia and Abyssinia: extending throughout India, Ceylon, and the Tenasserim Provinces.

SYNOPSIS OF SPECIES.

- 1. Discognathus lamta, D. 11, A. 7, L. 1. 33-36, 4 barbels. Interorbital space convex. Head $4\frac{1}{2}$ to $5\frac{1}{2}$ in the total length. A black spot behind gill-opening and generally a band along the side. Throughout India, Ceylon, and Tenasserim Provinces, Abyssinia and Aden.
- 2. Discognathus Jerdoni, D. 10, A. 7, L. l. 36, 4 barbels. Interorbital space concave. Head 61 to 61 in the total length. Wynaad and Bowany rivers in Madras.
- 3. Discognathus modestus, D. 10, A. 6, L. l. 35, 4 barbels. Interorbital space flat: 5 outer pectoral rays unbranched. Northern India (?).

Discognathus lamta and macrochir, Günther, Catal. vii, pp. 69 and 70.

Kul korava, Tam. "The stone Ophiocephalus, Pandi-pakke, Can.": Korafi-kaoli, Hind. (Mysore): Putterchettah, Hind. (N. W. Provinces): Choak-si, Beng.: Dhoguru and Koorka, Punj.

B. iii, D. 11 $\left(\frac{3-2}{8-9}\right)$, P. 15, V. 9, A. 7 $\left(\frac{2}{3}\right)$, C. 17, L. l. 32-36, L. tr. 4-4½/5, Vert. 18-14.

Length of head 5 to $5\frac{1}{2}$, of caudal 5 to $6\frac{1}{4}$, height of body 5 to 6 in the total length. Eyes—directed slightly upwards and outwards and situated in the commencement of the last half of the head, more rarely in its centre, diameter 5 to 8 in the length of head, 21 to 3 diameters apart. Interorbital space convex. Snout very diversified, either smooth, or covered with pores, and having or not having a deep transverse depression: in some specimens, as from the salt range in the Punjab (see Plate exxi, fig. 1), or from the Chumba State, there is a regular spinate covering to a gland on either side of the snout, in some all the glands are thus constructed. Fins—the dorsal arises midway between the end of the snout and the base of the caudal, and anterior to the origin of the ventral, it is usually less in height than the body. The pectoral shorter than the head: caudal slightly lobed. Air-vessel—small, its posterior portion minute. Ova small, numerous. Colours—greenish, with a bluish-green band along the centre of the body, and extending along the middle of the caudal fin. Generally a dark spot behind the gill-opening. Abdomen yellowish-green. Fins yellowish, stained darker at their margins. In specimens from the Tenasserim Provinces a black spot exists at the base of each dorsal ray, this is also seen in those from the Himalayas at Chumba, where the fins are all tipped with black. In Malabar and Canara some have a dark band along the side, with an orange one above and another below it.

Habitat.—From Syria throughout India and Ceylon to the Tenasserim Provinces, and likewise found in Abyssinia and at Aden. It attains at least 8 inches in length. This fish putrifies very rapidly after death, and generally dies almost as soon as removed from the water.

2. Discognathus Jerdoni, Plate CXXII, fig. 6.

Day, Proceed. Zool. Society, 1867, p. 288. Gonorhynchus gotyla, Jerdon, M. J. L. and Sc. 1849, p. 309 (not Gray and Hard.).

B. iii, D. 10 $\binom{2}{8}$, P. 16, V. 9, A. 7 $\binom{2}{5}$, C. 17, L. l. 36, L. tr. $4\frac{1}{2}/2\frac{1}{2}$.

Length of head $6\frac{1}{4}$ to $6\frac{1}{2}$, of caudal $6\frac{1}{4}$, height of body $6\frac{1}{4}$ in the total length. 31 to 4 in the length of the head, I diameter from end of snout, and 2 diameters apart. Interorbital space rather deeply concave. Snout in the young smooth, but in larger specimens it has a depression across it and some porcs. Barbels—two pairs. Fins—dorsal arising about midway between the end of snout and commencement of the origin of the anal fin, its height exceeds the length of the head. Pectoral rather longer than the head, but does not quite reach the ventral, which is equally long. Anal does not quite reach the caudal, which is deeply forked. Colours—olivaceous, becoming yellowish on the sides and beneath. A black spot behind the gill-opening. Pectoral and ventral fins yellowish, with the outer portion dark gray margined with orange. Dorsal, anal, and caudal yellowish, with gray markings, the lower caudal lobe gray, with a light outer edge.

This species is distinguished from D. lamta by its comparatively short head, large eye, concave interorbital

space, position of its dorsal fin, its elongated pectoral and ventral, and deeply forked caudal.

Habitat.—Bowany river at foot of Neilgherries in the Madras Presidency, also the Wynaad. specimen figured is upwards of 8 inches in length.

3. Discognathus modestus, Plate CXXII, fig. 5.

Mayoa modesta, Day, Proc. Zool. Soc. 1869, p. 553.

B. iii, D. 10 $\binom{2}{8}$, P. 15, V. 9, A. $6\binom{1}{8}$, C. 19, L. 1. 35, L. tr. $4\frac{1}{2}/3\frac{1}{2}$.

Length of head $5\frac{1}{4}$, of caudal 5, height of body $5\frac{1}{2}$ in the total length. Eyes—near the upper surface of the head, diameter $\frac{1}{4}$ of length of head, 2 diameters from end of snout, 2 diameters apart. Head broad, depressed. Interorbital space flat. Lower surface of head and chest flat. The snout overhangs the mouth, which is rather small, transverse, and nearly semilunar in shape. Mouth, with an adhesive sucker, which is posterior to the lower jaw. The lips are reflected from off both jaws, and have a tuberculated surface: margin of upper lip fimbriated. Barbels—four, one rostral and one maxillary pair, all being rather thick and short. Teeth pharyngeal, uncinate, 5, 3, 1-1, 3, 5. Fins—pectorals and ventrals horizontal, the former extending to the latter, which reaches the anal. First five outer pectoral rays simple. Dorsal arises in advance of the ventral. Caudal slightly forked. Scales-none on the chest. Colours-greenish-brown, with no marks existing except a dark blotch under the dorsal fin, and a mark at the base of the caudal.

Habitat.—Probably Northern India, two specimens exist in the Calcutta Museum, the longest being $3\frac{1}{2}$ inches.

Genus, 4—Oreinus, McClelland.

Schizothorax, Sect. A, and Schizopyge, sp. Heckel.

Abdomen rounded. Snout rounded, mouth inferior and transverse, mandibles short, broad, and flat, loosely joined together at the symphysis: margin of the lower jaw having a hard, horny covering, thickest internally, and a thick fringed lower lip with a free posterior edge, forming a sucker. Barbels four. Pharyngeal teeth pointed, hooked, 5, 3, 2/2, 3, 5. Dorsal fin rather short and arising opposite the ventrals, its last undivided ray osseous, serrated or entire: anal short. Scales very small; the vent and base of the anal fin in a sheath covered by an enlarged tiled row of scales. Lateral-line passing to the centre of the base of the caudal fin.

Although the serrated spine in the dorsal fin is commonly termed the last undivided ray or spine, such has merely reference to its being unbranched, for in reality this spine consists of two separate, compressed and serrated bones attached one to the other in their whole extent.

It must also be noticed that too much stress must not be laid upon the comparative size of the tiled row of scales to the diameter of the eye as such varies, as is easily explained. The number of scales remains the same throughout the fish's life, and therefore their size continues to increase in accordance with that of the body of the fish. The eye, however, does not continue increasing in the same proportion, so that a species in which its diameter is say 4 in the length of the head in the young, is 6 or even 8 in that of the adult. It naturally follows that the size of the tiled row of scales is often far greater in the adult in comparison to the dimension of the eye than it is in the young. Likewise it is very common to find specimens in which the height of the body is much less than normally exists, these appear half-starved or sickly fishes.

Geographical distribution.—Rivers and some lakes in the Himalayan and sub-Himalayan region extending to the confines of China.* These fishes are rarely found in the rivers of the plains at any distance from the base of the mountain ranges. This Genus and the four succeeding ones of Schizopygopsis, Schizothorax, Ptychobarbus, and Diptychus, consist of Carps, scaleless or more or less covered with minute scales. A membraneous slit exists anterior to the anal fin, which is laterally bounded by a row of vertically placed scales, like eave-tiles, and which are continued along the base of the anal fin. They form the Schizothoraxing of McClelland.

SYNOPSIS OF SPECIES.

1. Oreinus sinuatus, D. 4/7, A. 3/5. Anal scales about 1/2 as large as orbit. Black spots on body.

Afghanistan, Punjab, Cashmere, and along the Himalayas. 2. Oreinus Richardsonii, D. 3/8, A. 3/5. Anal Anal scales 2/3 as large as orbit. Colours uniform.

3. Oreinus plagiostomus, D. 3/8, A. 3/5. Anal scales about as large as orbit. Osseous dorsal ray weak.

Colours uniform. Afghanistan, Cashmere to Upper Assam. Geographical distribution.—Throughout the Himalayan and sub-Himalayan range to Assam and the confines of China.

1. Oreinus sinuatus, Plate CXXIV, fig. 4.

Schizothorax sinuatus, Heckel, Fische aus Kaschmir, p. 21, t. 2.

B. iii, D. $\frac{3-4}{6}$, P. 17, ∇ . 10, A. $\frac{2-3}{6}$, C. 19, L. l. 105, ∇ ert. $\frac{3.4}{3.3}$.

Length of head $5\frac{1}{2}$ to 6, of caudal $5\frac{1}{2}$, height of body $5\frac{1}{2}$ to $7\frac{1}{2}$ in the total length. Eyes—diameter 2/9 to 1/6 of length of head, 2 to $2\frac{1}{2}$ diameters from end of snout, 2 to $2\frac{1}{4}$ diameters apart, and almost entirely situated in the front 1/2 of the head. Interorbital space rather convex, more so in the adult than in the young: snout rounded, with a very slight appearance of pores. Mouth inferior, transverse: lower lip well developed, rugose, entire, having a free posterior edge, and forming an adhesive sucker. The posterior edge may be concave or slightly lobed in the middle or even straight. Inner side of lower lip covered with cartilage, which is extended on to its inferior surface, where, however, it is not so horny. Barbels—of about equal length and not quite so long as the eye. Pre-opercle with an emarginate posterior border. Teeth—pharyngeal, 5, 3, 2/2, 3, 5, crooked, pointed. Fins—dorsal commences a little before the ventrals, and slightly nearer to the snout than it does to the base of the caudal fin, its spine is rather strong, moderately serrated and rather longer than the head without the snout, the fin is rather higher than the body below it, its last ray is divided into two. Pectoral four-fifths as long as the head, and extending above halfway to the ventral, which last reaches two-thirds of

* Dr. Anderson brought a species of *Oreinus* from the confines of China when with the last Yunam expedition. It is allied to O. sinuatus and O. Richardsonii, but its body is deeper, its scales more oval in form and larger.

Digitized by Google

the distance to the anal, its last ray divided to its base. The anal has a narrow base and its length slightly varies, reaching when laid flat, the whole or only three-fourths of the distance to the base of the caudal, which is lobed in its posterior half. Free portion of tail slightly longer than deep. Scales—rows above the lateral-line about equal in size to those of the pierced row, rather smaller below it: about 16 to 20 rows between the lateral-line and base of ventral fin, and 21 to 25 between it and base of dorsal: tiled row to vent minute, each scale in it being from one-third to half the diameter of the orbit. Viscera—the diameter of the posterior portion of the air-vessel is small. The lobes of the liver are elongated, extending to opposite the anal fin, and having several lateral but parallel prolongations. In May (at Chumba) the ova of these fish inhabiting the main stream, were almost fully developed, being numerous and of a large size, whilst there were a considerable number of fry in the side streams of the Ravi. Colours-grayish, becoming white below, pre-opercle dashed with golden: lower fins tinged red. After death two or three rows of dark gray blotches appear above the lateral-line. Some have scattered black and occasionally red spots, and these have been termed Trout.

Habitat.—Afghanistan, Himalayan rivers, but not extending in the plains to far from their bases. It adheres to rocks by means of its sucker and is thus enabled to reside in mountain rapids. It attains at least 2 feet in length, is pretty good eating but bony; it is too rich for some people, but does not deleteriously affect

those used to it.

Length of head 4 to 6,* of caudal $4\frac{1}{2}$ to 5, height of body $5\frac{1}{4}$ to $6\frac{1}{4}$ in the total length. Eyes—in the middle or rather before the middle of the length of the head, diameter 5 to $6\frac{1}{2}$ in the length of head, width of interorbital space in adults nearly equals 1/2 length of head, it is almost flat. Snout obtuse. Mouth inferior, transverse, with a well-developed lower lip, which has its posterior free edge straight or rather convex. Occasionally there are large pores on the snout. Barbels—about 1/2 as long as eye. Tecth—pharyngeal, 4, 4, 2/2, 4, 4, crooked, pointed. Fins—dorsal commencing slightly before the ventral, and about midway between the snout and base of the caudal, its spine moderately strong, toothed, becoming nearly smooth in large specimens, and as long as the head excluding the snout. Pectoral 4/5 as long as the head. Ventral does not reach anal, nor the latter the caudal. Scales—24 rows between the lateral-line and base of the dorsal fin, and 19 between it and the ventral: the scales of the tiled row equal 2/3 of the diameter of the eye in the young, as high as the diameter of orbit in adults. Free portion of the tail as long as deep. Colours—bluish along the back, becoming silvery shot with gold on the sides and beneath. Head likewise glossed with purple and gold. In some specimens there are black spots on the sides and head.

Habitat.—The specimen figured was from Darjeeling. It inhabits Nepal, Boutan, and the sub-

Himalayan range.

3. Oreinus plagiostomus.

Schizothorax plagiostomus, Heckel, Fische aus Caschmir, p. 16, t. 1; Cuv. and Val. xvi, p. 213.

Oreinus plagiostomus, McClelland, Cal. Journ. Nat. Hist. ii, 1842, pp. 570, 581; Günther, Catal. vii, p. 160.

Capoeta micracanthus, Günther, Catal. vii, p. 81.

B. iii, D. 10-11 $(\frac{2}{8})$, P. 17, V. 11, A. 7 $(\frac{2}{5})$, C. 19, L. l. 110, L. r. 170.

Length of head $5\frac{1}{2}$ to 6, of caudal $5\frac{1}{2}$ to 6, height of body 4 to $5\frac{1}{2}$ in the total length. Eyes—diameter 41 to 8 in the length of head, and in or rather before the middle of the length of the head. Snout broad, interorbital space nearly flat, and equalling about 1/2 length of head: mouth transverse, inferior: lower lip with a nearly straight and free posterior margin, and studded with glands, some specimens have glands on the snout. Barbels—not so long as the eye. Teeth—pharyngeal, crooked, pointed, 5, 4, 2/2, 4, 5. Fins—dorsal osseous ray weak, its stiff portion as long as the head without the snout, its screature being feeble, almost absent in adults: the fin is not so high as the body, it commences somewhat in advance of the ventrals, and midway between the end of the snout, and the root of the caudal: anal when laid flat reaches the base of the caudal: the scales along its base well-developed, the largest being about the size of the orbit in the young, exceeding it in the adult. Colours—uniform silvery, or with black spots.

* In the Catalogue of Fishes of the British Museum it is stated of this species:—"Head very small, its length being 2/11 or 1/6 of the total (without caudal)." Having been permitted access to the same fish I found of those in spirit, 4 specimens from 3.3 to 3.8 inches long, head from 4 to 4\frac{3}{3} in the total with the caudal: one 4 inches long, head 4\frac{1}{3}; one 5\frac{1}{3} inches long, head 4\frac{1}{3}; and one 9 inches long, head 5\frac{1}{3}; in the total with the caudal fin. Amongst the skins one 10 inches long, head 5 in the total; one 15 inches long, head 5\frac{1}{3}; and one 18 inches long, head 6 in the total including the caudal fin.

O. Griffithi, McClelland, l. c. p. 581, is said to differ but little from the above, its intestines are six times the length of the body, its habitat is Afghanistan, Koonur river, Pushut.

Capoeta macracanthus, Günther, has a very weak dorsal spine.

Habitat.—Afghanistan, Cashmere, and Boutan.

Genus, 5—Schizopygopsis, Steindachner.

Abdomen rounded. Snout obtusely conical. Mouth transverse, inferior, with a slight cleft; mandible with a sharp anterior edge, having a horny covering, and the upper lip continuous with a short lateral one. Barbels absent. Pharyngeal teeth compressed, 4 or 3, 3/3, 3 or 4. Dorsal fin short, with a serrated ray, and situated nearly opposite to the ventrals: anal short. Scales small, few, and only present in the scapular region, except a scaled sheath to vent and along the base of the anal fin. Lateral-line continued to the centre of the base of the caudal. Ova comparatively large.

Geographical distribution.—Head waters of Indus, Tibet, and Eastern Turkestan.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Schizopygopsis Stoliczkæ, D. 4/7, A. 2/5.

1. Schizopygopsis Stoliczkæ, Plate CXXIV, fig. 2.

Steind. Verh. zool.-bot. Ges. Wien, 1866, p. 785; Günther, Catal. vii, p. 170; Day, Proc. Zool. Soc. 1876, p. 791.

B. iii, D. 10-11 $(\frac{3}{7},\frac{4}{8})$, P. 13, V. 11, A. $7(\frac{2}{8})$, C. 19.

Length of head 5 to $5\frac{3}{4}$, of caudal $5\frac{1}{2}$ to $5\frac{3}{4}$, height of body 7 to 8 in the total length. Eyes—diameter 4 to 5 in the length of the head, 1 to $1\frac{1}{2}$ diameters from the end of the snout, and $1\frac{1}{2}$ to 2 apart. The greatest width of the head equals its length behind the middle of the eyes, and its height equals its length excluding the snout. Mouth inferior, overhung by the snout, the maxilla reaches to below the front edge of the eye. An anterior, sharp, horny edge to the mandible. Fins—the dorsal as high as the body, it commences about midway between the end of the snout and the root of the caudal fin, its upper edge nearly straight, oblique: its last undivided ray osseous, and finely serrated. Pectoral not quite so long as the head, and reaching rather above halfway to the ventral, which latter arises below the middle of the dorsal and does not reach the anal. Anal rather above twice as high as its base is long, it extends to the caudal when laid flat. Caudal deeply forked. Colours—olive superiorly, becoming white on the sides and beneath, the whole covered with irregular

Habitat.—Leh and head waters of Indus, also tributaries of the Yarkand and Oxus rivers.

Genus, 6—Schizothorax, Heckel.*

Schizopyge, sp. Heckel: Racoma, sp. McClell.: Opistocheilus, pt. Bleeker.

Abdomen rounded. Snout conically rounded, and laterally somewhat compressed, with the mouth arched and antero-inferior, mandible neither broad, flattened, nor with a sharp margin, its edge sometimes having a thin, deciduous horny covering. Barbels four. Pharyngeal teeth pointed, hooked, 5, 3, 2/2, 3, 5. Dorsal fin rather short, with a strong, osseous, serrated ray, and arising opposite the ventrals: anal short. Scales very small, the vent and base of the anal fin in a sheath, covered by an enlarged tiled row. Lateral-line passing to the centre of the base of the caudal fin.

Geographical distribution.—Mountain streams and rivers of the Himalayan region, also Afghanistan and Turkestan.

* The following species of this Genus have also been recorded, some are figured in this work :-

A. Lower labial fold uninterrupted.

a. Dorsal spins strong, serrated.

1. Schizothorax barbatus, McClelland, Cal. Journ. Nat. Hist. ii, p. 580; Günther, Catal. vii, p. 168. Eye 1/5 of head. Upper jaw projecting. Origin of dorsal fin rather nearer caudal than snout: its spine very strong, serrated. Anal laid flat does not reach caudal. Tiled rows of scales small. Afghanistan.

 $\pmb{b.} \ \ \textit{Dorsal spine feeble, serrated}.$

2. Schizothoraz Ritchianus, McClell. Cal. Journ. Nat. Hist. ii, p. 580; Günther. Catal. vii, p. 168. Eye 1/5 of head. Upper jaw projecting. Origin of dorsal fin rather nearer caudal than snout: its spine feeble, serrated. Anal laid flat does not reach caudal. Tiled row of scales of moderate size. Afghanistan.

3. Schizothoraz Edeniana, McClelland, l. c. p. 579. Upper jaw the longer. Dorsal spine feebly serrated near its base. Scales

rather above the ordinary size. Cabul river.

B. Lower labial fold interrupted.

a. Dorsal spine strong, serrated.

4. Schizothoraz niger, Heckel, Fische aus Cashmir, p. 29, t. v; Günther, Catal. vii, p. 164. Eye 1/5 of head. Upper jaw the

SYNOPSIS OF SPECIES.

1.—Schizothorax progastus, D. 11-12, A. 7, L. l. 150. Snout elongated. Lower lip with a free posterior Dorsal spine coarse. Himalayan and sub-Himalayan range, from the head waters of the Ganges to Upper Assam.

2. Schizothorax esocinus, D. 12, A. 7. Lower labial fold interrupted. Dorsal spine coarse. Head waters

of Indus, Cashmere, and Afghanistan.

B. iii, D. 11-12 $(\frac{3}{8^{3}-9})$, P. 19, V. 11, A. 2/5, C. 19, L. l. 150-160.

Length of head $5\frac{1}{4}$ to $5\frac{1}{2}$, of caudal $5\frac{1}{2}$, height of body 6 in the total length. Eyes—from $4\frac{1}{2}$ to 6 diameters in the length of the head and situated in its middle. Interorbital space nearly flat: snout pointed. Width of head equals half its length. Depth of cleft of mouth equals the width of the gape. Upper jaw projecting: lip thick and fleshy, having a free posterior edge in its whole circumference, upper lip elevated in the centre, lower with a central lobe and a lateral one on either side. Lips internally covered with a thin, deciduous, cartilaginous layer. Barbels—four, the rostral about as long as the orbit, the maxillary pair rather shorter. Teeth—pharyngeal, crooked, pointed, 5, 3, 2/2, 3, 5. Fins—dorsal commences slightly in

longer. Barbels shorter than the eye. Origin of dorsal fin nearer caudal than snout: spine as long as head excluding snout. Anal

longer. Barbels snorter than the eye. Origin of dorsal in nearer candal than snout: spine as long as nead excluding shout. Anal laid flat, not reaching candal. Tiled rows of scales as wide as orbit. Small black spots on the sides. Cashmere.

5. Schizothorax punctatus, Day, Proc. Zool. Soc. 1876, p. 785, pl. exxiii, fig. 3. Eye 63 in length of head. Lower jaw the longer. Barbels as long as eye. Origin of dorsal fin nearer candal than snout: spine as long as postorbital portion of head. Anal laid flat does not reach candal. Tiled row of scales one-third diameter of orbit. Covered with black spots. Cashmere.

6. Schizothorax micropogon, Heckel, l. c. p. 41, t. viii, f. 1; Günther, l. c. p. 163. Eye 4½ in head. Upper jaw the longer. Barbels minute. Origin of dorsal fin much nearer candal than snout: spine as long as the head excluding snout. Anal laid flat does not reach candal. Tiled row of scales minute. Cashmere.

7. Schizothorax vilani/mas. Heckel, l. c. p. 44, t. viii, f. 2; Günther, l. c. p. 163. Eye 54 in length of head. Jaws of conditions are conditionally as the length of head. Jaws of conditions are conditionally as the length of head. Jaws of conditions are conditionally as the length of head. Jaws of conditions are conditionally as the length of head. Jaws of conditions are conditionally as the length of head. Jaws of conditions are conditionally as the length of head. Jaws of conditions are conditionally as the length of head. Jaws of conditions are conditionally as the length of head. Jaws of conditions are conditionally as the length of head. Jaws of conditions are conditionally as the longer.

Barbels minute. Origin of dorsal fin much nearer caudal than snout: spine as long as the head excluding snout. Anal laid flat does not reach caudal. Tiled row of scales minute. Cashmere.

7. Schizothorax planifrons. Heckel, l. c. p. 44, t. viii, f. 2; Günther, l. c. p. 163. Eye 5½ in length of head. Jaws of equal length. Barbels as long as eye. Origin of dorsal fin nearer caudal than snout: its spine 3/5 as long as head. Anal laid flat nearly reaches caudal. Tiled row of scales half width of eye. Cashmere.

8. Schizothorax Hugelii, Heckel, l. c. p. 36, t. vii; Günther, l. c. p. 164. Eye 6 in length of head. Upper jaw slightly the longer. Barbels shorter than eye. Origin of dorsal fin nearer caudal than snout: its spine short and feebly serrated. Anal laid flat nearly reaches caudal. Tiled row of scales much broader than the eye. Cashmere.

9. Schizothorax curvifrons. Heckel, l. c. p. 25, t. iii; Günther, l. c. p. 164. Eye 5½ in length of head. Upper jaw slightly the longer. Barbels half as long as eye. Origin of dorsal fin nearer caudal than snout: its spine nearly as long as head, and feebly serrated. Anal laid flat does not reach the caudal. Tiled row of scales small. Cashmere.

10. Schizothorax intermedius, McClelland, l. c. p. 579; Günther, l. c. p. 165; Day, l. c. p. 786, and Plate exxiv, f. 1. Eye 5½ in the length of head. Upper jaw the longer. Barbels as long as eye. Origin of dorsal fin nearer caudal than snout: its spine 2/3 to 4/5 as long as head, coarsely serrated. Anal laid flat reaches the caudal. Tiled row of scales half as deep as orbit. Afghanistan and Turkestan.

Turkestan.

11. Schizothoraz nasus, Heckel, l. c. p. 33, t. vi; Günther, l. c. p. 166. Eye 6 in length of head. Upper jaw the longer. Barbels shorter than the eye. Origin of dorsal fin midway between end of snout and root of caudal: its spine as long as head excluding the snout, rather finely serrated. Anal laid flat scarcely reaches the caudal. Tiled row of scales 1/2 as deep as orbit. Cashunere.

12. Schizothorax microcephalus, Day, l. c. p. 787, Plate exxv. fig. 2. Eye 7 in length of head. Upper jaw the longer, and overhung by snout. Barbels twice as long as eye. Dorsal fin commences rather nearer snout than caudal: its spine very weak and feebly serrated. Anal when laid flat reaches caudal. Tiled row of scales minute. Panja from a tributary of the Oxus.

13. Schizothorax longipinnis, Heckel, l. c. p. 27, t. iv; Günther, l. c. p. 166. Eye 5 in length of head. Upper jaw slightly the longer. Barbels nearly 1/2 as long as eye. Dorsal fin commences nearer caudal than snout: its spine moderately strong and serrated. Anal laid flat reaches caudal. Tiled row of scales not 1/2 as broad as orbit. Cashmere.

14. Schizothorax chrysochlorus, Day, l. c. p. 784, and Plate exxiii, fig. 2; Racoma chrysochlora, McClelland, l. c. p. 577, t. xv, f. 3; S. Biddulphi, Günther, Ann. and Mag. Nat. Hist. 1876, p. 400. Eyes from 5½ to 7 in length of head. Upper jaw the longer. Barbels at least as long as the eye. Dorsal fin arises midway between end of snout and base of caudal: its spine strong, serrated, and as long as the head. Anal when laid flat reaches 1/2 way to the caudal. Tiled row of scales 1/2 as broad as the eye. Afghanistan and Turkestan.

and Turkestan.

15. Schizothorax nobilis, Racoma nobilis, McClelland, l. c. p. 577, t. xv, f. 4. Eye about 6 in the length of head. Upper jaw the longer. Barbels longer than the eye. Dorsal fin arises nearer snout than base of candal: its spine as long as head without the snout, serrated. Anal if laid flat reaches the caudal fin. Tiled row of scales about as broad as orbit. Afghanistan.

16. Schizothorax labiatus, McClelland, l. c. p. 578, t. xv, f. 1. Eye 4 in the length of head. Barbels terminating in trident points. Upper jaw projecting. Origin of dorsal fin nearer caudal than snout: spine serrated posteriorly. Anal laid flat reaches the caudal fin. Afghanistan.

17. Schizothorax gobioides, Racoma gobioides, McClelland, l. c. p. 576, t. xv, f. 3. Eye 41 in the length of the head. Barbels longer than the eye. Upper jaw much the longer. Origin of dorsal fin midway between snout and base of the caudal: its spine as long as the head excluding the snout, and serrated posteriorly. Anal fin laid flat does not reach the caudal. Tiled row of scales about as broad as orbit. Afghanistan.

broad as orbit. Afghanistan.

18. Schizothorax brevis, Racoma brevis, McClelland, l. c. p. 578. "Head short and compressed. Lips covered with a thick fleshy membrane, which forms a loose appendage to the lower jaw. Depth of body nearly equal to 1/3 of its length. Fins small, rays slender, the dorsal spine slender and soft." Afghanistan.

Amongst the foregoing 18 species it is most probable that several will turn out to be synonyms: some of McClelland's examples may belong to the Genus Oreinus.

advance of the ventrals and midway between the end of the snout and root of the caudal fin, its osseous ray strong, coarsely serrated, and as long as the head behind the angle of the mouth. Pectoral does not reach the ventral, nor the latter the anal. Anal when laid flat nearly reaches the base of the caudal, which is deeply forked. Scales—in tiled row but little developed, the largest not being half as broad as the orbit. About 18 rows between the lateral-line and base of ventral fin. Colours—uniform silvery, sometimes having a few fine spots: fins with darkish edges.

McClelland placed this species as first amongst his Oreini. He, however, remarked "muzzle fleshy and pointed, lips thick, somewhat pendulous and muscular." * "Lengthened and fleshy snout, small mouth." "Body much compressed." This fish, when eaten, is said by the natives of Assam to occasion swimming of the head and temporary loss of reason for several days, without any particular derangement of the stomach.

Habitat.—Himalayas, from the head waters of the Ganges to Suddya in Upper Assam. It is common at Hurdwar where the Ganges debouches into the plains. It attains at least 20 inches in length.

3. Schizothorax esocinus, Plate CXXIII. fig. 4.

Heckel, Fische aus Cashmir, p. 48, t. ix; McClelland, Calcutta Journ. Nat. Hist. ii, p. 579: Günther, Catal. vii, p. 166; Day, Proc. Zool. Soc. 1867, p. 785.

B. iii, D. 12 ($\frac{4}{6}$), P. 20, V. 10, A. 7 ($\frac{8}{6}$), C. 20.

Length of head $4\frac{1}{4}$ to $4\frac{1}{2}$, of caudal $5\frac{3}{4}$, height of body $7\frac{1}{4}$ in the total length. Eyes—diameter $6\frac{1}{2}$ in the length of head, 2 diameters from the end of snout, and also apart. Interorbital space flat. The greatest width of the head equals its height. Mouth slightly oblique, horse-shoe shaped, the upper jaw the longer: the maxilla reaches to nearly below the front edge of the eye. Lower labial fold interrupted in the middle. A horny covering to inside of the lower jaw. Barbels—the rostral ones more than half longer than the eye, the maxillary a little shorter. Fins—the dorsal as high as the body, commencing slightly nearer the base of the caudal than to the end of the snout: its last undivided ray osseous, coarsely serrated posteriorly, whilst its bony portion is as long as the head excluding the snout. Pectoral does not quite reach the ventral, the latter which arises beneath the second or third undivided dorsal ray extends two-thirds of the distance to the anal. Length of base of anal about 3/7 of its height, when laid flat it reaches the caudal which is deeply forked. Free portion of the tail as high at its base as it is long. Colours—silvery, with numerous black spots, most distinct in the upper half of the body.

Habitat.—Leh or Ladak and head waters of the Indus, also Cashmere and Afghanistan.

Genus, 7-PTYCOBARBUS, Steindachner.

Abdomen rounded, snout conical, mouth arched, anterior or inferior. Two maxillary barbels. Pharyngeal teeth compressed 4, 3/3, 4. Dorsal fin situated opposite the ventrals, without or with a feeble osseous ray, which is smooth or serrated: anal short. Scales small, covering the body, and forming a sheath at the base of the vent and anal fin. Lateral-line continued to the centre of the base of the candal.

Geographical distribution. - Head waters of the Indus, Tibet and Kashgar.

SYNOPSIS OF INDIVIDUAL SPECIES.*

1. Ptycobarbus conirostris, D. 11, A. 8. Tibet.

1. Ptycobarbus conirostris, Plate CXXV, fig. 3.

Steind., Verh. zool.-bot. Ges. Wien, 1866, p. 789, t. 17, f. 4; Günther, Catal. vii, p. 169; Day, Proc. Zool. Soc. 1876, p. 789.

B. iii, D. $10 \binom{2}{8}$, P. 22, V. 10, A. 7-8, C. 19, L. 1. 95, L. tr. 24/-.

Length of head $4\frac{3}{4}$ to 5, of caudal $7\frac{1}{4}$, height of body $6\frac{3}{4}$ to $6\frac{3}{4}$ in the total length. Eyes—diameter from $4\frac{1}{4}$ to $5\frac{1}{4}$ in the length of head, 2 diameters from the end of snout, and $1\frac{1}{4}$ apart. The greatest width of the head is slightly less than its height, and equals its postorbital length. Month rather overhung by the snout: the maxilla reaches to below the front edge of the orbit. Lower labial fold very broad, uninterrupted. Barbels—a maxillary pair, which in the adult reach to the hind edge of the pre-opercle. Teeth—pharyngeal ones, 4, 3/3, 4. Fins—the dorsal situated midway between the snout and the base of the caudal fin, it has no osseous ray and is as high as the body below it. Pectoral as long as the head behind the nostril, and does not quite reach the ventral, which latter arises beneath the last few dorsal rays, and extends two-thirds of the distance to the base of the anal. Anal when laid flat reaches the base of the caudal, its base is $2\frac{1}{3}$ in its height. Scales—the tiled row small, not equalling 1/3 of the diameter of the eye. Colours—silvery, darkest on the back and upper half of the body, where most of the scales have dark edges. Upper surface of the

^{* 1.} Ptycobarbus laticeps, Day, Proc. Zool. Soc. 1876, p. 789, Plate CXXV, f. 1. D. 10, L. l. 145. One pair of maxillary barbels. Lower jaw somewhat the longer: head very broad and mouth wide. Last undivided dorsal ray weak, entire. From Kashgar.

Kashgar.

2. Ptycobarbus longiceps, Day, Proc. Zool. Soc. 1876, p. 790, and Fishes of Yarkand, Plate IV, f. 2, D. 12, A. 7, L. l. 112.

Last undivided dorsal ray osseous and feebly serrated. From Yarkand.

head spotted with black. Some dark spots on the dorsal fin, and sometimes a few light ones on the

Habitat.—Head waters of the Indus and Tibet.

Genus, 8-Diptychus, Steindachner.

Abdomen rounded: snout obtuse: mouth inferior, transverse, curved: lower jaw sharp, with an internal horny covering: lips continuous and having an uninterrupted labial fold across the mandible. Two maxillary barbels. Gill-opening narrow. Pharyngeal teeth compressed 4, 3/3, 4. Dorsal fin without osseous ray, commencing anterior to the ventrals: anal short: caudal forked. Scales small, not imbricate but scattered along the upper two-thirds of the body, the thoracic region, the sides and the tail, also a scaly sheath to the vent and base of the anal fin. Lateral-line continued to the centre of the base of the caudal.

Geographical distribution .- Tibet, Nepaul, and Yarkand.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Diptychus maculatus. D. 10-11, L. l. 80-90. Tibet, Nepaul, Yarkand.

1. Diptychus maculatus, Plate CXXIV, fig. 3.

Steind. Verh. zool.-bot. Ges. Wien, 1866, p. 788, t. 13, fig. 5; Günther, Catal. vii, p. 171; Day, Proc. Zool. Soc. 1876, p. 792.

? Diptychus Sewerzowi, Kess. Fish. Turkestan, p. 17, t. iv, f. 12.

B. iii, D. 10-11 $(\frac{2-3}{8-9})$, P. 19, V. 9, A. 7 $(\frac{2}{5})$, C. 19, L. 1. 80-90.

Length of head 5 to 6, of caudal 5 to 6, height of body $7\frac{1}{4}$ to 8 in the total length. Eyes—diameter $4\frac{1}{2}$ in the young to 6 in the adult in the length of the head, $1\frac{1}{4}$ to 2 diameters from the end of the snout, and 1 apart. The greatest width of the head equals its height or its length behind the front edge or middle of the eyes. Mouth inferior, transverse, having an anterior sharp horny covering to the lower jaw. Lower labial fold interrupted in the middle. Barbels—one on the maxilla hardly so long as the eye. Teeth—pharyngeal 4, 3/3, 4, crooked and pointed. Fins—dorsal as high as the body, it arises rather nearer the snout than the base of the caudal fin, its last undivided ray articulated. Pectoral not quite so long as the head and reaching rather above half way to the ventral, which latter commencing below the last dorsal ray extends half way to the anal. Height of anal nearly three times the length of its base, laid flat it reaches the caudal. Scales—scattered over the upper two-thirds of the body and pectoral region. Tiled row well-developed. Free portion of tail one half longer than high at its base. Colours—bluish, lightest inferiorly, indistinctly blotched and spotted in the upper half of the body: often a narrow dull band along the lateral-line, and a second below it. In some specimens the dorsal and caudal fins are much spotted.

Habitat.—Head waters of the Indus, Tibet, Nepaul, and affluents of the Yarkand river.

Genus, 9—LABEO, Cuvier.

Bangana, pt. Ham. Buch.: Rohita, pt. Cuv. and Val.: Tylognathus,* Heckel: Nandina, Gray: Hypselobarbus, Diplocheilus, Diplocheilichthys, Lobocheilus, Rohitichthys, Morulius, Schismatorhynchus, and Gobionichthys, Bleeker: Gobiobarbus, Dybowski.

Body moderately elongated, abdomen rounded, mouth sometimes auterior but mostly inferior, transverse, and semi-oval. Lips thick, covering the jaws, continuous at the angle of the mouth, and one or both having an inner transverse fold. A soft and moveable horny covering with a sharp margin on the inner side of one or both lips. Snout rounded, generally projecting beyond the mouth, mostly covered with tubercles, and sometimes having a lateral lobe or projection. Barbels when present, four or two: if only one pair they are on the maxilla, the second being on the snout, or they may be absent. \dagger Pharyngeal teeth hooked and in three rows, 5, 4, 2/2, 4, 5. Dorsal fin of moderate length or elongated, destitute of any osseous ray, and arising anterior to the commencement of the ventral. Anal short. Scales of large, moderate, or small size. Lateral-line running along the middle of the side of the tail. Gill-rakers usually short.

The horny layer, which is so common to the inside of the lips of the Schizothoracinæ is still perceptible in the fish of this Genus, in many of those of the plains taking on the character more of thin cartilaginous than The snout has sometimes a deep depression across it as observed in Discognathus. a horny covering.

The fins frequently increase in height and length more rapidly than do the proportions of the body; thus in adults we often perceive the upper edge of the dorsal fin more concave than in the young.

In some species having the least number of dorsal rays, the lips are much thinner than in the typical Labeos: should such have only two barbels they are maxillary, whereas in Cirrhinas they would be rostral.

* Dr. Günther (Catal. vii. p. 62), admitting the division of Tylognathus from Labeo is artificial, still adopts it for the following consistent reason, "by uniting these two Genera I should have been obliged to abandon the character of a long or short dorsal fin for the definition of other very natural Genera of Cyprinoids."

† As a rule the barbels in all specimens of a species are not subject to any variation in numbers, but L. angra appears to be an

Geographical distribution.—Tropical Africa, Syria, throughout the fresh-waters of India, Ceylon, and Burma, to the Malay Archipelago, &c.

SYNOPSIS OF SPECIES.

- Labeo nandina, D. 24-26, L. l. 42-44, L. tr. 6-7/8, 4 barbels. Bengal, Assam, and Burma.
 Labeo fimbriatus, D. 19-22, L. l. 44-47, L. tr. 9-10/8-9, 4 barbels. Sind, Punjab, Deccan, probably N. E. Bengal, Orissa, and Southern India.

3. Labeo nigrescens, D. 17-18, L. l. 36, L. tr. 6/7, 4 barbels. Nearly black. Canara.
4. Labeo calbasu, D. 16-18, L. l. 40-44, L. tr. 7½/8, 4 barbels. Slate colour. Throughout India and Burma.

5. Labeo Stoliczkæ, D. 17, L. l. 46-47, 2 maxillary barbels. Dark gray. Burma.

- 6. Labeo gonius, D. 16-18, L. l. 74-84, L. tr. 16/17, 4 barbels. Sind, Orissa, Bengal, N. W. Provinces, Assam, and Burma.

1. Labeo nandina, Plate CXXVI, fig. 1 and 2 (variety macronotus.)

Cyprinus nandina, Ham. Buch. Fish. Ganges, pp. 300, 388, pl. 8, f. 84.

Cirrhinus naudina and macronotus, McClell. Ind. Cyp. pp. 265, 269, 318, 319, pl. 41, f. 1.

Robita nandina, Cuv. and Val. xvi, p. 244, pl. 473.

Labeo nandina and macronotus, Günther, Catal. vii, pp. 51, 52.

Nandin, Beng.: Nga-ohn-don, Nga-ne-pyah, and Nga-yin-pounsa, Burmese.

B. iii, D. 24-26 $(\frac{2}{2}, \frac{3}{2}, \frac{4}{2})$, P. 15, V. 9, A. 7 $(\frac{2}{5})$, C. 19, L. 1. 42-44, L. tr. 6-7/8.

Length of head $4\frac{1}{2}$ to 5, of caudal $4\frac{1}{4}$ to $4\frac{1}{4}$, height of body 4 in the total length. Eyes—diameter Length of head $4\frac{1}{2}$ to 5, of caudal $4\frac{1}{4}$ to $4\frac{1}{2}$, height of body 4 in the total length. Eyes—diameter $4\frac{1}{4}$ to 5 in length of head, $1\frac{1}{4}$ diameters from end of snout, and $2\frac{1}{4}$ apart. Dorsal profile rather concave above the eyes: interorbital space flat. The greatest width of the head equals its length behind the angle of the mouth: the width of the mouth 1/3 of the length of the head. Snout obtuse, slightly projecting beyond the jaws, no lateral lobe: a few fine pores on snout. Lips thick and fringed, with a distinct inner fold above and below. Gill-rakers close together, about 1/3 as long as the eye. Barbels—four, and short. Fins—the dorsal commences midway between the snout and end of the base of the anal fin: its upper edge is somewhat convex. Ventral inserted below the ninth dorsal ray. Caudal deeply forked. Lateral-line—5 rows of scales between its conditions of the sides and kengethy a few elevely. and base of ventral fin. Colours-dark greenish above, becoming lighter on the sides and beneath: a few cloudy blotches along the sides: the centre of many of the scales reddish.

Variety Labeo macronotus, fig. 2. The eye in this form is about 2 diameters from the end of snout, and 3 apart. The gill-rakers are likewise a little shorter and more widely placed. The number of dorsal rays appears to equally vary in both varieties.

Habitat.—Bengal, Assam, and Burma. The specimen of L. nandina, figured, was from Gowhatty in Assam: the one of L. macronotus was from Moulmein in Burma. I have obtained it as high up the Irrawaddy as Mandalay.

2. Labeo fimbriatus, Plate CXXVI, fig. 3.

Cyprinus fimbriatus, Bloch, xii, p. 50, pl. 409; Bl. Schn. p. 441.

Cirrhinus fimbriatus and Leschenaultii, Jerdon, M. J. L. and Sc. 1849, pp. 304, 305.

Labeo fimbriatus and Leschenaultii, Günther, Catal. vii, p. 53. Ven-candee, Tam.: Ruchu and Gandumenu, Tel.: Bahrum, Ooriah.

B. iii, D. 19-22 $\left(\frac{3-4}{16-18}\right)$, P. 17, V. 9, A. 7 $\left(\frac{2}{5}\right)$, C. 19, L. l. 44-47, L. tr. 9-10/8.

Length of head $6\frac{1}{4}$ to $6\frac{1}{2}$, of caudal 4 to $4\frac{1}{2}$, height of body 4 to $4\frac{1}{2}$ in the total length. Eyes—diameter $3\frac{3}{4}$ to $4\frac{1}{2}$ in the length of head, $1\frac{1}{4}$ to $1\frac{1}{2}$ diameters from the end of snout, and 2 apart. Dorsal profile more convex than that of the abdomen. The greatest width of the head equals its length excluding the snout. Width of the mouth $3\frac{1}{2}$ in the length of the head, and slightly overhung by the snout which is obtuse, rather swollen and studded with minute pores, but destitute of a lateral lobe. Lips thick, continuous and having an inner fold above and below, both fringed. A cartilaginous layer on the inner side of both jaws. Barbels—rostral and maxillary pairs short. Teeth—pharyngeal, 5, 3, 2/2, 3, 5. Fins—dorsal commences somewhat nearly as long as the head, it does not reach the ventral. The ventral nearly extends to the anal, and the latter to the coulds. Candal deeply forked. Lateral line, for 7 rows of available terms it and the lateral to the coulds. to the caudal. Caudal deeply forked. Lateral-line—6 or 7 rows of scales between it and the base of the ventral fin. Colours—silvery along the back, becoming lighter on the sides and beneath. Fins, more especially the ventral, anal, and lower caudal lobe, stained with black. Sometimes a diffused dark blotch at the base of the

caudal, and which is almost invariably present in the young.

The only difference observed between L. nancar, H.B. and L. fimbriatus, Bloch, is that the former is said

to have "the edges of the lips smooth."

Habitat.—Sind, Punjab, the Deccan, and probably N. E. Bengal; also Southern India at least to Orissa, not recorded from Malabar or Canara. It attains a foot and a half in length, and is good eating, but bony.

3. Labeo nigrescens, Plate CXXVII, fig. 2.

Day, Proc. Zool. Soc. 1870, p. 371. Mul-vel and Kurri-minu, Canarese.

B. iii, D. 17-18($\frac{2}{14}$, $\frac{3}{15}$), P. 19, A. $7(\frac{2}{5})$, C. 19-21, L. l. 36, L. tr. 6/7.

Length of head 5, of caudal $4\frac{1}{2}$ to 5, height of body $3\frac{1}{2}$ in the total length. Eyes—diameter 4 to 5 in the length of head, 2 diameters from the end of snout and also apart. The greatest width of the head equals its length excluding the snout, which last is rather swollen and rounded, and somewhat projecting over the lower jaw; a small lateral lobe; glands over the whole of the snout. A very distinct labial fold both above and below: a deep transverse groove across the chin: lower lip deeply fringed. Barbels—the maxillary ones as long as the orbit, the rostral rather shorter. Fins—upper edge of the dorsal fin nearly straight, it commences midway between the front end of the snout and of the base of the analysis to the rost of the snout and the posterior end of the base of the analysis to the conditions of the snout and the posterior end of the base of the snout and the snout and the snout and the snout and snow the fourth dorsal for snow a snow that the snow that t reaches to above the ventral, the latter, which is inserted beneath the fourth dorsal ray, reaches to the anal. Anal rather elongated anteriorly, being 3/5 higher than its base is long, and if laid backwards it reaches the base of the caudal, which latter fin is deeply forked. $Scales-4\frac{1}{2}$ rows between the lateral line and base of the ventral fin. Colours—deep brown, each scale with a black spot at its base. Fins black.

Habitat.—Mangalore and South Canara. It is said to attain 18 inches in length.

4. Labeo calbasu, Plate CXXVI, fig. 4.

Nulla-gandu-menu, Telugu: Kalbasu and Kundna, Beng. and Cuggera (Soane): Mahlee, Assam: Kalabeinse, Ooriah and Hind.: Di, Punj.: Di-hee, Sind: Dai, Cutch: Kurri-minu, Canarese: Nga-nek-pya, Nganoo-than, and Nga-ong-tong, Burmese.

B. iii, D. $16-18(\frac{3}{13},\frac{3}{13})$, P. 19, V. 9, A. $7(\frac{2}{5})$, C. 19, L. 1. 40-44, L. tr. $7\frac{1}{2}/8$.

Length of head 5 to 6, of caudal 4 to 5, height of body 4 in the total length. Eyes—diameter 4 to 5 in the length of the head,* 1½ to 2 diameters from end of snout, and 2½ apart. Interorbital space nearly flat: width of head equals its length excluding the snout. Mouth rather narrow: snout obtuse and depressed, destitute of a lateral lobe but with pores. Lips thick, fringed (more especially the lower one), and each having a distinct inner fold. Gill-rakers very short. Barbels—four, the rostral slightly the longer, and about equal in length to the diameter of the orbit. Teeth—pharyngeal, crooked, 5, 4, 2-2, 4, 5. Fins—dorsal commences in advance of the ventrals, and midway between the snout and base of the caudal, its upper margin somewhat concave. Ventral commences below the fourth or fifth dorsal ray. Caudal deeply forked. Lateral-line—5½ to 6 rows of scales between it and the base of the ventral fin. Colours—blackish: sometimes, especially in examples from clear streams, many of the scales have a scarlet centre. Fins black, occasionally the end of the upper lobe of the caudal white.

In some districts, adults have very elongated fins, the first few dorsal rays reach even to the base of the caudal, the ventral extends to the end of the base of the anal, whilst the anal when laid flat reaches the middle of the caudal.

Habitat.—Punjab, Sind, Cutch, Deccan, Southern India and Malabar, from the Kistna through Orissa, Bengal, and Burma. It grows to 3 feet in length: were it not for its numerous bones, it would be excellent eating.

5. Labeo Stoliczkæ, Plate CXXXV, fig. 1.

Length of head $4\frac{1}{3}$, of caudal $4\frac{3}{4}$, height of body 4 in the total length. Eyes—diameter $3\frac{1}{2}$ to 4 in the length of head, about 1 diameter from end of snout, and 2 apart. The greatest width of the head equals its length excluding the snout: interorbital space flat. Snout not swollen, destitute of a lateral lobe, and not overhanging the upper jaw. A deep groove across the chin, with a distinct labial fold. Lower lip very finely fringed. Pores on the snout. Barbels—a very short maxillary pair concealed in the labial fold. Fins—upper edge of dorsal fin concave, it commences midway between the end of the snout and the posterior extremity of the base of the anal fin, it is 2/3 as high as the body below it, and the length of its base equals its greatest height. Pectoral as long as the head excluding the snout: ventral inserted below the fifth dorsal ray. Anal laid flat does not reach the caudal, which is forked. Lateral-line—7 to 8 rows of scales between it and the base of the ventral fin. Colours—of a deep leaden-silvery along the upper half of the body, white shot with gold beneath. A black mark behind the gill-opening.

Habitat.—Irrawaddy river, and also Moulmein. The specimen figured (life-size) was from Prome.

6. Labeo gonius, Plate CXXVII, fig. 1.

Length of head 5 to $5\frac{1}{2}$, of caudal 5 to $5\frac{1}{2}$, height of body 4 to $4\frac{1}{2}$ in the total length. Eyes—diameter $4\frac{1}{2}$ to 5 in the length of the head, $1\frac{1}{2}$ diameters from the end of snout, $2\frac{1}{2}$ apart. Dorsal profile more convex than that of the abdomen. The greatest width of the head equals its length excluding the snout. Mouth than that of the addomen. The greatest width of the head equals its length excluding the shout. Mouth rather narrow, its width equalling $3\frac{1}{2}$ in the length of the head: no lateral lobe, but numerous pores on the snout. Lips thick, and with a distinct inner fold in their entire circumference, both of which are fringed. A cartilaginous covering to inner side of both jaws. Barbels—rostral and maxillary ones present but short. Teeth—pharyngeal, plough-shaped, 5, 4, 2/2, 4, 5. Fins—the dorsal commences much nearer the snout than the base of the caudal fin, it is 2/3 as high as the body, and its upper edge is concave. Pectoral nearly or as long as the head. Ventral commences under the middle of the dorsal. Caudal deeply forked. Lateral-line—

Digitized by Google

[•] In specimens 31 inches long, the eye is at least 1/3 of the length of the head, and the upper edge of the dorsal tin

from 10 to 13 rows of scales between it and the base of the ventral fin. Colours—greenish along the back becoming lighter on the sides, scales darkest at their margins, many having red lunules on them.

In his MS. list of fish of the Rangpur district Hamilton Buchanan observes "the Kurchha of Goalpara,

by the people of Assam is called Ghoni."

This fish is extensively used for the purpose of stocking tanks, and the four species mentioned by Hamilton Buchanan, I consider as varieties of one. At Calcutta the form L. gonius is most common with D. 2/13, but I have seen two specimens with D. 9/14 from that locality. In Orissa and Ganjam the rows of scales along the lateral-line are about 74, with only about 9 rows of scales between the lateral-line and base of the ventral To the north, as at Scharanpore, the scales along the lateral-line only number 71, whilst there are 10 or 11 rows between it and the base of the ventral fin. In the Brahmaputra the form L. gonius is found as high as Gowhatty, where it mostly has D. $\frac{2}{14}$, with it is another form G. cursis with D. $\frac{2}{14}$, a rather higher body than is normal, and the scales in rather irregular rows, and some red spots on the sides, it has about 15 rows of scales

between the lateral-line and base of the ventral fin.

Habitat.—Indus in Sind, through the N.W. Provinces, Bengal, and Orissa to Ganjam, as low as the

Kistna: Assam and Burma. It attains nearly 5 feet in length.

Length of head $5\frac{3}{4}$ to 7, of caudal $4\frac{1}{2}$, height of body above 5, of dorsal fin 9 in the total length. Eyes—diameter 4 to $4\frac{1}{2}$ in length of head, $1\frac{1}{2}$ diameters from end of snout, and 3 apart. Interorbital space slightly convex. Body elongated and compressed, the abdominal profile rather more convex than the dorsal. Width of head equals its length behind the angle of the mouth. Mouth of moderate width and somewhat inferior, surrounded by fleshy, fringed lips, having a distinct inner fold above and below, but no lateral lobe. Sometimes numerous pores on the snout, extending posteriorly as far as the orbits, and below the nostrils. Barbels—four, minute. Gill-rakers very short. Fins—dorsal commences midway between the end of the snout, and end of base of anal fin, it is slightly in advance of the ventrals; its upper edge concave. Caudal very deeply forked. Lateral-line—5 or 5½ rows of scales between it and the base of the ventral fin. Colours—grayish, lightest beneath, scales with a reddish centre, edged with a darker shade. Usually a dull diffused dark spot on either side of the tail. Fins dusky.

Hubitat.—Rivers of South Malabar, Ceylon, and perhaps Bombay. It attains at least 13 inches in

8. Labeo rohita, Plate CXXVII, fig. 4.

Length of head $4\frac{1}{2}$ to 5, of caudal $4\frac{1}{2}$, height of body $4\frac{1}{3}$ in the total length. Eyes—diameter 4 to 6 in the length of the head, $1\frac{3}{4}$ to 2 diameters from end of snout, and 3 apart. Interorbital space flat. Dorsal profile more convex than that of the abdomen, it is somewhat concave over the orbit. The greatest width of the head equals its length excluding the snout. Width of mouth $3\frac{1}{4}$ in the length of the head. Snout obtuse, depressed, not or scarcely swollen, but projecting beyond the jaws: no lateral lobe: lips rather thick, fringed, and with a distinct inner fold above and below. Gill-rakers rather stiff, not closely set, about half as long as the eye. Barbels—a short and thin maxillary pair. A rostral pair are said to be sometimes present. Teeth—pharyngeal, plough-shaped, 5, 4, 3/3, 4, 5. Fins—the dorsal arises about midway between the snout and base of the caudal fin, it is not quite so high as the body, and its upper edge is moderately concave. Pectoral as long as the head excluding the snout. Ventral inserted below the third or fourth dorsal ray. Caudal deeply forked. Lateral-line—6 to 6½ rows of scales between it and base of ventral fin. Colours—bluish or brownish along the back, becoming silvery on the sides and beneath; sometimes there is a red mark on each scale. specimens the fins are black.

Habitat.—Fresh-waters of Sind, and from the Punjab through India and Assam to Burma. It is not found in Madras or the Western coast. It attains 3 feet or more in length. It is esteemed excellent as food, and propagated with care in ponds in Bengal.

9. Labeo porcellus, Plate CXXVIII, fig. 1.

Tylognathus porcellus, Heckel, in Hügels Kashmir, iv, p. 385. Labeo porcellus, Günther, Catalogue, vii, p. 54.

Length of head 6, of caudal $4\frac{1}{2}$, height of body $4\frac{1}{2}$ in the total length. Eyes—diameter 5 in the length of head, 2 diameters from the end of snout and also apart. Interorbital space rather convex. Dorsal profile rather more convex than that of the abdomen. The greatest width of the head equals its length excluding the snout. Width of the mouth equals 2/5 of the length of the head. Snout rather projecting. Lips thick, with a distinct inner fold to both jaws, which have each a thin cartilaginous internal covering. Gill-rakers small and rather closely set. Barbels—four, the maxillary rather longer than the rostral pair. Fins—dorsal not quite so high as the body, it commences somewhat in advance of the ventral, and midway between the snout and the posterior end of the base of the anal fin, its upper edge is rather concave. Pectoral as long as the head: ventral rather shorter. Caudal forked. Lateral-line—5 rows of scales between it and the base of the ventral fin. Colours—grayish superiorly, becoming dull white on the sides and beneath: most of the scales darkest at their edges. A dark spot, usually present, at the base of the caudal fin. A bluish spot behind the centre of the opercle, and which may be continued on to the shoulder. Fins grayish, darkest along their centres.

Habitat.—Poona and Bombay. The specimen figured (life-size) was from Poona.

10. Labeo potail, Plate CXXVII, fig. 3.

? Cyprinus potail, Sykes, Trans. Zool. Soc. ii, p. 354; Jerdon, M. J. L. and Sc. 1849, p. 302. Lewiscus potail, Bleeker, Beng. p. 25. Labeo potail, Day, Trans. Linn. Soc. Zool. 1876, p. 572. Dotondi, Mahr.

B. iii, D. 13-14 $\left(\frac{2}{11-12}\right)$, P. 17, V. 9, A. 7 $\left(\frac{2}{5}\right)$, C. 19, L. 1. 39-40, L. tr. 8/7.

Length of head $5\frac{1}{2}$, of caudal 4 to $4\frac{1}{2}$, height of body 4 to $4\frac{1}{2}$ in the total length. Eyes—situated in the commencement of the posterior half of the head, from 4 to 6 diameters in the length of the head. Interorbital space convex, and its width equals half the length of the head. Dorsal profile rather more convex than that of the abdomen. The greatest width of the head equals two-thirds of its length. Mouth narrow, its width being equal to 1/3 of the length of the head. Snout overhanging the mouth, with a slightly produced lateral-lobe: lower labial fold entire, a deep groove existing across the chin. Snout smooth, or with fine pores. A cartilaginous layer to inner side of both jaws. Barbels—a maxillary pair. Fins—dorsal commences rather nearer the snout than the base of the caudal fin, its upper margin is a little concave: the height of the fin two-thirds that of the body. Pectoral nearly as long as the head, and equals that of the ventral. Anal much highest anteriorly: caudal deeply forked, upper lobe the longer. Lateral-line— $5\frac{1}{2}$ rows of scales between it and base of the ventral. Colours—grayish, each scale with a red lunule, fins stained gray along their edges, and dorsal along its centre.

Sykes says C. potail has D. 13 $(\frac{3}{10})$, P. 14, no barbels. But I think he alluded to this species, which comes from the same locality.

Habitat.—Deccan, from Poona to the Tamboodra river. The specimen (10 inches long) was from Poona.

11. Labeo kontius, Plate CXXVII, fig. 5.

Cyprinus kontius, Jerdon, M. J. L. and Sc., 1849, p. 302. Cirrhinus rubro-punctatus, Jerdon, loc. cit. p. 303. Labeo kontius, Day, Proc. Zool. Soc. 1867, p. 289; Günther, Catal. vii, p. 55. Currumunnee candee and Curoo-moolee-candee, Tam.

B. iii, D. $15-16(\frac{3-4}{12-13})$, P. 15, V. 10, A. $7(\frac{9}{5})$, C. 19, L. 1. 38-41, L. tr. 7/8.

Length of head 6 to 7, of caudal $4\frac{1}{2}$, height of body $3\frac{3}{4}$ to 4 in the total length. Eye—in the immature it is usually in the middle of the length of the head, in the adult in the commencement of its last half, diameter $4\frac{3}{4}$ to 5 in the length of the head, 2 to $2\frac{1}{2}$ diameters from the end of snout, and $2\frac{1}{4}$ to $2\frac{1}{2}$ apart. Profile above the eyes rather concave, the interorbital space nearly flat: the greatest width of the head equals 3/4 of its length. Dorsal profile more convex than the abdominal. Muzzle blunt, truncated, covered with pores, and having a short fleshy lateral prolongation. Width of mouth $2\frac{1}{3}$ in the length of the head. Lips thick, with a distinct inner fold below, whilst the lower one is fringed. Snout overhanging the mouth. Gill-rakers widely set and about 1/3 of the diameter of the eye in length. Barbels—four, short. Teeth—pharyngeal, plough-shaped, 5, 4, 2-2, 4, 5. Fins—dorsal commences midway between the snout and hind end of the base of the anal, its upper margin is concave. Pectoral reaches to nearly above the ventral, whilst the latter does not reach the anal. Caudal deeply forked. Lateral-line—5 rows of scales between it and the base of the ventral. Colours—a general reddish or fleshy tinge, darkest along the back. In most of the specimens obtained from the Coleroon river, each scale had a red centre.

Habitat.—Rivers along the base of the Neilgherries, and the Cauvery and Coleroon in all their branches down to the coast. It grows to two feet in length.

3 z 2

12. Labeo caruleus, Plate CXXIX, fig. 3.

B. iii, D. $14(\frac{9}{12})$, P. 18, V. 9, A. $7(\frac{9}{5})$, C. 19, L. 1. 40, L. tr. 6/11.

Length of head $4\frac{3}{4}$, of caudal $4\frac{1}{2}$, height of body 4 in the total length. Eyes—4 diameters in the length of head, 1 diameter from the end of snout, and 2 apart. Interorbital space slightly convex. The greatest width of the head equals its length excluding the snout. Mouth narrow, its width equalling 2/7 of the length of the head. Snout overhanging the mouth: no lateral lobe. Lips continuous, and having a distinct inner fold in their entire circumference: both lips fringed. A horny inner covering to either lip. Barbels—no rostral ones, a short pair to the maxilla. Fins—dorsal arises anterior to the ventral, and slightly nearer to the end of the snout than the base of the caudal fin, anteriorly 2/3 as high as the body, its upper edge concave. Pectoral as long as the head excluding the snout, it does not reach the ventral nor the latter the anal. Anal when laid flat reaches the base of the caudal which is deeply forked. Lateral-line—6 rows of scales between it and the base of the ventral fin. Colours—bluish with a yellowish tinge on the sides and beneath. Onter half of anal nearly black, and a blackish lunule on the caudal.

Habitat.—River at the base of the Sind Hills. A single specimen obtained, which is figured life-size.

Nepura, Assam: Kul-ka-batta, Beng.: Gid and Giddah, Puni.: Mohaylee, Hind. (Hurdwar) and Gaywah.

Nepura, Assam; Kul-ka-batta, Beng.; Gid and Giddah, Punj.; Mohaylee, Hind. (Hurdwar) and Gaywah, Scharanpore.

B. iii, D. 12-13 $\left(\frac{2-5}{9-10}\right)$, P. 17, V. 9, A. 7 $\left(\frac{2}{5}\right)$, C. 19, L. 1. 41-44, L. tr. 8/9.

Length of head $5\frac{1}{2}$ to $6\frac{1}{4}$, of caudal 5, height of body 5 to $5\frac{1}{2}$ in the total length. Eyes—situated either in, or (in the young) rather before the middle of the length of the head, diameter 5 to $6\frac{1}{4}$ in the total length of head, and $2\frac{1}{2}$ to 3 diameters apart. Greatest width of the head equals its length excluding the snout. Dorsal profile more convex than that of the abdomen. Mouth rather narrow, snout overhanging the jaws, generally with a groove across it, and covered with pores: no lateral lobe. Lips thick and continuous, but the fold across the lower jaw is interrupted. A cartilaginous layer on inside of both lips. Gill-rakers, closely set, about 1/3 as long as the eye. Barbels—a small maxillary pair. Teeth—pharyngeal, plough-shaped, 5, 4, 2/2, 4, 5. Fins—dorsal arises midway between the front of the snout and the end of the base of the anal fin, its upper edge is slightly concave in the young, becoming deeply so in the adult. Pectoral does not extend to the ventral, nor the latter to the anal. Caudal deeply forked, the upper lobe the longer: its central rays being about 1/3 the length of the outer ones in the young, 2/7 in the adult. Scales—6 to 7 rows between the lateral-line and base of the ventral fin. Colours—grayish, darkest along the back, each scale tinged with red: a darkish band along the side, or short gray bars passing to the lateral-line.

Fins with a faint reddish hue. Outer edge of dorsal rather stained.

Hamilton Buchanan l.c. observes of C. dero "at each corner of the mouth is a minute tendril," thus showing the figure to be incorrect on this point. I have the young from Goalpara having the same proportions as given in H. B.'s figure. The specimen in the British Museum, Catal. of Cirrhina dyochila, "a. 41 inches long.

Cachar," is likewise identical.

Habitat.—Along the Sind hills and Himalayas, also in the Brahmaputra in Assam.

14. Labeo dyocheilus, Plate CXXX, fig. 1.

Cyprinus dyocheilus, McClelland, Ind. Cyp. pp. 268, 330, t. 37, fig. 1; Cuv. and Val. xvi, p. 461. ? Gobio bicolor, McClelland, l. c. pp. 278, 360, t. 40, f. 1; Cuv. and Val. xvi, p. 462.

Cirrhina dyocheilus, Günther, Catal. vii, p. 37.

Labeo falcatus, Günther, Catal. vii, p. 58 (not Bloch, or Gray and Hardwicke). Boalla, Hind.; Heel-gorya, Assamese; Nu-ga-dee, Sind.

B. iii, D. 13 $(\frac{2}{11})$, P. 17, V. 9, A. 7 $(\frac{2}{5})$, C. 19, L. l. 43, L. tr. $8\frac{1}{2}/7\frac{1}{2}$.

Length of head 5 to $5\frac{1}{2}$, of caudal $5\frac{1}{2}$, height of body $3\frac{3}{4}$ to $4\frac{1}{2}$ in the total length. Eyes—situated in the commencement of the posterior 1/2 of the head in the young, still further back in the adult: diameter from 6 to 9 in the length of the head, and from $3\frac{1}{2}$ to 5 apart. Width of head equals 2/3 of its length: its lower surface being very broad and flat. Snout conical, projecting, and with a distinct lateral lobe (in General

Hardwicke's figure there is a depression across the snout.) Mouth wide, equalling 1/2 to 2/5 the length of the head, it is directed downwards when the upper jaw is protruded. Lips of two jaws continuous, the fold across the lower jaw is interrupted. A horny inner covering to both lips. Pores on snout. Gill-rakers short. Barbels—one pair of short maxillary ones. Teeth—pharyngeal, plough-shaped, 5, 4, 3/3, 4, 5. Fins—dorsal commences midway between the end of the snout and the posterior end of the base of the anal fin, its upper margin concave, especially in the adult. Pectoral reaches the ventral, and the latter the base of the anal. Caudal deeply forked, its inner rays equalling about 1/3 of the length of the outer ones. Lateral-line—5 rows of scales between it and the base of the ventral fin. Colours—of a dull green, darkest above: fins darkest in the centre.

I have Sind specimens in which there exists a depression across the snout.

Habitat.—Sind hills and along the Himalayas to Sikkim and Assam. It is common in Assam. It attains at least 3 feet in length.

15. Labeo pangusia, Plate CXXXI, fig. 1.

Cyprinus pangusia, Ham. Buch. Fishes of Ganges, pp. 285, 386; Cuv. and Val. xvi, p. 429. Gobio pangusia, McClell. Ind. Cyp. pp. 279, 362, pl. 42, f. 1 (from H. B.'s MSS.) Labeo pangusia, Günther, Catal. vii, p. 58. Loannee, Beng.

B. iii, D. 13 $(\frac{2}{11})$, P. 15, V. 9, A. 7 $(\frac{2}{5})$, C. 19, L. 1. 40-42, L. tr. $7\frac{1}{2}/8$.

Length of head $5\frac{2}{3}$ to 6, of caudal $4\frac{1}{2}$ to 5, height of body $4\frac{1}{2}$ in the total length. Eyes—diameter $4\frac{1}{2}$ to $5\frac{1}{2}$ in the length of the head, and in or rather behind the middle of the length of the head. Dorsal profile more convex than that of the abdomen: body rather compressed. The greatest width of the head equals 2/3 of its length. Mouth narrow, its width equal to 3\frac{3}{4} in the length of the head. Snout obtuse, projecting over the jaws and having a very distinct lateral lobe. Lips not fringed, but thick, with a distinct inner fold which is not continued across the lower jaw. Snout covered with large pores. A cartilaginous covering to inner surface of both lips. Gill-rakers short and closely set. Barbels—a short maxillary pair, concealed in the labial fold. Teeth—pharyngeal, plough-shaped, 5, 4, 3/3, 4, 5. Fins—dorsal commences nearer the snout than the base of the caudal, it is nearly or quite as high as the body, and in the adult its upper edge is concave. Pectoral does not quite reach the ventral, nor the latter the and. Caudal deeply forked. Lateral-line—5½ to 6 rows of scales between it and the base of the ventral fin. Colours—of a dull green, becoming lighter on the sides and beneath, sometimes the base of each scale has a dark mark.

There is a variety of this fish at Scharanpore with a much higher body.

Habitat.—Himalayan range and generally through Sind, the Deccan, N. W. Provinces, to Bengal, Cachar and Assam. I have obtained it in the Himalayas at Kangra, and as high in Assam as Suddya.

16. Labeo angra, Plate CXXVIII, fig. 2.

Cyprinus angra, Ham. Buch. Fish. Ganges, pp. 331, 391.
? Cyprinus morala, pausius and musika, Ham. Buch. 1. c. pl. 18, f. 91, and pp. 332, 392; Cuv. and Val. xvi, p. 439.

Cyprinus (Bangana) Hamiltonii, Gray and Hard. Ill. Ind. Zool. (from H. B.'s MSS.)

? Gobio angra, Cuv. and Val. xvi, p. 319 (not McClelland).

Gobio boga, Bleeker, Beng. en Hind. p. 134.

Labeo morala, Günther, Catal. vii, p. 56.

Nga-loo, Burmese; (Khārsá, Hind. at Purniah; Mochhna on the Mahanunda, H. B.'s MSS.)

B. iii, D. 12-13 $(\frac{2-1}{10})$, P. 16, V. 9, A. 7 $(\frac{2}{3})$, C. 19, L. 1. 42, L. tr. 7/8.

Length of head $5\frac{3}{4}$, of caudal $4\frac{1}{3}$, height of body $5\frac{1}{4}$ in the total length. Eyes—diameter $3\frac{1}{4}$ to $4\frac{1}{2}$ in the length of the head, $1\frac{1}{4}$ to $1\frac{3}{4}$ diameters from the end of the snout, and 2 to $2\frac{1}{4}$ apart. Dorsal profile a little more convex than that of the abdomen. Snout overhanging the jaws, having a distinct lateral lobe on either side, and studded with pores. Mouth rather narrow, the lips continuous and with a deep groove across the chin: both lips fimbriated. Barbels—no rostral, but a short maxillary pair. Fins—dorsal as high as the body, arising rather nearer the snout than the base of the caudal fin, its upper edge concave. Pectoral nearly as long as the head. Ventral inserted beneath the first third of the dorsal. Caudal deeply forked. Lateral-line-5½ rows of scales between it and the base of the ventral fin. Colours—brownish along the back, with a black or bluish stripe passing from the eyes to the base of the caudal fin, where it ends in a black blotch. In Burmese examples the black lateral band is wanting, but the blotch at the side of the tail is present, and some have a second blotch at the commencement of the lateral-line. Instead of a maxillary barbel there exists

a fleshy flap inside the groove.

Gobio angra, McClelland (pp. 277, 354) is said to have D. 10, L. 1. 35, L. tr. 14 to base of ventral fin; the specimen, from which his description was drawn up, was apparently Cirrhina reba, which frequently in Assam has a dark line along the body and is termed Lasseem, which McClelland observes was the name of his

fish.

Hamilton Buchanan divided C. morala from C. angra, as in the latter the eyes are red, the minute first

dorsal ray is wanting, and it has two instead of four barbels. The long barbels shown in the figure are evidently due to an artistic error, as he says, "the tendrils are minute;" and in his MSS. he observes that one species scarcely differs from the other "in anything but the colours.

The specimen of Tylognathus boga, "a. young. River Hooghly," mentioned in the British Museum

Catal. vii, p. 64, is this species.

Habitat.—Assam, Bengal, and Orissa. Also Mandalay in upper Burma, and Sittoung in British Burma.

17. Labeo bata, Plate CXXIX, fig. 5.

Cyprinus bata, acra and cura, Ham. Buch. Fish. Ganges, pp. 283, 284, 386: Cuv. and Val. xvi, pp. 427, 428

Gobio lissorhynchus and anisurus, McClelland, Ind. Cypr. pp. 277, 278, 355, 360, pl. 40, f. 2, and pl. 55, f. 5; Cuv. and Val. xvi, p. 463.

Cirrhina anisura, Šteind., Sitz. Ak. Wiss., Wien, 1867, lvi, p. 66; Günther, Catal. vii, p. 37.

Crossocheilus bata, Day, Proc. Zool. Soc., 1869, p. 371.
Dunguda-porah, Ooriah: Dommarci-batta, Beng.; Gootellah, Hind.: Bango, N.W. Prov.: Tchirri, Cutch. B. iii, D. 11-12 $\binom{2-3}{6-10}$, P. 18, V. 9, A. $7\binom{2}{6}$, C. 19, L. 1. 37-40, L. tr. 7/6-7.

Length of head $5\frac{1}{2}$ to $5\frac{3}{4}$, of caudal 5 to $5\frac{1}{2}$, height of body $4\frac{1}{3}$ to $4\frac{3}{4}$ in the total length. Eyes—diameter 4 to $4\frac{1}{3}$ in the length of head, $1\frac{1}{4}$ to $1\frac{1}{3}$ diameters from the end of snout, 2 to $2\frac{1}{2}$ apart. The dorsal profile more convex than that of the abdomen: the greatest width of the head equals its length excluding the snout. The width of the mouth equals $3\frac{1}{3}$ in the length of the head, and in the adult is about three times as wide as the cleft is deep: snout slightly in advance of the jaws in the young but hardly so in the adult, when it is often covered with pores. Lips thin, continuous, the lower reflected from off the mandible, and with a shallow groove along its hind edge. A tubercle inside lower jaw above the symphysis. No horny covering inside jaws. Barbels—a pair of very short maxillary ones. Teeth—pharyngeal, plough-shaped or molariform, 5, 3, 2/2, 3, 5. Fins—the dorsal as high as the head is long, and with a concave upper edge, it commences slightly nearer the end of the snout than the base of the caudal fin. Pectoral about as long as the head and reaches the ventral which is rather shorter. Caudal deeply forked. Lateral-line—5½ rows of scales between it and the base of the ventral fin. Colours-vary with the age of the fish: generally silvery, darkest along the back, and with the lower fins stained orange: fine black dots on all the fins. When about four inches long, there are three or four small black spots on the fifth and sixth scales of the lateral-line, which gradually and almost entirely fade as age advances.

I have obtained a variety in Assam with the same number of rays and scales, but a more prominent snout, and with the lower lip fimbriated.

Habitat.—From the Kistna and Godavery rivers, through Orissa, Lower Bengal, and Assam. As this fish (which attains nearly two feet in length) is extensively used for stocking tanks, it is not improbable, as suggested by McClelland, that the three varieties mentioned by Hamilton Buchanan refer to one species.

18. Labeo microphthalmus, Plate CXXXII, fig. 4.

Labeo diplostomus, Beavan, Proc. Zool. Soc. 1872, p. 150, c. fig. (not Heckel).

B. iii, D. $13(\frac{3}{10})$, P. 18, V. 9, A. $7(\frac{2}{5})$, C. 19, L. 1. 41-43, L. tr. 8/9.

Length of head 6, of caudal $4\frac{2}{3}$ to 5, height of body $5\frac{1}{4}$ to $5\frac{3}{4}$ in the total length. Eyes—diameter $5\frac{1}{2}$ in the length of the head, 2 diameters from the end of snout, and 21 apart. Dorsal profile more convex than that of the abdomen. Snout overhanging the mouth, but not swollen, having a very indistinct lateral lobe: some specimens have a few small pores on the snout. Lips continuous: the groove across the lower jaw interrupted: mouth transverse, inferior: a cartilaginous or horny covering to inside of the lower jaw. The suborbital ring of bones comparatively wide being 2/3 that of the orbit. Barbels—a short maxillary pair. Teeth—pharyngeal, plough-shaped 5, 4, 2/2, 4, 5. Fins—the height of the dorsal equals or exceeds the length of the head, its upper edge is very concave, it arises midway between the end of the snout and the posterior extremity of the base of the anal fin. Pectoral does not reach the ventral. Caudal deeply forked. Scales $6\frac{1}{2}$ rows between the lateral-line and base of the ventral fin. The scales covering the thorax are very small, Colours—silvery, darkest in the upper half of the body: sometimes the scales are marked with red.

Lieut. Beavan's specimen from Murree of L. diplostomus is the above species, it is named in MSS.

Labeo Jerdoni, at the British Museum.

Habitat.—Himalayas, from the Punjab, Murree and Kangra, also Cashmere.

19. Labeo boggut, Plate CXXVIII, fig. 4.

Chondrostoma boggut, Sykes, Trans. Zool. Soc. ii, p. 359; Bleeker, Beng. p. 25; Jerdon, M. J. L. and Sc. 1849, p. 309.

Tylognathus striolatus, Günther, Catal. vii, p. 62.

Kolees, Mahr.: Loi, Cutch.

B. iii, D. $11-12(\frac{3}{8-9})$, P. 17, ∇ . 9, A. $7(\frac{2}{5})$, C. 19, L l. 60-65, L. tr. 11-12/14.

Length of head $5\frac{1}{2}$ to 6, of caudal $4\frac{1}{2}$, height of body $5\frac{1}{2}$ to $6\frac{1}{4}$ in the total length. Eyes—diameter $4\frac{1}{2}$ to 5 in the length of head, $1\frac{1}{2}$ to $1\frac{3}{2}$ diameters from the end of snout, and 2 apart. Dorsal profile rather

more convex than that of the abdomen. The greatest width of the head equals its length excluding the snout. Interorbital space convex. Snout thick, somewhat projecting beyond the jaws, but without any lateral lobe.*

A few pores on the snout. Lower labial fold complete: lower lip fimbriated: a horny covering to the inside of the lower lip. Gill-rakers very short and widely set. Barbels—a short maxillary, but no rostral pair. Fins—the dorsal commences nearer to the snout than the root of the caudal, it is as high as the body, its upper edge concave. Pectoral nearly as long as the head and does not reach the ventral, which latter is inserted under the middle dorsal rays. Ventral does not extend to the anal, nor the latter to the caudal which is deeply forked. Lateral-line—8 to 9 rows of scales between it and the base of the ventral fin. Colours—silvery, darkest superiorly. Fins orange. In some specimens a few light lines run along the sides, or a bluish band along the body. A dark spot usually present near the base of the caudal, and sometimes a smaller one on the lateral-line above the last third of the pectoral fin.

In specimens from the Hooghly the hearbals are very minute.

In specimens from the Hooghly the barbels are very minute.

Habitat.—Bengal, the Punjab, Central Provinces, Bombay, the Deccan, numerous at Jubbulpore and Cutch, also found at Madras. The specimen figured was from Poona. It attains at least 71 inches in length.

20. Labeo boga, Plate CXXVIII, fig. 3, and CXXXI, fig. 4.

? Cyprinus falcatus, Bloch, t. 412: Bl. Schn. p. 441.

B. iii, D. 11-13($\frac{2}{9}$ - $\frac{3}{10}$), P. 16, V. 9, A. 7($\frac{2}{5}$), C. 19, L. l. 37-39, L. tr. $6\frac{1}{2}$ -7/7, Vert. 17-15.

Length of head $5\frac{1}{4}$ to $5\frac{1}{2}$, of caudal 5, height of body $5\frac{1}{2}$ to $5\frac{3}{4}$ in the total length. Eyes—somewhat before the middle of the length of the head, $3\frac{3}{4}$ to 4 diameters in the length of head, 1 to $1\frac{1}{4}$ diameters from the end of snout, and $1\frac{1}{2}$ apart. Dorsal profile rather more convex than that of the abdomen. The greatest width of the head equals its length excluding the snout. Mouth rather narrow, its width equalling 1/3 of the length of the head. Snout moderately projecting beyond the jaws, no lateral lobe. Lips rather thick, the lower being reflected from off the republished of the profile of the head. of the head. Snout moderately projecting beyond the jaws, no lateral lobe. Lips rather thick, the lower being reflected from off the mandible and internally roughened. A thin layer of cartilage to inner surface of lower lip. Snout occasionally covered with large pores. Barbels—two minute maxillary ones. Teeth—pharyngeal. 5, 4, 3/3, 4, 5, plough-shaped. Fins—origin of dorsal considerably in advance of the ventrals, it is as long or longer than the head and commences nearer the snout than the base of the caudal, upper margin concave; caudal deeply forked, lobes of equal length. Lateral-line—5 rows of scales between it and the base of the ventral fin. Colours—orange, with the fins of a reddish tinge: sometimes a dark spot on the shoulder.

This may be Chondrostoma Duvaucellii, Cuv. and Val. It is allied to L. bata, but has a larger eye, a much lower body, a higher dorsal fin, whilst the lower jaw is not so much bent upwards anteriorly.

There is a variety of this fish in upper Burma having the head more compressed, and only $4\frac{1}{2}$ rows of

There is a variety of this fish in upper Burma having the head more compressed, and only $4\frac{1}{2}$ rows of scales between the lateral-line and base of the ventral fin.

Habitat.—Rivers of Gangetic Provinces, Madras, and Burma: said to attain a foot in length. Pl. cxxviii, f. 3, is from a Burmese specimen, and Plate cxxxii, f. 4, is an example from the Jumna.

21. Labeo nukta, Plate CXXVIII, fig. 5.

Cyprinus nukta, Sykes, Trans. Zool. Soc. ii, p. 325; Jerdon, M. J. L. and Sc. 1849, p. 303. Carassius auratus, pt. Günther, Catal. vii, p. 32 (not syn.)

Labeo nukta, Day, Journ. Asi. Soc. of Bengal, 1872, Vol. XLI, p. 319.

B. iii, D. 11 $\binom{3}{9}$, P. 15, V. 9, A. 7 $\binom{3}{6}$, C. 19, L. 1. 37-38, L. tr. 6/9.

Length of head 5 to $6\frac{1}{4}$, of caudal $4\frac{1}{4}$ to 5, height of body $4\frac{1}{2}$ in the total length. Eyes—diameter 6 in the length of the head, $2\frac{1}{4}$ diameters from the end of snout, and also apart. The greatest width of the head equals its length excluding the snout. Snout projecting over the mouth, and having a deep groove passing from one orbit to the opposite one, thus occasioning the appearance as if there were a blunt compressed knob between and before the orbits. Mouth transverse, of moderate width: the snout with a well-developed lateral lobe and a distinct inner fold to the lips at the angle of the mouth, and extending across the outer the lips at the angle of the lower jaw, from which the lip is reflected and studded with pores, but neither lips are fringed. Both lips with a thin deciduous horny layer internally. Some large pores on snout, forehead, and the rostral groove. Gill-rakers closely set and short. Barbels—a rudimentary maxillary pair. Lateral-line—badly marked, $4\frac{1}{2}$ rows of scales between it and the base of the ventral fin. Fins—dorsal arises midway between the snout and posterior extremity of the base of the anal fin, its anterior three rays are much elevated and higher than the body, the last besides being divided to its root is also somewhat prolonged, making the upper margin

* Some Cutch specimens have a groove across the snout, whilst their bodies are rather elongated. There is a very distinct ridge inside the mouth over the symphysis of the lower jaw, more especially seen in the young.

of the fin concave: ventral arises under the middle of the dorsal and scarcely reaches the anal, which fin is much highest anteriorly. Pectoral as long as the head. Caudal deeply forked. A row of scales along the base of the dorsal. Colours—silvery, with some red marks on the scales. Fins reddish, caudal edged with gray.

Habitat.—Poona and rivers of the Deccan. It attains at least 12 inches in length.

22. Labeo nigripinnis, Plate CXXXII, fig. 3.

B. iii, D. 11 $(\frac{2}{9})$, P. 17, V. 9, A. 7 $(\frac{2}{5})$, C. 19, L. 1. 40-42, L. tr. 8/8.

Length of head 5 to $5\frac{1}{4}$, of caudal $4\frac{1}{2}$ to 5, height of body $5\frac{1}{4}$ to $5\frac{3}{4}$ in the total length. Eyes—situated in the middle of the length of the head in the young, rather before it in the adult, diameter $4\frac{1}{3}$ in the length of the head, $1\frac{1}{3}$ diameters from the end of snout, and $1\frac{3}{4}$ apart. Dorsal profile somewhat elevated, abdominal nearly straight: the greatest width of the head equals its length behind the middle of the eyes. Snout projecting over the mouth which is inferior, and its width equals one-third of the length of the head, the lips continuous at the angle of the mouth: the lower lip thin and reflected from off the mandible, which has a thin cartilaginous covering. Large pores on the snout, which in some specimens has a groove across it. Barbels—a minute maxillary pair. Fins—dorsal commences midway between the end of the snout and the posterior extremity of the base of the anal fin, it is as high as the body and has a concave upper edge. Pectoral as long as the head excluding the snout, or even a little more. Ventral commences below the first third of the dorsal. Caudal deeply forked. Lateral-line—from 5 to $5\frac{1}{4}$ rows of scales between it and the base of the ventral fin. Colours—bluish along the back, becoming dull white on the sides and beneath. In some specimens the bases of the scales are dark coloured, some have a dull band along the side. Fins black in the adult, not always so in the young.

Habitat.—Sind hills and rivers at their bases.

23. Labeo Sindensis, Plate CXXXII, fig. 2.

Cirrhina Sindensis, Day, Proc. Asi. Soc. of Bengal, 1872, Vol. XLI, p. 319.

B. iii, D. 12-13 $(\frac{2-3}{10})$, P. 18, V. 9, A. 7 $(\frac{2}{5})$, C. 19, L. l. 43, L. tr. 8/9.

Length of head $6\frac{1}{4}$, of caudal $4\frac{1}{3}$, height of body $5\frac{1}{4}$ in the total length. Eyes—rather nearer snout than hind edge of opercles, diameter $5\frac{1}{2}$ in the length of the head, 2 diameters from the end of snout and $2\frac{1}{3}$ apart. Dorsal profile rather more convex than that of the abdomen. The greatest width of the head equals its length excluding the snout. Snout rather overhanging the mouth. Interorbital space slightly convex: no lateral lobe to snout, which in some specimens has a deep groove across it, and is covered with glands. Lips continuous at the angle of the mouth; the lower lip thin with a smooth edge, and reflected from off the mandible which has a thin cartilaginous covering. Barbels—a short maxillary pair. Fins—dorsal commences midway between the end of the snout and the posterior extremity of the base of the anal, it is rather higher than the body, its upper edge concave. Pectoral as long as the head excluding the snout. Ventral inserted under the middle of the dorsal fin. Caudal deeply forked. Lateral-line— $6\frac{1}{2}$ to 7 rows between it and the base of the ventral fin. Colours—silvery, with a reddish tinge, the bases of the scales darkest: fins reddish.

Habitat.—Sind, the Punjab (at Lahore and Hurdwar), also the Deccan at Poona. This fish is allied to L. bata, but differs in its much smaller eye, larger number of scales, &c. It attains at least 8 inches in length.

24. Labeo ariza, Plate CXXXII, fig. 5.

Cyprinus ariza, Buchanan, Journey Mysore, iii, p. 344, pl. 31, and Fish. Ganges, pp. 286, 386; McClelland, Ind. Cyp. pp. 279, 357; Cuv. and Val. xvi, p. 430.

Gobio Hamiltonii and Bovianus, Jerdon, M. J. L. and Sc. 1849, p. 307.

Tylognathus ariza, Günther, Catal. vii, p. 63.

B. iii, D. 11 $(\frac{9}{9})$, P. 18, V. 9, A. 7-8 $(\frac{2-3}{5})$, C. 19, L. 1. 38, L. tr. 6-7/8.

Length of head $5\frac{1}{4}$ to $5\frac{1}{2}$, of candal $5\frac{1}{4}$, height of body 4 to $4\frac{1}{2}$ in the total length. Eyes—rather nearer snout than hind edge of opercle, diameter $5\frac{1}{2}$ in the length of the head, 2 diameters from the end of snout, and $2\frac{1}{2}$ apart. Dorsal profile slightly more convex than that of the abdomen. Interorbital space nearly flat. The greatest width of the head equals its length behind the middle of the eyes: the width of the mouth equals 1/3 of the length of the head. Lips smooth, with a thin cartilaginous covering inside the lower jaw. A few pores on snout. Barbels—no rostral ones, a very short pair of maxillary ones. Fins—dorsal commences slightly nearer the snout than the base of the caudal fin, it is 3/4 as high as the body, and has a concave upper margin. Pectoral nearly as long as the head. Ventral inserted below the anterior third of dorsal fin, and not so long as the pectoral. Caudal deeply forked. Lateral-line— $5\frac{1}{2}$ rows between it and base of the ventral fin. Colours—leaden gray superiorly, becoming silvery on the sides and beneath.

Habitat.—Wynaad and Bowany river at the foot of the Neilgherry hills in Madras, also the Cauvery

river. It attains to about 91 inches in length.

25. Labeo kawrus, Plate CXXXI, fig. 5.

? Chondrostoma kawrus, Sykes, Trans. Zool. Soc. ii, p. 358, pl. 62, f. 2; Bleeker, Beng. p. 25; Jerdon, M. J. L. and Sc. 1849, p. 308.

B. iii, D. $11(\frac{2}{9})$, P. 17, V. 9, A. $7(\frac{2}{9})$, C, 19, L. 1. 38, L. tr. 6/6.

Length of head $5\frac{1}{2}$ to 6, of caudal $4\frac{1}{2}$ to $4\frac{2}{3}$, height of body $5\frac{1}{4}$ to $5\frac{1}{2}$ in the total length. Eyes—diameter 3½ to 3½ in the length of the head, 1 diameter from the end of snout, and 1½ apart. Dorsal and abdominal profiles about equally convex. Width of the head equals its length behind the middle of the eyes. Snout very obtuse and not overhanging the jaws. The cleft of the mouth commences below the level of the lower edge of the eye. Lips continuous at the angle of the mouth, the lower one very thin and reflected off the mandible, which is rounded and has a thin cartilaginous covering: edges of lips smooth. No tubercles on the snout. Barbels—a minute maxillary pair. Teeth—pharyngeal, plough-shaped, 5, 4, 3/3, 4, 5. Fins—dorsal commences midway between the end of snout and the posterior extremity of the base of the anal fin, it is rather higher than the head is long, its upper edge is concave. Pectoral nearly as long as the head. Caudal deeply forked. Lateral-line—rather indistinct in some specimens: $4\frac{1}{2}$ rows of scales between it and the base of the ventral fin. Colours—silvery, dorsal and caudal fins externally stained with gray: sometimes a dark blotch on the scales near the commencement of the lateral-line.

This fish, which is from the Deccan, agrees fairly with Sykes' description and figure.

had no lateral-line.

Habitat.—Poona and the Deccan: the specimen figured (7 inches long) was from Poona.

Genus, 10—OSTEOCHILUS, Günther.

Rohita, sp. Cuv. and Val.

Abdomen rounded. Mouth of moderate width, directed more or less downwards: lips thickened, continuous, fringed or crenulated, the lower being reflected from off the mandible, leaving it uncovered in the form of a sharp and hard, transverse, prominence. No tubercle at symphysis. Snout obtusely rounded. Barbels, four or two. Pharyngeal teeth 5, 4, 2/2, 4, 5. Dorsal fin without osseous ray, with a moderate number of branched ones (10 to about 20), commencing in advance of the ventrals. Anal with few rays. Scales of moderate or small size: no tiled row at base of anal fin. Lateral-line passing to the centre of the base of the caudal fin. Gill-rakers short.

Geographical distribution.—Burma and the Malay Archipelago.

SYNOPSIS OF SPECIES.

1. Osteochilus rostellatus, D. \(\frac{1}{2}\), A, \(\frac{3}{5}\), L. l. 54. Four barbels. Colours uniform. Burma.

2. Osteochilus Neilli, D. \(\frac{1}{2}\)\(\frac{5}{1}\)\(\frac{5}{6}\), A. 2/5, L. l. 34. Four barbels. A darkish band near commencement of lateral-line, and a dark mark before base of caudal fin. Burma.

3. Osteochilus cephalus, D. 3/13, A. 3/6, L. l. 40. Two barbels. Colours uniform. Pegu.

1. Osteochilus chalybeatus, Plate CXXIX, fig. 1.

Rohita rostellatus, Cuv. and Val. xvi, p. 256.

Rohita lineata, Cuv. and Val. xvi, p. 260.

Rohita chalybeata, Cuv. and Val. xvi, p. 271; Bleeker, Beng. p. 133 (not syn.)

Labeo chalybeatus, Günther, Catal. vii, p. 60.

Nga-leh, Burmese.

B. iii, D. $20(\frac{9}{18})$, P. 18, V. 9, A. $7(\frac{9}{6})$, C. 19, L. 1. 54, L. tr. 8/10.

Length of head 5, of caudal 5, height of body $4\frac{1}{4}$ in the total length. Eyes—diameter 4 in the length of head, $1\frac{1}{4}$ diameters from the end of snout, and 2 apart. Dorsal profile more convex than that of the abdomen, and rather concave over the orbits: the interorbital space nearly flat. The greatest width of the head equals its length excluding the snout. Snout overhanging the jaws and without any lateral lobe. Mouth rather narrow, its width being about 1/3 of length of head. Lips thick and fringed, with an inner fold above and below. Gill-rakers closely set and short. Barbels—the maxillary pair half as long as the orbit, the rostral ones shorter. Fins—the dorsal commences midway between the end of the snout and the posterior margin of the base of the anal fin. its upper edge is straight. Pectoral rather longer than the head excluding the snout, the base of the anal fin, its upper edge is straight. Pectoral rather longer than the head excluding the snout, it does not reach the ventral, nor the latter the anal. Anal laid flat just reaches the caudal, which is moderately forked. Scales—six rows between the lateral-line and base of the ventral fin. Colours—gray, becoming lighter below, narrow dark lines along the body: fins black.

Habitat.—Irrawaddy and Salwein rivers in Burma. The specimen figured was from Moulmein.

2. Osteochilus Neilli, Plate CXXX, fig. 2.

Day, Proc. Zool. Soc. 1870, p. 99.

B. iii, D. 17-18 $(\frac{3-3}{15-16})$, P. 15, V. 9, A. $7(\frac{3}{5})$, C. 19, L. 1. 34, L. tr. $5\frac{1}{2}/6\frac{1}{2}$.

Length of head $5\frac{1}{2}$, of caudal $4\frac{3}{4}$ to 5, height of body $3\frac{1}{4}$ in the total length. Eyes—diameter $3\frac{1}{2}$ in the

length of head, 12 diameters from the end of snout, and 2 apart. Dorsal profile more convex than that of the abdomen. The greatest width of the head equals its length excluding the snout. Interorbital space convex. Snout rounded and smooth, it scarcely overlaps the mouth which is of moderate width: no lateral lobe. Both lips fringed, with two, three, or more rows of well-developed papillæ internally: groove across the mandibles not complete; a cartilaginous covering internally to the lower jaw. Barbels—the rostral do not reach the orbit, the maxillary extend to beneath its centre. Teeth—pharyngeal, plough-shaped, 5, 4, 3/3, 4, 5. Fins—the dorsal commences before the ventral, and much nearer to the snout, than to the base of the caudal, its upper border is somewhat concave; caudal deeply forked. Scales-4 rows between the lateral-line and the base of the ventral fin. Colours—grayish-yellow, deepest superiorly, every scale being darkest at its base. A dull spot near the root of the caudal fin, and another ill-defined one near the commencement of the lateral-Fins, yellowish orange, dorsal darkest at its basal half.

Habitat.—Sittoung and Billing in Burma. The largest specimen, out of seven, measured six inches in

length.

3. Osteochilus cephalus.

Labeo cephalus, Cuv. and Val. xvi, p. 374, pl. 487.

B. iii, D. $16(\frac{5}{13})$, P. 20, V. 9, A. 9 (3/6), C. 19, L. l. 40, L. tr. 7/7.

Length of head $4\frac{1}{2}$, of caudal $4\frac{1}{2}$, height of body 4 in the total length. Eyes—1/5 of length of head, two diameters from end of snout. The dorsal profile is much more convex than the abdominal. Interorbital space convex. The snout projects beyond the jaws, it is rather swollen and has many pores opening on its surface: the mandible has a transverse free edge, with thick lip, both the upper and lower being fringed. Barbelsone short maxillary pair. Fins—the dorsal commences midway between the snout and base of caudal, and in advance of the ventrals, its upper border is concave. The anal laid flat reaches the caudal. Scales—41 rows between the lateral line and base of ventral fin. Colours—greenish, with the base of each scale darkest.

Habitat.—Pegu, attaining one foot in length.

Genus, 11—Dangila, Cuvier and Valenciennes.

Cyrene, sp. Heckel.

Abdomen rounded. Snout moderately depressed and obtusely rounded. Mouth transverse, more or less inferior. Lower jaw sharp, covered with a thin lip, and having a tubercle above the symphysis: upper lip fringed. Barbels small, one maxillary and one mandibular pair. Pharyngeal teeth, 5, 4 or 3, 2 or 3, 2 or 3, 3 or 4, 5. Dorsal fin rather long, without any osscous ray, and commencing in advance of the ventrals. Anal short, without a tiled row of scales. Scales of large, small, or moderate size. Lateral-line continuous, passing to the centre of the base of the caudal fin. Gill rakers short.

This genus might perhaps be considered as belonging to Cirrhina, merely differing in possessing a few more rays in the dorsal fin. As however it does not appear to extend into India proper, it is more convenient for the purpose of adverting to geographical distribution, to leave it as distinct, at least for the present.

Geographical distribution.—From Burma to the Malay Archipelago.

SYNOPSIS OF SPECIES.

Dangila Burmanica, D. 26-38, L. l. 39-40, L. tr. 7/9. Burma.
 Dangila Berdmorei, D. 26, L. l. 31, L. tr. 6/—. Tenasserim Provinces of British Burma.

1. Dangila Burmanica, Plate CXXXI, fig. 2.

Cirrhina Kuhlii, Day, J. A. S. of Beng. 1871, p. 133 (not Cuv. and Val.)

B. iii, D. $26-28(\frac{2}{24-\frac{5}{25}})$, P. 16, V. 9, A. $7(\frac{2}{5})$, C. 19, L. l. 39-40, L. tr. 7/9.

Length of head 7, of caudal 4½ to 5, height of body 4½ to 5 in the total length. Eyes—diameter 3 in the length of the head, 1 diameter from the end of snout, and 11 apart. Dorsal profile more convex than that of The greatest width of the head equals its length behind the middle of the eyes. Mouth transverse, with the snout slightly depressed and rounded: upper lip fringed: a small tubercle inside the lower jaw above the symphysis. Barbels—the maxillary pair as long as the eye, the rostral pair shorter. Teeth—pharyngeal, 5, 4, 3, 3, 4, 5. Fins—dorsal commences above the ninth scale of the lateral-line, its upper edge concave, and its highest rays 4/5 of the height of the body. Pectoral nearly as long as the head and does not reach the ventral. Upper caudal lobe the longer. Lateral-line—5 rows of scales between it and the base of the ventral fin. Colours-silvery, some of the scales with dark spots at their bases forming rows, or horizontal bands. Fins orange, the edges of the caudal stained.

This fish is closely allied to Dangila Kuhlii, C. V., but appears to have a shorter head and less number of

scales between the dorsal fin and lateral-line.

Habitat.—Moulmein and Tavoy (where it does not seem to be uncommon): several specimens obtained measured up to 10 inches in length. The example figured is 9.3 inches in length.

2. Dangila Berdmorei.

Dangila Berdmorei, Blyth, J. A. S. of Bengal, 1860, p. 162; Day, Proc. Zool. Soc. 1869, p. 554.

B. iii, D. $26(\frac{3}{3.5})$, V. 9, A. $7(\frac{3}{5})$, L. l. 31, L. tr. 6/?

Length of head 5, of caudal 4, height of body 4 in the total length. Eyes—diameter 2/5 of length of head, 3/4 of a diameter from end of snout. Pores on front of snout large. A distinct tubercle above symphysis. Lower lip rather thick, not fringed. Barbels—rostrals equal the length of the orbit. Fins—dorsal arises in the commencement of the second third of the total length. The pectoral does not quite reach the ventral. Caudal deeply forked. Scales—three and a half rows exist between the lateral-line and the base of the ventral fin. Colours—uniform in spirit.

Habitat.—Tenasserim Provinces of British Burma. Type in the Calcutta Museum.

Genus, 12—CIRRHINA, Cuvier and Valenciennes.

Bangana, pt. Ham. Buch.: Dangila, sp. Cuv. and Val.: Cyrene, sp. Heckel.: Mrigala, sp. Bleeker: Crossochilus, pt. Günther.

Abdomen rounded. Snout depressed and obtusely rounded, with the soft coverings extremely thin. Mouth broad, transverse. Upper lip fringed or entire, and not continuous with the lower lip. Lower jaw rather sharp, without any or with a thin lip, generally destitute of any horny covering, but having a small tubercle above the mandibular symphysis. Barbels small, four, two, or none. Pharyngeal teeth 5, 4, 2 or 3/2 or 3, 4, 5 or 5, 3, 2/2, 3, 5. Dorsal fin rather short, or of moderate length, without any osseous ray, and commencing in advance of the ventrals.

Anal fin short, without a row of tiled scales. Scales of large, small, or moderate size. Lateral-line continuous, passing to the centre of the base of the caudal fin. Gill-rakers short.

Geographical distribution.—Fresh waters of Beloochistan,* Sind, through Burma, and extending through the East Indian Archipelago.

SYNOPSIS OF SPECIES.

- Cirrhina cirrhosa, D. 17-19, L. l. 42-44. Four barbels. Upper lip entire. Southern India.
- 2. Cirrhina mrigala, D. 15-16. L. l. 40-45. Two barbels. Upper lip entire. Cutch, Sind, Punjab, Bengal and Burma.
- Cirrhina latia, D. 10-11. L. l. 38-40. Four barbels. Upper lip fringed. Sind, India generally.
 Cirrhina reba, D. 10-11. L. l. 35-38. One pair of short rostral barbels. Upper lip indistinctly fringed or entire. Throughout India.
 - 5. Cirrhina fulungee, D. 10, L. l. 48. Two barbels. Poona and the Deccan.

1. Cirrhina cirrhosa, Plate CXXXI, fig. 3.

B. iii, D. 17-19 $(\frac{3\cdot4}{14\cdot15})$, P. 19, V. 9, A. 8 $(\frac{3}{5})$, C. 19, L. 1. 42-44, L. tr. 8/9, Vert. 21/17.

Length of head $5\frac{1}{2}$ to 6, of caudal 5, height of body $4\frac{1}{4}$ to 5 in the total length. Eyes—diameter $3\frac{1}{4}$ in the length of the head, 1 diameter from end of snout, and $1\frac{1}{2}$ apart. Dorsal profile more convex than that of the abdomen. The greatest width of the head equals its length excluding the snout. Width of mouth equals 1/3 of the length of the head. Usually some fine pores on the snout, which does not project beyond the jaws. Barbels—the maxillary are about 1/3 as long as the eye, the rostral pair are rather longer. Teeth—pharyngeal teeth plough-shaped and with the sides of the outer ones roughened, 5, 4, 3/3, 4, 5. Fins—the daths as the bedy it arises considerably in advence of the ventrals and midway between the grount and the as high as the body, it arises considerably in advance of the ventrals, and midway between the snout and the posterior portion of the base of the anal fin, its upper margin concave: in some large specimens the first few rays are very elongated. Caudal deeply forked or lunated. $Scales-5\frac{1}{2}$ to $6\frac{1}{2}$ rows between lateral-line and the base of the ventral fin. Colours—silvery, every scale having a red centre, except along the abdomen where they are of a dull yellowish-white. Dorsal and caudal stained with gray, also the outer end of the anal and pectoral.

Habitat.—Godavery, Kistna and Cauvery rivers, and generally in southern India. Grows to 11 feet in length. Is a very active fish and fair eating, but bony.

2. Cirrhina mrigala, Plate CXXIX, fig. 4.

Cyprinus mrigala, Ham. Buch. Gang. Fish. pp. 279, 386, pl. 6, f. 79; McClelland, Ind. Cyp. pp. 276, 350.

B. iii, D. 15-16 $(\frac{3}{13}, \frac{3}{13})$, P. 15, V. 9, A. 8 $(\frac{3}{5})$, C. 15, L. l. 40-45, L. tr. $(\frac{3}{5}, \frac{7}{8})$.

Length of head 5 to $5\frac{1}{4}$, of caudal 5, height of body 4 to $5\frac{1}{4}$ in the total length. Eyes—in the anterior 1/2 of the head, diameter $3\frac{1}{2}$ to 4 in the length of the head, 1 to $1\frac{1}{4}$ diameters from the end of snout, and 2 apart. The greatest width of the head equals its length behind the middle of the eyes. Width of the mouth equals 2/5 of the length of the head. Pores present or absent on the snout. Teeth—pharyngeal teeth plough-shaped, 5, 4, 2/2, 4, 5. Fins—dorsal nearly as high as the body, it arises rather nearer to the snout than to the base of the caudal fin, and opposite the 12th scale of the lateral-line, upper margin of fin slightly concave, in Sind deeply so. Pectoral as long as the head excluding the snout, and does not reach the ventral. Caudal with sharp and deeply forked lobes, which have convex edges internally. Scales—51 to 6 rows between the latter and the base of the ventral $(4\frac{1}{2} \text{ in } C. plumbea)$. Colours—silvery, dark gray along the back, sometimes having a coppery tinge: the pectoral, ventral and anal, orange stained with black. Eyes

Cirrhina fulungee, Sykes, is very closely allied to C. mrigala, but its barbels are shorter.

Habitat.—Rivers and tanks in Bengal, Deccan, N. W. Provinces, Punjab, Sind, Cutch, and Burma, growing to 3 feet in length. It is an excellent species for stocking tanks with. I have taken it in Rangoon 18 pounds in weight.

3. Cirrhina latia, Plate CXXX, fig. 4.

B. iii, D. 10-11 (7^{3}) , P. 15, V. 9, A. 7 $(\frac{2}{5})$, C. 19, L. 1. 38-40, L. tr. 6/6, Vert. 15/17.

Length of head 6 to $6\frac{1}{2}$, of caudal $4\frac{1}{2}$ to 5, height of body $5\frac{1}{2}$ to 7 in the total length. Eyes—rather behind the middle of the head in the adult: in the middle in the young: diameter $3\frac{1}{2}$ to 5 in the length of the head, about 2 diameters from end of snout, and also apart. Dorsal profile more convex than the abdominal. Upper surface of the head rather broad: snout overhanging the jaws and having a small lateral lobe. Upper lip deeply indented on the edge, and each indentation (in some specimens) having a tricuspid termination, this is most seen in examples from Calcutta and Orissa, least so in those from Sind, the Punjab, and central Provinces: the surface rough as in Discognathus. Lower lip with a strong sharp horny covering, the lip at the angle having a sort of pendulous lobe: the under surface of the jaw with a round, callous, and rather elevated spot, which in the adult has a free anterior edge. Barbels—a rostral pair and sometimes a short maxillary pair. Teeth—pharyngeal, crooked, 5, 4, 2/2, 4, 5. Fins—dorsal commences about midway between the end of the snout and base of the caudal fin in the young, but rather nearer the snotked, upper lobe sometimes the longer. Lateral $line-3\frac{1}{2}$ to $4\frac{1}{2}$ rows between it and the base of the ventral fin. Colours—brownish-olive, irregularly spotted with black marks. Dorsal and caudal fins yellowish, stained with gray, the others orange.

This fish has much the character of a loach or of a Discognathus, adhering to stones in the beds of rivers.

Hamilton Buchanan observes that C. gohama differs very little from C. latia, but it dies very soon out of water,

and its form is somewhat deeper and more protuberant on the back.

Habitat.—Sind, Orissa, Bengal, N. W. Provinces, Punjab, Deccan, and along the Himalayas. It attains 8 inches in length.

In the British Museum these specimens are marked Crossochilus Rawulensis, Beavan.

4. Cirrhina reba, Plate CXXX, fig. 3.

Cyprinus reba, Ham. Buch. Fish. Ganges, pp. 280, 386; McClelland, Ind. Cyp. pp. 276, 354.

Gobio isurus and limnophilus, McClell. Ind. Cyp. pp. 279, 358, pl. 55, f. 3; Cuv. and Val. xvi, pp. 431, 464.

Chirchinichthys Dussumieri, Bleeker, Atl. Ich. Cyp. p. 28.

Gobio bangon, limnophilus and Dussumieri, Jerdon, M. J. L. and S. 1849, p. 308.

Cirrhina rewah, Steind. Sitz. Ak. Wiss. Wien, lvi. p.

Crossochilus reba, Günther, Catal. vii, pp. 72, 74.

Eelemose and Chittahri, Tel.; Chetchua-porah, Ooriah; Batta, Bengali; Rewah, Hind.; Soonnee, Punj. and Sind.; Lasseem, Assam.

B. iii, D. 10-11 $(\frac{3-3}{8-9})$, P. 16, V. 9, A. 8 $(\frac{3}{5})$, C. 19, L. l. 35-38, L. tr. 7/9.

Length of head 6 to $6\frac{1}{4}$, of caudal $4\frac{3}{4}$ to $5\frac{1}{4}$, height of body 4 to $4\frac{1}{2}$ in the total length. Eyes—diameter 4 in the length of head, 1 to $1\frac{1}{3}$ diameters from the end of snout, and nearly 2 apart. Dorsal profile slightly more convex than that of the abdomen. The greatest width of the head equals its length excluding the snout. Snout slightly projecting, more distinctly in the immature. Upper lip fringed in the young, sometimes entire in the adult. A thin cartilaginous layer covering inside of lower jaw. Pores on snout present or absent. Barbels—a short rostral pair, which may be absent: none on the maxilla. Teeth—pharyngeal, 5, 4, 1/1, 4, 5. Fins—dorsal commences slightly nearer the snout than the base of the caudal fin, and anterior to the ventral, upper margin of the fin concave. Pectoral nearly as long as head. Caudal with deep, sharp, lobes. Lateral-line—five to six rows of scales between it and the base of the ventral fin. Scales—hexagonal. Colours silvery, scales generally darkest at their edges, forming bluish longitudinal bands above the lateral-line. The young have sometimes a leaden-coloured band along the side.

Gobio angra, McClelland, Ind. Cyp. pp. 227, 354, I believe to be this species for reasons given at p. 541.

Gobio angraoides, Jerdon, from the Malabar coast of India, is perhaps only a variety of this species; it has however 44 rows of scales along the lateral-line, whilst the upper lip is scarcely fringed. Having obtained several specimens in South Canara I have come to the conclusion that it can only be considered.

That Cyprinus bangon (H. B.) McClelland, is C. reba, is I think unquestionable. H. B. observes in his MSS. list, Gorakpur district, "the Bhangan of Rangpur is here called Bukti." In the Rangpur list the description is nearly the same as part of C. reba, in the Fishes of the Ganges. In his Bhagalpur list he observes the Banghi Rewa is the Bhangan of Rangpur.

Habitat.—Throughout India, attaining a foot in length.

5. Cirrhina fulungee, Plate CXXXII, fig. 1.

Chondrostoma fulungee, Sykes, Trans. Zool. Soc. ii, p. 358; Bleeker, Beng. p. 25. Gymnostomus fulungee, Günther, Catal. vii, p. 76.

B. iii, D. 10 ($\frac{2}{8}$), P. 15, V. 9, A. 7 ($\frac{2}{5}$), C. 19, L. l. 48, L. tr. 8/9.

Length of head $5\frac{3}{4}$, of caudal $4\frac{3}{4}$, height of body $5\frac{1}{4}$ in the total length. Eyes—diameter 1/3 of the length of head, 2/3 of a diameter from the end of snout, and 1 apart. Dorsal and abdominal profiles about equally and slightly convex: the greatest width of the head equals its length excluding the snout. Snout slightly overhanging the mouth. The upper lip scarcely fimbriated, the two not continuous: the lower is reflected from off the mandible, which is transverse, sharp, having a tubercle above the symphysis, but no cartilaginous covering. Barbels—a very short rostral pair: none on the maxilla. Fins—the dorsal nearly as high as the body its upper edge conveys it compresses midway between the end of the spout and the posterior high as the body, its upper edge concave, it commences midway between the end of the snout and the posterior end of the base of the anal fin. Pectoral almost as long as the head, ventral of equal length. Caudal deeply forked. Lateral-line—6½ rows of scales between it and the base of the ventral fin. Colours—brownish along the back, divided by a light bluish band from a silvery abdomen: dorsal and caudal stained with gray. Habitat.—Poona and the Deccan.

Genus, 13—Semiplotus, Bleeker.

Abdomen rounded. Snout thick and prominent. Mouth wide, transverse, inferior, with a knob at the symphysis. No barbels. Pharyngeal teeth plough-shaped, 4, 3, 2/2, 3, 4. Dorsal fin long, its last undivided ray, strong, osseous, and either servated or entire. Anal rather short. Scales large: no tiled row at the base of the anal Lateral-line passing to the centre of the base of the caudal fin. Gill-rakers short.

Geographical distribution.—Assam and Chittagong Hill ranges, as well as Burma.

SYNOPSIS OF SPECIES.

A.—Dorsal ray serrated.

1. Semiplotus modestus, D. 24, A. 9-10, L. 1. 32-34. Last undivided dorsal ray osseous and serrated. Akyab.

B.—Smooth dorsal ray.

2. Semiplotus McClellandi, D. 3/25, A. 9, L. 1. 27. Last undivided dorsal ray osseous and entire. Colour, silvery. Assam and Burma.

A.—Serrated dorsal ray.

1. Semiplotus modestus, Plate CXXXIII, fig. 1.

Day, Proc. Zool. Soc. 1870, p. 101.

B. iii, D. $24(\frac{4}{20})$, P. 15, V. 9, A. $9-10(\frac{3}{6-7})$, C. 19, L. l. 32-34, L. tr. $7\frac{1}{3}/7\frac{1}{3}$.

Length of head $5\frac{1}{4}$ to $5\frac{1}{2}$, of caudal $4\frac{1}{4}$, height of body nearly 3 in the total length. Eyes—diameter 3 to $3\frac{1}{2}$ in the length of head, 1 diameter from end of snout, $1\frac{1}{4}$ diameters apart. Snout broad, obtuse, overhanging the mouth: several open pores on either side. Mouth inferior, transverse, a thin cartilaginous covering to the lower jaw. A small knob at the symphysis. The posterior extremity of the maxilla extends to beneath the middle of the orbit. Barbels—absent. Teeth—pharyngeal, 4, 3, 2/2, 3, 4. Fins—dorsal fin commences anterior to the origin of the ventral, and extends to above the analysis last under the lower than the second and a lower than the second and the last the second and the serrated, and as long as the head excluding the snout. The pectoral reaches the ventral and the latter the anal. Caudal forked. Lateral-line— $3\frac{1}{2}$ rows of scales between it and the base of the ventral fin. Colours—silvery, darkest in the upper half of the body. Ventrals and anal tipped with orange.

Habitat.—Hill ranges near Akyab: two specimens obtained, up to $5\frac{1}{2}$ inches in length.

B.—Smooth dorsal ray.

2. Semiplotus McClellandi, Plate CXXXIII, fig. 4.

Cyprinus semiplotus, McClell. Ind. Cyp. pp. 274, 346, pl. xxxvii, fig. 2; Cuv. and Val. xvi, p. 68. Semiplotus McClellandi, Bleeker, Atl. Ich. Cyp. p. 25; Günther, Catal. vii, p. 204. Sundaree, Sentoree, and Lah-bo-e, Assam.

B. iii, D. 27-28($\frac{3}{24-25}$), P. 16, V. 10, A. 9($\frac{3}{7}$), C. 19, L. 1. 27-33, L. tr. 6/6.

Length of head $5\frac{1}{2}$ to 6, of caudal 4 to $4\frac{1}{2}$, height of body $3\frac{1}{2}$ in the total length. Eyes—in the middle of the length of the head, diameter from 4 to 6 in the length of head, the width of the interorbital space equalling rather above half the length of the head. Dorsal profile more convex than that of the abdomen: the height of the head equals its length. Snout obtuse, and thickened: with a row of about 6 open pores, passing across it and towards the orbit. A horny covering to lower jaw. Barbels—absent. Teeth—pharyngeal, plough-shaped, 4, 3, 2/2, 3, 4. Fins—dorsal commences midway between the end of the snout and the end of the base of the anal fin, its height slightly exceeding half of that of the body, its last undivided ray strong, osseous, entire, and rather longer than the head excluding the snout. Pectoral nearly as long as the head, it reaches to above the ventral, which is inserted below the fourth or fifth dorsal ray. Anal laid flat nearly reaches the base of the caudal which latter is deeply forked. Lateral-line—nearly straight, $3\frac{1}{2}$ rows of scales between it and the base of the ventral fin. Colours—of a leaden silver, darkest superiorly: the pectoral, ventral, and anal orange

Griffith observes that the smaller examples are usually found near rapids, the larger ones in deeper water where of an evening they are seen rising, but refuse all baits. McClelland states that this fish is reckoned the most delicious in Assam. I can however record from personal observation that it is rich and very liable to set up intestinal irritation.

Habitat.—Rivers in Assam, especially in the upper portions of that district, but found as low as Goalpara: also Burma. It is often termed Rajah-mas, or "kings' fish" in upper Assam, as it is asserted that when captured it had to be taken to the Rajahs for their own consumption. As it is very common this explanation is improbable. More likely a tax was levied on its capture. It attains at least two feet in length.

Genus, 14—Scaphiodon, Heckel.

Capoëta, sp. and Chondrostoma, sp. Cuv. and Val. : Dillonia, Gymnostomus, sp. Heckel.

Abdomen rounded. Snout rounded. Mouth transverse, inferior, with the mandibular edge nearly straight and sharp: without any knob above the symphysis. The mandibles angularly bent inwards. A horny layer inside the lower jaw, which is not covered by lip. No lower labial fold. Barbels four, two, or absent. Pharynyeal teeth, plough-shaped, 5 or 4, 3, 2/2, 3, 4 or 5. Dorsal fin of moderate extent,* its last undivided ray being osseous and serrated or entire, or else articulated. Anal rather short. Scales large, of moderate or small size, and sometimes irregularly disposed. Lateral-line passing to the centre of the base of the caudal fin.

This genus is closely allied to Semiplotus, but its dorsal fin is of less extent.

* None of the following species agree with Dr. Günther's definition of the genus (Capoëta) Scaphiodon:—Dorsal fin "with not more than nine branched rays," all exceeding that number.

Geographical distribution.—Rivers of Western Asia extending to those in Sind and along the Western Ghauts, as low as the Neilgherry hills and rivers at their base.

SYNOPSIS OF SPECIES.

A.—A pair of maxillary barbels.

1. Scaphiodon Watsoni, D. 13, L. 1. 33, L. tr. 6/6. A pair of maxillary barbels. Last undivided dorsal ray, osseous, serrated. Sind hills and Punjab salt range.

2. Scaphiodon irregularis, D. 13, L. 1. 36, L. tr. 9/9. A pair of maxillary barbels. Last undivided dorsal ray osseous, serrated. Sind hills.

B.—Barbels absent.

3. Scaphiodon Thomassi, D. 14-15, L. 1. 39. Barbels absent. Last undivided dorsal ray articulated.

Silvery. South Canara.

4. Scaphiodon Nashii, D. 14-15, L. 1. 40-43. Barbels absent. Last undivided dorsal ray articulated.

A black band along the side; fins with black marks. Coorg, hill streams of Wynaad and South Canara.

5. Scaphiodon brevidorsalis, D. 14, L. l. 40. Barbels absent. Last undivided dorsal ray osseous, entire. Silvery. Rivers at base of Neilgherry hills.

A.—A pair of maxillary barbels.

1. Scaphiodon Watsoni, Plate CXXXV, fig. 2.

Day, Journal Asiatic Society of Bengal, 1872, Vol. xli, pt. ii, p. 324.

B. iii, D. $13(\frac{3}{10})$, P. 15, V. 8, A. $9(\frac{3}{7})$, C. 19, L. 1. 33, L. tr. 6/6.

Length of head 1/5, of caudal 1/5, height of body 2/9 of the total length. Eyes—situated in the last part of the anterior half of the head, diameter 2/9 of length of head, 1½ diameters from end of snout. Interorbital space rather convex. Snout rounded, rather overhanging the mouth, and covered with glands: mouth transverse, inferior: mandibles sharp, not enveloped by lip, and having a horny layer inside. Barbels—a maxillary pair as long as the eye. Teeth—pharyngeal, plough-shaped, 4, 3, 2/2, 3, 4. Fins—dorsal commences rather in front of the ventrals, and midway between the end of snout and base of caudal, its last undivided ray strong, osseous, serrated, as long as the head without the snout, and nearly as long as the branched rays which are two-thirds as high as the body. Pectoral as long as the head excluding the snout, but not reaching the ventrals. Caudal forked. Lateral-line—very slightly curved, $3\frac{1}{2}$ rows of scales between it and ventral fin. Colours—silvery, dashed with gold, lightest on the abdomen. Various and very irregular black spots on the body.

Habitat.—Rivers on Sind hills and salt range of the Punjab.

2. Scaphiodon irregularis, Plate CXXXV, fig. 3.

Day, Journal Asiatic Society of Bengal, 1871, Vol. xli, pt. ii, p. 324.

B. iii, D. 13(3), P. 17, V. 8, A. 2/7, C. 19, L. 1. 36, L. tr. 9/9.

Length of head 1/5, of caudal 1/5, height of body 1/5 of the total length. Eyes—situated rather before the middle of the length of head, $1\frac{1}{3}$ diameters from end of snout, and also apart. Interorbital space nearly flat. Snout somewhat rounded, covered with glands and having a depression across it from eye to eye. Mouth transverse, upper jaw slightly the longer. Barbels—a maxillary pair nearly as long as the eye. Fins—dorsal commences rather before the ventrals, midway between the end of the snout and the base of the caudal, its third undivided ray is osseous, weak, and serrated, nearly half as long as the head, whilst the fin is three-fourths as high as the body. Pectoral nearly as long as the head. Caudal forked, its lower lobe the longer. Scales two or three rows above the lateral-line are of a large oblong form, above which are numerous little irregular ones continued forwards to the head: $4\frac{1}{2}$ rows between the lateral-line and the base of the ventral fin. Colours—olive, shot with gold.

This species is closely allied to the last, from which it more especially differs in the scaling. Habitat.—Sind hills to 3500 feet elevation.

3. Scaphiodon Thomassi, Plate CXXXIV, fig. 1.

B. iii, D. 14-15 $(\frac{3}{11}, \frac{3}{12})$, P. 16, V. 9, A. 8 $(\frac{2}{6})$, C. 19, L. 1. 39, L. tr. 7/7.

Length of head $5\frac{1}{4}$ to 6, of caudal $4\frac{1}{4}$ to $4\frac{3}{4}$, height of body $3\frac{1}{2}$ in the total length. Eyes—diameter $4\frac{1}{3}$ in the length of the head, 2 to $2\frac{1}{4}$ diameters from the end of snout, and 2 apart. Height of head almost equals its length, its width is much less. Snout obtuse, overhanging the mouth, which is transverse: its width equalling that of the head behind the middle of the eyes. Mandible anteriorly with a horny covering. Lips not continuous, the upper one fringed. Large pores on the snout and upper lip, and a line of them continued to under the eye. Barbels—absent. Fins—dorsal arises slightly nearer the snout than the base of the caudal, it is 3/4 as high as the body, its last undivided ray weak, articulated. Pectoral as long as the head. Ventral arises under the fourth or fifth dorsal ray it does not quite reach the analytic plater when heid flat extends to arises under the fourth or fifth dorsal ray, it does not quite reach the anal, the latter when laid flat extends to the caudal, which is deeply forked. Scales—4½ rows between the lateral-line and the base of the ventral fin.

Colours—of a dull silvery colour along the back, with an indistinct silvery band along the side, and of a dull white beneath. A dark band along the dorsal fins, and caudal with a dark outer edge.

Habitat.—South Canara, from whence H. S. Thomas, Esq., of the Madras Civil Service, after whom I have named the species, sent me two examples.

4. Scaphiodon Nashii, Plate CXXXIII, fig. 3.

Barbus Nashii, Day, Proc. Zool. Soc. 1868, p. 584.

B. iii, D. 14-15 $(\frac{2-5}{11-12})$, P. 15, V. 9, A. 7 $(\frac{2}{5})$, C. 20, L. 1. 40-43, L. tr. 7/7.

Length of head $5\frac{1}{4}$ to 6, of caudal $4\frac{1}{4}$ to $4\frac{3}{4}$, height of body 4 to 5 in the total length. Eyes—diameter 3 to 4 in the length of the head, 1 to $1\frac{1}{2}$ diameters from the end of snout, and $1\frac{1}{4}$ to $1\frac{3}{4}$ apart. The greatest width of the head equals its length excluding the snout. Mouth broad, inferior, transverse, and overhung by the snout.* Lips thin, without any transverse fold across the lower one. Snout in the adult covered by papillæ. A thick horny covering inside the lower jaw in adults. Barbels—absent. Teeth—pharyngeal, crooked, sharp, 5, 4, 3/3, 4, 5. Fins—dorsal commences nearer the snout than the base of the caudal, it is 3/4 as high as the body, its upper edge concave, no osseous ray. Pectoral about as long as the head. Ventral arises below the middle of the dorsal fin, and does not quite reach the anal, nor the latter the caudal which is deeply forked. Free portion of the tail as long as high. Scales— $4\frac{1}{2}$ rows between the lateral-line and base of ventral fin. Colours—reddish-brown along the back, abdomen silvery. A black band passes from the eye to the centre of the caudal fin. A dark band along the middle third of the dorsal, which is edged superiorly by scarlet, a dark band on anal having a light anterior edge: a dark edging to the caudal. The young are silvery-gray along the back, becoming silvery on the sides: the lateral band terminates in a black blotch at the base of the caudal fin.

Habitat.—Coorg, hill-streams of South Canara and the Wynaad. I received a small specimen (4 inches long) in rather a mutilated condition from Fraserpett, collected by Dr. Nash in 1868; lately I have received two fine specimens from Mr. Thomas, collected in South Canara.

5. Scaphiodon brevidorsalis, Plate CXXXIII, fig. 2.

Semiplotus brevidorsalis, Day, Proc. Zool. Soc. 1873, p. 239. Mean-candee, Tamil.

B. iii, D. 14 $(\frac{3}{11})$, V. 9, A. 7, L. 1. 39-40, L. tr. 7-8/9.

Length of head 6, of caudal $4\frac{1}{2}$, height of body $3\frac{1}{3}$ in the total length. Eyes—diameter 3 to 4 in the length of head, and situated in or rather before the middle of its length, and $2\frac{1}{3}$ apart. Dorsal profile much more convex than that of the abdomen. Snout swollen, overhanging the jaws; mouth inferior, transverse: three rows of large pores across the snout, and extending on to the preorbital bone; knob at symphysis badly developed: a thin cartilaginous covering to both jaws. Upper lip crenulated. Barbels—absent. Fins—last undivided dorsal ray osseous, very strong, entire, longer than the head by a distance equal to one diameter of the orbit; dorsal fin commences midway between the snout and the base of the caudal, the fin two-thirds as high as the body below it. Pectoral falciform, extending to over the ventral, which last is long, reaching to the anal: caudal deeply forked. $Scales-4\frac{1}{2}$ rows between the lateral-line and the base of the ventral fin. Colours—silvery, darkest along the back, fins stained with gray.

Habitat.—Rivers below the Neilgherry hills in the Madras Presidency.

Genus, 15—Carassius, Nilsson.

Abdomen rounded. Snout obtuse and rounded. Mouth anterior, arched, and rather narrow: lips thin. No barbels. Pharyngeal teeth compressed and in a single series, 4/4. Dorsal fin long, commencing opposite the ventrals, and having its last undivided ray osseous and serrated: last undivided and ray osseous and normally serrated. Scales of moderate size. Lateral-line complete to the centre of the base of the caudal fin.

Geographical distribution.—Temperate portions of Europe and Asia; having been domesticated it has degenerated into numerous varieties.

SYNOPSIS OF SPECIES.

1. Carassius auratus, D. 15218, A. 3/5. From rifle green to silver or orange colours. Bombay? China, &c.

1. Carassius auratus.

Cyprinus auratus, Linn. Sys. Nat. vol. i, p. 527; Bl. Schn. p. 439; Lacép. vol. v, p. 553; Cuv. and Val. vol. xvi, p. 101; Richard, Ich. China, p. 293.

Carassius auratus, Bleeker, Atl. Ich. Cyp. p. 74; Günther, Catal. vol. vii, p. 32 (exclude Cyprinus Nukta.)

* The mouth in this species alters so with age, that until I had compared specimens of my Osteochilus Malabaricus with gradations of Scaphiodon Nashii since obtained, I could have not believed in their being identical. In the young the jaws are compressed, each with a cartilaginous covering: the lips at the angle are thick and continuous, not continued across the chin. As age increases the mouth widens, the cartilaginous covering becomes more horny, and the colours of the fish alter.

B. iii, D. $19-21(\frac{3}{16-18})$, P. 17, V. 9, A. $8(\frac{3}{5})$, C. 19, L. 1. 27-29, L. tr. $6\frac{1}{3}/10$, Vert. 18/13.

The gold carp is too well known to require any detailed description.

The almost endless deformities into which, due to domestication, this species has degenerated, may be briefly defined as follows. Vertebral column only deformed: fins also abnormal, the dorsal being decreased or even absent: the anal spine double: caudal enlarged and with three or four lobes. Occasionally the eves are protruding. As I doubt whether this fish has ever been found wild in India, I have not considered it

necessary to give a figure or its numerous synonyms.

Habitat.—Mr. Masters, according to Dr. Günther, sent three adult specimens from Bombay to the British Museum, still I suspect they were not captured wild in India, the nearest point where they are obtained in a state of nature, being high up in Upper Burma, or rather within the borders of China, from

whence Dr. J. Anderson brought examples.

Genus, 16-CATLA, Cuvier and Valenciennes.

Gibelion, Heckel; Hypselobarbus, Bleeker.

Head broad: snout with very thin integuments, upper lip absent, the lower moderately thick, having a continuous and free posterior margin. The lower jaw with a moveable articulation at the symphysis, but destitute of any prominent tubercle. No barbels. Gill rakers long, fine, and closely set. Eyes with free orbital margins. Pharyngeal teeth plough-shaped, 5, 3, 2 | 2, 3, 5. Dorsal fin rather long, without osseous ray, it commences somewhat in advance of the ventrals: anal short: caudal forked. Scales of moderate size, no tiled row along the base of the anal fin. Lateral-line continuous to the centre of the base of the caudal fin.

Geographical distribution.—This fish appears to be absent from Southern India, below the Kistna at Masulipatam: it is found in Sind, the Punjab, also in the N. W. Provinces, the Deccan, and throughout Bengal, Assam, and Burma as far as the Pegu river. It is said not to exist in Tenasserim, but is present in

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Catla Buchanani, D. 17-19, A. 8, L. 1. 40-43, L. tr. $7\frac{1}{2}/9$.

1. Catla Buchanani, Plate CXXXIV, fig. 5.

Cyprinus abramioides, Sykes, Trans. Zool. Soc. ii, p. 353, pl. 61, f. 2.

Human Lander of Transport abramioides Bleeker, Pro. Cyp. p. 275

Hypselobarbus (Tambra) abramioides, Bleeker, Pro. Cyp. p. 275. Botchee, Telugu: Catla, Bengal, Hind. and Punj.: Barkur, Ooriah: Nga-thaing, Burmese: Tambra, Hind. in Bombay: Boassa, Hind. in N. W. Provinces: Tay-lee, Sind.

B. iii, D. 17-19 $(\frac{3-4}{16})$, P. 21, V. 9, A. 8 $(\frac{3}{5})$, C. 19, L. 1. 40-43, L. tr. $7\frac{1}{2}/9$, Vert. 17/18.

Length of head $4\frac{1}{4}$ to $4\frac{3}{4}$, of caudal $4\frac{1}{4}$ to $4\frac{1}{2}$, height of body 3 to $3\frac{1}{2}$ in the total length. Eyes—in the anterior half of the length of the head, diameter o to 7 in the length of the head, 2 diameters from the end of the snout, and 3 apart. Dorsal profile much more convex than that of the abdomen. The greatest width of the shout, and 3 apart. Dorsal profile much more convex than that of the abdomen. The greatest width of the head equals its length behind the middle of the eyes. Mouth wide, lower jaw prominent: in large specimens some pores on the snout. Teeth—pharyngeal, plough-shaped, 5, 3, 2 | 2, 3, 5. Fins—dorsal commences in advance of the ventrals, is 2/3 as high as the body, and with a concave upper edge. Pectoral extends to the ventral, and the latter, in males, to the anal. Anal laid flat, reaches to beyond the commencement of the caudal. The fins in some specimens are much elongated. Lateral-line—from $5\frac{1}{2}$ to $6\frac{1}{2}$ rows of scales between it and the base of the ventral fin. Colours-grayish above, becoming silvery on the sides and beneath. Fins dark coloured, in some specimens nearly black.

This fish is largely employed for stocking tanks. In May, 1875, Mr. Mitchell had a tank 65 × 58 feet and 13 feet deep, dug upon his ground at Garden Reach, near Calcutta; into it were put some fry of this species, from 1/2 to 1 inch or less in length. September 22nd it was netted, and several dozens captured, one of the largest weighing 14 oz. and measuring 11 inches in length: the others were 1 or 2 oz. lighter. (Nature,

Dec. 9th, 1875, p. 107).

Habitat.—Sind, Punjab, through India to the Kistna, and eastwards through Bengal, and Burma to Siam. It attains at least 6 feet in length, and is much esteemed as food when not exceeding 2 feet, larger ones are coarse. It resides in fresh or brackish water, being found within tidal influence. "It is a very strong active animal, and often leaps over the seine of the fishermen, on which account, when fishing for the Catla, they usually fellow the net in canoes, and make a noise by shouting and splashing with their paddles." (Ham. Buchanan). It is said never to take a bait, but as it rises at natural flies, it could probably be taken with artificial ones.

Genus, 17—THYNNICHTHYS, Bleeker.

Mola, pt. Blyth.

Pseudobranchiæ present. Abdomen rounded. Head somewhat compressed: integuments over snout thin: upper lip absent: only a short labial fold on the side of the mandible. Mouth rather wide, antero-lateral, with the lower jaw somewhat prominent. No barbels. Gill rakers short or absent. Eyes in the middle of the depth of the head, and without any adipose lid. Pharyngeal teeth molariform, compressed, close together, 5, 3 or 4, 2 or 3 | 3 or 2, 4 or 3, 5. Dorsal fin short, without osseous ray: ventral commencing below the dorsal: anal short and entirely posterior to the dorsal. Scales small. Lateral-line complete, running to or a little below the centre of the base of the caudal fin. Intestinal tract narrow, and with numerous convolutions.

This Genus is separated from the succeeding one (Amblypharyngodon), irrespective of its pharyngeal teeth, because of the position of the dorsal, ventral, and anal fins, and its having an entire instead of an interrupted lateral-line.

Geographical distribution.—The Kistna and Godavery rivers in India from the Deccan to their terminations: also the Malay Archipelago.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Thynnichthys sandkhol, D. 12, A. 8, L. r. 120. Kistna and Godavery rivers.

1. Thynnichthys sandkhol, Plate CXXXIV, fig. 2.

Leuciscus sandkhol, Sykes, Trans. Zool. Soc. ii, p. 363; Bleeker, Beng. p. 68. Mola sandkhol, Day, Journ. Linn. Society, xii, 1876, p. 574.
Thymnichthys Cochinensis,* Günther, Ann. and Mag. Nat. Hist. 1876, p. 401. Kala-tala and Ahku-chappah, Tel.: Bareing, Ooriah.

B. iii, D. 12 $\binom{3}{9}$, P. 19, V. 9, A. 8 $\binom{3}{5}$, C. 19, L. r. 120, L. tr. 25-30/25.

Length of head 4 to $4\frac{1}{2}$, of caudal 4, height of body $3\frac{1}{4}$ to 4 in the total length. Eyes—in about the centre of the depth of the head, diameter 3 to 5 in the length of the head, 1 to $1\frac{1}{3}$ diameters from the end of snout, and $1\frac{1}{2}$ to $2\frac{1}{2}$ apart. Dorsal profile more convex than the abdominal. The width of the head equals 1/2, and the height 4/5, of its length. Teeth—pharyngeal, 5, 4, 3 | 3, 4, 5. Fins—dorsal 3/4 as high as the body, its upper edge concave, its origin is slightly in advance of that of the ventral, and about midway between the snout and base of the caudal fin, which latter is deeply lobed, the lower being the longer. Anal at some distance behind the vertical from the end of the dorsal. Scales-17 to 19 rows between the lateral-line and base of the ventral fin. Colours—silvery: head purplish.

Habitat.—Godavery and Kistna rivers, also the adjacent tanks. It attains above 18 inches in length.

Genus, 18—Amblypharyngodon, Bleeker.

Mola, Heckel and Blyth: Brachygramma, Day.

Pseudobranchiæ present. Abdomen rounded. Head somewhat compressed: integuments over snout thin: upper lip absent: only a short labial fold on the side of the mandible. Mouth rather wide, antero-lateral, with the lower jaw prominent. No barbels. Gill-rakers short or absent. Eyes in the middle of the depth of the head, and without any adipose membrane. Pharyngeal teeth molariform, with the crowns flat or concave, 3, 2, 1 | 1, 2, 3. Dorsal fin short, without osseous ray, and extending to nearly or quite above the commencement of the anal: ventral in advance of the dorsal. Scales small. Lateral-line incomplete.

Geographical distribution.—From Sind throughout the plains of India, Ceylon, and Burma.

SYNOPSIS OF SPECIES.

- 1. Amblypharyngodon Atkinsonii, D. 9-10, L. l. 55-65. Nine or ten rows of scales between lateral-line
- and base of ventral fin. Height of body $3\frac{1}{3}$ in the total length. Burma.

 2. Amblypharyngodon mola, D. 9, L. 1. 65-75. Nine or ten rows of scales between lateral-line and base of ventral fin. Height of body 4 to $4\frac{1}{4}$ in the total length. Sind, India (except the Malabar coast), Assam, and Burma.
- 3. Amblypharyngodon microlepis, D. 9, L. 1. 55-60. Five rows of scales between the lateral-line and base of the ventral fin. Height of body $4\frac{3}{4}$ to 5 in the total length. Hooghly, through Orissa, and down the Coromandel coast to Madras.
- 4. Amblypharyngodon melettinus, D. 9-10, L. l. 50-57. Four rows of scales between lateral-line and base of the ventral fin. Height of body 5 to $5\frac{1}{2}$ in the total length. (? Bombay), Malabar coast, and Southern India from the Neilgherries to Madras: also Ceylon.
- * The single skin described by Dr. Günther was erroneously stated to have come "from Cochin." It is a specimen which I personally obtained fresh, and preserved at Rajahmundry on the Godavery. I probably took it to the British Museum for comparison, and accidentally left it on the table.

1. Amblypharyngodon Atkinsonii, Plate CXXXIV, fig. 4.

? Leuciscus harengula, Cuv, and Val. xvii, p. 303, pl. 500. Mola Atkinsonii, Blyth, J. A. S. of Beng., 1860, p. 164. Nga-pan-ma, Burmese.

B. iii, D. 9- $10(\frac{2-3}{7})$, P. 15, V. 9, A. $8(\frac{2}{6})$, C. 19, L. l. 55-65, L. tr. 14/12.

Length of head 4 to $4\frac{2}{3}$, of caudal 5, height of body $3\frac{1}{3}$ in the total length. Eyes—in the front half of the head, 4 to $4\frac{1}{4}$ diameters in the length of the head, 1 diameter from end of shout, and $1\frac{1}{4}$ apart. Abdominal and dorsal profiles about equally convex. Teeth—pharyngeal, compressed and with flat crowns, 3, 2, 1/1, 2, 3. Fins—dorsal 2/3 as high as the body, its upper edge concave, it commences nearly midway between the anterior edge of the eye and the base of the caudal fin, and slightly behind the origin of the ventral. Anal arises on the vertical just posterior to the end of the dorsal. Lateral-line—ceases after 19 scales; there are 9 or 10 rows between it and the base of the ventral fin. Colours—silvery, with a golden gloss about the head.

This species is identical with an example of Leuciscus harengula, Cuv. and Val. shown to me as the type

at Paris, but which does not quite agree either with the figure or with the description.

Habitat.—Throughout native and British Burma. It attains at least 6 inches in length.

2. Amblypharyngodon mola, Plate CXXXV, fig. 4.

Cyprinus mola, Ham. Buch., pp. 334, 392, pl. 38, f. 92; Cuv. and Val. xvi, p. 440. Leuciscus mola, McClelland, Ind. Cypr. pp. 293, 407; Bleeker, Beng. en Hind. p. 140. 7 Leuciscus chitul, Sykes, T. Z. S. ii. p. 363.

Amblypharyngodon mola, Bleeker, Prod. Cyp. p. 409; Günther, Catal. vii, p. 202.

Mola Buchanani, Blyth, J. A. S. of Beng. 1860, p. 164.

Rhodeus macrocephalus? Jerdon, M. J. L. and S. 1849, p. 324.

Talla-maya, Tel.: Morara, Ooriah: Moah, Assam: Mukni, Punj.: Nga-beh-byoo and Nga-zen-zap, Burmese.

B. iii, D. $9(\frac{3}{7})$, P. 15, V. 9, A. $7(\frac{3}{8})$, C. 19, L. 1. 65-75. L. tr. 12/12.

Length of head about 5, of caudal 5, height of body 4 to 44 in the total length. Eyes—diameter 31 to 4 in the length of head, 3/4 to 1 diameter from the end of snout, and 11 apart. Dorsal profile more convex than that of the abdomen. Fins—origin of dorsal midway between front edge of eye and base of the caudal, it is behind the insertion of the ventral, its upper edge is concave. Caudal deeply forked. Lateral-line—extends along about 15 scales, and there are 9 or 10 rows between it and the base of the ventral fin. Colours—a silvery lateral band, and usually dark markings on the dorsal, caudal, and anal fins.

In some specimens from the Irrawaddi, I found the scales rather large, L. l. 65, and the origin of the

dorsal directly above the insertion of the ventral.

Habitat.—From Sind throughout India, (except the Malabar Coast,) Assam and Burma.

3. Amblypharyngodon microlepis, Plate CXXXV, fig. 5.

? Leuciscus pellucidus, McClelland, Ind. Cyp. pp. 293, 408.

Leuciscus microlepis, Bleeker, Beng. en Hind. p. 141. Amblypharyngodon microlepis, Bleeker, Prod. Cyp. 409; Kner, Novara Fische, p. 349.

Amblypharyngodon pellucidus, Günther, Catal. vii, p. 202.

B. iii, D. $9(\frac{2}{7})$, P. 14, V. 9, A. $7(\frac{2}{5})$, C. 19, L. l. 55-60, L. tr. 11/8.

Length of head $4\frac{3}{4}$ to 5, of caudal $4\frac{1}{4}$ to $4\frac{3}{4}$, height of body $4\frac{3}{4}$ to 5 in the total length. Eyes—diameter 3½ to 4 in the length of the head, less than 1 diameter from the end of snout. Dorsal profile rather more convex than that of the abdomen. Fins—origin of dorsal midway between middle or hind edge of eye and base of the caudal fin, and slightly behind the origin of the ventral, its upper edge concave, its last ray is divided to its base: caudal forked, lower lobe the longer. Lateral-line—ceases after a few scales, 5 rows between it and

the base of the ventral fin. Colours—a rather broad silvery lateral band.

This species is distinguished by the much fewer number of scales (4 or 5) between the row which carries the lateral-line and the base of the ventral fin, than is seen in the common (9 to 10)

A. mola.

McClelland's fish may be an elongated example of A. mola, I have not taken this species in Assam. Habitat.—From the Hooghly through Orissa and down the Coromandel Coast to Madras.

4. Amblypharyngodon melettinus, Plate CXXXIV, fig. 3.

Leuciscus melettinus, Cuv. and Val. xvii, p. 304, pl. 501; Jerdon, M. J. L. and Sc. 1849, p. 322. Rhodeus Indicus, Jerdon, M. J. L. and Sc. 1849, p. 324. Brachygramma Jerdoni, Day, Proc. Zool. Soc. 1865, p. 304. Amblypharyngodon Jerdoni, Day, Fishes of Malabar, p. 217, pl. 17, f. 1.

Wumboo, Mal.: Oolaree, Tam.: Kali-koraji, Hind., Paraga, Can.

4 B 2

B. iii, D. 9-10($\frac{2-5}{7}$), P. 15, V. 9, A. 7-8($\frac{2-5}{5}$), C. 19, L. 1. 50-57, L. tr. 10/8.

Length of head 5 to $5\frac{1}{2}$, of caudal 5, height of body 5 to $5\frac{1}{2}$ in the total length. Eyes—4 diameters in the length of the head, 1 diameter from end of snout, and $1\frac{1}{4}$ apart. Teeth—pharyngeal, with rather concave summits, 3, 2, 1/1, 2, 3. Fins—origin of dorsal is behind the insertion of the ventral, its upper edge concave: caudal rather deeply forked. Lateral-line—extends along 15 to 20 rows of scales, 4 rows between it and the base of the ventral fin. Colours—greenish along the back, becoming silvery on the sides and beneath, a bright greenish-yellow band, divides the colours of the back from a silvery line passing along the side.

In Cuv. and Val.'s figure the lateral-line is uninterrupted, also there are too many scales between it,

and the base of the ventral fin.

Habitat.—(Bombay, according to Cuv. and Val.) Malabar Coast, and southern India, from the Neilgherries to Madras, also Ceylon.

Genus, 19-Barbus, Cuvier and Valenciennes.

Puntius, pt. Ham. Buch.: Labeobarbus, Varicorhinus, pt. Rüpp.: Systomus, pt. McClell.: Capoëta, sp. Cuv. and Val.: Pseudobarbus, Bielz.: Luciobarbus, Heckel: Cheilobarbus, sp. Smith: Balantiocheilus, Hemibarbus, Cyclocheilichthys, Siaja, Anematichthys, Hypselobarbus, Gonoproktopterus, Gnathopogon, Hampala, sp. Bleeker: Enteromius, sp. Cope.

Mouth arched, and anterior or inferior: jaws closely invested by the lips, which may have leathery lobes, but no horny covering.* Barbels four (Barbodes, Bleeker): or two (Capoëta, Cuv. and Val.): or none (Puntius, H. Buch.). Eyes without adipose lids. Pharyngeal teeth 5 or 4, 3 or 4, 2 or 3 | 2 or 3, 3 or 4, 4 or 5. Dorsal fin rather short, commencing nearly opposite the root of the ventral: its last undivided ray being either ossified and serrated or entire, or articulated and not osseous: anal rather short, in some species its second ray ossified, or its last undivided ray may even be serrated (B. prodozyson, Bleeker). Scales large, of moderate or small size: anal scales not enlarged. Lateral-line may be complete, or incomplete, when the former it is continued to opposite the centre of the base of the caudal fin.

This most extensive Genus has been subdivided by various authors into numerous genera and sub-genera, but, passing gradually one into another, they have in the majority of instances failed to be permanently accepted. The three sub-genera of those with 4, 2, or 0 barbels are useful and apparently correct, for the occasional abnormal absence of one or more of these appendages in fish which are so extensively kept in an artificial state in tanks, does not appear sufficient reason why such natural subdivisions should be excluded from Ichthyological systems.

It is remarkable how very similar the Barbus Mahicola, C.V. which has 2 barbels, is to the B. filamentosus, C.V. with none. If a number of examples are examined it will be found that in some these appendages are very minute, the barbels being, as a rule, smallest in specimens obtained furthest from the hills. In South Canara, the Wynaad, and base of the Neilgherries, where the barbels are large, the B. Mahicola abounds: towards Cochin and up the Coromandel coast as far as Madras they are small or absent, and the B. filamentosus is the type. Here, undoubtedly, the question must force itself on one's notice, are we dealing with two distinct species, or one in a state of transition? If the latter, which is the original form? The adult of Barbus punctatus and B. phutunio are often exactly similar, but in the immature form the first retains its original colour, not so the second. Barbus chola and B. tetrarupugus are similar, except as to the presence of a black spot behind the opercle in the latter: whilst Barbus ticto shows considerable variations. Great changes evidently occur in some species if they are removed to another locality, thus Barbus conchonius, which has been imported from the plains and introduced into the Nainee tal lake is evidently losing the servature of its dorsal spine, in time, if this change goes on, the species will become more like B. terio than the original form.

The majority of those species which constitute the sub-genus Barbodes (4 barbels), provided they are soberly coloured, attain a large size: the brilliant coloured ones are mostly residents of clear and rapid mountain streams or rivers contiguous to hills and are generally small. A strong dorsal spine is usually (if not invariably) a sign that the species is one that lives in the vicinity of high mountains up the streams of which it ascends to breed, an exception, however, has to be made of those forms having serrated dorsal spines, and which are usually residents of waters of the plains. Considerable individual variations exist as to the comparative length and size of the dorsal spine, as a rule it increases in strength in the adult. In immature examples the last undivided dorsal ray may appear to be articulated in the young, although it is osseous in the adult.

Species of the sub-genus Capoeta (2 barbels) never attain the size reached by many of the Barbodes: some, more especially when residing in mountain streams, have vivid colours. The species of the sub-genus Puntius are mostly of small size, whilst a few are brilliantly coloured.

Amongst these sub-genera a most natural subdivision appears to be into those with the last undivided dorsal ray osseous and serrated or smooth, or others in which the bony element is absent: whilst even further subdivisions are easily made, if desired, into whether the fin rays are elongated, or the lateral-line is complete or incomplete.

* Birbus lithopidos is an exception.

† In counting the numbers of rows of scales between the lateral-line and insertion of the ventral fin, such is done in species in which the former is incomplete, from the row of scales on which the lateral-line would have existed had it been completed.

Geographical distribution.—Europe, and throughout Asia and Africa. Representatives of this genus exist in most, if not all, Indian and Burmese rivers and tanks, the larger species being generally termed Mahseers. Some attain an enormous size as 90 lb. and upwards, these are more residents in rivers along the bases of hills or large rapids, but a few have even a more extended range. The number of species appears to diminish as the Malay Archipelago is approached, whilst those forms having 4 barbels and also with an osseous and serrated dorsal ray largely increase in proportion to the others.

SYNOPSIS OF SPECIES.

A.—With four barbels, (Barbodes.)

- a. Last undivided dorsal ray, osseous and serrated.
- 1. Barbus chagunio, D. 3/8, A. 3/5, L. l. 44-47. Pores on snout and head. Colours uniform. Orissa, Bengal and N.W. Provinces, and Assam.

 Barbus clavatus, D. 3/8, A. 3/5, L. l. 42. Pores on snout. Colours uniform. Sikhim.
 Barbus sarana, D. 3-4/8, A. 3/5, L. l. 32-34. Colours uniform: in Burma the caudal has a dark inner edge. Sind, India, Ceylon and Burma.

4. Barbus chrysopoma, D. 4/8, A. 3/5, L. l. 28-30. A dark lateral blotch. Coasts of India, Deccan,

Madras, and Darjeeling.

- 5. Barbus pinnauratus, D. 3/8, A. 3/5, L. 1. 27-29. A black lateral blotch, fins orange. Bombay, Canara, and down the Malabar Coast to Ceylon, Southern India, and up the Coromandel Coast at least as high
- 6. Barbus pleurotænia, D. 3/8, A. 2/6, L. 1. 28. A black band from eye to middle of tail. Ceylon. 7. Barbus goniosoma, D. 3/8, A. 2/5, L. 1. 24. Serrated dorsal ray weak. Colours uniform. Mergui, to Sumatra.
 - 8. Barbus roseipinnis, D. 3/8, A. 2/5, L. l. 22. Caudal, anal, and ventrals red. Pondicherry.

b. Last undivided dorsal ray, osseous and entire.

- 9. Barbus dubius, D. 4/9, A. 2/5, L. l. 42. No pores on snout. 5 rows of scales between l. l. and base of ventral fin. Dorsal spine strong, nearly as long as head. Bowany river in Madras.

 10. Barbus micropogon, D. 4/9, A. 2-3/5, L. l. 39-41. Dorsal spine strong, a little longer than the head,

- 3 rows of scales between l. l. and base of ventral fin. Mysore, Bowany river in Madras, and Western Coast.

 11. Barbus chilinoides, D. 3/7-8, A. 2/5, L. l. 32-35. Lower lip with a continuous transverse fold. Dorsal spine strong. 3 rows of scales between l. l. and base of ventral fin. Ganges, Himalayas and Assam.

 12. Barbus Carnaticus, D. 4/8, A. 2/5, L. l. 30-32. Lower labial fold interrupted. Dorsal spine strong.

 3½ rows of scales between l. l. and base of ventral fin. Bowany river in Madras, and Western Coast.

 13. Barbus hexagonolepis, D. 3/9, A. 2/5, L. l. 28-31. Lower labial fold interrupted. Dorsal spine strong, as long as the head excluding the snout.

 2 to 2½ rows of scales between l. l. and base of ventral fin. Assam.
- 14. Barbus Dukai, D. 4/9, A. 2/5, L. l. 28-29. Lower labial fold interrupted. Large pores on cheeks. Dorsal spine strong, as long as head excluding the snout. $2\frac{1}{2}$ rows of scales between l. l. and base of ventral Darjeeling.
- 15. Barbus tor, D. 3/9, A. 2/5, L. l. 25-27. Dorsal spine strong, as long as the head excluding the snout. Upper jaw the longer, lips lobed. 2½ rows of scales between I. l. and base of ventral fin. Rapids throughout India.

16. Barbus hexastichus, D. 3-4/9, A. 2/5-6, L. 1. 25-26. Dorsal spine strong. 2½ rows of scales between

1.1. and base of ventral fin. Himalayas, River Jumna, and perhaps Ceylon.

- 17. Barbus Bovanicus, D. 3/9, A. 3/5, L. 1. 24-26. Lower labial fold entire. Dorsal spine of moderate strength and as long as the head excluding the snout. 2½ rows of scales between l. l. and base of ventral fin. Bowany river in Madras.
- 18. Barbus sophore, D. 3/9, A. 2/5, L. l. 25. Dorsal spine weak, $2\frac{1}{2}$ rows of scales between l. l. and base of ventral fin. Assam and Khasia hills.
- 19. Barbus Stracheyi, D. 2/9, A. 2/5, L. l. 23. Dorsal spine strong. 2½ rows of scales between l. l. and base of ventral fin. Tenasserim and Burma.
 - c. Last undivided dorsal ray articulated, or if osseous very weak.*
- 20. Barbus curmuca, D. 3/9, A. 3/5, L. l. 41. 3\frac{1}{4} rows of scales between l. l. and base of the ventral fin. Western ghauts of India.
- 21. Barbus lithopidos, D. 3/9, A. 3/5, L. l. 38-39. 4 rows of scales between l. l. and base of the ventral Of a slate-colour. South Canara.
- 22. Barbus Thomassi, D. 3-4/9, A. 3/5. L. l. 31-34. $2\frac{1}{2}$ rows of scales between l. l. and base of the ventral fin. Each scale with a red mark: dorsal and caudal fins lake colour. South Canara.

23. Barbus spinulosus, D. 3/9, A. 3/7. Sikhim.

* I have included those species in which the last undivided ray is not enlarged, but some of which have its lower portion more or less osscous in the adult stage.

24. Barbus pulchellus, D. 3/9, A. 2/5, L. 1. 30-32. $3\frac{1}{2}$ rows of scales between 1. 1. and base of ventral fin.

Upper half of body dark coloured: a light band from eye to caudal fin. Canara.

25. Barbus Dobsoni, D. 3-4/9, A. 3/5, L. 1. 30-32. Length of head 6 in the total. 3½ rows of scales between 1. 1. and base of overtral fin. Poona and the Deccan.

26. Barbus Jerdoni, D. 3/9, A. 3/5, L. 1. 27-28. Length of head 5 to 5½ in the total. 2½ to 3½ rows of scales between 1. 1. and base of overtral fin. Poona and the Deccan. scales between l. l. and base of ventral fin. Canara. 27. Barbus Wynaadensis, D. 4/8, A. 3/5, L. 1. 26-28. 21 to 3 rows of scales between 1. 1. and base of

ventral fin. Wynaad hills. 28. Barbus Stevensonii, D. 3/9, A. 3/5, L. l. 27. 2½ rows of scales between l. l. and base of ventral fin.

- Akyab. 29. Barbus Neilli, D. 4/9, A. 3/5, L. l. 24-26. 31 rows of scales between l. l. and base of ventral fin.
- Kurnool and the Deccan. 30. Barbus Malabaricus, D. 3-4/9, A. 3/5, L. 1. 24. 11 rows of scales between 1.1. and base of the ventral

Western ghauts of India. 31. Barbus innominatus, D. 3/9, A. 2/5, L. 1. 24. 3 rows of scales between 1. 1. and base of ventral fin.

Ceylon. 32. Barbus compressus, D. 3/9, A. 3/5, L. l. 22. 31 rows of scales between l. l. and base of ventral fin.

Cashmere? 33. Barbus Blythii, D. 3/9, A. 3/5, L. 1. 22. 2½ rows of scales between 1. 1. and base of ventral fin.

Tenasserim.

34. Barbus melanampyx, D. 3/8, A. 2/5, L. 1. 20. 2 rows of scales between l. l. and base of ventral fin. Red, with three vertical black bands. Rivers along Western Ghauts as low as Travancore.

B.—With two barbels (Capoëta).

a. With osseous, serrated, dorsal ray.

35. Barbus macrolepidotus, D. 4/8, A. 2/6, L. 1. 26. 21 rows of scales between I. I. and base of ventral. Tavoy to the Malay Archipelago.

b. Osseous dorsal ray, entire.

36. Barbus chola, D. 3/8, A. 2/5, L. 1. 26-28. Narrow suborbitals. 3 to 3½ rows of scales between 1. 1. and base of ventral fin. A lateral blotch, and two bands on dorsal fin. India and Burma.

37. Barbus parrah, D. 3/8, A. 3/5, L. 1. 25. Wide suborbitals. 3½ rows of scales between l. 1. and base of ventral fin. A dark lateral blotch. Southern India and Malabar.

38. Barbus Burmanicus, D. 4/8, A. 2/5, L. l. 26. 2 rows of scales between l. l. and base of ventral fin.

39. Barbus tetrarupugus, D. 2-3/8, A. 2/5, L. 1. 24-26. 3\frac{1}{2} rows of scales between 1. 1. and base of ventral A black spot behind gill-opening, a second near base of caudal fin: a band on dorsal fin.

(except Mysore, Madras and the Western coast). 40. Barbus dorsalis, D. 3-4/8, A. 3/5, L. 1. 24-25. 2½ rows of scales between l. l. and base of ventral fin. A black spot at end of base of dorsal fin. Mysore, Southern India and Ceylon.

- Last undivided dorsal ray articulated, or if osseous very weak.
- 41. Barbus kolus, D. 3-4/9, A. 3/5, L. 1. 40-43. 4 to 5 rows of scales between 1. 1. and base of ventral Deccan, and throughout the Kistna river, Central Provinces.

- 42. Barbus Denisonii, D. 2-3/8, A. 3/5, L. l. 28. $2\frac{1}{2}$ rows of scales between l. l. and base of ventral fin. Body longitudinally banded. Hill ranges of Travancore.

 43. Barbus melanostigma, D. 2/8, A. 2/5. 3 rows of scales between l. l. and base of ventral fin. A light band along the side: a deep black lateral blotch. Wynaad hills, also Bowany and Cauvery rivers.

 44. Barbus arenatus, D. 2/8, A. 3/5, L. l. 26. $3\frac{1}{2}$ rows of scales between l. l. and base of ventral fin.
- Madras.
- 45. Barbus Puckelli, D. 2/7, A. 3/5, L. 1. 24. 21 rows of scales between 1. 1. and base of ventral fin. A black mark along the base of dorsal fin. Mysore.

46. Barbus amphibius, D. 2-3/8, A. 2/5, L. 1. 23-24. 2 rows of scales between 1. 1. and base of ventral fin. A dark lateral blotch sometimes present. Western coast of India, Deccan, and Southern India.

47. Barbus arulius, D. 3/8, A. 2/5, L. 1. 23. 2½ rows of scales between 1. 1. and base of ventral fin. Body vertical banded. Western Ghauts and Southern India.

48. Barbus Mahicola, D. 3/8, A. 2/5 L. l. 21. 2½ rows of scales between l. l. and base of ventral fin. A deep lateral blotch. Western and Southern India, also Ceylon.

C.—Without barbels (Puntius).

a. With osseous serrated dorsal ray.

49. Barbus apogon, D. 4/8, L. l. 36, complete. $5\frac{1}{2}$ rows of scales between l. l. and ventral fin. Each scale with a dark base. Burma to the Malay Archipelago.
50. Barbus ambassis, D. 3/8, L. l. 36, incomplete. 6 rows of scales between lateral-line and ventral fin. A black lateral blotch, another at base of anterior dorsal rays. Southern India, Orissa, Bengal and Assam.

51. Barbus conchonius, D. 3/8, L. 1. 26, incomplete; 4½ rows between lateral-line and ventral fin. A black spot on side over anal fin. From the Punjab throughout Bengal, the Deccan, Orissa and Assam.

52. Barbus ticto, D. 3/8, L. 1. 23-26, incomplete. Two black spots, one at commencement of lateral-line, another at the side of the tail. Throughout India.

53. Barbus Stoliczkanus, D. 2/8, L. 1. 25, complete. Two black marks on lateral-line. Darjeeling and

- Burma.
- 54. Barbus punctatus, D. 3/8, L. l. 23, complete. Two black spots one below the commencement of lateral-line, the other near its termination. Malabar coast and Madras.

55. Barbus gelius, D. 3/8, L. l. 25, incomplete. A black band over tail, a black spot across the bases of the first 6 dorsal rays, and another over base of anal. Orissa, Bengal, and Assam.

56. Barbus phutunio, D. 2-3/8, L. l. 20-23, incomplete. Four vertical black bands on a brown body, and a dark one down the centre of the dorsal fin. Bengal, Orissa, Ganjam and Assam.

57. Barbus Cumingii, D. 3/8, A. 3/5, L. l. 21, incomplete. 3 rows of scales between l. l. and base of

ventral fin. Two dark vertical bands. Ceylon.

58. Barbus nigrofasciatus, D. 3/8, L. l. 20, complete. Three vertical black bands on body. Southern

Ceylon. 59. Barbus guganio, D. 2/8, L. l. incomplete. Bengal and Assam.

b. Osseous dorsal ray, entire.

60. Barbus stigma, D. 3/8, L. 1. 23-36, complete. A dark mark near the posterior extremity of the lateral-line, another across the base of the middle dorsal rays, Throughout India and Burma.

61. Barbus chrysopterus, D. 3/8, L. l. 23-25, complete. Fins black tipped. Sind, Punjab, N. W.

Provinces, Assam, N. India.

62. Barbus thermalis, D. 3/8, A. 3/5, L. 24, incomplete. 31 rows of scales between 1. l. and base of

ventral fin. A dark mark at side of base of tail. Ceylon.

63. Barbus terio, D. 3/8, L. l. 21-23, incomplete. A black mark on side above the anal fin, sometimes continued by a band to the caudal, a second indistinct one under posterior end of dorsal. Orissa, Bengal, and Punjab.

c. Last undivided dorsal ray articulated, or if osseous very weak.

64. Barbus Punjabensis, D. 3/8, L. l. 43, incomplete. A silvery band along the side, a black spot at

base of caudal, and two first dorsal rays black. Lahore in the Punjáb, also Jubbulpore.
65. Barbus unimaculatus, D. 3/8, L. l. 24, incomplete. A black mark at base of each dorsal ray. Sitang

river in Burma.

66. Barbus Waagenii, D. 2-3/8, A. 2/5, L. 1. 23, incomplete. A lateral blotch. Punjab salt-range.

67. Burbus cosuatis, D. 3/8, L. l. 22, incomplete. Uniform, a dark spot across the middle of the anterior dorsal rays. Throughout India.

68. Barbus vittatus, D. 2/8, L. 1. 20-22, incomplete. Four black spots on the side, and a black streak

down the dorsal fin. Cutch, Malabar, Mysore and Madras.

- 69. Barbus filamentosus, D. 3/8, L. 1. 21, complete. Branched dorsal rays elongated. A black mark near posterior end of lateral-line, and each caudal lobe with a black extremity. Malabar coast and Southern India.
- 70. Barbus puntio, D. 3/8, L. l. 23, incomplete. A black band encircles the free portion of the tail. Bengal and Burma.

A.—With four Barbels (Barbodes).

- a. Last undivided dorsal ray, osseous and serrated.
- 1. Barbus chagunio, Plate CXXXVI, fig. 2 (variety spilopholus), and CXL, fig. 2.

Cyprinus chagunio, Ham. Buch. Fishes of Ganges, pp. 295, 387.

Rohita chagunio, Cuv. and Val. xvi. p. 257.

Barbus chagunio, spilopholus and sarana, (not H. B.) McClell. Ind. Cyp. pp. 272, 341, pl. 9, f. 4; Bleeker, Beng. p. 60; Day, Proc. Zool. Soc. 1869, p. 373.

Barbus spilopholis, Cuv. and Val. xvi, p. 171; Günther, Catal. vii, p. 96.

Barbus Beavani, Günther, Catal. vii, p. 96.

Jerruah, Beng.: Chaguni, Behar.: Pootee keintah, Assam.

B. iii, D. $11(\frac{3}{8})$, P. 15, V. 9, A. $8(\frac{3}{6})$, C. 19, L. l. 44-47, L. tr. 11/9.

Length of head 4½ to 5, of caudal 5, height of body 4 to 4½ in the total length. Eyes—diameter 5 to $6\frac{1}{2}$ in length of head, 2 to 3 diameters from end of snout, $1\frac{1}{2}$ diameters apart. Suborbital region, cheeks and anterior superior margin of the orbit usually covered with numerous pores. Mouth somewhat inferior but directed forwards. Barbels—both pairs rather longer than the orbit. Fins—dorsal commences midway between the end of the snout and the base of the caudal fin, its last undivided ray is osseous, strong, with coarse teeth: its length equals rather more than that of the head excluding the snout: some of the last few anal rays in large specimens may be elongated, (B. spilophilus), but more frequently not so. Lateral-line—complete, with from $5\frac{1}{2}$ to $6\frac{1}{2}$ rows of scales between it and the base of the ventral fin: 15 rows before the dorsal fin. Free portion of the tail as high as long. Colours—uniform silvery, with a pinkish tinge, the scales towards the back sometimes being darkest at their bases: fins reddish with light outer edges, the summit of the dorsal fin

sometimes black. The young have a silvery band along the side.

McClelland mistook H. Buchanan's figure of the Cyprinus chagunio, (it was marked C. kunta) for Barbus sarana, but found out his error previous to publishing the figure (which he consequently suppressed). That a fish, "the same with the kunamoo of Dr. Russell," as Buchanan describes the sarana, can be identical (as advanced by Dr. Günther) with C. kunth is incredible. H. Buchanan in his MSS. list of fish observes, "The Darangi of the Tistá is, in some places called kuntá. It has a great affinity with the Curmuca which is described in my account of Mysore." The C. chagunio, of which the figure labelled C. kunta is the representative, is placed next to the C. curmuca, and it is stated p. 294, "This and the following species have a great resemblance to the Cyprinus cirrhosus of Bloch: but the callosities of the head are neither mentioned in Bloch's description nor represented in his figure;" showing how alike he must have considered the two to be. If C. kunta is not C. chagunio, what does it represent? and where is the figure of chagunio?

Habitat.—From Orissa, throughout Bengal, Assam, Behar and the N. W. Provinces to the Punjab, but not recorded from Sind, the Decean, Western coast, Mysore, Madras, or Burma. It attains at least 18 inches

The figure of the variety B. spilopholus (Plate CXXXVI) is from an Assam example, 7.5 inches in length: that on plate CXL is from a Delhi specimen.

2. Barbus clavatus.

McClelland, Cal. Journ. Nat. Hist. 1845, p. 280, pl. 21, f. 2; Günther, Catal. vii, p. 97.

B. iii. D. $11(\frac{3}{8})$, P. 16, V. 10, A. $8(\frac{3}{8})$, C. 19, L. l. 42, L. tr. 6/4.

Height of the body 1/4 of the length excluding the caudal fin. Eyes—large and in the middle of the length of the head. Snout covered with small thorny tubercles. Barbels-two well-developed pairs. Finslast undivided dorsal ray osseous, strong, serrated, and as long as the body is high. Scales—11½ rows in an oblique line from the base of the ventral to the dorsal. The figure shows 4½ rows between the lateral-line and base of the ventral which would give 61 above the lateral-line. Colours—blue superiorly becoming white beneath: the fins pale bluish white.

Habitat.—A single specimen (7 inches long) was obtained from a river at the base of the Sikhim

mountains in Bengal.

Barbus immaculatus and Russellii, Günther, Catal. vii, p. 121.

Pungella, Tam.: Giddi-kaoli, Durhie and Potah, Hind.: Gid-pakke, Can.: Kannaku, Tel.: Sarana, Ooriah and Beng.: Jundoori, Punj.: Pop-pree and Kuh-nah-nee, Sind.: Sen-nee, Assam: Nga-khon-mah-gyee and Nga-chong, Burmese.

B. iii, D. $11(\frac{3}{8})$, P. 15, V. 9, A. $8(\frac{3}{5})$, C. 19, L. 1. 32-34, L. tr. $5\frac{1}{2}$ -6/6.

Length of head 5 to $5\frac{1}{4}$, of caudal 5, height of body $3\frac{1}{2}$ to $3\frac{2}{3}$ in the total length. Eyes—diameter $4\frac{1}{4}$ to $4\frac{3}{4}$ in the length of head, 1 to $1\frac{1}{3}$ diameters from the end of snout, and 2 diameters apart. Profile of the back elevated. Interorbital space convex. Lower labial fold interrupted. No pores on the snout. Barbels—the rostral pair about as long as the orbit, the maxillary pair longer, sometimes equalling 11 diameters of the orbit. Fins—dorsal commences slightly nearer the snout than the base of the caudal fin and opposite the insertion of the ventral, its last undivided ray osseous, strong in the adult, finely serrated posteriorly, and with its stiff portion 2/3 as long as the head, the fin is 1/2 to 2/3 as high as the body, with its upper edge concave. Lateral-line—complete, from $3\frac{1}{2}$ to 4 rows of scales between it and the base of the ventral fin: 10 to 11 rows before the dorsal fin. Colours—silvery, darkest superiorly, opercles shot with gold: the young have occasionally a dull blotch on the lateral-line before the base of the caudal fin. Mostly some dark spots behind the opercle. When the fish is fresh there are sometimes horizontal bands along the rows of scales in the upper half of the body. Fins whitish or yellowish-white, and externally stained with gray.

In some Deccan specimens the eye is sometimes as large as 1/4 of the length of the head. As a rule in adult specimens the length of the head is about 1/4 of the total length excluding the caudal fin. The body in

the young is more compressed and somewhat higher than in the adult.

Barbus sarana, McClelland, is B. chagunio, Ham. Buch. The two type specimens B. russelli, Günther, from Sind, have L. l. 32-34 (not 27 as stated). Barbus rodactylus, McClelland, Ind. Cyp. p. 273, from Lower Assam, has no characters pointed out by which it may be distinguished from the above.

Habitat.—Sind and the Punjab, throughout India, Assam and Burma, in which latter country the caudal fin has sometimes a black upper and lower edge and a dark mark at the base of each scale. It attains at least a foot in length. The specimen figured (9 inches long) was from Assam.

4. Barbus chrysopoma.

Cuv. and Val. xvi, p. 165, pl. 466; Bleeker, Beng. p. 60; Day, Fishes of Malabar, p. 208; Günther, Catal. vii, p. 113.

? Barbus Polydori, Cuv. and Val. xvi, p. 170; Bleeker, Beng. p. 60. Systomus chrysopoma, Jerdon, Madras Journ. Lit. and Sc. 1849, p. 314. Munduttee, Mal.

B. iii, D. 12 $(\frac{4}{8})$, P. 17, V. 9, A. 8 $(\frac{3}{6})$, C. 19, L. 1. 28-30, L. tr. 6/6.

Length of head $4\frac{1}{3}$ to 5, of caudal $4\frac{1}{2}$, height of body $3\frac{2}{3}$ in the total length. Eyes—diameter $3\frac{1}{4}$ to $3\frac{1}{4}$ in the length of the head (at 2.6 inches in length the eye is at least $2\frac{1}{4}$ in the length of the head), 1 diameter from the end of snout, and 1 to 1½ apart. Height of head almost equals its length. Profile of back somewhat elevated. Interorbital space flat. Lower labial fold interrupted. Barbels—the rostral very thin, not so long as the eye: the maxillary as long as the orbit. Fins—dorsal commences midway between the front edge of the eye and the base of the caudal fin and opposite the insertion of the ventral, its last undivided ray osseous, of moderate strength, finely serrated posteriorly, and with its stiff portion as long as the head excluding the snout: the height of the fin is 2/3 to 3/4 that of the body below it, its upper edge concave. Lateral-line—complete, and a little more concave than in the next species, whilst it is sometimes sinuous in the last part of its course, 4 rows of scales between it and the base of the ventral fin: 12 rows before the base of the dorsal fin. Colours—dark silvery, lightest beneath, opercles shot with purple and gold. A dark vertical band behind the opercles and a dull spot on the lateral-line just anterior to the base of the caudal fin. Upper and lower margins of the caudal grayish: the other fins golden.

The eyes in this species are larger and not so far apart as in B. sarana: the length of the head in adults

becomes shorter, and the eye larger, and the interorbital space flat.

Habitat.—Fresh waters along the coasts of India from Cutch to Bengal, also the Deccan, Mysore, and Madras. I have likewise received it from Darjeeling.

5. Barbus pinnauratus, Plate CXXXIX, fig. 3.

? Barbus gibbosus and subnasutus, Cuv. and Val. xvi, pp, 154, 155; Bleeker, Beng. p. 60. Puntius (Barbodes) chrysopoma, Bleeker, Ceylon, p. 15, t. 3, f. 1 (not Cuv. and Val.). Cyclocheilichthys pinnauratus, Day, Proc. Zool. Soc. 1865, p. 300. Puntius pinnauratus, Day, Fish. Malabar, p. 209, pl. xv, f. 2. Barbus pinnauratus, Günther, Catal. vii, p. 114. Barbus spilurus, Günther, Catal. vii, p. 114.

B. iii, D. 11 $(\frac{3}{8})$, P. 17, V. 8, A. 7 $(\frac{2}{5})$, C. 19, L. 1. 29-30, L. tr. $5\frac{1}{3}$ -6/6.

Length of head 5 to $5\frac{1}{3}$, of caudal 4 to $4\frac{1}{2}$, height of body $3\frac{1}{3}$ to $3\frac{1}{2}$ in the total length. Eyes—diameter $3\frac{1}{2}$ in the length of the head, nearly to, or quite 1 diameter from the end of snout, and $1\frac{1}{4}$ to $1\frac{2}{3}$ apart. Body compressed. Dorsal and abdominal profiles about equally convex. Snout rather obtuse. Interorbital space a little convex. Lower labial fold interrupted. Barbels—the maxillary pair are one half longer than the orbit, the rostral pair a little shorter. Fins—dorsal commences midway between the end of the snout and the base of the caudal fin, it is slightly in advance of the insertion of the ventral, 2/3 as high as the body, having its upper edge concave, its last undivided ray osseous (weak in the young, but strengthening with age), as long as the head excluding the snout, and posteriorly serrated. Lateral-line—complete, $3\frac{1}{3}$ or 4 rows of scales between it and the base of the ventral fin: 10 rows before the dorsal fin. Free portion of the tail as high as long. Colours—silvery along the back and upper half of the body, becoming white shot with gold beneath: most of the scales with black bases. A dark band behind the opercles and a black blotch on the lateral-line, commencing about the twenty-fourth scale. Opercles and fins orange, caudal with a black superior and inferior edge.

B. gibbosus, Cuv. and Val. xvi, p. 155, from Allepey, may be this species, described from a specimen with a short head (6 in the total length). I have obtained similar starved or unhealthy examples.

Digitized by Google

Habitat.—From fresh waters at Coconada down the East coast of India to Ceylon, and inland as far as the Neilgherries, also along the Western ghauts and rivers at their bases. The largest example obtained was 10½ inches in length. This form and B. chrysopoma may be merely varieties of a single species, whilst B. sarana is closely allied. The example figured (life-size) was from the Wynaad.

6. Barbus pleurotænia.

Puntius (Barbodes) pleurotænia, Bleeker, Cobit. et Cypr. Ceylon, in Nat. Verh. Holl. Maatsch. Harl. 1864, p. 13, t. 8, f. 2.

Barbus pleurotænia, Günther, Catal. vii, p. 120.

B. iii, D. 11 $(\frac{3}{6})$, P. 14, V. 9, A. 8 $(\frac{3}{5})$, C. 19, L. 1. 27-29, L. tr. $5/4\frac{1}{2}$.

Length of head about $5\frac{1}{4}$, of caudal 5, height of body 4 in the total length. Eyes—diameter 2/7 of length of head, 1 to $1\frac{1}{4}$ diameters from end of snout, and slightly more apart. Body compressed, a little elevated; upper jaw slightly the longer. Lower labial fold interrupted. Barbels—both pairs somewhat longer than the orbit. Fins—dorsal commences over the ventral, and midway between the end of the snout and the base of the caudal: its last undivided ray is osseous, very strong, serrated posteriorly, and as long as the head, the upper margin of the fin concave: caudal forked. Lateral-line—complete, $2\frac{1}{2}$ rows of scales between it and the root of the ventral: 10 rows before the dorsal fin. Colours—a black band extends from the eye to the termination of the central caudal rays.

Habitat.--Ceylon.

7. Barbus goniosoma, Plate CXXXVII, fig. 2.

Puntius (Barbodes) goniosoma, Bleeker, Prod. Cyp. p. 349, and Atl. Ich. Cyp. p. 105, t. 31, f. 1. Barbus goniosoma, Günther, Catal. vii, pp. 124.

B. iii, D. 11 $\binom{3}{8}$, P. 15, V. 8, A. 7 $\binom{3}{6}$, C. 19, L. I. 24, L. tr. $4\frac{1}{2}/4\frac{1}{2}$.

Length of head about 5, of caudal $5\frac{1}{5}$, height of body $3\frac{1}{5}$ in the total length. Eyes—diameter 2/7 of length of head, 1 diameter from end of snout, and $1\frac{1}{4}$ apart. Body elevated to the base of dorsal fin, whilst it is strongly compressed. Rostral barbels extend to below the middle of the eye: the maxillary ones to opposite the posterior margin of the orbit. Fins—origin of dorsal slightly posterior to the insertion of the ventrals, and midway between the anterior margin of the orbit and the base of the caudal: its spine is osseous, strong, as long as the head without the snout, and finely serrated posteriorly in its whole extent: the fin is 1/2 as high as the body. Caudal forked, the lower lobe the longer. Lateral-line— $2\frac{1}{3}$ rows of scales between it and the base of the ventral fin: 9 rows before the dorsal. Free portion of the tail rather higher than long. Colours—silvery, fins orange.

Hubitat.—Mergui to Sumatra. I have obtained specimens at the first place up to 6 inches in length.

8. Barbus roseipinnis.

Cuv. and Val. xvi, p. 169; Bleeker, Beng. p. 60; Jerdon, M. J. L. and Sc. 1849, p. 314.

B. iii, D. 11 $(\frac{3}{8})$, A. 7 $(\frac{2}{6})$, C. 20, L. l. 22.

Dorsal profile elevated. Eyes—large. Barbels—four, thin and long. Fins—dorsal with its last undivided ray osseous, of moderate length and serrated. Colours—silvery: ventral, anal and caudal fins reddish, the lower border of the last tinged with black.

Habitat.—Pondicherry, from whence M. Belanger brought specimens $4\frac{1}{2}$ inches in length, which unfortunately had been mislaid when I was last in Paris.

b. Last undivided dorsal ray, osseous and entire.

9. Barbus dubius, Plate CXXXVII, fig. 1.

Puntius (Barbodes) dubius, Day, Proc. Zool. Soc. 1867, p. 291. Barbus dubius, Günther, Catal. vii, p. 127.

Collee-aringean candee, Tam.

B. iii, D. 12 $(\frac{4}{9})$, P. 17, V. 9, A. 7 $(\frac{2}{5})$, L. 1. 42-45, L. tr. 9/8.

Length of head $5\frac{1}{4}$, of caudal $4\frac{1}{2}$, height of body $4\frac{1}{2}$ in the total length. Eyes—diameter $4\frac{1}{2}$ in length of head, $1\frac{1}{3}$ diameters apart, and also from end of snout. Dorsal profile rather more convex than that of the abdomen. Barbels—rather short, the rostral pair being about equal to half the diameter of the orbit: whilst the maxillary are a little longer. Snout somewhat elevated. Fins—dorsal spine osseous, smooth, and strong, it is nearly as long as the head, the fin commences somewhat nearer to the end of the snout than the base of the caudal, and a little in advance of the insertion of the ventral. Lateral-line—complete, $4\frac{1}{2}$ to 5 rows of scales between it and the base of the ventral fins: 14 rows before the dorsal fin. Colours—uniform silvery, with the bases of the scales darkest.

Habitat.—Bowany river at the foot of the Neilgherries. The example figured was 10 inches in length.

10. Barbus micropogon, Plate CXXXVI, fig. 3, and CXXXVIII, fig. 4.

Cuv. and Val. xvi, p. 188; Bleeker, Beng. p. 60; (Günther, Catal. vii, p. 126, not synonymous). Barbus gracilis, Jerdon, M. J. L. and Sc. 1849, p. 313 (not Schleg.).

Barbus Mysorensis, Jerdon, l. c.

Puntius gracilis, Day, Proc. Zool. Soc. 1867, p. 290, and 1870, p. 290. Barbus conirostris, Günther, Catal. vii, p. 127.

Coatee candee, Tamil.

B. iii, D. 13 ($\frac{4}{9}$), P. 17, V. 10, A. 7-8 ($\frac{2-3}{9}$), C. 19, L. 1. 39-41, L. tr. 6-7/7.

Length of head $4\frac{3}{4}$ to $5\frac{1}{2}$, of caudal 5, height of body 4 to $4\frac{1}{2}$ in the total length. Eyes—in the middle of the length of the head, diameter $3\frac{1}{2}$ to $4\frac{1}{2}$ in length of head, $1\frac{1}{4}$ diameters apart and also from end of snout. Interorbital space flat. Dorsal profile elevated. Snout conically pointed, and adults have pores on the preorbital, and even all across the snout. Cleft of mouth extending about half the distance to below the anterior margin of the orbit; upper jaw slightly the longer. Lower labial fold interrupted. Barbels—the rostral extend to below the anterior third of the orbit, the maxillary ones to below its posterior margin. Teeth—pharyngeal, crooked, pointed, 4, 3, 2/2, 3, 4. Fins—dorsal commences slightly before the insertion of the ventrals, and midway between the end of the snout and the base of the caudal fin: its osseous ray is strong, smooth, and somewhat compressed: its stiff portion being slightly longer than the head. Pectoral 3/4 as long as the head. Caudal deeply forked. Lateral-line—complete, but becomes lost in old specimens: 3 to 3½ rows of scales between it and the ventral fin: 15 rows anterior to the dorsal fin. Free portion of the tail as high as long. Colours—cheeks golden, body with a greenish tinge superiorly, becoming white tinged with gold below the lateral-line, the base of each scale somewhat the darkest. Fins darkest along

Cuv. and Val. type (3 inches in length) is still in a good state of preservation at Paris. The variety B. Mysorensis, Jerdon, has numerous large pores on the snout and preorbital.

Habitat.—Rivers around the base of the Neilgherries, and Wynaad and South Canara range of hills, also Mysore. It attains a large size, some were personally introduced into the Ootacamund lake. The example figured on plate exxxvi (7.5 inches in length) was from the Wynaad: the specimen on plate exxxviii (life-size) was from the Bowany.

Barbus Himalayanus, Day, Journal As. Soc. of Beng. xli, pt. ii, 1872, p. 525.

Chit-rah-too, Punj.

B. iii, D. 10-11 $(\frac{3}{6})$, P. 17, V. 9, A. 7 $(\frac{2}{6})$, C. 19, L. 1. 32-35, L. tr. $5\frac{1}{2}/6$.

Length of head 5, of caudal 6, height of body $5\frac{1}{4}$ in the total length. Eyes—diameter 4 to 5 in the length of head, $1\frac{1}{4}$ diameters from end of snout, and two diameters apart. Body elongated, dorsal and abdominal profiles about equally convex. Mouth directed forwards, with the upper jaw slightly the longer: the snout overhangs the mouth. Some examples have a depression across the snout. There are numerous fine glands over the cheeks and opercles: lips moderately thick, the lower without a lobe, but with a continuous transverse fold. Barbels—the rostral and maxillary pairs of about the same length, and equal $1\frac{1}{2}$ diameters of the orbit. Fins—dorsal commences about midway between end of snout and base of the caudal fin, its last undivided ray is osseous, very strong, entire, its stiff portion being about three-fifths of the length of the head. Anal laid flat reaches the base of the caudal, which is deeply forked. Lateral-line-complete, there are three rows of scales between it and the base of the caudal fin. Colours—golden above, becoming silvery beneath, the margins of the scales with numerous fine black dots: a black mark behind the opercle. Fins reddish.

The specimen of B. micropogon, Günther (not C.V.), in the British Museum, 30 inches long, is a very badly stuffed skin, only one side has been preserved. It has evidently been stretched.

Habitat.—Himalayas, as far to the east as Assam, it is also found in the Ganges. It attains 21 feet in length. The example figured (life-size) was from near Simla.

12. Barbus Carnaticus, Plate CXXXVII, fig. 3.

Jerdon, M. J. L. S. 1849, p. 311: Günther, Catal. vii, p. 128.

Puntius (Barbodes) Carnaticus, Day, Proc. Zool. Soc. 1867, p. 292.

Poaree candee, Saal candee, Shellee, Tamil.: Giddi-kaoli, Hind.: Gid-pakke, Can.

B. iii, D. $12(\frac{4}{8})$, P. 15, V. 9, A. $7(\frac{2}{5})$, C. 19, L. 1. 32, L. tr. 5/6.

Length of head $5\frac{3}{4}$, of caudal $4\frac{1}{2}$ to 5, height of body 3 to 4 in the total length. Eyes—diameter 3 to 4 in the length of the head, 1 diameter from the end of snout, and $1\frac{1}{2}$ to 2 apart. Interorbital space flat. Dorsal profile more convex than that of the abdomen. Upper jaw the longer. Lower labial fold interrupted. Teeth—

Digitized by Google

pharyngeal, pointed, curved, 5, 3, 2/2, 3, 5. Barbels—thin, both pairs shorter than the eye. Fins—the dorsal 3/4 as high as the body with a concave upper edge: it commences anterior to the insertion of the ventral, and midway between the snout and the base of the caudal fin, its last undivided ray is a strong, broad, smooth spine, nearly as long as the head in the immature, and sometimes longer in the adult, especially in specimens from Canara. Pectoral as long or rather longer than the head. Anal laid flat reaches the caudal. Lateral-line—complete, $3\frac{1}{2}$ rows of scales between it and the base of the ventral fin: 12 rows anterior to the dorsal fin. Free portion of the tail as high at its base as it is long. Colours—greenish-brown along the back, becoming dull white glossed with gold on the sides and beneath. Fins grayish. Eyes golden.

Habitat.—Rivers along the bases of the Neilgherries, Wynaad, and South Canara hills. It attains at least 25 lbs. in weight. Some have been introduced into the Ootacamund lake. The figure is from a young specimen, life size, the dorsal spine not being well-developed, and the snout not so obtuse as in older specimens.

13. Barbus hexagonolepis, Plate CXXXVII, fig 4.

McClelland, Ind. Cyp. pp. 270, 336, pl. 41, f. 3. Bokar and Boolooah, Assam.

B. iii, D. $12\binom{5}{9}$, P. 17, V. 9, A. $7\binom{2}{5}$, C. 19, L. l. 28-31, L. tr. $4\frac{1}{2}/4\frac{1}{2}$.

Length of head 5 to $5\frac{1}{2}$, of caudal 5 to $5\frac{1}{2}$, height of body 5 to $5\frac{1}{2}$ in the total length. Eyes—diameter 5 to 6 in the length of the head, $1\frac{1}{2}$ to 2 diameters from the end of the snout, and $2\frac{1}{2}$ apart. Dorsal and abdominal profiles equally and slightly convex. Interorbital space rather convex. Upper jaw the longer. Lower labial fold interrupted. Opercle higher than wide. Sometimes pores on the cheeks. Barbels—the maxillary reach nearly to below the hind edge of the propercle, the rostral ones are shorter. Fins—dorsal 2/3 as high as the body, it commences somewhat anterior to the insertion of the ventral, and about midway between the end of the snout and the base of the caudal fin, its last undivided ray is strong, osseous, smooth, with its stiff portion as long as the head excluding the snout. Pectoral as long as the head excluding the snout, and not reaching the ventral. Anal laid flat does not extend to the base of the caudal which is deeply forked. Lateral-line—complete, 2 to $2\frac{1}{2}$ rows of scales between it and the ventral: 10 to 11 rows before the dorsal. Exposed portion of scales somewhat hexagonal. Free portion of tail rather longer than high. Colours—deep bluish-gray, fins darker.

The character of the interrupted groove behind the lower lip at once distinguishes this species from B. hexastichus.

Habitat.—Assam in the larger rivers, and those from the Himalayas. It attains upwards of 2 feet in length, and takes a fly or bait freely. The specimen figured (9 inches in length) was from Suddya. McClelland considered Cyprinus putitora, Ham. Buch. as a variety of this species, it is said to attain 9 feet in length.

14. Barbus Dukai, Plate CXLIII, fig. 3.

B. iii, D. $13(\frac{4}{9})$, P. 15, V. 9, A. $7(\frac{2}{5})$, C. 19, L. 1. 28-29, L. tr. 4/4.

Length of head $4\frac{3}{4}$ to 5, of caudal $4\frac{3}{4}$ to 5, height of body $4\frac{1}{3}$ to 5 in the total length. Eyes—diameter $3\frac{2}{3}$ to 4 in the length of the head, $1\frac{1}{4}$ diameters from the end of snout, and $1\frac{1}{3}$ apart. Body elongated and compressed. Interorbital space rather convex. Sides of snout and below the eye with large open tubercles. The maxilla reaches to beneath the commencement of the orbit. Lower labial fold interrupted. Barbels—the rostral pair are slightly longer than the orbit, the maxillary pair almost reach the angle of the preopercle. Fins—the dorsal commences rather nearer the snout than the base of the caudal fin, and a little in advance of the insertion of the ventral, its last undivided ray is strong, osseous, with its stiff portion as long as the head excluding the snout, the fin is 3/4 as high as the body below it, having its upper edge very concave. Lateral-line—complete, $2\frac{1}{2}$ rows between it and the base of the ventral fin: 9 rows before the dorsal fin. The scales covered with numerous horizontal striæ. Free portion of the tail rather longer than high. Colours—of a leaden tinge along the upper portion of the body, becoming dull white shot with gold on the sides and beneath, edges of scales darkest. Fins yellow, with a dark band having a lighter outer edge along the upper and lower edge of the caudal fin.

Habitat.—Teesta river Darjeeling, from whence Dr. Duka sent me several examples, and after whom I have named it. The specimen figured (life-size) is the largest: its having pores on the side of the mouth would seem to denote that it is not the fry of some larger species.

15. Barbus tor, Plate CXXXVI, fig. 5; and CXL, fig. 1.*

Cyprinus, tor, mosal and putitora? Ham. Buch. Fish. Gang. pp. 303, 306, 388; Gray and Hard. Ind. Zool.; McClelland, Ind. Cyp. pp. 271, 303, 337, 388, pl. xli, f. 3; Cuv. and Val. xvi, p. 197; Jerdon, M. J. L. and S. 1849, p. 311.

Burapatra, Assam: Poo-meen-candee, Tam.: Naharm, Hind.: Kukhiah, Punj.: Joon-gah, Petiah and Kurreah, Sind.

B. iii, D. $12(\frac{3}{9})$, P. 19, V. 9, A. 7-8($\frac{2-3}{5}$), L. l. 25-27, L. tr. 4/4.

Length of head 4 to 5, of caudal $4\frac{3}{4}$ to 5, height of body $4\frac{1}{3}$ to $5\frac{1}{2}$ in the total length. Eyes—diameter $6\frac{1}{4}$ to $7\frac{1}{2}$ in the length of the head in moderately sized specimens but much larger in the young (at 3.5 inches in length being $3\frac{1}{2}$ in the length of the head; at 5 inches, $4\frac{1}{2}$), 2 to $2\frac{1}{4}$ diameters from the end of snout, and 2 apart. Interorbital space flat. Opercle 1/4 higher than wide: the maxilla reaches to below the front edge of the eye: snout pointed: jaws of about the same length: lips thick, with an uninterrupted fold across the lower jaw, and both the upper and lower lips in some specimens are discount of the maxilla line. Down profile more convex than the abdominal in some examples, not so with an uninterrupted fold across the lower jaw, and both the upper and lower lips in some specimens produced in the mesial line. Dorsal profile more convex than the abdominal in some examples, not so in others. Barbels—the maxillary pair longer than the rostral ones, and extend to below the last third of the eye. Fins—the dorsal arises opposite the ventral and is 3/4 as high as the body, its last undivided ray is smooth, osseous, strong, and of varying length and thickness. Himalayan, Bengal, and Central Indian specimens generally have the spine strong, and from 1/2 to 2/3 the length of the head, it rarely exceeding this extent. In Canara, Malabar, and Southern India, where the lips are largely developed (see Pl. CXL.) the spine is very much stronger and as long as the head excluding the spout. Pectoral as long as the head excluding the snout, it reaches the ventral which is little shorter. Anal laid flat does not reach the base of the caudal which is deeply forked. Lateral-line—complete, 2 to $2\frac{1}{2}$ rows of scales between it and the base of the ventral fin: 9 rows before the dorsal. Free portion of the tail longer than high. Colours—silvery or greenish along the upper half of the body, becoming silvery shot with gold on the sides and beneath. Lower fins reddish yellow.

This fish is the celebrated "Maha seer" of sportsmen in India. The various large barbels in Assam are

termed "Petiah," with a specific name prefixed to denote the species alluded to.

Barbus macrocephalus, McClelland, from along the Eastern Himalayas and Upper Assam, has not the length of the head, "2/5 only of the total (without the caudal)"—(Günther); but without the head or caudal, or 2/7 of the total excluding the caudal fin. It has rather a longer head (4½ in the total) than is usual, its eye is nearer the front end of the head, whilst the upper bone of the suborbital ring is very wide.

Barbus tor, H. B., or progenius, McClell., shows great variation in the length of the head which seems to augment in proportion with the less two in the body is often much higher, whilst the lips are very

much more developed than in the last variety.

Habitat. - Generally throughout India, but in the largest size, and greatest abundance in mountain streams or those which are rocky.

16. Barbus hexastichus, Plate CXXXVI, fig. 4.

Barbus hexastichus, McClelland, Ind. Cyp. pp. 269, 333, pl. 39, f. 2; Günther, Catal. vii, p. 129. ? Labeobarbus tor, Blecker, Ccylon, 1864, p. 10, t. 2 (not Ham. Buch.) ? Barbus longispinis, Günther, Catal. vii, p. 132. Lobura, Assam.

B. iii, D. $12-13(\frac{3-4}{9})$, P. 17, V. 9, A. $7(\frac{2}{5})$, C. 19, L. l. 25-26, L. tr. 4/5.

Length of head 5 to 6, of caudal 5 to $5\frac{1}{2}$, height of body $4\frac{1}{2}$ to 5 in the total length. Eyes—diameter 1/5 of length of head, $1\frac{1}{2}$ diameters from end of snout, 2 diameters apart. Interorbital space slightly convex. Opercle higher than wide. Lips moderately thick, the lower one without or with a badly developed lobe, but having a shallow and continuous transverse fold. Mouth rather inferior, directed anteriorly: the upper jaw slightly the longer. Sometimes pores on the cheeks. Barbels—longer than the eye. Fins—dorsal fin with its osseous ray strong, smooth, and from half as long as head to as long as the head without the snout, it commences somewhat nearer the snout than the base of the caudal, the latter being deeply forked, with the lower lobe the longer. Pectoral as long as the head excluding the snout. Lateral-line—complete, 2 to $2\frac{1}{4}$ rows of scales between it and the base of the ventral fin: 10 rows before the dorsal fin. Free portion of the tail longer than high. Colours—brownish, tinged with green along the upper edge of the body, becoming dull white shot with yellow on the sides and below: caudal and anal reddish. The fry have a black spot before the base of the caudal fin.

Habitat.—Rivers on and around Himalayas, Cashmere, Sikhim and Assam, growing to 3 feet in length. The example figured is 10.5 inches long and from Assam. Specimens from the plains appear to have the head comparatively longer than those from the hills. Ceylon examples, which seem to be a variety, have a longer dorsal spine it being equal to or a little longer than the head.

17. Barbus Bovanicus, Plate CXXXVIII. fig. 1.

B. iii, D. $12(\frac{3}{9})$, P. 17, ∇ . 9, A. $8(\frac{3}{5})$, C. 19, L. 1. 24-26. L. tr. $4\frac{1}{2}/4\frac{1}{3}$.

Length of head $4\frac{2}{3}$, of caudal $4\frac{1}{4}$, height of body $3\frac{2}{3}$ in the total length. Eyes—diameter $3\frac{2}{3}$ in the length of the head, 1 to $1\frac{1}{4}$ diameters from the end of snout, and $1\frac{2}{3}$ apart. Dorsal profile somewhat more convex than that of the abdomen. Interorbital space flat. Snout somewhat obtuse. Upper jaw the longer. Lower labial fold in the adult complete, with a moderately developed median lobe, but such is not apparent in the young. Barbels-rostral pair extend to beneath first 1/3 of the eye, the maxillary pair to the posterior edge of the preopercle. Fins—dorsal 2.3 as high as the body, with a concave upper edge, it commences anterior to the ventrals and midway between the end of snout and the base of the caudal fin: its last undivided ray is osseous, of moderate strength, its stiff portion being as long as the head excluding the snout. Pectoral as long as the head posterior to the nostrils and longer than the ventral. Anal laid flat reaches the caudal. Free portion of the tail as long as high. Lateral-line—complete, $2\frac{1}{3}$ rows of scales between it and the base of the ventral fin: 10 rows before the dorsal fin. Colours—greenish, with a golden tinge, darkest along the back.

Habitat.—Bowany river at base of Neilgherry hills in Madras. The largest specimen obtained 5 inches

in length.

18. Barbus sophore, Plate CXLIII, fig. 4.

Cyprinus sophore, Ham. Buch. Fish. Ganges, pp. 310, 389, (part) and (pl. 19, f. 86 not synonymous). Barbus sophore, Day, Proc. Zool. Soc. 1869, p. 376 (not Günther).

B. iii, D. 12 $\binom{3}{6}$, P. 15, V. 9, A. 7 $\binom{2}{5}$, L. 1. 25, L. tr. $3\frac{1}{2}/4\frac{1}{2}$.

Length of head $4\frac{1}{2}$, of caudal $4\frac{1}{2}$, height of body $3\frac{1}{2}$ in the total length. Eyes—3 to $3\frac{1}{4}$ in the length of the head, nearly 1 diameter from end of snout, and also apart. Cleft of mouth extending to below the first third of the orbit. Upper jaw the longer. Lower labial fold interrupted. Barbels—long and thin, the maxillary pair 1/2 longer than the eye: the rostral pair slightly shorter. Fins—dorsal ray weak, osseous, entire, and as long as the head without the snout: the fin arises slightly before the ventral, and midway between the end of the snout and the root of the caudal. Lateral-line—complete, 21 rows between it and the base of the ventral: 9 rows before the dorsal fin. Scales—with numerous longitudinal striæ. Colours—silvery, with a lateral blotch.

Systomus sophore, McClelland, is the same as Barbus stigma, C. V.

That Barbus stigma destitute of barbels, has been generally considered identical with B. sophore, H. B. does not admit a doubt; it also agrees with H. B.'s figure in which no barbels are shown. But in the text he observes "there are four tendrils, so very minute as often to be scarcely perceptible." When examining the collection of fishes of the Asiatic Society of Bengal, in the Calcutta Museum, I came across an old bleached specimen without any label to say from whence it had been received, it was $3\frac{1}{2}$ inches long to the base of the caudal fin, the latter being injured from pressure. Since then about 12 more specimens have been received from the Khasia hills, thus ascertaining its habitat. Buchanan appears to have mixed up two species—the geographical distribution and figure give B. stigma, as is also evident from the markings on the scale; the text B. sophore which has 4 barbels.

Habitat.—Assam and Khasia hills.

19. Barbus Stracheyi, Plate CXXXIX, fig. 4.

Barbus Malabaricus, Day, Proc. Zool. Soc. 1869, p. 619, (not Jerdon). Barbus (barbodes) Stracheyi, Day, J. A. S. of B. 1871, p. 307.

B. iii, D. $11(\frac{2}{9})$, P. 17, V. 9, A. $7(\frac{2}{5})$, C. 17, L. 1. 23, L. tr. $3\frac{1}{2}/5$.

Length of head $4\frac{1}{2}$, of caudal 6, height of body $4\frac{1}{2}$ in the total length. Eyes—diameter 5 in the length of head, $1\frac{1}{2}$ diameters from end of snout, $2\frac{1}{2}$ diameters apart. Mouth without enlarged lips: lower labial fold interrupted. Upper jaw somewhat the longer. Summit of head flat. Barbels—long, the rostral pair reaching to below the centre of the orbit, and the maxillary pair to beneath its posterior margin. Fins-dorsal osseous ray strong, smooth, and as long as the head without the snout, it commences midway between the end of the snout and the base of the caudal fin. Lateral-line—complete, $2\frac{1}{2}$ rows of scales between it and the base of the ventral fins. Colours—uniform silvery. Habitat.—Akyab and Moulmein.

I have named this species after General Strachey, C.B., F.R.S., who I have to thank for assistance in enabling me to prosecute my enquiries into the fish and fisheries of India.

c. Last undivided dorsal ray articulated, or if osseous very weak.

20. Barbus curmuca, Plate CXLI, fig. 1.

Cyprinus curmuca, Buchanan's Journey in Mysore, iii, p. 344, pl. xxx, and Fishes of Ganges, pp. 294, 387; McClelland, Ind. Cyp. pp. 276, 353.

Gobio curmuca, Cuv. and Val. xvi, p. 317. Gobio curmuca and Canarensis, Jerdon, M. J. L. and Sc. 1849, p. 306. Barbus curmuca, Day,* P. Z. S. 1873, p. 707.

B. iii, D. 12 $\binom{3}{6}$, P. 16, V. 9, A. 8 $\binom{3}{6}$, C. 18, L. 1. 41, L. tr. 8/7.

Length of head 5, of caudal $4\frac{1}{3}$, height of body 5 in the total length. Eyes—diameter $4\frac{1}{3}$ in the length of the head, $1\frac{1}{2}$ diameters from the end of the snout, and also apart. Snout conical, head compressed, interorbital space transversely concave. Dorsal profile more convex than that of the abdomen. In adults a band of open pores from the preorbital along the cheek. Barbels—two maxillary pairs, the lower as long as the eye, the upper 1/2 as long. Fins—dorsal as high as the body, its upper edge concave, it arises anterior to the insertion of the ventral, and rather nearer the snout than to the base of the caudal fin, its last undivided ray weak and articulated. Lateral-line—complete, $3\frac{1}{2}$ rows between it and the base of the ventral fin: 15 rows anterior to the dorsal fin. Caudal deeply forked, its lobes pointed. Free portion of the tail as long as high. Colours—silvery, lightest on the sides and beneath: tips of the caudal blackish. In the young, the middle third of the caudal is orange, and it is tipped with black.

Habitat.—Western ghauts of India, attaining to at least 4 feet in length. Jerdon obtained it from

Palghaut and Arriacode in South Malabar.

21. Barbus lithopidos, Plate CXXXVIII, fig. 2.

Day, Proceedings Zoological Society, 1873, p. 708.

Kuri meen, Canarese.

B. iii, D. 12 $\binom{3}{9}$, P. 15, V. 10, A. 8 $\binom{3}{5}$, C. 19, L. 1. 38-39, L. tr. 7/7.

Length of head $5\frac{3}{4}$ to $6\frac{1}{3}$, of caudal 4, height of body $4\frac{3}{4}$ in the total length. Eyes— $3\frac{3}{4}$ to $4\frac{1}{4}$ diameters in length of head, 1 to $1\frac{1}{2}$ diameters from end of snout, and $1\frac{1}{3}$ apart. Body compressed, dorsal and abdominal profiles equally and moderately convex. Interorbital space somewhat convex. Upper jaw slightly the longer: lower labial fold interrupted: a thin cartilaginous covering internally to either jaw. Large examples have pores on the preorbital. Barbels—both pairs thin, and about as long as the orbit. Fins—dorsal high in fort, equalling the height of the body, its upper edge concave, the origin of the fin is anterior to the insertion of the ventral, and midway between the end of the snout and the base of the caudal fin, its last undivided ray weak and articulated. Pectoral and ventral of equal length, and as long as the head. Caudal very deeply forked. Lateral-line—complete, 4 rows of scales between it and base of ventral fin: 14 rows before the dorsal. Free portion of the tail as high at its base as it is long. Colours—slaty, as are the fins, having their outer rays whitish. Pectoral yellowish, tail greenish. Adults are more yellow, with a gray band behind the opercle, and some of the scales scarlet.

Habitat.—South Canara, where it is not uncommon in the rivers, and attains 2 feet in length. The specimen figured is 7.4 inches long.

22. Barbus Thomassi, Plate CXXXVII, fig. 5.

Day, Proceedings Zool. Soc. 1873, p. 707.

Kem-pu-per-ru-wul, Canarese (Red Mahaseer).

B. iii, D. 12-13 ($\frac{3-4}{9}$), P. 17, V. 10, A. 8 ($\frac{3}{5}$), C. 19, L. 1. 31-34, L. tr. 6/6.

Length of head $5\frac{3}{4}$ to $6\frac{1}{4}$, of caudal $3\frac{3}{4}$ to $4\frac{1}{3}$, height of body 4 to $4\frac{1}{2}$ in the total length. Eyes—high up, diameter $3\frac{3}{4}$ to 4 in the length of head, $1\frac{1}{3}$ diameters from the end of snout, and also apart. Dorsal profile about equally convex with that of the abdomen. Interorbital space slightly convex. Snout rather pointed: upper jaw the longer: lower labial fold interrupted. Height of head equals its length excluding the snout. Barbels—thin, the maxillary not so long as the eye, the rostral pair shorter. Fins—dorsal high anteriorly, equalling the height of the body, its origin is anterior to the insertion of the ventral, and midway between the end of the snout and the base of the caudal fin: its upper edge very concave, and its last undivided ray weak and articulated. Pectoral and ventral of equal length, and 4/5 as long as the head: caudal deeply forked, the upper lobe the longer. Lateral-line—complete, $2\frac{1}{2}$ rows of scales between it and the base of the ventral fin: 12 rows anterior to the dorsal. Free portion of the tail as high at its base as it is long. Colours—silvery along the back, each scale with a red lunule: dorsal and caudal fins of a lake colour, the last being usually edged with

black. Ventral and anal also lake colour, stained with grayish-black. Most of the scales with a dark base.

Habitat.—South Canara, attaining at least $3\frac{1}{2}$ feet in length. I have named the species after Mr. H. S. Thomas, M.C.S., who first brought the fish to my notice. The specimen figured is 9.5 inches in length.

23. Barbus spinulosus.

McClelland, Cal. Journ. Nat. Hist. p. 280, pl. 21, f. 3; Bleeker, Beng. p. 60; Günther, Catal. vii, p. 128.

* Since the above was in type, Captain Beavan's "Fresh-water Fishes of India," with the list of species revised by Dr. Günther, has come under my notice. It is suggested that Barbus curmuca (H. B.) Day, from Malabar, may be a local variety of Barbus curmuca, Beavan and Günther. The figure of their fish is given, and represents B. kolus, not B. curmuca. The example seems to have come from the Central Provinces where B. kolus exists, but B. curmuca is not found.

B. iii, D. 12 $(\frac{3}{9})$, P. 15, V. 9, A. 10 $(\frac{3}{7})$, C. 19, L. 1. 32.

Length of head 5, height of body $4\frac{1}{2}$ in the total length. Back a little elevated. Eyes—before the middle of the length of the head. Dorsal profile but slightly arched. Snout short. Fins—dorsal without osseous ray, commencing midway between the end of the snout and the base of the caudal. Colours - greenish above, white below: fins pale.

McClelland observes "length of the head is equal to a fourth part of the length of the body," or 5 in the

total excluding the caudal fin: but in the figure it is shown as 41.

. Habitat.—Sikhim, from whence a single specimen, 7 inches long, was obtained by McClelland.

24. Barbus pulchellus, Plate CL, fig. 3.

Day, Proc. Zool. Soc. 1870, p. 372.

Katladi, Canarese, Tulu, Mal. B. iii, D. 12 $(\frac{3}{9})$, P. 17, V. 9, A. 7 $(\frac{2}{5})$, C. 19, L. 1. 30-32, L. tr. 5-6/5 $\frac{1}{2}$.

Length of head 6 to $6\frac{1}{2}$, of caudal $4\frac{1}{2}$ to 5, height of body 4 to $4\frac{1}{2}$ in the total length. Eyes—diameter $3\frac{1}{2}$ in length of head, $1\frac{1}{4}$ diameters from the end of the snout, and $1\frac{3}{4}$ apart. There is a very gradual rise from the snout to the base of the dorsal fin. Interorbital space nearly flat. Porce on the snout. Barbels four, the maxillary pair being the longest, equalling one-third of the length of the head. Teeth—pharyngeal, crooked, pointed, 4, 3, 2/2, 3, 4. Fins—dorsal arises slightly anterior to the ventral and rather nearer to the snout than the base of the caudal fin, its upper border is concave, it is two-thirds the height of the body, having its last undivided ray weak, smooth, and articulated. Caudal deeply forked. Scales—3½ rows between the lateral-line and the base of the ventral fin. Colours-all the scales above a line going direct from the eye to centre of the caudal fin are of a deep gray, with dark bases; below or in the inferior half of the body all are silvery gray: fins with dark edges.

Habitat.—South Canara, frequenting the inland streams. Two specimens up to $17\frac{1}{2}$ inches long were given me by H. S. Thomas, Esq., Madras Civil Service. The figure is 1/3 the size of the example.

25. Barbus Dobsoni, Plate CXXXIX, fig. 6.

Day, Journal, Linnean Society, 1876, Zool. xii, p. 574.

B. iii, D. 12-13($\frac{3-4}{9}$), P. 14, V. 9, A. 8($\frac{3}{5}$), C. 19, L. 1. 30-32, L. tr. $5\frac{1}{2}$ -6/ $5\frac{1}{2}$.

Length of head 6, of caudal $4\frac{1}{2}$, height of body $3\frac{1}{4}$ to $3\frac{1}{2}$ in the total length. Eyes—diameter $3\frac{1}{3}$ in the length of the head, nearly 1 diameter from end of snout, and $1\frac{1}{2}$ apart. Dorsal profile elevated. Snout a little obtuse. Interorbital space slightly concave. Mouth narrow. The upper jaw the longer. Lower labial fold interrupted. Barbels—thin, the maxillary ones as long as the eye, the rostral somewhat shorter. Teeth—pharyngeal, crocked and pointed 5, 3, 2/2, 3, 5. Fins—dorsal commences somewhat in advance of the insertion of the ventral, it is about 2/3 as high as the body, its last undivided ray articulated and smooth. Pectoral as long as the head. Lateral-line—complete, 3½ rows of scales between it and the ventral fin: 12 rows anterior to the dorsal. Free portion of the tail nearly as high at its base as it is long. Colours—bluish above becoming lighter on the sides and beneath, fins edged with gray, upper corner of dorsal and ends of caudal blackish.

This fish is closely allied to B. Jerdoni, of which it may be a local variety.

Habitat.—Deccan from whence Dr. A. J. Dobson sent me specimens: I likewise obtained this species at Kurnool, in September, 1866, and also at Poona. The example figured is 7.5 inches in length.

26. Barbus Jerdoni, Plate CXXXVIII, fig. 5.

Day, Proc. Zool. Soc. 1870, p. 372.

Say-meen, Can.: Cha-meen, Tulu: Ta-meen, Mal.

B. iii, D. $12(\frac{3}{9})$, P. 15, V. 9, A. $8(\frac{3}{5})$, C. 19, L. l. 27-28, L. tr. 6/4.

Length of head 5 to $5\frac{1}{4}$, of caudal 4, height of body 4 in the total length. Eyes—diameter 3 to $3\frac{1}{4}$ in length of head, 1 to $1\frac{1}{2}$ diameters from end of snout, and $1\frac{1}{2}$ apart. Interorbital space nearly flat. The height of the head nearly equals its length. A considerable rise to the commencement of the dorsal fin. Body compressed. Mouth narrow: upper jaw the longer. Lower labial fold interrupted. Barbels—thin, the maxillary being as long as the orbit, the rostral slightly shorter. Fins—last undivided dorsal ray articulated, weak and not enlarged: the fin which is 4/5 as high as the body below it, commences midway between the snout and the base of the caudal. Pectoral as long as the head and nearly reaching the ventral which is of the same length. Anal laid flat reaches somewhat beyond the root of the caudal fin which is deeply forked. Lateral-line—complete, rather concave: $2\frac{1}{9}$ to $3\frac{1}{2}$ rows of scales between it and the base of the ventral: 12 rows before the dorsal fin. Free portion of the tail rather higher than long. Colours-silvery, fins which have an orange tint, tipped with black.

Habitat.—Rivers in Canara below the Ghauts, attaining 18 inches in length. The example is figured life-size.

27. Barbus Wynaadensis, Plate CXXXVIII, fig. 3 and CXXXIX, fig. 2.

Day, Journal Linn. Soc. 1873, Zool. xi, p. 528.

B. iii, D. $13(\frac{4}{9})$, P. 17, V. 9, A. $8(\frac{3}{5})$, C. 19, L. 1. 26-28, L. tr. 4/6.

Length of head $4\frac{3}{4}$ to 5, of caudal 5 to $5\frac{1}{2}$, height of body $4\frac{1}{4}$ to 5 in the total length. Eyes—diameter 5 in the length of head, $1\frac{1}{2}$ to 2 diameters from the end of snout, and $1\frac{3}{4}$ apart. No considerable rise to the base of the dorsal fin. Snout conical. Upper jaw the longer overlapping the lower. Interorbital space nearly flat. Lower labial fold interrupted. Barbels—the maxillary pair as long or longer than the orbit, the rostral 1/4 shorter. Fins—the dorsal 2/3 as high as the body, its origin is a little anterior to the ventral, its last undivided ray weak, osseous, with an articulated extremity. Lateral-line—complete, $2\frac{1}{2}$ to 3 rows of scales between it and the base of the ventral fin: 10 rows before the dorsal fin. Free portion of the tail rather longer than high. Colours—leaden silvery along the back with a deak hand running from helping tail rather longer than high. Colours—leaden silvery along the back, with a dark band running from behind the eye to the middle of the base of the caudal fin where it sometimes ends in a round black blotch. Abdomen of a light orange colour. Fins stained with gray at their edges.

Habitat.—Vithry in the Wynaad where it is common in the larger streams. It attains at least 8 inches

in length. The examples are figured life-size.

28. Barbus Stevensonii, Plate CXXXV, fig. 6.

Day, Proc. Zool. Soc. 1870, p. 100.

B. iii, D. $12(\frac{3}{9})$, P. 17, V. 9, A. $8(\frac{3}{5})$, C. 19, L. 1. 27, L. tr. $4\frac{1}{2}/5$.

Length of head $4\frac{1}{2}$, of caudal nearly 4, height of body $4\frac{1}{2}$ in the total length. Eyes—diameter 2/7 of length of head, 1 diameter from end of snout and apart. Body elongated and compressed: dorsal profile but little arched. Upper jaw the longer. Lower labial fold interrupted. Barbels—the maxillary extend to below the posterior extremity of the orbit, the rostral are shorter. Fins-dorsal with a smooth, weak, osseous ray, as long as the head excluding the snout: it is rather lower than the body, arising midway between the end of the snout and the base of the caudal, whilst it is slightly in advance of the ventrals. Lateral-line—complete, there are $2\frac{1}{2}$ rows of scales between it and the base of the ventral fin: and 9 before the dorsal fin. Colourssilvery, upper portion of the body the darker: numerous black specks along the side: a black spot at the base of the caudal, and a dark band along the dorsal fin.

Habitat.—Hills near Akyab. I named this species after the late Colonel Stevenson, Commissioner at Akyab, who procured for me several new sorts of fish from that locality. It is figured life-size.

29. Barbus Neilli, Plate CXL, fig. 4.

Day, Proceedings Zoological Society, 1868, p. 581.

? Barbus khudree, Sykes, Fishes of Deccan, p. 357; Blecker, Beng. p. 60; Jerdon, Madr. J. L. and Sc. 1849, p. 313.

B. iii, D. $13(\frac{4}{9})$, P. 15, V. 10, A. $8(\frac{3}{5})$, C. 19, L. l. 24-26, L. tr. $4\frac{1}{2}/4$.

Length of head $4\frac{1}{2}$ to 5, of caudal 5, height of body $3\frac{1}{2}$ to 4 in the total length. Eyes—diameter $4\frac{1}{2}$ to 5 in the length of the head, 1½ diameters from the end of snout and also apart. Dorsal and abdominal profiles about equally convex. Interorbital space nearly flat. Snout conical with the upper jaw slightly the longer. Lower labial fold continuous. Barbels—the rostral pair reach the front edge of the eye, the maxillary pair equal 1½ diameters of the orbit. Tecth—pharyngeal, curved, 5, 3, 2/2, 3, 5. Fins—origin of dorsal rather nearer base of caudal fin than the end of the snout, and anterior to the insertion of the ventral, it is 2/3 as high as the body, its upper edge concave, its last undivided ray osseous, entire, and very weak. Pectoral as long as the head excluding the snout, and longer than the ventral. Anal laid flat reaches the base of the caudal which is forked. Lateral-line—complete, $3\frac{1}{2}$ rows of scales between it and the ventral fin: 9 rows anterior to the dorsal. Free portion of the tail as high as long. Colours—silvery above the lateral-line with a tinge of yellow below it. Fins with a bluish tinge in some specimens, reddish in others. The young have a dark spot at the base of the caudal fin. Eyes golden.

Hubitat.—Kurnool on the Tamboodra river. The largest specimen personally seen was 38 lbs. weight, but it is said to attain to 50 or 60 lbs. The example figured is stuffed, and 22 inches in length.

30. Barbus Malabaricus, Plate CXXXVIII, fig. 6.

Jerdon, M. J. L. and Sc. 1849, p. 312.

B. iii, D. 12-13 ($\frac{3-4}{9}$), P. 17, V. 9, A. 8 ($\frac{3}{5}$), C. 19, L. 1. 24, L. tr. 4/4.

Length of head $4\frac{2}{3}$ to 5, of caudal 5, height of body $4\frac{1}{2}$ to $4\frac{3}{4}$ in the total length. Eyes—diameter 5 in the length of head, $1\frac{\pi}{3}$ diameters from end of snout, and 2 apart. Dorsal and abdominal profiles about equally and moderately convex. Interorbital space slightly convex. Upper jaw the longer: lips thick: lower labial fold complete and with a median lobe. Barbels—the maxillary pair reach to below hind edge of eye, the rostral pair are shorter. Fins—dorsal 2/3 as high as the body, its origin is anterior to the insertion of the post-orbital length of the head. Fins—complete 11 rows of scales between it and the rentral fine fins—complete 11 rows of scales between it and the rentral fine fins—complete 11 rows of scales between it and the rentral fine fins—complete 11 rows of scales between it and the rentral fine fins—complete 11 rows of scales between it and the rentral fine fins—complete fins—comp orbital length of the head. Lateral-line—complete, 1; rows of scales between it and the ventral fin: 9 rows anterior to the dorsal. Free portion of the tail rather longer than high. Colours—bluish, becoming white on the abdomen. Fins usually blue. Eyes red. Sometimes the fish is brown: and the dorsal, pectoral, and ventral, red. Or the front edge of dorsal and anal and upper and lower borders of the caudal may be dark.

Digitized by Google

I have seen an example in which the height of the body was only 4 in the total length, but it otherwise resembled the typical form.

Habitat.—From South Canara down the Western Ghants to the Travancore hills. Mr. Ballard has captured it at Courtallum with a fly. It attains at least 18 inches in length.

31. Barbus innominatus.

Leuciscus binotatus, Blyth, Journ. Asiat. Soc. of Beng. 1854, p. 290 (not K. and v. H.) Barbus innominatus, Day. Proceedings Zool. Soc. 1869, p. 556.

B. iii, D. 12 ($\frac{3}{6}$), P. 15, V. 9, A. 7 ($\frac{2}{5}$), C. 17, L. 1. 24, L. tr. $4\frac{1}{2}/4\frac{1}{2}$.

Length of head $3\frac{1}{2}$, of caudal $3\frac{1}{2}$, height of body $3\frac{1}{3}$ in the total length. Eyes—diameter $3\frac{1}{2}$ in length of the head, I diameter from the end of the snout and also apart. Barbels—the rostral nearly reach the orbit, the maxillary pair are shorter. Fins—dorsal commences midway between the snout and the base of the caudal, its last undivided ray osseous, weak, and entire. Caudal forked. Lateral-line—3 rows of scales between it and the base of the ventral fin. Colours—a black spot at the base of the caudal fin, none now apparent on the dorsal.

Habitat.—Ceylon, from whence Mr. Blyth received specimens up to 1.1 inches in length, presented by Dr. Kelaart.

32. Barbus compressus.

Day, Proc. Zool. Soc. 1869, p. 555.

B. iii, D 12 ($\frac{3}{6}$), P. 15, V. 9, A. 8 ($\frac{3}{6}$), C. 17, L. l. 22, L. tr. 4/5.

Length of head 5, of caudal 5, height of body 4 in the total length. Eyes—diameter 2/9 of length of head, $1\frac{1}{2}$ diameters from end of snout and also apart. Head much compressed: mouth inferior, upper jaw the longer: the whole of the cheeks covered with porcs: the posterior extremity of the maxilla extends to below the anterior margin of the orbit. Barbels—rostrals reach to beneath the centre of the orbit, the maxillary to the angle of the preopercle. Fins—dorsal half as high as the body, it arises midway between the snout and the base of the caudal, commencing slightly in advance of the ventrals, its last undivided ray is osseous, not enlarged, and entire. Upper caudal lobe the longer. Lateral-line—complete, $3\frac{1}{2}$ rows of scales between it and the base of the ventral fin. Colours—silvery, fins stained darker.

Habitat.—The native country of the type specimen is uncertain, but the fish was found in a bottle in the Calcutta Museum with an Oreinus from Cashmere. It is a fine specimen in excellent preservation.

33. Barbus Blythii.

Capoeta macrolepidota (? K. and v. Hass.), Blyth, J. A. S. of Beng. 1860, p. 157 (not C.V.). Barbus Blythii, Day, Proc. Zool. Soc. 1869, p. 555.

B. iii, D. 12 $\binom{3}{6}$, P. 15, V. 9, A. 8 $\binom{5}{6}$, C. 17, L. 1. 22, L. tr. 4/5.

Length of head 4, of caudal 4, height of body 3½ in the total length. Eyes—diameter 2/5 of length of head, 3/4 of a diameter from the end of snout and also apart. Preorbital covered with pores. Barbels—well developed, the rostral reaching the eye, and the maxillary to below the centre of the orbit. Fins—dorsal arises midway between the snout and the base of the caudal, its last undivided ray articulated: it commences slightly in advance of the ventrals. Caudal deeply forked. Lateral-line—complete, 2½ rows between it and the base of the ventral fin. Colours—uniform silvery in spirit.

the ventral fin. Colours—uniform silvery in spirit.

Habitat.—Tenasserim provinces. Specimen two inches long. This fish is very similar to Barbus compressus, and may perhaps be the young.

34. Barbus melanampyx, Plate CXXXIX, fig. 1.

B. iii, D. 11 $(\frac{3}{8})$, P. 15, V. 8, A. 7 $(\frac{3}{8})$, C. 15, L. 1. 20, L. tr. $3\frac{1}{8}/3\frac{1}{2}$.

Length of head $4\frac{1}{2}$, of caudal 4 to $4\frac{1}{2}$, height of body 3 to $3\frac{1}{3}$ in the total length. Eyes—diameter 3 to $3\frac{1}{4}$ in the length of head, from 3/4 to 1 diameter from end of snout, 1 diameter apart. Dorsal profile more convex than that of the abdomen. Cleft of mouth extends to below the anterior edge of the orbit: numerous pores on the snout. Lower labial fold interrupted. Barbels—rostral short, the maxillary equal in length to one diameter of the orbit. Teeth—pharyngeal, in three rows, curved, sharp, 5, 3, 2/2, 3, 5. Fins—dorsal scarcely higher than long, no osseous ray: it commences midway between the end of the snout and the base of the caudal fin, which latter is deeply forked. Lateral-line—complete, 2 rows of scales between it and the base of the ventral fin: 7 rows before the dorsal fin. Colours—of a deep dull red, with three black cross bands, the

first from below the whole of the base of the dorsal to just beneath the lateral-line, the second commences four scales beyond the posterior extremity of the base of the dorsal and descends to one scale below the lateral-line, whilst the last is just before the base of the caudal and often wanting. Fins pinkish, edged with black. Habitat.—The Wynaad, Neilgherry and Travancore ranges of hills and streams along their bases: also

the Cauvery river. It rarely attains three inches in length.

B.—With two barbels (Capoëta).

With an osseous, serrated dorsal ray.

35. Barbus macrolepidotus, Plate CXLII, fig. 1.

B. iii, D. $12(\frac{4}{5})$, P. 17, V. 9, A. $7(\frac{2}{5})$, C. 19, L. 1. 26, L. tr. 5/5.

Length of head $4\frac{1}{2}$, of caudal 5, height of body $4\frac{1}{4}$ in the total length. Eyes—diameter 5 to $5\frac{1}{4}$ in the length of head, $1\frac{1}{2}$ diameters from end of snout and also apart. Snout pointed, upper jaw slightly the longer; head compressed with its upper surface nearly flat. The posterior extremity of the maxilla extends to a little behind the anterior edge of the orbit. No pores on the snout. Barbels—the maxillary as long as the orbit. Fins—dorsal commences slightly nearer the snout than the base of the caudal, and opposite the insertion of the ventrals, its last undivided ray is weak, (scarcely osseous), and finely serrated in nearly its whole extent. Caudal deeply forked. Lateral-line—with $2\frac{1}{2}$ rows of scales between it and the base of the ventral fin: 10 rows before the dorsal fin. Free portion of the tail as high at its base as it is long. Colours silvery, lightest on the sides and below: fins orange, anterior edge of the dorsal and outer margins of the caudal A badly developed darkish band from the dorsal to the ventral fin.

Habitat.—Tavoy to the Malayan Peninsula: an example, personally obtained from the first locality, is

figured life-size.

b. Osseous dorsal ray strong, entire.

36. Barbus chola, Plate CXLII, fig. 4.

Koroon, Tam.: Kerrundi, Beng.: Nga-khon-ma, and Nga-lowah, Burmese: Pittha-kerrundi, "bitter carp" Ooriah: Chaddu paddaka, Tel.: Katcha karawa, Hind.

B. iii, D. $11(\frac{3}{8})$, P. 15, V. 9, A. $7(\frac{2}{8})$, C. 19, L. 1. 26-28, L. tr. $5\frac{1}{2}/5$.

Length of head $4\frac{1}{2}$ to $4\frac{3}{4}$, of caudal $4\frac{1}{2}$, height of body $3\frac{1}{4}$ to $3\frac{3}{4}$ in the total length. Eyes—diameter $3\frac{1}{2}$ to 4 in the length of the head, 3/4 to 1 diameter from end of snout, and $1\frac{1}{4}$ apart. Suborbital ring of bones narrow, their depth not being 1/3 of that of the uncovered portion of the cheek. Interorbital space slightly convex. Dorsal profile more convex than that of the abdomen. Jaws equal anteriorly. Barbels—a single maxillary pair not so long as one diameter of the orbit. Fins—dorsal 3/5 as high as the body, it commences opposite the ventrals and midway between the end of the snout and the base of the caudal fin, its last undivided ray is osseous and smooth, with the stiff portion moderately strong and as long as the head excluding the snout. Lateral-line—complete, from 3 to 3½ rows of scales between it and the base of the ventral fin: 10 to 12 rows before the dorsal fin. Free portion of the tail rather higher than long. Colours—silvery, opercles shot with purple and gold. A dark blotch is usually present on the side of the free portion of the tail from the 23rd to the 25th scales of the lateral-line; in some Malabar examples it is intensely black. A dark mark along the base of the anterior of the dorsal rays, and a row of dark spots along its centre. Occasionally there is a dark mark behind the gill-opening, especially in Bengal and Assam examples.

In Burma the dorsal spine is stout, and that fin as well as the anal low. In Bengal and Punjab examples the eye is rather large, often being 1/3 of the length of the head. In two species from Central India, received from Captain Neill, the head is small, barbels short, and no black mark exists except the spot behind the

gill-opening.

Habitat.—From Malabar and the Wynaad, through Madras, Orissa, the Punjab, Bengal, and Gangetic Provinces, the Central Provinces, Assam, also Akyab and Burma to Mergui. It attains to about 5 inches in length. As food it is bitter: in some localities in Burma oil is obtained from it during the breeding season. The figure (life-size) is from a Madras specimen.

Length of head 5, of caudal $4\frac{1}{2}$ to 5, height of body $3\frac{3}{4}$ to 4 in the total length. Eyes—diameter 3 to $3\frac{1}{4}$ in the length of the head, 3/4 to 1 diameter from end of snout, $1\frac{1}{4}$ diameters apart. Interorbital space slightly convex: the third suborbital bone 2/3 as deep as the uncovered portion of the cheek below it. Dorsal profile more convex than that of the abdomen. Barbels—fine, and equal to two-thirds of the length of the orbit. Fins-dorsal commences midway between the end of the snout and the base of the caudal fin, its last undivided ray is osseous, weak in the young but strengthening with age, and as long as the head without the snout: height of fin 2/3 that of the body. Lateral-line—complete, $3\frac{1}{2}$ rows of scales between it and the base of the ventral fin: 8 rows before the dorsal fin. Colours—back greenish, divided from a silvery abdomen by a dark bluish line. Cheeks golden red. Pectoral, ventral, and anal tinged with yellow; dorsal and caudal darks. dusky. A diffused black spot on the lateral-line extending from the twentieth to the twenty-second scales. Eyes golden.

Habitat.—Malabar, Mysore, and Madras, attaining at least 6 inches in length. The example figured (life-size) was from Kurriavanoor in the Cochin State.

38. Barbus Burmanicus, Plate CXLI, fig. 4.

B. iii, D. $12(\frac{4}{8})$, P. 15, V. 9, A. $7(\frac{2}{5})$, C. 17, L. 1. 26, L. tr. 4/4.

Length of head $4\frac{1}{2}$ to 5, of caudal $4\frac{1}{2}$ to 5, height of body $3\frac{1}{3}$ in the total length. Eyes—diameter $3\frac{1}{4}$ to $3\frac{1}{2}$ in the length of the head, I diameter from the end of snout, and $1\frac{1}{2}$ apart. A considerable rise from the snout to the base of the dorsal fin. Snout pointed. Interorbital space convex. The maxilla does not reach to below the orbit. Lower labial fold interrupted. Barbels—a very short maxillary pair. Fins—dorsal 2/3 as high as the body, it commences midway between the end of the snout and the base of the caudal and opposite the insertion of the ventral, its last undivided ray is osseous, strong, entire, and about as long as the head. Lateral-line-2 rows of scales between it and the base of the ventral fin: 10 rows before the dorsal fin. Colours—silvery along the back, becoming lighter on the sides and beneath: a dull blotch before the base of the caudal fin. Fins silvery, with a dull band down the centre of the dorsal.

This species is allied to B. chola, but has shorter barbels, a stronger dorsal spine, and only 2 rows of scales between the lateral-line and base of ventral fin, &c.

Habitat.—Burma, the example (figured life-size) was from Mergui.

Length of head 4 to $4\frac{1}{4}$, of caudal $4\frac{1}{2}$, height of body 3 to $3\frac{1}{4}$ in the total length. Eyes—diameter 2/7of length of head, 1 diameter from end of snout, and $1\frac{1}{3}$ apart. Interorbital space slightly convex. Body compressed. Lower label fold interrupted. Dorsal profile considerably elevated. Barbels—a maxillary pair, thin and equal to 2/3 of the length of the orbit. Fins—dorsal 2/3 as high as the body, it commences opposite the insertion of the ventral, and midway between the snout and the base of the caudal: osseous dorsal ray of moderate strength, and its stiff portion as long as the head excluding the snout. Lateral-line—complete, $3\frac{1}{2}$ rows of scales between it and the base of the ventral: 8 to 10 rows before the dorsal fin. Free portion of the tail as long as high. Colours—a round black spot on the lateral-line behind the gill-openings, and a second midway between the end of anal and base of the caudal fins, and rather more forward than in B. chola, being on the 18th to 20th scales of the lateral-line. Dorsal and anal tipped with black, sometimes the upper half of the former stained darkish, and a black band along its centre, most distinct anteriorly, and more so in Assam

than in Bengal specimens.

Hamilton Buchanan observes that C. titius and C. ticto have the utmost resemblance, and should Barbus punctatus be found as far East as Calcutta it might possibly be B. titius. McClelland says this species is without barbels, and the dorsal and abdominal profiles equally convex. He shows the eye too small, and unites the marks on the dorsal fin: still it seems to be this species which I have obtained from the same locality as McClelland.

Habitat.—Orissa, Bengal, Assam, N. W. Provinces, Punjab and Sind, also the Decean. It attains nearly 5 inches in length. The specimen figured (life-size) was from Assam.

40. Barbus dorsalis, Plate CXLII, fig. 2.

Systomus dorsalis and ? tristis, Jerdon, M. J. L. and Sc. 1849, pp. 314, 316. Barbus dorsalis, tetraspilus, and Layardi, Günther, Catal. vii, pp. 142, 144. Lambi kaoli, Hin.: Saal candee, Tam.: Mar-pakke, Can.

B iii, D. 11-12 ($\frac{3-4}{8}$), P. 15, V. 9, A. 8 ($\frac{3}{6}$), C. 19, L. 1. 24-25, L. tr. $4\frac{1}{2}/4$.

Length of head $4\frac{1}{2}$, of caudal $4\frac{1}{2}$ to 5, height of body 4 to $4\frac{1}{4}$ in the total length. Eyes—diameter 4 to $4\frac{1}{2}$ in length of head, from $1\frac{1}{4}$ to $1\frac{1}{2}$ diameters from end of snout, $1\frac{1}{2}$ diameters apart. Third suborbital bone as wide as the cheek below it. Body compressed, a considerable rise to the base of the dorsal fin. The head is conical anteriorly, the snout pointed, and the upper jaw the longer. Interorbital space flat. Lower labial fold interrupted. Barbels—a maxillary pair 2/3 as long as the eye. Teeth—pharyngeal, 5, 3, 2/2, 3, 5. Fins—dorsal commences rather in front of the ventral, and nearly midway between the end of the snout and base of the caudal fin, its last undivided ray is osseous, smooth, moderately strong, and its stiff portion as long as, or a little longer than, the head without the snout. Caudal forked. Lateral-line—complete. Scales—8 or 9 rows between occiput and base of dorsal fin: $2\frac{1}{2}$ rows between lateral-line and base of ventrals. Free portion of the tail as high as long. Colours—uniform silvery, frequently the scales in upper two-third base of long livery with dark bases. A black spot at the posterior portion of the base of the dorsal, which more or less disappears after maceration.

B. tatraspilus differs from B. dorsalis in having a dark spot before the base of the caudal fin. Habitat.—Kurnool, Mysore, throughout Madras as low as the Cauvery and Coleroon rivers and Ceylon. It does not attain a large size. The specimen figured was from Madras.

c. Last undivided dorsal ray articulated, or if osseous very weak.

41. Barbus kolus, Plate CXLI, fig. 2.

Sykes, Trans. Zool. Soc. ii, p. 357, pl. 62, f. 1; Günther, Catal. vii, p. 136. Capoeta kolus, Bleeker, Beng. p. 62. Hypselobarbus (Gonoproktopterus) kolus, Bleeker, Prod. Cyp. p. 275.

Barbus Guentheri, Day, Proc. Zool. Soc. 1868, p. 582.

Nilusu, Telugu.

B. iii, D. 12-13($\frac{3-4}{9}$), P. 15, V. 9, A. $8(\frac{3}{5})$, C. 19, L. l. 40-43, L. tr. 10/8.

Length of head $5\frac{1}{4}$ to $5\frac{1}{2}$, of caudal 4, height of body 4 to $4\frac{1}{2}$ in the total length. Eyes—upper margin near the profile, diameter $3\frac{3}{4}$ to 4 in the length of the head, $1\frac{1}{4}$ diameters from end of snout and also apart. Interorbital space flat. Body compressed, a considerable rise in the profile from the occiput to the dorsa! fin. Upper jaw the longer, overlapping the lower. Barbels—extend rather beyond the middle of the eye. Teeth—pharyngeal, pointed, uncinate, 5, 3, 2/2, 3, 5. Fins—the dorsal 3/4 as high as the body, inserted in advance of the ventral and rather nearer the snout than the base of the caudal fin, which last is deeply forked. Lateral-line—complete, 4 to 5 rows of scales between it and the base of the ventral fin. Free portion of the tail rather longer than high. Colours—silvery, with a tinge of yellow: dorsal, caudal, and anal tipped with gray.

Habitat.—Central Provinces, Deccan, and throughout the Kistna, Tamboodra, and Godavery rivers. It

attains upwards of a foot in length.

42. Barbus Denisonii, Plate CXLIII, fig. 2.

Labeo Denisonii, Day, Proc. Zool. Soc. 1865, p. 299. Puntius Denisonii, Day, Fish. Malabar, p. 212, pl. 16, f. 2. Barbus Denisonii, Günther, Catal. vii, p. 146.

B. iii, D. 10-11 ($\frac{2-3}{8}$), P. 15, V. 9, A. 8 ($\frac{5}{6}$), C. 19, L. 1. 28, L. tr. $4\frac{1}{2}/4\frac{1}{2}$.

Length of head 6, of caudal 5, height of body 5 in the total length. Eyes—diameter $3\frac{1}{2}$ in the length of head, 1 diameter from end of snout, and $1\frac{1}{2}$ apart. Dorsal and abominal profiles slightly and about equally convex. Mouth small, directed forwards and rather downwards, with upper jaw slightly the longer. Snout obtuse. Lower labial fold interrupted. Barbels—a maxillary pair one-third longer than the orbit. Teeth—pharyngeal, pointed and curved at their extremities, 4, 3, 2/2, 3, 4. Fins—dorsal arises rather before the ventrals, and midway between the end of the snout and the posterior extremity of the base of the anal fin, none of its rays osseous. Caudal deeply forked. Lateral-line—complete, $2\frac{1}{2}$ rows of scales between it and ventral fin: 9 rows before the dorsal fin. Caudal peduncle rather longer than high. Colours—silvery, with a black band passing from the snout to the centre of the base of the caudal fin, above it runs a horizontal scarlet Caudal with an oblique black band crossing the posterior third of each lobe.

Habitat.—Mundikyum in the Travancore hill ranges, where the Rev. H. Baker procured several

specimens for me. It attains six inches in length.

43. Barbus melanostigma, Plate CXLIII, fig. 1.

Systomus Carnaticus, Jerdon, M. J. L. and Science, 1849, p. 315. B. iii, D. 10 ($\frac{2}{8}$), P. 15, V. 9, A. 7 ($\frac{2}{8}$), C. 19, L. 1. 26, L. tr. $\frac{5}{4}$.

Length of head $4\frac{1}{2}$ to $4\frac{2}{3}$, of caudal $4\frac{3}{3}$, height of body $3\frac{1}{3}$ to $3\frac{2}{3}$ in the total length. Eyes—diameter $3\frac{1}{3}$ in the length of the head, 1 diameter from the end of snout, and $1\frac{1}{2}$ apart. Dorsal and abdominal profiles about equally convex: a slight depression over the nape: interorbital space nearly flat. Mouth narrow, upper jaw overlapping the lower: lower labial fold interrupted. Third suborbital bone as deep or rather deeper than the uncovered portion of the cheek below it. Barbels—a maxillary pair about half as long as the orbit. Fins dorsal 3/4 as high as the body, having a concave upper edge, commencing rather in advance of the insertion of the ventral, it is midway between the end of the snout and the base of the caudal fin, its last undivided ray very weak, osseous inferiorly, and articulated in its upper half. Caudal deeply forked. Free portion of the tail rather higher than long. Lateral-line—complete, very slightly concave: 3 rows of scales between it and the base of the ventral fin: 8 rows before the dorsal. Colours—silvery superiorly, becoming white on the sides and beneath, a light band along the side: a deep black blotch on the side of the tail, commencing on the twenty-first or twenty-second scales: dorsal and caudal stained with gray, sometimes a dark band along the side.

This fish has a very much deeper body than B. amphibius, and also a much darker blotch on the side of the tail. Its mouth is not so anterior as in B. chola, and its third suborbital much deeper, &c.

Habitat.-Wynaad hills in Malabar. Jerdon also obtained specimens in the Bowany river and from the Cauvery.

44. Barbus arenatus, Plate CXLII, fig. 7.

B. iii, D. $10(\frac{2}{8})$, P. 15, V. 9, A. $8(\frac{5}{6})$, C. 19, L. 1. 26, L. tr. 4/6.

Length of head $4\frac{3}{4}$, of caudal 6, height of body 4 in the total length. Eyes—diameter $4\frac{1}{4}$ to 5 in the length of the head, 1½ diameters from end of snout, and 2 apart. Suborbital ring of bones very narrow. Body thick, its width equalling 4/7 of its height. Dorsal profile more convex than that of the abdomen. The maxilla does not reach to below the orbit. Barbels—a single maxillary pair which reaches to beneath the first third of the eye. No pores on the head. Fins—last undivided dorsal ray fine, smooth, osseous inferiorly, becoming articulated superiorly, the fin commences before the insertion of the ventral and midway between the end of the snout and the base of the caudal fin. Lateral-line—complete, 3½ rows of scales between it and the base of the ventral fin: 11 rows anterior to the dorsal fin. Colours—silvery, without any markings. In some examples a darkish band along the dorsal fin.

Habitat.—Madras. The example is figured life size.

45. Barbus Puckelli, Plate CXLIII, fig. 5.

Puntius (Capoëta) Puckelli, Day, Proc. Zool. Soc. 1868, p. 197.

B. iii, D. $9(\frac{2}{7})$, P. 15, V. 9, A. $8(\frac{3}{5})$, C. 19, L. l. 24, L. tr. 4/5.

Length of head $5\frac{1}{4}$, of caudal 6, height of body $4\frac{1}{2}$ in the total length. Eyes—diameter $3\frac{1}{2}$ in the length of head, 2/3 of a diameter from end of snout, and 11 diameters apart. Dorsal and abdominal profiles both equally and slightly convex, whilst the thickness of the fish equals its height. Mouth almost anterior, upper jaw slightly the longer. The posterior extremity of the maxilla does not reach to below the orbit. No pores on the head, its summit rather convex. Barbels—a thick maxillary pair, reaching to beneath the anterior edge of the eye. Teeth—pharyngeal, plough-shaped, 5, 3, 2/2, 3, 5. Fins—last undivided dorsal ray weak and cartilaginous, the fin commences before the ventral, and midway between the end of the snout and the base of the candal, which last is lobed in its posterior half. Lateral-line—complete, 2½ rows of scales between it and the base of the ventral fin: 10 rows before the base of the dorsal fin. Colours—greenish-yellow along the back, with a red mark on the opercle, and a scarlet stripe extending along the middle of the side. A deep black mark on the dorsal fin from the base of the third to that of the sixth branched rays. Very fine dark spots over the scales especially at their bases. An indistinct black mark on the lateral-line from the nineteenth to the twenty-first scales.

Habitat.—Bangalore, where it is said to be common. The figure is from a single specimen given me by Major Puckell.

46. Barbus amphibius, Plate CXLII, fig. 8.

Capoëta amphibia, Cuv. and Val. xvi, p. 282, pl. 478; Bleeker, Beng. p. 62.

Systomus amphibius, Jerdon, M. J. L. and S. 1849, p. 315. Puntius Hamiltonii, Day, Fishes of Malabar, p. 213.

Barbus amphibius, Günther, Catal. vii, p. 141; Day, Proc. Zool. Soc. 1870, p. 373. Oolee perlee, Mal.

B. iii, D. 10-11($\frac{2-3}{8}$), P. 15, V. 9, A. $7(\frac{2}{5})$, C. 19, L. 1. 23-24, L. tr. 5/4.

Length of head $4\frac{3}{4}$ to 5, of caudal 5, height of body $4\frac{1}{4}$ to 5 in the total length. Eyes—diameter $3\frac{1}{2}$ in the length of head, 1 diameter from end of snout, and $1\frac{1}{4}$ apart. Interorbital space nearly flat. Mouth narrow, snout somewhat rounded, the upper jaw slightly the longer. Barbels—a thin maxillary pair reaching to below the centre of the eye. Fins—the dorsal 2/3 as high as the body, with its osseous ray feeble, smooth, and half as long as the head, it arises somewhat in advance of the ventrals, and rather nearer the end of snout than

the base of the candal: the latter fin deeply forked. Lateral-line—complete, 2 rows of scales between it and the base of the ventral fin: 8 rows before the dorsal. Free portion of the tail rather longer than high. Colours upper half of body steel-blue, becoming white tinged with golden on the sides and beneath. Sometimes a band along the side, and a black spot on either side of the tail anterior to the caudal fin, this becomes indistinct after specimens have been long macerated, but is very apparent in fresh ones especially those from the Malabar coast; it is not well-marked, and often absent in those taken in Bombay. Fins yellowish, upper edge of dorsal usually stained with black. In the monsoon time a crimson band along the sides is sometimes present.

Habitat.—Central India, Deccan, Bombay and the Western coast of India, Madras and up the coast as high as Orissa. Generally attaining to about 6 inches in length. The specimen figured (life-size) was from

Jubbulpore.

47. Barbus arulius, Plate CXLII, fig. 5.

Systomus arulius and rubrotinctus, Jerdon, M. J. L. and S. 1849, p. 317. Puntius arulius, Day, Proc. Zool. Soc. 1867, p. 294. Barbus arulius, Day, l. c. 1868, p. 585, and 1870, p. 373, (not Günther).

B. iii, D. $11(\frac{3}{8})$, P. 15, V. 9, A. $7(\frac{2}{6})$, C. 18, L. l. 21-23, L. tr. $4\frac{1}{2}/4\frac{1}{2}$.

Length of head $4\frac{1}{2}$ to 5, of caudal $4\frac{1}{2}$ to 5, height of body $3\frac{3}{4}$ to 4 in the total length. Eyes—diameter $3\frac{1}{4}$ in the length of the head, 1 diameter from the end of snout and also apart. Dorsal profile rather more onvex than that of the abdomen. Upper jaw overlapping the lower. Lower labial fold interrupted. Barbels—a pair of long maxillary ones. Teeth—pharyngeal, 5, 3, 2/2, 3, 5, sharp and curved at their extremities. Fins—no osseous dorsal ray, the fin which is 2/3 as high as the body commences midway between the end of the snout and the base of the caudal, which last is deeply emarginate. Lateral-line—complete, 2½ rows of scales between it and the base of the ventral fin: 9 rows before the base of the dorsal fin. Free portion of the tail as high at the base of the ventral fin: 9 rows before the base of the dorsal fin. its base as it is long. Colours-olive-green on the back, becoming silvery-white dashed with reddish green over the abdomen. A black blotch, about two scales in width, passes from below the origin of the dorsal fin as low as the lateral-line: a second from just below the posterior extremity of the dorsal to the base of the anal: and a third across the free portion of the tail before the caudal fin. Dorsal, caudal and anal pinkish with a black bar across the summit of the first, whilst the caudal is stained at its edges.

In Barbus rubrotinctus, the barbels appear to have been overlooked.

Habitat.—Wynaad and Neilgherry range of hills and the rivers at their bases, and at least as far south as Cottayam in Travancore: also in the Cauvery, from whence it has been procured at Seringapatam where it is termed Aruli. It attains 4 inches or more in length. The example figured (life-size) was from the Wynaad.

48. Barbus Mahecola, Plate CXL, fig. 5.

Leuciscus Mahecola, Cuv. and Val. xvii, p. 305, pl. 502 (Barbels omitted); Bleeker, Beng. p. 68; Jerdon, Madr. Journ. Lit. and Science, 1849, p. 322.

Barbus filamentosus, Günther, Catal. vii, p. 145 (not Cuv. and Val.).

Puntius (Capoëta) lepidus, Day, Proc. Zool. Soc. 1868, p. 196.

B. iii, D. 11 $(\frac{3}{8})$, P. 15, V. 9, A. 7 $(\frac{2}{5})$, C. 19, L. 1. 21, L. tr. 5/4.

Length of head $4\frac{3}{4}$ to 5, of caudal 4 to $4\frac{1}{4}$, height of body $3\frac{1}{4}$ to $3\frac{1}{4}$ in the total length. Eyes—diameter $3\frac{1}{4}$ in length of head, 1 diameter from end of snout, $1\frac{1}{4}$ diameters apart. Body compressed. Lower jaw the shorter. Lower labial fold interrupted in the mesial line. In some specimens the snout is covered with large shorter. Lower label for interrupted in the mesha line. In some specimens the shout is covered with large pores. Barbels—a thin maxillary pair extending to below the centre of the orbit in some specimens, very minute in others (see remarks, p. 556). Fins—last undivided dorsal ray articulated, smooth, feeble: the branched rays are elongated in the adult, the fin commences midway between the snout and the base of the caudal fin. Caudal deeply lobed. Lateral-line—complete, $2\frac{1}{2}$ rows of scales between it and the base of the ventral. Free portion of the tail rather higher at its base than it is long. Colours—silvery white, with a deep black oval mark on the lateral-line from about the fourteenth to the eighteenth scales. A dark band along the dorsal fin. Caudal red, tipped with black.

Having examined the type of Leuciscus Mahecola, I find it to be this species. The barbels were overlooked by both the Artist and Valenciennes. The length of the barbels varies in this species, as has been observed (see p. 556). In the Bowany river the snouth is very tuberculated, as also in examples from Pondicherry. Some examples have a dark spot behind the gill-opening.

Habitat.—From Canara down the Western coast and along the base of the Neilgherries, and Travancore hills, also Ceylon. It attains at least 6 inches in length.

C. Without barbels (Puntius).

a. Last undivided dorsal ray osseous and serrated.

49. Barbus apogon, Plate CXLI, fig. 3.

Barbus apogon, (Kuhl) Cuv. and Val. xvi, p. 392; Günther, Catal. vii, p. 150. Systomus apogon and apogonoides, Bleeker, Nat. Tyds. Ned. Ind. iii, p. 428, and ix, p. 150.

Cyclocheilichthys (anematichthys) apogon and apogonoides, Bleeker, Prod. Cyp. pp. 378, 379, and Atl. Ich. Cyp. pp. 88, 89, t. 29, f. 2, and t. 30, f. 3.

Systomus macularius, Blyth, J. A. S. of B. 1860, p. 159.

Barbus macularius, Günther, Catal. vii, p. 150; Day, Proc. Zool. Soc. 1869, p. 557. Nga-ta-zee and Nga-lay-toun, Burmese.

B. iii, D. 12 $\binom{4}{8}$, P. 17, V. 10, A. 8 $\binom{3}{5}$, C. 19, L. 1. 36-37, L. tr. $7\frac{1}{2}/7$.

Length of head $5\frac{1}{4}$, of caudal 4, height of body $3\frac{1}{4}$ in the total length. Eyes—diameter $3\frac{1}{4}$ to 4 in the length of the head, 1 to $1\frac{1}{4}$ diameters from the end of snout and also apart. Body strongly compressed, and rising abruptly from the nape to the base of the dorsal fin. Lower jaw overlapped by the upper when the mouth is closed. Fins—dorsal arises rather behind the insertion of the ventral and midway between the front edge of the eye and the base of the caudal fin, its last undivided ray strong, serrated, and its stiff portion rather shorter than the head. First three anal rays rather stiff. Caudal deeply forked. Lateral-line—complete, 5½ (4 in some specimens) rows of scales between it and the ventral fin: 15 rows of scales anterior to the base of the dorsal fin. Free portion of the tail as high at its base as it is long. Colours—silvery, each scale with a dark spot at its base.

Habitat.—Tenasserim and throughout Burma (certainly as high as Mandalay) to the Malay Archipelago. It attains at least 8 inches in length.

50. Barbus ambassis, Plate CXLV, fig. 1.

Day, Proc. Zool. Soc. 1868, p. 583.

Bunkuai, Ooriah.

B. iii, D. 11 $\binom{3}{8}$, P. 11, V. 9, A. 7 $\binom{2}{5}$, C. 19, L. 1. 36, L. tr. 6/8.

Length of head 5 to $5\frac{1}{3}$, of caudal 4, height of body $3\frac{1}{3}$ in the total length. Eyes—diameter nearly 2/5of length of head, 1/2 diameter from end of snout, 1 diameter apart. Upper jaw slightly the longer. Barbels—absent. Teeth—pharyngeal, sharp, crooked, 5, 3, 2/2, 3, 5. Fins—dorsal spine osseous, strong, and posteriorly serrated, having about 15 teeth, the fin commences slightly anterior to the ventral, and midway between the end of the snout and the base of the caudal, which last is deeply lobed. Scales-small and deciduous. Lateral-line—incomplete, becoming indistinct in the posterior two-thirds of the body, 6 rows of scales between it and the base of the ventral fin: 15 rows before the dorsal fin. Colours—light greenish, with a silvery band along the side. A small black spot at the base of the anterior dorsal rays, and a black blotch at the side of the tail.

Habitat.—Madras, Orissa, Bengal, and Assam at least as high as Suddya. It attains about 3 inches in length.

51. Barbus conchonius, Plate CXLIII, fig. 7.

Cyprinus conchonius, Ham. Buch. Fish. Gang. pp. 317, 389; Cuv. and Val. xvi, p. 394.

Systomus conchonius and pyrrhopterus, McClell. Ind. Cyp. pp. 285, 286, 383, 384, pl. 44, f. 1 and 8 (from Ham. Buch. MSS.); Bleeker, Beng. pp. 60, 62.

Barbus conchonius and pyrrhopterus, Günther, Catal. vii, pp. 153, 157.

Kunchon pungti, Bengali.

B. iii, D. 11 $(\frac{3}{8})$, P. 11, V. 9, A. 7 $(\frac{2}{5})$, C. 19, L. 1. 24-26, L. tr. $5\frac{1}{2}/6\frac{1}{2}$.

Length of head 5, of candal 4, height of body $2\frac{2}{3}$ in the total length. Eyes—diameter 1/3 of length of head, nearly 1 diameter from end of snout, and $1\frac{1}{4}$ apart. Body elevated. A slight concavity over the nape, followed by a considerable rise to the base of the dorsal fin. Barbels—absent. Fins—the dorsal 3/5 as high as the body, its last undivided ray osseous, moderately strong and serrated, as long as the head without the snout: the fin commences rather anterior to the insertion of the ventral, and midway between the anterior extremity of the orbit and the base of the caudal, which latter is forked in its last half. Lateral-line incomplete, ceasing after 8 or 10 scales: 4 to $4\frac{1}{3}$ rows of scales between it and the base of the ventral fin: 9 rows before dorsal fin. Free portion of the tail as high at its base as it is long. Colours—a large round black spot on the middle of the side above the posterior portion of the anal fin: opercles lake colour. Fins orange, dorsal with its upper half blackish.

Naince tal specimens have the dorsal spine much less coarsely serrated than those from the plains, from

whence they were introduced not many years since; they have also a darkish band along the side.

Habitat.—Assam, Lower Bengal, Orissa, Behar, N. W. Provinces, Punjab, and the Deccan: attaining at least 5 inches in length.

52. Barbus ticto, Plate CXLIV, fig. 7.

Cyprinus ticto, Ham. Buch. pp. 314, 389, pl. 8, f. 87; Cuv. and Val. xvi, p. 393.

Systomus ticto, McClell. Ind. Cyp. p. 382; Bleeker, Beng. pp. 62, 128; Jerdon, M. J. L. and Sc. 1849, p. 318.

Rohtee ticto, Sykes, Trans. Zool. Soc. 1841, p. 365.

Systomus tripunctatus, Jerdon, M. J. L. and Sc. 1849, pp. 316, 317.

Barbus ticto, Günther, Catal. vii, p. 153.

Kaoli and Kotree, Hind.: Kah-nee potiah, Assam.

B. iii, D. 11 $(\frac{3}{8})$, P. 15, V. 9, A. 7 $(\frac{3}{6})$, C. 19, L. l. 23-26, L. tr. 5-6/6.

Length of head 5, of caudal 4½ to 5, height of body 3 to 3½ in the total length. Eyes—diameter 3 in length of head, 2/3 of a diameter from end of snout, 1 diameter apart. Body strongly compressed and elevated. Upper jaw slightly the longer. Teeth—pharyngeal, crooked, pointed, 5, 3, 2/2, 3, 5. Fins—osseous dorsal ray strong and serrated, three-quarters as long as the head, fin half as high as the body. Caudal forked. Lateral-line—incomplete, ceasing after 6 or 8 scales: 4 or 5 rows of scales between the lateral-line and base of the ventral fin, and 11 before the dorsal fin. Colours—silvery, sometimes stained with red, a black spot on the side of the tail before the base of the caudal fin and immediately behind the anal: a smaller one (frequently absent) at the commencement of the lateral-line. Fins often black, sometimes orange.

A single specimen from Calcutta shows a lateral-line distinct for 6 scales, indistinct for 10 more, when it ceases. Cutch examples have 23 to 25 scales along the lateral-line, and one specimen had two blotches on either side of the base of the caudal fin. In Sind the dorsal spine is thin and very finely serrated. One Ganjam example had L. l. 27, as had also one from Bheer Bhoom. In Orissa they had as a rule L. l. 25, in the

Wynaad L. l. 23.

Habitat.—Sind, throughout India and Ceylon. The specimen figured (life-size) was from Assam. It rarely exceeds 4 inches in length.

53. Barbus Stoliczkanus, Plate CXLIV, fig. 8.

Barbus McClellandi, Day, Proc. Zool. Soc. 1869, p. 619 (not Cuv. and Val.) Barbus Stoliczkanus, Day, Journal Asiatic Soc. Bengal, 1871, pt. ii, p. 328.

B. iii, D. 10-11($\frac{2}{8}$), P. 14, V. 9, A. $7(\frac{2}{5})$, C. 19, L. 1. 25, L. tr. 5/6.

Length of head 1/6, of caudal 1/5, height of body 1/3 of the total length. Eyes—diameter 3 in length of head, 1/2 to 2/3 of a diameter from end of snout, $1\frac{1}{2}$ apart. Interorbital space flat. Mouth small. Barbels—absent. Teeth—pharyngeal, crooked, 5, 3, 2/2, 3, 5. Fins—osseous dorsal ray nearly as long as the head excluding the snout, serrated, but less strongly than in B. ticto, the serratures are likewise rather irregular, the fin commences midway between the snout and the base of the caudal, which latter is forked. Lateral-line—complete, there are $3\frac{1}{2}$ rows of scales between it and the base of the ventral fin: 9 rows before the dorsal fin. Colours—silvery, an oblong black mark on the lateral-line about the third scale, and a deep black mark above and a little behind the posterior extremity of the anal fin on the 18th and 19th scales, superiorly it extends almost to the back, whilst it is yellow anteriorly. Fins orange.

Some Darjeeling examples agree with the Burmese fish.

Habitat.—Eastern Burma, where it supersedes B. ticto. It attains 4 inches in length. The specimen figured (life-size) was from Moulmein.

54. Barbus punctatus, Plate CXLIV, fig. 5.

Systomus conchonius, Jerdon, Madr. J. L. and Sc. 1849, p. 317 (not Cyprinus conchonius, H. B.) Puntius punctatus, Day, Proc. Zool. Soc. 1865, p. 302, and Fishes of Malabar, p. 214, pl. vii, f. 1. Putter perlee, Mal.

B. iii, D. $11(\frac{3}{8})$, P. 15, V. 9, A. $7(\frac{2}{5})$, C. 18, L. l. 23-24, L. tr. 5/5.

Length of head $5\frac{1}{4}$, of caudal $4\frac{1}{4}$ to 5, height of body 3 to $3\frac{1}{4}$ in the total length. Eyes—diameter $2\frac{1}{4}$ in the length of head, 1/2 a diameter from end of snout, and 1 diameter apart. Interorbital space flat. Dorsal profile more convex than that of the abdomen. Fins—dorsal fin commences over the ventral, and midway between end of snout and base of the caudal, its upper border slightly concave, its last undivided ray osseous, strong, serrated, and about as long as the head: the fin 2/3 as high as the body. Caudal forked. Lateral-line—complete, 3 rows of scales between it and the base of the ventral fin: 8 rows before the dorsal fin. Free portion of the tail as high as long. Colours—olive-green superiorly, becoming white on the abdomen. A diffused black spot on the twentieth and twenty-first scales of the lateral-line. The anterior half of the third or fourth scale from the opercle, in the row next below the lateral-line, black. Fins yellowish, dorsal and anal tipped with orange. Dorsal with two rows of black spots, and in Malabar examples a short intermediate one anteriorly. In some specimens there is a light edge round the caudal blotch, and a silvery band along the sides.

Habitat.—Malabar and Coromandel coast. It does not appear to exceed 3 inches in length.

55. Barbus gelius, Plate CXLV, fig. 3.

Cyprinus gelius and canius, Ham. Buch. Fish. Gang. pp. 320, 390; Cuv. and Val. xvi, pp. 396, 397. Systomus gelius and canius, McClell. Ind. Cyp. pp. 286, 287, 386, 387, pl. 44, f. 4 and 6 (from Ham. Buch. MSS.); Bleeker, Beng. pp. 60 and 129.

Barbus gelius, Günther, Catal. vii, p. 154; Day, Proc. Zool. Soc. 1869, p. 374.

Cutturpoh, Ooriah: Gili pungti, Beng.

B. iii, D. $10-11(\frac{2-3}{8})$, P. 15, V. 9, A. $8(\frac{3}{5})$, C. 19, L. 1. 23-24, L. tr. 4/5.

Length of head $4\frac{1}{4}$ to $4\frac{1}{2}$, of caudal 4, height of body 3 to $3\frac{1}{4}$ in the total length. Eyes—diameter $2\frac{1}{3}$ in length of head, 1/2 a diameter from end of snout, 1 diameter apart. Third suborbital bone broad. Dorsal profile rather elevated. Barbels—absent. Fins—dorsal arises slightly in advance of the ventrals, its osseous ray is strong, rather coarsely serrated, and as long as the head excluding the snout, the fin 2/3 as high as the body: caudal deeply forked. Lateral-line—incomplete, ceasing after 5 or 6 scales: 3 rows of scales between lateral-line and base of ventral fin: 8 rows before the dorsal fin. Colours—reddish brown, with a black band over the tail a little anterior to the base of the caudal fin, and another less distinct behind the base of that fin. A silvery band along the side. The peritoneum being black appears like an irregular dark blotch. A black spot passes across the base of the anterior half of the dorsal, extending one-third the distance up the rays. A black band over the base of the anal, highest in front. Occiput also black.

Habitat.—Ganjam, Orissa, Bengal, and Assam. It attains at least 2 inches in length. The example

figured (life-size) was from Debrooghur in Upper Assam.

56. Barbus phutunio, Plate CXLV, fig. 4.

Cyprinus phutunio, Ham. Buch. Fish. Gang. pp. 319, 390; Cuv. and Val. xvi, p. 395.
Systomus leptosomus, McClell. Ind. Cyp. pp. 287, 387, pl. 44. f. 2, (from Ham. Buch. MSS.)
Systomus phutunio, Bleeker, Bengal, pp. 62 and 128, (not Cyp. and Cobit. Ceylon, 1864-65, p. 12, t. iv, f. 4.)

Barbus phutunio, Günther, Catal. vii, p. 154; Day, Proc. Zool. Soc. 1869, p. 375.

Kudji-kerundi, Ooriah; Phutuni pungti, Beng.

B. iii, D. $10-11(\frac{2-3}{8})$, P. 15, V. 9, A. $8(\frac{3}{6})$, C. 19, L. 1. 20-23, L. tr. 8-10.

Length of head 4 to $4\frac{2}{3}$, of caudal 4, height of body 3 to $3\frac{1}{4}$ in the total length. Eyes—diameter $2\frac{1}{2}$ in the length of head, 1/2 to 3/4 of a diameter from end of snout, 1 diameter apart. Dorsal profile more elevated than the abdominal. Mouth small. Barbels—absent. Fins—dorsal osseous ray serrated, the serratures often becoming indistinct in the adult: the fin commences opposite the ventrals, and midway between the end of the snout and the base of the caudal, which latter is rather deeply forked. Lateral-line—incomplete, only extending along three or four scales: from it to the base of the ventral are 3 rows: 9 rows before the dorsal fin. Colours—reddish-brown, with a black band passing from the back to opposite the middle of the pectoral fin: a second from the back to the posterior end of the base of the anal: two other lighter bands pass downwards, one from the anterior, the other from the posterior extremity of the dorsal. A dark band down the centre of the dorsal, another at the base of the caudal. The adult in its colours becomes very similar to B. punctatus, the pectoral band decreases in size, whilst that on the dorsal fin breaks up into spots.

Habitat.—Ganjam, Orissa and through Bengal and Burma, attaining 3 inches in length.

57. Barbus Cumingii.

Puntius phutunio, Bleeker, Cyp. and Cobit. Ceylon, 1864, p. 12, t. iv, f. 4 (not H. Buch.) Barbus cumingii, Günther, Catal. vii, p. 155.

B. iii, D. $11(\frac{3}{8})$, P. 15, V. 9, A. $8(\frac{3}{6})$, C. 19, L. 1. 21, L. tr. $3\frac{1}{2}/3\frac{1}{2}$.

Length of head 5, of caudal $4\frac{1}{4}$, height of body 3 in the total length. Eyes—diameter $2\frac{3}{4}$ in the length of head, 2/3 of a diameter from the end of snout, and 1 apart. Dorsal profile more convex than that of the abdomen. Mouth small. Suborbital bones very deep. Barbels—absent. Fins—the dorsal commences midway between the end of the snout and base of the caudal fin, and opposite the insertion of the ventral, its last undivided ray is rather weak, osseous, and finely serrated. Pectoral reaches the ventral. Anal rather small. Caudal deeply forked. Lateral-line—incomplete, ceasing after 4 scales: 3 rows of scales between the lateral-line and base of the ventral fin: and 9 before the base of the dorsal. Colours—two dark vertical bands, one descending to the pectoral fin: the second across the free portion of the tail. Each scale with a silvery vertical streak (? a post-mortem appearance.)

Habitat.—Ceylon attaining to at least 2 inches in length.

58. Barbus nigrofasciatus, Plate CXLIV, fig. 6.

Günther, Catal. vii, p. 155.

B. iii, D. $11(\frac{3}{8})$, P. 15, V. 9, A. $7(\frac{2}{6})$, C. 19, L. 1. 20-21.

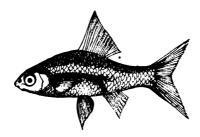

Length of head $4\frac{3}{4}$, of caudal $3\frac{2}{3}$, height of body $2\frac{3}{3}$ in the total length. Eyes—diameter 3 to $3\frac{1}{4}$ in the length of head, I diameter from end of snout and also apart. Body oval, strongly compressed: interorbital space convex. Mouth small, upper jaw the longer. Barbels—absent. Fins—dorsal lower than the body, it commences opposite the ventrals, its osseous ray is strong and finely serrated. Caudal deeply forked. Lateralline—complete, 3 rows of scales between it and the base of the ventrals. Colours—reddish, with a black band passing from eye to eye: body with three vertical black bands, the first from the back to the middle of the pectoral fin, the second from the base of the dorsal to behind the base of the ventral, and the third across the free portion of the tail. Dorsal, anterior portion of ventral and outer edge of anal black. The bands are not in exactly the same position in all specimens.

The example figured (life-size) is from a specimen in the British Habitat.—Southern Ceylon. Museum.

59. Barbus guganio.

Cyprinus guganio, Ham. Buch. Fishes, Ganges, pp. 338, 339, 392. Leuciscus guganio, Cuv. and Val. xvi, p. 445; Bleeker, Beng. p. 68. Gugani, Beng.

B. iii, D. $10(\frac{2}{5})$, P. 12, V. 9, A. 7.

CYPRINUS GUGANIO (H. B.'s MS. figure.)

"Head oval, small, blunt and dotted. Mouth small. The jaws protrude in opening, the upper is the longest. * * The eyes are far forwards on the sides of the head and large." Fins—the dorsal is near the middle, its osseous ray is strong and serrated. Scales—large and firmly adherent. Lateral-line—incomplete. Colours—the back dotted.

Habitat.—Gangetic provinces and Assam. It scarcely exceeds an inch and a half in length. This species is evidently allied to Barbus ambassis, p. 576.

b. Osseous dorsal ray entire.

60. Barbus stigma, Plate CXLI, fig. 5.

Cyprinus sophore, Ham. Buch. Fish. Ganges, plate xix, fig. 86 (not pp. 310, 389.)
Systemus sophore, McClell. Ind. Cyp. pp. 285, 382; Bleeker, Beng. p. 62; Jerdon, M. J. L. and S. 1849, p. 316 (not Ham. Buch.)

Puntius modestus, Kner, Novara Fische, p. 348, t. 15, f. 3.

Barbus sophore and modestus, Günther, Catal. vii, pp. 152, 156.

Barbus stigma, Day, Proc. Zool. Soc. 1868, p. 198, 1869, p. 375.

Chadu-perigi, Tel.: Patia-kerundi, Ooriah: Katcha-karawa and Pottiah, Hin.: Katch-karawa, Can.: Nga-kkoon-ma, Burm.

B. iii, D. 11-12($\frac{3}{8^2-9}$), P. 17, V. 9, A. 8($\frac{3}{8}$), C. 19, L. 1. 23-26, L. tr. $4\frac{1}{2}$ -5/5, Vert. 15/14.

Length of head 5, of caudal 5, height of body $3\frac{1}{2}$ to $3\frac{3}{2}$ in the total length. Eyes—diameter $3\frac{1}{2}$ to 4 in length of head, 1/2 to 1 diameter from end of snout, $1\frac{1}{2}$ to 2 diameters apart. Dorsal profile much more convex than that of the abdomen, and a little concave over the occiput. Upper jaw slightly the longer. Lower labial fold interrupted. Barbels—absent. Teeth—pharyngeal, crooked, 5, 3, 2/2, 3, 5. Fins—dorsal 1/2 to 2/3 as high as the body, its last undivided ray osseous, rather weak or of moderate strength, entire, as long as the head without the snout, or even less; it commences rather in advance of the insertion of the ventral, and midway between the end of the snout and the base of the candal Lateral line—complete 3 to 31 raws of midway between the end of the snout and the base of the caudal. Lateral-line—complete, 3 to 3½ rows of scales between it and the base of the ventral fin: 8 to 9 rows before the dorsal fin. Occasionally in the N.W. Provinces and Bengal specimens occur with 1. 1. 27. Free portion of tail as high as long. Colours—silvery, with a scarlet lateral band at some seasons, and a dark mark across the base of the middle dorsal rays, this last being occasionally absent. A round black blotch, more or less distinct, at the root of the caudal fin.

The type of L. Duvaucelii is still in good preservation at Paris, and is this species.

Habitat.—Sind, throughout India and Burma as high as Mandalay. As food it is bitter. In January, 1868, I found 1850 developed ova in one female fish at Madras. It attains at least 5 inches in length.

61. Barbus chrysopterus, Plate CXLIII, fig. 6.

Systomus chrysopterus, McClell. Ind. Cyp. pp. 285, 383; Bleeker, Beng. p. 60.

4 E 2

Barbus chrysopterus, Günther, Catal. vii, p. 152.

Pottiah, Punj.: Durru, Sind.

B. iii, $11(\frac{3}{8})$, P. 17, V. 9, A. $7(\frac{3}{8})$, C. 19, L. 1, 23-25, L. tr. 5/5.

Length of head 5, of caudal $4\frac{1}{2}$, height of body 3 in the total length. Eyes—diameter 3 to $3\frac{1}{2}$ in length of the head, 3/4 to 1 diameter from end of snout. Upper profile slightly concave over the nape, rising considerably to the base of the dorsal fin, and much more convex than that of the abdomen. Body compressed. Third suborbital bone very narrow. Mouth narrow, horse-shoe shaped, the upper jaw very slightly the longer when the mouth is closed. Fins—dorsal arises over or slightly in advance of the ventral, and midway between the end of the snout and the base of the caudal, its smooth osseous ray is not strong and as long as the head without the snout; upper margin of the dorsal fin slightly concave, its height is only slightly above one-half of that of the body. The pectoral extends to the ventral, and the latter to the anal. Lower caudal lobe slightly the longer. Lateral-line—complete, $3\frac{1}{2}$ rows of scales between it and the base of the ventral fin: 9 rows before the dorsal fin. Colours—dull silvery, darkest along the back, and each scale having a dark base formed by fine black dots. Dorsal, ventral, and anal fins generally stained with black spots at their extremities, but in some specimens only the anal. A dark mark at the base of 3rd to 7th divided dorsal rays, sometimes a dark mark at base of the tail.

Habitat.—Assam, Bengal, N. W. Provinces, Punjab and Sind. The specimen figured (life-size) was from Roorkee.

62. Barbus thermalis.

Leuciscus thermalis, Cuv. and Val. xvii, p. 94, pl. 490. Barbus thermalis, Günther, Catal. vii, p. 143 (not synon.).

B. iii, D. 11 ($\frac{3}{8}$), P. 15, V. 9, A. 8 ($\frac{3}{5}$), C. 19, L. l. 24, L. tr. $5\frac{1}{2}/5\frac{1}{2}$.

Length of head $4\frac{1}{4}$, of caudal $4\frac{1}{4}$, height of body $3\frac{1}{3}$ in the total length. Eyes—diameter $3\frac{1}{2}$ in length of head, I diameter from end of snout. Dorsal profile more convex than the abdominal. Body very compressed. Jaws of about equal length: interorbital space convex. Barbels—absent. Fins—dorsal commences nearer the end of snout than the base of caudal fin, it is only two-thirds as high as the body, its osseous ray moderately strong, rather longer than the head without the snout. Lateral-line—incomplete, ceasing after eight scales. Colours—silvery, a round black finger mark on either side of the free portion of the tail anterior to the base of the caudal fin, and a second at the base of the first few dorsal rays.

Habitat.—From a hot spring in Ceylon; attaining at least 3 inches in length. This description is from the type specimen which is at Paris.

63. Barbus terio, Plate CXLIV, fig. 3.

Cyprinus terio, Ham. Buch. Fish. Gang. pp. 313, 389; Cuv. and Val. xvi, p. 398. Systomus gibbosus, McClell. Ind. Cyp. pp. 286, 385, pl. 44, f. 7. (from Ham. Buch. MSS.) Systomus terio, Bleeker, Beng. p. 62. Barbus terio, Günther, Catal. vii, p. 153; Day, Proc. Zool. Soc. 1869, p. 376. Kakachia-kerundi, Ooviah: Teri pungti, Beng.

B. iii, D. $11(\frac{3}{8})$, P. 15, V. 9, A. $7(\frac{2}{5})$, C. 19, L. 1. 22-23, L. tr. 5/5.

Length of head 4 to $4\frac{1}{2}$, of caudal 4, height of body 3 in the total length. Eyes—diameter $2\frac{3}{4}$ to 3 in length of head, 3/4 to 1 diameter from end of snout, $1\frac{1}{4}$ diameters apart. Interorbital space flat. Body compressed, dorsal profile more convex than that of the abdomen, there being a considerable rise from the snout to the base of the dorsal fin. Upper jaw slightly the longer. Barbels—absent. Fins—dorsal arises slightly in advance of the ventrals, and midway between the end of snout and base of the caudal, its last undivided ray is osseous, entire, moderately or very strong, and nearly as long as the head: the fin is almost as high as the body below it. Lateral-line—incomplete, ceasing after 3 or 4 scales: 3 rows between the lateral-line and base of the ventral fin: 9 rows in front of the dorsal fin. Colours—silvery, greenish along the back, and each scale having a number of fine black spots most numerous at the anterior margin. A large black blotch in the middle of the side over the posterior extremity of the anal, which is sometimes extended in the median line as far as the tail. A very indistinct black blotch (most apparent in the immature) exists under the posterior extremity of the dorsal passing downwards to the middle of the fish. Fins yellowish, their margins stained with black, the dorsal having a median band. In some specimens there is a dark mark at the bases of the scales.

Habitat.—Orissa, Bengal to the Punjab. It attains 3 or 4 inches in length. The specimen figured (lifesize) was from Orissa.

c. Last undivided dorsal ray articulated, or if osseous very weak.

64. Barbus Punjaubensis, Plate CXLV, fig. 2.

Day, J. A. S. of B. 1871, p. 334.

B. iii, D. $11(\frac{3}{8})$, V. 9, A. $7(\frac{2}{5})$, C. 19, L. 1. 43, L. tr. 8/?.

Length of head 2/11, of caudal 1/4, height of body 2/7 of the total length. Eyes—rather large, situated in the anterior half of the head, 1/3 of a diameter from end of snout. Mouth small, horse-shoe shaped, with the upper jaw slightly overhanging the lower. Abdominal profile more convex than that of the back. Barbels—absent. Fins—dorsal two-thirds as high as the body below it, arising midway between the snout and the base of the caudal fin, its last undivided ray is weak and articulated. Caudal deeply forked, with pointed lobes. Lateral-line—incomplete, 14 rows of scales before the base of the dorsal fin. Colours—silvery, with a burnished silvery stripe along the side, and a black spot at the base of the caudal fin. Two first dorsal rays and intermediate membrane deep black.

Very similar in appearance to B. ambassis, but at once distinguished by the character of its last undivided

dorsal ray, which is articulated, and not osseous and serrated.

Habitat.—Sind, Ravi river at Lahore, also Jubbulpore; it is a small species, attaining about 2 inches in length. Nearly all my specimens were spoiled before I was able to put them into spirit.

65. Barbus unimaculatus, Plate CXLV, fig. 5 (twice natural size).

Systomus unimaculatus, Blyth, J. A. S. of Bengal, 1860, p. 159; Day, Proc. Zool. Soc. 1869, p. 557. B. iii, D. 11 $\binom{3}{8}$, P. 11, V. 8, A. 7 $\binom{2}{5}$, C. 19, L. 1. 24-25, L. tr. $4\frac{1}{2}/4\frac{1}{2}$.

Length of head $3\frac{1}{2}$, height of body 3 in the total length. Eyes—diameter 3 in the length of head, 1 diameter from the end of snout and also apart. Mouth small, extending half the distance to below the orbit. Lower labial fold interrupted. Barbels—absent. Fins—dorsal with the last undivided ray osseous, entire, weak, and nearly as long as the head: it commences midway between the snout and the base of the caudal fin. Lateral-line—incomplete, becoming lost opposite the posterior extremity of the dorsal fin: 3 rows of scales between it and the base of the ventral fin: 9 rows before the dorsal fin. Colours—silvery, a black mark at the base of each dorsal ray.

Habitat.—A number of fry up to 1_{10}^8 inches in length from the Sitang river in Burma are in the Calcutta Museum; what they would be, when adults, it is difficult to determine, but, as the lateral-line is incomplete, they probably never would grow to large fish. The species is very similar to Burbus thermalis, C.V. (not Günther), but its head is a little longer, whilst the latter is from Ceylon.

66. Barbus Waageni, Plate CXLIV, fig. 4.

Day, Journal Asiatic Society of Bengal, xli, pt. ii, 1872, p. 325.

B. iii, D. 10-11 ($\frac{2-3}{8}$), P. 15, V. 9, A. 7 ($\frac{2}{5}$), C. 20, L. l. 23, L. tr. 4/7.

Length of head 4, of caudal 4 to $4\frac{1}{2}$, height of body 3 to $3\frac{1}{3}$ in the total length. Eyes—diameter $3\frac{3}{4}$ to 4 in the length of the head, 3/4 to 1 diameter from end of snout, and $1\frac{1}{4}$ apart. Dorsal profile considerably elevated. Height of the head equals its length: its upper surface flat: snout obtuse. Upper jaw the longer. Lower lip very thick, the transverse fold interrupted. Barbels—absent. Fins—dorsal 1/2 as high as the body below it, it commences nearer the base of the caudal fin than the front end of the snout, its upper edge is straight: last undivided ray articulated. Pectoral as long as the head excluding the snout. Caudal forked. Lateral-line—incomplete, ceasing about the seventh scale: $4\frac{1}{2}$ rows between it and the base of the ventral fin: 12 rows anterior to the dorsal fin. Caudal peduncle as high at its base as it is long. Colours—silvery, darkest superiorly: a dark blotch on the side of the tail on about the seventeenth and eighteenth rows of scales.

Habitat.—Chua Saidar Shah in the Punjab Salt range. This species was received from Dr. Waagen,

after whom I named it.

67. Barbus cosuatis, Plate CXLIV, fig. 1.

Cyprinus cosuatis, Ham. Buch. Fish. Gang. pp. 338, 392; Cuv. and Val. xvi, p. 444. Systomus malacopterus, McClell. Ind. Cyp. pp. 287, 386, pl. 44, f. 9 (from H. B. MSS.). Rohtee pangut, Sykes, Trans. Zool. Soc. ii, p. 365.

Lewiscus cosuatis, Bleeker, Beng. pp. 66, 139.

Barbus cosuatis, Günther, Catal. vii, p. 157.

Koswati, Beng.

B. iii, D. 11 $(\frac{3}{8})$, P. 13, V. 9, A. 7 $(\frac{9}{5})$, C. 19, L. 1. 22, L. tr. 3/3.

Length of head 4 to $4\frac{1}{4}$, of caudal 4, height of body $3\frac{1}{3}$ in the total length. Eyes—diameter $2\frac{1}{3}$ to $2\frac{5}{4}$ in length of head, 1/2 a diameter from end of snout, 1 diameter apart. A considerable rise to base of dorsal fin. Mouth small: upper jaw slightly the longer. No lower labial fold. Fins—dorsal without any osseous ray, it commences midway between the end of the snout and the base of the caudal fin, its upper edge is oblique and its height exceeds that of the body below it. Lateral-line—incomplete, the row of scales on which it is situated is larger than the others, 2 rows between it and the base of the ventral fin: 8 or 9 rows before the base of the dorsal fin. Colours—silvery, the scales having dark bases: a black band along the top of the dorsal, another across its middle also on the anterior anal rays.

Habitat.—Bengal, through the N. W. Provinces, the Deccan and Bombay, and down the Western coast as low as Cottayam in Travancore. It attains 2 or 3 inches in length. The specimen figured (life-size) was

from Jubbulpore.

68. Barbus vittatus, Plate CXLIV, fig. 2.

Puntius vittatus, Day, Proc. Zool. Soc. 1865, p. 303, Fish. Malabar, p. 215, pl. 13, f. 1. Barbus vittatus, Günther, Catal. vii, p. 156. Puntius sophore, Kner, Novara Fische, p. 347 (not Ham. Buch.). Kooli, Hind.

B. iii, D. 10 $\binom{2}{8}$, P. 12, V. 9, A. 7 $\binom{2}{5}$, C. 20, L. 1. 20-22, L. tr. 3/4.

Length of head 4 to $4\frac{1}{2}$, of caudal 5, height of body $3\frac{1}{2}$ in the total length. Eyes—diameter from 1/2 to 1/3 in the adult of the length of head, 2/3 of a diameter from end of snout, $1\frac{1}{2}$ diameters apart. Dorsal and abdominal profiles about equally convex. Mouth small. Barbels—absent. Fins—last undivided dorsal ray articulated, weak, and entire: the fin commences somewhat in advance of the ventrals, and midway between the snout and the base of the caudal fin, the latter being forked. Lateral-line-incomplete, ceasing after about 5 scales, 3 rows between it and the base of the ventral fin: 8 rows before the dorsal fin. Colours—silvery, generally with four black spots in the adult, one just before the dorsal, one below its posterior margin, another at the base of the caudal, and a fourth at the base of the anal. The dorsal has a vertical black streak, and a black tip with orange markings. In the immature the colours vary; when the fish is about eight-tenths of an inch long, a vertical stripe begins to show itself in the posterior third of the dorsal fin, the summit of which also becomes edged with black, whilst there are some irregular orange markings: in very young specimens the line of demarcation between the green of the back, and the silvery abdomen, appears like a white band running from the eye to the middle of the tail. In some specimens one or more of the spots are absent.

Habitat.—Mysore, Madras, Wynaad, Malabar, Ceylon, and Cutch, attaining 11 inches in length. The specimen figured (life-size) was from Madras.

69. Barbus filamentosus.

Leuciscus filamentosus, Cuv. and Val. xvii, p. 95, pl. 492; Bleeker, Beng. p. 68. Systomus assimilis, filamentosus and Madraspatensis, Jerdon, Madr. Journ. Lit. and Sc. xv, pp. 318, 319. Puntius filamentosus, Day, Fish. Malabar, p. 215.

B. iii, D. $11\binom{3}{8}$, P. 15, V. 9, A. $7\binom{2}{5}$, C. 19, L. 1. 21, L. tr. 4/4.

Length of head 5, of candal 4, height of body 3 to $3\frac{1}{2}$ in the total length. Eyes—diameter $3\frac{1}{2}$ in the length of head, 2/3 to 1 diameter from end of snout, $1\frac{3}{4}$ apart. Interorbital space nearly flat. Body strongly compressed and elevated. Generally large pores over the snout. Barbels—absent. Fins—dorsal arises slightly nearer snout than base of the caudal fin, its last undivided ray is osseous, smooth, and feeble, while the divided caudal forms of large populations of scales. whilst the divided ones are all more or less elongated in the adult. Lateral-line—complete, 2 rows of scales between it and the base of the ventral: 7 rows before the dorsal fin. Colours—silvery, each scale having a metallic green edging, whilst a more or less distinct black blotch exists on the lateral-line, on the fourteenth and fifteenth scales, and before the base of the caudal fin. A very curious change occurs in this fish immediately after death, the whole of its body becoming scarlet. Caudal red, tipped with black, and edged with white: dorsal and ventral nearly black.

Habitat.—Western coast and Southern India, attaining 6 inches in length. It is so similar to B. Mahecola (except in wanting barbels) that I have not figured it.

70. Barbus puntio, Plate CXLV, fig. 6.

Cyprinus puntio, Ham. Buch. Fish. Ganges, pp. 318, 389.

Systomus puntio, Bleeker, Beng. p. 62.
Barbus puntio, Günther, Catal. vii, p. 154; Day, Proc. Zool. Soc. 1870, p. 100.

B. iii, D. 11 $(\frac{3}{8})$, P. 15, V. 9, A. 7 $(\frac{2}{5})$, C. 21, L. 1. 23, L. tr. 5/4.

Length of head 4 to $4\frac{1}{3}$, of caudal $3\frac{1}{2}$, height of body 3 to $3\frac{1}{4}$ in the total length. Eyes—diameter 2/5 of length of head, 1/2 to 3/4 of a diameter from end of snout, 1 diameter apart. Dorsal profile considerably elevated. Mouth small. Barbels—absent. Fins—last undivided dorsal ray osseous and entire, the fin commences rather in advance of the ventrals, and midway between the anterior margin of the orbit and the base of the caudal fin, the latter deeply forked. Lateral-line—only extending distinctly for a few scales, but very indistinctly to the base of the caudal fin: 2½ rows between it and the base of the ventral fin: 8 rows before the dorsal fin. Colours—silvery, a wide black band encircles the free portion of the tail, and includes the tip of the anal fin. Dorsal orange tipped with black.

Habitat.—Bengal and British Burma. It only attains about 3 inches in length.

Dorsal fin commencing very distinctly posterior to the ventrals, but not extending to above the anal, which last is short or of moderate length (5 to 11 branched rays).

Genus, 17-NURIA, Cuv. and Val.

Esomus, Swainson.

Abdomen rounded. Pseudobranchiæ present: mouth narrow, directed obliquely upwards, suborbitals broad.

Barbels four, the rostral shorter than the maxillary pair: pharyngeal teeth crooked, pointed, 5/5. Dorsal fin without osseous ray, and with few branched ones, it is inserted posterior to the ventral, but does not extend to over the anal, the latter having but few or a moderate number of branched rays: scales of moderate size. Lateral-line, when present, passing to the lower half of the base of the caudal fin. Gill-rakers short.

Geographical distribution.—Continent of India, Ceylon, Burma, and the Nicobars.

SYNOPSIS OF INDIVIDUAL SPECIES.

- 1. Nuria danrica, D. 2/6, A. 3/5, L. l. 30-34. Lateral-line present or absent. A black lateral band. India, Ceylon, Burma, and Nicobars.

Mola and Mah-wa, N. W. Provinces: Nga-zin-byoon, Burmese.

B. iii, D. 8 $(\frac{2}{6})$, P. 15, V. 9, A. 8 $(\frac{3}{6})$, L. 1. 30-34, L. tr. 5-6/3.

Length of head $5\frac{1}{4}$ to $5\frac{1}{2}$, of caudal 5 to $5\frac{1}{2}$, height of body $5\frac{1}{2}$ in the total length. Eyes—diameter $3\frac{1}{4}$ to $3\frac{1}{2}$ in the length of head, 1 diameter from end of snout and apart. Barbels—the rostral not so long as the head, the maxillary ones extend to the base of the ventral or even to that of the caudal fin. Fins—the dorsal commences nearer the base of the caudal than the head: pectoral varies with age, being generally proportionately longer in the immature: sometimes the anal fin is higher than the dorsal, especially in the immature. Lateral-line—usually present, entire: 2 rows of scales between it and the base of the ventral: 18 before the dorsal fin. Colours—a broad black lateral band, sometimes absent.

Variety Nuria alta, Blyth, Plate exlv, fig. 8, is a Burmese form, which differs in the height of its body,

being $4\frac{1}{4}$ (instead of $5\frac{1}{4}$) in the total length, and its anal fin being a little lower.

Variety Nuria Malabarica, Day, Plate cxlv, fig. 7, is a form found along the coasts of India, Burma, and the Nicobars. It is distinguished by the entire absence of the lateral-line, but is otherwise exactly similar

Habitat.—India, Ceylon, Burma and the Nicobars. Dr. Cumberland found it in a hot stream of 112° Fahr. at Pooree, M. Regnaud in a hot stream at Cannia in Ceylon: it attains 5 inches in length.

Genus, 18-RASBORA, Bleeker.

Leuciscus, sp. Cuv. and Val.: Megarasbora, Günther.

Abdomen rounded. Pseudobranchiæ present. Cleft of mouth oblique, lower jaw slightly prominent, having one central and on either side a lateral prominence, fitting into corresponding emarginations in the upper jaw. Barbels two (rostral), or none. Eyes with free lids. Pharyngeal teeth 5, 3 or 4, 2/2, 3 or 4, 5. Dorsal fin without any osseous ray and few branched ones, inserted posterior to the origin of the ventral but not extending to above the anal, which latter is short. Scales large, or of moderate size. Lateral-line concave, continued to the middle or lower half of the caudal fin. Gill-rakers short and lanceolate.

Geographical distribution.—Africa, India, Ceylon, Burma, to the Malay Archipelago.

SYNOPSIS OF SPECIES.

A. Barbels present (Megarasbora).

1. Rasbora elanga, D. 2/7, A. 2/5, L. l. 40-44. Bengal, Assam and Burma.

B. Barbels absent (Rasbora).

2. Rasbora daniconius, D. 2/7, A. 2-3/5, L. 1. 30-34. Mostly a black lateral stripe. Continent of India, Ceylon and Zanzibar.

3. Rasbora Buchanani, D. 2/7, A. 2/5, L. l. 26.29. Caudal black edged. From Mysore throughout India, Assam and Burma.

A. Barbels present (Megarasbora).

1. Rasbora elanga, Plate CXLVI, fig. 1.

Cyprinus elanga, Ham. Buch. Fish. Ganges, pp. 281, 386; Cuv. and Val. xvi, p. 415.

Leuciscus dystomus, McClell. 1nd. Cyp. pp. 292, 406, pl. 56, f. 4.

Leuciscus elanga, Bleeker, Beng. p. 66. Rasbora elanga, Günther, Catal. vii, p. 198.

Dahwiee, Hind.; Elang. Assam.

B. iii, D $9(\frac{2}{7})$, P. 15, V. 8-9, A. $7(\frac{2}{5})$, C. 19, L. 1. 40-44, L. tr. 7-8/6.

Length of head 5 to $5\frac{1}{2}$, of caudal 6, height of body $4\frac{1}{2}$ to 5 in the total length. Eyes—diameter from 3 to 4 in the length of head, 1 diameter from end of snout, $1\frac{1}{2}$ diameters apart. Head pointed, its greatest width equalling 1/2 its length, jaws of equal length, prominences and emarginations well-defined. Barbels—one pair of short rostral ones. Teeth—pharyngeal, 5, 4, 2/2, 4, 5. Fins—dorsal commences midway between the posterior margin of the orbit and the base of the caudal fin. The pectoral, which is nearly as long as the head, does not reach the ventral. Caudal forked. Lateral-line—1½ to 2 rows of scales between it and base of ventral fin: 14 rows before the base of the dorsal fin. Colours—silvery, with sometimes a leaden-coloured band along the upper portion of the side.

Habitat.—Bengal, Assam and Burma: attaining at least 8 inches in length.

B. Barbels absent (Rasbora as restricted).

2. Rasbora daniconius, Plate CXLVI, fig. 2, and fig. 3 (var. R. Neilgherriensis).

Cyprinus daniconius and anjana, Ham. Buch. Fish. Ganges, pp. 327, 329, 391, pl. 15, f. 89; Cuv. and Val. xvi, pp. 435, 436.

B. iii, D. $9(\frac{2}{7})$, P. 15, V. 9, A. $7(\frac{2}{5})$, C. 19, L. 1. 31-34, L. tr. $4\frac{1}{5}/5$, Vert. 18/14.

Length of head $4\frac{1}{2}$ to 5, of caudal 5, height of body $4\frac{1}{2}$ to $5\frac{1}{4}$ or even 6 in the total length. Eyesdiameter $3\frac{2}{3}$ to 4 in the length of head, 1 diameter from end of snout and also apart. The greatest width of the head equals its postorbital length. Prominences and emarginations on jaws well defined. Cleft of mouth extends to beneath anterior margin of orbit. Teeth—pharyngeal, curved, sharp, 5, 3, 2/2, 3, 5. Fins—dorsal 2/3 the height of the body, it commences nearer the base of the caudal than the front edge of the snout, and rather nearer origin of ventral than that of anal in some examples, at an equal distance in others. Lateral-line—descends very gradually for the depth of 2 rows of scales: 2 rows of scales between it and ventral fin: 14 rows in front of base of dorsal fin. Colours—a black band, more or less distinct, passes from the eye to the base of the caudal. Sometimes it only exists just at its termination and thus forms a spot at the side of the base of the tail: or in some young specimens a bright silvery band superiorly edged with yellow is seen along

the sides. Caudal occasionally with its lobes tipped with gray.

Dr. Günther considers Rasbora Einthovenii, Bleeker, to be identical with this species. R. Neilgherriensis appears to be a large variety attaining 8 inches in length, it has usually 34 rows of scales, the same number is seen in many Deccan examples. R. Zanzibarensis, Playfair, Fish. Zanzibar, p. 119, pl. xvii, f. 4, shows no

appreciable difference from this species.

Habitat.—Continent of India, Ceylon, Burma, Malay Archipelago and Zanzibar, attaining 8 inches in length. It is much more common than R. Buchanani.

3. Rasbora Buchanani, Plate CXLV, fig. 10.

B. iii, D. $9(\frac{2}{7})$, P. 15, V. 9, A. $7-8(\frac{2}{5-6})$, C. 19, L. 1. 26-29, L. tr. $4\frac{1}{2}/3$.

Length of head 5, of caudal 5, height of body 4 in the total length. Eyes—diameter 31 in the length of head, about 1 diameter from end of snout, and rather more apart. Abdominal profile more convex than the dorsal. Prominences on jaws well-developed. Fins-dorsal commences nearer the base of the caudal than the snout. Lateral-line—concave, 2 rows of scales between it and the base of the ventral fin: 12 rows anterior to the base of the dorsal fin. Colours—silvery, a faint streak along the side, caudal usually tipped with black, especially in Burmese examples.

Habitat.—Continent of India, Assam, Burma and Pinang: in India it is most common in the valley of the Ganges and along the Coromandel Coast. It attains 4 or 5 inches in length. The example figured (life-

size) was from Moulmein.

Genus, 22—Aspidoparia (Heckel) Bleeker.

Morara, Bleeker.

Abdomen rounded. Mouth small, inferior, the lower jaw having a sharp crescentic edge destitute of lip. Barbels absent. Suborbital ring of bones of moderate width or broad. Pharyngeal teeth, 4, 4, 2/2, 4. 4, or 4, 3/3, 4. Dorsal fin without osseous and with rather few branched rays, commencing opposite to or behind the origin of the ventrals, but not extending to above the anal, which latter has a moderate number (10 to 12) of rays. Scales of moderate size. Lateral-line concave, and passing along the lower half of the base of the caudal fin.

Geographical distribution.—Throughout Bengal, Assam, Bombay, and Orissa as far as the Kistna river,

also Burma.

SYNOPSIS OF SPECIES.

1. Aspidoparia morar, D. 9-10, A. 10-12, L. 1. 38-42. India generally (except the Western coast and South of the river Kistna), Assam and Burma.

2. Aspidoparia jaya, D. 9, A. 9, L. 1. 52-60. N.W. Provinces and Assam.

1. Aspidoparia morar, Plate CXLVI, fig. 4.

Cyprinus morar, Ham. Buch. pp. 264, 384, pl. 31, f. 5; Gray and Hard. Ill. Ind. Zool. (from H. Buch.); Cuv. and Val. xvi, p. 459.

Leuciscus morar, McClell. Ind. Cyp. pp. 294, 410; Sykes, P. Z. Soc. 1841, p. 363; Bleeker, Beng. pp. 68, 136; Jerdon, M. J. L. and Sc. 1849, p. 323.

Morara morar, Bleeker, Prod. Cyp. p. 115.

Aspidoparia sardina, Heckel, Russ. Reis. ii, 3, p. 288; Günther, Catal. vii, p. 285.

Bayi, Ooriah: Morari and Morar, Beng.: Pa-o-char and Chilwa, Punj.: Ka-reer-re, Sind.: Amlee, Dec.: Chippuah, Chelluah, Hind. (N. W. P.): Mou-ah and Boreala, Assam.: Nga-hpyen-boo and Yen-boung-za, Burmese.

B. iii, D. 9-10 $(\frac{2}{7-8})$, P. 15, V. 8, A. 10-12 $(\frac{2}{8-10})$, C. 19, L. 1. 38-42, L. tr. $5\frac{1}{2}/5$, Vert. 14/21.

Length of head 5 to $5\frac{3}{4}$, of caudal 5, height of body 4 to $5\frac{1}{4}$ in the total length. Eyes—diameter 3 to $3\frac{2}{3}$ in the length of head, 3/4 to 1 diameter from end of snout, and 1 apart. Snout very obtuse. Upper jaw the longer, and overlapping the lower. The cheek covered by a broad suborbital ring of bones. Teeth—pharyngeal, 5, 4, 2/2, 4, 5, plough-shaped, the outer row much larger than the inner ones. Fins—dorsal higher than long, with a concave superior margin: it arises midway between the posterior margin of the orbit and the base of the caudal: pectoral as long as the head. Lateral-line—2½ to 3 rows of scales between it and the base of the ventral fin: 20 rows before the base of the dorsal fin. Colours—back light brown, divided from the silvery side by a burnished streak.

Habitat. - Sind, Punjab, Continent of India (except the Western coast, and localities south of the Kistna river), also Assam and Burma. It attains at least 7 inches in length. In one specimen, captured in Orissa, the anal fin was entirely absent.

2. Aspidoparia jaya, Plate CXLV, fig. 9.

Cyprinus jaya, Ham. Buch. Fish. Ganges, pp. 333, 392; Cuv. and Val. xvi, p. 439.

Leuciscus margarodes, McClell. Ind. Cyp. pp. 294, 411.

Leuciscus jaya, Bleeker, Beng. p. 68.

Aspidoparia jaya, Günther, Catal. vii, p. 286. Chola, Assam.: Pahruah, Hind. (N. W. P.).

B. iii, D. 9 ($\frac{2}{7}$), P. 15, V. 8, A. 9 ($\frac{2}{7}$), C. 21, L. 1. 52-60, L. tr. 7/10.

Length of head $5\frac{1}{4}$ to $5\frac{1}{2}$, of caudal $4\frac{1}{4}$ to $4\frac{1}{2}$, height of body 5 in the total length. Eyes—diameter 2/7 of length of head, 3/4 to 1 diameter from end of snout, $1\frac{1}{2}$ diameters apart. Mouth generic, considerably overhung by the snout. Both the preorbital and first suborbital bones touch the upper lip: only about half the cheek is covered by the suborbital ring of bones. Teeth—pharyngeal, 4, 3/3, 4, the outer row plough-shaped and compressed, the inner consisting of very minute teeth. Fins—dorsal commences midway between the snout and the base of the caudal, and opposite the insertion of the ventral. Caudal lobes of equal length. Scales—

Digitized by Google

586

deciduous. Lateral-line—curving at its termination on to the lower half of the caudal fin: 4½ rows of scales between it and the base of the ventral fin. Colours-silvery, back darkest.

Habitat.-Hurdwar on the Ganges and Assam.

C. - Dorsal fin commencing above the interspace between the ventrals and anal, generally extending to over the latter, which is of moderate length or elongated (7 to 33 branched rays).

Genus, 23—Rohtee, Sykes.

Osteobrama, Heckel; Smiliogaster, Bleeker.

Pseudobranchive present. Mouth anterior, lips thin. Abdomen rounded. Barbels present or absent, Pharyngeal teeth, 6 or 5 or 4, 4 or 3, 2 or 3/3 or 2, 3 or 4, 4 or 5 or 6. sometimes they are quite rudimentary. Dorsal fin short, having an osseous servated spine, and commencing opposite the interspace between the bases of the ventral and anal fins, the latter of which has many rays. Scales small. Lateral-line passing nearly to the centre of the base of the caudal fin. Gill-rakers short.

Geographical distribution.*—India generally, and Burma.

SYNOPSIS OF SPECIES.

b. With four barbels.

- 1. Rohtee Bakeri, D. 11, A. 14, L. l. 44. Travancore.
- 2. Rohtee Neilli, D. 12, A. 20, L. l. 59. Bowany river, Madras Presidency.
 - c. Without any, or with only rudimentary barbels.
- 3. Roltee cotio, D. 11-12, A. 29-36, L. l. 55-70. Sind, India (except Malabar and south of the Kistna). and Burma.
 - Rohtee Vigorosii, D. 11, A. 25-28, L. I. 75-80. Deccan and throughout Kistna and Godavery rivers.
 Rohtee Belangerii, D. 11-12, A. 20-21, L. I. 68-73. Godavery river and Burma.
 Rohtee Ogilbii, D. 11, A. 16, L. I. 55. Deccan, the Kistna and Godavery rivers.

1. Rohtee Bakeri, Plate CXLVII, fig. 1.

Day, Proceed. Zool. Soc. 1873, p. 240.

B. iii, D. $11(\frac{3}{8})$, P. 13, V. 10, A. $14(\frac{3}{11})$, L. l. 44, L. tr. 8/7.

Length of head from 5 to 6, of caudal $3\frac{1}{2}$ to $3\frac{2}{3}$, height of body from 4 to $4\frac{1}{2}$ in the total length. Eyes—longest transversely, diameter 2/5 of length of head, 2/3 of a diameter from end of snout, and 1 apart. Profile over nape rather concave, a considerable rise to the base of the dorsal fin. Mouth small, horseshoe-shaped, upper jaw the longer. Barbels—four, all very short. Fins—dorsal rather higher than the body, and commencing midway between the end of the snout and the base of the caudal, its spine weak, as long or rather longer than the head, and serrated posteriorly in almost its whole extent. Caudal deeply forked, lobes of equal length. Scales-51 rows between the lateral-line and the base of the ventral fin: 15 rows before the base of the dorsal fin. Colours-silvery, caudal and dorsal edged with black.

Habitut.—Cottayam in Travancore, from whence I received specimens up to 4½ inches in length, collected by the Rev. H. Baker, after whom I named the species.

2. Rohtee Neilli, Plate CXLVI, fig. 5.

Day, Proceedings Zool. Soc. 1873, p. 239.

B. iii. D. $12(\frac{1}{8})$, P. 13, V. 10. A. $20(\frac{3}{17})$, C. 19, L. 1. 59, L. tr. 12/18.

Length of head $4\frac{3}{4}$, of caudal $4\frac{3}{4}$, height of body $3\frac{1}{2}$ in the total length. Eyes—diameter $2\frac{2}{3}$ in the length of the head, 2/3 of a diameter from end of snout, and also apart. Interorbital space very concave. Profile over nape concave, from thence a considerable rise to the base of the dorsal fin. Upper jaw somewhat the longer. Barbels-two pairs, all about as long as the eye. Fins-dorsal commences midway between the front edge of the eye and the base of the caudal fin, it is 3/4 as high as the body, its last undivided ray osseous, very strong, serrated, and as long as the head excluding the snout. Pectoral nearly as long as the head. Ventral arises beneath the fourth dorsal ray and reaches the commencement of the anal. Caudal deeply forked. Lateral-line strongly marked in its first few scales, the rows of scales nearly regular: 8 rows between the lateral-line and base of ventral fin. Free portion of the tail as long as high. Colours—silvery, opercles golden.

Habitat.—Bowany river at base of the Neilgherry hills.

^{*} A difficulty exists respecting the localities given for the following specimens in the British Museum collection:—Osteobrama rapax. Günther, or Rohtee Vigorsii, Sykes, is stated to have been presented by Lieut.-Col. Playfair from the "northern parts of the Indian Peninsula." Referring to Preface, p. iv and to Labeo striolatus, Günther, p. 62—L. bognut, Sykes, one is led to conclude that by this term is meant Poona in the Deccan. The same expression for Poona is seen under the head of Osteobrama or Rohtee Ogilbii, Sykes, in B. M. catalogue, vii, p. 324!

B. iii, D. 11-12($\frac{3-5}{6}$), P. 13, V. 10, A. 29-36($\frac{2-3}{27-33}$), C. 19, L. 1. 55-70, L. tr. 9-15/14-21.

Length of head $5\frac{1}{3}$ to 6, of caudal $4\frac{1}{2}$ to 5, height of body 3 to $3\frac{1}{3}$ in the total length. Eyes—diameter $2\frac{1}{4}$ to 3 in the length of head, 1/2 a diameter from the end of the snout, and 1 to $1\frac{1}{4}$ apart. Profile over nape concave, from thence a great rise to the base of the dorsal fin. Upper jaw slightly the longer. Barbels—absent or very rudimentary. Fins—dorsal commences rather nearer the snout than the base of the caudal fin, its osseous ray is weak and serrated. Pectoral reaches to over the ventral and the latter to the anal. Caudal lobed, the lower lobe the longer. Scales—vary in number along the lateral-line, whilst in some specimens (var. cotio) the rows are very irregular in the last 3/4 of the body below the lateral-line. The number of rows between the lateral-line and base of the ventral fin also varies, being most in the variety R. cotio (12-13), whereas in R. Alfrediana there are rarely more than 7 or 8: 24 rows of scales before the base of the dorsal fin. Colours—silvery, darkest along the back and sometimes with a silvery lateral band. Some have a black blotch before the base of the dorsal fin, and another on the nape.

These two forms which diverge as widely as given in the two figures show every intermediate gradation. Osteobrama cotio, Günther, is not this species, but identical with R. Vigorsii, Sykes—Osteobrama rapax, Günther. Habitat.—From Sind throughout India (except the Malabar Coast and south of the Kistna) and Burma. It attains at least 6 inches in length.

4. Rohtee Vigorsii, Plate CXLVII, fig. 3.

Sykes, Trans. Zool. Soc. 1841, p. 36, pl. 63, f. 3; Day, Proc. Zool. Soc. 1869, p. 379. Systomus Vigorsii, Bleeker, Beng. p. 62. Abramis Vigorsii, Jerdon, M. J. L. and Sc. 1849, p. 319. B. iii, D. $11(\frac{3}{8})$, P. 19, V. 10, A. $25-28(\frac{2-3}{2\cdot3-\frac{3}{2\cdot6}})$, C. 19, L. l. 75-80, L. tr. 16-18/21.

Length of head 5, of caudal 4 to 5, height of body 3 to 4 in the total length. Eyes—diameter 3 to 3½ in the length of head, 1 diameter from end of snout and also apart. Body very compressed. Dorsal profile elevated, a concavity from the snout to over the nape. Mouth anterior, the lower jaw being somewhat longer than the upper, whilst posteriorly the cleft of the mouth extends to below the anterior margin of the orbit. Preorbital nearly as high as broad, suborbitals very narrow. Barbels—absent or a very rudimentary maxillary pair. Teeth—pharyngeal, crooked, 5, 4, 2/2, 4, 5. Gill-rakers short and rather widely separated. Fins—dorsal commences midway between the base of the ventral and anal, its spine strong and deeply denticulated, its osseous portion not so long as the head. Pectoral as long as the head excluding the snout. Caudal deeply forked, lower lobe the longer. Lateral-line—most strongly developed in the first few scales: 11 rows between the lateral-line and base of the ventral fin: 34 rows before the base of the dorsal fin. Colours—greenish superiorly, silvery beneath: snout black: the caudal fin slightly stained with gray. The young have a silvery band along the side.

Habitat.—Deccan, Kistna and Godavery rivers to their terminations. It attains at least 9 inches in length.

Digitized by Google

Length of head $5\frac{1}{3}$ to 6, of caudal $3\frac{2}{3}$ to 4, height of body 3 to $3\frac{1}{3}$ in the total length. Eyes—diameter 3 to $3\frac{1}{4}$ in length of head, 3/4 of a diameter from end of shout, $1\frac{1}{2}$ diameters apart. Lower jaw slightly the shorter. Dorsal profile much elevated, a slight concavity over the nape in Bengal specimens. Preorbital of moderate width, the rest of the suborbital ring narrow. Teeth—pharyngeal, 4, 3, 2/2, 3, 4, with the outer one in each row serrated on its edges. Gill-rakers rudimentary. Fins—dorsal commences about midway one in each row serrated on its edges. Gill-rakers rudimentary. Fins—dorsal commences about midway between the base of the caudal and the end of the snout, its osseous ray is strong and serrated posteriorly, the bony portion being as long as the head. Caudal deeply lobed, the lower slightly the longer. Lateral-line—bony portion being as long as the head. Caudal deeply lobed, the lower slightly the longer. Lateral-line—14 rows of scales between it and the base of the ventral fin: 25 rows before the base of the dorsal fin. 14 rows of scales between it and the base of the ventral in 20 rows before the base of the dorsal in. Colours—silvery, back grayish, and the Indian variety is partially banded in the young. Sometimes a dark streak from the shoulder to the base of the pectoral fin. The very young have a black band over the free portion of the tail.

The late Dr. Bleeker and Dr. Günther who have not seen this fish, have considered it the type of a genus (Smiliogaster), which is said to have the entire abdominal edge trenchant. Valenciennes expressly observes, "mais sans aucune dentelure comme celles des clupées"

mais sans aucune dentelure, comme celles des clupées." Habitat.—The Godavery river, and throughout Burma, but the specimens from the latter locality are darker in colour and want the vertical bands. It attains 15 inches and more in length.

B. iii, D. $11(\frac{3}{8})$, P. 15, V. 10, A. $16(\frac{3}{18})$, C. 20, L. l. 55, L. tr. 13/11.

Length of head 5 to 6, of caudal 4 to $4\frac{1}{4}$, height of body 3 to $3\frac{1}{4}$ in the total length. Eyes—diameter Length of head 3 to 0, of candar wo xx, height of body 5 to 54 in the work length. Byes—manteter 2\frac{2}{3} to 3\frac{1}{2} in length of head, 2/3 to 1 diameter from end of snout, 1\frac{1}{2} diameters apart. Dorsal profile rather more convex than that of the abdomen. Cleft of mouth extending to below the anterior edge of the orbit, lower more convex than that of the abdomen. Teeth—pharyngeal, curved, pointed, 5, 4, 2/2, 4, 5. Fins—dorsal commences is the convex that the base of the condel its essents for extending the converted. Destroy midway between the snout and the base of the caudal, its osseous ray strong, and coarsely serrated. Pectoral reaches to above the ventral. Caudal lobed in its last two-thirds. Lateral-line-9 or 10 rows of scales between it and the base of the ventral fin. Colours--purplish silvery along the back, becoming silvery-white from about four rows of scales above the lateral-line. The young sometimes have a dark spot at the base of the caudal fin, and 4 or 5 narrow black bands descending from the back to the middle of the side.

Habitat.—Deccan, the Kistna and Godavery rivers, attaining 6 inches or more in length.

Genus, 24-Barilius, Hamilton Buchanan.

Opsarius, sp. McClelland; Pachystomus, Heckel; Chedrus, Swains.; Shacra, Bleeker; Opsaridium, Peters; Pteropsarion and Bola (not H. B.) Günther.

Abdomen rounded. Pseudobranchiæ present. Mouth anterior, sometimes oblique, huving a moderate or deep Jaws compressed, the lower usually with a knob above the symphysis, and an emargination to receive it in the upper jaw. Suborbital ring of bones generally broad, more especially the third, which may even be entirely behind the vertical from the posterior margin of the orbit. Barbels four (Pachystomus, "Heckel," Bleeker), or two (Bendilisis, Bleeker), or none (Barilius, Ham. Buch.); occasionally very rudimentary ones are present. Pharyngeal teeth in two or three rows, hooked, 5, 3 or 4, 2 or 1/1 or 2, 4 or 3, 5; or else 5, 2 or 3, 4/4, 3 or 2, 5. Dorsal fin without osseous ray, of moderate length, inserted posteriorly to the ventrals, sometimes extending to above the anal, which latter is somewhat elongated. Scales of moderate or small size. Lateral-line concave, continued on to the middle or lower half of the caudal,* or incomplete, or absent. Gill-rakers very short, or even absent. The genera Barilius and Danio are somewhat difficult to diagnose apart, from descriptions alone: the

former however has the snout compressed, the mouth anterior, and usually spots or vertical bars on the body. In Danio the upper jaw is rather broad, the mouth directed obliquely upwards, the apex of the lower jaw being nearly or quite on a level with the dorsal profile: the body with longitudinal bands. Adult specimens of Barilius

have usually open pores or glands on the snout and jaws.

Geographical distribution.—Fresh waters of India, Ceylon, and Burma, extending to the Malay Archipelago; also found in the Nile and East Africa.

SYNOPSIS OF SPECIES.

A. With four barbels. (Pachystomus).

- 1. Barilius vagra, D. 9, A. 13-15, L. l. 42-44. With 10 vertical bars. Sind Hills, Himalayas, Ganges, Jumna and Brahmaputra.
- * Where this line terminates evidently cannot have very great signification, for I have observed it in B. gatensis on one side of an example going to the middle of the base of the caudal fin, and on the other side to its lower lobe.

 Barilius modestus, D. 9, A. 12-13, L. 1. 43. Back dark, sides silvery. Sind and Punjab.
 Barilius radiolatus, D. 9, A. 12, L. 1. 56-62. Silvery. Central India.
 Barilius shacra, D. 9, A. 10, L. 1. 60-70. Twelve vertical bars. Bengal, N.W. Provinces and Assam.
 Barilius bendelisis, D. 9, A. 9-10, L. 1. 40-43. Short vertical bars: each scale with a black spot in adults. From Western Ghauts throughout India (not Sind) to Assam.

B.—With two barbels. (Bendilisis).

6. Barilius barila, D. 9, A. 13-14, L. l. 43-46. With 14 or 15 vertical bars. Bengal, Orissa, and Lower Assam.

C.—Without or with only rudimentary barbels. (Barilius).

7. Barilius Bakeri, D. 13, A. 16-17, L. l. 38. A row of large spots. Travancore. 8. Barilius gatensis, D. 10-12, A. 15-17, L. l. 40. With 15 vertical bars. Western Ghauts and

9. Barilius Canarensis, D. 12-13, A. 14-16, L. 1. 38. Two rows of spots. Canara.
10. Barilius barna, D. 9, A. 13-14, L. 1. 39-42. Nine vertical bands. Orissa, Bengal, Assam.
11. Barilius guttatus, D. 9, A. 14, L. 1. 44-48. Two rows of spots. Burma.
12. Barilius tileo, D. 9, A. 13, L. 1. 70-75. Two rows of spots. Bengal and Assam.
13. Barilius Evezardi, D. 9, A. 14-15, L. 1. 40. Silvery. Poona.
14. Barilius bola, D. 10-11, A. 13, L. 1. 88-94. Two rows of blotches. Orissa, Bengal, Assam.

A.—With four barbels. (Pachystomus.)

B. iii, D. $9(\frac{2}{3})$, P. 16, V. 9, A. $13-15(\frac{2}{3}-\frac{3}{3})$, C. 19, L. l. 42-44, L. tr. 7-8/4, Vert. 16-23.

Length of head 5 to $5\frac{1}{2}$, of caudal 5, height of body 5 to 6 in the total length. Eyes—diameter $3\frac{1}{2}$ to 4 in length of head, 1 diameter from end of snout, and $1\frac{1}{4}$ apart. The posterior extremity of the maxilla extends to beneath the middle of the orbit; lower jaw slightly the longer. Third suborbital bone twice as deep as the uncovered portion of the cheek below it. Jaws of equal length anteriorly, the upper sometimes a little notched, the lower covered with large pores in the adult. Axillary process very short. Barbels—rostral nearly half as long as the head, maxillary pair very short. Teeth—pharyngeal, crooked, 5, 3, 2/2, 3, 5. Fins—dorsal higher than long, commencing midway between the posterior edge of the orbit and the root of the caudal, its last two rays being over the anal; pectoral not quite so long as the head: caudal deeply forked. Lateral-line—2 to $2\frac{1}{2}$ rows of scales between it and the base of the ventral fin: 20 rows before the base of the dorsal fin. Colours—silvery, 10 to 14 dark bands (sometimes indistinct) descend from the back to the lateral-line: fins yellowish, the edge of the caudal stained grayish.

Both Ham. Buch. and McClelland overlooked the barbels.

Habitat.—Sind hills, rivers in the Himalayas and Sub-Himalayan range, Jumna and Ganges, also the Punjab and Assam. It attains above five inches in length. Kelaart sent a Ceylon specimen to the E. I. Museum.

2. Barilius modestus, Plate CLI, fig. 3.

? Opsarius bicirrhatus, McClelland, Cal. Journ. Nat. Hist. ii, 1842, p. 582.

? Leuciscus bicirrhatus, Bleeker, Beng. p. 66. ? Barilius bicirrhatus, Günther, Catal. vii, p. 290.

Barilius modestus, Day, J. A. S. of Beng. 1872, p. 4.

B. iii, D. $9(\frac{2}{7})$, P. 15, V. 9, A. $12-13(\frac{2}{10^2-11})$, C. 19, L. l. 43, L. tr. $6/4\frac{1}{2}$.

Length of head $5\frac{1}{2}$, of caudal $5\frac{1}{2}$, height of body $5\frac{1}{4}$ in the total length. Eyes—diameter 4 in the length of the head and situated in its anterior half, 1 diameter from end of snout and also apart. Suborbital ring of bones wide, the third nearly touching the preopercular ridge. Upper jaw slightly the longer, and notched at its end in large examples. The posterior extremity of the maxilla reaches to below the middle of the orbit. Barbels—rostral extend to beneath the front margin of the eyes, the maxillary pair minute. Axillary process short. Fins—dorsal two-thirds as high as the body below it, commencing midway between the middle of the caudal lobes and the snout: it is entirely, or all but the last ray, in advance of the anal. Pectoral nearly as long as the head, but not reaching the ventrals, which last extend half way to the base of the anal. Lateral-line very slightly concave, two and a half rows of scales between it and the base of the ventral fin: 19 rows before the base of the dorsal fin. Colours—back brownish, strongly defined from the silvery sides: caudal edged with dark: the other fins yellow: a dark band along the dorsal.

Habitat.—The Indus in Sind, and the Ravi river at Lahore. It attains four or five inches in length.

3. Barilius radiolatus.

Günther, Catal. vii. p. 287.

B. iii, D. 10 $\binom{2}{8}$, P. 17, V. 9, A. $12(\frac{2}{10})$, C. 19, L. 1. 56-62, L. tr. 9-10/6.

Length of head $4\frac{1}{4}$ to $4\frac{1}{2}$, height of body $4\frac{1}{2}$ in the total length excluding the caudal fin. Eyes—diameter 3 in length of head, 3/4 to 1 diameter from end of snout, and rather more apart. The posterior extremity of the maxilla extends to a little behind the front edge of the orbit; lower jaw slightly projects when the mouth is closed. The third suborbital bone nearly reaches the preopercular ridge. Axillary process short. Barbels—Two short pairs. Fins.—the dorsal higher than long, commencing midway between the eye and the root of the caudal fin, its last ray not extending so far as to above the anal. Pectoral does not reach the ventral nor the latter the anal. Caudal apparently deeply forked. Lateral-line—2 rows of scales between it and the base of the ventral fin: 24 rows before the base of the dorsal fin. The specimens in the British Museum are in a very bad state, their tails having been almost destroyed.

Habitat. - Central India.

4. Barilius shacra, Plate CXLVIII, fig. 5.

B. iii, D. $9(\frac{2}{7})$, P. 15, V. 8, A. $10(\frac{2}{8})$, C. 19, L. 1. 60-70, L. tr. 10-11/9.

Length of head 5 to $5\frac{1}{4}$, of caudal $5\frac{1}{2}$, height of body 5 in the total length. Eyes—diameter $3\frac{1}{2}$ to 4 in the length of head, 1 diameter from end of snout, and also apart. Snout compressed, jaws of about equal length in front. The maxilla reaches to below the anterior margin of the orbit: third suborbital bone 2/3 as wide as the uncovered portion of the cheek below it. Barbels—the maxillary pair as long as the eye, the rostral slightly longer. Axillary process extends to rather behind the origin of the pectoral fin. Teeth—pharyngeal, 5, 3/3, 5, crooked. Fins—dorsal commences midway between the anterior margin of the orbit and the base of the caudal fin, its last ray is over the first of the anal. The six outer pectoral rays strong, more especially in the adult. Caudal deeply forked. Gill rakers—rudimentary. Lateral-line—goes to the centre of the base of the caudal fin, about 7 rows of scales between it and the base of the ventral fin: 25 before the dorsal fin. Colours—back olive, rest of the body pinkish silvery: about twelve incomplete bars go from the back downwards towards the lateral line, a dark bar along the upper third of the dorsal fin. The lower two-thirds of the vertical fins stained in some examples.

Habitat.—From Hurdwar down the valley of the Ganges, the N.W. Provinces and Assam. The species is said to attain 5 inches in length.

Chedrus cocsa, Stein. Stein. Ak. Wiss. Wien, 1867, lvi, p. 52.

Barilius bendelisis and cocsa, Günther, Catal. vii. p. 288.

Khoksa, Beng.; Pak-tah, Kun-nul, Dah-rah, Burreah and Puck-wah-ree, Punj.; Johra, Mahr.: Aguskitti Tam.

B. iii, D. $9(\frac{2}{7})$, P. 15, V. 9, A. $9-10(\frac{2-3}{7-8})$, C. 18, L. l. 40-43, L. tr. 7-8/5.

Length of head $4\frac{3}{3}$ to $5\frac{1}{4}$, of caudal 5 to $5\frac{1}{2}$, height of body $4\frac{1}{4}$ (to $5\frac{1}{4}$ in the young) in the total length. Eyes—diameter $4\frac{1}{4}$ to $4\frac{3}{3}$ in length of head, $1\frac{1}{2}$ diameters from end of snout, and $1\frac{1}{4}$ apart. The maxilla reaches to below the first third of the orbit. The third suborbital bone varies in depth from being equal, to twice as high as the uncovered portion of the cheek below it. Open pores on the snout and lower jaw in the adult or even in the young in examples from hilly districts, sometimes pores on preorbital. Axillary process broad, lancet-shaped and longer in some examples than in others. Barbels—four, generally short, the rostral pair occasionally

absent. Teeth-pharyngeal, 5, 4, 2/2, 4, 5. Fins-dorsal higher than its base is long, it commences nearer the base of the caudal fin than the snout, and does not extend to over the anal. Pectoral may or may not reach the ventral, its outer six rays are thickened and very stiff in some examples, especially males from the hills. Ventral in some does, in others does not reach the vent. Caudal forked, lower lobe usually slightly the longer. Lateral-line— $2\frac{1}{2}$ to $3\frac{1}{2}$ rows of scales between it and the base of the ventral fin: 20 rows before the base of the dorsal fin. Colours—silvery shot with purple: back of a slaty gray descending in bars towards the lateral-line, and most distinct in immature specimens. In adults these bars become indistinct and sometimes lost. Each scale in adults with a black spot at its base, and two on each forming the lateral-line, but no spots in the young. Fins whitish, tinged with orange. A gray margin to the dorsal and caudal, the lower lobe of which is sometimes stained black. Shoulder process black-edged.

This fish shows considerable alterations in colour and form as it gets older, whilst there are likewise

individual variations that deserve notice as such have been considered species.

Barilius bendelisis, fig. 7, is the young, with the bars well marked, the spots on the scales not yet developed, and in which the size of the third suborbital shows great variations in comparison with the extent of the uncovered portion of the cheek below it. The example figured was from Mysore, near where Buchanan

obtained his type.

Variety B. cocsa, fig. 8, shows rather a deep third suborbital bone, the eyes a little larger, the dorsal,

The size of the axillary process and the presence

pectoral and ventral not so developed as in the next variety. The size of the axillary process and the presence or absence of bars on the back are subject to individual variation. Some dissected at Simla were females.

Variety B. chedra, fig. 9, has the third suborbital less deep than in the preceding form, the dorsal, pectoral and ventral more developed, and the axillary process larger. The outer pectoral rays are very stiff.

The example figured, was a male from Simla.

The MSS. figure of Leuciscus rubripes, Jerdon, appears to be intended for this fish. The ova of this species is large, I found them breeding at Cuttack, in the month of November.

Habitat.—Assam and Himalayas through the continent of India as far as the Western ghauts, not recorded from the coast of Malabar or Canara nor from Sind. Found also in Ceylon from whence Dr. Kelaart brought some specimens to the museum of the East India Company. It attains at least six inches in length.

B.—With two barbels. (Bendilisis.)

Gilland and Caedra, Beng.: Persee, Hind.

B. iii, D. $9(\frac{2}{7})$, P. 13, V. 9, A. 13-14($\frac{2}{10^3-11}$), C. 19, L. l. 43-46, L. tr. 7/5.

Length of head 5 to 51, of caudal nearly 5, height of body 51 to 51 in the total length. Eyes—diameter The posterior extremity of the maxilla reaches to below the anterior third of the orbit. Third suborbital bone wide and nearly touching the preopercular ridge. Barbels—a small rostral pair. Teeth—pharyngeal, crooked, pointed, 5, 4, 3/3, 4, 5. Fins—dorsal commences metabolic margin of the orbit and the bare of the grade for a reliable condition. and the base of the caudal fin, and is almost entirely in advance of the anal. Pectoral nearly as long as the head but does not quite reach the ventral: lower caudal lobe the longer. Lateral-line— $1\frac{1}{2}$ to 2 rows between it and the base of the ventral fin: 18 rows before the dorsal fin. Colours-silvery, with 14 or 15 vertical blue bands in the middle third of the side of the fish.

In the example of B. barila, referred to in the B. M. Catal. the author has overlooked the barbels, which

though small are present.

Habitat.—Delhi, N. W. and Central Provinces, Bengal, Orissa, and Lower Assam. It grows to 4 inches in length.

C.—Without any or with only rudimentary barbels. (Barilius).

7. Barilius Bakeri, Plate CLI, fig. 2.

Day, Proc. Zool. Soc. 1865, p. 305, and Fish. Malabar, p. 218, pl. 18. Pteropsarion Bakeri, Günther, Catal. vii, p. 284.

B. iii, D. $13(\frac{3}{10})$, P. 15, V. 9, A. $16-17(\frac{2-3}{14})$, C. 17, L. 1. 38, L. tr. 9/4.

Length of head $4\frac{1}{4}$ to $4\frac{2}{3}$, of caudal $4\frac{1}{3}$, height of body $3\frac{1}{4}$ to $3\frac{3}{4}$ in the total length. Eyes—diameter 4 in length of head, 1 diameter from end of snout, $1\frac{1}{4}$ diameters apart. Mouth compressed, lower jaw the longer with a knob above the symphysis. The posterior extremity of the maxilla extends to nearly below the centre of the orbit. Suborbital ring of bones wide, the third almost entirely covering the cheek. Some pores exist along the margin of the lower lip, on the snout, and on the anterior edge of the preorbital. Barbels—absent. Teeth—pharyngeal, curved and pointed, 5, 4, 2/2, 4, 5. Fins—dorsal commences nearly midway between the front edge of the eye and the base of the caudal, extending to above the fourth anal ray: caudal forked, lower lobe slightly the longer. Lateral-line—2 rows of scales between it and the base of the ventral fin. Gill-rakers rudimentary. Colours—grayish, becoming white on the abdomen. A row of large bluish spots along the side. Dorsal, anal, and pectoral fins margined with white, and having dark gray

Caudal gray in the centre.

This species is very closely allied to B. Canarensis, of which it may be merely a local variety. forms the type of genus Pteropsarion, Günther, excluded from Barilius on account of its possessing more than 9 branched dorsal rays* and suborbitals entirely covering the cheeks (which they do not quite effect). As B. gatensis, with an equally broad suborbital ring, has 8 branched dorsal rays, I cannot consider such a subdivision of the genus as natural or desirable.

Habitat.—Hill ranges of Travancore, whence I received several specimens collected by the Rev. H.

Baker. It attains 6 inches in length.

8. Barilius gatensis, Plate CXLIX, fig. 2.

Barilius gatensis, Günther, Catal. vii, p. 291; Day, Proc. Zool. Soc. 1870, p. 373.
Choaree (at Coonoor) and Aart-candee (Bowany), Tam. "River carp."

B. iii, D. $10-12(\frac{2}{8}-\frac{3}{9})$, P. 15, V. 9, A. $15-17(\frac{3}{12}-\frac{3}{14})$ C. 18, L. l. 39-40, L. tr. 8/5.

Length of head $4\frac{1}{3}$ to $4\frac{1}{2}$, of caudal $5\frac{1}{2}$ to $6\frac{1}{2}$, height of body 4 to $4\frac{1}{3}$ in the total length. Eyes—diameter 3 to $4\frac{1}{2}$ in the length of head, 1 to $1\frac{1}{3}$ diameters from end of snout, $1\frac{1}{2}$ diameters apart. Mouth pointed, its cleft extending to below the centre of the orbit. The third suborbital bone is about three times as broad as the uncovered portion of the cheek below it. The anterior portion of the snout and the sides of the jaws covered with large glands: there are likewise some on the lower jaw. Barbels—two very minute pairs which appear to be sometimes wanting. Teeth—pharyngeal, crooked, pointed, 5, 3 or 4, 2/2, 4 or 3, 5. Fins—dorsal companyons midway between the end of the spect and the middle of the could fin extending to above the third commences midway between the end of the snout and the middle of the caudal fin, extending to above the third anal ray. Pectoral as long as the head excluding the snout, its outer ray stiff. Caudal moderately lobed, the lower very slightly the longer. Lateral-line—2½ rows of scales between it and the base of the ventral fin. Colours—silvery gray with about 15 vertical bars descending from the back, and which become more or less broken up in the adult. Dorsal and anal with dark bases and light margins. The females and young generally

have smooth scales, whereas most of the adult males have one or more rough spots on each.

Habitat.—Western Ghauts of Malabar and Neilgherry hills, up to about 5000 feet above the level of the sea. It attains at least 6 inches in length. The example figured (life-size) was from the Neilgherry hills.

9. Barilius Canarensis, Plate CXLIX, fig. 1.

Opsarius Canarensis and Malabaricus, Jerdon, M. J. L. and S. 1849, p. 329. Barilius Canarensis, Day, Proc. Zool. Soc. 1870, p. 374.

B. iii, D. $12-13(\frac{9}{10-11})$, P. 15, V. 9, A. $14-16(\frac{9}{12-14})$, C. 21, L. 1. 38, L. tr. 9/4.

Length of head $4\frac{1}{2}$ to $4\frac{3}{4}$, of caudal 5 to $5\frac{1}{2}$, height of body $3\frac{1}{2}$ to $3\frac{3}{3}$ in the total length. Eyes—diameter $3\frac{1}{2}$ in length of head, 1 diameter from end of snout and also apart. Suborbitals nearly cover the cheek. The posterior extremity of the maxilla reaches to below the anterior third of the orbit. Barbels—absent. Fins—the dorsal fin commences midway between the snout and the base of the caudal. -the dorsal fin commences midway between the snout and the base of the caudal. Lateral-line-21 rows of scales between it and the base of the ventral fin: 15 rows before the dorsal fin. Gill-rakers distinct. Coloursgreenish above, golden on the sides, a single or double row of large vertical green spots along the body. Fins gray, with broad white margins.

Opsarius Malabaricus, Jerdon, appears to be a variety of this species. I have received a very complete series from Canara, collected by H. S. Thomas, Esq., C. S., and I can find no difference, except in the dorsal fin being a little higher and a row of small blue spots (9-12) exists along the middle of the side, sometimes 2 rows

being present in the first third of the body.

Habitat.—Canara and Malabar on the Western coast; attaining 6 inches in length.

10. Barilius barna, Plate CXLVIII, fig. 1 (young), and 2 (adult).

Bahri, Ooriah: Balisundree and Oz-o-la, Assam.

B. iii, D. $9(\frac{2}{7})$, P. 15, V. 9, A. 13-14 $(\frac{3}{10^3-11})$, C. 19, L. 1. 39-42, L. tr. 8-9/6.

* Pteropsarion is said to have "dorsal fin elongate, with more than 9 branched rays;" and Barilius to have "dorsal fin short, with less than 9 branched rays"!

Length of head $4\frac{3}{4}$ to $5\frac{1}{4}$, of caudal 5, height of body $3\frac{1}{2}$ to 4 in the total length. Eyes—diameter $2\frac{1}{3}$ to $3\frac{1}{2}$ in the length of the head, 2/3 to 1 diameter from the end of snout, and $1\frac{1}{3}$ apart. Third suborbital bone thrice as deep as the uncovered portion of the cheek below it. The maxilla reaches to beneath the first third of the orbit: the adult has open pores on both jaws and snout. Axillary process reaches to above the base of the pectoral fin. Barbels—absent. Fins—dorsal varies considerably, commencing midway between the eye and the base of the caudal fin, it is elevated in some specimens but not in others, while the last ray may extend (especially in the young) almost to the base of the caudal fin. The pectoral reaches to above the ventral, and in the young has its outer rays thickened. The ventral does not extend to the anal in the young, its inner rays are very thick. Anal commences under the middle or end of the dorsal fin. Lateral-line-21 rows of scales between it and the base of the ventral fin: 16 rows before the base of the dorsal fin. Colours—of a dull green in the adult, with from 9 to 11 vertical dark bands on the body: dorsal and caudal fins edged with black. The young (B. papillatus) have the back gray, the sides silvery shot with gold, and from 7 to 9 narrow deep blue vertical bands. Fins yellow, the dorsal and caudal stained externally with black.

Habitat.—Assam, the Ganges and its branches, Bengal and Orissa. It attains 5 inches or more in

length. Fig. 1 shows how much more forward the anal is in the young than in the adult fig. 2.

11. Barilius guttatus, Plate CXLIX, fig. 3.

Opsarius guttatus, Day, Proc. Zool. Soc. 1869, p. 620. Nga-la-wah, Burm.

B. iii, D. $9(\frac{2}{7})$, P. 15, V. 9, A. $14(\frac{3}{11})$, C. 17, L. 1. 44-48, L. tr. 9/5.

Length of head $4\frac{1}{2}$ to $4\frac{2}{3}$, of caudal $4\frac{1}{2}$ to 5, height of body $5\frac{1}{2}$ to 6 in the total length. Eyes—diameter 4 to 5 in the length of the head, 1 to $1\frac{1}{4}$ diameters from the end of snout and apart. Cleft of mouth deep, extending nearly 1 diameter behind the orbit. Snout compressed: upper jaw the longer. A well-developed knob above symphysis of lower jaw. Suborbitals very broad, more especially the hindermost which is nearly behind the vertical from the posterior margin of the orbit, and almost covers the cheek. Barbels—a rudimentary rostral or maxillary pair may be present. Fins—dorsal commences midway between the posterior extremity of the orbit and the base of the caudal, being opposite the interspace between the ventral and anal fins. Caudal forked, lower lobe slightly the longer. Lateral-line—complete, 2 rows of scales between it and the ventral fin: 23 rows before the base of the dorsal fin. Colours—silvery shot with purple, one or two rows of blue spots. along the side. Lower caudal lobe orange, its upper lobe with a dark edging, and a dark band along the upper half of the lower lobe.

Habitat.—Irrawaddi from Prome to Mandalay; attaining at least 7 inches in length.

12. Barilius tileo, Plate CXLIX, fig. 5.

Cyprinus tileo, Ham. Buch. Fish. Ganges, pp. 276, 385; Cuv. and Val. xvi, p. 420; Gray and Hard. Ill. Ind. Zool. (from H. B.'s MSS.)

Opsarius maculatus and brachialis, McClell. Ind. Cyp. pp. 297, 417, 418, pl. 47, f. 4, and pl. 48, f. 6; Cuv. and Val. xvi, p. 471.

Leuciscus brachialis and tileo, Bleeker, Beng. pp. 60 and 68.

Barilius tileo, Steind. Sitz. Ak. Wiss. Wien, 1867, lvi, p. 61; Günther, Catal. vii, p. 287.

Tilei, Sel-len, Boolla and Sund-u-a-rie, Assam.

B. iii, D. $9(\frac{3}{7})$, P. 14, V. 9, A. $13(\frac{3}{10})$, C. 20, L. 1. 70-75, L. tr. 14/7.

B. iii, D. $9(\frac{2}{7})$, P. 14, V. 9, A. $13(\frac{3}{10})$, C. 20, L. 1. 70-75, L. tr. 14/7.

Length of head $4\frac{3}{4}$ to $5\frac{1}{4}$, of caudal $4\frac{3}{4}$, height of body $4\frac{2}{3}$ in the total length. Eyes—diameter 4 to $4\frac{1}{2}$ in the length of the head, 1 to $1\frac{1}{3}$ diameters from the end of of snout, and $1\frac{1}{2}$ apart. Abdominal profile more convex than the dorsal. Head compressed, snout pointed. Upper jaw slightly the longer when the mouth is closed: symphysial knob not developed. The posterior extremity of the maxilla reaches to beneath the middle of the eye. Suborbital ring of bones broad, the third being about equal to twice the extent of the uncovered portion of the cheek below it. The width of the opercle equals half the distance between the middle of the eye and hind end of the head. Axillary process well-developed, having a soft scaled prolongation. Barbels—very rudimentary or entirely absent. Fins—dorsal commences midway between the hind edge of the eye and the base of the caudal fin, the anal being behind the vertical from its last ray. Pectoral as long as the head excluding the snout. Caudal deeply forked, lower lobe the longer. Lateral-line— $3\frac{1}{2}$ to $4\frac{1}{2}$ rows of scales between it and the base of the ventral fin: 30 rows before the base of the dorsal fin. Colours—bluish along the back, becoming silvery on the sides and beneath: two or more rows of blue spots and blotches, having a vertical character, along the sides. Dorsal and caudal fins dark gray, with a light pinkish edge: the other fins yellowish. fins yellowish.

Habitat.—Bengal and Assam, attaining at least 5 inches in length.

13. Barilius Evezardi, Plate CXLVIII, fig. 6.

Day, Journ. Asiatic Soc. of Bengal, 1872, Pt. ii, p. 326.

B. iii, D. $9(\frac{2}{7})$, P. 13, V. 9, A. $14-15(\frac{2}{12-13})$, C. 19, L. l. 40, L. tr. 6-7/4.

Length of head $5\frac{1}{3}$, of caudal $5\frac{1}{3}$, height of body 5 to $5\frac{1}{3}$ in the total length. Eyes—diameter 3 in the 4 G

length of the head, 3/4 of a diameter from end of snout, and 1 apart. Snout compressed, lower jaw slightly the longer and with a well-developed knob at the symphysis: the maxilla reaches to below the front edge of the eye. Suborbital ring of bones rather wide, the third being more than twice as deep as the uncovered portion of the cheek below it. Barbels—absent. Teeth—pharyngeal, curved, pointed, 5, 3/3, 5. Fins—the dorsal commences about midway between the hind edge of the orbit and the posterior end of the caudal fin, its last half being above the anal. Pectoral as long as the head. Caudal forked, the upper lobe the longer. Lateral-line—2 rows of scales between it and the base of the ventral fin. Colours—silvery, of a brown tint along the back, and a lateral burnished silvery band. Dorsal, caudal, and anal fins orange, the first two edged with block with black.

The prominences on the jaw and general appearance of this fish with the absence of the usual vertical bars so common in Barilius, gives the species a great resemblance to Rasbora, from which however it may be at once distinguished by the number of rays in the anal fin; whilst its distinctly rounded (not cutting) abdomen shows it not to be a Chela.

Habitat.—Poona, up to 4½ inches in length. This species was originally received from Col. Evezard, after whom it is named.

14. Barilius bola, Plate CXLIX, fig. 4.

Cyprinus bola and goha, Ham. Buch. Fish. Ganges, pp. 274, 275; Gray and Hard. Ill. Ind. Zool. (from H. B.'s MSS.); Cuv. and Val. xvi, pp. 423, 424.

Opsarius gracilis and megastomus, McClell. Ind. Cyp. pp. 297, 298, 419, 420, pl. 47, f. 1, and pl. 48, f. 5. Cyprinus bola and goha, Cuv. and Val. xvi, pp. 423, 424; Bleeker, Beng. pp. 66, 68. Bola goha, Günther, Catal. vii, p. 293.

Opsarius goha, Day, Proc. Zool. Soc. 1869, p. 379. Bugguah, Ooriah.: Korang, Assam: Bola, Beng.: Buggarah, Hind.

B. iii, D. 10-11 $\binom{3}{7-8}$, P. 13, V. 9, A. 13 $\binom{3}{10}$, C. 19, L. l. 88-94, L. tr. 12-15/9-11.

Length of head $4\frac{1}{2}$ to $4\frac{2}{3}$, of caudal $5\frac{1}{2}$, height of body 5 to 6 in the total length. Eyes—before the middle of the length of the head, diameter $4\frac{1}{2}$ to 7 in the length of head, $1\frac{1}{3}$ to 2 diameters from end of snout, and apart. Head compressed, snout pointed, a well developed knob above symphysis of the lower jaw. Suborbital ring of bones wide, especially the third which is wider than the opercle, the width of which last equals one-third of the distance between the middle of the eye and the hind edge of the opercle. Mouth deeply cleft, the posterior extremity of the maxilla extending nearly one diameter of the orbit behind the posterior margin of the eye. Barbels—absent. Fins—dorsal fin 1/3 higher than long, it commences midway between the angle of the preopercle and the base of the caudal, its last ray being scarcely over the first of the anal. Caudal lobed, the lower lobe slightly the longer. Lateral-line $-4\frac{1}{2}$ to 5 rows of scales between it and the base of the ventral fin: 40 rows before the base of the dorsal fin. Colours—silvery with two or more vertical rows of bluish blotches along the sides, the upper being about twelve to twenty, and the lower intermediate; some spots also on the head. Lower half of the dorsal fin slightly gray. Caudal orange, stained with gray and black. Pectoral, ventral, and anal orange, the colours being somewhat similar to those of a trout: it often goes by that name amongst Europeans.

Habitat.—Orissa, Bengal, N. W. Provinces, Assam and Burma, attaining at least a foot in length: one killed in Assam by Mr. Hannay, is stated to have weighed 5lb. It is a very game fish, takes the fly well, and is one of those termed Rajah mas, or "chief of the fishes" in the Assam rivers.

Genus, 25 *- Danio, Ham. Buchanan.

Perilampus, sp., McClell.: Paradanio and Devario, Bleeker.

Body compressed, abdomen rounded. Pseudobranchiæ present. Cleft of mouth shallow, directed obliquely upwards, the end of the lower jaw usually forming a portion of the dorsal profile. Suborbitals broad. Barbels four, or two, or none. Pharyngeal teeth hooked, 5, 3, 2/2, 3, 5. Dorsal fin moderately elongated, its posterior rays being opposite the anal which is long. Scales of moderate size. Lateral-line concave, passing to the lower half of Gill-rakers short.

Geographical distribution .-- These prettily marked little fish are found throughout India, Burma, and Ceylon.

SYNOPSIS OF SPECIES.

1. Danio devario, D. 18-19, A. 18-19, L. l. 41-48. No barbels. Sind, Punjab, N. W. Provinces, central India, Deccan, Bengal, Orissa, and Assam.

* Genus, 25a-Tinca, Cuvier.

Tinca vulgaris, Cuvier, or the Tench, has been introduced into the waters of the Neilgherry hills and is thriving around Ootacamund.

- 2. Danio spinosus, D. 15-16, A. 19-20, L. l. 55-65. No barbels, or a short rostral pair. One or two spines on the margin of the orbit. Burma.
- 3. Danio Malabaricus, D. 12-15, A. 15-19, L. l. 35-37. Rostral barbels, sometimes rudimentary maxillary ones. South Malabar.
- 4. Danio equipinnatus, D. 12-14, A. 14-16, L. l. 32-31. Rostral and maxillary barbels. Himalayas, Assam, Tenasserim, the Deccan.
 - 5. Danio dangila, D. 11-13, A. 17-18. Two pairs of long barbels. Bengal, Behar, Darjeeling.
- 6. Danio chrysops, D. 13, A. 18. No barbels. Bengal.
 7. Danio Neilyherriensis, D. 12-14, A. 13-14, L. 1. 35-37. Rostral and sometimes maxillary barbels. Neilgherry Hills, Madras.
- 8. Danio rerio, D. 9, A. 15-16, L. l. 26-28. Long rostral and usually maxillary barbels. Blue bands. Bengal and Coromandel coast as low as Masulipatam.
- 9. Danio albolineatus, D. 9, A. 13-15, L. l. 31-33. Two pairs of long barbels. A scarlet horizontal band. Moulmein.
- 10. Danio nigrofasciatus, D. 9, A. 13, L. l. 30-32. A maxillary pair of barbels. Blue bands. Pegu and Moulmein.

1. Danio devario, Plate CL, fig. 4.

B. iii, D. 18-19 $(\frac{3}{15}, \frac{3}{16})$, P. 13, V. 8, A. 18-19 $(\frac{3}{15}, \frac{3}{16})$, C. 19, L. l. 41-48, L. tr. 11/5.

Length of head 5 to $5\frac{1}{4}$, of caudal 4, height of body $3\frac{1}{4}$ to $3\frac{1}{2}$ (or even 4) in the total length. Eyes—diameter 1/3 of length of head, 3/4 of a diameter from end of snout, $1\frac{1}{4}$ diameters apart. Posterior extremity of maxilla extends to beneath the anterior margin of the orbit; lower jaw the longer. Third suborbital bone broad. Barbels—absent. Fins—dorsal commences slightly anteriorly to the anal, and midway between the anterior margin of the orbit and the base of the caudal. Caudal lunated. Lateral-line—2½ rows of scales between it and the base of the ventral fin: 16 rows before the base of the dorsal fin. Colours—greenish superiorly, silvery white inferiorly. The anterior part of the body is reticulated in its centre by steel-blue lines, divided from one another by narrow vertical yellow bands. Three bluish lines, divided by yellow ones, are continued backwards to the caudal fin, where the two lower amalgamate, and passing upwards become lost on the superior half of the caudal fin.

Habitat.—Sind, Orissa, Bengal, N.W. Provinces, Deccan, Punjab and Assam, attaining 4 inches in length.

2. Danio spinosus, Plate CL, fig. 5.

Day, Proc. Zool. Soc. 1869, p. 621.

B. iii, D. 15-16($\frac{9-3}{13}$), P. 13, V. 7, A. 19-20($\frac{5}{16-17}$), C. 19, L. l. 55-65, L. tr. 12-14/4.

Length of head 5 to $5\frac{1}{4}$, of caudal 5, height of body 3 to $3\frac{1}{2}$ in the total length. Eyes—diameter 3 to 3½ in the length of head, 1 diameter from end of snout and also apart. Body strongly compressed: a slight concavity over the occiput. Lower jaw prominent. Third suborbital bone wide and touches the preopercular In adults there is a sharp spine directed forwards above the anterior superior margin of the orbit, and a second broader and blunter before the centre of the eye on the preorbital. In immature examples these spines are equally sharp. Barbels—a small rostral pair. Fins—the dorsal commences midway between the posterior extremity of the orbit and the base of the caudal, its first five or six rays are in advance of the anal. Pectoral as long as the head. Caudal lunate. Lateral-line— $3\frac{1}{2}$ rows of scales between it and the base of the ventral fin. Colours—silvery, with an ill-defined lateral band, and some vertical yellow lines in the anterior half of the body. Dorsal and anal grayish, with reddish margins anteriorly. In the immature there is a dark humeral spot, and a steel-blue lateral band goes to the centre of the caudal fin, which has a scarlet stripe along the last half of its centre. Some examples have a wide blue central band, and two narrow parallel ones superiorly, and the same number inferiorly, they are divided by yellow ground colour.

Habitat.—Burma; attaining at least 4 inches in length.

Length of head 5 to $5\frac{1}{2}$, of caudal 5 to $5\frac{1}{2}$, height of body $3\frac{1}{2}$ to 4 in the total length. Eyes—diameter 3 to $3\frac{1}{2}$ in the length of head, 1 diameter from end of snout, and $1\frac{1}{3}$ apart. Third suborbital bone nearly touches the preopercular ridge. Barbels—rostral half as long as the orbit, maxillary ones very short, in some specimens the latter are entirely absent. Fins—the dorsal arises midway between the base of the caudal fin and the posterior edge of the eye, its anterior half is in advance of the anal. Colours—back steel-blue, some irregular vertical yellow lines on the fore-part of the body, and three or four blue bands along the sides, the central ones coalescing so as to form a broad bluish band along the middle of the caudal fin.

Habitat.—Western coast of India and Ceylon; attaining 6 inches in length.

4. Danio æquipinnatus, Plate CL, fig. 6.

Perilampus aquipinnatus, McClelland, Ind. Cyp. p. 393, pl. 60, f. 1.

Leuciscus aquipinnatus, Blecker, Beng. p. 66. Leuciscus lineolatus, Blyth, J. A. S. of Bengal, 1858, p. 219. Perilampus affinis, Blyth, loc. cit. 1860, p. 163.

Danio lineolatus, Günther, Catal. vii, p. 283. Pteropsarion aquipinnatus, Günther, Catal. vii, p. 285.

B. iii, D. $12-14(\frac{2}{10-12})$, P. 17, V. 8, A. $14-16(\frac{2}{12-14})$, C. 19, L. 1. 32-34, L. tr. $6-7/3\frac{1}{2}$.

Length of head 5, of caudal 5 to $5\frac{1}{4}$, height of body 4 to $4\frac{1}{4}$ in the total length. Eyes—diameter 2/7 to 1/4 of length of head, 1 diameter from end of snout, and $1\frac{1}{4}$ apart. Third suborbital bone nearly touches the preopercular ridge. Cleft of mouth oblique and extending to under the anterior margin of the orbit, a bluntish knob at the symphysis. Barbels—rostral half as long as the orbit, the maxillary ones minute. Fins—the dorsal arises midway between the centre of the orbit and the base of the caudal fin, extending to over the anterior anal rays, it is 2/3 as high as the body. Pectoral as long as head without the snout, nearly reaching the ventral, which last does not extend as far as the anal. Caudal forked but not deeply so. Lateral-line— 12 rows of scales between it and the base of the ventral fin: 13 rows before the dorsal fin. Colours—yellowish white, a wide bluish band extends along the body from the eye to the centre of the base of the caudal fin, in its course are sometimes several round silvery spoken it is another narrow band (which occasionally joins the central one anteriorly); there are two other lighter bands above the central one. The intermediate ground colour is yellow. Fins yellowish. Dorsal and anal fins each with a broad bluish band along their outer half. In some specimens there is a dark mark behind the gill-opening.

Habitat.—Himalayas at Darjeeling and the whole of the Assam district as high as Suddya, the Naga and Garo hills, Tenasserim and the Deccan.

5. Danio dangila, Plate CL, fig. 3.

Cyprinus dangila, Ham. Buch. Fish. Ganges, pp. 321, 390; Cuv. and Val. xvi, p. 403. Perilampus reticulatus, McClell. Ind. Cyp. pp. 290, 397, pl. 45, fig. 1 (from H. B.'s MSS.)

Nuria dangila, Bleeker, Beng. p. 62. Danio dangila, Blecker, Atl. Ich. vol. i, p. 29; Günther, Catal. vii, p. 282.

B. iii, D. 11-13($\frac{3}{0}$, $\frac{3}{11}$), P. 12, V. 7, A. 17-18($\frac{3}{14}$, $\frac{3}{15}$), C. 20, L. 1. 38. L. tr. $7/4\frac{1}{2}$.

Length of head 5, of caudal 5, height of body $3\frac{1}{2}$ to 4 in the total length. Eyes—diameter 1/3 of length of head, 3/4 of a diameter from end of snout. Lower jaw the longer, with a knob at the symphysis. Mouth oblique. Barbels—rostral a little shorter than the head; maxillary pair slightly longer. Fins—the posterior dorsal rays are above the anterior ones of the anal. Caudal slightly emarginate. Scales— $2\frac{1}{2}$ rows between the lateral-line and base of the ventral fin: 18 rows before the dorsal fin. Colours—back clive colour, abdomen a lateral posterior by sides with several narrow blue lines, which in the anterior half or two-thirds of the body, form a lateral posterior is dealer and back the specimen from beautiful network; a dark spot behind gill covers. Anal fin with two or three blue stripes. A specimen from Darjeeling was deficient in ventral fins.

Habitat.—Bengal, Behar, Himalayas at Darjeeling, also the hills above Akyab; grows to 5 or 6 inches in length.

6. Danio chrysops.

Leuciscus chrysops, Cuv. and Val. xvii, p. 308; Bleeker, Beng. p. 66.

B. iii, D. $13(\frac{3}{10})$, P. 17, V. 8, A. $18(\frac{3}{10})$, C. 19, L. l. 45, L. tr. $8\frac{1}{2}/4$.

Length of head $4\frac{2}{3}$, of caudal $4\frac{2}{3}$, height of body 4 in the total length. Eyes—diameter $2\frac{2}{3}$ in length of head, 1/2 a diameter from end of snout, and 1 apart. Snout obtuse, upper jaw slightly the longer. Third suborbital bone nearly as wide as the uncovered portion of the check below it. Dorsal profile rather more

convex than that of the abdomen. Fins—the dorsal commences midway between the middle of the eye and base of the caudal fin, it is entirely in advance of the anal, and 2/3 as high as the body below it. Lateral-line —curves downwards in the pectoral region from whence it proceeds direct to the centre of the base of the caudal. Colours—silvery, the upper two-thirds of the body darker than the lower.

Habitat.—Bengal. The type specimen (nearly 4 inches long) is in a good state of preservation at

Paris.

7. Danio Neilgherriensis, Plate CL, fig. 2.

Paradanio Neilgherriensis, Day, Proc. Zool. Soc. 1867, p. 296. Danio neilgherriensis, Günther, Catal. vii, p. 283. Cowlie, Tamil.

B. iii, D. $12-14(\frac{3}{6-11})$, P. 15, V. 7, A. $13-14(\frac{3}{11}-\frac{3}{2})$, C. 19, L. l. 35-37, L. tr. 6-7/4, Vert. 12/20.

Length of head $4\frac{1}{2}$ to 5, of caudal $4\frac{1}{4}$ to 5, height of body 4 to $4\frac{1}{4}$ in the total length. Eyes—diameter 3 to $3\frac{1}{2}$ in the length of head, 2/3 of a diameter from end of snout, $1\frac{1}{4}$ diameters apart. Abdominal profile more convex than the dorsal one. The maxilla reaches to below the front edge of the eye. Lower jaw anterior, with a slight knob at its extremity. The third suborbital bone almost touches the preopercular ridge. Barbels—a short rostral pair, and sometimes rudimentary maxillary ones. Teeth—pharyngeal, crooked, pointed, 5, 4, 2/2, 4, 5. Fins—dorsal commences midway between the end of the snout and the base of the caudal fin, it extends to above the fourth or fifth anal ray. Caudal forked. Scales—15 rows before the base of the dorsal fin. Colours—back greenish, sides silvery, with a purplish tinge along the abdomen: a badly marked broad, steel-blue stripe, extends from behind the eye to the caudal fin, while it is bounded above and below by a narrow yellow edging. The young usually have light horizontal bands.

Habitat.—Rivers on the Neilgherry Hills, attaining 3½ inches in length.

8. Danio rerio, Plate CLI, fig. 4.

Cyprinus rerio and chapalio, Ham. Buch. Fish. Ganges, pp. 323, 324, 390; Cuv. and Val. xvi, pp. 406, 416

Perilampus striatus, McClell. Ind. Cyp. pp. 290, 397, pl. 46, f. 1 (from H. B.'s MSS.)

Nuria rerio, Bleeker, Beng. p. 62.

Barilius rerio, Gunther, Catal. vii, p. 292.

Danio lineatus, Day, Proc. Zool. Soc. 1868, p. 198, and 1869, p. 378. Poncha-geraldi. Ooriah.

B. iii, $9(\frac{2}{7})$, P. 13, V. 8, A. $15-16(\frac{2-3}{12-13})$, C. 19, L. l. 26-28, L. tr. 6.

Length of head 5 to $5\frac{1}{4}$, of caudal 4 to 5, height of body $4\frac{2}{3}$ to 5 in the total length. Eyes—diameter about 3 in length of head, 1/2 a diameter from end of snout, and 1 diameter apart. Lower jaw the longer. Barbels—rostral short, maxillary ones reaching the end of opercle. Teeth—pharyngeal, crooked, pointed, 5, 3, 1/1, 3, 5. Fins—dorsal commences opposite the anal, and is situated in the middle of the total length: dorsal and anal highest anteriorly: caudal deeply forked. Lateral-line—absent. Colours—four metallic blue lines along the sides (separated by three narrow silvery ones), and forming three bands on the caudal fin. Dorsal with a blue edging. Anal with three longitudinal blue bands.

Habitat.—Bengal and as low down the Coromandel coast as Masulipatam. It attains to about 2 inches

in length.

9. Danio albolineata, Plate CL, fig. 1.

Nuria albolineata, Blyth, J. A. S. of Bengal, 1860, p. 163. Danio Stoliczkæ, Day, Proc. Zool. Soc. 1869, p. 621.

B. iii, D. $9(\frac{2}{7})$, P. 13, V. 7, A. $13-15(\frac{2}{11-13})$, C. 19, L. 1. 31-33, L. tr. $5\frac{1}{2}/3$.

Length of head $4\frac{1}{2}$, of caudal $4\frac{1}{2}$ to 5, height of body from 4 to $4\frac{1}{2}$ in the total length. Eyes—diameter $2\frac{1}{2}$ to 3 in the length of head, 3/4 of a diameter from end of snout, and 1 apart. Body moderately compressed. Lower jaw anterior. Cleft of mouth very oblique, the maxilla extending to below the front edge of the orbit. Barbels.—maxillary reach beyond the base of the pectoral fin, rostral ones to the posterior margin of the orbit. Teeth—pharyngeal 5, 4, 2/2, 4, 5. Fins—dorsal commences slightly in advance of the anal, and rather nearer the base of the caudal than the snout. Caudal fin emarginate. Lateral-line—incomplete 1½ rows of scales between it and the base of the ventral fin: 16 rows before the base of the dorsal fine down. -greenish superiorly: a scarlet band with a dark lower edge, commences from below the base of the dorsal fin, it gradually widens, and is continued to the centre of the base of the caudal. Dorsal margined with red. Anal with a yellow stripe along its centre.

Habitat.—Moulmein in tanks and streams. It attains two inches in length.

10. Danio nigrofasciatus.

Barilius nigrofasciatus, Day, Proc. Zool. Soc. 1869, p. 620.

B. iii, D. $9(\frac{2}{7})$, P. 15, V. 7, A. $13(\frac{2}{11})$, C. 19, L. 1. 30-32, L. tr. 7.

Length of head 2/11, of caudal nearly 1/3, height of body 2/7 of the total length. Eyes—diameter nearly 1/2 of length of head, 1/4 of a diameter from end of snout, 1 diameter apart. Barbels—rostral absent; the maxillary pair extend to below the orbit. Fins—dorsal situated over the first portion of the anal, and midway between the posterior extremity of the orbit and the base of the caudal, which last is lunated. Lateral-line—absent. Colours—a dark bond resping along the side of the body and a good datted line below. Lateral-line—absent. Colours—a dark band passing along the side of the body, and a second dotted line below it. Dorsal and anal spotted with black in lines. In some specimens the body is intensely blue.

Habitat.—Pegu and Moulmein. Out of 20 specimens none exceeded 7/10 of an inch in length.

B.—A portion or the whole of the abdominal edge trenchant.

a. Dorsal fin opposite the anal, which latter is elongated (9 to 21 branched rays.)

Genus, 26—Perilampus, McClelland.

Chela, Swainson: Laubuca, Bleeker: Cachius and Eustira, Günther.

Pseudobranchiæ present. Body oblong, compressed, with a cutting abdominal edge. Mouth directed obliquely upward. Barbels absent. Pharyngeal teeth in three rows 5, 4 or 3, 2 or 1/1 or 2, 3 or 4, 5, uncinate. Dorsal fin rather short, without any osseous ray, and commencing opposite or behind the origin of the anal, which last has many rays. Outer ventral ray elongated. Scales of moderate size. Lateral-line concave, passing to the lower half of the base of the caudal fin.

Geographical distribution.—Fresh waters of India, Ceylon, and Burma.

SYNOPSIS OF SPECIES.

Perilampus atpar, D. 9, A. 22-24, L. l. 55-65. India generally, and Burma.
 Perilampus laubuca, D. 9, A. 19-23, L. l. 34-37. Ganjam, Orissa, Bengal, Assam and Burma.
 Perilampus Ceylonensis, D. 12, A. 17, L. l. 35. Ceylon.

11. Perilampus atpar, Plate CLI, fig. 6.

Cyprinus cachius and atpar, Ham. Buch. Fish. Ganges, pp. 258, 259, 384; Cuv. and Val. xvi, pp. 453, 454. Chela atpar, Gray and Hard. Ill. Ind. Zool.

Perilampus cachius and psilopteromus, McClell. Ind. Cyp. pp. 289, 396, pp. 289, 396, pl. 46, f. 6, and f. 4, (from H. B.'s MSS.)

Chela anastoma, Swainson, Fishes, ii, p. 285.

B. iii, D. $9(\frac{2}{7})$, P. 10, V. 5-6, A. $22-24(\frac{2-3}{18-2})$, L. l. 55-65, L. tr. 10-13/4.

Length of head $5\frac{1}{2}$ to 6, of caudal $4\frac{1}{2}$ to 5, height of body 4 to $4\frac{1}{4}$ in the total length. Eyes—diameter 3 to 4 in length of head, 3/4 of a diameter from end of snout, $1\frac{1}{2}$ diameters apart. Body strongly compressed, the abdominal edge being cutting. Cleft of mouth oblique, extending to nearly beneath the margin of orbit. Teeth—pharyngeal, 5, 4, 1/1, 4, 5, crooked, pointed. Fins—dorsal commences opposite the beginning of the second third of the anal. Pectoral elongate. Ventral with an elongated outer ray extending to the middle or even end of the anal fin. Caudal forked. Lateral-line—4 rows of scales between it and base of ventral fin. Colours silvery, with a burnished lateral band. Dorsal and caudal fins yellow.

Habitat.—Sind, throughout India and Burma; attaining 4 inches in length.

2. Perilampus laubuca, Plate CLI, fig. 5.

Cyprinus laubuca and ? dancena, Ham. Buch. Fish. Ganges, pp. 260, 342, 384, 393; Cuv. and Val. xvi, p. 456.

Laubuca guttata, Bleeker, Atl. Ich. Cyp. p. 33.

Perilampus laubuca, Day, Proc. Zool. Soc. 1869, pp. 380, 614.

Bankoe, Ooriah: Nga-me-loung, Burmese: Layubuka and Dankena, Beng.: Dannahrah, Hind.;

Moh-do-nee-konah and Her-bag-gi, Assam: Coon-che-li-e, N. W. Prov.

B. iii, D. $10-11(\frac{2}{8-9})$, P. 13, V. 7, A. $19-23(\frac{2}{17-21})$, C. 19, L. l. 34-37, L. tr. 6-7/5.

Length of head 5 to 6, of caudal 5, height of body $3\frac{1}{2}$ to $4\frac{1}{4}$ in the total length. Eyes --diameter 3 to $3\frac{1}{3}$ in the length of head, 3/4 to 1 diameter from end of snout, $1\frac{1}{4}$ diameters apart. Body strongly compressed with

the abdominal edge cutting from below the pectoral to the anal fin. Teeth—pharyngeal, 5, 4, 1/1, 4, 5. Fins—dorsal arises midway between the hind edge of the orbit and the posterior extremity of the caudal fin, and slightly behind the origin of the anal. Pectoral reaching anal. Caudal deeply forked. Lateral-line—curved downwards, 3½ rows of scales between it and the base of the ventral fin. Colours—silvery, with some golden vertical stripes during life. Fine dots over the body, and a black mark, shot with green, above the base of the pectoral fin, and another at the base of the caudal: the last third of the lobes of the caudal fin in some, especially Burmese specimens, are tipped with black. The black spot on the side of the tail is absent in some examples.

Habitat.—Ganjam, Orissa, Bengal, Central India, Assam and Burma; attaining at least 3½ inches in length.

The example figured was from Burma.

3. Perilampus Ceylonensis.

Eustira Ceylonensis, Günther, Catal. vii, p. 331.

B. iii, D. 12 $(\frac{2}{10})$, P. 17, V. 7, A. $17(\frac{2}{15})$, C. 19, L. 1. 35, L. tr. $7\frac{1}{2}/2$.

Length of head 4, of caudal 4, height of body 4 in the total length. Eyes—diameter 1/3 of length of head, 3/4 of a diameter from end of snout. Posterior extremity of maxilla extends to below the anterior margin of the orbit: lower jaw the longer. Fins—origin of dorsal opposite commencement of anal. Pectoral reaching the ventral. Colours—uniform silvery.

Habitat.—Ceylon. The specimens in the British Museum are nearly 2 inches in length.

Genus, 27—CHELA,* Ham. Buchanan.

Oxygaster, v. Hass.; Leuciscus, sp. Cuv. and Val.: Salmophasia, Swainson; Macrochirichthys and Paralaubuca, Bleeker.

Body rather elongate and compressed: abdominal edge cutting. Pseudobranchia present. Mouth directed somewhat upwards, with the lower jaw prominent, and generally with a knob above the symphysis. Barbels absent. Pharyngeal teeth hooked and slender, in two or three rows. Dorsal fin short, without any osseous ray, situated principally or entirely opposite the anal, which latter has an elongated base. Pectorals long. Caudal forked. Scales of moderate or small size. Lateral-line concave.

Dr. Günther suggests the following sub-genera:

a. The trenchant thoracic edge anterior to the pectoral supported by the dilated bones of the forearm.— OXYGASTER.

a. Pharyngeal teeth in three rows. Oxygaster. Macrochirichthys.

β. " " two " Macrochirichthys.

b. The thoracic edge not supported by the dilated bone of the forearm. Securicula.

Geographical distribution.—Sind, Continent of India, Burma, and extending to the Malay Archipelago.

Generally termed Vellache-candee in Tamil: Bay-ree-saie and Baarsee, Tel.: Bounce-putti, Ooriah: Took,

Punjab.

It appears that several individual variations occur amongst the species belonging to this genus, not only in the number of anal rays, but also in the number of scales, as well as in that of the rows between the dorsal fin and the lateral-line. Irrespective of this the comparative width of the suborbital ring of bones to that of the uncovered portion of the cheek is liable to vary in examples of the same species.

SYNOPSIS OF SPECIES.

A.—Bones of forearm support the edge of thorax, (Oxygaster).

1. Chela gora, D. 9-10, A. 15-16, L. l. 140-160, L. tr. 18-20/18. Sind, Continent of India except its southern portion.

B.—Bones of forearm do not support the edge of thorax, (Securicula).

2. Chela Sladoni, D. 10, A. 20-21, L. l. 65-68, L. tr. 10/8. Irrawaddi river.

* Descriptions have been published by Hamilton Buchanan and Sykes, of some small fishes belonging to this genus, also to Barilius. As I am unable to recognize them with certainty, I place them in this note:—

1. Cyprinus hoalius, Ham. Buch. "Fish. Ganges," pp. 336, 392; Cuv. and Val. xvi, p. 442. Leuciscus hoalius, Bleeker, Beng. p. 68. D. 9, V. 9, A. 10. Much compressed. Green above, silvery below. Northern Bengal to 5 inches in length.

2. Cyprinus borelio, Ham. Buch. 1. c. pp. 336, 392; Cuv. and Val. xvi, p. 443. Leuciscus borelio, Bleeker, Beng. p. 66. D. 9, V. 8, A. 11, C. 18. Long and compressed. Silvery above tinged with green: deep yellow below. Eyes silvery. Gangetic Provinces, to 4 inches. This may belong to genus Barilius, and be the young of B. bendelisis.

3. Cyprinus solio, H. Buch. 1. c.; Cuv. and Val. xvi, p. 444. Leuciscus solio, Bleeker, Beng. p. 68. D. 9, V. 8, A. 11. Only differs from last in colour of belly. Kosi river. This and the last are probably the same.

4. Chela jorah, Sykes, "Transactions, Zool. Soc." ii, p. 361. Leuciscus jorah, Bleeker, Beng. p. 68; Jerdon, Madras J. L. and Sc. 1849, p. 323. D. 10, P. 12, V. 8, A. 11, C. 18. Compressed fish. Back dark, with purplish shade, sides and abdomen silvery. Beema river, near Pairgaon in the Deccan.

5. Chela alkootee, Sykes, 1. c. p. 362. Leuciscus alkootee, Bleeker, Beng. p. 66; Jerdon, 1. c. p. 324. D. 10, P. 10, V. 7, A. 10. Sides slightly compressed, back and belly rounded (?); back straight. Scales very minute. Lateral-line quite straight (?). Silvery, with a black circle round the eye. Deccan, to 1 inch in length.

PHYSOSTOMI.

3. Chela sardinella, D. 9, A. 21, L. 1. 48, L. tr. $7\frac{1}{2}/4$. Burma.

- Chela sardinella, D. 9, A. 21, L. 1. 48, L. tr. 7½/4. Burma.
 Chela untrahi, D. 9, A. 17-19, L. 1. 55-65, L. tr. 8-9/5. Orissa, Madras.
 Chela argentea, D. 9-10, A. 17-19, L. 1. 43-45, L. tr. 6½-7/3. Southern India.
 Chela Punjabensis, D. 9, A. 16-17, L. 1. 90-110, L. tr. 12/9. Punjab and Sind.
 Chela phulo, D. 9, A. 19-20, L. 1. 80-90, L. tr. 12-15/6. Continent of India.
 Chela boopis, D. 9-10, A. 14-15, L. 1. 38-40, L. tr. 6-6½/3. South Canara.
 Chela description of the contral and the contral and

9. Chela clupeoides, D. 9, A. 13-15, L. l. 80-93, L. tr. 12-15/6. Cutch, Nerbudda river, Deccan, southern India and Burma.

10. Chela bacaila, D. 9, A. 13-15, L. l. 86-110, L. tr. 17-19/6. Sind, India (except portions of the Deccan, western coast and south of the Kistna) also Assam, and perhaps Burma.

A.—Bones of forearm support the edge of thorax (Oxygaster).

1. Chela gora, Plate CLI, fig. 8.

Cyprinus gora, Ham. Buch. Fish. Ganges, pp. 263, 384; Cuv. and Val. xvi, p. 458. Opsarius pholicephalus, McClell. Ind. Cyp. pp. 295, 415, pl. 47, fig. 2. Leuciscus ghora, Cuv. and Val. xvi, p. 458; Bleeker, Beng. p. 68. Chela gora, Günther, Catal. vii, p. 332; Day, Proc. Zool. Soc. 1869, p. 381. Hum-catchari, Ooriah.: Ghora chela, Beng.: Chel-hul, Hind.: Bounchi and Kundul, Punj.

B. iii, D. 9-10($\frac{2-3}{7}$), P. 15, V. 8, A. 15-16($\frac{2}{1\cdot 3-1\cdot 4}$), C. 19, L. 1. 140-160, L. tr. 18-20/18, Vert. 46.

Length of head 5 to $5\frac{1}{4}$, of caudal 6 to $6\frac{1}{2}$, height of body 6 in the total length. Eyes—diameter 1/5 of length of head, $1\frac{1}{4}$ diameters from end of snout, $1\frac{1}{4}$ diameters apart. The bones of the forearm support the thoracic edge, the keeled portion of the abdominal profile commences posterior to the ventral fin. Suborbital ring of bones broader than the diameter of the eye, but only covering two-thirds of the cheek. Teeth—pharyngeal, 5, 3, 1/1, 3, 5. Gill-rakers very short, 8 in the lower branch of the outer branchial arch. Fins dorsal commences slightly in advance of the anal, and in the last 1/3 of the distance between the hind edge of the preopercle and the base of the caudal fin. Pectoral 1/3 longer than the head. Scales—extend forwards on the head to above the nostrils. Colours—silvery.

Habitat.—Sind, Punjab, N. W. Provinces, Bengal, Orissa, and Assam. It attains at least 9 inches in

length.

B.—Bones of forearm do not support the edge of thorax (Securicula).

2. Chela Sladoni, Plate CLII, fig. 3.

Day, Proc. Zool. Soc. 1869, p. 622.

B. iii, D. $10(\frac{2}{8})$, P. 11, V. 8, A. $20-21(\frac{2}{16^{2}-19})$, C. 21, L. l. 65-68, L. tr. 10/8.

Length of head 6 to $6\frac{1}{4}$, of caudal 5, height of body 5 to $5\frac{1}{4}$ in the total length. Eyes—diameter $3\frac{1}{3}$ to $3\frac{1}{4}$ in the length of head, 3/4 of a diameter from end of snout. Posterior extremity of the maxilla reaches to beneath the anterior third of the orbit. Suborbital ring of bones is half as deep as the diameter of the orbit, and 2/3 wider than the uncovered portion of the cheek below it. Thoracic edge not supported by dilated bones of the forearm. The serrated abdominal margin commences opposite the base of the pectoral fin. Teeth—pharyngeal, crooked 5, 4, 2/2, 4, 5. Fins—dorsal commences opposite the anal. Pectoral as long as the head but does not reach the ventral: lower caudal lobe the longer. Colours—silvery, caudal black edged.

Habitat.—Irrawaddi in Burma, extending northwards as far as Mandalay.

3. Chela sardinella, Plate CLII, fig. 1.

Leuciscus sardinella, Cuv. and Val. xvii, p. 344. Chela sardinella, Günther, Catal. vii, p. 338. Nga-koon-nyat, Burm.

B. iii, D. $9(\frac{2}{7})$, P. 13, V. 8, A. $21(\frac{2}{10})$, L. l. 48, L. tr. $7\frac{1}{2}/4$.

Length of head 6, of caudal 6, height of body $5\frac{1}{2}$ to 6 in the total length. Eyes—diameter $3\frac{1}{2}$ to 4 in the length of head, 1 diameter from end of snout, nearly 1 diameter apart. The maxilla extends to below the front edge of the eye. The bones of the forearm are not dilated and do not support the thoracic edge which is smooth, the keeled portion commences opposite the pectoral fin. Suborbital ring of bones broad, but do not touch the preopercular ridge. Teeth—pharyngeal, 5, 4, 3/3, 4, 5. Fins—dorsal commences above or slightly behind the origin of the anal. The pectoral does not reach the ventral, nor the latter the anal. Caudal deeply forked, the lower lobe the longer. Colours-silvery.

Habitat.—Irrawaddi river at Rangoon, also the Salwein at Moulmein. It attains to at least 6 inches in length.

4. Chela untrahi, Plate CLI, fig. 7.

Day, Proc. Zool. Soc. 1869, p. 381. Untrahi, Ooriah.

B. iii, D. $9(\frac{2}{7})$, P. 13, V. 7, A. 17-19 $(\frac{2}{14},\frac{2}{17})$, C. 17, L. l. 55-65, L. tr. 7-9/5.

Length of head $5\frac{1}{2}$ to 6, of caudal 5 to $5\frac{1}{2}$, height of body $5\frac{1}{4}$ to 6 in the total length. Eyes—upper margin near the profile, diameter 3 to $3\frac{1}{4}$ in the length of head, 2/3 of a diameter from end of snout, nearly 1 diameter apart. Dorsal profile nearly horizontal: abdominal profile with a cutting edge from opposite the base of the pectoral fin. Mouth very oblique, knob on symphysis minute. Lower jaw in advance of the upper, the maxilla extending to below the anterior margin or first third of the orbit. Suborbital ring of bones wide, but they do not touch the preoperation of the degree smooth and not supported by dilated bones of forearm. Fins—pectorals 1/3 longer than the head, reaching ventrals. Dorsal arises midway between the pesterior margin of the orbit and the posterior extremity of the could fine anal commences below the middle posterior margin of the orbit and the posterior extremity of the caudal fin: anal commences below the middle of the dorsal fin. Caudal lobed, the lower lobe the longer. Scales—deciduous, extending forwards on the nape to opposite the middle of the orbit. Lateral-line—curves downwards, 1 row of scales between

it and base of ventral fin: 47 rows before the base of the dorsal fin. Colours—silvery.

At one time I thought this might be Pelecus flavipinnis, Jerdon, M. J. L. and Sc. 1849, p. 327, but his

MS. figure looks more like Chela clupeoides.

Habitat.—Mahanuddi river in Orissa, also the Cauvery and Coleroon in Southern India. It attains at least eight inches in length.

5. Chela argentea, Plate CLII, fig. 2.

Leuciscus acinaces, Cuv. and Val. xvii, pl. 509 (not descrip. p. 347). ? Pelecus diffusus, Jerdon, M. J. L. and S. 1849, p. 327. Chela argentea, Day, Proc. Zool. Soc. 1867, p. 301: Günther, Catal. vii, p. 334.

? Chela diffusa, Günther, Catal. vii, p. 334. Chaya-vellachee or Vellachee-cundee, Tam. "The white carp."

B. iii, D. 9-10($\frac{2-3}{7-8}$), P. 15, V. 8, A. 17-19($\frac{3}{1-4-1-6}$), C. 19, L. l. 43-45, L. tr. $6\frac{1}{2}$ -7/3.

Length of head $5\frac{1}{2}$ to $5\frac{2}{3}$, of caudal $5\frac{1}{2}$ to $5\frac{2}{3}$, height of body 5 to $5\frac{1}{2}$ in the total length. Eyes—diameter $3\frac{1}{2}$ in length of head, 1 diameter from end of snout and also apart. Cleft of mouth extending to below the anterior third of the orbit, a knob above symphysis of the lower jaw. Suborbital ring of bones broad and nearly covering the cheek, the third almost touching the preopercular ridge. The thoracic edge in front of the pectoral fins is not supported by the dilated bones of the forearm, and is without a sharp edge. Teeth—pharyngeal, curved, pointed, 5, 3, 2/2, 3, 5. Fins—dorsal situated in the posterior third of the distance between the snout and the base of the caudal fin, and over the commencement of the anal. Dorsal and anal highest anteriorly. Pectoral reaches the ventral Caudal deeply lobed. Lateral-line—descends countly for the highest anteriorly. Pectoral reaches the ventral. Caudal deeply lobed. Lateral-line—descends gently for the first twelve scales, finally attaining the centre of the candal: $1\frac{1}{2}$ rows of scales between it and the base of the ventral fin: 27 to 30 rows anterior to the dorsal fin. Free portion of tail 1/2 longer than high at its base. Colours—silvery, with a lateral band which fades after death: caudal dark edged, as is also occasionally the anal.

Dr. Jerdon gives about 50 scales in C. diffusa along the side, and observes that his species is found in the Cauvery and all its tributaries. I did not obtain it in the lower portions of the Cauvery, but C. argentea

was likewise absent, and I suspect the two are identical.

The specimen shown me at Paris as the type of Chela acinaces is the above species, and agrees with Cuv. and Val. figure, except in the number of the anal rays. The diameter of the eye is $3\frac{1}{4}$ in the length of the head (not $2\frac{1}{2}$ as stated in the text), whilst the anal fin has 16 not 13 rays. The description may perhaps refer to C. boopis, but that fish does not seem to be found in Mysore.

Habitat.—Bowany river at the base of the Neilgherries, Cauvery river and Mysore attaining 6 inches in

length.

6. Chela Punjabensis, Plate CLIII, fig. 2.

Day, Journ. As. Soc. of Bengal, pt. ii, 1872, p. 25. Took, Punj.

B. iii, D. $9(\frac{2}{7})$, P. 11, V. 6, A. $16-17(\frac{2-5}{14-15})$, C, 19, L. l. 90-110, L. tr. 12/9.

Length of head 6, of caudal 6, height of body $4\frac{1}{2}$ to 5 in the total length. Eyes—diameter $2\frac{1}{2}$ to $2\frac{2}{3}$ in length of head: 1/2 a diameter from end of snout. The posterior extremity of the maxilla extends to nearly beneath the anterior margin of the orbit. Lower jaw the longer. The suborbital ring of bones broad, and the third three times as deep as the uncovered portion of the check below it. Dorsal profile nearly horizontal: abdominal edge cutting from opposite the base of the pectoral fin. Edge of thorax not supported by dilated bones of the forearm. Fins—dorsal arises midway between the posterior margin of the opercle, and the posterior extremity of the lobes of the caudal. Pectoral longer than the head, but does not quite reach the base of the ventral, which last fin only extends half the distance to the anal: the latter commences opposite

the origin of the dorsal. Lower lobe of caudal the longer. Scales—moderately deciduous, they extend forwards to opposite the suborbital ring of bones: there is a slight elevation along the centre of each: 51 rows between the lateral-line and the base of the ventral fin. Colours—silvery, with a burnished silvery band along the side. Cheeks tinged with pink.

Habitat.—Lahore, in the Ravi river, also the Indus in Sind. It attains at least 21 inches in length.

7. Chela phulo, Plate CLIII, fig. 1.

Cyprinus phulo, Ham. Buch. Fish. Ganges, pp. 262, 384; Cuv. and Val. xvi, p. 457.

Opsarius albulus, McClelland, Ind. Cyp. pp. 296, 416, pl. 48, fig. 10. Chela Owenii, Sykes, Trans. Zool. Soc. 1841, p. 361, pl. 63, fig. 1. Leuciscus phula, Bleeker, Beng. p. 68.

Leuciscus Owenii, Bleeker, l. c.

Pelecus Owenii, Jerdon, M. J. L. and S. 1849, p. 328.

Chela phulo, Günther, Catal. vii, p. 334; Day, Proc. Zool. Soc. 1869, p. 381.

Phul chela, Beng.; Dunnahree, Hind.; Took and Bung-ka-charl, Punj.; Muk-ka, Sind.; Sel-konah, Assam.

B. iii, D. $9(\frac{2}{7})$, P. 13, V. 9, A. $18-19(\frac{2}{16-18})$, C. 19, L. l. 80-87, L. tr. 12-15/6.

Length of head $5\frac{1}{2}$, of pectoral 5, of caudal 5, height of body $4\frac{1}{2}$ to 5 in the total length. Eyes—diameter $3\frac{1}{2}$ in length of head, 1/2 a diameter from end of snout, 1 diameter apart. Abdominal profile cutting behind the base of the pectoral fin. Third suborbital bone nearly as deep as the uncovered portion of the cheek below it. The maxilla extends to under the front margin of the orbit. The thoracic edge is not supported by the dilated bones of the forearm. Fins—dorsal commences midway between the posterior extremity of the orbit and the posterior extremity of the caudal fin, and opposite the origin of the anal. Caudal deeply forked, lower lobe the longer. Lateral-line—curves gently downwards. Colours - silvery, with a bright silvery lateral band.

There is a variety in Upper Assam with more rows of scales along the lateral-line, 100-110, and rather a

more pointed head.

Habitat.—Assam, Bengal, Orissa, Central India and the Deccan as far southwards as the Tamboodra and Kistna rivers; attaining 5 inches or more in length.

Chela boopis, Plate CLII, fig 4.

? Leuciscus acinaces, Cuv. and Val. xvii, p. 347 (not pl. 509). Chela boopis, Day, Proc. Zool. Soc. 1873, p. 708.

B. iii, D. 9-10($\frac{2-3}{7}$), P. 15, V. 9, A. 14-15($\frac{2-3}{12-13}$), C. 21, L. l. 38-40, L. tr. 6-6 $\frac{1}{2}$ /3.

Length of head $5\frac{1}{4}$ to $5\frac{1}{2}$, of caudal $5\frac{1}{2}$, height of body 5 to $5\frac{1}{4}$ in the total length. Eyes—diameter $2\frac{1}{2}$ to 3 in the length of the head, 3/4 of a diameter from the end of snout and also apart. Cleft of the mouth extends to beneath the front edge of the orbit. Suborbital ring of bones almost covers the cheek. The dilated bones of the forearm do not support the thoracic edge, which is not sharp. Fins—dorsal commences slightly in advance of the anal, but extends to over it. Caudal deeply forked. Lateral-line—2 to $2\frac{1}{4}$ rows of scales between it and the base of the ventral fin: 22 to 24 rows before the dorsal fin. Colours—silvery, with a burnished lateral band: dorsal caudal, and anal edged with black.

This differs from C. argentea, in having fewer scales, a larger eye and less deeply cleft mouth.

Habitat.—South Canara and? Mysore; attaining at least 5 inches in length.

9. Chela clupeoides.

Cyprinus clupeoides, Bloch, xii, p. 49, t. 408, fig. 2. Clupea cyprinoides, Bloch, Schn. Syst. Ich. p. 427. Chela balookee and ? teckaree, Sykes, Trans. Zool. Soc. ii, p. 360, 362. Leviscus clupeoides and Dussumieri, Cuv. and Val. xvii, p. 342, pl. 508.

Leuciscus belookee and ? teekaree, Bleeker, Beng. p. 68.

Pelecus affinis, Jerdon, M. J. L. and S. 1849, p. 327.

? Perilampus teekanee, Jerdon, l. c. p. 326.

Chela clupcoides, Günther, Catal. vii, p. 333. Netteli. Tam.

B. iii, D. $9(\frac{2}{7})$, P. 13, V. 9, A. 13-15 $(\frac{2}{11-13})$, C. 19, L. 1. 80-93, L. tr. 12-15/6.

Length of head $5\frac{1}{2}$ to $5\frac{3}{4}$, of caudal $5\frac{1}{2}$ to $6\frac{1}{4}$, height of body $5\frac{1}{2}$ * in the total length. Eyes—diameter 4 in the length of head, 1 diameter from end of snout, 3/4 of a diameter apart. A well developed knob on symphysis: suborbital ring of bones wide, the third 4/5 as deep as the uncovered portion of the cheek below it. Thorax, which has a smooth edge, is not supported by any dilated bones of the forearm. Teeth—pharyngeal, 5, 4, 2/2, 4, 5. Fins—dorsal situated in the posterior 2/5 of the body, and 1/2 in advance of the

* In some badly nourished examples I have seen the height of the body only equal to 71 in the total length. Such are common at Madras in the dirty Coon river.

anal. Pectoral 1/4 longer than the head, but does not reach the ventral. Caudal lobed, the lower lobe the longer. Scales—deciduous and placed in sinuous rows: those on upper surface of the head extend forwards to opposite the hind edge of the orbit. Lateral-line—2 rows of scales between it and the base of the

ventral fin. Colours—silvery.

This species or variety is closely allied to C. bacaila, from which it is chiefly divided by the number of scales. In Cutch I found A. $(\frac{2}{11^2-13})$, L. l. 83-92, L. tr. 13-14/6: at Jubbulpore on the Nerbudda, A. $(\frac{2}{12^2-13})$, L. l. 80-90, L. tr. 14-15/6: in the Deccan, A. $(\frac{2}{13^2-15})$, L. l. 84-93, L. tr. 13/6: at Madras, A. $(\frac{2}{11^2-13})$, L. l. 80-87, L. tr. 12-15/6: to the South of Madras at the Cauvery river, A. $(\frac{2}{12^2-13})$, L. l. 80-91. L. tr. 14-15/6.

See remarks under next species, C. bacaila.

Leuciscus novacula, Val. in Jacq. Voy. Ind. Orient. pl. xv, f. 2; Cuv. and Val. xvii, p. 345; Bleeker, Beng. p. 69, and Chela novacula, Günther, Catal. vii, p. 334, appears to be this species. The type specimen has L. 1. 80 (not 60, as given in Cuv. and Val.)

Habitat. - Cutch, Jubbulpore, Mysore, the Deccan, Madras Presidency, and Burma. It attains at least 6 inches in length, and is very good eating.

10. Chela bacaila, Plate CLII, fig. 5.

Cyprinus bacaila, Ham. Buch. Fish. Ganges, pp. 265, 384, pl. 8, fig. 76; Cuv. and Val. xvi, p. 460. Opsarius bacaila and leucerus, McClell. Ind. Cyp. pp. 295, 414, 415, pl. 47, fig. 3; Cuv. and Val. xvi, p. 470.

Leuciscus cultellus and bacaila, Cuv. and Val. xvii, p. 341, pl. 507; Bleeker, Beng. pp. 66, 137.

Salmophasia oblonga, Swainson, Fishes, ii, p. 284. Pelecus cultellus, Jerdon, M. J. L. and S. 1849, p. 326.

Chela bacaila, Günther, Catal. vii, p. 332; Day, Proc. Zool. Soc. 1869, p. 382.

Jellahri, Ooriah: Chelliah, Hind.

B. iii, D. $9(\frac{9}{7})$, P. 13, V. 9, A. $13-15(\frac{9}{11-13})$, C. 19, L. l. 86-110, L. tr. 17-19/6-10.

Length of head $5\frac{1}{4}$ to 6, of caudal $5\frac{1}{4}$, height of body $5\frac{1}{2}$ to 6 in the total length. Eyes— $3\frac{1}{2}$ to $3\frac{3}{4}$ in length of head, snout slightly longer than the eye: eyes I diameter apart. Bones of the forearm not dilated, and not supporting the abdominal edge anterior to the pectoral fin. Cleft of mouth reaches to below the first fourth of the eye. Suborbital ring of bones broad, nearly covering the cheek. Teeth—pharyngeal 5, 4, or 3, 2/2, 3, or 4, 5. Fins—first anal ray is below the middle of the dorsal fin: pectoral nearly reaches the ventral, whilst the latter does not quite extend to the anal. Scales—extend forwards on the head to nearly opposite the posterior margin of the orbit. Colours—uniform silvery.

Under C. clupeoides, I observed that, excluding the Nerbudda river and Cutch, it is a southern form, but is also found in Burma. This species or variety is restricted more to the Valley of the Ganges and its affluent streams, also to the Punjab and down the Indus. It is distinguished by the large number of its scales, which I have found as follows: Assam, A. $\frac{1}{13}$, L. l. 102-108, L. tr. 18/6; Sone river, A. $\frac{2}{13}$, L. l. 98, L. tr. 18/6: Orissa, A. $\frac{2}{13}$, L. 86-98, L. tr. 14-18/6 (some of these appeared to be intermediate forms between this species and the last); Calcutta, A. $\frac{1}{12}$, L. l. 90-110, L. tr. 17-19/6; Scharunpore, A. $\frac{2}{13}$, L. l. 95-100, L. tr. 18-19/6: Sind, A. $\frac{2}{13}$, L. l. 92-96, L. tr. 17-19/6. One specimen from Bezwarah had A. $\frac{2}{13}$, L. l. 95, L. tr. 12/6.

Habitat.—Throughout India except Malabar, Mysore, and Madras, and parts of the Deccan. Dr. Günther gives Moulmein as one of its localities. It attains at least 7 inches in length.

FAMILY, V-CYPRINIDE.*

SYNOPSIS OF GENERA.

Sub-Family, I-Cyprinina.

Air vessel when present, not enclosed in bone.

A.—Abdomen rounded not trenchant.

- a. Dorsal fin commencing nearly opposite the ventrals. Anal short (5 to 7 branched rays).
- 1. Homaloptera. Anterior portion of body depressed: snout spatulate: mouth on lower surface of head: 6 barbels. Pharyngeal teeth in one row. Outer pectoral rays unbranched, or simply bifurcated. Scales small. Himalayas and Western ghauts in India, Java and Sumatra, p. 525.

 2. Psilorhynchus. Anterior portion of body somewhat depressed: snout rather spatulate. Mouth inferior: no barbels. Outer pectoral rays unbranched. Scales of moderate size. Hill streams and rivers in

Bengal and Assam, p. 526.

- 3. Discognathus. Mouth inferior, with a suctorial disk on the chin: 4 barbels. Pharyngeal teeth in 3 Scales of moderate size. Pectoral fins sub-horizontal. India, Ceylon, and Burma, also Aden and Abyssinia, p. 527.
- * As part iii. of this work, ending p. 552, was published in 1877, a synopsis of the CYPRINIDE had to be deferred until the present number: otherwise it would have been inserted at p. 524, immediately after the definition of the Family.

4. Oreinus. Mouth inferior, with the mandibles loosely joined together: a suctorial disk on the chin: 4 barbels. Pharyngeal teeth in 3 rows. Scales small, with the vent and base of anal fin enclosed by a tiled row. Last undivided dorsal ray osseous and may be serrated. Himalayan and sub-Himalayan range, extending to the confines of China, p. 529.

5. Schizopygopsis. Mouth inferior: mandibles with a sharp horny covering. No barbels. Pharyngeal teeth in two rows. A serrated dorsal ray. Scales present in scapular region, a tiled row enclosing vent and base of anal fin. Tibet and Turkestan, p. 531.
6. Schizothorax. Mouth antero-inferior: four barbels. Pharyngeal teeth in three rows. A serrated

dorsal ray. Scales small: vent and base of anal fin enclosed in a tiled row. Himalayan region, Afghanistan and Turkestan, p. 531.

7. Ptycobarbus. Mouth anterior or inferior: two barbels. Pharyngeal teeth in two rows. Dorsal with

or without a feeble osseous ray, which is sometimes serrated. Scales small: vent and base of anal fin enclosed in a tiled row. Head waters of Indus, Tibet and Kashgar, p. 533.

8. Diptychus. Mouth inferior: lower jaw with a horny covering: two barbels. Pharyngeal teeth in two rows. Dorsal fin without any osseous ray. Scales small, not imbricated: a sheath to vent and base of anal

Tibet, Nepaul, and Yarkand, p. 534.

9. Labeo. Mouth anterior or inferior: lips thick, those of the two jaws continuous at the angle, and one or both with an inner fold: sometimes a lateral lobe to the snout: barbels, four, two, or none. Pharyngeal teeth in three rows. Dorsal fin rather or very elongated and without any osseous ray. Scales large, of moderate size, or small. Africa, Syria, India, Ceylon, and Burma to the Malay Archipelago, p. 534.

10. Osteochilus. Differs from Labeo in its lips being reflected from off the mandible leaving it uncovered

as a sharp, hard, transverse prominence. Burma and the Malay Archipelago, p. 545.

11. Dangila. Snout somewhat depressed: mouth more or less inferior: upper lip fringed: lower jaw sharp, covered by a thin lip, and with a tubercle above the symphysis: barbels four or two. Pharyngeal teeth Dorsal fin clongated and without any osseous ray. Scales large, of moderate size, or small. in three rows.

Burma to the Malay Archipelago, p. 546.
12. Cirrhina. Mouth transverse: snout somewhat depressed: lips thin, those of the two jaws not continuous, a small tubercle above the symphysis of the lower jaw. Barbels four, two, or none. Pharyngeal teeth in three rows. Dorsal fin short or of moderate length, without any osseous ray. Scales large, of Scales large, of

moderate size, or small. Beloochistan, Sind, India, Burma, and Malay Archipelago, p. 547.

13. Semiplotus. Snont thick: mouth inferior, with a knob at the symphysis: no barbels. Pharyngeal teeth in three rows. Dorsal fin long, with a strong osseous ray that is serrated or entire. Scales large. Assam,

Chittagong hills, and Burma, p. 549.

14. Scaphiodon. Snout rounded: mouth transverse, inferior: a horny layer inside lower jaw which is not covered by lip: four, two, or no barbels. Pharyngeal teeth in three rows. Dorsal fin of moderate extent, with its last undivided ray articulated, or else osseous and scrrated, or entire. Scales of varying size. Western Asia, Sind, Western ghauts of India, p. 550.

15. Carassius. Mouth anterior: lips thin: no barbels. Pharyngeal teeth in one row. Dorsal fin long, with an osseous serrated ray. Scales of moderate size. Temperate portions of Europe and Asia, ? India,

p. 552.

16. Catla. Head broad: snout with thin integuments: lower lip with a continuous transverse fold: lower jaw with a moveable articulation at the symphysis: gill-rakers long: no barbels. Pharyngeal teeth in three rows. Dorsal rather long, without any osseous ray. Scales of moderate size. Sind, India (except its southern portion) Assam, Burma, and Siam, p. 553.

17. Thynnichthys. Upper lip absent: mouth antero-lateral: no barbels. Pharyngeal teeth molariform,

compressed, and in 3 rows. Dorsal fin without any osseous ray and inserted opposite the ventral. Scales small,

lateral-line complete. Deccan, Kistna and Godavery rivers, also the Malay Archipelago, p. 554.

18. Amblypharyngodon. Differs from Thynnichthys in having the crowns of its pharyngeal teeth flat or concave: the dorsal fin extending to nearly or quite above the anal: and the lateral-line incomplete. Sind,

India, Ceylon, and Burma, p. 554.

- 19. Barbus. Mouth anterior or inferior: jaws closely invested by lips, which may or may not have leathery lobes: four, two, or no barbels. Pharyngeal teeth in three rows. Dorsal fin short, with its last undivided ray articulated or osseous, which last may be serrated or entire. Scales of large, moderate, or small size. Lateral-line complete or incomplete. Europe, Asia and Africa, p. 556.
 - b. Dorsal fin commencing very distinctly posterior to the ventrals, but not extending to above the anal, which last is short or of moderate length (5 to 11 branched rays).

20. Nuria. Mouth narrow, directed obliquely upwards: four barbels, the maxillary pair very long. Pharyngeal teeth in one row. Dorsal fin without osseous ray. Scales of moderate size. India, Ceylon, Burma

and Nicobar islands, p. 582.

21. Rasbora. Mouth oblique, lower jaw with one central and on either side a lateral prominence fitting into corresponding emarginations in the upper jaw: a pair of rostral barbels or none. Pharyngeal teeth in three rows. Dorsal fin without any osseous ray. Scales large or of moderate size. Africa, India, Ceylon, Assam, Burma, to the Malay Archipelago, p. 583.

- 22. Aspidoparia. Mouth small, inferior: lower jaw with a sharp crescentic edge but no lip: no barbels. Pharyngeal teeth in two or three rows. Dorsal fin without osseous ray. Scales of moderate size. Sind, India (except southern portion and Malabar Coast) Assam and Burma, p. 585.
 - Dorsal fin commencing above the interspace between the ventral and the anal, generally extending to over the latter, which is of moderate length or elongated (7 to 33 branched rays).

23. Rohtee. Mouth anterior: lips thin. Barbels present or absent. Pharyngeal teeth in three rows. Dorsal fin with an osseous serrated ray: anal clongated. Scales small. Sind, India, and Burma, p. 586.

- 24. Barilius. Mouth anterior or oblique, with a deep cleft: jaws compressed: four, two, or no barbels. Pharyngeal teeth in two or three rows. Dorsal fin without osseous ray. Scales of moderate or small size. Lateral-line concave. Nile, East Africa, and fresh waters of India, Ceylon, and Burma to the Malay Archipelago.
- 25. Danio. Mouth directed obliquely upwards: cleft shallow: mandibles rather broad: four, two, or no barbels. Pharyngeal teeth in three rows. Dorsal fin without osseous ray and extending to above a long anal. Scales of moderate size. Lateral-line concave. Continent of India and Burma, p. 594.

B.-A portion or the whole of the abdominal edge trenchant.

26. Perilampus. Mouth directed obliquely upwards: no barbels. Pharyngeal teeth in three rows. Dorsal fin without osseous ray, inserted over the anterior anal rays. Scales of moderate size. Lateral-line concave. India and Burma, p. 598.

27. Chela. Mouth directed upwards with a knob above the symphysis of the lower jaw: no barbels. Pharyngeal teeth in two or three rows. Dorsal fin without osseous ray, a portion or the whole of it situated above the anal: pectorals long. Scales of moderate or small size. Lateral-line concave. India and Burma to the Malay Archipelago, p. 599.

B. Sub-Family, II-Cobitidina.

Pseudobranchiæ absent. Body elongated, oblong, compressed or cylindrical, but never depressed. Snout and lips fleshy. Mouth small, inferior, and furnished with from six to twelve barbels. Pharyngeal teeth few and in one row. Vertical fins spineless. Dorsal fin with a varying number of rays (8-30); anal with few (7.8); ventrals present or absent. Scales small and cycloid when present, and usually immersed in mucus: rarely present on the head. Lateral-line single. Air-vessel entirely, or partially, enclosed in a bony capsule.

Geographical distribution.—Loaches are found in tanks and rivers throughout the hills and plains of India and Burma, but apparently are absent from the Andaman islands. These fish are mostly captured by baling out tanks commencing to dry up, but as they move about in the mud, they are usually difficult to capture.

Uses.—They are all good for food.

SYNOPSIS OF GENERA.

A.—With an erectile spine near the orbit.

1. Botia. Six to eight barbels, four rostral, two maxillary, and sometimes two mandibular. Spine suborbital. No scales on head. Dorsal fin (10 to 15 rays) commencing somewhat before the origin of the ventral: caudal forked. Air-bladder in two portions, the anterior being partially enclosed in bone. Sind, Valley of Ganges, Himalayas, Assam, Burma to the Malay Archipelago, p. 606.

2. Acanthopsis. Eight barbels, two being mandibular. Spine before the orbit. Dorsal fin (12 rays) opposite the ventrals: caudal forked. No scales on head. Burma to the Malay Archipelago, p. 608.

3. Somileptes. Six barbels, none on mandibles. Eyes prominent. Spine suborbital. Dorsal fin (10 rays) commences slightly behind the ventrals: caudal entire. No scales on the head. Himalayas, Khasia hills, and Assam p. 608.

hills, and Assam, p. 608.

4. Lepidocephalichthys. Eight or more barbels, four rostral, two maxillary, the rest mandibular. Spine suborbital. Dorsal fin short, commences nearly opposite the ventrals: caudal entire or slightly emarginate. Scales on the head. Continent of India, Ceylon, Assam, Burma to the Malay Archipelago, p. 609.

5. Acanthophthalmus. Six barbels, one rostral, and two maxillary pairs. Spine suborbital. Dorsal fin short, in the last third of the body, but anterior to the anal: ventrals present. N. E. India, Assam, and upper Burma, p. 610. 6. Apua.

6. Apua. Eight barbels, one rostral, two maxillary and one mandibular pairs. Spine suborbita Dorsal fin short (8 rays) in the last third of the body, but anterior to the anal: no ventrals. Burma, p. 611. Spine suborbital.

7. Jerdonia. Eight barbels, two being mandibular. Spine suborbital. Dorsal fin long (30 rays) commencing anterior to the ventral. Madras, p. 611.

B.—Without an erectile spine near the orbit.

8. Nemachilichthys. Six barbels, two rostral, and one maxillary pairs. Snout elongated. Eyes elevated. Dorsal fin of moderate length (13 rays) above the ventrals: caudal forked. Deccan, p. 611.

9. Nemachellus. Six barbels, two rostral and one maxillary pairs. Dorsal of moderate length or short (8 to 17 rays) commencing opposite the ventrals. Sind, India, Ceylon, Assam, Burma, and the Malay Archipelago, p. 612.

PHYSOSTOMI.

A. - With an erectile spine near the orbit.

Genus, 1—Botia, Gray.

Hymenophysa and Schistura, McClelland: Diacanthus, Swainson: Syncrossus, Blyth.

Body oblong, compressed, with the dorsal profile more or less elevated. Eye with a free circular eyelid. Barbels six to eight: four on the snout united at their bases, two on the upper jaw, if eight the extra ones are on the mandibles. A biful, erectile, suborbital spine present. Dorsal fin commences anterior to the root of the ventral; caudal forked. No scales on the head. Air-bladder in two divisions, the anterior being partially enclosed in a bony capsule,

whilst the posterior portion is free in the abdominal cavity.

Hamilton Buchanan observes of the Loaches, "those which are striped are more beautiful fishes (than those with cloud-like marks) resembling the appearance of the others but slightly, and differing a good deal in

habits, especially in swimming higher and in not remaining so stationary at the bottom," p. 349.

Geographical distribution.—Found throughout the Valley of the Ganges, the Sind hills, the Himalayas, Assam, Burma to the Malay Archipelago.

SYNOPSIS OF SPECIES.

- Botia nebulosa. D. 15, A. 7. Barbels six. Darjeeling.
 Botia dario. D. 12-13, A. 7-8. Barbels eight. Bengal, N. W. Provinces, Assam and Cachar.
 Botia geto. D. 13, A. 7. Barbels eight. Sind, Punjab, Himalayas, Valley of Ganges and Assam.
- Botia Almorhæ. D. 11-12, A. 7-8. Barbels eight. Himalayas and Khasia hills.
 Botia Berdmorei. D. 13-15, A. 7. Barbels eight. Burma and Tenasserim.
 Botia histrionica. D. 10, A. 7. Barbels eight. Pegu.

1. Botia nebulosa.

Blyth, Proc. A. S. of Beng. 1860, p. 165; Day, Proc. Zool. Soc. 1869, p. 550.

B. iii, D. $15(\frac{3}{12})$, P. 13, V. 8, A. $7(\frac{2}{5})$, C. 17.

Length of head 5, of caudal 5, height of body 5 in the total length. Eyes—in the middle of the length of head: 2 diameters from end of snout and also apart. Profile of back slightly elevated. A bifid erectile spine below the orbit.* Barbels—two rostral pairs extending as far as to the anterior margin of the orbit, whilst the maxillary ones are slightly longer. Fins—dorsal commences midway between the base of the caudal and the snout, and opposite the end of the pectoral. Ventral commences under the sixth dorsal ray. Caudal lobes slightly rounded. Scales—small, 13 rows between the lateral line and the base of the ventral fin. Colours—brownish, with a leaden band along the side. Dorsal and caudal barred in spots. An ocellus at the upper margin of the base of the caudal fin.

Habitat.—Darjeeling, from whence Dr. Wallich sent an example, 4½ inches long, to the Calcutta

Museum.

2. Botia dario, Plate CLIV, fig. 1.

Cobitis dario, Ham. Buch. Fish. Ganges, pp. 354, 394, pl. 29, f. 95; Cuv. and Val. xviii, p. 85; Bleeker, Beng. pp. 70, 143.

Schistura dario, McClell. Ind. Cyp. pp. 306, 444, pl. 61, f. 8.

Diacantha flavicauda, Swainson, Fishes, ii, p. 310. Botia dario, Günther, Catal. vii, p. 366.

Sahinga, Punj.; Bucktea, Hind.

B. iii, D. $12-13(\frac{5}{6-10})$, P. 14, V. 8, A. $7-8(\frac{5}{6-6})$, C. 19.

Length of head $4\frac{1}{2}$ to 5, of caudal 5, height of body $4\frac{1}{2}$ to 5 in the total length. Eyes—in about the middle of the length of the head, 5 diameters in the length of the head, 2 to 21 diameters from the end of snout, and 2 apart. Snout rather obtuse. Suborbital spine reaches to below the hind edge of the eye. Barbelseight. Posterior portion of air-vessel free in the abdominal cavity. Fins-dorsal commences midway between the end of the snout and the base of the caudal fin. Scales—very indistinct. Colours—seven or eight oblique bands descend from the back to the abdomen, and two or three, or even more, cross either lobe of the caudal fin.

Habitat.—Bengal, N. W. Provinces, Assam, and Cachar.

3. Botia geto, Plate CLIV, fig. 2.

Cobitis geto, Ham. Buch. Fish. Ganges, pp. 355, 394, pl. xi, f. 96; Cuv. and Val. xvii, p. 84.; Bleeker,

Schistura geto, McClelland, Ind. Cyp. pp. 306, 444, pl. 61, f. 9.

Diacantha zebra, Swainson, Fishes, ii, p. 310.

Botia rostrata, Günther, Catal. vii, p. 367.

Shee-nharo, Sind.

• The suborbital spine was damaged in the unique example.

B. iii, D. $12(\frac{3}{6})$, P. 14, V. 8, A. $7(\frac{2}{5})$, C. 19.

Length of head $5\frac{1}{4}$, of caudal 5, height of body 5 to $5\frac{1}{4}$ in the total length. Eyes—generally slightly behind the middle of the length of the head, diameter 7 in the length of head, 4 diameters from end of snout. Interorbital space not quite equal to 2 diameters of the orbit. Body and head compressed. Snout pointed, usually longer than the remaining portion of the head. Suborbital spine as a rule not extending to below the posterior margin of the orbit. Barbels—eight. Depth of free portion of tail $1\frac{1}{4}$ in its length. Fins—dorsal arises midway between the anterior margin of the orbit and the base of the caudal, which last has sharp lobes. Scales—minute, but more distinct than in B. dario. Colours—body, in the adult, with irregular and partly confluent brown cross bands, which enclose variously sized round yellowish or bluish spots. Dorsal and anal fins with two: pectoral, ventral, and each lobe of the caudal, with three black cross bands. In the young the bands on the body form arches, four or five in number, passing over a dark vertical band or mark. The proportion of the body and size of the suborbital spine rather vary with age.

Habitat.—From Sind, through the Punjab, Himalayas, Valley of the Ganges, Jumna, Sone river, and

Assam. The specimen figured was from a stream in the Sind hills.

4. Botia Almorhæ, Plate CLIV, fig. 5.

Gray, Zool. Misc. 1831, p. 8; Günther, Catal. vii, p. 367.

Botia grandis, Gray and Hardw. Ind. Zool.; Cuv. and Val. xviii, p. 86. Schistura grandis McClell. Cal. J. N. H. ii, p. 586. Cobitis grandis, Bleeker, Beng. p. 70.

B. iii, D. $11-12(\frac{2}{9-10})$, P. 14, V. 8, A. $7-8(\frac{2}{5-6})$, C. 19.

Length of head $4\frac{1}{2}$, of caudal 5, height of body 5 to $5\frac{1}{3}$ in the total length. Eyes—rather behind the middle of the length of the head, 3 diameters from end of snout, and 2 apart. Body, head, and snout compressed. Suborbital spine strong, extending to below the hind edge of the orbit. Barbels—eight. Fins dorsal commences midway between the posterior nostrils and the base of the caudal fin in the adult: but between the latter and front end of the snout in the immature. Scales—present. Colours—body reticulated with gray on a yellow ground: fins yellow: the dorsal, pectoral, and anal, with four transverse dark bands, the pectoral and each caudal lobe with five. Sometimes examples are vertically banded, each band being reticulated.

Habitat.—Cashmere, Almorah and Khasia hills. It attains at least, 6 inches in length. The specimen figured was procured for me at Almorah by Dr. Govan.

5. Botia Berdmorei, Plate CLIV, fig. 3.

Syncrossus Berdmorei, Blyth, J. A. S. of Bengal, 1860, p. 166. Botia Berdmorei, Day, Proc. Zool. Soc. 1869, p. 549. Nga-tha-lay-doh and Shoay-zagay, Burmese.

B. iii, $13-15(\frac{2}{118})$, P. 13, V. 8, A. $7(\frac{2}{5})$, C. 17.

Length of head $4\frac{2}{3}$ to 5, of caudal 5, height of body 5 to $5\frac{1}{3}$ in the total length. Eyes—in about the middle of the length of the head, diameter 6 to 7 in the length of head, 4 diameters from end of snout and $1\frac{1}{3}$ Body compressed. Suborbital spine reaches to below the middle of the eye. Barbels—six. Fins dorsal commences midway between the posterior nostril or the orbit and the base of the caudal fin. Scales—minute. Colours—buff, with 10 or 11 vertical darkish bands, extending from the back to the abdomen. Head likewise banded, and a dark line from the eye to the snout. Numerous oblong blotches over the body, sometimes commencing opposite the orbit and ceasing about the end of the pectoral fin, in other examples being continued all over the body. Dorsal fin with three or four rows of spots, and sometimes a large one at the base of the last three or four rays: caudal with five or six: anal with two.

This species appears closely allied to B. hymenophysa, Bleeker, but differs in its dorsal fin, and also in its

colours, &c.

Habitat.—The Irrawaddy river in Burma, and waters in its vicinity, certainly as high as Mandalay: also Tenasserim. The example figured (life-size) was from Mandalay.

6. Botia histrionica, Plate CLIV, fig. 4.

Blyth, J. A. S. of Bengal, 1860, p. 166; Day, Proc. Zool. Soc. 1869, p. 550.

B. iii, D. $10(\frac{2}{8})$, P. 15, V. 8, A. $7(\frac{2}{5})$, C. 19.

Length of head 5, of caudal 5, height of body $4\frac{2}{3}$ in the total length. Eyes—small, diameter 1/6 of length of head, $2\frac{1}{2}$ diameters from end of snout, 2 diameters apart. Suborbital spine very strong and extending to opposite the posterior margin of the orbit. Barbels—eight. Fins—dorsal arises nearer the base of the caudal than the end of the snout: it is slightly in advance of the ventrals. Caudal deeply forked. Scales-inconspicuous. Colours-olive, with five dark vertical bands on the body, and two on the head. All the fins with two broad brown bars.

Habitat.—Burma. The single example (figured) came from Pegu, and is in the Calcutta Museum.

Genus, 2—Acanthopsis, v. Hasselt.

Prostheacanthus, Blyth.

Body very elongated, snout long and compressed. Barbels eight, two being mandibular. A small, bijid, erectile spine, situated in advance of the orbit. Dorsal fin opposite to the ventrals; caudal forked. Geographical distribution. - Burma to the Malay Archipelago.

SYNOPSIS OF INDIVIDUAL SPECIES.

- 1. Acanthopsis choirorrhynchus. D. 11, A. 8. Burma, &c.
 - 1. Acanthopsis choirorrhynchus, Plate CLV, fig. 1.

Cobitis choirorrhynchus, Bleeker, Nat. Tyds. Ned. Ind. vii, p. 95.

Prostheacanthus spectabilis, Blyth, Proc. A. S. of B. 1860, p. 167.

Acanthopsis choirorrhynchus, Bleeker, Atl. Ich. Cyp. p. 9, t. i, f. 3; Günther, Catal. vii, p. 365; Day, Proc. Zool. Soc. 1869, p. 549.

Nga-tha-lay-doh, Burmese.

B. iii, D. $11(\frac{2}{9})$, P. 11, V. 7, A. $8(\frac{5}{5})$, C. 11.

Length of head 5, of caudal 6, height of body 9 in the total length. Eyes—diameter 1/6 of the length of head, 4 diameters from the end of snout, 1/2 a diameter apart. Body elongated and compressed a rise from the snout to the occiput. Snout produced: nostrils nearer the end of the snout than to the anterior margin of the orbit. An erectile bifid spine situated between the nostrils and the orbit, and on a level with its lower margin. Barbels—eight, all short. Fins—dorsal commences midway between the snout and the base of the caudal fin, it is slightly in advance of the ventral. Caudal lobed, the lower slightly the longer. Scales—minute. Lateral-line—complete. Colours—brownish, with 12 bands across the back, and the same number of blotches along the lateral-line: two rows of blotches along the dorsal, and three across the anal fins.

Habitat.—Burma, and the eastern portion of Sumatra.

Genus, 3—Somileptes (Swainson) Bleeker.

Body elongated and compressed, dorsal profile nearly horizontal: snout elongated. Eyes prominent. Six barbels—four on the snout, and two on the upper jaw. A small erectile, bifid, suborbital spine. Dorsal fin inserted slightly behind the ventral: caudal entire.

Geographical distribution.—From Orissa through Bengal to Assam.

SYNOPSIS OF SPECIES.

- 1. Somileptes gongota, D. 10, A. 8. Barbels short. Assam.
 - 1. Somileptes gongota, Plate CLV, fig. 2.

Cobitis gongota, Ham. Buch. Fish. Gang. pp. 351, 394; Bleeker, Beng. p. 70; Günther, Catal. vii, p. 363. Cobitis cucura, Ham. Buch. pp. 352, 394; McClelland, Ind. Cyp. pp. 303, 434, t. 51, f. 2 (from H. B.'s MSS.), young; Cuv. and Val. xviii, p. 70; Bleeker, Beng. p. 73.

Cobitis oculata, McClelland, Ind. Cyp. pp. 303, 433, t. 51, f. 1, (from H. B.'s MSS.) adult.

Cobitis amnicola, Cuv. and Val. xviii, p. 68; Bleeker, Beng. p. 70.

Canthophrys albescens, Swainson, Fishes, ii, p. 310.

Somileptes bispinosa, Swainson, Fishes, ii, p. 311; Bleeker, Atl. Ich. Cyp. p. 3.

Reetah, Assam.

B. iii, D $10(\frac{2}{8})$, P. 10, V. 7, A. $7(\frac{2}{5})$, C. 16.

Length of head $5\frac{1}{4}$, of caudal $6\frac{1}{4}$, height of body 7 in the total length. Eyes—high up, situated rather behind the middle of the length of the head. Snout with its upper edge rather concave, it and the rest of the head covered with fine warty excrescences. Suborbital spine bifid, and reaching to below the first half of the eye. Barbels—rather short, extending nearly half way to below the eyes. Fins-origin of dorsal opposite the root of the inner ventral ray, and midway between the hind edge of the eye and the base of the caudal fin: caudal entire. Scales—small, 17 rows between lateral-line and base of ventral fin. Colours—an undulated band along the side of the body, giving off vertical bars towards the back, or else oblique blotches with light edges descending from the back or placed irregularly on the body. Dorsal and caudal fins with transverse rows

Habitat.—Assam, Bheer Bhoom, and Khasia hills. The example figured (life-size) was from the Khasia hills.

Genus, 4-LEPIDOCEPHALICHTHYS, Bleeker.

Platacanthus, Day; Misgurnus, sp. Günther.

Body elongated and moderately compressed, back not elevated. Six or eight barbels, four of which belong to the mandibles. A large, erectile, bifid, suborbital spine. The sub- and post-orbital regions, and also the upper part of the mandities. A targe, erectile, bild, subtricted spine. The sub- and post-orbital regions, and also the upper part of the opercle scaled. Dorsal fin short, commencing opposite, or nearly so, to the ventral; the internal ray of the pectoral fin may be modified into a flat osseous spine; candal truncate or slightly emarginate.

As regards the barbels in this genus, it must be remarked that on either side of the mandible is a skinny

flap, ending internally in a barbel, and externally being connected to the maxillary barbel. Along the outer

edge of this flap, short barbels to the number of two or three, are generally developed.

This genus is separated from Cobitis not only by the mandibular flap being provided with barbels, but also due to the existence of scales on the head, in the sub- and post-opercular regions. The pectoral ray modified into a spine which exists in this genus, and also in Jerdonia, and in the European Cobitis tænia, is employed for digging into the sand, in which way they rapidly bury themselves on the approach of danger as I have frequently observed in an aquarium.

Geographical distribution. - India, Burma, Ceylon, and the Malay Archipelago.

SYNOPSIS OF SPECIES.

1. Lepidocephalichthys guntea, D. 8, A. 7, L. l. 115. Length of head $6\frac{1}{2}$ to $6\frac{3}{4}$ in the total. 25 to 30 rows of scales between the base of the anal fin and the back. India, except the Malabar coast and south of the Kistna.

2. Lepidocephalichthys thermalis. D. 8, A. 7. Length of head 5½ in the total. 30 to 40 rows of scales between base of anal fin and the back. Southern India, Malabar, and Ceylon.

3. Lepidocephalichthys Berdmorei. D. 8, A. 7-8. Length of head 6 to 6½ in the total. About 40 rows of scales between base of anal fin and the back. Burma.

1. Lepidocephalichthys guntea, Plate CLV, fig. 4.

Cobitis guntea, Ham. Buch. Fish. Ganges, pp. 353, 394; McClelland, Ind. Cyp. pp. 303, 434, t. 51, f. 3 (from H.B.'s MSS.); Cuv. and Val. xviii, p. 67; Bleeker, Beng. p. 70; Günther, Catal. vii, p. 363; Day, Proc. Zool. Soc. 1869, p. 383.

Bleeker, Beng. p. 70.

Cobitis maya, Sykes, Trans. Zool. Soc. ii, p. 367. Canthophrys vittatus, Swainson, Fishes, ii, p. 310. Misgurnus lateralis, Günther, Catal. vii, p. 346. Kondaturi and Gupkari, Ooriah.

B. iii, D. 8-9($\frac{2}{6^27}$), P. 8, V. 7-8, A. $7(\frac{2}{6})$, C. 16, L. l. ca. 115.

Length of head $6\frac{1}{2}$ to $6\frac{3}{4}$, of caudal 6, height of body $5\frac{3}{4}$ to $6\frac{1}{2}$ in the total length. Eyes—situated rather before the middle of the length of the head, diameter 1/5 of length of head, $1\frac{1}{2}$ diameters from end of snout, and one diameter apart. Body compressed. Barbels—two rostral and a maxillary pair, all longer than the orbit: a fleshy flap from the lower surface of the manibles on either side joins the maxillary barbel, and each has one or two barbels along its edge. Fins—dorsal arises midway between the orbit and the base of the caudal fin: caudal generally entire, its centre rays however, may be somewhat shortened or even lengthened. Inner pectoral ray sometimes modified into a flat spine having a branched termination. Scales—distinct, and covering not only the suborbital ring of bones on the head but also going in a band from the eye to above the opercles: 25 to 30 rows between the base of the anal fin and the back. Lateral-line—absent. Colours—generally dirty yellowish, with a light band extending from the centre of the snout, and ending in a black occllus above the middle of the base of the caudal fin; below this band are a series of dark blotches festooned inferiorly, whilst the back is similarly marked. Dorsal and caudal with numerous rows of dark spots, but only about 4 on the caudal in Deccan examples, and often two rows on the anal fin.

VARIETY, L. balgara, Plate CLVI, fig. 12.

Cobitis balgara, Ham. Buch. Fish. Gang. pp. 356, 394; Cuv. and Val. xviii, p. 74.

Schistura balgara and aculeata, McClell. Ind. Cyp. p. 307, pl. 53, f. 2 (from H.B.'s MSS.); Cuv. and Val. xviii, p. 70; Bleeker, Beng. p. 70.

Canthophrys olivaceus, Swainson, Fishes, ii, p. 310. Lepidocephalichthys balgara, Günther, Catal. vii, p. 365; Day, P. Z. S. 1870, p. 70.

Jubbi cowri, Ooriah.

This closely resembles the above but has its body a little more elongated, and its caudal fin is sometimes cut rather more square: in a few examples the ventral fin is slightly in advance of the dorsal but not so in others.

Occasionally, examples after having been kept some time in spirit, show a brownish back separated from a

wide brown, black, or green central band, by a light line, otherwise coloured as described above (Misgurnus lateralis, Gunther).*

Habitat.—Punjab, throughout India (except Mysore and south of the Kistna, and also the Malabar coast.) I have them from Darjeeling, and several localities on the Himalayas.

2. Lepidocephalichthys thermalis, Plate CLV, fig. 3.

Cobitis thermalis, Cuv. and Val. xviii, p. 78; Bleeker, Beng. p. 70.

Lepidocephalichthys thermalis, Bleeker, in Verh. Holl. Maat. Haar. 1864, Cyprin. and Cobit. Ceylon, p. 6, t. i, f. 1; Günther, Catal. vii, p. 364; Day, Proc. Zool. Soc. 1869, p. 383.

Cobitis Carnnaticus, Mysorensis, and ?rubripinnis, Jerdon, M. J. L. and S. 1849, pp. 331, 332, 333.

Platacanthus agrensis, Day, Fishes of Malabar, p. 204, pl. 14, f. 1.

Assaree, Tam.: Jubbi cowri, Ooriah: Bálu, Hind.

B. iii, D. $8(\frac{3}{6})$, P. 7, V. 7, A. $7(\frac{3}{6})$, C. 16.

Length of head $5\frac{1}{2}$, of caudal 6, height of body $5\frac{1}{2}$ in the total length. Eyes—almost entirely in the anterior 1/2 of the head. Suborbital spine, strong. Barbels—eight, the longest extending to below the anterior margin of the orbit. Fins—origin of orsal slightly in advance of the ventral, and nearer the root of the caudal than the snout. Caudal slightly emarginate. The inner pectoral ray is modified in some adult males into a flat osseous spine which is used for diving down into the mud. Scales—distinct, about 30 rows between the base of the anal fin and the back. Colours—sandy, with irregular blotches on the lateral-line, and others along the back; a black spot generally exists at the base of the upper half of the caudal fin. Dorsal fin with black spots or bars, caudal with four bands. A dark streak often extends from the eye to the end of the snout.

I found 2,500 eggs in a female example.

Habitat.—Southern India, the Malabar coast, the Wynaad, and Ceylon.

3. Lepidocephalichthys Berdmorei, Plate CLIII, fig. 3.

Acanthopsis Berdmorei, Blyth, Proc. Asi. Soc. of Bengal, 1860, p. 168.

Acanthopsis micropogon, Blyth, 1. c.

Cobitis Berdmorei, Day, Proc. Zool. Soc. 1869, p. 550.

Nga-tha-lay-doh, Burmese.

B. iii, D. $8(\frac{2}{6})$, P. 10, V. 8, A. $7-8(\frac{2}{6-6})$, C. 17.

Length of head 6 to $6\frac{1}{4}$, of caudal 6 to $6\frac{1}{4}$, height of body $5\frac{1}{4}$ to 6 in the total length. Eyes—situated just before the middle of the length of head, 2 diameters from the end of the snout. Suborbital spine bifid, and extending to beneath the first third of the orbit. Barbels—two pairs of rostral and a maxillary pair extending to below the hind edge of the orbit: the mandibular flap with two or three pairs of short ones. Fins—dorsal 2/3 as high as the body below it, commencing slightly posterior to the ventral and midway between the hind edge of the eye or even of the head and the base of the caudal fin, the latter of which is slightly emarginate. Pectoral does not reach quite half way to the ventral. Scales—small, about 40 rows between the anal fin and the back; several rows (about 12) along the suborbital ring of bones. Colours—of a rich yellowish-brown, with a dark line along the body composed of spots, upper surface of body covered with fine markings: a black spot at the base of the caudal fin. Dorsal and caudal fins lineated with fine spots: some also on the outer portions of pectoral, ventral, and anal.

Habitat.—Moulmein in Burma, where it is common.

Genus, 5.—Acanthophthalmus, v. Hasselt.

Pangio, Blyth.

Body elongated and strongly compressed. An erectile, bifid, suborbital spine. Six barbels, one rostral and two maxillary pairs. Dorsal fin situated in the posterior third of the body, anterior to the anal, but posterior to the ventrals.

Geographical distribution.—North-east Bengal, Assam and Burma.

SYNOPSIS OF INDIVIDUAL SPECIES.

- 1. Acanthophthalmus pangia. D. 8, A. 7. Cinnamon colour. N.E. Bengal to Upper Burma.
 - 1. Acanthophthalmus pangia, Plate CLV, fig. 5.

Cobitis pangia, Ham. Buch, Fish. Ganges, pp. 355, 394; Cuv. and Val. xviii, p. 75; Bleeker, Beng. p. 70.

Cobitis cinnamomea, McClell. Ind. Cyp. pp. 304, 435, pl. 51, f. 5. (from H. B.'s MSS.). Canthophrys rubiginosus, Swainson, Fishes, ii, p. 310.

Pangio cinnamomea, Blyth, Proc. A. S. of B. 1860, p. 169.

* Dr. Günther's three examples of Misgurnus lateralis in the British Museum, have all well-developed suborbital spines, whereas in his definition of genus Misgurnus, he correctly observes, "no suborbital spine." What he terms "the outer longer pair" of mandibular barbels" are identical with what are considered "maxillary barbels," in his genus Lepidocephalichthys.

? Acanthophthalmus Javanicus, Bleeker, Cyp. Proc. p. 75, and Atl. Ich. Cypr. p. 11, t. 2, f. 3. Acanthophthalmus pangia, Günther, Catal. vii, p. 370. Pangya, Beng.: Nga-tha-lay-doh, Burmese.

B. iii, D. $8(\frac{2}{6})$, P. 10, V. 6-7, A. $7(\frac{2}{5})$, C. 17.

Length of head $7\frac{1}{2}$ to 8, of caudal 8, height of body $7\frac{1}{2}$ to 8 in the total length. Eyes—minute. Barbels—six, the longest about 2/5 of the length of the head. Fins—the dorsal arises in commencement of the posterior third of the distance between the eye and the base of the caudal fin, and midway above the interspace between the ventral and the anal. Caudal entire. Scales—distinct. Colour—light cinnamon.

Habitat.—North-east Bengal, the northern portions of the British and Upper Burma. I have received an example from below Darjeeling, collected by Mr. Mandelli: it agrees with the others, except in having no scales, but as it is not in a good state, I conclude they may have been rubbed off.

Genus, 6-APUA, Blyth.

Body elongated and compressed. A small, erectile, bifid, suborbital spine. Eight barbels, one rostral pair, one maxillary pair, and two mandibular pairs. Dorsal fin in the posterior third of the body, but anterior to the anal. Ventral fins absent.

Geographical distribution.—The single species of this genus, which has yet been discovered, was obtained near Pegu in British Burma.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Apua fusca, D. 8, A. 8. Burma.

1. Apua fusca, Plate CLV, fig. 6.

Blyth, Journal Asiatic Society of Bengal, 1860, p. 169; Günther, Catal. vii, p. 371; Day, Proc. Zool. Soc. 1869, p. 349.

B. iii, D. $8(\frac{2}{6})$, P. 11, A. $8(\frac{2}{6})$, C. 16.

Length of head $7\frac{1}{2}$ to 8, of caudal 9, height of body $7\frac{1}{2}$ to 8 in the total length. Eyes—small, diameter 9 in length of head, 4 diameters from end of snout: a barbel-like flap between the nostrils. A small erectile bifid spine below the orbit. Barbels—six, the longest 1/3 the length of the head. Fins—dorsal arises in the commencement of the last 1/3 or 1/4 of the distance between the eye and the base of the caudal fin, and is half as high as the body: caudal rounded. Scales—minute. Colours—brownish, with a longitudinal darker band.

Habitat.—Pegu in Burma. It attains at least 2½ inches in length.

Genus, 7-JERDONIA, Day.

Platacanthus, sp. Day.

Body elongated, and moderately compressed. Eight barbels, two of which are mandibular. A free, erectile, bifid, suborbital spine. Dorsal fin long (twenty-seven branched rays), commencing before the ventrals; the internal ray of the pectoral fin modified into a flat osseous spine; caudal slightly emarginate. Geographical distribution.—Madras Presidency.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Jerdonia maculata, D. 30, A. 9. Madras.

1. Jerdonia maculata, Plate CXLIV, fig. 6.

Platacanthus maculatus, Day, Proc. Zool. Soc. 1867, p. 941, and 1870, p. 700.

B. iii, D. $30(\frac{3}{37})$, P. 5/1, V. 8, A. $9(\frac{3}{8})$, C. 21.

Length of head 2/11, of caudal 1/5, height of body 1/6 of the total length. Eyes—diameter 1/6 of length of head, two diameters from end of snout. Dorsal profile slightly ascends to the commencement of the dorsal fin. Suborbital spine reaches to beneath the anterior third of the orbit. Scales—small, but distinct. Colours—grayish, becoming dirty white along the abdomen. A dark lateral band extends from the eye to the tail: along its first half are three black spots, whilst the whole extent of the back is irregularly lineated. Fins—yellow. Dorsal with four black bands. Caudal with three bands and a dark margin. A black mark at the base of the tail, with a smaller one above and another below it.

Habitat.-Madras.

B.—Without an erectile spine near the orbit.

Genus, 8-NEMACHILICHTHYS.

Body elongated. Dorsal profile not elevated. Snout rather compressed and elongated. Eyes rather

prominent. Barbels six, two rostral and one maxillary pair. No spine on the head. Dorsal fin of moderate length, commencing somewhat in advance of the ventrals. Caudal forked.

The appearance is very similar to Acanthopsis, but there is no spine on the head.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Nemachilichthys Ruppelli, D. 13, A. 7. Greenish yellow, with brown bands: fins yellow, with black bands or rows of spots. Deccan.

Nemachilichthys Ruppelli, Plate CLV, fig. 7.

Cobitis Ruppelli Sykes, Trans. Zool. Soc. ii, p. 366, pl. 64, fig. 1; Bleeker, Beng. p. 70. Nemacheilus Ruppelli, Day, J. A. S. Beng. 1872, p. 184.

B. iii, D. $13(\frac{2}{11})$, P. 13, V. 8, A. $7(\frac{2}{5})$, C. 19.

Length of head $5\frac{1}{4}$, of caudal 5, height of body $7\frac{1}{2}$ in the total length. Eyes—slightly behind the middle of the length of the head, $2\frac{1}{4}$ diameters from end of snout. Head pointed. Barbels—four well developed rostral ones joined at their bases, and nearly 1/2 as long as the head, also a maxillary pair. Fins—dorsal arises midway between the snout and base of the caudal which is forked: the upper margin of the dorsal fin straight. Scales—moderately developed. Lateral-line—distinct. Colours—greenish yellow except the abdomen which is white, short brown bars along the lateral-line, and the rays of the dorsal and anal barred. Caudal with four posteriorly directed V-shaped brown bars. A black spot at the base of the upper caudal lobe.

The elongated snout of this species is very similar to that seen in Acanthopsis, but it has no spine on the head: its rostral barbels arise on one base as seen in Botia.

Habitat.—Deccan. The example figured (life size) was from Poona.

Genus, 9-Nemacheilus, van Hasselt.

Acoura and Acourus, Swains.: Acanthocobitis, Peters: Oreias, Sauvage: Diplophysa, Kessler.*

Body elongated. Dorsal profile nearly horizontal. Barbels eight or six, when the former number is present, the extra pair belongs to the posterior nostrils; none on the mandibles. No spine on the head. Dorsal fin of moderate length, or short, situated opposite the ventrals.

This genus has been subdivided into those species which have upwards of twelve dorsal rays (Acanthocobitis), and those with less than twelve. As this arbitrary division is not a natural one, it is not adopted here. Another subdivision has been instituted into those in which the tail is forked, and those in

which it is entire. The genus, may, however, be subdivided into those with eight and those with six barbels.

Amongst these little fishes there are several subjects that have to be mentioned, which though of consequence in some carps appear to be of less value in the loaches. The height of the body is liable to vary considerably in accordance with whether it is well or ill nourished. The number of rays in the dorsal fin in some (N. botia) appear to be subject to variation. Sometimes the preorbital is raised and with a free lower edge, while this may not occur in all examples of the same species: and the form of the caudal fin likewise is occasionally inconstant, being slightly convex, concave, or cut square in fishes of the same species.

Some species are strongly compressed posteriorly, and in those from hilly regions we sometimes see folds

of skin more or less covering the eye like a lid.

Geographical distribution.—Fresh waters of India, Ceylon, and Burma.

SYNOPSIS OF SPECIES.

a. With eight barbels.

1. Nemacheilus Evezardi, D. 9. Greenish, with small dark blotches. Poona in the Deccau.

b. With six barbels.

Nemacheilus pavonaceus, D. 16-20. Body barred; caudal slightly notched.
 Nemacheilus rubidipinnis, D. 15-16. Body with 12 to 15 bands. Caudal emarginate. Tenasserim.
 Nemacheilus botia, D. 11-14. Body irregularly blotched. Caudal entire or slightly emarginate.

Throughout India and Ceylon, except Malabar.

5. Nemacheilus monoceros, D. 12. Caudal and dorsal fins barred. Caudal rounded. Assam.

6. Nemacheilus pulchellus, D. 12. Caudal forked. Yellow blotches on body. Fins barred. Bowany

- 7. Nemacheilus sinuatus, D. 10-11. Caudal cut square. Vertical brown bands, with shorter intermediate ones. Dorsal and caudal barred. Wynaad.
- * This includes species from Western Turkestau, having the air-vessel in two parts, the anterior enclosed in a bony capsule, the posterior free and elongated in the abdominal cavity.

8. Nemacheilus Guentheri, D. 10-11. Reticulated with brown. Caudal forked. Neilgherries.

Nemacheilus semiarmatus, D. 10-11. Irregular spots and bars on the body and fins. Caudal forked. Neilgherries.

10. Nemacheilus corica, D. 10. About 13 blotches along the side. Caudal forked. N.E. Bengal,

Punjab, Assam.

- 11. Nemacheilus rupicola, D. 9-11. Eleven to 17 brown bands on the body, as wide or wider than the
- ground colour. Dorsal and caudal banded or spotted. Caudal forked. Himalayas.

 12. Nemacheilus montanus, D. 9-10. Eleven to 12 vertical bands. Caudal emarginate. Himalayas.

 13. Nemacheilus striatus, D. 11-12. Sixteen to 20 vertical bands, wider than the ground colour. Caudal emarginate. Wynaad.

14. Nemacheilus multifasciatus, D. 10. Snout compressed, eye small; numerous vertical bands, widest in last 1/2 of body. Caudal lobed. Darjeeling and Assam.

15. Nemacheilus Denisonii, D. 10. Mouth of moderate width. Nine to 12 vertical bands wider than the ground colour. Caudal lobed. Southern India and the Deccan.

16. Nemacheilus notostigma, D. 10. Snout compressed: eye of moderate size. Ten to 14 vertical bands wider than the ground colour. Caudal lobed. Ceylon.

17. Nemacheilus zonalternans, D. 11. Ten to 11 vertical bands, with intermediate ones superiorly.

Dorsal and caudal spotted. Caudal entire. Tenasserim provinces.

18. Nemacheilus Ladacensis, D. 10. Sixteen to 18 interrupted and sinuous bands. Caudal lobed or

emarginate. Tibet.

19. Nemacheilus zonata, D. 9. Eleven to 15 dark zones encircle the body, which are not half the width of the ground colour. Caudal forked. Assam, Jumna and Ganges rivers, and Orissa.

20. Nemacheilus cincticauda, D. 10. Ten brown zones encircle the body, usually wider than the ground colour. Caudal slightly forked. Upper Assam and Burma.

21. Nemacheilus triangularis, D. 10. Seven black-edged angular bands on the body. Caudal

emarginate. Travancore.

22. Nemacheilus savona, D. 10-11. Ten to 12 very narrow white bands. Caudal slightly emarginate.

Bengal and N.W. Provinces.

- 23. Nemacheilus Beavani, D. 10. Dark bands, wider than the interspaces. Caudal forked. Cossie river and Bowany.
- 24. Nemacheilus spilopterus, D. 9-10. Eleven to 15 irregular bands. Caudal slightly emarginate. Himalayas, Assam and Cochin China.

25. Nemacheilus marmoratus, D, 9. Mottled with brown. Caudal entire. Cashmere.

26. Nemacheilus Stoliczkæ, D. 9. Marbled with brownish black. Caudal emarginate. Head waters of Indus, also Tibet.

Nemacheilus Blythii, D. 9. Brownish. Caudal forked. India? Nemacheilus Butanensis, D. 9. Caudal rounded. Boutan. 27.

28.

29. Nemacheilus gracilis, D. 9. Brownish. Caudal emarginate. Head waters of Indus. 30. Nemacheilus turio, D. 8, (10?) Spotted and blotched. Caudal emarginate. Assam.
31. Nemacheilus guttatus, D. 8. Dark blotches. Caudal entire. Upper Assam.

a. With eight barbels.

1. Nemacheilus Evezardi, Plate CLIII, fig. 11.

B. iii, $9(\frac{3}{7})$, P. 12, V. 8, A. $7(\frac{3}{5})$, C. 17.

Length of head $5\frac{1}{3}$, of caudal 5, height of body 6 in the total length. Eyes—just before the middle of the length of the head and rather minute, about 3 diameters from the end of the snout and the same apart. Head broad, its width equalling its length without the snout, which is rounded. No spine on the head. Barbels—well developed, one pair of nasal, reaching to opposite hind edge of the eye: two pair of rostral, and one maxillary pair. Fins—dorsal commences opposite to the ventrals and midway between the anterior margin of the orbit and the base of the caudal; upper edge of dorsal fin slightly convex; pectoral longer than the head, and reaching three quarters of the distance to the base of the ventral. Caudal rounded. Scales—very minute. Lateral-line—indistinct. Colours—greenish, with small dark blotches having a vertical direction, a dark spot at the base of the caudal fin, which has four V-shaped bands: some spots on dorsal fin: outer half of pectoral dark.

Habitat.—Poona. A single specimen received amongst a collection which Colonel Evezard assisted in

procuring. The example is figured life size.

b. With six barbels.

2. Nemacheilus pavonaceus, Plate CLIII, fig. 12.

Cobitis pavonacea, McClelland, Ind. Cyp. pp. 305, 437, pl. 52, fig. 1; Cuv. and Val. xviii, p. 37; Bleeker, Beng. p. 70.

Nemacheilus pavonaceus, Günther, Catal. vii, p. 348. Acanthocobitis longipinnis, Peters, Mon. Ak. Wiss. Berl. 1861, p. 712.

B. iii, D. $16-20(\frac{2-3}{3-3-8})$, V. 8, A. $7(\frac{2}{5})$, C. 19.

Length of head $5\frac{3}{4}$, of caudal $7\frac{1}{6}$, height of body 6, of dorsal fin $5\frac{1}{2}$ in the total length. Eyes—in the middle of the length of the head, diameter 2/9 of length of head, 2 diameters from end of snout. In some specimens the pre-orbital forms a blunt spine. Fins—dorsal situated rather in front of the middle of the total length, it commences nearer to the snout than to the base of the caudal, which latter is slightly emarginate. Scales—absent. Colours—body crossed by about twenty half bars of a darkish gray: a dark occlus surrounded by a light margin exists upon the upper portion of the base of the caudal fin. Dorsal and caudal barred.

Habitat.—Assam.

3. Nemacheilus rubidipinnis, Plate CLIII, fig. 4.

Cobitis rubidipinnis and semizonata, Blyth, Proc. Asi. Soc. of Beng. 1860, pp. 170, 171. Nemacheilus rubidipinnis and semizonata, Günther, Catal. vii, p. 348.

B. iii, D. $15 \cdot 16(\frac{2}{13 \cdot 14})$, P. 14, V. 8. A. $7(\frac{2}{5})$, C. 19.

Length of head $5\frac{3}{4}$, of caudal $5\frac{3}{4}$, height of body 6 in the total length. Eyes—in the middle of the length of the head, 2 diameters from the end of snout, and 12 apart. The greatest width of the head equals its length excluding the snout. (The spine-like process projecting from the middle of the upper lip is the end of the premaxillaries.) Barbels—the two rostral pairs reach to below the front edge of the eye. The maxillary pair are of about equal length. Fins—dorsal commences in advance of the ventral, and rather nearer the snout than the base of the caudal fin, its upper edge is oblique: pectoral as long as the head and reaching rather above 2/3 of the distance to the ventral, which last goes rather above 1/2 way to the anal. Scales—very distinct all over the body: 15 rows between the lateral-line and base of the ventral fin. Caudal nearly entire. Colours-reddish brown, with 12 to 16 irregular darkish bands descending from the back and ending in dark spots below the lateral-line: 4 to 6 oblique bands on the dorsal fin: 6 to 8 irregularly vertical bars on the caudal, which has a black ocellus on the upper half of its base.

Habitat.—Tenasserim. I am indebted to Dr. Anderson of the Calcutta Museum for the example

4. Nemacheilus botia, Plate CLVI, fig. 5.

Cobitis botia and bilturio, Ham. Buch. Fish. Ganges, pp. 350, 358, 394, 395; Cuv. and Val. xviii, pp. 35, 72; Bleeker, Beng. p. 70.

Cobitis binucronata, ocellata and scaturigina, McClell. Ind. Cyp. pp. 304, 435, 436, pl. 51, fig. 4, and 6

(from H. B.'s MS.)

Nemacheilus botia and urophthalmus, Günther, Catal. vii, pp. 348, 349; Day, P. Z. S. 1869, p. 382.

Bil-turi and Balli-potiah, Assam; Soon-da-lee, Punj.

B. iii, D. 12-14($\frac{2}{10^2-12}$), P. 11, V. 8, A. $7(\frac{2}{6})$, C. 17.

Length of head $4\frac{1}{2}$ to $5\frac{1}{2}$, of caudal $4\frac{1}{2}$, height of body $4\frac{3}{4}$ in the total length. Eyes—diameter $3\frac{3}{4}$ to 4 in the length of head, $1\frac{1}{4}$ to $1\frac{3}{4}$ diameters from end of snout and $1\frac{1}{4}$ apart. The greatest width of the head equals half its length. Preorbital has in some specimens a projection which is movable below the orbit (N. botia), whilst in others it is entirely concealed by the skin (N. bilturio). Barbels—long, the maxillary pair reaching to below the posterior edge of the eye. Fins—dorsal commences rather nearer the snout than to the base of the caudal fin, whilst the length of its base equals that of the head, its upper edge nearly straight. Pectoral as long as the head. Ventral inserted under the middle of the dorsal, caudal slightly notched. Scales—distinct. Lateral-line—complete, 12 rows of scales between it and the base of the ventral fin. Colours —grayish, with from 10 to 14 short bars on the lateral-line, and a number of irregular blotches above it, sometimes forming bands over the back. Dorsal fin orange and with rows of black spots: caudal with about seven irregular bars of a > shape, and a black ocellus on the upper portion of the base of the fin.

The Cobitis scaturigina, McClell. is an elongated variety, the height of the body being about 6½ in the

total. I have obtained it in Assam.

Variety, Nemacheilus aureus, Plate CLVI, fig. 4.

D. 11-12($\frac{2}{0-1}$). Dorsal fin of much less extent than in N. botia. Lateral-line ceases opposite the posterior end of the dorsal fin.

This form I consider cannot be a distinct species, as I have received three examples from Poona all with an incomplete lateral-line, whilst the number of rays in the dorsal fin were $\frac{1}{2-1}\frac{3}{6-1}$, thus giving all the intermediate forms. The back is not quite so high as is usual, but I find some Assam examples show the intermediate links.

Habitat.—Sind, Punjab and throughout India (except the Malabar coast and South of the River Kistna),

Ceylon, common in Assam. Although the variety N. aureus is found in Assam, it is more abundant than N. botia in the upper portion of the Ganges and Jumna. It is also the form in the Nerbudda, and through the Deccan, where however the N. botia is likewise to be obtained.

5. Nemacheilus monoceros.

Cobitis monoceros, McClell. Ind. Cyp. pp. 305, 438, pl. 52. fig. 2; Cuv. and Val. xviii, p. 38; Bleeker, Beng. p. 70.

Nemacheilus monoceros, Günther, Catal. vii, p. 358.

B. iii, D. 12, P. 12, V. 8, A. 6, C. 18.

Length of head 1/4 of the total without the caudal fin. Eyes—situated behind the middle of the length of the head. Fins—(according to the figure): upper margin of dorsal nearly straight, caudal rounded. Colours—body greenish-yellow with a silvery lustre, opercles tinged with green. Caudal and dorsal streaked with numerous small brown bars.

Habitat.—Assam.

6. Nemacheilus pulchellus, Plate CLVI, fig. 7.

Day, Journ. Linn. Soc. xi, p. 528.

B. iii, D. $12(\frac{2}{10})$, P. 15, V. 9, A. $7(\frac{2}{5})$, C. 21.

Length of head $5\frac{1}{2}$, of caudal $4\frac{1}{2}$, height of body 5 in the total length. Eyes—rather small, in the middle of the length of the head, about two diameters from end of snout, and rather above one apart. Cleft of mouth reaches 1/2 way to below orbit. Anterior profile of head very abrupt. The greatest width of the head equals its length excluding the snout. Barbels—six, the rostral thicker than the maxillary pair, and none more than one diameter of the orbit in length. Fins—dorsal commences slightly nearer snout than base of caudal, its upper edge oblique: the fin equal to the height of the body below it. Pectoral as long as the head, its central rays the longest, it reaches 2/3 of the distance to the ventral, which latter extends nearly 3/4 of the way to the anal, the last laid flat reaching the base of the caudal which has sharp lobes. Scales—very minute, most apparent in the posterior portion of the body. Lateral-line—moderately distinct. Colours—this beautiful little loach is of grayish colour, becoming whitish below: there are along the side between the head and middle of the dorsal fin two rows of large, vertical, canary-yellow spots, having deep black margins: posterior to which they become wide vertical bands 2/3 as wide as the ground colour. Caudal with three or four oblique black bands, and a deep black spot at the centre of its base. Dorsal yellowish-orange at its upper anterior portion, two wide black bars along its centre, and one across the anal.

Habitat.—Bowany River to 21 inches in length.

7. Nemacheilus sinuatus, Plate CLVI, fig. 3.

Day, Proc. Zool. Soc. 1870, p. 371.

B. iii, D. $10-11(\frac{3}{8-9})$, P. 12, V. 8, A. $7(\frac{3}{5})$, C. 18.

Length of head 5, of caudal $5\frac{1}{2}$ to 6, height of body 6 in the total length. Eyes—situated slightly before the middle of the length of the head, $2\frac{1}{2}$ diameters from end of snout, $1\frac{1}{2}$ diameters apart. The greatest width of the head equals its length excluding the snout. Barbels—long and thin. Fins—dorsal arises slightly in advance of the ventrals, and midway between the snout and the base of the caudal, which last is cut square, but some of the outer rays are rather the shortest. Scales—distinct: 10 rows between the lateral-line and the base of the ventral fin. Lateral-line—ceases opposite the middle or end of the dorsal fin. Colours -olive, with irregular vertical brown bands, having shorter intermediate ones. A black ocellus at the upper portion of the base of the caudal fin. Dorsal yellow, with three or four rows of black spots. Caudal orange with four > shaped bars, the centre of each of which is inverted.

Habitat.—Wynaad.

8. Nemacheilus guentheri, Plate CLVI, fig. 10.

Day, Proc. Zool. Soc. 1867, p. 285; Günther, Catal. vii, p. 361.

B. iii, D. 10-11($\frac{1}{7-8}$), P. 11, V. 7, A. $7(\frac{9}{6})$ C. 19.

Length of head $5\frac{1}{2}$, of caudal 6, height of body 7 in the total length. Eyes—situated just before the middle of the length of the head, $1\frac{1}{2}$ diameters from end of snout, 1 diameter apart. Width of the head equals its length behind the orbit. Free portion of tail longer than deep. Fins—upper margin of dorsal oblique, the fin commences about midway between the end of the snout and the base of the caudal, which last is lobed. Pectoral extends three-fifths of the distance to the base of the ventral. Scales-small, but distinct. Lateral-line-incomplete. Colours-pinkish, coarsely reticulated with olive brown markings, leaving three rows of large spots along the side: a black band at the base of the caudal fin, which has two indistinct dark bands across either lobe, the extremities of which are stained. Two rows of fine black dots along the dorsal fin, and one across the anal.

Habitat.—Rivers along the lower slopes and base of the Neilgherry hills.

9. Nemacheilus semiarmatus, Plate CLVI, fig. 11.

Day, Proc. Zool. Soc. 1867, p. 286; Günther, Catal. vii, p. 353.

B. iii, D. 10-11($\frac{3-3}{6}$), P. 12, V. 7, A. $7(\frac{2}{6})$, C. 18.

Length of head $5\frac{1}{4}$, of caudal $5\frac{1}{2}$, height of body $5\frac{1}{3}$ in the total length. Eyes—diameter $4\frac{1}{2}$ in the length of head, $1\frac{1}{2}$ diameters from end of snout, 1 diameter apart. The greatest width of the head equals its length excluding the snout. Free portion of tail as deep as long. Fins—origin of dorsal midway between the snout and the basal half of some of its outer rays being generally stiffened by osseous matter. Caudal lobed in its last half. Scales—minute, becoming most distinct in the last half of the body. Lateral-line—complete. Colours—light brown, with numerous irregularly shaped spots and bars proceeding from the back towards the lateral-line: head brownish, with a dark line from the snout through the orbit. Dorsal fin with about three rows of dark spots: caudal irregularly barred: a dark line runs along the centre of the back.

Habitat.—Bowany and Seegoor rivers along the base of the Neilgherry hills: also imported into tanks on

those mountains.

10. Nemacheilus corica, Plate CLVI, fig. 1.

Cobitis corica, Ham. Buch. Fish. Ganges, pp. 359, 395; Cuv. and Val. xviii, p. 36; Bleeker, Beng. p. 70.

Schistura punctata, McClell. Ind. Cyp. pp. 308, 442, pl. 53, f. 4 (from H.B.'s MS).

Acoura cinerea, Swainson, Fishes, ii, p. 310. Nemacheilus corica, Günther, Catal. vii, p. 361.

Khorika, Beng.

B. iii, D. $10(\frac{2}{8})$, P. 13, V. 8, A. $7(\frac{2}{5})$, C. 17.

Length of head $5\frac{1}{2}$, of caudal 5, height of body 6 in the total length. Eyes—of moderate size, in the middle of the length of the head: nearly 2 diameters from the end of the snout. The greatest width of the head equals its length excluding the snout. Barbels—thin, the external rostral pair longer than the orbit. Fins -dorsal commences anterior to the ventral and nearer to the snout than to the base of the caudal, which last is lobed in its posterior half, the lower being the longer: upper margin of dorsal fin oblique. Third and fourth pectoral rays produced, reaching the base of the ventral fin. Scales—visible in the posterior half of the body. Colours—bluish, with about thirteen black blotches along the middle of the side, and smaller ones above and descending to between them: usually a silvery band along the middle of the side.

Habitat.-N.E. Bengal, Punjab and Assam.

11. Nemacheilus rupicola, Plate CLIII, fig. 9.

Schistura rupicola, McClelland, Journ. Asiat. Soc. Beng. vii, pl. 55 f. 3, and Ind. Cyp. pp. 309, 441, pl. 57, f. 3.

Cobitis rupecula, Cuv. and Val. xviii, p. 40; Bleeker, Beng. p. 70.

? Cobitis microps, Steind. Verh. Zool. Bot. Ges. Wien, 1866, p. 794, t. 13, f. 3.

Nemacheilus rupecula and? microps, Günther, Catal. vii, pp. 351, 357.

Saant-al, Punj.

B. iii, D. 9-11($\frac{2}{7}$ - $\frac{3}{8}$), P. 10, V. 8, A. $7(\frac{2}{8})$, C. 18.

Length of head $5\frac{1}{2}$, of caudal 6, height of body 7 to 8 in the total length. Eyes—small, in the middle of the length of the head: the width of the interorbital space equals about 3/4 the length of the snout. Head nearly as wide as long. Mouth transverse and snout obtuse in the adult. Free portion of tail not as deep as long. Fins—the dorsal's upper margin oblique, it commences midway between the nostrils and the base of the caudal fin: pectoral extends a little above half the distance to the ventral. Caudal emarginate. Scales—absent, or minute in the posterior half of the body. Lateral-line—complete. Colours—yellowish, with 12 to 17 vertical brown bands, much narrower than the intermediate ground colour, and decreasing in width below the lateral-line, they are sometimes incomplete as shown in the figure: a wide dark band across the base of the caudal, which fin as well as the dorsal has several rows of spots forming bands: a dark mark at the base of the anterior dorsal rays, sometimes another at the base of the middle ones.

Habitat.—Himalayas and? Tibet at 16,000 feet above the sea.

12. Nemacheilus montanus, Plate CLIII, fig. 6.

Schistura montana, McClell. Ind. Cyp. pp. 307, 440, t. 57, f. 1. Cobitis montana, Cuv. and Val. xviii, p. 69; Bleeker, Beng. p. 70. Saant-at, Punj.

B. iii, D. 9-10($7^{\frac{2}{8}}$), P. 10, V. 7, A. $7(\frac{8}{5})$, C. 19.

Length of head $5\frac{1}{2}$ to $5\frac{2}{3}$, of caudal 5 to 6, height of body $8\frac{1}{3}$ in the total length. Eyes—small,

diameter 1/5 of the length of the head and situated before the middle of its length, rather above 1 diameter apart. The greatest width of the head equals its length, excluding the snout which is rather pointed. The preorbital is in the form of an obtuse moveable projection, which is sometimes covered by skin. Barbels—short, but stout. Fins—dorsal commences midway between the posterior margin of the orbit and the base of the caudal fin. Pectoral reaches above half way to the root of the ventral: caudal with rounded lobes in the adult, more pointed in the young. Free portion of the tail 2/3 as deep as long. Scales—minute. Colours—eleven to twelve vertical brown bands, each from nearly as wide to three times as broad as the buff interspaces. Caudal with a black band at its base, and a bar across each lobe. Dorsal with a black base and a black mark at the base of its two first rays, and a dark bar across its centre.

Nemachilus montanus, Günther, although closely resembling the typical form, is not this species, but N. multifasciatus. His description is from two specimens in the British Museum which are thus noted in the catalogue. "Simla. ab. Probably the typical specimens, from the collection of the East India Company." This supposition I consider incorrect: the specimens were from the collection of the East India Company, but without any locality attached. McClelland (Calcutta Journal Natural History, 1842, ii, p. 573), enumerates the species he sent to Europe up to that time, and the only loaches were, 1 Cobitis Boutanensis and 1 C. marmorata: and in the Chronological list of the contributions to the Museum at the Indian house (see preface to the Catalogue of Mammalia, 1851), it will be seen that he only sent one collection. However, many fish from other parts were received at various periods, but as this species appears to be absent from Simla, I prefer confining McClelland's two names of Simla species to the two forms of loaches now found there, and which agree moderately well with his descriptions.

Habitat.--Himalayas: attaining at least 41 inches in length.

13. Nemacheilus striatus, Plate CLIII, fig. 8.

Day, Proc. Zool. Soc. 1867, p. 347; Günther, Catal. vii, p. 353. Cul-irum, and Kul-nukura, Tamil.

B. iii, D. $11 \cdot 12(\frac{2}{6-10})$, P. 11, V. 8, A. $7(\frac{2}{5})$, C. 17.

Length of head $5\frac{1}{2}$ to 7, of caudal 6 to 7, height of body 8 to 9 in the total length. Eyes—in the middle of the length of the head, two diameters from the end of snout and $1\frac{1}{2}$ apart. The greatest width of the head equals 1/2 its length. Barbels—well developed, the external rostral pair reaching the posterior, and the internal to the anterior margin of the eye: whilst the maxillary one extends to the hind edge of the orbit. Fins—dorsal arises slightly in advance of the ventrals, and nearer the snout than the base of the caudal fin: the caudal slightly lobed at its posterior extremity. Scales—developed, especially in the posterior part of the body. Lateral-line—well marked: 15 rows of scales between it and the base of the ventral fin. Colours—light reddish brown, with narrow vertical bands darker than the ground colour, and most distinct in the posterior portion of the body, where there are from 12 to 16 behind the commencement of the dorsal fin, and several more between that and the head, which last is marked all over with black lines and spots. A black band at the base of the caudal fin. Dorsal brilliant orange, with a black edge having a light external margin, and a dark base: or else one or two rows of spots. Anal orange with some dull black spots: caudal likewise yellow and spotted in two rows.

Habitat.—Wynaad at 3000 feet elevation. It attains 2½ inches in length.

14. Nemacheilus multifasciatus, Plate CLIII, fig. 7.

? Schistura subfusca, McClelland, Ind. Cyp. pp. 308, 443, pl. 53, f. 5. ? Cobitis subfuscus, Cuv. and Val. xviii, p. 80; Bleeker, Beng. p. 70. Nemachilus montanus, Günther, Catal. vii, p. 350 (not Schistura montana, McClelland). Nemachilus subfuscus, Günther, l. c. p. 351.

B. iii, D. $10(\frac{2}{8})$, P. 11, V. 9, A. $7(\frac{2}{5})$, C. 18.

Length of head $5\frac{1}{2}$, of caudal $5\frac{1}{4}$, height of body 6 in the total length. Eyes—situated partly before the middle of the length of the head, $2\frac{1}{4}$ to $2\frac{2}{3}$ diameters from end of snout and $1\frac{3}{4}$ apart. No enlargement of the preorbital, Snout compressed. Mouth narrow. Barbels—the maxillary pair rather longer than the eye, the two rostral pairs slightly shorter. Fins—dorsal commences about midway between the end of the snout and the base of the caudal fin, which latter is lobed in its last fourth. Pectoral reaches half way to the ventral. Scales—small, most distinct in the last half of the body. Lateral-line—complete. Colours—vertical bands as wide as the ground colour, pass from the back to the lower surface of the abdomen, those between the head and the dorsal fin are numerous, whilst there are about five posterior to it. In some examples these anterior bands coalesce. A dark band at the base of the caudal and dark marks on the head radiating from the eye. Fins yellow, the dorsal with four bands of spots and an equal number or more on the caudal. Ventral and anal with two bands each.

Habitat.—Darjeeling and Assam. The example figured (life size) was from Darjeeling.

15. Nemacheilus Denisonii, Plate CLIII, fig. 5.

Cobitis montanus, Jerdon, M. J. L. and S. 1849, p. 332 (not McClelland).

4 K

Nemacheilus Denisonii, Day, Proc. Zool. Soc. 1867, p. 287; Günther, Catal. vii, p. 352. B. iii, D. $10(\frac{2}{3})$, P. 11, V. 7, A. $7(\frac{2}{5})$, C. 17.

Length of head 5 to $5\frac{1}{2}$, of caudal $5\frac{1}{2}$, height of body $6\frac{1}{2}$ in the total length. Eyes—situated in the anterior half of the head, diameter 1/6 of length of head, 2 diameters from end of snout, and also apart. The greatest width of the head equals its length excluding the snout. Barbels—the maxillary extend to the opercle, the rostral pairs are shorter. Fins—the dorsal commences midway between the end of snout and base of caudal, which last is lobed. Pectoral extends rather above 1/2 the distance to the ventrals. Scales—minute. Lateral-line—complete. Colours—reddish brown, having from nine to twelve dark vertical zones, those anterior to the dorsal fin sometimes coalescing rather irregularly across the back. Dorsal fin with three rows of fine black spots and a black base. Caudal irregularly spotted in bands. Some dull spots on the ventral and anal fins. Most of the head marbled with black dots.

There is a variety of this fish at Poona and elsewhere in the Deccan, its dorsal and caudal fins are more spotted, whilst its body bands are more numerous having less width of ground colour.

Habitat.—Neilgherry and Coorg hills, and rivers at their bases; Mysore and the Deccan. The example figured was from the Neilgherries.

16. Nemacheilus notostigma.

Bleeker, Verh. Holl. Maatsch. Haarl. 1864, Cobit. et Cyp. Ceylon, p. 5, t. i, fig. 2; Günther, Catal. vii, p. 352.

B. iii, D. $10(\frac{2}{5})$, V. 7, P. 13, A. 7-8($\frac{2-3}{5}$), C. 19.

Length of head $5\frac{1}{3}$ to 6, of caudal 5, height of body $5\frac{2}{3}$ in the total length. Eyes—diameter 5 in length of head, 2 diameters from end of snout, $1\frac{1}{4}$ apart. Snout compressed and pointed. Barbels—all rather longer than the eye. Fins—dorsal highest in front, it arises midway between the snout and base of caudal tin, being a little in advance of the ventrals: it is not quite so high as the body below it. Pectoral nearly as long as the head. Caudal lobed in its posterior third. Scales—indistinct. Colours—with ten to fourteen vertical bands on the body, broader than the interspaces. A dark mark at the base of the caudal, which is banded. A black spot at the base of the anterior dorsal rays, and a bar across the lower portion of the fin in its last half, a single band across its centre.

This fish is very similar to N. Denisonii, but has a shorter head, a more compressed snout and rather a lower dorsal fin. N. multifasciatus is also very similar, but has a much smaller eye.

Habitat.—Ceylon.

17. Nemacheilus zonalternans.

Cobitis zonalternans, Blyth, J. A. S. of B. 1860, p. 172. Nemacheilus zonalternans, Day, Proc. Zool. Soc. 1869, p. 551.

B. iii, D. 2/9, A. $11(\frac{2}{9})$ P. 11, V. 9, A. $7(\frac{2}{5})$, C. 19.

Eyes—of moderate size, rather above 1 diameter from end of snout. Fins—dorsal arises anterior to the insertion of the ventral, and rather nearer the snout than the base of the caudal, which latter fin is entire. Scales—distinct. Colours—ten to eleven bars descend down the lower 2/3 of the body to the abdomen, with intermediate half bands superiorly between them. Dorsal and caudal fins spotted in bands.

Habitat.—Tenasserin Provinces, from whence Major Berdmore sent two specimens, 1.4 and 1.6 inches

respectively in length.

18. Nemacheilus ladacensis.

Günther, Catal. vii, p. 356; Day, Proc. Zool. Soc. 1876, p. 747, and Fishes, Yarkand, plate iv, fig. 4. B. iii, D. 10($\frac{2}{8}$), V. 9, A. 8($\frac{2}{6}$), C. 19.

Length of head 5, of caudal $5\frac{1}{4}$. height of body $5\frac{1}{4}$ in the total length. Eyes—diameter 5 to $5\frac{1}{4}$ in length of head, $2\frac{1}{2}$ diameters from end of snout and 2 apart. Free portion of tail 1/2 as high as long. Barbels—the maxillary ones scarcely reach the front edge of the eye, the longest rostral ones to below the front nostril. Fins—upper margin of dorsal oblique, with its anterior angle rounded, it commences between the front edge of the eye and the root of the caudal, which latter is emarginate. Pectoral extends rather above half way to the base of the ventral. Scales—absent. Colours—of a light fawn, with 16 or 18 interrupted darker and sinuous bands passing from the back down the sides: a silvery lateral band. Dorsal and caudal finely spotted in lines: a darkish band on pectoral, ventral, and anal fins.

Habitat.—Tibet, from whence two specimens were procured.

19. Nemacheilus zonatus, Plate CLVI, fig. 2.

Schistura zonata, McClell, Ind. Cyp. pp. 308, 441, pl. 53, fig. 1. Cobitis zonata, Cuv. and Val. xviii, p. 39; Bleeker, Beng. p. 72. Nemacheilus mugah, Day, Proc. Zool Soc. 1869, p. 382. Mugah, Beng.

B. iii, D. $9(\frac{2}{7})$, P. 11, V. 8, A. $7-8(\frac{2}{5})$, C. 17, L. 1. 110.

Length of head 5, of caudal 5, height of body $6\frac{1}{2}$ in the total length. Eyes—diameter 1/5 of length of head, two diameters from end of snout, $1\frac{1}{2}$ diameters apart. Body with rather compressed sides. The free portion of the base of the caudal rather longer than high. Snout pointed: no enlargement of pre-orbital. The greatest width of the head equals its postorbital length. Barbels—all about as long as the eye. Fins dorsal arises midway between snout and base of caudal, its upper margin is straight: pectorals extend a little above half way to the base of ventrals: caudal forked. Scales—small, but distinct: there being twelve rows above the lateral-line, and thirteen between it and the base of the ventral fin. Lateral-line—commences by two roots, which soon coalesce, when it is continued to the base of the caudal. Colours—yellowish, with a green tinge: about fifteen brown bands, one-third as wide as the ground colour, pass across the back and descend on either side below the lateral-line: a few near the head, and some in the posterior third of the body are interrupted. Upper surface of head marbled with black. Fins immaculate, but the two first anal rays are black anteriorly, and there are also slight black marks near the end of the ventrals and on the outer side of the pectorals. Rostral barbels orange. The young have a wide silvery band along the side, ending in a dark mark at the base of the caudal fin.

Habitat.—Throughout the Jumna and Ganges rivers and their affluents, Bheer Bhoom, Assam and Orissa. It attains at least two inches in length: the example figured (life-size) was from Midnapore.

20. Nemacheilus cincticauda, Plate CLVI, fig. 6.

Cobitis cincticauda, Blyth, J. A. S. of B. 1860, p. 172. Nemacheilus cincticauda, Day, Proc. Zool. Soc. 1869, p. 552.

B. iii, D. 10(2), P. 11, V. 8, A. 7(2), C. 19.

Length of head $5\frac{1}{4}$, of caudal $4\frac{1}{2}$, height of body $6\frac{1}{2}$ to 7 in the total length. Eyes—situated in the middle of the length of the head, 2 diameters from end of snout, $1\frac{1}{4}$ diameters apart. Preorbital projecting and with a free lower edge in some but not in all examples. Barbels—well-developed, the maxillary reaching to below the front edge of the orbit. The free portion of the tail longer than high. Fins—dorsal with its upper margin straight, it arises nearer the snout than the base of the caudal, which last is slightly forked with pointed lobes. Pectoral extends three-fourths of the distance to the ventral. Scales—minute. Colours—yellowish, with ten regular brown zones encircling the body, and sometimes but not always broader than the ground colour, or the bands may be broken up and irregular: a dark bar at the base of the caudal, and a dark band between the eye and the snout: occasionally a dark mark on the opercle. Dorsal with some black spots.

Habitat.—Burma. The example figured was from Prome.

21. Nemacheilus triangularis, Plate CLIII, fig. 10.

Day, Proc. Zool. Soc. 1865, p. 295, and Fishes of Malabar, p. 203, pl. 14, fig. 1; Günther, Catal. vii, p. 352.

B. iii, D. $10(\frac{2}{8})$, P. 11, V. 9, A. $7(\frac{2}{5})$, C. 19.

Length of head $5\frac{1}{3}$, of caudal $5\frac{1}{3}$, height of body 6 in the total length. Eyes-diameter $4\frac{3}{4}$ in length of head, 2 diameters from end of snout and 1 apart. The greatest width of the head equals half its length.

Barbels—of moderate length. Fins—upper margin of dorsal fin oblique, it commences midway between the end of the snout and the base of the caudal, which latter is emarginate. Scales—small but distinct in the last portion of the body: upwards of 20 rows between the lateral-line and base of the ventral fin. Lateral-line—complete. Colours—yellowish, with about seven black-edged bands on the body and head disposed in a shape. Dorsal with three irregular rows of black spots. Pectoral, ventral, and anal unspotted, but stained at their margins. Several oblique bars across each lobe of the caudal which has a black mark at its base.

Habitat.—Travancore hills.

22. Nemacheilus savona, Plate CLV, fig. 8.

Cobitis savona, Ham. Buch. Fish. Ganges, pp. 357, 394; McClelland, Ind. Cyp. pp. 308, 442, pl. 53, fig. 3 (from H. B.'s MS.); Cuv. and Val. xviii, p. 32; Bleeker, Beng. p. 70.

Acoura obscura, Swainson, Fishes, ii, p. 310.

Nemachilus savona, Günther, Catal. vii, p. 354.

Savon-khorka, Beng.

B. iii, D. 10-11($\frac{2-3}{8}$), P. 10, V. 7, A. 7($\frac{2}{5}$), C. 18.

Length of head $4\frac{1}{2}$ to $4\frac{3}{4}$, of caudal $5\frac{1}{2}$ to 6, height of body 6 in the total length. Eyes—rather large, rather behind the middle of the length of the head, 2 diameters from the end of snout, and 1½ apart. Head, as broad as it is long without the snout. Barbels—long, the rostral and maxillary ones reach the eye. Fins dorsal with its upper edge rather convex, it arises midway between the anterior edge of the orbit and the base of the caudal fin, and its commencement is before the origin of the ventrals. Pectoral extends two-thirds of the distance to the ventral, which last scarcely reaches half way to the anal. Caudal very slightly emarginate, its lobes being rounded. Lateral-line—incomplete. Scales—small, most distinct in the posterior portion of the body. Colours—purplish, becoming lighter on the abdomen, having from ten to twelve very

narrow vertical white bands, not above 1/8 or 1/6 as wide as the ground colour, a black band at the root of the caudal fin; a black blotch at the base of the first few dorsal rays, on to which the white body bands are continued, and four or five rows of dark spots on the fin. Caudal with narrow bands of dark spots: two bands

also on the ventral and anal fins.

Habitat.—Bengal and N. W. Provinces. I received some specimens from the hills near Ranigunj. The example figured (life-size) was from the N.W. Provinces.

23. Nemacheilus Beavani, Plate CLVI, fig. 8.

Nemachilus beavani, Günther, Catal. vii, p. 350. Nemacheilus chryseus, Day, Journ. Linn. Society, Zool. xi, p. 529.

B. iii, D. $10(\frac{2}{8})$, P. 11, V. 7, A. $7(\frac{2}{5})$, C. 19.

Length of head 5, of caudal $5\frac{3}{4}$, height of body $5\frac{1}{2}$ to $5\frac{3}{4}$ in the total length. Eyes—small, just before the middle of the length of the head. The greatest width of the head equals half its length. Preorbital not enlarged. Free portion of the tail as long as deep. Barbels—six, four rostral and two maxillary. Fins dorsal with an oblique upper edge, it arises slightly nearer the end of the snout than the base of the caudal. Pectoral extends two-thirds of the distance to the root of the ventral. Caudal lobed. Scales-minute. Colours—body with nine dark cross bands, broader than the lighter interspaces, a black streak across the root of the caudal. Dorsal and caudal rays with blackish dots. The bands appear to be absent in some specimens.

Habitat.—Bowany river in Madras and Mysore, also Orissa. The example figured (life-size) was from

the Bowany.

24. Nemacheilus spilopterus, Plate CLIII, fig. 9.

Cobitis spilopterus, Cuv. and Val. xviii, p. 27, pl. 522. Nemachilus spilopterus, Günther, Catal. vii, p. 358.

B. iii, D. 9-10($\frac{2}{7-8}$), P. 15, V. 7, A. $7(\frac{2}{5})$, C. 19.

Length of head $5\frac{3}{4}$ to 6, of caudal $6\frac{1}{2}$ to 7, height of body $8\frac{1}{3}$ to 9 in the total length. Eyes-near the summit of the head and in or rather before the middle of its length, 2 diameters from end of snout, and 12 apart. No enlargement of the preorbital. Barbels—short. Free portion of tail about twice as long as high. Fins—dorsal with an oblique upper margin, it commences midway between the end of the snout and the root of the caudal. Pectoral reaches half way to the base of the ventral. Caudal slightly emarginate. Scales—absent. Colours—greenish yellow, with from eleven to fifteen irregular bands crossing the back, and a black band across the root of the caudal fin. A black blotch at the base of the three first dorsal rays, two bands along the fin, another along its base, and three on caudal.

This species is very closely allied to N. montanus, differing in the form of the head, size of the eye, and pectoral fin, also in the markings of the dorsal and caudal.

Habitat.—Himalayas, Assam, and Cochin China.

25. Nemacheilus marmoratus, Plate CLV, fig. 9.

Cobitis marmorata, Heckel, Fisch. Kaschmir, p. 76, t. 12, figs. 1-2, and Hügel, Kaschmir, iv, p. 380; Cuv. and Val. xviii, p. 41; Bleeker, Beng. p. 70.

Cobitis vittata, Heckel, l. c. p. 80, figs. 3, 4; and Hügel, Kaschmir, iv, p. 382; Cuv. and Val. xviii, p. 42; Bleeker, Beng. p. 72.

Nemachilus marmoratus, Günther, Catal. vii, p. 356; Day, Proc. Zool. Soc. 1876, p. 798.

B. iii, D. $9(\frac{2}{7})$, P. 11, V. 7, A. $7(\frac{2}{5})$, C. 17.

Length of head $4\frac{3}{4}$ to 5, of caudal 5, height of body 7 in the total length. Eyes—situated in the middle of the length of the head: two diameters from the end of snout. Free portion of tail from 11 to 2 times as long as high. Fins—upper margin of dorsal fin oblique, commencing midway between the end of the snout and the root of the caudal, which latter is somewhat convex or cut square at its extremity. Pectoral reaches half way to the root of the ventral. Scales—absent. Colours—marbled or irregularly blotched and mottled with brown. Fins more or less spotted. In some specimens a dark band exists along the body and some bars over the back of the tail. (N. vittata.)

Habitat.—Cashmere Lake.

26. Nemacheilus Stoliczkæ, Plate CLV, fig. 10.

Cobitis Stoliczkæ and tenuicauda, Stein. Verh. zool-bot. Ges. Wien, 1866, p. 793, t. 14, fig. 2, and t. xvii, f. 3.

Nemachilus tenuicauda, Stoliczkæ and Griffithii, Günther, Catal. vii, pp. 357, 360.

Nemacheilus Stoliczke, Day, Proc. Zool. Soc. 1876, p. 795, Fishes of Yarkand, Plate v, fig. 2.

B. iii, D. $9(\frac{2}{7})$, P. 13, V. 8, A. $7(\frac{2}{5})$, C. 15.

Length of head 6, height of body 8 in the total length. Eyes—diameter 8 in length of the head, 3 diameters

from end of snout and 2 apart. Barbels—the maxillary the longest and reach to below the hind edge of the eye. Fins—origin of dorsal nearer root of caudal than end of snout, its upper margin oblique with the anterior corner rounded. Pectoral extends a little above half way to the root of the ventral. Caudal slightly

emarginate. Scales—absent. Colours—grayish along the back, becoming lighter beneath, marbled all over with dark green or black spots or bands. Dorsal, caudal, and sometimes outer pectoral rays barred.

The examples of N. griffithii in the British Museum* belong to this species. The chief point of difference between the two descriptions appears to have consisted in the N. Stoliczkæ, being "scaleless," and the griffithii having "scales" which, however, it has not. Having drawn the author; it features that the discrepancy between what exists and the text of the catalogue, he has been good enough to inform me that "scales' appertaining to the species must be a misprint for "scaleless."

Habitat.—Leh or Ladak and waters going directly into the Indus near its source, and Tibet, also

Yarkand where the streams go into the Yarkand river.

27. Nemacheilus Blythii.

Day, Proc. Zool. Soc. 1869, p. 552.

B. iii, D. $9(\frac{2}{7})$, V. 9, A. $7(\frac{2}{5})$, C. 19.

Length of head 5, of caudal 5, height of body 61 in the total length. Eyes -diameter 2/9 of length of head, 1 diameter from end of snout, $1\frac{1}{4}$ apart. Barbels—longer than the orbit. Fins—dorsal commences midway between the snout and the base of the caudal fin, which latter has sharp lobes.

Colours—brownish, becoming lighter on the abdomen; a dark band at the base of the caudal.

Habitat.—Doubtful. Two specimens 3 inches long exist in the Calcutta Museum. Scales - minute.

28. Nemacheilus Butanensis.

Cobitis Boutanensis, McClell. C. J. N. H. ii, p. 586; Bleeker, Beng. p. 70. Nemachilus butanensis, Günther, Catal. vii, p. 358.

B. iii, D. 9, V. 7, A. 7.

Length of head $5\frac{1}{2}$, of caudal $5\frac{1}{2}$, height of body 7 in the total length. Eyes—small, in the middle of the length of the head. Free portion of tail elongated and compressed, its depth being 2/3 of its length. Fins—upper margin of dorsal convex, it commences nearer to the end of the snout than to the root of the caudal, which latter is rounded. The pectoral does not extend half way to the base of the ventral. Scales distinct. Colours-doubtful.

Habitat.—Boutan, where it attains 5 inches in length. McClelland's type in the British Museum is in a bad state, and quite unfit to figure from.

29. Nemacheilus gracilis.

Day, Proceedings Zoological Soc. 1876, p. 798, and Fishes of Yarkand, Plate iv, fig. 5.

B. iii, D $9(\frac{2}{7})$, P. 13, V. 8, A. $8(\frac{2}{6})$, C. 17.

Length of head $5\frac{1}{2}$, of caudal $6\frac{1}{3}$, height of body $6\frac{1}{3}$ in the total length. Eyes—diameter 11 in length of head, 4 diameters from end of snout, and $2\frac{1}{2}$ apart. The greatest width of the head equals its length excluding the snout. Barbels—the maxillary ones about twice as long as the eye, the outer rostral pair reach the hind nostril: the inner are shorter. Fins—dorsal commences midway between the eye and base of the caudal fin, its upper edge is nearly straight, it is not quite so high as the body below it. Pectoral not quite so long as the head, it reaches rather above half way to the ventral, which latter is inserted somewhat in advance of the origin of the dorsal and extends 1/2 way to the anal. Anal laid flat reaches 1/2 way to the base of the caudal, which latter is slightly emarginate. Free portion of the tail half as high at its base as it is long. Scales—absent. Colours—brownish along the back, becoming yellowish beneath: dorsal and caudal with dull spots.

Habitat.—Basgo on the head waters of the Indus.

30. Nemacheilus turio.

Cobitis turio, Ham. Buch. Fish. Ganges, pp. 358, 395; Cuv. and Val. xviii, p. 33; Bleeker, Beng. p. 70 Cobitis gibbosa, McClell. Ind. Cyp. pp. 304, 436, pl. 52, fig. 7 (from H. B.'s MS.) Cobitis arenata, Val. in Jacq. Voy. Ind. Poiss. pl. 15, fig. 1; Cuv. and Val. xviii, p. 28; Bleeker, Beng.

p. 70.

Acoura argentata, Swainson, Fishes, ii, p. 310. Nemachilus turio, Günther, Catal. vii, p. 360. Turi, Assam.

* The first fishes brought me as types of N. griffithii, were examples of Genus Lepidocephalichthys, whereupon I suggested a transposition of labels had occurred: a month subsequently two others were produced as the real types and which I have considered such, as their lengths agreed with what had been asserted in the Catalogue.

B. iii, D. 8 (10?), P. 12, V. 8, A. 7, C. 19.

Length of head (according to figure) about 1/5, of caudal 1/5, height of body 1/5 of the total length. Eyes—of moderate size. Free portion of tail appears higher than long. Back elevated. Fins—dorsal commences midway between the end of the snout and the base of the caudal fin: pectoral nearly reaches the ventral. Caudal emarginate. Colours—body irregularly spotted and blotched.

Habitat.—Assam, said to have been taken at Goalpara.

31. Nemacheilus guttatus.

Cobitis guttata, McClell. Ind. Cyp. pp. 305, 438, pl. 52, fig. 5, 6; Cuv. and Val. xviii, p. 79; Bleeker, Beng. p. 70.

Nemachilus guttatus, Günther, Catal. vii, p. 360.

B. iii, D. 8.

This species is said to have only four barbels. Colours-light green with dark blotches. Habitat.—Joorhath in Upper Assam.

FAMILY, VI—CLUPEIDÆ, Cuvier.

Gill-openings usually very wide: pseudobranchiæ, when present, well developed. Abdomen mostly compressed, generally into a sharp edge, and usually serrated. Opercular pieces four. Eyes lateral, with or without adipose lids. Margin of the upper jaw formed mesially by the premaxillaries, laterally by the without adipose hids. Margin of the upper jaw formed mesially by the premaxillaries, laterally by the maxillaries, which are composed of three pieces not ossified together. Mouth may have a deep cleft, with small premaxillaries and the maxilla elongated, and either the upper or lower jaw projecting: or the mouth may be transverse. Barbels absent. Fin rays articulated. A single dorsal with a few or moderate number of weak rays: anal sometimes many-rayed. Scales on the body: as a rule none on the head. Lateral-line mostly absent. Stomach with a "cul de sac." Air-vessel more or less simple. Pyloric appendages, when present, numerous.

The herrings are well represented in the Seas of India, and are largely consumed by the native population. As a rule they are much more abundant along the Malabar than the Coromandel Coast. The oil Sardine (Clupea longiceps), comes in vast numbers more especially to Malabar, but is uncertain as to its movements, occasionally being absent for many consecutive years, as will be alluded to under the head of the species. The Hilsa fish (Clupea ilisha), at certain periods of the year ascends the larger rivers for the purpose of depositing its ova,* and is then captured in enormous quantities, its flesh being considered a great

delicacy.

Geographical distribution.—The herrings are found in most seas and many enter fresh waters.

SYNOPSIS OF GENERA.

First group—Engrauliformes.

Upper jaw prominent. Mouth with a very deep cleft. Premaxillaries small and united to the maxillaries, the latter being elongated. Eyes covered by skin.

1. Engraulis—No pectoral filaments. Extent of union between the gill-membranes short. Abdomen serrated, p. 624.

2. Coilia—Upper pectoral rays produced into free filaments. Abdomen serrated, p. 630.

Second group-Chatoessiformes.

Mouth transverse, narrow, nearly or quite inferior, with the upper jaw projecting over the lower. Eyes with free adipose lids. Abdomen serrated.

3. Chatoëssus. Fourth branchial arch with an accessory organ, p. 632.

Third group—Clupe Eformes.

Upper jaw not projecting. Eyes with free adipose lids. Abdomen serrated.

- 4. Clupea-Mouth antero-lateral. Teeth minute or absent. Abdominal servature commencing at the thorax or pectoral fins, p. 634.
- 5. Corica—Mouth antero-lateral. Teeth when present rudimentary. Abdominal serrature commencing behind the pectoral fins, p. 641.
 - 6. Pellona—Under jaw projecting and obtuse. Ventral fins present: anal elongated, p. 642.
 7. Opisthopterus—Similar to Pellona but destitute of ventral fins, p. 646.

 - 8. Raconda-Similar to Pellona but destitute of ventral and anal fins, p. 646.

Fourth group—Dussumieriæformes.

Mouth antero-lateral, the upper jaw not projecting. Eyes with free adipose lids. No osseous gular plates. Abdominal edge smooth.

- 9. Dussumieria—Dorsal opposite the ventral fin. Teeth small, but not deciduous, p. 647. 10. Spratelloides—Dorsal opposite the ventral fin. Teeth, if present, deciduous, p. 648.

Fifth group—ALBULÆFORMES.

Mouth inferior and of moderate width: upper jaw projecting. Teeth in jaws.

- 11. Albula—Branchiostegals numerous. Eyes with free adipose lids. Abdomen smooth and not serrated. Lateral-line distinct, p. 648.
- * Anadromous is a term employed for such as live for the most part of the year in the sea, where they attain maturity, but deposit their ova in fresh waters. Hind "on the fisheries of Canada."

Sixth group—Elopsæformes.

Mouth antero-lateral, lower jaw the longer. An osseous gular plate. Abdomen rounded and smooth.

12. Elops—Pseudobranchiæ well developed. Scales small, p. 649.

13. Megalops—Pseudobranchiæ rudimentary or absent. Scales large, p. 650.

Seventh group—CHANINÆFORMES.

Mouth anterior, transverse, small. Eyes subcutaneous. Teeth absent. Gill-membranes entirely united. Abdomen rounded and smooth.

14. Chanos. Scales small, p. 651.

First group—Engrauliformes.

Mouth with a very deep cleft: upper jaw prominent. Premaxillaries small and united to the maxillaries, the latter being elongated. Eyes covered by skin.

Genus 1—Engraulis, Cuvier.

Stolephorus, Lacépède: Thryssa and Telara, Cuvier: Setipinna, Swainson: Pterengraulis, Lycengraulis,

Lycothrissa and Heterothrissa, Günther.

Branchiostegals short and rather numerous. Gill-openings wide, the membrane connecting the two sides being short, thus leaving the isthmus uncovered. Body oblong or elongated, compressed, and serrated along the abdominal edge. Cleft of mouth lateral: snout conical: the upper jaw the longer maxillaries of varying length, but always long, having a membraneous attachment to the cheeks. Teeth small, sometimes of unequal size, usually present on the jaws, vomer palatine and pterygoid bones. The dorsal fin may be wholly or partially in advance of or entirely posterior to the origin of the anal: the upper pectoral rays may or may not be prolonged: anal with many or a moderate number of rays. Scales large or of moderate size.

SYNOPSIS OF SPECIES.

a. Dorsal fin in advance of that of the anal.

1. Engraulis Hamiltonii, D. 1+13, A. 40-41, L. l. 44, L. tr. 11-12. Height of body 41 in the total length. Snout slightly projecting. Maxilla nearly reaches base of pectoral fin. Black venules on shoulder. Seas of India to Malay Archipelago.

Engraulis Malabaricus, D. 1+14-15, A. 40-43, L. 1. 39-40, L. tr. 11-12. Height of body 3\frac{3}{4} in the total length. Snout slightly projecting. Maxilla reaches gill-opening. Venules on shoulder: pectoral fin sometimes black. Seas of India.

3. Engraulis mystax, D. 1+13-15, A. 35-38, L. l. 45, L. tr. 12. Height of body $4\frac{1}{2}$ to $4\frac{3}{4}$ in the total length. Snout projecting. Maxilla reaches base of pectoral fin. Venules on shoulder. Seas of India to Malay Archipelago.

4. Engraulis Kammalensis, D. 1+13-14, A. 34-38, L. l. 36-38, L. tr. 9-10. Height of body 4 in the total length. Snout projecting. Maxilla reaches gill-opening. Venules on shoulder. Seas of India.

5. Engraulis boelama, D. 14-16, A. 29-32, L. l. 41, L. tr. 8. Height of body 5 in the total length. Snout projecting very much. Maxilla reaches slightly behind mandibular joint. Bluish, becoming silvery

on the sides. Red Sea through those of India to Mysol and Manado.
6. Engraulis setirostris, D. 1 + 14-16, A. 34-38, L. l. 36-44, L. tr. 11. Height of body 41 to 5 in the total length. Snout very slightly projecting: angle of mouth below hind edge of eye. Maxilla reaches end of ventral fin. Greenish, with silvery sides. Red Sea, Seas of India to Malay Archipelago.

7. Engraulis Dussumieri, D. 1 + 13-15, A. 34-36, L. 1. 40-42, L. tr. 9. Height of body 4½ to 4½ in

the total length. Snout considerably projecting: angle of mouth far behind the hind edge of the eye. Maxilla reaches to ventral fin. Seas of India to the Malay Archipelago.

b. Dorsal fin partly or entirely above the anal.

8. Engraulis telara, D. 1+14-15, A. 70-80, L. l. 52, L. tr. 14. Height of body $4\frac{1}{2}$ in the total length. Snout slightly projecting. Maxilla reaches gill-opening. Upper pectoral ray elongated. Fresh and brackish waters of Bengal and Burma.

9. Engraulis breviceps, D. 1+17, A. 60-64, L. l. 54-56, L. tr. 14. Height of body 4 to $4\frac{1}{2}$ in the total length. Lower jaw slightly prominent. Maxilla reaches mandibular joint. Upper pectoral ray elongated.

Bay of Bengal to the Malay Archipelago.

10. Engraulis taty, D. 1 + 13-15, A. 51-57, L. 1. 42-46, L. tr. 12. Height of body 3\frac{3}{4} to 4 in the total length. Shout slightly projecting. Maxilla reaches gill-opening. Upper pectoral ray elongated. Seas

and estuaries of India to the Malay Archipelago.

11. Engraulis purava, D. 1+13, A. 45-47, L. 1. 46, L. tr. 12. Height of body $4\frac{1}{4}$ to $4\frac{1}{2}$ in the total length. Snout not projecting. Maxilla reaches base of pectoral fin. Seas and estuaries of India to the

Malay Archipelago.

12. Engraulis Commersonianus, D. 14-16, A. 19-21, L. 1. 38-40, L. tr. 8-9. Height of body 51 to 51 in the total length. Snout projecting considerably. Maxilla reaches gill-opening. A broad, silvery, lateral band. Seas of India to the Malay Archipelago.

13. Engraulis Indians, D. 15-16, A. 19, L. l. 40, L. tr. 8-9. Height of body 6 to 6½ in the total length. Snout projecting considerably. Maxilla enlarged and truncated opposite mandibular joint. A broad, silvery, lateral band. Seas and estuaries of India to the Malay Archipelago.

14. Engraulis tri, D. 1+14-15, A. 20-22, L. l. 38, L. tr. 8. Height of body 5 to 51 in the total length.

Snout projecting. Maxilla reaches gill opening. A silvery lateral band.

a. Origin of dorsal fin in advance of that of the anal.

1. Engraulis Hamiltonii, Plate CLVII, fig. 4.

Clupea, Russell, Fish. Vizag. ii, p. 72, and Poorawah, fig. 189.

Thryssa poorawah, Cuvier, Règne Anim.: Jerdon, M. J. L. and Sc. 1851, p. 145. Thryssa Hamiltonii, Gray and Hard. Ill. Ind. Zool.

Thryssa subspinosa, Swainson, Fishes, ii, p. 293; Jerdon, M. J. L. and Sc. 1851, p. 145.

Engraulis Grayi, Bleeker, Haring. p. 41, and Ich. Riouw, p. 492; Kner, Novara Fische, p. 333.

Engraulis Hamiltonii, Cuv. and Val. xxi, p. 66; Bleeker, Beng. p. 74; Day, Fish. Malabar, p. 239; Günther, Čatal. vii, p. 395.

Stolephorus Hamiltoni, Bleeker, Ceram, p. 261, and Atl. Ich. vi, t. 259, f. 5.

Engraulis poorawah, Bleeker, Atl. Ich. vi, p. 132.

B. xii, D $1+13(\frac{2}{11})$, P. 12, V. 7, A. 40-41 $(\frac{2}{37^2},\frac{2}{30})$, C. 19, L. l. 44, L. tr. 11-12.

Length of head $5\frac{1}{4}$ to $5\frac{1}{2}$, of caudal $5\frac{1}{4}$, height of body $4\frac{1}{4}$ in the total length. Eyes—subcutaneous, $4\frac{1}{4}$ diameters in the length of the head, 3/4 of a diameter from the end of snout, and 1 apart. Snout slightly in advance of the end of the lower jaw: the maxilla enlarged opposite the mandibular joint and nearly reaching the base of the pectoral fin: opercle rather more than twice as high as wide. Teeth—fine ones in jaws, vomer, palate and on the tongue. Fins—dorsal commences about midway between the end of the snout and the base of the caudal fin, which latter has the lower lobe somewhat the longer. Pectoral reaches to above the middle of the small ventrals. Anal commences behind the vertical from the last dorsal ray. Scales—scutes strong, anterior to the ventral there are 16, and 10 posterior to it. Gill-rakers—about 13 along the horizontal limb of the outer branchial arch: they are nearly as long as the eye. Pseudobranchiæ rudimentary. Colours—bronze along the back, which in the fresh state is divided by a silvery band from the purple and gold tinted abdomen. Black venules on the shoulder behind the upper half of the opercle. Fins yellow, dorsal sometimes edged with black.

Habitat.—Sind, through seas of India to the Malay Archipelago.

2. Engraulis Malabaricus, Plate CLVII, fig. 5.

Clupea Malabarica, Bloch, plate 432.

Clupea, Russell, Fish. Vizag. ii, p. 75, and Poorwa, fig. 194.

Thryssa Cuvieri and Malabaricus, Swainson, Fishes, ii, p. 293.

Monangoo, Mal.: Poor-relan, Tam.

B. xii, D. $1 + 14.15(\frac{2-3}{12})$, P. 14, V. 7, A. $40.43(\frac{2-3}{3-3-40})$, C. 20, L. 1. 39-40, L. tr. 11-12.

Length of head 5, of caudal $5\frac{1}{2}$, height of body $3\frac{3}{4}$ in the total length. Eyes—subcutaneous, diameter $4\frac{1}{2}$ in the length of head, 3/4 of a diameter from end of snout, and $1\frac{1}{4}$ apart. Snout slightly in advance of the lower jaw. Maxilla dilated above the mandibular joint, it extends posteriorly to the gill-opening. Teeth—fine ones in the jaws and on the palate. Fins—dorsal commences rather nearer to the snout than to the base of the caudal fin. Anal commences behind the vertical from the last dorsal ray. Pectoral reaches the base of the ventral. Scales—regularly arranged: 17 scutes before and 9 or 10 behind the base of the ventral fin. Gill-rakers about 1/2 the length of the eye, from 21 to 25 on the horizontal branch of the outer branchial arch. Pseudobranchiæ rudimentary. Colours—silvery shot with gold and purple: black venules on the shoulder, fins yellow: dorsal and end of caudal edged with dark. Pectoral sometimes, but not usually, black. Habitat.—Coasts of Sind and through the seas of India.

3. Engraulis mystax, Plate CLVII, fig. 3.

Clupea mystax, Bloch, Schneider, p. 426, t. 83. Thryssa mystax, Cuv. Règne Anim.; Richards. Ich. China, p. 309.

Engraulis mystax, Cuv. and Val. xxi, p. 67; Bleeker, Beng. p. 74, and Atl. Ich. vi, p. 132, t. 261, f. 2 (not Haring. p. 43); Cantor, Catal. Mal. Fish. p. 307.

Thryssa porava, Bleeker, Madura, p. 14.

Engraulis mystacoides, Bleeker, Haring. p. 42; Günther, Catal. vii, p. 396. Engraulis Hamiltoni, Kner, Novara Fische, p. 334. Stolephorus (Thyssa) mystax, Bleeker, Atl. Ich. vi, t. 261.

B. xii-xiv, D. $1+13-15(\frac{3}{10},\frac{3}{12})$, P. 12, V. 7, A. $35-38(\frac{2}{3},\frac{3}{3},\frac{3}{3})$, C. 19, L. l. 45, L. tr. 12

Length of head 5, of caudal $5\frac{1}{2}$, height of body $4\frac{1}{2}$ to $4\frac{3}{4}$ in the total length. Eyes—subcutaneous, diameter $4\frac{1}{4}$ in the length of head, 1 diameter from end of snout, and $1\frac{1}{4}$ apart. Snout projecting: the diameter $4\frac{1}{4}$ in the length of head, I diameter from end of snout, and $1\frac{1}{4}$ apart. Snout projecting: the maxilla enlarged opposite the mandibular joint, it extends backwards to opposite the base of the pectoral fin. Opercle twice as high as wide. Fins—dorsal commences midway between the snout or anterior end of the orbit and the base of the caudal, which latter has the lower lobe usually the longer: anal commences just posterior to the last dorsal ray: pectoral extends to the last third of the small ventrals. Scales—nine strong scutes behind the ventral fin and 16 or 17 weaker ones before it. Gill-rakers as long as the eye, 13 on the horizontal limb of the outer branchial arch, 2/3 as long as the eye. Pseudobranchiæ rudimentary. Colours black venules over the scapular region, the dorsal and caudal yellow, the latter having a black upper and posterior end, at least in the young.

Bleeker observes that Engranlis Hamiltonii, Cuv. and Val. xxi, p. 66=Bleeker, Haring, p. 43, and E. Valenciennesi, Atl. Ich. p. 133 and Stolephorus (Thryssa) Valenciennesi, Atl. Ich. t. 260, f. 6, is not this species: having a more squat body, L. l. 35-36, L. tr. 11-12.

Habitat.—Seas and estuaries of India to the Malay Archipelago and China.

4. Engraulis Kammalensis, Plate CLVII, fig. 1.

Bleeker, Ich. Madura, p. 13, and Atl. Ich. vi, p. 131.

Engraulis rhinorhynchus, Bleeker, Haring, p. 40, and Borneo, p. 434; Kner, Novara Fische, p. 334; Günther, Catal. vii, p. 394; Day, Proc. Zool. Soc. 1869, p. 384.

Stolephorus (Thryssa) Kammalensis, Blecker, Atl. Ich. t. 265, f. 2.

B. x-xi, D. $1+13-14(\frac{1}{10}-\frac{1}{11})$ P. 12, V. 7, A. $34-38(\frac{1}{31}-\frac{1}{35})$, C. 19, L. 1. 36-38, L. tr. 9-10.

Length of head $4\frac{1}{2}$, of caudal 5, height of body 4 in the total length. Eyes—subcutaneous, diameter 4 in the length of head, I diameter from the end of snout and also apart. Snout projecting beyond the lower jaw, which latter anteriorly reaches to below the front edge of the eye. Maxilla enlarged opposite the angle of the mouth, and extending posteriorly to opposite the gill-opening. Teeth—fine in jaws, vomer, and palate. Fins—dorsal commences rather nearer the base of the caudal than the end of the snout, or else midway between those points. Pectoral reaches to opposite the end of the small ventral, which is inserted rather in advance of the origin of the dorsal; anal commences a short distance behind the last dorsal ray. Scalesfourteen scutes before and eight behind the base of the ventral fin. Gill-rakers—twenty-two on the horizontal branch of the outer branchial arch. Pseudobranchiæ rudimentary. Colours—silvery, tinged with gold: the upper portion of the head, dorsal, and caudal fins yellowish, with numerous fine black dots. Dark venules on the shoulder extending indistinctly over the back.

Habitat.—Ceylon, Bay of Bengal to the Malay Archipelago, attaining about six inches in length. The

example figured (life size) was from Orissa.

5. Engraulis boelama, Plate CLVIII, fig. 7.

Clupea boelama, Forsk. Descr. Anim. p. 72; Bl. Sehn. p. 429.

Engraulis nesogallicus, Bennett, Proc. Zool. Soc. i, 1831, p. 168.

Engraulis boelama, Cuv. and Val. xxi, p. 35; Günther, Catal. vii, p. 393, Fish. Zanz. p. 123, Proc. Zool. Soc. 1871, p. 671; Bleeker, Atl. Ich. vi, p. 130; Klunz. Verh. z. b. Ges. Wien. 1871, p. 597.

Stolephorus boelama, Bleeker, Amb. p. 291, and Atl. Ich. vi, t. 260, f. 1.

B. xi, D. $14-16(\frac{2}{12},\frac{2}{13})$, P. 13, V. 7, A. $29-32(\frac{2}{27},\frac{2}{29})$, C. 20, L. l. 41, L. tr. 8.

Length of head $4\frac{1}{2}$, of caudal $5\frac{1}{2}$, height of body 5 in the total length. Eyes—subcutaneous, diameter 1/4 of length of head, nearly 1 diameter from the end of snout, and 1 apart. Greatest height of the head equals its length excluding the snout. Snout compressed, pointed, and projecting considerably beyond the end of the jaws. Maxilla obliquely truncated posteriorly and reaching slightly beyond the mandibular joint. Teeth—small, equal in both jaws: a small patch on vomer: a single band on palate. Fins—origin of dorsal nearer the end of the snout than the base of the caudal: anal commences a short distance behind the last dorsal ray. Pectoral nearly reaches the ventral, which is inserted below the anterior dorsal rays. Scales—regularly arranged, scutes very indistinct, not extending above 1/2 way between base of the pectoral and ventral fins, 4 or 5 being before and 8 or 9 behind the base of that fin. Gill-rakers fine, closely set, about 21 or 22 on the outer branch of the lower branchial arch, they are nearly as long as the eye. Colours-bluish above, becoming silvery on the sides and beneath: head glossed with gold.

It is observed in Cuv. and Val. that its flesh is poisonous (not only to men but to the lower animals), if prepared previous to removing the head and intestines.

Habitat.—From the Red sea and coast of Zanzibar through the seas of India to the Andamans, also recorded by Günther from Mysol and Manado. The example, figured life-size, was from Port Blair.

6. Engraulis setirostris.

Clupea setirostris, Brouss. Ich. Dec. i, tab.; Bonn. Ich. p. 186, t. 76, f. 316; Gmel. Linn. p. 1407; Bl. Schn. p. 428; Russell, Fish, Vizag. ii, p. 80, and Yeka-poorawah, fig. 201; Lacépède, Poissons, v, p. 425

Thryssa sctirostris, Cuvier, Règn. Anim.

Clupea mystacina, Forst. Desc. Anim. Ed. Licht. p. 295.

Engraulis setirostris, Cuv. and Val. xxi, p. 69; Bleeker, Beng. p. 74, Haring. p. 44, and Atl. Ich. vi, p. 134; Günther, Catal. vii, p. 397.

Thryssa macrognathus, Bleeker, Madura, p. 14.

Stolephorus setirostris, Bleeker, Amb. p. 291, and Atl. Ich. t. 261, f. 1.

B. x-xi, D. $1+14-16(\frac{3}{11},\frac{3}{13})$, P. 14, V. 6, A. $34-38(\frac{3}{31},\frac{3}{33})$, C. 17, L. l. 36-44, L. tr. 11.

Length of head $5\frac{3}{4}$ to $6\frac{1}{2}$, of caudal 5, height of body $4\frac{1}{4}$ to 5 in the total length. Eyes—diameter $3\frac{1}{4}$ to 4 in length of head, 1/2 a diameter from end of snout, and 1 apart. Snout hardly projecting. The angle of the mouth is beneath the hind edge of the eye. The maxillary very prolonged, extending to the posterior end of the ventral fin or even beyond. Teeth—fine in jaws, present also on tongue, vomer, palatines and pterygoids. Fins—origin of dorsal midway between end of snout and base of caudal fin: the anal commences just posterior to the last dorsal ray. Abdominal edge spinate: 17 spines before and 9 behind the insertion of the ventral fin. Gill-rakers 10 on the horizontal limb of the outer branchial arch. Colours—greenish along the back, becoming silvery on the sides and beneath. Black venules in the region of the scapula.

Habitat.—From the Red Sca through the seas of India to the Malay Archipelago.

7. Engraulis Dussumieri, Plate CLVIII, fig. 4.

Cuv. and Val. xxi, p. 69; Bleeker, Haring. p. 43, Atl. Ich. vi, p. 133, and Stolephorus Dussumieri, t. 260, f. 2; Kner, Novara Fische, p. 333.

Engraulis Hamiltoni, Cuv. and Val. xxi, p. 66 (not Gray and Hardwicke).

Engraulis auratus, Day, Fish. Malabar, p. 238, pl. xix, f. 2.

Engraulis mystax, Günther, Catal. vii, p. 397 (not Bl. Schn.)

B. xii, D. $1+13-15(\frac{2-3}{11-12})$, P. 12, V. 7, A. $34-36(\frac{3}{31-33})$, C. 17, L. l. 40-42, L. tr. 9-10.

Length of head $4\frac{1}{3}$ to $4\frac{2}{3}$, of caudal 5 to $5\frac{1}{2}$, height of body $4\frac{1}{4}$ to $4\frac{1}{2}$ in the total length. Eyes—subcutaneous, diameter 4 in the length of the head, 2/3 of a diameter from the end of snout and 1 apart. The snout projects considerably over the mouth: the angle of the mouth is far behind the posterior margin of the orbit. The maxilla dilated opposite the mandibular joint, clongated posteriorly and almost or quite reaching the ventral fin. Teeth—fine ones in the jaws. Fins—dorsal commences rather nearer snout than the base of caudal fin, it is situated entirely in advance of anal, which commences a short way behind it. Pectoral as long as head without the snout. Ventral inserted slightly in advance of the vertical from the origin of the dorsal. Caudal forked, lower lobe the longer. 7 to 8 strong spines behind the ventral fin and 13 to 14 anterior to it. Pseudobranchiæ rudimentary. Colours—coppery, becoming silvery below, a large black shoulder spot passing over the back: caudal straw-coloured with a dark extremity.

Habitat.—Seas of India to the Malay Archipelago. The example figured (life-size) was from Madras.

b. Dorsal fin partly or entirely above the anal.

8. Engraulis telara, Plate CLVIII, fig. 2.

Clupea telara and phasa, Ham. Buch. Fish. Ganges, pp. 240, 241, 382, pl. 2, f. 72.

Engraulis brevijilis, telara and phasa, Cuv. and Val. xxi, pp. 54, 56, 59, pl. 608: Bleeker, Beng. en Hind. pp. 74, 147.

Setipinna truncata and megalura, Swainson, Fishes, ii, p. 292.

Engraulis telara, Günther, Catal. vii, p. 401.

B. xii-xiii, D. $1 + 14 \cdot 15(\frac{2-3}{12})$, P. 15, V. 7, A. $70 \cdot 80(\frac{2}{68}, \frac{2}{78})$, C. 19, L. 1. 52, L. tr. 14.

Length of head 6 to 7, of caudal 6 to $6\frac{1}{2}$, height of body $4\frac{1}{2}$ in the total length. Eyes—subcutaneous, diameter $4\frac{1}{2}$ in the length of head, 3/4 of a diameter from end of shout and $1\frac{1}{2}$ apart. Abdominal profile more prominent than the dorsal, snout slightly overhanging the mouth: the maxilla extends to opposite the gillopening, it is enlarged above the mandibulary joint, from whence it is cut straight to its pointed extremity. Opercle twice as high as wide. Teeth—fine in both jaws, rather larger in the palate: and some fine ones on the Fins—origin of dorsal slightly posterior to that of the anal, much nearer snout than the base of the caudal fin. Pectoral with its superior ray elongated to opposite the centre of anal fin (in some examples this ray is only slightly produced), whilst the fin itself extends as far as to opposite the posterior end of the ventral: lower caudal lobe the longer, the upper being truncated; the length of the base of the anal fin is considerably more than 1/2 the distance from the end of the snout to the caudal fin. Scales—very deciduous, some over the base of the anal and dorsal fins: seven spinate scales behind the ventral and 15 or 16 anterior to it. Pseudobranchiæ rudimentary. Gill-rakers rather longer than the eye. Colours—greenish along back, becoming silvery dashed with gold along the abdomen, dorsal and caudal yellow, with the upper lobe of the caudal and the upper margin of the dorsal stained with black: pectoral in the young yellowish, but in the adult of a deep blue-black except the elongated ray which is usually uncoloured in its posterior three-fourths: ventral and anal also uncoloured.

Habitat.—Orissa, Bengal, Cachar and Burma, in which latter country I have taken is as high up as Mandalay. It attains at least 16 inches in length. The example figured (life-size) was from Calcutta.

9. Engraulis breviceps.

Cantor, Catal. Mal. Fish. p. 306; Günther, Catal. vii, p. 401. Engraulis Pfeifferi, Bleeker, Borneo, p. 433. Setipinna breviceps, Bleeker, Atl. Ich. vi, p. 157. Stolephorus (Setipinna) Pfeifferi, Bleeker, l. c. t. 263, f. 3.

B. xvi-xix, D. $1 + 17(\frac{3}{14})$, P. 14, V. 7, A. $60-64(\frac{3}{57-61})$, C. 17, L. l. 54-56, L. tr. 14.

Length of head 7 to $7\frac{2}{5}$, of caudal fin 5 to 6, height of body 4 to $4\frac{1}{2}$ in the total length. Eyes—diameter $5\frac{1}{2}$ to 6 in the length of the head, 3/4 of a diameter from end of snout, and 1 to $1\frac{1}{2}$ apart. Lower jaw slightly the longer: maxilla truncated opposite the mandibular joint. Opercle high and narrow. Teeth—small ones in the investment of the same of the sam in the jaws, tongue, and palate. Fins—dorsal commences about midway between the snout and base of the caudal fin. Pectoral with its upper ray prolonged. Anal commences somewhat in advance of the dorsal, the length of its base being equal to half the total length excluding the caudal fin. Scales—the whole of the abdominal edge serrated. Gill-rakers widely set and longer than the eye: 11 on the lower branch of the outer branchial arch. Colours—greenish-yellow on the back, becoming silvery on the sides and beneath: the body with some dark blotches in its upper half. Fins yellow, the dorsal, caudal, and last half of the anal having dark margins.

Habitat.—Bay of Bengal to the Malay Archipelago.

10. Engraulis taty, Plate CLVIII, fig. 5.

Cuv. and Val. xxi, p. 60; Cantor, Catal. p. 306; Bleeker, Haring. p. 35 and Beng. p. 74; Day, Fish. Malabar, p. 240: Günther, Catal. vii, p. 400.

Engraulis tenuifilis, Cuv. and Val. xxi, p. 62.

Engraulis telaroides, Bleeker, Madura, p. 13. Sctipinna taty, Bleeker, Atl. Ich. vi, p. 136. Stolephorus taty, Bleeker, Atl. Ich. vi, t. 260, f. 7.

B. xi-xii, D. $1 + 13-15(\frac{3}{10}-\frac{3}{12})$, P. 15, V. 7, A. $51-57(\frac{3}{48-34})$, C. 19, L. l. 42-46, L. tr. 12.

Length of head 6 to $6\frac{1}{2}$ ($5\frac{1}{3}$ in the very young), of caudal $5\frac{1}{4}$, height of body $3\frac{3}{4}$ to 4 in the total length. Eyes—subcutaneous, diameter 4 in the length of head, 1/2 to 2/3 of a diameter from the end of snout, and $1\frac{1}{2}$ apart. Snout projecting over the lower jaw: the maxilla extends backwards beyond the mandibular joint where it is dilated, posteriorly it is truncated. Teeth—fine in the jaws, a few villiform ones on the vomer, and numerous on the palatines and pterygoids. Fins—dorsal arises nearer the snout or midway between it and the root of the caudal, the anal is nearly half as long as the total length excluding the caudal fin, it begins below the middle of the dorsal: first pectoral ray having (but not invariably) a long filamentous ending: caudal lobed, the lower the longer. Scales - twelve scutes posterior to the base of the ventral fin and about 23 anterior to it. Gill-rakers lanceolate and rather widely set. Colours—upper surface of head and back green, or greenish-yellow, sparingly dotted with black: sides, abdomen, cheeks, and opercles silvery: dorsal, caudal, and anal yellow, some black dots on dorsal: ventrals and pectorals yellowish, the latter sometimes dark: the edges and posterior margins of the caudal blackish. Iris silvery, supraorbital half bluish-black.

I have seen an example from Bombay with some black blotches on it.

Habitat.—Seas and estuaries of India and the Malay Archipelago. It attains at least six inches in length and is eaten either fresh or salted. The example figured (life-size) was from Orissa.

11. Engraulis purava, Plate CLVII, fig. 2.

Clupea, Russell, Fish. Vizag. ii, p. 73, and Peddah-poorawah, pl. 190.

Clupea purava, Ham. Buch. Fish. Ganges, pp. 238, 382.

Thryssa megastoma, Swainson, Fishes, ii, p. 293.

Pussai and Tampara, Ooriah.

B. xii, D. $1 + 13(\frac{3}{10})$, P. 15, V. 6, A. $45-47(\frac{9}{43-40})$, L. l. 46, L. tr. 12.

Length of head $5\frac{3}{4}$ to 6, of caudal $5\frac{3}{4}$ to 6, height of body $4\frac{1}{4}$ to $4\frac{1}{2}$ in the total length. Eyes—subcutaneous, diameter $4\frac{1}{2}$ to 5 in the length of the head, 3/4 of a diameter from end of snout and 1 apart. Snout slightly elevated and rather projecting (in adults) beyond the extremity of the lower jaw. Smooth portion of the opercle rather above twice as high as wide, and oblique in its direction. The maxilla rather dilated opposite the mandibular joint and gradually decreasing in width, it reaches nearly to the base of the pectoral fin. Teeth—fine ones in both jaws. Fins—the dorsal commences midway between the snout and the base of the caudal fin, or rather nearer the latter in some examples. Pectoral reaches the ventral which does not extend half way to the base of the anal. Anal commences beneath the posterior dorsal rays. Caudal forked. Scales in regular horizontal lines, with a fine row at the base of the dorsal and anal fins: there are 15 or 16 spinate scales between the throat and the base of the ventral fin, and 10 or 11 between the ventral and the base of the anal. Colours—silvery, steel-blue along the back and a golden tinge about the head: dorsal and caudal fins yellowish, the others uncoloured. Gill-rakers-lanceolate, rather widely set, and the largest are about as long

Habitat.—Seas and estuaries of Sind, both sides of India, also the Malay Archipelago. It attains at least 12 inches in length.

12. Engraulis Commersonianus, Plate CLVIII, fig. 1.

Stolephorus Brownii, Bleeker, Amboina, p. 291.

Engraulis Commersonianus, Günther, Catal. vii, p. 388.

B. xi-xiii, D. 14-16($\frac{2}{12^{2}+4}$), P. 15-16, V. 7, A. 19-21($\frac{2}{17^{2}+19}$), C. 19, L. l. 38-40, L. tr. 8-9, Cec. pyl. 16.

Length of head 5 to $5\frac{1}{4}$, of candal $5\frac{1}{4}$ to $5\frac{1}{2}$, height of body $5\frac{1}{4}$ to $5\frac{3}{4}$ in the total length. Eyes—subcutaneous, $3\frac{1}{2}$ diameters in the length of the head, 1/2 to 2/3 of a diameter from end of snout, and nearly 1 apart. Snout pointed, projecting considerably beyond, and overlanging the mouth. The maxilla moderately dilated opposite the mandibular joint and continued to the gill-opening. Height of the head 1/4 less than its length. Teeth—fine ones in the jaws, vomer, and palate. Fins—dorsal commences nearer the base of the caudal than to the front end of the snowt, and posterior to the insertion of the ventral: the anal commences below the middle of the dorsal. Scales—very decidnous. Pseudobranchiæ well-developed. Colours—silvery, greenish above, opercles shining silvery shot with gold. A large black spot, sometimes indistinct, just behind the occiput. A broad silvery band passes from the centre of the posterior margin of the opercle to the centre of the caudal, becoming widest posteriorly. Abdomen light buff-colour. Fins yellowish, with minute black dots.

Eyes silvery, orbital margin dark. Caudal shot with bluish.

Habitat.—Seas of India to the Malay Archipelago. It attains to about 8 inches in length, and is much esteemed for cating. It is known as whitebait amongst Europeans, and is captured in India in great numbers. In the Straits Cantor states that large quantities of them are preserved for exportation to China and India, as well as for home consumption, forming a delicious condiment known under the designation of "Red-fish." The following is the mode of preparation:—"After the heads have been removed, the fishes, (those of middling size are preferred) are cleansed, salted (in the proportion of one to eight parts of fish) and deposited in flat glazed earthen vessels. In the latter they are for three days submitted to pressure, by means of stones placed on thin boards or dried plantain leaves. The fishes are next freed from salt, and saturated with vinegar and cocoa-palm toddy, after which are added powdered ginger and black pepper (the latter mostly entire), and some brandy and powdered "red rice." After having been kept for three days, a little more vinegar is added before placing the fishes in well closed jars or bottles. They should be kept four or five months before being used."—Cautor, p. 305. "Red rice is a variety of Oryza sativa called glutinosa, steeped in an infusion of cochineal."

13. Engraulis Indicus, Plate CLVIII, fig. 3.

Clupea atherinoides, Russell, Fish. Vizag. ii, p. 71, and Nattoo, pl. 187 (not Linn.)

Stolephorus Russellii, Bleeker, Ternate, p. 236

Stolephorus Indicus. Bleeker, Atl. Ich. vi, p. 127, t. 259, f. 2.

Nattoo, Tel.: Nettellee, Tam.: Zoo-roo-cart-dah, Andam.

B. xi-xiii, D. $15-16(\frac{1}{16}s_{13})$, P. 15, V. 7, A. $19(\frac{5}{16})$, C. 19, L. l. 40, L. tr. 8-9.

Length of head $4\frac{2}{3}$ to 5, of caudal $5\frac{3}{4}$ to 6, height of body 6 to $6\frac{1}{2}$ in the total length. Eyes—subcutaneous, diameter $3\frac{1}{2}$ in the length of the head, 2 3 to 3 4 of a diameter from end of snout, and 1 apart. Body moderately compressed, the dorsal and abdominal profiles, equally and slightly convex. The greatest height of the head equals its length excluding the snort. Snort pointed and projecting considerably beyond the jaws. Maxilla enlarged and truncated opposite the mandibular joint. Teeth—small in the jaws, tongue, and palate. Fins—dorsal commences nearer the base of the caudal fin than to the end of the snout, its first half in advance of the origin of the anal. Scales-very deciduous; 4 scutes before the base of the ventral fin. Pseudobranchiæ present. Gill-rakers closely set, not so long as the eye. Colours-silvery, dashed with green along the back, and sometimes some dark spots behind the occiput. A brilliant silvery band passes from opposite the upper edge of the eye to the middle of the caudal fin.

Habitat. - Seas of India to the Malay Archipelago. It ascends tidal rivers.

14. Engraulis tri, Plate CLVIII, fig. 6.

Blecker, Haring. p. 40 and Borneo, p. 455; Günther, Catal. vii, p. 389. Stolephorus tri, Bleeker, Atl. Ich. vi, p. 128, t. 262, f. 1.

B. xi, D. $1 + 14 \cdot 15(\frac{2}{12 \cdot 13})$, P. 13, V. 7, A. $20 \cdot 22(\frac{3}{17 \cdot 19})$, C. 17, L. 1. 38, L. tr. 8.

Length of head 5 to $5\frac{1}{4}$, of caudal $5\frac{1}{4}$, height of body 5 to $5\frac{1}{4}$ in the total length. Eyes—subcutaneous, diameter $3\frac{1}{2}$ in the length of the head, 1/2 to 3/4 of a diameter from the end of snout and 1 apart. Body compressed, the abdominal profile more convex than the dorsal. The greatest height of the head equals its length excluding the snout. Snout pointed and projecting considerably beyond the jaws. Maxilla enlarged opposite the mandibular joint, pointed posteriorly and reaching to the gill-opening. Teeth—present on jaws, vomer, palatines, and pterygoids. Fins—dorsal commences between the front edge of the eye and the base of the caudal fin. Ventral inserted on a line anterior to the origin of the dorsal. Anal commences under the middle of the dorsal. middle of the dorsal. Scales—regularly arranged and not very deciduous. Scutes, 4 long slender ones before the ventral fin. Gill-rakers, the longest not quite so long as the eye, about 25 in the horizontal branch of the outer branchial arch. Colours—silvery shot with purple: a silvery band passes from opposite the eye to the base of the caudal fin: a dark spot behind occiput.

Bleeker observes that this species has 32 to 35 scales along the lateral-line.

Habitat.—From Bombay through the seas and estuaries of India to the Malay Archipelago. It ascends the Hooghly as high as Calcutta. It attains about 4 inches in length.

Genus, 2—Coilia, Gray.

Mystus, Lacép.; Trichosoma, Swains.; Chætomus, McLelland; Collia, Schleg.; Leptonurus, Bleeker.

Branchiostegals nine to eleven. Body elongated, compressed and tapering to a pointed tail: abdomen trenchant and serrated. Snout pointed and projecting. Mouth cleft to behind the eye: the maxilla produced posteriorly. Teeth on the jaws, vomer, palatine, and pterygoid bones, also on the tongue. A single rather short dorsal fin placed in the anterior portion of the back: anal elongated and confluent with the caudal: some of the appearance produced into produce the state of medicate or enables. upper pectoral rays produced into moderately thick filaments. Scales of moderate or small size.

In an example of a species (C. Dussumieri) of this genus captured in Orissa, a portion of the tail has been lost and a new caudal fin has sprung from the excised end: it is nearly twice as long as seen in normal examples.

A.—The maxilla does not extend posteriorly beyond the head.

1. Coilia Reynaldi, P. 5-6 + xii, A. 116, L. 1. 55. Pectoral fin short: free rays long: some spines before ventral fin: no spots on body. Bengal.

2. Coilia ramcarati, P. 6 + vi, A. 95-110, L. 1. 70. Pectoral fin short: free rays long: five spines before ventral fin: no spots on body. Bengal.

3. Coilia Cantoris, P. 6 + vi, A. 75, L. 1. 58. Pectoral fin short: free rays long: five spines before ventral fin: no spots on body. Bengal.

4. Coilia quadragesimalis, P. 6+vi, A. 42. Pectoral fin short: free rays long: no spots on body. Bengal.

B.—The maxilla does extend posteriorly beyond the head.

5. Coilia Dussumieri, P. 9+v-vi, A. 105. Pectoral fin nearly as long as head: upper rays long: five

or six spines before ventral fin: two or three rows of round yellow spots. India to the Malay Archipelago.
6. Coilia Borneensis, P. 6 + ix-xii, A. 77-95. Pectoral fin short: free rays long: five spines before ventral fin: no spots. Seas and estuaries of India to the Malay Archipelago.

1. Coilia Revnaldi.

Coilia Reynaldi, Cuv. and Val. xxi, p. 81; Bleeker, Beng. p. 74, and Atl. Ich. vi, p. 141, t. 266, f. 1. B. ix, D 1 + 14($\frac{3}{11}$), P. 5-6 + 12, V. 6, A. 116, C. 10, L. 1. 55, L. tr. 10-11.

Length of head 7, of caudal fin $9\frac{1}{2}$, height of body 6 in the total length. Eyes—diameter 1/4 of length of head, 1 diameter from end of snout, and $1\frac{1}{2}$ apart. The distance from the end of the snout to the anal fin is less than 1/3 of the total length: the maxilla extends nearly to the end of the opercles, close to the origin of the pectoral fin. Snout overhanging the upper jaw, which last is longer than the mandibles. Teeth-fine in both jaws. Fins—the dorsal commences in the first fourth of the total length: the anal under or slightly beyond the posterior margin of the dorsal. Dorsal with a spine a very little distance anterior to the fin. Pectoral short, with the upper rays prolonged nearly to the middle of the body. Anal longer than in C. ramcarati, continuous with the caudal. Scales—twelve sharp spines exist along the abdominal edge, which is serrated in front of the ventrals. Colours—silvery-white, with pinkish reflections.

Habitat.—The Hooghly at Calcutta.

2. Coilia ramcarati, Plate CLIX, fig. 2.

Mystus ramcarati, Ham. Buchanan, Fish. Ganges, pp. 233; Gray, Zool. Mis. p. 9; McClelland, Calc. Journ. Nat. Hist. iv, p. 406.

Engraulis (coilia) Hamiltonii, Gray and Hard. Ill. Ind. Zool. (from H.B.'s MSS.)

Ramcarati coilia, Gray, Zool. Mis. p. 9.
Coilia Hamiltoni, Gray, l. c.; Cuv. and Val. xxi, p. 79; Bleeker, Beng. p. 74.
Chatomus Hamiltonii, McClelland, Calcutta J. N. History, iv, p. 406.
Trichosoma Hamiltonii, Swainson, Fishes, ii, p. 292.
Coilia ramcarati, Günther, Catal. vii, p. 402.

B. xi, D. $1 + 14(\frac{2}{12})$, P. 6 + vi, V. 12, A. 95-110, L. l. 70, L. tr. 9-10.

Length of head 6, of caudal 10 to 11, height of body 51/4 in the total length. Eyes—subcutaneous, diameter 5 in the length of the head, 3/4 of a diameter from the end of snout, and 1½ apart. Maxilla dilated above the mandibular joint, behind which it is truncated. Snout somewhat projecting beyond the mouth. The distance between the snout and dorsal fin is 1/4 of the total length. Teeth—fine and rather widely set in jaws, also on palate. Fins—the six lower pectoral rays are very short and almost concealed in a scaly sheath, the free ones reach to about the middle of the length of the fish. Ventral as long as the postorbital length of the head and inserted slightly before the front edge of the dorsal. The length of the base of the anal is about 1/3 of the distance between the gill-opening and base of the caudal fin, the upper ray of the latter fin being the longest. Scales—five spinate ones anterior, and 10 or 11 posterior to the base of the ventral fin. Gill-rakers rather fine and closely set, about 28 in the horizontal branch of the outer branchial arch. Pseudobranchia present. Colours—generally golden, with a darkish stain behind the gill-opening: the last half of the anal and the whole of the caudal blackish: no golden spots on the body.

In the Catalogue of Fishes of British Museum it is erroneously observed that the abdomen is not serrated in front of the ventral fin, it should be pectoral as I have convinced myself by examining the specimens in the British Museum. This is also shown in H. Buchanan's figure, of which a copy exists in Gray and Hardwicke, l. c.

Habitat.—Rivers and estuaries of Bengal.

3. Coilia Cantoris.

Bleeker, Beng. pp. 74 and 148.

B. ix, D. $1 + 13(\frac{9}{10})$, P. 6 + vi, V. 7, A. 75, C. 10, L. l. 58.

Length of head 6, of caudal fin $8\frac{1}{4}$, height of body $6\frac{1}{3}$ in the total length. Snout pointed and projecting beyond the mouth. Eyes—diameter $4\frac{1}{2}$ in the length of the head, 2/3 of a diameter from the end of snout. The maxilla obliquely truncated and not extending to the branchial aperture. Teeth—in jaws, small and equal. Fins—dorsal commencing in the second fourth of the length of the body. Pectoral rays short, the free ones not reaching so far as to the anal fin: ventral not half so long as the head. Length of the base of the anal rather above 1/2 that of the total length. Scales—five spines on the abdominal edge before the ventral fin and 10 behind it. Colours—without marks.

Habitat.—One young example nearly 4 inches long was captured in the Hooghly. The above description is from the type.

4. Coilia quadragesimalis.

Cuvier and Val. xxi, p. 83; Bleeker, Bengal, p. 74; Günther, Catal. vii, p. 404.

B. x, D. 15, P. 6 + vi, V. 8, A. 42, C. 25.

Height of body $4\frac{3}{4}$ in the total length. Eye—small. Mouth obtuse: the maxilla truncated and does not extend posteriorly behind the angle of the jaw. Teeth—small, those on the vomer very distinct. Fins—dorsal inserted at the posterior end of the first third of the length of the body. Pectoral short, its 6 free rays equal 1/2 the total length. The anal commences a little before the middle of the total length. Colours—silvery shot with gold and having nacreous reflections: fins yellowish.

Habitat.—One example 6 (French) inches long, from the Ganges.

5. Coilia Dussumieri, Plate CLVIII, fig. 8.

Cuv. and Val. xxi, p. 81, pl. 610; Bleeker, Beng. p. 74; Day, Fish. Malabar, p. 242. Leptonurus chrysostigma, Bleeker, Madura, p. 14. Oorialli, Ooriah.

B. xi, D. $1+13-14(\frac{3}{10^2-11})$, P. 9+v-vi, V. 7, A. $105(\frac{3}{10^2})$, C. 12, L. 1. 80, L. tr. 9.

Length of head 6 to $6\frac{1}{3}$, of caudal 11, height of body $5\frac{1}{3}$ in the total length. Eyes—subcutaneous, diameter 4 to $4\frac{1}{4}$ in the length of the head, 3/4 of a diameter from the end of snout and $1\frac{1}{4}$ apart. Maxilla dilated opposite the mandibular joint and extending posteriorly to the gill-opening. Snout projecting beyond

the mouth. The distance between the snout and the first dorsal ray is 1/4 of the total length. Teeth—fine ones in jaws and palate. Fins—six upper pectoral rays produced to about the middle of the length of the fish, the longest of the lower rays equalling the head excluding the snout: ventral not 1/2 as long as the head, it is inserted below the middle of the dorsal fin. The length of the base of the anal is nearly equal to 3/4 of the distance between the gill-opening and the base of the caudal fin, the upper ray of which last is the longest, they decrease in length to the most inferior one. Scales—five or six spinate ones anterior to the ventral fin, and eight posterior to it, they commence just behind the insertion of the pectoral fin. Gill-rakers—rather fine, closely set, from 21 to 25 in the lower branch of the outer branchial arch, the longest being as long as the eye. Pseudobranchiæ absent. Colours—golden, with two or three rows of round burnished golden spots along the lower half of the side.

Coilia quadrifilis, Günther, Catal. vii, p. 403, appears to be a a variety having only 4 free filaments to the pectoral fin.

The variety figured by Bleeker has a much higher body than the typical form: it is also found in Bombay

Habitat.—Very numerous at Bombay, seas and estuaries of India to the Malay Archipelago. It attains at least 7 inches in length. The example figured (life-size) was from Orissa where it is common.

6. Coilia Borneensis, Plate CLIX, fig. 1.

Bleeker, Haring, p. 45, Borneo, p. 437 and Atl. Ich. vi, p. 139, t. 262, fig. 3; Günther, Catal. vii, p. 403.

B. x, D. $1+14(\frac{2}{12})$, P. 6+ix-xii, V. 7, A. 77 to 95, L. l. 76, L. tr. 9.

Length of head $5\frac{1}{3}$ to $6\frac{1}{3}$, of caudal 5 to 7, height of body 5 to $5\frac{1}{2}$ in the total length. Eyes—diameter 5 to 5½ in the length of the head, 1 diameter from the end of snort and 1½ apart. Maxilla dilated above the mandibular joint and continued backwards as far as the gill-opening. The distance between the snout and the dorsal fin is 1/4 of the total length. Teeth—generic. Fins—the six lower pectoral rays short: the 12 upper ones extend almost to the middle of the length of the body of the fish. Ventrals about 1/2 as long as the head. The length of the base of the anal equals 2/5 of the distance between the snout and the base of the caudal fin. Scales—four or five fine spines along the abdominal edge between the bases of the pectoral and the ventral fins: 5 behind the latter. Colours—golden, fins yellowish without any black marks.

Habitat.—Madras, Burma where it is common in the Irrawaddy river, also the Malay Archipelago.

Second group—Chatoessiformes.

Mouth transverse, narrow, nearly or quite inferior, with the upper jaw projecting over the lower. Eyes with free adipose lids. Abdomen serrated.

Genus 3—Chatoessus, Cuvier and Valenciennes.

Dorosoma, Rafinesque; Gonostoma, v. Hasselt; Anodontostoma, Blecker.

Branchiostegals from four to six. Body oval, short, deep, and moderately compressed: with a sharp, serrated abdominal edge. Snout overhanging a rather narrow transverse mouth. The superior combs of the first branchial arch unite with those of the opposite side, forming two angles, one pointing forwards, the other backwards: the fourth branchial arch having an accessory respiratory organ. Teeth absent from jaws. A single dorsal fin, having the last ray prolonged in some species; ventrals anterior to or below the dorsal fin; anal commencing posterior to the dorsal and with a moderate number of, or many rays; caudal forked. Air-vessel large, rounded anteriorly, pointed posteriorly. Cœcal pylori numerous. Pseudobranchiæ well developed.

SYNOPSIS OF SPECIES.

A.—Last dorsal ray not prolonged.

- Chatoessus chacunda, D. 17-19, A. 19-20, L. l. 40-42, L. tr. 13-14. India to the Malay Archipelago. Chatoessus modestus, D. 14-16, A. 27-28, L. l. 47, L. tr. 17. Burma. Chatoessus mannina, D. 14-15, A. 22-24, L. l. 58-63, L. tr. 22-24. Fresh waters of India except its southern portion and the Deccan.

B.—Last dorsal ray prolonged.

4. Chateossus nasus, D. 15-17, A. 22-24, L. l. 46-50, L. tr. 18-19. Seas of India to the Malay Archipelago and beyond.

A.—Last dorsal ray not prolonged.

? Chatoëssus tampo, Cuv. and Val. xxi, p. 117. Chatoëssus selanghat, Bleeker, l. c. p. 47, and Nat. Tyds. Ned. Ind. iii, p. 458 (variety). Dorosoma chacunda, Bleeker, Atl. Ich. vi, p. 143, t. 261, fig. 5 and 6.

Muddeeru, Tel.; Kore-paig-dah, And.

B. vi, D. 17-19 $(\frac{3}{14},\frac{4}{16})$, P. 15, V. 8, A. 19-20 $(\frac{2}{17},\frac{2}{16})$, C. 19, L. 1. 40-42, L. tr. 13-14.

Length of head $4\frac{1}{2}$ to 5, of caudal $4\frac{1}{2}$ to $4\frac{3}{4}$, height of body $2\frac{1}{2}$ to $2\frac{2}{3}$ in the total length. Eyes—diameter $3\frac{1}{2}$ to $3\frac{3}{4}$ in the length of the head, 2/3 of a diameter from the end of snout, and 1 apart. Head as Snout projecting considerably beyond the gape of the transverse mouth. Opercie rather more than twice as high as wide. Fins—origin of dorsal nearer the snout than the base of the caudal fin, no elongated ray. Pectoral as long as the head excluding the snout. Caudal forked. Ventral inserted below the middle of the dorsal fin. Scales—with smooth edges, regularly arranged; 28 spines along the abdominal and thoracic edge, 16 or 17 of which are anterior to the ventral fin. Colours—golden shot with purple, lines formed of spots along the rows of scales in the upper third of the body, a black spot on the shoulder.

The variety C. selanghat, is more elongated, its height being 3 to $3\frac{1}{2}$ in the total length: the height of the head only equals its length excluding the snout: its body is stouter. It is common in Burma and at the

Habitat.—Seas and estuaries of India and Burma to the Malay Archipelago. It attains at least 8 inches in length.

2. Chatoëssus modestus, Plate CLX, fig. 1.

Day, Proc. Zool. Soc. 1869, p. 622.

B. vi, D. 14-16($\frac{3}{11-13}$), P. 16, V. 8, A. 27-28($\frac{3}{24-25}$), C. 21, L. 47, L. tr. 17.

Length of head 5 to $5\frac{1}{4}$, of caudal 4 to $4\frac{1}{2}$, height of body $2\frac{3}{4}$ to 3 in the total length. Eyes—diameter 3 to $3\frac{1}{2}$ in length of head, 3/4 of a diameter from end of snout, and 1 apart: profile above the nape slightly concave, then a great rise to the base of the dorsal fin: abdominal profile equally convex: snout moderately projecting over the lower jaw. The upper jaw reaches to opposite the enterior margin of the orbit, where it is bent suddenly downwards. Fins—dorsal commences slightly nearer to the snout than to the base of the caudal fin: it is high anteriorly, its upper edge concave. Pectoral reaches to above the ventral, which latter is inserted somewhat in advance of the origin of the dorsal. Scales—regularly arranged, with smooth edges, 17 to 18 serrations anterior to the ventral fin, and 11 to 12 posterior to it. Gill-rakers closely set and short, not exceeding 1/3 of the diameter of the eye. Free portion of the tail higher than long. Colours—yellowish shot

Habitat.—Along the Bassein River as high as the Een-gay-gyee Lake, also the Selwein at Moulmein.

Many specimens were taken up to $5\frac{1}{2}$ inches in length.

3. Chatoëssus manminna, Plate CLX, fig. 2.

Clupanodon manminna and cortius, Ham. Buch. Fish. Ganges, pp. 247, 249, 383. Chatoëssus manminna, Cuv. and Val. xxi, p. 114; Bleeker, Beng. p. 76. Chatoëssus cortius, Cuv. and Val. xxi, p. 115; Günther, Catal. vii, p. 410. B. vi, D. $14-15(\frac{2}{12}-\frac{3}{13})$, P. 15, V. 8, A. $22-24(\frac{3}{10}-\frac{3}{31})$, L. l. 58-63, L. tr. 22-24.

Length of head $4\frac{2}{3}$ to 5, of caudal $4\frac{2}{3}$ to $5\frac{1}{3}$, height of body $3\frac{2}{3}$ to $3\frac{3}{4}$ in the total length. Eyes—diameter 3 to 3½ in the length of the head, 2/3 to 3/4 of a diameter from end of snout, and 1 apart. Abdominal profile usually much more convex than the dorsal. Snout prominent. Maxilla not reaching to the orbit. Teeth absent. Fins—dorsal commences rather nearer the snout than the base of the caudal, and slightly in advance of the origin of the ventral, its last ray is slightly prolonged. Pectoral reaches the ventral. Caudal deeply forked, lower lobe the longer. Scales—irregularly arranged: 29 to 32 rows before the base of the dorsal fin:

scutes strong, 17 between the throat and the base of the ventral fin, and 13 behind it. Gill-rakers rather closely set, and quite 1/3 as long as the eye. Colours—silvery glossed with gold: cheeks purplish: back with a bluish-green tint, and usually a black spot on the shoulder. Fins yellowish, the dorsal and caudal with dark outer edges.

Hamilton Buchanan termed the form destitute of the shoulder mark C. cortius.

Habitat.—Fresh waters of Sind, and the districts watered by the Indus and its branches, also the affluents and main streams of the Ganges, Jumna, Brahmaputra and Mahanuddi. It is spread through the tanks and estuaries of India and Assam, except the Deccan, Southern and Western India, and Ceylon. It attains at least 11 inches in length.

Digitized by Google

b.—Last dorsal ray prolonged.

B. vi, D. 15-17 $(\frac{3-4}{12},\frac{4}{13})$, P. 15, V. 8, A. 22-24 $(\frac{2}{20},\frac{2}{22})$, C. 19, L. l. 46-50, L. tr. 18-19.

Length of head $4\frac{1}{2}$ to 5, of caudal $4\frac{1}{4}$ to $4\frac{1}{2}$, height of body $3\frac{1}{4}$ to $3\frac{1}{2}$ in the total length. Eyes—diameter 33 to 4 in the length of the head, 2/3 to 1 diameter from the end of snout, and 11 apart. Gape of mouth nearly twice as wide as the cleft is deep and overhung by the snout. Smooth portion of the opercle not quite twice as high as wide. Fins—the dorsal commences much nearer the snout than the root of the caudal, its last ray elongated, in some examples reaching to the base of the caudal fin. Pectoral as long as the head excluding the snout. Ventral inserted under the anterior dorsal rays. Caudal deeply forked. Gill-rakers short and rather widely set. Scales—with serrated edges, placed in regular rows; 28 scutes along the abdominal and thoracic edge, about 15 of which are anterior to the ventral fin: 18 rows of scales before the base of the dorsal fin. Colours-back grayish-green, with the centre of each scale in the first seven rows the darkest, thus forming horizontal lines, the lower of which do not extend to the caudal. Abdomen whitish, shot with gold. A bluish spot (sometimes absent) on the shoulder behind the upper half of the opercle. Preopercle of a brilliant golden tint. Dorsal greenish-yellow, with the posterior margin stained blackish. Pectoral, ventral, anal, and caudal yellowish, the last with a dark extremity.

This fish is figured in Bonnaterre, Enc. Method. pl. 76, as Caillen Tassart, and given as Clupea thrissa,

p. 186.

Habitat.—Seas of India to the Malay Archipelago and Philippine Islands. It is good eating, but bony.

Third group—Clupe Eformes.

Upper jaw not projecting. Eyes with free adipose lids. Abdomen serrated.

Genus, 4—CLUPEA, sp. Artedi.

Clupanodon, Lacép. (pt.): Harengula, Rogenia, Spratella, Sardinella, Clupconia, Kowala, Meletta, Alausa, Cuv. and Val.: Clupalosa, Amblygaster and Clupcoides, Blecker: Opisthonema, Brevoortia and Alausella,

Body oblong or sub-elongated, with the serrature of the abdomen extending anteriorly into the thoracic region: upper jaw not projecting beyond the lower. Mouth anterior or antero-superior. Teeth, when present, rudimentary and deciduous. Dorsal fin situated opposite the ventrals: anal with a moderate, or large number of rays: caudal forked. Scales large, of moderate, or more rarely of small size. Pseudobranchia well developed.

Hyrtl, Denkschr. Ak. Wiss. Wien, x, 1855, p. 49, has remarked upon a rudimentary accessory branchial organ in one species of this genus from Brazil, Clupea aurea = Clupanodon aureus, Agassis in Spix. Pisc. Bras. p. 52, t. 51.

Fishes of this genus are often much broader across the back when captured in fresh or brackish water than are those taken in the sea. Perhaps one reason is, that they enter the former localities to breed and whilst in good condition, whereas they return to the ocean to recover their health after breeding.

This genus has been sub-divided in accordance with its teething, a mode which is liable to the great objection that the teeth are small and deciduous. I would add to this that the same species shows great diversity, thus Sardinella longiceps, Cuv. and Val. was stated to have teeth on the palatines, pterygoid bones, and on the tongue: the same species captured from Malabar not having visible teeth, was placed as Alosa scombrina, Cuv. and Val. (see p. 637): again, Meletta lile, Cuv. and Val. destitute of teeth on the vomer, as seen in India, appears to be identical with Clupea argyrotomia, Bleeker, said to possess vomerine teeth. It is a subject well worthy of examination if, in some species, dentition is more developed as we progress eastwards. It is therefore necessary to remember while investigating species of Clupea, that the dentition is liable to variations as the teeth are deciduous.

SYNOPSIS OF SPECIES.

A.—Teeth in lower jaw.*

a. - Teeth on tongue, palatines, pterygoids, but none on the vomer.

1. Clupea kowal, D. 19, A. 20-22, L. 1. 45, L. tr. 11-12. Length of head 5, height of body 31/3 to 31/2 in the total. Eyes 3 in length of head. Seas of Africa and India to the Malay Archipelago.

2. Clupea atricanda, D. 18, A. 17-19, L. l. 44-45, L. tr. 11. Length of head $4\frac{3}{4}$, height of body $4\frac{5}{4}$ in the

- 2. Coupea arricanal, D. 18, A. 17-19, L. I. 44-45, L. tr. 11. Length of head $4\frac{7}{4}$, height of body $4\frac{7}{4}$ in the total. Eyes $3\frac{7}{4}$ to 4 in length of head. Caudal black tipped. Andamans to the Malay Archipelago.

 3. Clupea Klunzei, D. 17-18, A. 17-18, L. I. 45, L. tr. 11-12. Length of head $4\frac{1}{3}$ to $4\frac{7}{3}$, height of body $4\frac{1}{4}$ to $4\frac{7}{4}$ in length of head. Eyes 3 to $3\frac{1}{4}$ in the length of head. Seas of India to the Malay Archipelago.

 4. Clupea lengular property, D. 17-18, A. 18-20, L. 1. 40, L. tr. 11-12. Length of head 5 to $5\frac{1}{4}$, height of body $5\frac{1}{4}$ to 6 in the total length. Eyes $3\frac{1}{3}$ to 4 in the length of head. Ceylon to the Malay Archipelago.

 5. Clupea longiceps, D. 16-17, A. 14-16, L. I. 45-48. Length of head $3\frac{3}{4}$ to 4, height of body 5 to $5\frac{1}{4}$ in the total length. Eyes $4\frac{1}{4}$ to 5 in the length of head. Seas of Sind and India to the Malay Archipelago.
- - b.—Teeth on tongue and palatines, none on pterygoid or vomer.
- 6. Clupea fimbriata, D. 18-19, A. 19-20, L. l. 45-48. Length of head 5 to $5\frac{1}{4}$, height of body 4 to $4\frac{3}{4}$ in the total length. Eyes $3\frac{1}{4}$ in length of head. Red Sea, seas of India to the Malay Archipelago.

c.—Teeth on tongue, none on palatines, pterygoids, or vomer.

7. Clupea Sindensis, D. 16-17, A. 18-19, L. 41-44, L. tr. 11. Length of head $4\frac{1}{5}$ to 5, height of body $4\frac{1}{2}$ to $4\frac{1}{5}$ in the total length. Eyes $4\frac{1}{4}$ in length of head. Tail fin sometimes dark tipped. Seas of Africa and

B.—No teeth in the jaws.

a.-Teeth on pterygoids and on the tongue: none on vomer or palatines.

8. Clupea lile, D. 14-15, A. 17-20, L. l. 38-40, L. tr. 9-10. Length of head 5 to 5½, height of body 3½ to $3\frac{2}{3}$ in the total length. Eyes 3 to $3\frac{1}{4}$ in length of head. Seas of India to the Malay Archipelago.

b.—No teeth inside mouth.

9. Clupea variegata, D. 15-18, A. 24-29, L. 1. 90, L. tr. 35. Length of head 4\frac{1}{2} to 4\frac{2}{3}, height of body 3

in the total length. Eyes 4 to $4\frac{1}{4}$ in the length of head. Fresh waters of Burma.

10. Clupea chapra, D. 14-16, A. 21-24, L. 1. 80-110, L. tr. 33-35. Length of head $4\frac{1}{3}$ to $4\frac{1}{2}$, height of body $3\frac{1}{2}$ to 4 in the total length. Eyes $3\frac{1}{2}$ in the length of head. Fresh waters of India.

11. Clupea ilisha, D. 18-19, A. 19-22, L. 1. 46-49, L. tr. 17-19. Length of head $4\frac{1}{4}$ to $4\frac{1}{2}$, height of body $3\frac{1}{2}$ to $3\frac{3}{4}$ in the total bench. Eyes before the middle of length of head. Persian Gulf and seas of India

to Burma and the Malay Archipelago: ascending rivers to breed.

12. Clupea kanagurta, D. 17, A. 20-21, L. 1. 42-45, L. tr. 13-14. Length of head $4\frac{1}{4}$, height of body $3\frac{1}{4}$ to $3\frac{1}{4}$ in the total length. Eyes just in front of middle of length of head. Seas and estuaries of India and the

Malay Archipelago.

13. Clupea toli, D. 16-17, A. 19-20, L. 1, 39-40, L. tr. 13-14. Length of head 5 to 5½, height of body $3\frac{1}{2}$ to 4 in the total length. Eyes $4\frac{1}{4}$ in length of head, 1 diameter from end of snout. Seas of India to the Malay Archipelago and China.

14. Chupea melanura, D. 15-16, A. 18-19, L. l. 38-40, L. tr. 10-11. Length of head 5, height of body 4 to 5 in the total length. Eyes 3 to 32 in length of head, 1 diameter from end of snout. Seas of India to the

Malay Archipelago.

A.-Teeth in lower jaw.

a.—Teeth on tongue, palatines, pterygoids, but not on the vomer.

1. Clupea brachysoma, Plate CLXIII, fig. 3.

Kowala thoracata (Cuv. and Val. xx, p. 363?); Bleeker, Beng. p. 74; Cantor, Malay. Fish. p. 296; Jerdon, Mad. Journ. Lit. and Science, 1851, p. 145. Sardinella brachysoma, Bleeker, Haring. p. 19.

Clupea brachysoma, Günther, Catal. vii, p. 423; Bleeker, Atl. Ich. vi, p. 104, t. 267, f. 2. Alosa kowal, Günther, Fish. Zanzibar, p. 123.

Clupca kowal, Günther, Catal. vii, pp. 450-60 (pt.); Bleeker, Atl. Ich. vi, p. 109.

Currudden touddy, Mal.

B. vi, D. $19(\frac{3}{16})$, P. 17, V. 8, A. $20-22(\frac{9}{18},\frac{3}{10})$, C. 20, L. l. 45, L. tr. 11-12.

Length of head 5, of caudal $4\frac{1}{2}$, height of body $3\frac{1}{3}$ to $3\frac{1}{2}$ in the total length. Eyes—with broad adipose lids, diameter about 3 in the length of the head, nearly 1 diameter from the end of snout, and 4/5 of a diameter apart. Abodminal profile more convex than the dorsal. Lower jaw rather prominent: maxilla reaching to below the first third or middle of the eye. Opercle rather more than twice as high as wide. Teeth—a few on

* In some instances these are lost, occasionally they are very minute or even not developed.

either side of symphysis of lower jaw, fine ones on tongue, palatine and pterygoid bones: none on the vomer. Fins-dorsal commences midway between the end of the snout and the posterior extremity of the base of the anal fin. Pectoral reaches to above the ventral, the latter fin being inserted beneath the centre of the dorsal. Last two anal rays rather prolonged. Caudal deeply forked and covered with fine scales. Scales—regularly arranged, their edges crenulated, and with numerous transverse striæ. Scutes well developed, 18 before and 12 behind the base of the ventral fin. Free portion of the tail rather higher than long. Colours—greenish superiorly, the bases of the scales being a little dark: caudal fin dark tipped.

This fish is the species described by Cantor, and the teeth as he observes are distinct in his examples in the lower jaw, palatine and pterygoid bones. The height of its body, size of its eye and length of its caudal fin at once serve to distinguish it from C. fimbriata.

Habitat.—East Coast of Africa, Seas of India to the Malay Archipelago. It appears to be rare in

India. The example figured was from Cochin.

2. Clupea atricauda, Plate CLXIV, fig. 5.

Harengula melanurus, Bleeker, Ceram, p. 245.

Clupea atricauda, Günther, Catal. vii, p. 426; Bleeker, Atl. Ich. vi, p. 106, t. 268, f. 5.

B. vi, D. $18(\frac{3}{15})$, P. 17, V. 8, A. 17-19 $(\frac{2-3}{15-17})$, C. 20, L. l. 44-45, L. tr. 11.

Length of head $4\frac{3}{4}$, of caudal 5, height of body $4\frac{3}{4}$ in the total length. Eyes—with broad adipose lids, diameter $3\frac{2}{3}$ to 4 in the length of the head, about 1 diameter from end of snout and 2/3 of a diameter apart. Dorsal and abdominal profiles nearly equally and slightly convex. The greatest height of the head equals its length excluding the snout. Lower jaw projecting beyond the upper: the posterior extremity of the maxilla reaches to beneath the first third of the eye, numerous fine radiating lines on the cheeks: opercle twice as high as broad. Teeth—a few small ones in front of lower jaw, a narrow band along the tongue, and some deciduous ones on the palatines and pterygoids, but none on the vomer. Fins—dorsal commences midway between the end of the snout and above the posterior extremity of the base of the anal fin. Pectoral as long as the head excluding the snout, and reaching 2/3 of the way to the ventral, which last is inserted beneath the middle of the dorsal fin. Last two anal rays thickened and slightly elongated. Lower caudal lobe sometimes slightly the longer. Gill-rakers numerous, closely set, and about 1/3 as long as the eye. Scales—regularly arranged, with crenulated outer margin: scutes small anteriorly, becoming stronger under the middle of the base of the pectoral fin, and 13 behind the base of the ventral. Colours—dark steel blue along the back and upper third of the body, divided by a yellowish line from the silvery sides and abdomen, which are glossed with blue and purple. Caudal with its extremity deep brown or black.

Habitat.—Andamans to the Malay Archipelago. The example figured was from Port Blair.

Clupea Klunzei, Plate CLXIII, fig. 1.

Harengula Klunzei, Bleeker, Ternate, p. 209.

Harengula Moluccensis, Bleeker, Ternate, p. 609.

Clupea Moluccensis, Günther (pt) Catal. vii, p. 427.

Clupea (Harengula) Moluccensis and Klunzei, Bleeker, Atl. Ich. vi, p. 107, t. 263, f. 1 and 2.

B. vi, D. 17-18($\frac{3}{16}$, P. 16, V. 8, A. 17-18($\frac{2}{16}$, C. 20, L. l. 45, L. tr. 11-12.

Length of head $4\frac{1}{2}$ to $4\frac{2}{3}$, of caudal 5 to $5\frac{1}{2}$, height of body $4\frac{1}{2}$ to $4\frac{3}{4}$ in the total length. Eyes – with broad adipose lids, diameter 3 to 31 in the length of the head, 1 diameter from the end of snout and 2/3 of a diameter apart. Dorsal and abdominal profiles about equally and slightly convex. Head about 1/5 longer than deep. Lower jaw prominent: maxilla reaching to beneath the middle of the eye: cheeks with numerous radiating strie: opercle twice as high as wide. Teeth—a few on lower jaw, tongue, palatine and pterygoid bones: none on the vomer. Fins—dorsal commences midway between the end of the snout and above the posterior end of the base of the anal. Pectoral as long as the head excluding the snout, and reaching 2/3 of the distance to the base of the ventral, which last is inserted below the middle of the dorsal fin. Last two anal rays rather thickened and slightly elongated. Gill-rakers fine, about 1/3 as long as the eye, about 38 in the outer branch of lower branchial arch. Scales—in regular rows, with the edges roughened or finely crenulated. Thirty badly-developed scutes, about 13 behind the base of the ventral fin. Colours—bluish along the back becoming silvery white shot with purple on the sides and below.

Bleeker distinguished C. Moluccensis from Klunzei, chiefly by the length of the head in the former being 1/4 of that of the body excluding the caudal fin, and of the latter $3\frac{1}{2}$ to $3\frac{2}{3}$.

Habitat.—Ceylon, Andamans and Nicobars to the Malay Archipelago. The example figured was from the Andamans.

4. Clupea leiogaster.

Sardinella leiogaster, Cuv. and Val. xx, p. 270; Bleeker, Beng. p. 72.

Clupea leiogaster, Bleeker, Atl. Ich. vi, p. 102, t. 262, f. 6; Kner, Novara Fische, p. 327; Klunz.

Length of head 5 to $5\frac{1}{4}$, of candal $5\frac{1}{2}$ to 6, height of body $5\frac{1}{2}$ to 6 in the total length. Eyes—with broad adipose lids, diameter $3\frac{1}{3}$ to 4 in the length of the head, 1 diameter from end of snout, and 3/4 to 4/5 of a diameter apart. Dorsal and abdominal profiles equally and slightly convex. The maxilla reaches to below the front edge of the eye. Opercle more than twice as high as wide. Teeth—in lower jaw, the palatines and pterygoids, and along the centre of the tongue, but none on the vomer. Fins—dorsal commences rather nearer the base of the caudal fin than the end of the snout. Ventral inserted beneath the second fourth of the dorsal. Pectoral as long as the head excluding the snout. Length of base of anal not quite equal to 1/2 the length of the head. Scales—with indistinct transverse strie, and rough edges: scutes badly developed, about 32 in number. Colours—bluish green superiorly, becoming silvery white on the sides and beneath: sometimes a brownish mark on the shoulder. A longitudinal band along the body, with from 13 to 20 intensely blue spots. spots.

Habitat.—Ceylon, to the Malay Archipelago.

Length of head $3\frac{3}{4}$ to 4, of caudal 6, height of body 5 to $5\frac{1}{4}$ in the total length. The greatest height of the head equals its length behind the centre of the eye. Eyes—with broad adipose lids, diameter $4\frac{1}{2}$ to 5 in the length of head, $1\frac{1}{4}$ diameters apart, and 1 to $1\frac{1}{4}$ from end of snout. Lower jaw slightly the longer, the maxilla reaches to beneath the first 1/3 or centre of the eye. Opercle twice as high as wide. Teeth—fine ones on the tongue, very deciduous ones on palatines and more rarely on the pterygoids, very minute or absent from the lower jaw: none on the vomer. Fins—dorsal commences rather nearer the snout than the base of the caudal fin, its upper edge concave, its last two rays short. Pectoral as long as the postorbital portion of the head: ventral inserted in a line rather behind the middle of the dorsal. Anal low, the length of its base not quite 1/2 that of the head: its last two rays thickened and rather elongated. Caudal forked. Scales—indistinctly crenulated on the outer edge, and regularly arranged: 13 rows before the base of the dorsal fin: about 18 badly-developed scutes before and 13 or 14 behind the base of the ventral fin. Gill-rakers very numerous, about 1/2 longer than the eye. Colours—bluish along the back with golden reflections, abdomen silvery shot with purple, and sometimes a golden line divides the colour of the back from that of the sides: head of the same colour as the body, with a large greenish gold spot on the upper margin of the opercle and preopercle: dorsal greenish: caudal stained with green, the other fins transparent.

Dr. Bleeker having given me an excellent example of his C. lemuru, I could find no external difference between it and the Malabar oil sardine. The former however was said to have narrow bands of minute teeth on the tongue, palatine, and pterygoid bones, and such were visible in the example I received. The Clupea scombrina, C. V., was stated by Valenciennes and Günther to have no teeth on the tongue or palate, whereas I observed (C. Neohowii) that such existed in Malabar examples. I have since returned to Malabar and examined some hundreds of these fishes respecting this question, and in some examples certainly I was unable to see palatines and pterygiod teeth. Curiously the British Museum specimen (skin, preserved by myself) examined by Dr. Günther showed no palatine teeth; another example preserved the same day has no pterygoid but only a narrow strip of palatine teeth. On the Coromandel coast the palatine teeth become more distinct (C. longiceps), and according to Bleeker, would seem to be invariably present in examples from the Malay Archipelago.

Habitat.—Sind, down the Western coast of India, more rarely on the Eastern, Ceylon, the Andamans to the Malay Archipelago, where Bleeker observed C. lemuru. They attain about 8 inches in length, and large quantities of oil are made from them in Malabar; but along the Coromandel coast they never appear to arrive in sufficient quantities, whilst those that come are rarely fat as in Malabar. Abundant in some years, they occasionally forsake their haunts for several consecutive seasons, returning again in enormous quantities.

b.—Teeth on tongues and palatines, none on pterygoids or vomer.

Clupea gibbosa, Bleeker, Celebes, p. 72, and Atl. Ich. vi, p. 106, t. 266, f. 6. Clupea fimbriata, Günther, Catal. vii, p. 427 (part); Bleeker, Atl. Ich. vi, p. 105, t. 271, f. 5. Clupea Sundaica, Bleeker, Atl. Ich. vi, p. 105. Kich-uk-louar, Sind; Cuttay-charlay, Malabar: Poonduringa, Tam.: Charree-addee, Hind. B. vi, D. $18-19(\frac{4}{14-15})$, P. 15, V. 8, A. $19-20(\frac{2}{17-18})$, C. 20, L. l. 45-48, L. tr. 11-12.

Length of head 5 to $5\frac{1}{4}$, of caudal $4\frac{1}{2}$ to $4\frac{2}{3}$, height of body 4 to $4\frac{3}{4}$ or even 5 in the total length. Eyes—diameter $3\frac{1}{4}$ in length of head, nearly 1 diameter from end of snout and also apart. Abdominal more convex than the dorsal profile. Lower jaw slightly prominent: the maxilla reaches to below the first third of the eye. Opercle about twice as high as wide: sub-opercle nearly triangular and rather longer than high. Teeth—deciduous in the jaws, a band along the middle of the tongue, a patch on the palatines, none on the vomer or pterygoids. Fins—dorsal rather higher anteriorly than its base is long, it commences midway between the end of the snout and the posterior extremity of the base of the anal, its upper border concave. Pectoral reaches 2/3 of the way to the ventral, the last fin being inserted under the middle of the dorsal. Last two anal rays thickened and a little prolonged. Caudal deeply forked. Scales—regularly arranged, with their free edges jagged. Scutes moderately developed, 14 or 15 posterior to the ventral fin, and 16 or 17 before it. Free portion of the tail rather higher than long. Colours—bluish-green, the sides silvery. Dorsal fin with numerous fine black dots, and a black mark at the base of its anterior rays. Caudal with bluish reflections and tipped with dark.

I think it evident that this is the fish alluded to by Russell, he observes that making their appearance in March they are abundant through the summer months. Having examined the figure of C. Neolowii with the late Dr. Bleeker, we came to the conclusion that it might be intended for this species.

Sardinella lineolata, Cuv. and Val. xx, p. 272, appears from the description, to differ from this species

in the posterior frontals not being striated.

Having received some examples of *C. gibbosa* and *C. tembang*, Bleeker, from the Leyden Museum, and named by the author, I consider them identical with the foregoing. I have figured the highest example I have, in some the height of the body is only 1/5 of that of the total length, the variations in this respect being very

Habitat.—Red Sea, seas of India to the Malay Archipelago. It abounds in certain years off the Malabar

coast. The example figured (life-size) was from Vizagapatam.

7. Clupea Sindensis, Plate CLXIII, fig. 2.

? Meletta venenosa, Cuv. and Val. xx, p. 377.

? Alosa venenosa, Günther, Fish. Zanzibar, p. 122.

? Clupea venenosa, Günther, Catal. vii, p. 449. B. vi, D. 16-17($\frac{3}{13-14}$), P. 15, V. 8, A. 18-19($\frac{3}{16-17}$), C. 21, L. l. 41-44, L. tr. 11.

Length of head $4\frac{1}{5}$ to 5, of caudal fin $5\frac{1}{2}$ to 6, height of body $4\frac{1}{2}$ to $4\frac{1}{5}$ in the total length. Eyes—with rather broad adipose lids, diameter $4\frac{1}{4}$ in the length of head, $1\frac{1}{4}$ diameters from end of snout and 1 apart. The greatest height of the head rather exceeds its length excluding the snout. Lower jaw prominent. The maxilla reaches to below the first 1/4 of the eye. Preorbital with a raised and branched ridge. Opercles smooth: opercle about twice as high as wide: sub-opercle low and truncated posteriorly. Teeth—a narrow band along the tongue, fine ones in lower jaw, none on the vomer, palatines, or pterygoids. Fins-dorsal commences nearer the snout than the base of the caudal, its entire base being midway between these two points. Pectoral reaches 2/3 of the distance to the ventral, which latter fin is inserted below the middle of the dorsal. Scaleswith their edges a little rough (especially in large examples) and having some vertical lines. Scutes not well developed, 13 to 14 behind the base of the ventral fin. Gill-rakers closely set, nearly as long as the eye. Gill cavity in Indian examples of a deep brown or black. Colours—back of an intensely deep blue; sides golden, shot with purple and blue. Fins yellowish, a black spot at base of dorsal anteriorly, and its upper edge dark: the end of the caudal lobes sometimes dark. There are also lines along the rows of scales in the upper 2/3 of the body: a small dark shoulder mark which is more or less lost in the adult.

Habitat.—Seas of the Seychelles, Sind and Bombay. It attains at least 8 inches in length. The example

figured (life-size) was from Kurrachee.

B.—No teeth in jaws.

a .- Teeth on pterygoids and tongue, none on vomer or palatines.

8. Clupea lile, Plate CLXII, fig. 1.

Meletta lile, Cuv. and Val. xx, p. 378; Bleeker, Beng. p. 74.

Alausa champil, Cautor, Malay. Fish. p. 302 (not Gray and Hardwicke).

Rogenia argyrotænia, Bleeker, Haring. p. 26, and Banka, p. 457; Kner, Novara Fische, p. 328.

Clupea argyrotænia, Günther, Catal. vii, p. 423; Bleeker, Atl. Ich. vi, p. 101, t. 264, fig. 5. Clupea lile, Günther, Catal. vii, p. 450.

B. vi, D. $14-15(\frac{3}{11},\frac{3}{12})$, P. 13, V. 8, A. $17-20(\frac{2}{15-\frac{2}{18}})$, C. 21, L. l. 38-40, L. tr. 9-10.

Length of head 5 to $5\frac{1}{3}$, of caudal 5 to $5\frac{1}{3}$, height of body $3\frac{1}{4}$ to $3\frac{2}{3}$ in the total length. Eyes—with broad adipose lids, diameter 3 to $3\frac{1}{4}$ in the length of head, 2/3 of a diameter from end of snout and also apart. Dorsal profile nearly horizontal, abdominal very convex. Snout obtuse, lower jaw slightly the longer. The maxilla reaches to below the first third of the orbit. Smooth portion of opercle 1/4 higher than wide: subopercle almost triangular. Teeth—present on pterygoids, and a band along the centre of the tongue: none on jaws, vomer, or palatines. Fins—dorsal commences nearer the snout than the base of the caudal fin: its upper edge concave: pectoral not reaching to above the ventral, the latter being inserted under the anterior dorsal rays. Caudal moderately forked. Gill-rakers closely set and 1/2 as long as the eye: pseudobranchiæ well developed. Scales—rather adherent and in regular rows: their edges smooth: about 15 rows before the base of the dorsal fin: scutes strong, from 16 to 18 anterior, and 11 to 12 posterior to the base of the ventral fin. Free portion of tail as deep as long. Colours—golden shot with purple, a brilliant silvery band along the side, as deep as one scale. Caudal dark tipped, shot with blue. A brilliant bronze coloured spot on occiput.

In Clupea argyrotenia, Bleeker, that author noticed teeth on the vomer, the existence of which is denied by Günther: Dr. Bleeker having examined one of my Bombay examples with those in his collection, considered them to be distinct, the candal fin being more dark in specimens from the Malay Archipelago.

them to be distinct, the caudal fin being more dark in specimens from the Malay Archipelago.

Habitat.—Seas of India and Burma to the Malay Archipelago. It attains to about 4 inches in length.

The example figured (life-size) was from Bombay. It is found in vast numbers along the Western coast of India.

b.—No teeth inside mouth.

9. Clupea variegata, Plate CLXI, fig. 4.

Day, Proc. Zool. Soc. 1869, p. 623.

B. vi, D. 15-18($\frac{3-4}{12-13}$), P. 17, V. 8, A. $24-29(\frac{3}{21}-\frac{3}{20})$, C. 17, L. l. 90, L. tr. 35.

Length of head $4\frac{1}{2}$ to $4\frac{2}{3}$, of caudal 4 to $4\frac{1}{2}$, height of body 3 in the total length. Eyes—with broad adipose margins, diameter 4 to $4\frac{1}{2}$ in length of head, 3/4 of a diameter from end of snout, above 1 apart. Abdominal profile more convex than the dorsal. Jaws of about equal length: the maxilla extending to beneath the centre of the orbit. Opercles smooth. Teeth—very minute on tongue if present: none on jaws, vomer, or palatines. Fins—dorsal commences rather nearer to the snout than to the base of the caudal: ventrals situated below the first third of the dorsal fin: anal in the posterior third of the distance between the posterior margin of the orbit and the base of the caudal fin. Scales—regularly arranged behind a line from the opercles to the base of the anal fin, anterior to which they are very irregular. Pseudobranchiæ well developed. Gill-rakers closely set, and not quite as long as the eye. Serrated scales commence under the middle of the pectoral; ten are posterior to the ventral fin, and about ten anterior to it. Colours—silvery, glossed with gold and bronze. A dark humeral spot. A row of about 18 bars passes across the back and descends a short way over the sides. Dorsal fin with a black band in the lower portion of its posterior half. End of tail tipped with black.

This appears to be the Burmese representative of C. chapra. Habitat.—Irrawaldi and its branches. Many specimens procured up to 7 inches in length.

Length of head $4\frac{1}{3}$ to $4\frac{1}{2}$ (4 in the young), of caudal $4\frac{1}{2}$ to 5, height of body $3\frac{1}{2}$ to 4 in the total length. Eyes—with broad adipose lids, diameter $3\frac{1}{2}$ to 4 in the length of head, 2/3 of a diameter from end of snout, and 1 to $1\frac{1}{4}$ apart. Abdominal profile more convex than the dorsal: the maxilla straight and rather narrow, reaching to below the anterior third or centre of the orbit: opercle 2/3 wide as deep: sub-opercle large, tapering posteriorly. Teeth—absent. Fins—origin of dorsal opposite or slightly before that of the ventral, and a little nearer the snout than the base of the caudal fin, it is highest anteriorly: pectoral does not quite reach the ventral, anal highest in front: caudal deeply forked, lower lobe slightly the longer, centre rays not so long as one diameter of the orbit. Scales—smooth, placed in horizontal rows except over the abdomen: 18 to 19 scutes anterior and 9 to 10 posterior to the ventral fin: 23 to 25 rows before the base of the dorsal fin.

Colours—silvery shot with gold, back rather dark, and edge of caudal stained darkest: a dark spot, which is sometimes absent, on the shoulder. Gill-rakers—closely set, very numerous and rather shorter than the eye, caudal peduncle as high as long.

Habitat.—Fresh waters of rivers and tanks of Sind and throughout India as far south as the Kistna River, but absent from the Malabar coast and Madras. It attains at least 8 inches in length.

B. vi, D. $18-19(\frac{1}{15},\frac{3}{16})$, P. 15, V. 9, A. $19-22(\frac{7}{17},\frac{2}{10})$, C. 19, L. 1. 46-49. L. tr. 17-19, Vert. 12/32-34.

Length of head $4\frac{1}{4}$ to $4\frac{1}{2}$, of caudal 5, height of body $3\frac{1}{2}$ to $3\frac{3}{4}$ in the total length. Eyes—with broad adipose lids, situated some distance before the middle of the length of the head, and from 1 to $1\frac{1}{2}$ diameters from the end of snout, and $1\frac{1}{2}$ apart. The posterior extremity of the maxilla reaches to below the middle or even hind edge of the orbit: lower jaw not projecting beyond the upper. The greatest width of the opercle equals about 2/3 of its height: sub-opercle rounded posteriorly. Teeth—absent. Fins—dorsal commences a little nearer the snout than the base of the caudal fin, its upper edge concave. Pectoral reaches to above the origin of the ventral, which latter fin is inserted beneath the anterior half of the dorsal. Caudal deeply forked. Caudal peduncle as deep as long. Scales—in regular rows: many over the caudal fin. Gill-rakers numerous and as long as the eye: 16 to 17 scutes before and 14 to 15 behind the insertion of the ventral fin. Pseudobranchiæ well developed. Colours—silvery, shot with gold and purple: no spots in the adult, but a row of them along the upper third of the body in the immature, the most distinct of which is behind the upper third of the opercle. (I have seen them in examples from the Sunderbunds up to 10 inches in length.) The young are usually of a bronze colour along the back, with silvery sides and a burnished silvery band going from above the eye to the upper half of the caudal fin, whilst the caudal fin is often deeply edged with black in its entire circumference.

The main body of these fish swarm up all the larger rivers of India and Burma, generally as soon as the monsoon commences, whilst an important matter appears to be the rapidity of the current. The numerous Indian rivers spanned by weirs, destitute of fish passes, is causing enormous injury to these fisheries. Almost fruitless to deposit their eggs below these structures when between the sea and their spawning beds, whilst they are unable to pass them, their partial or even entire extermination in such rivers appears to be merely a question of time.

Amongst such rivers as I have personally examined, the following appears to be the periods when these fish most commonly ascend. In the Cauvery and Coleroon of Madras, they pass up with the first burst of the South-west Monsoon (about the first or second week of June), and continue for the succeeding four months but in smaller quantities, some evidently being late breeders, perhaps younger fish. In the Kistna, which has a great velocity, the freshes commence in June, continuing to the end of October, after which the river subsides, although it is not fordable until the middle or end of January: a few of these fishes arrive at the end of September when the strength of the current is subsiding, but it is the middle of October and two following months, that the main body ascends, while they are absent by April. In the neighbouring river, the Godavery, which has a less rapid current, the fish ascend earlier, being most numerous from July to September. In the Hooghly they continue their ascent throughout the South-west Monsoon, continuing to nearly the end of the year. They have been observed in the Irrawaddi in Burma as high as Mandalay, in October. They are excellent as food until they have deposited their ova, when they become thin and positively unwholesome. Their flavour has been compared to a combination of that of the salmon and herring: they are rather heavy of digestion.

Habitat.—Persian Gulf ascending the Tigris, the coasts of Sind, India, and Burma, passing up the large rivers to breed, also the Malay Archipelago. I have taken them as high as Delhi, and Hamilton Buchanan records them from Agra and Cawnpore.

12. Clupea kanagurta, Plate CLXII, fig. 4.

Length of head $4\frac{1}{4}$, of caudal $4\frac{1}{2}$, height of body $3\frac{1}{4}$ to $3\frac{1}{2}$ in the total length. Eyes—with a broad adipose membrane on either side, diameter 4 in the length of the head, 1 diameter from the end of snout and about 1 apart. Abdominal profile more convex than that of the back. The thickness of the body at the shoulder equals 2/5 of its height. Greatest width of the smooth portion of the opercle is nearly 1/2 its depth: subopercle tapering behind to its posterior-superior angle. Lower jaw scarcely projects beyond the upper. The maxilla extends posteriorly to below the hinder third of the orbit. Teeth—absent. Fins—dorsal commences midway between the front end of the snout and the end of the base of the anal fin, its greatest height rather exceeds the length of its base: its upper edge concave. Pectoral rather more than 1/2 as long as the head and does not quite reach to above the ventral, which last is situated rather behind the middle of the dorsal, and extends 2/5 of the distance to the base of the anal. Free portion of the tail rather higher at its base than long. Scales—regularly arranged: scutes 27, 11 behind the base of the ventral fin. Colours—bluish green superiorly, gold dotted with purple on the sides and beneath. Generally a row of about six or eight oval spots pass in a line from behind the upper edge of the opercle along the side. Upper edge of dorsal with a dark mark. Habitat.—East Coast of Africa, Sind, coasts of India to the Malay Archipelago.

13. Clupea toli, Plate CLXII, fig. 2.

Clupea Sinensis, Bloch, t. 405; Bl. Schn. p. 424 (? Gmel. Linn. p. 1408).

Alausa toli, Cuvier and Valenciennes, xx, p. 435: Cantor, Catal. p. 299; Bleeker, Beng. p. 74.

Clupea toli and chapra (not Ham. Buch.) Günther, Catal. vii, p. 447.

Alosa toli, Bleeker, Atl. Ich. vii, p. 113, t. 265, f. 4.

Oolum, Tamil.

B. vi, D. 16-17($\frac{3-4}{13-14}$), P. 14, V. 9, A. 19-20($\frac{3-3}{17}$), C. 24, L. l. 39-40, L. tr. 13-14.

Length of head 5 to $5\frac{1}{2}$, of caudal $4\frac{1}{4}$, height of body $3\frac{1}{4}$ to 4 in the total length. Eyes—with broad adipose lids, diameter $4\frac{1}{4}$ in the length of head, 1 diameter from end of snout, and also apart. Lower jaw rather projecting beyond the upper, which latter is notched at its extremity. Opercle 1/2 to 3/4 higher than wide: subopercle tapering posteriorly. Teeth—absent from the jaws. Fins—dorsal commencing nearer the snout than the base of the caudal fin, its entire base being midway between those two points, it is 1/5 higher than long and concave superiorly. Pectoral as long as the head excluding the snout and not reaching the ventral, which latter is inserted under the commencement of the last half of the dorsal fin. Caudal deeply forked, its lobes being longer than the head, especially in adult examples. Caudal peduncle a little longer than deep. Scales—regularly arranged, striated, and with crenulated or jagged edges: fine ones on the caudal fin. Scutes well developed, 17 to 18 before, and 12 to 13 posterior to the base of the ventral fin. The longest gill-rakers in the young, about equal the diameter of the eye, they are said to be longer in some adults. Pseudobranchiæ well developed. Colours—silvery, shot with yellow and purple, a dark shoulder spot in the young.

The eye is comparatively smaller and the caudal lobes much longer in the adult than in the young. C. macrura is very similar but has L. l. 44 to 46, and its scales with smooth edges, whilst its longest gill-rakers are stated to be much shorter than the eye. I can find no difference between C. chapra, Günther,

and C. toli, C. V.

Professor Peters (April 4th, 1878) observes of C. Sinensis, Bloch, "We have a dried specimen, which still has an original label, hardly visible, glued to it, and which after a careful examination and comparison, I take for the type of the figure, although it has a black spot on the shoulder, or behind the operculum, not shown in the figure.

* * I am of opinion C. Sinensis, Bloch. is C. toli, Cuv. and Val."

Habitat.—From Bombay through the seas of India to the Malay Archipelago and China. It attains at

Habitat.—From Bombay through the seas of India to the Malay Archipelago and China. It attains at least 3 feet in length. It does not appear to ascend rivers to breed like the C. ilisha, but is sometimes found at their mouths. The example figured (life-size) was from Bombay.

14. Clupea melanura.

Alausa melanurus, Cuv. and Val. xx, p. 441; Bleeker, Bali, p. 10, Haring. p. 32; Day, Fish. Malabar, p. 235.

Clupea melanura, Günther, Catal. vii, p. 449; Bleeker, Atl. Ich. vi, p. 111, t. cclxix, f. 5.

B. vi, D. $15-16(\frac{3}{12}-\frac{4}{15})$, P. 13, V. 8, A. $18-19(\frac{3}{15}-\frac{3}{16})$, C. 19, L. 1. 38-40, L. tr. 10-11.

Length of head 5, of caudal 5, height of body 4 to 5 in the total length. Eyes—with very narrow adipose lids, diameter 3 to $3\frac{1}{2}$ in length of head, 1 diameter from end of snout, 3/4 of a diameter apart. Dorsal profile very nearly straight: abdominal more convex: lower jaw rather longer than the upper: the maxilla extending to beneath the anterior third or middle of the orbit. Teeth—absent, or a few above the symphysis of the lower jaw. Fins—dorsal commences opposite to or slightly in front of ventral, and a little nearer

* In Dr. Günther's Catalogue of the Fishes in the British Museum, he gives Alausa toli, Cantor, as a synonym of this species, recording amongst the examples present—"a. b. Adult and young, skins. Pinang from Dr. Cantor's collection." This is very misleading, as Dr. Cantor's type was 1 foot 6 inches, a length this species never attains. The longest of the two examples in the British Museum is about 12 inches, and though not Cantor's type, is the true Clupea toli, C. V. the smaller specimen is C. kanagurta.

Digitized by Google

the snout than to the base of the caudal fin: pectoral does not reach the ventral, which latter does not extend half-way to the base of the anal: caudal deeply forked, the lower lobe the longer. Scales—in regular horizontal rows, with two or three raised lines along their base, 25 serrated scales along the abdominal edge. Colours—back blue, shot with purple: a fine yellow line dividing it from the silvery sides and abdomen: a blue spot on the opercle; outer third of caudal lobes black.

Habitat.—Seas of India and the Malay Archipelago.

Genus, 5—Corica, Hamilton Buchanan.

Clupeoides and Clupeichthys, Bleeker.

Body oblong, moderately compressed. Lower jaw the longer. Teeth, when present, rudimentary and deciduous. Dorsal fin situated nearly opposite the ventral: anal of moderate extent, its last rays may be thickened and detached. Caudal forked. Scales of medium size: abdomen serrated, serrature usually commencing behind the pectoral fins. Geographical distribution.—India to the Malay Archipelago.

SYNOPSIS OF SINGLE SPECIES.

? Clupeoides pseudopterus, Günther, Catal. vii, p. 452. Corica pseudopterus, Bleeker, Atl. Ich. vi, p. 98, t. 260, f. 3.

Cutwaal ursi and God-haee, Ooriah.

B. vi, D. $15 \cdot 16(\frac{2}{12},\frac{1}{13})$, P. 13, V. 8, A. $14 \cdot 15 + ii(\frac{2}{12},\frac{1}{13})$, C. 19, L. l. 40-42, L. tr. 10.

Length of head $5\frac{1}{4}$ to $5\frac{1}{2}$, of caudal $5\frac{1}{2}$, height of body 5 to $5\frac{1}{3}$ in the total length. Eyes—diameter 2/5 of length of head, 1/2 a diameter from end of snout, 2/3 of a diameter apart. Body elongated, strongly compressed. Maxilla reaches to below the middle of the orbit. Fins—dorsal arises rather nearer the base of the caudal than the snout, and rather behind the origin of the ventrals: the anal commences under the posterior extremity of the dorsal and has its last two rays detached: caudal forked in its posterior third, the lower lobe the longer. Scales—10 or 11 serrated scales along its abdominal edge, commencing below the pectoral fin: anterior to the ventral fin there are 10 or 11, and 7 or 8 posterior to it. Colours—silvery, with a light band.

Habitat.—Orissa and Bengal: rarely attaining above 2 inches in length. The example figured (life-size)

was from Orissa.

Genus, 6-Pellona, Cuvier and Valenciennes.

Ilisha, Gray: Platygaster, Swainson.

Branchiostegals six. Body rather elongated and strongly compressed, with the thoracic and abdominal edges serrated. Mouth of moderate size, upper jaw generally emarginate and shorter than the lower. Fine sharp teeth in the jaws, palatines, and pterygoid bones, also on the tongue, but none on the vomer. Dorsal fin small, median. Ventrals small, inserted anterior to the dorsal: anal elongated. Scales large, or of moderate size, rarely small.

Owing to the individual variations amongst examples of this genus they are difficult to distinguish:

besides which, the types of Cuvier and Valenciennes require to be thoroughly re-examined.

SYNOPSIS OF SPECIES.

A.—Dorsal fin almost or entirely in advance of the anal.

1. Pellona filigera, A, 46-50, L. l. 50, L. tr. 15-16. Head $5\frac{1}{4}$, height of body $3\frac{3}{4}$ to 4 in the total length. Scutes 22-23 before, 10-12 behind ventral fin. Bombay.

2. Pellona elongata, A. 40-49, L. l. 52-56, L. tr. 16. Head $4\frac{3}{4}$ to $5\frac{1}{4}$, height of body $4\frac{1}{4}$ to $4\frac{1}{2}$ in the total length. Scutes 20-24 before, and 8-10 behind ventral fin. Seas of India to Japan.

3. Pellona motius, A. 40-41, L. l. 43-45, L. tr. 12-13. Head 5, height of body 4 to $4\frac{1}{4}$ in the total length. Scutes 15-16 before, and 7-8 behind ventral fin. Fresh waters and estuaries of Bengal and Orissa.

4. Pellona Indica, A. 39-40, L. l. 44, L. tr. 13-14. Head $4\frac{1}{3}$, height of body $3\frac{1}{4}$ to $3\frac{1}{2}$ in the total length. Scutes 18 before, and 7-8 behind ventral fin. East coast of Africa, seas of India to the Malay Archipelago.

5. Pellona ditchela, A. 36-40, L. l. 40-44, L. tr. 14. Head $4\frac{1}{2}$, height of body $4\frac{1}{4}$ in the total length. Scutes 23 before, and 10 behind ventral fin. Coromandel coast of India.

Scutes 23 before, and 10 behind ventral fin. Coromandel coast of India.

6. Pellona Hoevenii, A. 36, L. l. 43. Head 4½, height of body 3½ in the total length. Scutes 13 before, and 9 behind ventral fin. A bone armed with teeth situated in place of ligament between premaxillary and maxillary bones. Coromandel coast of India to the Malay Archipelago.

B.—Dorsal fin situated entirely or partially over the anal.

7. Pellona brachysoma, A. 46-51, L. 43-44, L. tr. 14-15. Head 4½ to 4½, height of body 3½ to 3½ in the total length. Scutes 18 before, and 8 behind ventral fin. Seas of India to the Malay Archipelago.

8. Pellona megaloptera, A. 43-50, L. l. 48-50, L. tr. 14-15. Head $4\frac{1}{4}$ to $4\frac{2}{3}$, height of body $3\frac{2}{3}$ to 4 in the total length. Scutes 22 anterior, and 8 behind ventral fin. Seas of India to the Malay Archipelago.

9. Pellona Sladeni, A. 44, L. l. 48, L. tr. 10. Head 5, height of body 51 in the total length. Scutes 23 anterior, and 10 behind ventral fin. Irrawaddi river in Burma.

10. Pellona Leschenaultii, A. 42, L. 1. 70. Height of body 4 in the total length. Pondicherry.

A.—Dorsal fin almost or entirely in advance of the anal.

1. Pellona filigera, Plate CLXV, fig. 4.

Cuvier and Valenciennes, xx, p. 322; Bleeker, Beng. p. 72. ? Pellona xanthoptera, Bleeker, Haring. p. 49, and Nat. Tyds. Ned. Ind. ii, p. 439; Günther, Catal. vii, p. 457.

? Ilisha xanthoptera, Bleeker, Atl. Ich. vi, p. 122, t. 265, f. 3.

B. vi, D. $18-19(\frac{3-4}{15-16})$, P. 17, V. 8, A. $46-50(\frac{3}{43}\frac{3}{47})$, C. 19, L. l. 50, L. tr. 15-16.

Length of head $5\frac{1}{4}$, of caudal 5, height of body $3\frac{3}{4}$ to 4 in the total length. Eyes—diameter 3 in the length of the head, 3/4 of a diameter from the end of snout, and 1/3 apart. Abdominal profile much more convex than that of the back: a slight concavity over the front end of the head. The maxilla reaches to below the middle of the eye. The posterior portion of the ridges on the occiput are parallel one to the other. Teeth in jaws, tongue, and palate. Fins—dorsal commences about midway between the snout and base of the caudal fin, its posterior rays are not above the anal. Ventral fin very short, situated midway between subopercle and base of the anal. Pectoral reaches to above the ventral, its upper ray is very broad. Length of base of anal fin equals $2\frac{2}{3}$ in the total length excluding the caudal fin. Caudal lobes elongated. Scales—19 to 20 rows anterior to the base of the dorsal fin. Scutes well developed 22 to 23 before, and 10 or 12 posterior to the base of the ventral fin. Colours—of a coppery tinge along the back, sides silvery, with mother-of-pearl reflections. Dorsal and pectoral fins black tipped.

Habitat.—Bombay, to 1 foot in length.

2. Pellona elongata, Plate CLXIV, fig. 3, and CLXV, fig. 1.

Length of head $4\frac{3}{4}$ to $5\frac{1}{4}$, of caudal fin 5, height of body $4\frac{1}{4}$ to $4\frac{1}{2}$ in the total length. Eyes—diameter $3\frac{1}{4}$ to 4 in the length of head, 1 diameter from end of snout, and 1/2 a diameter apart. Abdominal profile more convex than that of the back. The maxilla reaches to below the middle of the eyes. The posterior halves of the ridges on the occiput are nearly parallel one to the other. Teeth—in jaws, tongue and palate. Fins—dorsal commences midway between the snout and the base of the caudal fin, its last rays do not extend to over the commencement of the anal. Ventral minute, situated midway between the hind margin of the head and the commencement of the anal fin. Length of base of anal fin equal from 3 to $3\frac{1}{4}$ in the total length excluding the caudal fin. Scales—abdominal scutes well developed, 20 to 24 anterior, and eight or ten posterior to the base of the ventral fin. Colours—silvery, shot with mother-of-pearl. Fins yellowish, edge of dorsal

It appears possible that this may be P. novacula, Cuv. and Val. xx, p, 319, but is not P. novacula,

Bleeker, wherein the maxilla extends posteriorly to nearly behind the hind edge of the orbit.

Habitat.—Seas of India to the Malay Archipelago, China, and Japan. The example figured Plate CLXIV, fig. 3 (half natural size), was from Sind. A variety with a more pointed head and rather fewer scales (l. l. 46, L. tr. 14), is figured (half natural size), Plate CLXV, fig. 1, from Bombay.

3. Pellona motius, Plate CLXV, fig. 3.

B. vi, D. $16-17(\frac{3}{13}-\frac{3}{14})$, P. 15, V. 7, A. $40-41(\frac{3}{37}-\frac{3}{38})$, L. 1. 43-45, L. tr. 12-13.

Length of head 5, of caudal fin 51, height of body 4 to 41 in the total length. Eyes—diameter 1/3 of length of head, 3/4 of a diameter from end of snout, and 1/2 a diameter apart. Body very compressed,

abdominal profile more convex than that of the back. The maxilla reaches to beneath the middle of the orbit. The posterior halves of the ridges on the summit of the head are nearly parallel one to the other. Teeth—on jaws, tongue and palate. Fins—origin of dorsal fin slightly nearer to the should than to the base of the caudal, and situated entirely in front of the anal, the length of the base of this latter fin being equal to 1/3 of that of the total length excluding the caudal fin: ventral fin nearly as long as the eye. Scales—16 rows anterior to the base of the dorsal fin: there are seven to eight scutes along the abdominal profile posterior to the base of the ventral, and 15 or 16 anterior to it. *Colours*—silvery, with mother-of-pearl reflections, and having a burnished lateral-band. There are some fine dots on the fins, and along the edges of some of the scales. Caudal fin with a dark outer edge: a dark band along the middle of the dorsal fin.

Habitat.—Assam, Bengal and Orissa, descending as low as the coast. It does not appear to attain much

above 4 inches in length. The example figured (life-size), was from Orissa.

4. Pellona Indica, Plate CLXIV, fig. 4.

Clupea, Russell, Fish. Vizag. ii, p. 78, and Ditchoee, pl. 192. Platygaster Indicus, Swainson, Fishes, ii, p. 294.

Pellona Indicus, Jerdon, M. J. L. and Sc. 1851, p. 145. Ilisha Indica, Bleeker, Atl. Ich. vi, p. 118, t. 259, f. 4.

Poo-na-no-dah, Andamanese.

B. vi. D. $17(\frac{3}{14})$, P. 16, V. 7, A. $39-40(\frac{3}{36}\frac{3}{37})$ C. 17, L. l. 44, L. tr. 13-14.

Length of head $4\frac{1}{3}$, of caudal fin $4\frac{3}{4}$, height of body $3\frac{1}{4}$ to $3\frac{1}{3}$ in the total length. Eyes—diameter $2\frac{3}{3}$ to 3 in the length of head, 2/3 of a diameter from end of snout and 1/2 a diameter apart. Abdominal profile more convex than the dorsal. The maxilla reaches to below the anterior 1/3 of the eye. Opercle rather more than twice as high as wide, not striated. The posterior halves of the ridges on the occiput are parallel one to the other. Teeth—in the jaws, tongue, palatine and pterygoid bones. Fins—dorsal commences rather nearer the snout than the base of the candal fin, its base being entirely, or almost so, in advance of that of the anal, the length of the base of the latter fin being $2\frac{3}{4}$ to 3 in that of the body excluding the caudal fin. Ventral small, shorter than the eye and inserted rather in advance of the origin of the dorsal. Scales—with the edges rather roughened, and having one or two vertical lines: 25 to 26 scutes, 18 being between the throat and base of ventral fin. Colours—greenish along the back, becoming silvery shot with purple and gold on the sides and below: dorsal fin often tipped with black.

Pellona micropus, C. V. xx, p. 320, appears to be closely allied to this species, D. 17, A. 42, L. l. 47. Height of body $3\frac{1}{3}$ in the total length: 27 scutes along the abdominal edge.

Habitat.—East Coast of Africa, seas of India to the Malay Archipelago.

5. Pellona ditchela, Plate CLXV, fig. 5.

Clupea, Russell, Fish. Vizag. ii, p. 72, and Ditchellee, pl. 188. Pellona ditchela, Cuv. and Val. xx, p. 314; Bleeker, Beng. p. 72.

B. vi, D. $18(\frac{3}{15})$, P. 16, V. 6, A. $36-40(\frac{3}{83},\frac{3}{87})$, C. 19, L. l. 40-41, L. tr. 14.

Length of head $4\frac{1}{2}$, of caudal fin 5, height of body $4\frac{1}{4}$ in the total length. Eyes—diameter about 1/3 of length of head, nearly 1 diameter from end of snout, and 1/2 a diameter apart. Abdominal profile rather more convex than the dorsal. The maxilla reaches to below the middle of the orbit: anteriorly a bone, armed with teeth instead of a ligament, connects the premaxillaries to the maxilla (as in P. Hoevenii), The posterior halves of the ridges on the occiput converge. Teeth—in jaws, tongue, and palate. Fins—origin of the dorsal rather nearer the snout than the base of the caudal fin, whilst the fin is entirely in advance of the anal. Ventral nearly as long as the eye. Length of base of the anal equal to $3\frac{1}{2}$ in the total length excluding the caudal fin. Scales—scutes well developed, 23 anterior and 10 posterior to the base of the ventral fin.

Colours—silvery, with a burnished lateral-band, the upper edge of the dorsal fin rather dark.

This may be Clupea melastoma, Bl. Schn. p. 427, and Pellona melastoma, Cuv. and Val. xx, p. 308, which

has A. 34.

Habitat.—Coromandel Coast of India. I received several examples from Madras, where they were collected by Dr. Keess. Unfortunately they are not in a good state of preservation. None are larger than the example figured.

6. Pellona Hoevenii, Plate CLXV, fig. 6.

Bleeker, Haring. p. 21, and Nat. Tyds. Ned. Ind. iii, p. 712; Günther, Catal. vii, p. 455. Ilisha Hoevenii, Bleeker, Atl. Ich. vi, p. 117, t. 269, f. 2.

B. vi, D. $18(\frac{3}{15})$, P. 17, V. 7, A. $36(\frac{3}{55})$, L. 1. 43, L. tr. 13.

Length of head $4\frac{1}{2}$, of caudal 5, height of body $3\frac{1}{2}$ in the total length. Eyes—diameter $2\frac{2}{3}$ to 3 in the length of the head, 3/4 of a diameter from end of snout, and 1 apart. Abdominal profile rather more convex than that of the dorsal. The maxilla reaches to below the middle of the eye. Opercle rather more than twice

as high as wide. The posterior halves of the ridges on the occiput meet posteriorly. Teeth—on the jaws, tongue, palatine and pterygoid bones: also along a small accessory bone extending between the premaxillaries and the superior maxillary. Fins—dorsal commences rather nearer the snout than the base of the caudal fin, and is entirely or almost so, in advance of the anal: the length of the base of the latter fin being $3\frac{1}{3}$ in the distance between the snout and the base of the caudal. Ventral small, shorter than the eye. Scales—with the edges almost smooth: 22 scutes, 13 being anterior to the base of the ventral fin. Colours—greenish along the back, becoming silvery with mother-of-pearl reflections on the sides and beneath.

The chief points of difference between this species and P. ditchoa, consist in the posterior halves of the ridges in the occipital region being convergent and not parallel to one another: and in the ligament extending anteriorly from the premaxillaries to the maxillaries being replaced by a toothed bone.

Habitat.—Coromandel Coast of India where it abounds, to the Malay Archipelago.

B.—Dorsal fin situated entirely or partially above the anal.

7. Pellona brachysoma, Plate CLXIV, fig. 2.

Bleeker, Verh. Bat. Gen. xxiv, Haring. p. 22; Günther, Catal. vii, p. 456. Ilisha brachysoma, Bleeker, Atl. Ich. vi, p. 118, t. 267, f. 5.

Paunia puice, Ooriah.

B. vi, D. $16-17(\frac{3}{13},\frac{3}{14})$, P. 16, V. 7, A. $46-51(\frac{3}{43},\frac{3}{48})$, C. 17, L. 1. 43-44, L. tr. 14-15.

Length of head $4\frac{1}{3}$ to $4\frac{2}{3}$, of caudal fin 5, height of body $3\frac{1}{4}$ to $3\frac{1}{2}$ in the total length. Eyes—diameter 3 in the length of head, 3/4 of a diameter from end of snout, and 1/2 a diameter apart. Abdominal profile more convex than that of the back. The maxilla extends to below the middle of the orbit. The posterior halves of the ridges on the occiput are nearly parallel one to the other. Teeth—on tongue, jaws, and palate. Fins—the dorsal commences midway between the snout and the posterior end of the base of the anal, over which latter fin its last few rays extend. Ventral small. Length of base of the anal fin $2\frac{1}{2}$ to $2\frac{2}{3}$ in the total excluding the caudal fin. Scales—18 scutes anterior to the ventral fin, and 8 posterior to it. Colours—golden glossed with purple.

Habitat.—Seas of India to the Malay Archipelago.

8. Pellona megaloptera, Plate CLXV, fig. 2.

Clupea, Russell, ii, p. 73, and Jangarloo, pl. 191.

Platygaster megalopterus, Swainson, Fishes, ii, p. 294.

Pellona Leschenaultii, Bleeker, Java. 11 (not Cuv. and Val.)

Pellona Russellii, Bleeker, Haring. p. 23. Pellona megalopterus, Jerdon, M. J. L. and Sc. 1851, p. 145.

Pellona motius, Günther, Catal. vii, p. 456 (part).

Ilisha megaloptera, Bleeker, Atl. Ich. vi, p. 119, t. 264, f. 6.

B. vi, D. $17-18(\frac{3}{14},\frac{3}{15})$, P. 17, V. 7, A. $43-50(\frac{3}{40},\frac{3}{47})$, C. 17, L. l. 48-50, L. tr. 14-15.

Length of head $4\frac{1}{3}$ to $4\frac{2}{3}$, of caudal fin $4\frac{1}{2}$, height of body $3\frac{2}{3}$ to 4 in the total length. Eyes—diameter $2\frac{2}{3}$ to 3 in the length of the head, 3/4 of a diameter from end of snout, and 1/4 of a diameter apart. Abdominal profile slightly more convex than that of the back. The maxilla extends to nearly beneath the middle of the orbit. The posterior halves of the occipital ridges are parallel *Teeth*—on jaws, tongue, and palate. *Fins*—dorsal commences about midway between the snout and the base of the caudal fin, its last few rays are above the commencement of the anal, its first ray is over the centre of the interspace between the ventral and origin of the anal fins. Pectoral reaches to above the ventral, which last is not half so long as the eye, and is sometimes entirely absent. Length of base of anal equal to nearly 1/3 of the length of the body excluding

the caudal fin. Scales—22 scutes anterior, and 8 posterior to the ventral fin.

Pellona Dussumieri, C. V. xx, p. 316, pl. 596, may be this species, but if so the ventral fins are shown larger than I have seen them in the fish: in fact they are minute and even absent in some examples. The origin of the dorsal fin is also shown as immediately above the insertion of the ventral.

Habitat. - Seas of India to the Malay Archipelago.

9. Pellona Sladeni, Plate CLXIV, fig. 1.

Day, Proceedings of the Zoological Society, 1869, p. 623.

B. vi, $13(\frac{3}{10})$, P. 11, V. 7, A. $44(\frac{3}{41})$, C. 21, L. 1. 48, L. tr. 10.

Length of head 5, of caudal fin 8, height of body 54 in the total length. Eyes—diameter 1/4 of length of head, I diameter from end of snout. Ridges on the occiput slightly diverge posteriorly. The maxilla reaches to below the middle of the eye. Fins—first two dorsal rays in advance of anal, the remainder of the fin over it, it arises midway between the base of the caudal and the posterior extremity of the opercle. Pectoral reaches to nearly the end of the ventral, which is small. Caudal forked. 23 spinate scales exist on the abdominal profile anterior to the ventral fins, and 10 posterior to them. Colours—silvery, opercles golden: caudal edged with black.

Habitat.—Irrawaddi as high as Mandalay. A single example obtained, 7 inches in length.

10. Pellona Leschenaultii.

Cuv. and Val. xx, p. 311; Bleeker, Beng. p. 72; Günther, Catal. vii, p. 459.

D. 21, P. 17, V. 8, A. 42, C. 27, L. 1. 70.

Height of body nearly 4 in the total length. Suborbital and opercle striated. Teeth-very distinct in premaxillaries and mandibles. Fins—pectoral large and rounded towards its extremity, and extending beyond the insertion of the ventrals which last are small, and arise about 8 or 9 rows of scales anterior to the origin of the dorsal. Anal elongated. Colours—silvery.

Habitat.—A single dried example (20 inches long) was brought from Pondicherry.

Genus, 7—Opisthopterus, Gill.

Pristigaster, sp. Cuv.

Branchiostegals six. Body oblong, compressed. The lower jaw projecting; the maxilla elongated posteriorly. Small sharp teeth in the jaws, palatines, pterygoids and tongue: none on the vomer. Dorsal fin situated behind the commencement of the anal, which has many rays: ventrals absent. Scales of moderate or small size, very deciduous: serrature along the abdominal profile well developed.

This genus is closely allied to the last, the chief difference being absence of ventral fins. Amongst

examples of Pellona occasional ones are seen in which this fin is deficient.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Opisthopterus tartoor, A. 56-62, L. l. 50. From Beloochistan through the seas of India to the Malay Archipelago.

1. Opisthopterus tartoor, Plate CLXIII, fig. 5.

Tartoore, Russell, Fish. Vizag. ii, p. 74, pl. 193.

Pristigaster tartoore, Cuv. Reg. Anim.; Cuv. and Val. xx, p. 328; Bleeker, Haring. p. 25; Day, Fish. Mal. p. 232; Günther, Catal. vii, p. 460.

Pristigaster Indicus, Swainson, Fishes, ii, p. 294; Jerdon. M. J. L. and Sc. 1851, p. 146.

Opisthopterus tartoor, Gill, Clupein. Proc. Acad. Nat. Phil. 1861, p. 38; Bleeker, Clupeoid. p. 296, and Atl. Ich. vi, p. 123, t. 263, f. 5.

B. vi, D. 15-17($\frac{3}{12}$, P. 14, A. 56-63($\frac{3}{54}$, C. 17, L. 1. 50, L. tr. 12.

Length of head $5\frac{1}{2}$ to $5\frac{3}{4}$, of caudal 6, height of body $3\frac{2}{3}$ to 4 in the total length. Eyes—diameter $2\frac{3}{4}$ to 3 in length of head, 2/3 of a diameter from end of snout, 1/3 of a diameter apart. The maxilla reaches to below the anterior third or middle of the orbit, its length nearly half of that of the head: lower jaw very prominent: opercle 1/3 to 3/4 higher than wide. Teeth—on jaws, tongue, palatine, and pterygoid bones. Fins—origin of dorsal rather nearer base of caudal than to the axilla: the pectoral, somewhat longer than the head, reaches to over the first anal ray, and that fin commences midway between the end of the snout and the posterior extremity of its own base: caudal forked. Scales—very deciduous: 28 to 32 spines along the lower profile. Gill-rakers about 28, and nearly as long as the eye. Pseudobranchiæ well developed. Colours—silvery.

Dr. Bleeker questions whether the Malay Archipelago species is identical with the Malabar one, as in the latter the pectorals are longer than the head, reaching to the commencement of anal fin, the body is higher, and the caudal shorter.

Habitat.—From Gwadur in Beloochistan and Sind, through the seas of India to the Malay Archipelago. It attains at least 9 inches in length.

Genus, 8-RACONDA, Gray.

Apterygia, Gray.

Branchiostegals six. Body ollong, compressed. The lower jaw projecting: the maxilla may be elongated posteriorly or truncated. Small teeth on the jaws, palatines, pterygoids, and tongue: none on the vomer. Dorsal and ventral fins absent: anal elongated. Scales rather small and deciduous. Serrature along the abominal profile developed but weak.

This genus differs from the last in having no dorsal fin. It appears that the species is more abundant along the coast of India than in the Malay Archipelago.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Raconda Russelliana, A. 92, L. l. 64. Bay of Bengal to the Malay Archipelago.

Apterygia Hamiltonii, Cuv. and Val. xx, p. 333. Pristigaster Russellianus, Günther, Catal. vii, p. 462.

B. vi, P. 13, A. $92(\frac{9}{90})$, C. 19, L. l. 64, L. tr. 12.

Length of head 6½ to 7, of caudal 7, height of body 4½ to 4½ in the total length. Eyes—diameter 3 to 3½ in length of head, 2/3 to 3/4 of a diameter from end of snout and also apart. Body strongly compressed: end of lower jaw forms a portion of the dorsal profile which is concave above the orbit, whilst the anterior portion of the abdominal profile is very convex: snout obtuse: maxilla extends to opposite the middle of the eye. Teeth—fine along the whole extent of the maxilla, also on the lower jaw, palate and tongue. Fins—upper pectoral ray enlarged, it does not extend so far as to above the root of the anal: caudal does he for the control to the control of deeply forked, the lower lobe the longer. Scales—in regular horizontal rows, covering body and along the base of the anal fin, they are very deciduous: from 31 to 38 weak scutes along the abdominal edge. Gill-rakers nearly as long as eye and about 28 in number on the lower branch of the outer branchial arch. Pseudobranchiæ well developed. Colours—a narrow dark bluish band along the back, succeeded by a light bronze line, which is divided by a lighter and wider band from a broad silvery one passing from the head to the caudal fin. A deep brown or black spot exists on the shoulder, which is sometimes continued on to the opercle. The young are a beautiful purple with a silvery band.

Habitat.—Bay of Bengal to the Malay Archipelago, the young are common in the Sunderbunds.

Fourth group—Dussumieriæformes.

Mouth antero-lateral, the upper jaw not projecting. Eyes with free adipose lids, no osseous gular plate. Abdominal edge smooth.

Genus, 9-Dussumieria, Cuvier and Valenciennes.

Gill-membranes entirely separate. Body Branchiostegals numerous: pseudobranchiæ well developed. somewhat elongated, compressed: ablomen rounded, not serrated. Snout pointed: upper jaw not projecting: cleft of mouth of moderate width. Eyes with broad adipose lids. Small fixed teeth in the jaws, and villiform ones on the palatines, pterygoids, and on the tongue, but absent from the vomer. Dorsal fin opposite to the ventral: anal of moderate length. Scales of medium or rather small size, very deciduous. Pyloric appendages numerous.

Geographical distribution.—From Sind throughout the seas of India to the Malay Archipelago and China.

SYNOPSIS OF SPECIES.

1. Dussumieria Hasseltii, D. 17-20, A. 15-16, L. l. 52-56. Height of body $5\frac{1}{3}$ to $6\frac{1}{3}$ in the total length.

Canara, Coromandel Coast of India to the Malay Archipelago and China.

2. Dussumieria acuta, D. 19-20, A. 14-17, L. l. 40-42. Height of body 5 to 5\frac{1}{4} in the total length. Sind, through the seas of India to the Malay Archipelago.

1. Dussumieria Hasseltii, Plate CLXVI, fig. 5.

Bleeker, Chiroc. p. 13, or Nat. Tyds. Ned. Ind. i, p. 422 (ex parte). Dussumieria elopsoides, Günther, Catal. vii, p. 466 (not Bleeker).

B. xv-xix, D. 17-20($(\frac{3-4}{14-16})$, P. 15, V. 8, A. 15-16($\frac{3-3}{13}$), C. 19, L. 1. 52-56, L. tr. 12.

Length of head $4\frac{1}{2}$ to 5, of caudal $4\frac{1}{2}$ to 5, height of body $5\frac{2}{3}$ to $6\frac{1}{3}$ in the total length. Eyes—with broad adipose lids, diameter 4 to 4½ in the length of the head, 1½ diameters from the end of snout, and 1 apart. Snout pointed, the greatest height of the head equals its length excluding the snout. The maxilla reaches to beneath the front edge of the orbit: jaws of the same length anteriorly, or the lower slightly projecting. Teeth—in a single row in the jaws, also present on the tongue, palatines, and pterygoids. Fins—dorsal commences midway between the hind edge of the eye and the base of the caudal fin: ventral inserted beneath the last half of the dorsal. Scales—very deciduous. Gill-rakers rather widely set, the longest being about 1/2 as long as the eye, and 19 on the lower branch of the outer branchial arch. The branchiostegals of the left side overlap those of the right to a slight extent. Colours—of a beautiful green, shot with blue. Upper margin of the opercle and along the back of a light blue, below which is a bronzed line, and below that again a silvery one shot with pink. Caudal shot with blue, green, and gold. Upper surface of head and eye emerald green. Pectoral, ventral, and anal white, except the first ray of the pectoral which has a little black on it. Dorsal yellowish-green. End of snout greenish. Eyes white.

Habitat.—From Canara and the Coromandel Coast of India to the Malay Archipelago and China. The

largest example obtained in Canara was 8 inches in length. It is not nearly so common as the D. acuta.

2. Dussumieria acuta, Plate CLXVI, fig. 4.

B. xiv-xv, D. 19-20($\frac{3-4}{10-17}$), P. 14, V. 8, A. 14-17($\frac{2-3}{13-14}$), C. 21, L. l. 40-42, L. tr. 11-12.

Length of head 5 to $5\frac{1}{2}$, of caudal 5, height of body 5 to $5\frac{1}{4}$ in the total length. Eyes—with broad adipose lids, diameter 1/4 of length of head, $1\frac{1}{4}$ diameters from the end of the snout and nearly 1 apart. Abdominal profile more convex than that of the back. Height of head equals its length excluding the snout. Snout pointed: lower jaw slightly the longer when the mouth is closed. The maxilla reaches to below the front edge of the eye. Opercle twice as high as wide. Teeth—in a single row in the jaws, also present on tongue and palate, but not on the vomer. Fins—the dorsal commences midway between the front edge of the eye and the base of the caudal fin: ventral inserted beneath the last half of the dorsal. Scales—very deciduous. Gillrakers rather widely set, 1/2 as long as the eye, and about 22 in the horizontal branch of the outer branchial arch. Colours—the same as in D. Hasseltii.

Cantor says this species has been preserved à huile. It is termed a Sardine by the inhabitants and

residents in Malabar, where it is very common and is excellent eating.

Habitat.—From Sind through the seas of India to the Malay Archipelago. It attains at least 7 inches in length.

Genus, 10—Spratelloides, Bleeker.

Branchiostegals six: pseudobranchiæ well developed. Gill-membranes entirely separated: no osseous gular plate. Body elongated, moderately compressed or sub-cylindrical: abdomen rounded. Snout compressed: the mouth anterior, having a lateral cleft: the upper jaw not overlapping the lower. Eyes without adipose lids. Teeth small and deciduous, but may be present on the jaws, vomer, pterygoids, and tongue. Dorsal fin placed opposite the ventrals: anal of moderate length or short. Scales of medium size, rather deciduous. Pyloric appendages in moderate

Geographical distribution.—Western Coast of India, Malay Archipelago to Australia, also the North Pacific.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Spratelloides Malabaricus, D. 14, A. 18, L. 1. 38, L. tr. 9. Silvery, Malabar.

1. Spratelloides Malabaricus, Plate CLXI, fig. 5.

Day, Proceedings Zoological Society, 1873, p. 240.

B. vi, D. 13-14($\frac{3}{10^{-13}}$), P. 13, V. 8, A. 18-19($\frac{4}{14^{-1}15}$), C. 19, L. 1. 38, L. tr. 9.

Length of head (its proportion increases with age) $4\frac{1}{2}$ to $5\frac{3}{4}$, of caudal $5\frac{1}{4}$, height of body $5\frac{1}{4}$ in the total length. Eyes—subcutaneous, diameter 1/3 of length of head, 1 diameter from the end of snout, and 3/4 of a diameter apart. Abdominal profile rather more convex than the dorsal. Lower jaw rather longer than the upper. The maxilla reaches to below the front edge or first 1/3 of the orbit. Teeth—minute and deciduous in both jaws. Fins—dorsal commences slightly anterior to the origin of the ventral, and rather nearer the end of snout than the base of the caudal fin, which latter is deeply forked. Colours-light yellowish-green superiorly, a silvery stripe along the side, abdomen silvery: upper caudal lobe with a bluish posterior edge: some fine black points along the back: upper edge of eye dark green.

Habitat.—Western Coast of India, in rivers and estuaries. It attains 3 inches in length, and is not

uncommon.

Fifth group—ALBULINÆFORMES.

Mouth inferior and of moderate width: upper jaw projecting. Teeth in jaws.

Genus, 11—ALBULA, Gronovius.

Butyrinus, Lacép.: Glossodus (Cuv.) Agassiz.: Conorhynchus (Nozeman), Bleeker, Atl. Ich.

Branchiostegals eleven to sixteen. Gill-membranes entirely separated. Body oblong or elongated. Abdominal edge rounded and not keeled. Snout pointed, projecting beyond the mouth. Eyes with a broad annular adipose covering. Villiform teeth on the jaws, vomer, and palatine bones: granular on the tongue, pterygoid and sphenoid bones. Dorsal fin situated opposite to the ventrals: the anal shorter than the dorsal. Scales rather small, not deciduous: lateral-line present. Pseudobranchiæ well developed. Pyloric appendages numerous.

Length of head $4\frac{1}{2}$ to 5, of caudal fin $4\frac{3}{4}$ to 5, height of body $5\frac{1}{2}$ to $6\frac{1}{2}$ in the total length. Eyes—diameter 4 to 5 in the length of the head, 1 to $1\frac{1}{3}$ diameters apart. The maxilla reaches to below the front edge of the eye. Teeth—generic. Fins—the ventral inserted beneath the last half of the dorsal. Colours-

Habitat.—Rea Sea, seas of Africa, India, the Malay Archipelago and America, also the Pacific.

Sixth group—ELOPSÆFORMES.

Mouth antero-lateral: lower jaw the longer. An osseous gular plate. Abdomen rounded and smooth.

Genus, 12—Elops, Linnœus.

Branchiostegals numerous: pseudobranchiæ. Gill-membranes entirely separated. Body rather elongated and compressed. An osseous gular plate is attached to the symphysis of the mandibles and covers the intermediate part. Mouth wide, anterior, lower jaw the longer. Villiform teeth in the jaws, vomer, palatine and pterygoid bones, also on the tongue and base of the skull. Ventrals opposite to the dorsal, which last has a few rays more than the anal. Scales small. Lateral-line distinct. Pyloric appendages numerous.

B. xxix-xxxv, D. $22-24(\frac{1}{18}\frac{4}{10})$, P. 19, V. 6, A. $15-17(\frac{1}{18}\frac{4}{10})$, C. 19, L. 1. 95-100, L. tr. 12/14.

Length of head $4\frac{1}{2}$ to 5, of caudal 5, height of body 5 in the total length. Eyes—diameter $4\frac{1}{8}$ to 5 in the length of head, 3/4 to 1 diameter from the end of snout, and the same apart. Body elongated, sub-fusiform; abdomen rather wide and smooth; both profiles, nearly horizontal and of almost equal curves. The under jaw slightly shorter than the upper, and rather thickened at its extremity: cleft of mouth oblique: the maxilla extends to rather behind the posterior margin of the orbit. Teeth-numerous and villiform in both jaws, while they are continued along the anterior edge of the maxilla: on vomer in a triangular patch, and also on the palatines where there are about ten rows. Fins—dorsal commences rather nearer to the base of the caudal fin than to the snout, it is highest in front with a concave upper edge: anal rather more concave than the dorsal: caudal deeply lobed in its posterior three-fourths. Scales—a few fine rows form a sort of sheath to dorsal and anal fins, also some over the root of caudal. Lateral-line—11 rows of scales between it and the base of the ventral fin. Colours—silvery: fins yellowish, with a greenish tinge.

Habitat.—Red Sea, East coast of Africa, through the seas of India to the Malay Archipelago and beyond.

It attains a considerable length.

Genus, 13-Megalops, Commerson.

Branchiostegals numerous: pseudobranchiæ absent. Gill-membranes entirely separated. Body oblong and compressed. Mouth anterior, lower jaw prominent. A narrow bony plate adherent to the symphysis of the mandibles, and covering the space intermediate between the two bones. Villiform teeth in the jaws, vomer, palatine, and pterygoid bones, also on the base of skull and on the tongue.

SYNOPSIS OF INDIVIDUAL SPECIES.

Elops apalike, Day, Fishes of Malabar, p. 228.

Punnikowu and Naharn, Ooriah: Cunnay, Mal.: Moran cundai, Tamil.: Nga-tan-youet, Burmese.

B. xxiv-xxvi, D. 19-21($\frac{2}{17^2-19}$), P. 15-16, V. 10, A. 24-27($\frac{2}{22^2-25}$), C. 19, L. 1. 37-42, L. tr. 5-6/6.

Length of head $4\frac{1}{4}$ to 5, of caudal fin 4 to 5, height of body $4\frac{1}{4}$ to 5 in the total length. Eyes—with narrow adipose lids, diameter $3\frac{1}{4}$ to $3\frac{1}{2}$ in the length of head, about 1/2 a diameter from end of snout and also apart: the size of the eye in large specimens is frequently comparatively larger than in small ones. Lower jaw prominent: the maxilla reaches to opposite the hind edge of the eye. Teeth—villiform in both jaws, on the vomer, palatines, pterygoids, and sphenoid. Fins—dorsal commences opposite the ventral and about midway between the snout and base of the caudal fin, it is 2/3 as high as the body below it, its upper edge concave, and its last ray prolonged. Caudal deeply lobed, the lobes rather more expanded in the immature than in the adult fish. Lateral-line—each tube terminating posteriorly in 6 or 8 branches. Colours—summit of head dark olive, back bluish-green in the adult, lighter in the immature. Abdomen silvery, with bluish reflections. The margins of the scales of a brilliant silver, as are also the lateral-line and the sides of the head. The centre of the jaws black. Dorsal and caudal grayish, minutely dotted with black, and the margins blackish, as is also the last elongated dorsal ray. Pectoral, ventral, and anal diaphanous, with some black dots, the last anal ray Eves silvery, with the orbital margin having a dark tint. The pupils are oval pointing downwards.

Bleeker divided his eight examples of the above into 4 species, thus:

A.—Height of body $3\frac{2}{3}$ to $4\frac{1}{2}$ in its length. Eyes 3 to 5 in length of head. This included M. macropterus with length of base of anal fin 5, of head $3\frac{1}{2}$ to 4 in that of the body; M. filamentosus, anal $5\frac{1}{3}$, head 4; M. kundinga, anal 6, head $3\frac{1}{2}$.

B.—Height of body 43 to 5 in its length. M. cyprinoides, with length of base of anal 53, of head 31 to 3? in that of the body.

Habitat.—East coast of Africa, fresh waters and estuaries of India, Ceylon, Malay Archipelago, China, and Polynesia. It is occasionally captured in rivers, but much more commonly found in tanks.

Sixth group-Chaninæformes.

Teeth absent. Gill-membranes entirely Mouth anterior, transverse, small. Eres subcutaneous. united. Abdomen rounded and smooth.

Genus, 14—Chanos, Lacépède.

Lutodeira, (Kuhl), Rüppell.

Branchiostegals four: pseudobranchiæ present. Gill-membranes entirely united below and not attached to the isthmus. Body moderately elongated and compressed: abdomen rounded. An accessory branchial organ in a recess behind the true gill-cavity. Mouth small, anterior and transverse. Teeth absent. Ventral fin opposite the dorsal, which last has more rays than the anal. Caudot deeply cleft. Scales rather small. Lateral-line distinct. Airvessel with a constriction. Pyloric appendages numerous.

Length of head $5\frac{1}{4}$ to $5\frac{1}{2}$, of caudal 4 to $4\frac{1}{2}$, height of body $4\frac{2}{3}$ to $5\frac{1}{4}$ in the total length. Eyes—subcutaneous, diameter $3\frac{1}{2}$ to $3\frac{3}{4}$ in the length of head, 3/4 to 1 diameter from the end of snout, and $1\frac{1}{4}$ apart. Body elongated: upper surface of head flat: upper jaw overhanging the lower. The maxilla extends to under the anterior margin of the orbit. Opercle nearly twice as high as wide. Fins—dorsal fin highest in front, its upper margin concave, and along its base are two rows of scales, it arises midway between the front edge of the eye and the base of the caudal fin. Pectoral pointed, with an elongated scaly appendage at its base: ventral inserted under the middle of the dorsal, having a long basal scale. Anal very small: the lower margin of the fin concave, with two rows of scales along its base: caudal deeply lobed, and its centre covered by two semilunar laminæ of scales. Scales—small, covering the body: there are some rows of enlarged ones over the nape. Gill-rakers short. Colours—summit of head and back of a brilliant glossy blue, fading into silvery on nape. Gill-rakers short. Colours—summit of head and back of a brilliant glossy blue, fading into silvery on the abdomen: snout light brown. Dorsal and caudal rays grayish, which, as well as the membranes, are dotted with light brown, and both these fins are margined with black. The caudal semi-lunar laminæ of scales pale slate colour, the pectorals and ventrals white, with the anterior halves of their external surfaces minutely dotted with dark brown, their elongated appendages bright silvery. The anal white, with the anterior half

dotted with black. Iris silvery, orbital half pale brownish.

Habitat.—Red Sea, seas of India to the Malay Archipelago and beyond. Attains 3 feet at least in length: is called the milk fish or white mullet by Europeans in South Canara, where Hyder Ali introduced it

from the sea into tanks of fresh and brackish water where it still thrives.

FAMILY, VII—CHIROCENTRIDÆ.

Pseudobranchiæ absent. Body much elongated and compressed. Margin of upper jaw formed by the premaxillaries mesially, and the maxillaries laterally. Opercular apparatus complete. Barbels absent. A single rayed dorsal fin belonging to the caudal portion of the vertebral column. Body with thin, deciduous Stomach with a blind sac: intestinal canal short. No pyloric appendages. Air-vessel present. Branchiostegal rays 8.

Only one genus is known of this family which is confined to the Red Sea, and those of India to the Malay Archipelago. Bleeker placed this family amongst his Clupeoidei, and next to the group Dussumieriformes.

Genus, 1—CHIROCENTRUS, Cuvier.

Branchiostegals eight. Abdomen with a sharp but not serrated margin. Gill-membranes united for a short distance: gill-opening wide. Eyes subcutancous. Cleft of mouth oblique and deep: the lower jaw the longer. A row of canines in the mandible, and a horizontal pair in the premaxillaries: minute teeth on the palatines, pterygoids, and tongue. A single short dorsal fin placed far backwards opposite to a long anal: an elongated osseous appendage in the axilla: ventrals very small. Scales thin, small, and deciduous. Air-vessel cellular.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Chirocentrus dorab, D. 16-17, A. 31-36. Red Sea, seas of India to the Malay Archipelago and beyond.

1. Chirocentrus dorab, Plate CLXVI, fig. 3.

Clupea dorab, Forsk. p. 72, No. 108; Gmel. Lin. p. 1409; Russell, Fish. Vizag. ii, 78, and Wahlah, pl. 199; Lacép. v, p. 458.

Esox chirocentrus, Lacép. v, p. 317, t. 8, f. 1.

Clupea dentex, Bl. Schn. p. 428.

Chirocentrus dorab, Rüppell, N. W. Fische, p. 81; Cuv. and Val. xix, p. 150, pl. 565; Richard. Ich. China, p. 311; Bleeker, Chiroc. p. 10, and Atl. Ich. vi, p. 92, t. 271, f. 3; Cantor, Catal. p. 277; Jerdon, M. J. L. and Sc. 1851, p. 146.; Day, Fishes of Malabar, p. 223; Kner, Novara Fische, p. 340; Günther, Cat. vii, p. 475; Klunz. Fische Roth. Meer. Verh. z. b. Ges. Wien, 1871, p. 606.

Chirocentrus nudus, Swainson, Fishes, ii, p. 294.

Chirocentrus hypselosoma, Bleeker, Singap. p. 71, Chiroc. p. 25, and Atl. Ich. vi, p. 93, t. 269, f. 3. Mooloo-alley and Kiru-wahlah, Tam.: Wahlah, Tel.: Kunda, Ooriah.

B. viii, D. 16-17($\frac{4}{12^2-3}$), P. 14-15, V. 6-7, A. 31-36($\frac{4}{27^2-32}$), C. 19.

Length of head $6\frac{1}{2}$ to $7\frac{1}{4}$, of caudal $5\frac{1}{4}$, height of body $6\frac{1}{2}$ to 9 in the total length. Eyes—diameter $4\frac{1}{4}$ in length of head, 1/2 of a diameter apart, and 2/3 to 1 diameter from end of snout. Upper lip terminating anteriorly in a short mesial flap. Lower jaw the longer. The maxilla reaches to below the hind edge of the eye. Teeth—one pair of long, sharp, straight and approximating ones exist near the centre of the premaxillaries, the remainder of which, and the whole extent of the maxilla, is armed with sharp straight teeth of irregular lengths, and becoming smaller at the posterior extremity of the jaw. Each mandible has a row of about 12 sharp laterally compressed teeth, of which the two first are the shortest, and those most anterior have an oblique anterior direction, while the posterior ones gradually become directed more and more backwards until the last form an acute angle with the jaw. Five or six large card-like teeth on the palatine bones, and a small oval group of velvety ones on the pterygoid. Fins—the ventral commences midway between the end of the snout and the base of the caudal: the dorsal is in about the posterior third of the body, above the anal. Along the whole extent of the lower margin of the abdomen are short hair-like rays. Scales—small and deciduous. Lateral-line—indistinctly marked. Air-vessel—small, elongated and cellular. Colours—bluish-green along the back: silvery on the sides and abdomen.

Bleeker considered the above to consist of two species, C. dorab, height of body 7, length of head 6 in its length without the caudal fin, and scales smaller than in C. hypselosoma, the latter having, height of body $5\frac{1}{2}$, length of head $5\frac{3}{3}$ in its length without the caudal fin.

Habitat.—Red Sea, through the seas of India to the Malay Archipelago and beyond. It attains at least 12 feet in length. When captured it bites at everything near it.

* The mucous membrane of the intestinal canal has been said to have spiral folds, a character usually attributed to the highest class of fish. Having carefully examined the anatomy of a fine specimen in a good state of preservation, I do not find this to exist. The mucous membrane is puckered into longitudinal folds, but there is no trace of a spiral one in the single example examined

FAMILY, VIII—NOTOPTERIDÆ.

Pseudobranchiæ absent. Body oblong, or more or less elongated and compressed. Tail prolonged and tapering. Margin of the upper jaw formed by the premaxillaries mesially, and the maxillaries laterally. Opercular apparatus incomplete, the subopercle being absent. A parieto-mastoid cavity on either side of the head connected with the interior of the skull. Barbels absent. Dorsal fin, if present, single, and belonging to the caudal portion of the vertebral column; ventrals rudimentary or absent: anal fin with numerous rays and confluent with the caudal. Head and body with small scales. Lateral-line present. Abdominal edge servered enterior to the ventral fine. Stomach without any blind sec. Two pyloric appendances. Air vessel serrated anterior to the ventral fins. Stomach without any blind sac. Two pyloric appendages. Air-vessel present, and sub-divided internally. Branchiostegal rays from 3 to 9. The ova fall into the cavity of the abdomen before exclusion.

Geographical distribution.—Fresh and brackish waters of West Africa, also of the continent of India to the Malay Archipelago.

Genus, 1-Notopterus, Lacépède.

Mystus, sp. Ham. Buch.: Xenomystus, Günther.

Branchiostegals from 3 to 9. Gill-membranes partly united. Snout obtuse, convex. Muciferous channels on head well-developed. Cleft of mouth lateral. Preopercle and occasionally some of the other bones of the head serrated. Teeth in jaws, vomer, palatine and sphenoid bones, also on the tongue. Dorsal fin present (Notopterus) or absent (Xenomystus). Ventrals when present, rudimentary and united together. Air-vessel divided internally, with two horns anteriorly, which are in connection with the auditory organs: posteriorly it likewise ends in two branches which become divided from one another by the hæmal spines. Intestines short. Cæcal pylori long.

Geographical distribution.—The species without dorsal fins appear to be confined to West Africa: the remainder are Asiatic or African.

SYNOPSIS OF SPECIES.

1. Notopterus kapirat, A. 100-110. Scales on cheeks much larger than on body. Maxilla does not extend beyond the hind edge of orbit. India to the Malay Archipelago.

2. Notopterus chitala, A. 110-125. Scales on cheeks not much larger than on body. Maxilla extends far beyond hind edge of orbit. Sind and India to the Malay Archipelago.

Length of head 5 to $5\frac{1}{2}$, of caudal fin 12, height of body $3\frac{1}{2}$ to 4 in the total length. Eyes—diameter $4\frac{1}{2}$ to 5 in the length of head, 2/3 to 1 diameter from the end of snout, and 1 apart. Dorsal profile not so convex as that of the abdomen. The maxilla reaches to below the middle of the orbit. Preorbital serrated: lower edge of preopercie with a double serrated margin. Teeth—an external row of strong curved ones in either jaw, with an internal finer one. Several rows of fine teeth in vomer and palate: some also present on the tongue. Fins—dorsal commences nearly midway between the snout and end of the caudal fin. Scales—those on the cheeks much larger than those on the body: about 28 serrations along the abdominal edge between the throat and the insertion of the ventral fin. Colours—silvery, darkest on the back: some gloss of yellow about the head. Numerous fine grayish spots everywhere. Upper surface of dorsal whitish. Eyes golden.

Habitat.—Fresh and brackish waters of India to the Malay Archipelago. Grow to 2 feet or more in

length.

2. Notopterus chitala, Plate CLIX, fig. 5.

Notopterus chitala, Günther, Catal. vii, p. 479; Bleeker, Atl. Ich. vi, p. 147.

Chitul, Ooriah: See-tul, Assam.: Gundun, Sind.: Chitala, Beng.

B. viii-ix, D. 9-10($\frac{1-2}{7-0}$), P. 16, V. 6, A. 110-125 (135), C. 12-14, L. 1. 180, Cæc. pyl. 2.

Length of head $4\frac{1}{2}$ to 5, of caudal fin $15\frac{1}{2}$, height of body $3\frac{1}{2}$ to 4 in the total length. Eyes—diameter 7 to 8 in the length of head, 3/4 of a diameter from end of snout, and nearly 1 apart. Upper profile of head deeply concave. Snout rather prominent: the maxilla extends posteriorly to about the length of 1 diameter of the eye behind the hind edge of the orbit. Preorbital entire: lower edge of preopercle very finely serrated. Teeth—villiform in both jaws with an external enlarged row, most developed opposite centre of the upper jaw: also villiform in vomer and palatines. Some teeth likewise present on the tongue, the largest being in front. Fins—ventrals minute: anal and caudal confluent. Scales—cycloid, small, extending over body, opercles, and some of the fins: and from the nape as far as to opposite the preopercle: those on the head not being much larger than those on the body. There are about 51 serrations along the abdominal edge between the throat and the insertion of the ventral fin. Lateral-line—nearly straight and in upper third of the body. Colours—superiorly coppery-brown with about 15 transverse silvery bars joining over the back: sides silvery: fins stained with grayish spots, which are like black stars in the caudal region, placed in a single or double row close to the anal fin and sometimes extending the whole length of its base. Air-vessel—long, thick, with a partition down its centre, whilst posteriorly it is continued on either side of the hemal spines, half way to the caudal fin. Cæcal-pylori—very long and with transverse ruge internally: intestines short.

"The belly is uncommonly rich and well-flavoured: but the back contains numerous small bones, and a strong prejudice exists against using this fish as food, owing to its being supposed to live on human carcases."—

Ham. Buch.

Habitat.—Fresh waters of Sind, Lower Bengal, Orissa, Assam, Burma, and Siam to the Malay Archipelago. It attains at least 4 feet in length.

FAMILY, IX—SYMBRANCHIDÆ.

Gill-openings confluent into a single slit, which is situated on the abdominal surface. Gills well developed or rudimentary. Body elongated. The humeral arch may or may not be attached to the skull. Margin of the upper jaw formed by the premaxillaries, the maxillaries being internal and parallel to them. Barbels absent. Palatine teeth, when present, in a single row or a narrow band. Vertical fins rudimentary, in the form of mere folds of skin, and no paired ones. Scales, if present, minute. Vent far behind the head. An accessory breathing sac present or absent. Air-vessel absent. Ribs present. Stomach destitute of a blind sac. No pyloric appendages. Ovaries with oviducts.

The Families Symbranchidæ and Murænidæ belong to the Physostomi apodes of some authors, and the former tropical family is fairly represented in the continent of India, whereas the latter is more numerous in the seas than in the fresh waters.

Geographical distribution.—Fresh and brackish waters of tropical Asia and America; also Western Australia and Van Diemen's land.

SYNOPSIS OF GENERA.

First group—AMPHIPNINA.

Humeral arch not attached to the skull; an accessory breathing apparatus. Scales present.

1. Amphipnous. Palatine teeth in a single row, p. 655.

Second group—Symbranchina.

Humeral arch attached to the skull. No accessory breathing apparatus. Scales absent.

2. Monopterus. Gills rudimentary, p. 656.

3. Symbranchus. Gills well-developed, p. 657.

First group—Amphipnina.

Humeral arch not attached to the skull. An accessory breathing apparatus. Scales present.

Genus, I-AMPHIPNOUS. Müller.

Pneumabranchus, McClelland.

Branchiostegals six. Gill membranes almost entirely grown to the isthmus, and having a single transverse opening. Three branchial arches with the laminæ rudimentary, divided by narrow slits. A respiratory air sac exists on the neck behind the head communicating with the gill cavity. Palatine teeth in a single, well-developed row. Scales present and arranged in longitudinal rows.

This amphibious fish, when kept in an aquarium, may be observed to constantly rise to the surface for the purpose of respiring atmospheric air direct. It usually remains with its snout close to the surface and in like manner lies in the grassy sides of ponds and stagnant pieces of water, so that without trouble it may obtain its modicum of air. McClelland observed (Cal. Journ. Nat. Hist. v, p. 195). "I have had two live Cuchias by me now for a period of twelve months; they are still as well as when I first obtained them, though from an ignorance of their proper food, as well as a desire to know how long they are capable of existing without any, they had nothing to eat during that period to within the last few months, when some small fish and shrimps were put alive into the vessel."

In Amphipnous cuchia, we find "that of all the arches the second alone possesses laminæ for the purposes of breathing: and those consist merely of a few long fibrils attached to the middle of the arch and occupying but a very small extent of its surface: the third supports in the place of laminæ, a thick and semi-transparent tissue, which in large individuals of the species possesses a fringed or denticulated appearance on its edge; whilst the third and fourth are bare, having only the membrane that fills up the space between the arches reflected over them. The principal organs of respiration are two small bladders, which the animal has the power of filling with air, immediately derived from the atmosphere. They are placed behind the head, one on each side of the neck, above the superior or vertebral extremities of the branchial arches, and are covered over by the common integument, presenting externally when distended with air, two protuberances of a round shape. . . . They present, when separated from their surrounding attachments and inflated with air, thin, transparent, membranous parieties, resembling the posterior portions of the lungs of a serpent. . . .

Of the whole volume of blood contained in the branchial artery, one-third passes through the gills and respiratory bladder, whilst the other two-thirds are conveyed directly from the heart to the aorta without being exposed to the action of the air." Taylor, Gleanings in Science, ii, p. 173, and Edinb. Journ. of Sc. v, 1831, p. 33; Hyrtl, Denk. Ak. Wiss. Wien, 1858, xiv, c. tab.

Ophichthys punctatus, Swainson, Fishes, ii, p. 336.

Pneumobranchus striatus, leprosus (white and spotted), and albinus (orange yellow), McClelland, Cal. J. N. H. v, pp. 192, 195, 196, 219.

Cuchia, Ooriah and Beng.: Nga-sheen, Burmese.

Length of head (from gill-opening) 6 to 8 in the distance between the snout and the anus: length of tail 4 to 41 in the entire length. Eyes—two to three diameters from end of snout and situated in the anterior 1/4 or 1/5 of length of the head, about midway between the end of the snout and the posterior extremity of the jaws: a valved nostril opens above the orbit: a second, round and patent, in front of the snout. Upper jaw slightly the longer: lips fleshy. Teeth—a single row of small ones in the premaxillaries, except opposite the symphysis: a single band of large, curved, compressed and backwardly directed ones on either palatine: and a single row of moderately large ones on either ramus of the mandibles. Fins—a rudimentary dorsal commences slightly anterior to the vertical of the anus. Scales—distinct and longitudinally arranged. Gill-openings—inferior, the membrane adherent to the isthmus. Vertebræ 106/65. Colours—greenish, or of a chestnut-brown, becoming lighter on the abdomen: numerous black spots over the body: occasionally they are seen flesh-coloured.

One 13 inches in length in the Calcutta Museum, has the following label:-"From Seeb-Saugor, presented by S. E. Peel, Esq. This fish was hoed out of stiff blue clay as I was standing overlooking men at work, making a bund, June 24th, 1865. No water had been seen near for some time."

"Natives reject it as food and imagine that its bite is fatal to cattle, although less powerful on the human kind,—a supposition highly improbable" (Ham. Buch.).

Habitat.—Fresh and brackish waters of Punjab, extending to Bengal, Orissa, Assam and Burma. It attains at least two feet in length.

Second group—Symbranchina.

Humeral arch not attached to skull: no accessory breathing apparatus. Scales absent.

Genus, 2-Monopterus, Lacépède.

Fluta, Bl. Schn.; Ophicardia, McClelland; Apterigia, Basilewski.

Branchiostegals five or six. Gill-membranes almost entirely attached to the isthmus, having a single transverse Three branchial arches separated by moderately wide intermediate slits, with the laminæ rudimentary or absent. Palatine teeth in a narrow band. Scales absent. No accessory breathing sac.

Dareste observed a complete absence of branchial laminæ in three examples of Monopterus Javanensis.

Monopterus marmoratus and helvolus, Richards, Ich. China, p. 316.

Ophicardia xanthognatha, Richards, l. c.

Apterigia saccogularis, nigromaculata and immaculata, Basilewsky, Nouv. Mém. Nat. Mosc. x, 1855, pp.

247, 248, t. 2, f. 2, and t. 8, f. 2.

Length of head 9 to 12 in the distance between the end of the snout and the vent: length of body about four or five times that of the tail. Eyes—situated about midway between angle of mouth and end of snout, diameter 1/8 of length of head, 2 diameters from end of snout and 1 to 11 apart. Greatest diameter of tish at the occiput. Profile of upper surface of the head descends somewhat suddenly from above the eyes to the snout, which last is pointed and somewhat compressed. Extent of cleft of mouth equals about 1/3 in the distance between end of snout and gill-opening. Tail narrow and tapering to a point. Teeth—conical, and in a band tapering towards the angle of the mouth: the palatine band resembles those in the jaws. Fins—dorsal commences above or a little before the vertical from the vent. Colours—light-greenish, with or without dark spots; or else the whole body nearly black.

"This eel is numerous at Chusan, in streamlets, canals and estuaries. As it is a favourite article of food it is kept by the inhabitants of Chusan in large jars, with fresh water. But it is capable of living a considerable time out of water. It is of voracious habits, feeding on smaller fishes, and it takes hooks baited with earth-worms." (Cantor, l. c.)

Habitat.—This fish is confined to fresh or brackish waters of Burma, the Malay Archipelago and China.

Genus, 3—Symbranchus, Bloch.

Unibranchapertura, Lacépède; Pneumabranchus and Ophisternon, McClelland; Tetrabranchus, Bleeker.

Branchiostegals six. Gill-membranes not attached to the isthmus, having a single transverse opening. Four branchial arches with well-developed gills. Palatine teeth in a band. Scales absent. No accessory breathing sac.

Geographical distribution.—Fresh and brackish waters of India to the Malay Archipelago and Australia. Also tropical America.

1. Symbranchus Bengalensis, Plate CLXVII, fig. 2.

Ophisternon Bengalensis, McClelland, Cal. J. N. H. v, pp. 197, 220, t. 2, f. 1, 2; Kaup, Apod. p. 121, f. 76; Bleeker, En. Pisc. p. 179.

Symbranchus immaculatus, Cantor, Catal. p. 337.

Tetrabranchus microphthalmus, Bleeker, Borneo, p. 69 (young).

Symbranchus Bengalensis, Bleeker, Atl. Ich. iv, p. 119, t. 192, f. 1; Day, Fishes Malabar, p. 251,

Günther, Catal. viii, p. 16.

Length of head 9 to 12 in the distance between the end of snout and anus. Eyes—diameter about 1/20 of length of head. The girth of the body is equal to about three times its height. Snout anteriorly rounded, lips fleshy, the upper jaw rather the longer: cleft of mouth extending to some distance behind the orbits. Teeth—in upper jaw fine and pointed, and do not meet at the symphysis, those on either side terminating in a triangular patch, with a narrow edentulous interspace: those in the lower jaw rather larger, with a narrow edentulous interspace between those of each side, laterally they are in a single row: palatine teeth in a band. Fins—the dorsal commences before the anal, which is situated in the last fourth or fifth of the total length, the caudal is hardly conspicuous: all the fins are low. Lateral-line—conspicuous. Colours—of a dull dirty brownish red in estuaries, lightest on the abdomen. In clearer water it is greenish or blackish green, the abdomen being the lightest.

Habitat.—Estuaries and fresh waters within the influence of the tides along the coasts of India and Malay Archipelago, to the Philippines: attaining to several feet in length. It appears to be more common in Bengal

than in Malabar.

FAMILY, X—MURÆNIDÆ, Müller.

Body elongated, cylindrical, or band-shaped: the humeral arch not attached to the skull. The branchial openings in the pharynx may be wide or narrow slits. Margin of upper jaw constituted anteriorly by the premaxillaries, which are more or less coalescent with the vomer and ethmoid, whilst laterally the sides of the upper law are formed by the maxillaries which are furnished with teeth. Vertical fins, when of the upper jaw are formed by the maxillaries which are furnished with teeth. Vertical fins, when present, confluent or separated by a projecting tail: pectorals present or absent. Scales, when present, rudimentary. Vent may be situated close to the root of the pectoral fins, or a long distance posterior to the head. The heart may be situated just, or a long distance, behind the gills. Stomach with a blind sac. No pyloric appendages. Ovaries destitute of oviducts.

Eels (Anguilla) have by some authors been considered as hermaphrodites. Both Syrski and Dareste have observed upon the male organs in eels, and the latter author found that the variety (Pimpernau) in which they were present, had female organs in some marine examples. Large sterile females ascend rivers but their ova are said not to come to maturity. Dareste also observed male organs in Anguilla marmorata, from the seas (?) of India.

A number of larval fishes have been termed Leptocephali or "glass eels." Some of them it has been suggested may be early arrested development, the fishes dying before attaining their perfect state. "To this form belong all the various Leptocephali and Hyoprorus." L. Spallanzanii is said by Dareste to be a young conger. "Tilurus is a similar form arrested in its development, but cannot be the offspring of a murænoid fish. Stomiasunculus, Kaup, is the young of Stomias; Porobronchus, Kaup, the young of Fierasfer acus; and Esunculus, Kaup, probably that of Alepocephalus."—(Günther.)

Eels are generally known as Velangoo or Pamboo meen, Tamil (snake fish).

SYNOPSIS OF GENERA.

First Group-MURÆNIDÆ PLATYSCHISTÆ.

Branchial openings in the pharynx are wide slits.

- a.—Heart close behind gills. Tail longer or scarcely shorter than the trunk. Nostrils lateral or superior: tongue free: caudal fin continued round the end of tail: pectorals present or absent: scales present or absent.
- 1. Anguilla. Pectoral fins present: dorsal commences some distance behind the nape. Rudimentary scales, p. 659.

 2. Congromurana. Pectoral fins present; dorsal commences above gill-opening. Cleft of mouth reaches
- to below middle of eye: large muciferous cavities on skull. Teeth in bands. Scaleless, p. 660.
- 3. Uroconger. Pectoral fins present: dorsal commences above gill-opening. Cleft of mouth reaches to behind middle of eye. Maxillary teeth biserial: vomerine uniscrial. Scaleless, p. 661.
- b.—Heart close to gills: tail not shorter than trunk. Nostrils lateral or superior: tongue not free: caudal fin continued round the end of tail: pectorals present or absent. Scaleless.
- Pectoral fins present. Canine teeth in jaws anteriorly: strong teeth on vomer. Posterior nostril opposite upper part or middle of eye, p. 661.
 - 5. Saurenchelys. Pectoral fins absent. Posterior nostril lateral and in front of orbit, p. 663.
- c.—Heart close to gills. Nostrils labial: tongue not free: caudal fin continued round the end of tail: pectorals present or absent. Scaleless.
 - 6. Muranichthys. Pectoral fins absent. Body elongated, vermiform, p. 663.
- d.—Heart close to gills. Nostrils labial: tongue not free: end of tail free, being without fin rays: pectorals when present rudimentary. Vomerine teeth present or absent. Scaleless.
 - 7. Ophichthys. Vomerine teeth present, p. 663.
- e.—Heart placed a long distance behind the gills: tail shorter than the trunk: posterior nostril in front of the eye: vertical fins little developed: pectorals, if present, rudimentary.
 - 8. Moringua. Eyes small. Cleft of mouth narrow. Teeth in a single row, p. 666.

Second Group-Murænidæ engyschistæ.

Branchial openings in the pharynx are narrow slits.

9. Murana. Pectorals absent: vertical fins well-developed. Posterior nostril a round and patent opening, p. 667.

10. Gymnomuræna. Fins absent, except a rudimentary one round end of tail, p. 674.

Bleeker divides the Muranidae into four sub-families: Günther into two, which last I have considered as groups.

First Group-MURÆNIDÆ PLATYSCHISTÆ.

Branchial openings in the pharynx are wide slits.

a.—Heart close behind gills. Tail longer or scarcely shorter than the trunk. Nostrils lateral or superior. Tongue free. Caudal fin continued round the end of tail. Pectorals present or absent. Scales present or absent.

Genus, 1—Anguilla, Cuvier.

Muræna (sp.) Artedi: Terpolepis (pt.) McClelland: Paranguilla, Bleeker.

Gill-openings of moderate extent, situated near the base of the pectoral fins. Upper jaw not projecting beyond the lower. Teeth small and in bands. Dorsal fin commences at some distance behind the nape: pectorals present. Small scales present, which are imbedded in the skin.

Geographical distribution.—Fishes of this genus appear to be distributed in fresh waters throughout the habitable globe, being reputed to be only absent in the Arctic regions, and probably in cold districts as Turkestan.

Numerous species of this genus have been recorded and more are almost yearly being added to the present mass of synonyms. There appear to be two distinct forms in India, but they are subject to variations in the origin of the dorsal fin as regards its position in respect to the vent: and likewise, but to a minor extent, in the character of its bands of teeth, and the position of the eye. The comparative size of the bodies of these fish also varies with age and the existence of suitable food in the locality they inhabit.

Eels attain a large size in India, but not to the immense length (300 feet long) attributed to those of the Ganges by Pliny. Being seldom eaten except by the lower classes there is but little demand for them. In Java, the eel according to Bleeker, is considered by the natives to be a serpent, and they say it attacks small goats and even children. It migrates overland from one river to another when desirous of change.

SYNOPSIS OF SPECIES.

1. Anguilla Bengalensis. Origin of dorsal fin situated about midway in the interspace between the gill-opening and origin of anal fin. Islands in the Indian Ocean, Continents of India and Burma.

2. Anguilla bicolor. Origin of dorsal fin situated above, rather in front of, or slightly behind the vent. Coasts of India and the Andamans to the Malay Archipelago.

1. Anguilla Bengalensis, Plate CLXVIII, fig. .1

Muræna anguilla and maculata, Ham. Buch. Fish. Ganges, pp. 22, 23: Day, Fish. Mal. p. 244 (in part). Anguilla Bengalensis, Gray and Hardw. Ill. Ind. Zool. (from H. B.'s MSS.); Günther, Catal. viii, p.

27. Anguilla Elphinstonei, Sykes, Trans. Zool. Soc. ii, p. 377, pl. 67, f. 3; Jerdon, M. J. L. and Sc. 1849, p. 346.

Anguilla Mauritiana, Bennett, Proc. Zool. Soc. 1831, p. 113; Günther, Catal. viii, p. 25.

Anguilla brevirostris, variegata, nebulosa and Arracana, McClelland, Cal. Journ. Nat. Hist. v, pp. 177, 178, 179, pl. v, f. 1 and 2, pl. vi, f. 1 and 2, pl. ix, f. 7; Bleeker, Beng. p. 153.

Anguilla marmorata, Kaup, Apod. p. 43, f. 32 (not Quoy and Gaim).

B. xii, D. 250-305, P. 18, A. 220-250, C. 10-12.

Length of head 3 to 3k in the distance between the snout and the vent: length of tail 3/7 more than that of the trunk. The distance between the gill-opening and the origin of the dorsal fin is 1/3 or 1/4 more than the length of the head: that between the origin of dorsal and anal fins equals the length of the head. Head rather broader than the body: snout not broad. Lower jaw prominent. Length of the cleft of the mouth equals nearly or quite 1/3 in that of the head, while it extends behind the posterior edge of the orbit, the latter being $2\frac{1}{2}$ in the length of the snout. Lips well-developed. Teeth—the vomerine band does not extend posteriorly so far as the maxillary one, the mandibular teeth divided by a longitudinal groove. Fins —pectoral equals about 2/7 of the length of head. Colours—brownish superiorly, becoming yellowish on the

Digitized by Google

sides and beneath: the whole of the upper surface of the body, in some examples, covered with black spots and blotches, some of which are continued on to the dorsal fin which has a light edging: anal with a dark marginal band and a light outer edging.

Anguilla Mauritiana, Bennett: A. labrosa, Richardson: Muræna maculata, Bleeker: Anguillæ Johannæ, Günther: Murana marmorata, Kner, are terms employed for an eel. which appears to be a variety of this fish, in which the origin of the dorsal fin is only about 1/2 the length of the head before the vent.

"It is astonishing Lacépède should make such a fuss about an animal which has every appearance of a serpent, without the vivid colours, by which most of these reptiles are adorned. It is an irritable creature, swelling its head whenever angered; and constantly, when it can, buries itself in putrescent carcases," Ham.

Habitat.—Islands in the Indian Ocean, continent of India and Burma. It is common at the Andaman Islands. It probably extends its range to the Malay Archipelago, Formosa and the Pacific. It attains four feet and upwards in length and is much rarer on the hills than in the plains. Some have been introduced into the waters on the Neilgherry hills in Madras.

Muræna moa, malgumora and sidat, Bleeker, Atl. Ich. iv, p. 10, 11, t. 146, f. 1, t. 147, f. 3, t. 148, f. 1.

Jee-tah-dah, Andamanese.

B. xii, D. 220-245, P. 18, A. 200-220, C. 10-12.

Length of head $3\frac{1}{4}$ to $3\frac{1}{2}$ in the distance between the snout and the vent: length of tail 1/4 to 1/6 more than that of the trunk. Eye-rather varies in size, usually about 21 diameters in the length of the snout. Head very slightly broader than the body: snout rather broad: lower jaw scarcely longer than the upper. Extent of cleft of mouth equal to rather above 1/3 of the length of the head, and extending to at least 1 diameter of the orbit behind the eye in the adult, to below it in the immature. Lips thick. Teeth—bands of nearly equal width, the vomerine reaching nearly as far backwards as those on the maxilla. Fins—dorsal commences above the vent or slightly before or behind it. Colours—of a dark olive superiorly, becoming yellowish beneath.

Dr. Günther observes that Anguilla virescens, Peters, from the West Coast of Africa is scarcely distinct from A. sidat, Bleeker.

The example figured (22 inches in length) was from the Andamans. Habitat.—Coasts of India to the Andamans and the Malay Archipelago.

Genus, 2-Congromurana, Kaup.

Gnathophis, Kaup: Ophisoma and Ariosoma, Swainson.

Gill-openings wide. Eyes large. Cleft of mouth not extending behind the middle of the eye. Bones in forepart of head with large mucous canals. Posterior nostril patent and opposite the middle of the front edge of the eye: the anterior nostril tubular. Teeth small and pointed forming bands, those in the jaws not constituting a cutting edge: vomerine band elongated and narrow. Dorsal fin commencing nearly opposite the gill-opening: the pretoral and also the vertical fins (which are continuous round the tail) well developed. Scaleless.

Geographical distribution.—Tropical and sub-tropical seas.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Congromurana anago-Vertical fins with a narrow dark edge. Coromandel coast of India to the Malay Archipelago.

1. Congromurana anago, Plate CLXIX, fig. 2.

Congromuræna anagoides, Bleeker, Atl. Ich. iv, t. 149, f. 3.

Congromuræna anago, Günther, Catal. viii, p. 42.

B. viii, P. 14, D. 170-196, A. 122-145, C. 10.

Length of head $2\frac{1}{2}$ to $2\frac{2}{3}$ in the distance between the end of the snout and the vent: length of trunk about 1/3 less than that of the tail. Extent of cleft of mouth equals 3 to $3\frac{1}{4}$ in the length of the head, it ceases below the middle of the eye. Eyes—large, diameter 1 to $1\frac{1}{4}$ in the length of snout, and 2/3 of a diameter apart. Lips rather thick: upper jaw the longer. Teeth—of about the same size: the vomerine band extending backwards to about 1/2 the length of the maxillary band. Fins—dorsal commences slightly behind the gill-opening: pectoral nearly 1/2 as long as the head. Colours—brownish along the back, becoming dull white beneath. Fins yellow, the vertical ones with a narrow black edging. Upper half of pectoral occasionally stained with black.

Habitat.—Coromandel coast of India to the Malay Archipelago. The example figured, which is $11\frac{1}{3}$ inches long, was from Madras.

Genus, 3-UROCONGER, Kaup.

Congerodon, Kaup.

Gill-openings rather wide. Muciferous cavities on jaws moderately developed. Hind nostril in the form of a slit opposite the upper third of the orbit: front nostril not tubular. Eyes rather large. Cleft of mouth reaching to rather behind the middle of the orbit. Teeth fine, conical, and subequal in size: those in the jaws biserial, the vomerine ones in a single elongated row and small. Dorsal fin commences above the root of the pectoral: all the fins well-developed. Scaleless.

Geographical distribution-Seas of India to the Malay Archipelago, China, and the Philippines.

1. Uroconger lepturus, Plate CLXX, fig. 1.

Congrus lepturus, Richards. Voy. Sulphur, Fish. p. 106, pl. 56, fig. 1-6, and Voy. Erebus and Terror,

Fish. p. 109; Bleeker, Sumatra, p. 45.

Uroconger lepturus, Kaup, Apod. p. 110; Bleeker, Atl. Ich. iv, p. 29, t. 149, fig. 1; Kner, Novara Fisch. p. 373; Günther, Catal. viii, p. 44.

B. ix, P. 10, D. 200-220, C. 10, A. 120-150.

Length of head $2\frac{1}{4}$ to $2\frac{3}{4}$ in the distance between the end of the snout and the vent: length of trunk about 1/2 that of the tail. Cleft of mouth rather oblique and ceasing below the hind edge of the eye, its extent equals about 2/5 of the length of the head. Eyes—diameter 2 to $2\frac{1}{4}$ in the length of the snout, and 1 to $1\frac{1}{6}$ diameters apart. Snout depressed, with a row of slit-like openings above the edge of the upper lip. Teeth—rather large, and unequal in size: those in the maxilla and mandible in two rows, and placed a slight distance apart, the inner row somewhat the larger: vomerine teeth in a single pointed row about equal in size to the inner maxillary row, one of the anterior teeth is sometimes enlarged. Fins-dorsal commences above the base of the pectoral, which latter equals about 1/4 of the length of the head. Colours—brownish superiorly, becoming dull white beneath: a row of white-edged glandular openings along the lateral-line. Vertical fins edged with black.

Habitat.—Seas of India to the Malay Archipelago and China.

b.—Heart close to gills. Tail not shorter than the trunk. Nostrils lateral or superior. Tongue not free. Caudal fin continued round the end of tail: pectorals present or absent. Scaleless.

Genus, 4—Murænesox, McClelland.

Cynoponticus, Costa and Brachyconger, Bleeker.
Gill-openings wide approximating to the abdomen. Snout rather elongated, the upper jaw the longer. Two pairs of nostrils, the posterior of which are opposite to the upper part or centre of the orbit. Teeth in the jaws rather fine, with some canines anteriorly: vomer with several rows of teeth, the middle of which are large and conical or compressed. Dorsal fin commencing above the gill-opening, it, the anal, caudal, and peotoral well developed. Anus a long distance from the gill-opening. Scaleless.

The comparative proportions of the parts in these fishes vary considerably with age, season, and food.

SYNOPSIS OF SPECIES.

1. Muranesox telabon. Vomerine teeth large and without basal lobes. Seas and estuaries of India to the Malay Archipelago.

2. Muranesox telabonoides. Vomerine teeth slender, the posterior ones with basal lobes: the external mandibular row directed outwards. Seas and estuaries of India to the Malay Archipelago.

3. Murænesoz cinereus. Vomerine teeth large and having a basal lobe: external mandibular row not directed outwards. Red Sea, seas and estuaries of India to the Malay Archipelago.

B. xvii-xix, P. 15-16, D. 270-285, C. 10, A. 195-210.

Length of head 1/3 of the distance between end of snout and vent: length of trunk about 1/4 less than that of the tail. Extent of cleft of mouth about 1/2 of length of head. Eyes—diameter 1/3 of length of snout, 1 diameter apart. Teeth—on the vomer consisting of a row of moderately large, lanceolate, widely set ones, without any basal lobes: mandibular teeth much smaller than the vomerine ones and those in the external row not directed outwards. Fins—dorsal commences a short distance before the base of the pectoral: the anal under about the fifty-fifth dorsal ray, just posterior to the vent. Each fin-ray arises by two distinct roots. Colours—upper surface of back and head olive, becoming brown posteriorly: abdomen dull white, becoming silvery inferiorly. The throat, cheeks, and gill covers with golden reflections: vertical fins with dark margins.

Habitat.—Seas of India to the Malay Archipelago: attaining ten feet or more in length.

B. xviii-xix, P. 15, D 245-250, C. 10, A. 200-205.

Length of head 1/3 of the distance between end of snout and vent: length of trunk rather less than that of the tail. Extent of the cleft of the mouth equals about 1/2 of the length of the head. Eyes—diameter $3\frac{1}{4}$ to $3\frac{3}{4}$ in the length of the snout, and 1 diameter apart. Teeth—the anterior ones on the vomer are straight, slender, compressed, and elongated, whilst the posterior ones have a small basal lobe in front and behind: the outer mandibular teeth are directed outwards. Fins—dorsal commences in advance of the base of the pectoral, the latter fin equals $3\frac{3}{4}$ in the length of the head. Colours—silvery becoming white on the abdomen: vertical fins yellowish, with a narrow black outer border.

Habitat.—Seas and estuaries of India to the Malay Archipelago. This is the rarest of the three forms of this genus found in India. The example figured is 36 inches in length, and from the Hooghly at Calcutta.

B. xx-xxii, P. 14-16, D. 230-270, C. 10, A. 190-220.

Length of head $2\frac{1}{2}$ to $2\frac{2}{3}$ times in the distance between end of snout and vent: length of trunk rather less than that of the tail. Extent of cleft of mouth equals rather less than 1/2 of the length of the head, Eyes—diameter $2\frac{1}{4}$ to $2\frac{1}{2}$ in the length of the snout, and 1 diameter apart. Teeth—the vomerine are straight, compressed, and with a basal lobe anteriorly and posteriorly: the mandibular teeth are very much smaller than the vomerine ones, and those in the external row are not bent outwards (as in M. telabonoides). commences slightly in advance of the gill-opening. The pectoral 31/4 in the length of head. Colours—silvery, becoming white on the abdomen: vertical fins yellowish, with either a narrow or wide outer black edge: pectoral yellow or black.

Habitat.—Red Sea, seas and estuaries of India to the Malay Archipelago and Australia. It is the most

common species of the genus in the seas of India.

FAMILY, X-MURÆNIDÆ.

Genus, 5-Saurenchelys, Peters.

Gill-openings of a moderate width. Snout much produced. Nostrils lateral, the front one near the end of snout, the hind one close in front of orbit. Teeth rather small and in several rows. Pectoral fins absent: vertical fins well developed. Air-vessel and pyloric appendages absent. Scaleless.

Geographical distribution.—Coromandel coast of India (and? Mediterranean).

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Saurenchelys Petersi. Vertical fins with a dark edge. Sea at Madras.

1. Saurenchelys Petersi, Plate CLXVIII, fig. 6.

Length of head 21 times between end of snout and vent: length of trunk 31 times in that of the tail: extent of the cleft of the mouth 1/2 the length of the head. Eyes—diameter 3 in the length of the snout, and 1 diameter apart. Teeth—canines present anteriorly: the vomerine teeth large, compressed, but without any basal lobes. Fins—dorsal commences a short distance behind the gill-opening, it is low anteriorly becoming gradually more developed, and is continuous posteriorly with a dark edge, it and the anal become almost black in the last 1/4 of their extent.

This fish appears very similar, if not identical, with S. cancrivora, Peters (Monat. Ak. Wiss. Berlin,

1864, p. 397), which however was believed to have been obtained from the Mediterranean.

Habitat.—The single example (figured life-size) was taken from the sea in Orissa.

c .- Heart close to gills. Nostrils labial. Tongue not free. Caudal fin continued round the end of tail: pectorals present or absent. Scaleless.

Genus, 6-MURÆNICHTHYS, Bleeker.

Body elongated and cylindrical. Gill-openings narrow. Eyes small. Nostrils on the edge of the upper jaw. Dorsal fin low or rulimentary, commencing a long distance posterior to the gill-opening. Pectorals absent. Geographical distribution.—Seas of India to the Malay Archipelago.

SYNOPSIS OF SPECIES.

1. Murænichthys Schultzei. Dorsal fin commences before the vent. Andamans to the Malay Archipelago.

2. Muranichthys vermiformis. Dorsal fin commences behind the vent. Ceylon.

1. Murænichthys Schultzei, Plate CLXIX, fig. 3.

Murænichthys Schultzei, Bleeker, Mur. p. 71, Visch. Batav. p. 506, Atl. Ich. iv, p. 33, t. 148, f. 3; Günther, Catal. viii, p. 52.

Length of head $2\frac{2}{3}$ to 3 in the distance between the end of the snout and the vent: length of the trunk 3/5 of that of the tail. Extent of cleft of mouth equals 1/3 of the length of the head. Eyes—of moderate size, situated midway between the angle of the mouth and the end of the snout. Upper jaw somewhat the longer. Teeth—in jaws pointed, in 3 rows, the inner the larger: the palatine teeth in two rows with obtuse crowns. Fins—the dorsal low, commencing in the last 1/6 of the distance between the gill-opening and the Pectorals absent. Colours—brownish along the back, becoming or a yellowish green on the sides and below.

Habitat.—Andaman Islands to the Malay Archipelago. The single example (figured life-size) was procured at the Andamans.

2. Murænichthys vermiformis.

Chilorhinus (Murænichthys) vermiformes, Peters, Monats. Ak. Wiss. Berl. 1866, p. 524.

Murænichthys vermiformis, Günther, Catal. viii, p. 53.

Angle of the mouth slightly posterior to the eye. Teeth in the jaws and on the vomer in a single row. The origin of the dorsal fin behind the vent.

Habitat.—Ceylon.

d. Heart close to gills. Nostrils labial. Tongue not free. End of tail free, being without fin rays: pectorals when present rudimentary. Vomerine teeth present or absent. Scaleless.

Genus, 7—OPHICHTHYS, Ahl.

Ophisurus Pacilocephalus and Cacilia, Lacép.: Cacula, Vahl.: Sphagebranchus, Bl. Schn.: Muranopsis, Lesueur: Dalophis, Raff.: Leptognathus, Swainson: Apterichthys, Duméril: Leptorhynchus, Smith: Ichthyapus, Bris. de Barneville: Centrurophis, Pæcilocephalus, Microdonophis, Cæcilophis, Herpetoichthys, Brachysomophis,

Elapsopis, Mystriophis, Echiopis, Scytalophis, Leptorhinophis, Pisoodonophis, Lamnostoma, Anguisurus, Cirrhimuræna, Callechelys, Ichthyapus, Ophisuraphis, Crotalopsis, Kaup: Achirophichthys, Bleeker: Macrodono-

phis and Uranichthys, Poey.

Gill-openings may be close together. Snout greatly or moderately produced. Cleft of mouth wide or of medium width: lips may or may not be fringed. Teeth in jaws and on vomer, either pointed and granular, or small and conical: in the maxilla they may be in from one to four rows, or in bands; while in the mandibles they may be in one or two rows: canines present or absent. Dorsal fin, when present, commences either in advance of or nearly above the gill-opening, or behind the root of the pectoral: the pectorals, when present, may be rudimentary, or only developed in the adult, or else of moderate size: anal present or absent: extremity of tail free.

This Genus has been considered by some authors as a Family: the various Genera composing which have been included in a single but sub-divisible genus in the British Museum Catalogue, premising that in all the extremity of the tail is free, and that there are vomerine teeth.

SYNOPSIS OF SPECIES.

a. Teeth obtuse or granular: pectorals present or absent.

1. Ophichthys boro—Head 3½ to 4 times in length of trunk: body nearly 2/3 of total length. Seas and estuaries of India to the Malay Archipelago: it ascends rivers.

2. Ophichthys microcephalus—Head 7\frac{1}{3} to 8 times in length of trunk: body rather above 1/3 of the

total length. Malabar.

- 3. Ophichthys colubrinus Head 8 to 9 times in length of trunk: body about 1/2 of total length. Body surrounded by brown rings, between which are sometimes spots. Andamans to the Malay Archipelago.
 - b. Teeth pointed and in a single row: pectorals absent.
- 4. Ophichthys Orientalis—Head 31 to 4 times in length of trunk: body 1/2 of total length. Ceylon and Bay of Bengal.
- 5. Ophichthys ornatissimus—Head 7½ in length of trunk: body about as long as tail: 16 to 17 large dark spots along the lateral-line. Malabar.
 - a. Teeth obtuse or granular: pectorals present or absent.

1. Ophichthys boro, Plate CLXXI, fig. 2.

Ophisurus boro, hijula and harancha, Ham. Buch. Fish. Gang. pp. 20, 21, 363, t. v, f. 5; Gray, Ill. Ind. Zool. (from H. B.'s MSS.); McClell. Calc. Journ. Nat. Hist. v, p. 211, tab. 12, fig. 4; Richards. Ichth. Chin. p. 313, and Voy. Ereb. and Terr. Fish. p. 99, 102; Bleek. Beng. p. 156; Cant. Cat. Fish. p. 322, pl. 5, fig. 2 (teeth).

Ophisurus rostratus, vermiformis, minimus and caudatus, McClell. l. c. pp. 184, 185, 211, 212, t. 10, f. 3, and t. 12, f. 2 and 3.

Ophisurus puncticulata, immaculata and acuminata, Swainson, Fishes, ii, p. 334.

Ophisurus potamophilus, Bleek. Borneo, p. 458, and Muræn, p. 68.
Pisoodonophis boro, Kaup, Apod. p. 17; Bleek. Atl. Ichth. iv, p. 62, tab. 164, fig. 3; Day, Fish. Malabar, p. 248.

Piscodonophis potamophilus, Kaup, Apod. p. 20; Bleek. l. c. p. 63, tab. 172, fig. 2. Ophichthys hyala and boro, Günther, Catal. viii, pp. 60, 77.

B. xxix-xxxi, D. 320-400, P. 13, A. 250-270.

Length of head (to gill-opening) from $3\frac{1}{2}$ to 4 times in the distance between the snout and the vent: length of trunk nearly 2/3 of the total. Eyes—from 2 to $2\frac{1}{2}$ or even 3 diameters from end of snout and slightly nearer angle of mouth that the end of snout. Upper jaw the longer: cleft of mouth extending some distance behind the eye. Snout rather depressed in the young, and obtuse in the adult. Teeth—granular, in a large patch on maxilla, and in several smaller rows on premaxillaries: large and in several rows on the vomer. Externally two granular rows in mandible, with an internal pointed one. The form of the teeth is subject to considerable variation, thus they are usually conical in the young, which character may be retained in the adult age, O. hyala: or the young in some instances have globular headed teeth: the number of rows of teeth is not constant. Fins—dorsal low, it commences about the length of the pectoral behind its posterior margin, not quite reaching the tip of the tail. Pectoral rounded or pointed, it equals about one-fourth of the distance between the snout and its base. Anal low, it does not extend on to the tip of the tail. Colours—greenish-olive above with many minute black spots, becoming greenish-white below, the dorsal fin with a dark edging.

Hamilton Buchanan divided his species apparently chiefly by the colour. O. hijala has pale spots along the lateral-line: O. boro destitute of spots and wanting a lateral-line: O. harancha, destitute of spots but having a lateral-line.

The natives in some parts of Bengal, imagine that this fish proceeds from the ear of a porpoise.

When breathing this fish distends its gill cavities with air taken in at its mouth, whilst it can also

respire from that contained in the water. If its gill-openings are kept firmly closed, it takes in air by its mouth: should its mouth be kept shut it struggles until released so as to be able to respire. If the gills are exposed by removing the gill-membranes, it slowly moves its branchiæ, and is able to respire without taking in air by the mouth.

Habitat.—Seas and estuaries of India and Malay Archipelago, ascending large rivers to far above tidal

reach. It attains to at least 24 inches inches in length.

2. Ophichthys microcephalus, Plate CLXX, fig. 2.

Length of head from $7\frac{1}{3}$ to 8 in the distance between the end of the snout and the vent: tail nearly twice as long as trunk (1^7_{θ}) . Eyes—of moderate size, situated behind the middle of the distance between the snout and angle of the mouth. Extent of cleft of mouth from end of snout equal to $3\frac{1}{2}$ in the length of the head. Anterior tubular nostrils well-developed. Teeth—obtusely conical and in three rows. Fins—low, the dorsal commences over the last third of the pectoral fin, neither it nor the analis continued round the end of the tail. Pectoral 31/4 to 31/3 in the length of the head. Colours - olive above, becoming of a dull yellow on the sides and beneath: fins externally stained with dark.

Habitat.—Three examples, none less than 25 inches in length, were captured in Malabar.

3. Ophichthys colubrinus, Plate CLXVII, fig. 4.

Muræna colubrina, Boddaert, in Pallas's Neue Nord. Beytr. ii, 1781, p. 56, pl. 2, fig. 3.

Birandonophis fasciatus, Kaup. Apod. p. 23

Pisoodonophis fasciatus, Kaup, Apod. p. 23.
Ophichthys colubrinus, Günther, Catal. viii, p. 81: Klunz. Verh. z. b. Ges. Wien, 1871, p. 610.

"B. xxv, circ. D. 510, circ. A. 318, circ. P. 10, circ." Bleeker.

Length of head 8 to 9 times in the distance between the end of the snout and the vent: length of trunk about equal to that of the tail: snout projecting. Extent of cleft of mouth equals about 2/7 to 1/4 of the length of the head. Eyes-rather small, situated behind the middle of the cleft of the mouth. Snout rather pointed. Teeth—with rounded crowns and in two rows. Fins—the dorsal fin commences in front of the gill-opening just behind the nape: it and the anal are rather low: pectoral rudimentary. Colours—numerous (25) to 35) brown rings surround the body. In some examples a dark round spot exists in the interspace between each ring on the body.

Habitat.—Red Sea, Andamans to the Malay Archipelago, and beyond.

b.—Teeth pointed and in a single row: pectoral fins absent.

4. Ophichthys Orientalis, Plate CLXXI, fig. 1.

Muræna, Russell, Fish. Vizag. i, p. 26, and Manti-bukaro-paumu, pl. 37.
Dalophis Orientalis, McClelland, Cal. Journ. Nat. Hist. 1845, v, p. 213; Jerdon, M. J. Lit. and Science, 1851, p. 151.

Lamnostoma pictum, Kaup, Apodal Fish. p. 23, f. 11. Sphagebranchus Orientalis, Kner, Novara Fische, p. 380.

Ophichthys Orientalis, Günther, Catal. viii, p. 87.

Length of head 31 to 4 in the distance between the end of the snout and the anus: tail as long as the trunk. Eyes-small, placed rather behind the middle of the length of the head. Gill-openings are longitudinal slits almost parallel one to the other. Snout projecting, extending beyond the lower jaw, and the openings of the nostrils on the lower surface. Teeth—pointed and in a single row. Fins—the dorsal commences at a short distance behind the gill-openings, it and the anal being low: pectorals absent. Colours—olive becoming lightest beneath: one or two rows of round whitish spots across the occiput, having a short, forward directed line of

similar spots on either side.
"Very common at Madras. The boys catch it at the edge of the surf by bruising a crab in their hands and throwing it into the water, then walking about over the spot, and when they feel an eel about their feet they stoop down and suddenly dash it on to the sand with both hands. If thrown on the moist sand they burrow themselves, tail foremost, almost instantaneously."—(Jerdon).

Habitat.—Seas and estuaries of Ceylon and up the Bay of Bengal, certainly as high as Orissa. It attains at least a foot in length.

5. Ophichthys ornatissimus.

Herpetoichthys ornatissimus, Kaup, Apodal Fish. p. 7, f. 5.

Ophichthys ornatissimus, Day, Fish. Malabar, p. 67; Günther, Catal. viii, p. 67.

Digitized by Google

Length of head from snout to gill-opening $7\frac{1}{2}$ in the length of the trunk: length of tail rather less than that of the trunk. Head depressed. Eyes—near end of snout. Jaws of nearly equal length. Teeth—pointed, the maxillary and front vomerine ones in a double, the remainder in a single row. Fins-dorsal low, commencing behind the end of the pectoral, the latter with 24 rays and about 1/4 of the length of the head. Colours—irregular dark spots on the head. One transverse and two longitudinal rows of white spots on the occiput: two curved whitish lines between the eye: sixteen to seventeen large, round, black spots along the lateral-line which are separated by another band of spots of different sizes. Dorsal fin with black marginal spots and stripes.

Habitat.—Malabar. An example 20.8 inches long, was obtained by Dussumier.

e.—Heart placed a long distance behind the gills. Tail shorter than the trunk. Posterior nostril in front of Vertical fins little developed: pectorals, if present, rudimentary.

Genus, 8-Moringua, Gray.

Raitaborna, Gray: Ptyobranchus, McClell.; Pterurus, Swainson: Aphthalmichthys, Kaup: Pseudomoringua, Bleeker.

Buly sub-cylindrical with the trunk considerably longer than the tail. Gill-openings rather narrow and inferior: heart fur posterior to the branchia. Cleft of mouth narrow. The posterior nostril situated in front of the cye. Teeth in a single row. Vertical fins limited to the tail: pectorals, if present, small. Scales absent. Geographical distribution.—Seas of India to the Malay Archipelago and Japan.

SYNOPSIS OF SPECIES.

1. Moringua raitaborua. Length of head 6 to 61 in that of the trunk: trunk longer than the tail.

Estuaries of Ganges to the Malay Archipelago.

2. Moringua macrocephala. Length of head 53 in that of the trunk: trunk at least 2/3 longer than the tail. Ganges to the Malay Archipelago.

1. Moringua raitaborua, Plate CLXX, fig. 3.

Muræna raitaborua, Ham. Buch. Fish. Ganges, pp. 25, 364.
Raitaborua Hamiltonii and Hardwickii, Gray, Zool. Misc. p. 9, and Ill. Ind. Zool. c, fig. (from H. B. MS.)

McClell. Calc. Journ. Nat Hist. v, pp. 200, 201, 203, 223, and pl. 9, fig. 3, 4 (half grown), 5 and 6, pl. 10, fig. 1 and 2.

Pterurus maculatus, Swainson, Fishes, ii, p. 334.

Anguilla (Moringua) raitaborua, Bleeker, Nat. Tyds. Ned. Ind. iv, p. 228, tab. 1.

Moringua raitaborua, Bleeker, Beng. p. 154; Kaup, Apod. p. 106; Günther, Catal. viii, p. 90.

Moringua macrochir, Bleeker, Batav. p. 71, or Atl. Ichth. iv, p. 15, pl. 147, fig. 4 (young); Kner, Novara Fische, p. 389.

Moringua lumbriciformis, Kaup, Apod. p. 107 (half grown).

Length of head from snout to gill-opening 6 to $6\frac{1}{2}$ in the distance from snout to vent: length of tail from 2/5 to 3/8 of the entire length. Height of body equals 1/3 of length of head. Eyes-rather high up, and 2 to 3 diameters from end of snout: jaws of equal length in front, or the lower slightly the longer. Cleft of mouth extends above 1 diameter of the orbit behind its posterior margin. Gill-opening a slit at the side of the pectoral fin. Teeth—in a single row directed backwards, pointed. Fins—dorsal slightly developed, it commences about the length of the head posterior to the anus: the anal arises a short distance behind the orifice of anus: both fins are interrupted in their middle, but posteriorly developed and join the caudal. Pectoral equals about one-sixth of its distance from the snout. Lateral-line—distinct. Colours—coppery, olive,

or even purplish above, becoming silvery underneath: some black dots. Vertebræ 90 + 14.

Muræna vamos, Ham. Buch. Fish. Ganges, pp. 24, 364, may be the Moringua linearis, Gray, Zool. Misc. p. 9, and Gray and Hardw. Ill. Ind. Zool. and Pachyurus linearis, Swainson, Fishes, ii, p. 335, it is placed by Dr. Günther as a doubtful synonym of Moringua lumbricoidea, Richardson. McClelland, under Ptyobranchus linearis, C. J. N. H. v, p. 222, observes, "I suspect this species is fabricated from a drawing in the Buchanan collection, Botanical Gardens, Calcutta, in which the dorsal and anal are both represented by mistake, winding in a spiral form round the end of the tail, which has been accidentally twisted." Buchanan says of M. vamos, head nearly twice as wide as body. Upper jaw blunt, projecting far beyond the lower, which is sharp pointed. Nostrils tubular. Vertical fins confluent: pectorals present. Dull green above, dirty white beneath. From the estuaries of the Ganges, where it is said to attain 7½ cubits in length.

Habitat.—Estuaries of the Ganges to the Malay Archipelago: attaining at least 22 inches in length.

2. Moringua macrocephala.

Aphthalmichthys macrocephalus, Bleeker, Ned. Tyds. Dierk. i, p. 165, and Atl. Ich. iv, p. 17, t. 147, f. 2. Moringua macrocephala, Günther, Catal. viii, p. 92.

Length of head from snout to gill-opening $5\frac{3}{4}$ in the distance from snout to vent: trunk at least 2/3 longer than tail. Cleft of mouth about 1/5 of the length of the head. Fins—a few rays at the end of the tail, otherwise the vertical and pectoral fins are reduced to mere cutaneous folds.

Habitat.—India and the Malay Archipelago.

Second group-Murænidæ engyschistæ. Branchial openings in the pharynx are narrow spots.

Genus, 9-Muræna, sp. Artedi.

Gymnothorax, Bloch: Murænophis, Lacép.: Echidna, Forst.: Theorodontis, Strophidon, and Lycodontis, McClell.: Sidera, Eurymyctera, Thyrsoidea, Limamuræna, Polyuranodon, Pucilophis, Gymnomuræna, Priodonophis, and Twniophis, Kaup: Pseudomurana, Johnson.

Body moderately or exceedingly elongate. Gill-openings narrow. A tubular nostril on either side of the upper surface of the snout: the posterior nostril a round foramen between the eyes or opposite the antero-superior edge of the eye, it may or may not be furnished with a tube. Teeth well developed and acute or molariform: the maxillary teeth may be in one or two rows. Dorsal fin elevated or not so: the end of the tail surrounded by fin, which is occasionally rudimentary. Pectorals absent.

Geographical distribution.—Seas of tropical and temperate regions: some species ascend tidal rivers. The dentition in some of these fishes alters considerably with age, whilst in others it is not constant in every individual of the same species.

SYNOPSIS OF INDIAN SPECIES.

A .- Teeth pointed: the posterior nostrils not tubular.

a .- Tail and trunk of about the same length.

- 1. Murana meleagris. Teeth biserial. Black with numerous yellow dots. From East Coast of Africa and Indian Ocean to the Malay Archipelago and the Pacific.
- 2. Murana tile. Teeth biserial. Brownish yellow with fine white spots, streaks, or marks: and which may be lost in the adult. Seas and estuaries of Bengal to the Malay Archipelago.

 3. Murana sathete. Teeth biserial. Greenish-olive with silvery dots along the lateral-line. Bay of
- Bengal to Pinang.
- 4. Murana punctata. Teeth uniserial. Dark purplish covered with fine white spots. Coromandel coast of India.
- 5. Murana Ruppellii. Teeth uniserial. Yellow with 18 to 20 dark bands, 3 of which are on the head. Andamans to the Malay Archipelago.
 6. Muræna reticularis. Teeth uniserial. About 16 dark bands encircle body, none being on the head.
- Seas of India to China and Japan.
- 7. Muræna punctatofasciata. Teeth uniserial. From 28 to 35 more or less complete dark bands: head with dark marks. Seas of India to the Malay Archipelago.

 8. Muræna tessellata. Teeth uniserial. Dark spots on head, body and fins, separated by narrow light
- lines or interspaces. East Coast of Africa, seas of India to China.
- 9. Murana fimbriata. Teeth uniserial. Olive-brown: a few dark spots on head, and many irregular ones on body and fins. Madagascar, seas of India to the Malay Archipelago.
- 10. Murana pseudothyrsoidea. Teeth uniserial. Brown covered with fine spots on head and body amongst which are reticulated yellow lines: a black spot usually exists at gill-opening. Sind, seas of India to the Malay Archipelago.
- 11. Murana undulata. Teeth uniserial Light brown covered with irregular dark blotches and usually reticulated lines, most distinct in the posterior half of the body. Red Sea, East Coast of Africa, seas of India to the Pacific.
- 12. Muriena flavimarginata. Teeth uniserial: vomerine band bifurcated in front. Light brown marbled with darker: gill-opening in a black spot: fins usually with a light outer edge. Red Sea, seas of India to the Malay Archipelago.
- 13. Murana afra. Teeth uniserial. Brownish-black or blotched. Indian Ocean to tropical parts of Atlantic.

b.—Tail at least twice as long as trunk.

14. Muræna macrura. Teeth biserial. Uniform brown, the fins nearly black. Seas of India to the Malay Archipelago.

B.—Teeth in jaws pointed: globular on vomer.

15. Muræna thyrsoidea. Teeth biserial. Light brown covered with closely set purplish spots and light intermediate lines forming a network: anal fin sometimes with a light outer edge. Andamans to the Malay Archipelago.

16. Murana picta. Teeth in jaws uniserial. Gray with arborescent black markings and marbling. East Coast of Africa, seas of India to the Malay Archipelago and beyond.

4 Q 2

C.—Teeth generally obtuse or molariform.

17. Murana zebra. Tail 1/3 of the total length. Brown, with from 30 to 100 narrow white or yellow Red Sea, East Coast of Africa to the Malay Archipelago and the Pacific.

18. Murana nebulosa. Tail a little shorter than the trunk. From 20 to 25 dark blotches along the side

with some white spots in the centre of each. Red Sea, Indian and Pacific Oceans.

19. Murana polyzona. Tail 1/3 longer than the trunk. Brown with from 25 to 30 narrow, yellow, whole or half bands. Red Sea, Indian and Pacific Oceans.

20. Murana nigra. Tail about as long as trunk. Black. Andamans.

A .- Teeth pointed: the posterior nostrils not tubular.

a .- Tail and trunk of about the same length.

Muræna meleagris.

Shaw, Nat. Misc. p. 220 and General Zool. iv, pt. i, p. 32; Richards. Voy. Erebus and Terror, Fish. p. 93; Günther, Catal. viii, p. 100.

Thyrsoidea chlorostigma and meleagris, Kaup, Apodal Fish, pp. 89, 91.

Murana chlorostigma, Bleeker, Fische Java, p. 160. Gymnothorax chlorostigma, Bleeker, Atl. Ich. iv, p. 97, t. clxxviii, f. 2. Gymnothorax meleagris, Bleeker, Fauna Madagas. pt. iv, Poissons, p. 73.

Length of head $3\frac{1}{3}$ to $3\frac{2}{3}$ in the distance between the end of the snout and the vent: tail rather longer than the trunk. Eyes—small, $2\frac{1}{4}$ in the length of the snout: anterior nasal tubes very short. Length of cleft of mouth equal to $2\frac{2}{3}$ in the length of the head. The mouth can be completely closed. Gill-opening narrow. Teeth—in two rows, except on the vomer and side of the mandibles. Canines rather small. Colours—brownishblack, covered with numerous yellow dots that are smaller than the eye.

Hubitut.—From the East Coast of Africa, the Seychelles and the Mauritius throughout the seas of

India to the Malay Archipelago and the Pacific. It attains a large size.

2. Muræna tile, Plate CLXX, fig. 4.

Muranophis tile, Ham. Buch. Fish. Ganges, pp. 18, 363.

Strophidon* literata, punctata and maculata, Cal. Journ. Nat. Hist. v, pp. 186, 187, 202, 203, 215, and pl. vii, figs. 2 and 3. pl. viii, fig. 1.

Murana vermiculata and gracilis, Richards. Erebus and Terror, Fish. p. 92; Bleeker, Beng. p. 78.

Muræna punctata and literata, Bleeker, Muræn. p. 42.

Murana tile, Cantor, Catal. p. 331; Blecker, Beng. pp. 78, 159, and Borneo, p. 427; Günther, Catal. viii, p. 112.

Murana literata, Bleeker, Beng. p. 78. Thyrsoidea tile, Kaup, Apod. p. 93, f. 66.

Gymnothorax tile, Bleeker, Atl. Ich. iv, p. 97, t. clxxviii, fig. 1, and Fauna Madagas. pt. iv, Poiss. p. 73; Kner, Novara Fische, p. 335.

Length of head $3\frac{3}{4}$ to $4\frac{1}{4}$ in the distance between the end of the snout and the vent: tail rather shorter or about the same length as the trunk. Eyes—rather small, about 2 to $2\frac{1}{2}$ diameters from the end of snout and situated slightly nearer the angle of the mouth than to the end of the snout: length of cleft of mouth equals about $3\frac{1}{4}$ in that of the head: anterior nasal tubes short. Gill-opening about as wide as the eye. Teeth—in two rows, except the lateral ones of the lower jaw: canines small. Colours-of a brownish yellow, or greenish, becoming lighter beneath: the body covered with small white spots, specks or marks, which sometimes have a dark border, or they may be entirely absent in adults.

McClelland remarks that S. literata has D. 334, A. 182; S. punctata D. 392, A. 190; whilst S. maculata

is a copy of Ham. Buch, figure of Muranophis tile, and is probably the young of S punctata.

Habitat.—Bourbon, seas and estuaries of Bengal to the Malay Archipelago. It ascends tidal rivers and is common in the Hooghly at Calcutta, where it attains about 2 feet in length. The example figured was from

3. Muræna sathete.

Muranophis sathete, Ham. Buch. Fish. Ganges, pp. 17, 363. Lycodontis longicandata, McClelland, Cal. J. N. H. v, 187, pl. viii, f. 2.

Strophidon longicaudata, McClelland, l. c. p. 215.

Thyrsoidea sathete, Kaup, Apod. p. 86.

Length of head $4\frac{1}{4}$ to 5 in the distance between the end of the snout and the vent: tail rather longer (considerably says McClelland) than the trunk. Eyes—small, $2\frac{1}{4}$ to $2\frac{1}{2}$ diameters from the end of the snout, 2 apart, and midway between the angle of the mouth and the end of the snout. Length of the cleft of the

* Misprinted Lycodontis, see errata in C. J. N. H. v, p. 202.

mouth equals about $3\frac{2}{3}$ in the length of the head: jaws nearly equal in length anteriorly. Teeth—the maxillary, anterior vomerine and anterior mandibular teeth biserial, the rest uniserial. Colours—Head, body, and fins dark greenish-olive, becoming of a greenish-yellow inferiorly: silvery dots along the lateral-line.

A stuffed example 32.5 in length exists in the British Museum, which is said to belong to this species: it

was presented by J. Reeves, Esq. (Kaup,) so probably came from China. McClelland assigns D. 484, A. 394, Vertebræ 211, to this species.

Habitat.—Bay of Bengal, Pinang.

4. Muræna punctata, Plate CLXXIII, fig. 1.

Gymnothorax punctatus, Bl. Schn. p. 526.

Muræna, Russell, Fish. Vizag. i, p. 22, and Calamaia paum, pl. 32.

Muræna punctata, Richard. Voy. Erebus and Terror, Ich. p. 83; Bleeker, Beng. p. 78; Kaup, Apod. p. 64; Günther, Catal. viii, p. 102.

Length of head $3\frac{1}{2}$ in the distance between the end of the snout and the vent: tail rather longer than the trunk. Eyes—of moderate size, situated midway between the angle of the mouth and end of the snout: anterior nasal tubes about 1/2 as long as the orbit. Length of cleft of mouth equal to half the length of the head: the mouth can be completely closed. Gill-opening about twice as large as the orbit. Teeth—in a single row, from 18 to 22 on either side of the mandible, the anterior of which are the longest. Can be a single row, from 18 to 22 on either side of the mandible, the anterior of which are the longest. size. Colours-purplish black, with black streaks radiating from the eye: the whole of the fish covered with pure white spots having a dark edge, and which are largest posteriorly, but nowhere exceed the size of the pupil of the eye.

Habitat.—Coromandel Coast of India. It attains to a large size. Russell observes that it was not eaten, as it was considered to be of a poisonous nature, whilst its flesh smelt very rank even when just

captured.

5. Muræna Ruppellii.

Muræna colubrina, Lacép. v, pp. 627, 641, 642, pl. xix, fig. 1 (not Boddaert); Richards. Erebus and Terror, Fish. p. 88; Bleeker, Flores, p. 335.

Muræna reticulata, Rüpp. Atl. Fische, p. 117 (not Bloch).

Dalophis Rupelliæ, McClelland, Cal. Journ. Nat. Hist. v, p. 213.

Murcena Ruppellii, Günther, Catal. viii, p. 104; Klunz. F. Roth. Meer. 1871, p. 615.

Length of head $3\frac{1}{3}$ to $3\frac{2}{3}$ in the distance between the end of the snout and the vent: tail about 1/5 longer than the trunk. Eyes—rather above 1/2 the length of the snout, and situated nearly midway between angle of mouth and end of snout: anterior nasal tubes scarcely 1/2 the length of the eye. Snout slightly compressed: extent of cleft of mouth $2\frac{2}{3}$ in the length of the head. Gill-opening about as the eye. Teeth in a single row (the young may have one or two extra teeth forming an inner maxillary row), from 20 to 23 in either mandible: canines of moderate size: the mouth can be completely closed. Colours—yellowish, with from 18 to 20 black rings encircling the head and body: they are narrower than the ground colour: the first 3 are on the head, the others sometimes become less distinct as age increases.

Habitat.—Andamans and Malay Archipelago.

6. Muræna reticularis.

Gymnothorax reticularis and reticulatus, Bloch, t. 416; Bl. Schn. p. 528.

Murana reticularis, Bleeker, Beng. p. 78; Günther, Catal. viii, p. 105.

Length of head $3\frac{1}{3}$ in the distance between the end of the snout and the vent: tail a little longer than the trunk. Eyes—diameter 2/3 of the length of the snout, situated rather nearer angle of mouth than end of snout. Anterior nasal tubes very short: snout short and very slightly compressed. Extent of cleft of mouth 1/3 of the length of the head. Gill-opening of about the same size as the eye. Teeth—in a single row, some being slightly serrated: about 13 in either mandible: the canines small, the mouth can be completely closed. Colours—head and back spotted and dotted with brown: about 16 dark cross bands on the body, wider than the ground colour, and most distinct in the lower half of the body and on the dorsal fin. The first well-marked ventral band is behind the gill-opening.

Habitat. - Seas of India to China and Japan.

7. Muræna punctatofasciata, Plate CLXIX, fig. 4.

Muræna catenata, Bleeker, Amboina, p. 66 (not Richard. etc.)

Gymnothorax punctato-fasciatus, Bleeeker, Gymnoth. Ind. Arch. p. 167, and Atl. Ich. iv, p. 99, t. clxxv, f. 4.

Muræna punctato-fasciata, Günther, Catal. viii, p. 106.

Length of head $3\frac{3}{4}$ to $4\frac{1}{4}$ in the distance between the end of the snout and the vent: tail slightly longer than the trunk. Eyes—situated about midway between the end of the narrow snout and the angle of the mouth, 2/3 the length of snout. Mouth can be completely closed, the extent of its cleft equals 1/3 of the length of the head. Gill-opening about the same size as the eye. Body rather slender. Teeth—pointed and in a single row, without any basal lobe, occasionally there are 2 or 3 teeth forming an inner maxillary row: canines of moderate size: 16 to 17 teeth in either mandible. Colours—of a reddish brown, darkest along the back. From 28 to 35 dark, more or less complete rings of an irregular character on the body and fins.

Head and ground colour between the rings, with blotches, spots, and fine lines.

Habitat.—Seas of India to the Malay Archipelago. The example figured was from Madras, and is 13

inches in length.

8. Muræna tessellata, Plate CLXXI, fig. 4.

Gymnothorax favagineus, Bloch, Schn. p. 525, t. 105.

Murana python and favaginea, Kaup, Apodal Fish. p. 68, f. 52, 53.

Thyrsoidea tessellata and isingteena, Kaup, l. c. pp. 75, 76, f. 57.

Gymnothorax isingteena and tessellatus, Blecker, Atl. Ich. iv, pp. 92, 93, t. clxxi, f. 3, clxxii, f. 1, and clxxxi, f. 1.

Length of head to gill-opening 3 to $3\frac{2}{3}$ in the distance between the end of the snout and the anus: tail slightly longer or shorter than the trunk. Snout compressed. Eyes—situated slightly before the middle of the distance between the angle of the mouth and the end of the snout. Length of cleft of mouth $2\frac{1}{3}$ to $2\frac{1}{2}$ in the distance between the end of the snout and the gill-opening. Anterior nasal tubes 1/2 as long as eye. Teethlarge, compressed, pointed, and in the adult in a single row, occasionally in the young a short internal row in the maxilla. Fins—dorsal commences above the gill-opening. Colours—dark polygonal or rounded spots on the head, body, and fins, which are separated by narrow light lines or interspaces; most or all of the spots are wider than the ground colour.

Habitat. From the East Coast of Africa and the Mauritius, through the seas of India to the Malay Archipelago, and China. The example figured, which is 28 inches in length, came from Vizagapatam.

9. Muræna fimbriata, Plate CLXXII, fig. 1.

Bennett, Proc. Zoological Society, 1831, vol. i, p. 168; Günther, Catal. viii, p. 108.

Muræna bullata, Richards. Voy. Erebus and Terror, Fish. p. 86: Kaup, Apod. p. 81. f. 60.

Gymnothorax fimbriatus, Bleeker, Fauna Madagascar, etc., pt. iv, Poiss, p. 72.

Length of head 3 to 31 in the distance between the end of the snout and the vent: tail 1/3 longer than the trunk. Eye—rather nearer the angle of the mouth than the end of the narrow snout, from which last it is distant from $1\frac{2}{3}$ to 2 diameters. Extent of cleft of mouth equal to 1/3 of the length of the head. Gillopening smaller than the eye. Teeth—pointed, and in a single row, without any basal lobe, occasionally there are 2 or 3 teeth in a second inner maxillary row. Colours—olive brown, with a few black spots on the head, and numerous irregularly formed ones on the body, dorsal and anal fins, many take a vertical direction, and few are larger than the eye. Fins with a white edge. In some examples the spots are in 2 or 3 regular longitudinal

A fine life-size drawing of this species, 16½ inches long, exists in Sir W. Elliot's collection, it is termed Chuka pam, captured October 22nd, 1850.

Habitat.—Madagascar, Coromandel Coast of India, Andaman islands to the Malay Archipelago.

10. Muræna pseudothyrsoidea, Plate CLXXIII, fig. 3.

Bleeker, Celebes, p. 778, and Muræn. p. 44; Kaup, Apod. p. 65; Günther, Catal. viii, p. 112. Gymnothorax pseudothyrsoideus, Bleeker, Atl. Ich. iv, p. 104, t. exc, f. 2.

Length of head $3\frac{1}{2}$ to $3\frac{3}{3}$ in the distance between the end of the snout and the vent: tail a little shorter than the trunk. Eyes—nearer end of snout than angle of mouth, $1\frac{2}{3}$ to 2 diameters in the length of the snout, and $1\frac{1}{3}$ apart. The extent of cleft of mouth $2\frac{1}{4}$ the length of the head. The gill-opening about 1/3 wider than the eye. Teeth—in a single row, about 18 or 20 in either mandible, the 2 anterior being canines: canines of moderate size, the mouth can be completely shut: one or two of anterior vomerine series, subulate and larger than those in the premaxillaries. *Colours*—brownish, covered with fine dark spots on the head and body, amongst which are reticulated yellow lines, most distinct in the caudal region. Sometimes a white edge to fins. Gill-opening usually surrounded by a black spot.

Habitat.—Coasts of Sind and India to the Malay Archipelago.

Gymnothorax cancellatus, Bleeker, Atl. Ich. iv, p. 93, t. clxxvi, f. 3, and t. clxxvii, f. 2, and t. clxxxiii, fig. 1; Kner, Novara Fische, p. 384.

Gymnothorax Agassizi, Bleeker, 1. c. p. 95, t. clxxxv, f. 2.

Muræna nubila, Günther, Fish. Zanz. p. 127 (not Richardson).

Muræna undulata, Günther, Catal. viii, p. 110; Klunz. F. Roth. Meer. 1871, p. 615.

Length of head $3\frac{1}{4}$ to $3\frac{1}{3}$ in the distance between the end of the snout and the vent: tail a little longer than the trunk. $Eyes-1\frac{3}{4}$ to 2 diameters from the end of the snout, and about midway between the angle of the mouth and the end of the snout. Length of cleft of mouth $2\frac{1}{3}$ to $2\frac{1}{2}$ in the length of the head. Gill-opening about as wide as the eye. Anterior nasal tube short. Mouth cannot be completely shut: snout pointed. Teeth—in a single row, occasionally one or two additional ones forming an inner row in the maxilla: normally 4 pairs of canines in the mandibles, and 18 to 20 teeth in either ramus of mandibles: 2 canines in the maxilla. Colours—of light brownish, covered with irregularly sized blotches, and usually light reticulated lines over the body most distinct posteriorly: no black spot at gill-opening: no white edge to

Habitat.—Red Sea, East Coast of Africa, seas of India to the Malay Archipelago and Pacific Ocean. The figure on plate CLXXI, is from an example figured life-size: that on plate CLXXIII, is from an adult.

12. Muræna flavimarginata.

Rüppell, Atl. p. 119, t. xxx, f. 3; Günther, Fish. Zanzibar, p. 127, and Catal. viii, p. 119; Klunz. Fische

Gymnothorax flavomarginatus, Bleeker, l. c. t. clxxvi, f. 2, and t. clxxviii, f. 3, and Fauna Madagascar, pt. iv, Poissons, p. 72.

Length of head $3\frac{2}{3}$ to 4 in the distance between the end of the snout and the vent: tail rather shorter than the trunk. Eyes—small, from 2 to $2\frac{1}{2}$ diameters in the length of the snout, and situated about midway between the angle of the mouth and the end of the snout. Anterior nasal tubes very short: snout rather elevated. Length of cleft of mouth $2\frac{1}{2}$ in the length of the head. The mouth can be completely closed. Gill-opening wider than the eye. Teeth—in a single row, except the vomerine band which is bifurcated anteriorly: canines of moderate size. Colours—light brown or yellowish brown, marbled or spotted with darker: the head and end of tail nearly black. Gill-opening in a black spot. Fins usually with a light edge.

Klunz. Fische Roth. Meer. 1871, p. 616, considers Murana Javanica, as distinct from M. flavi-

Habitat.—Red Sea, Seychelles Archipelago, Bourbon, Mauritius, and seas of India to the Malay Archipelago.

Muræna afra, Günther, Catal. viii, p. 123.

Length of head $3\frac{3}{4}$ in the distance between the end of the snout and the vent: tail slightly longer than the trunk. Eyes—diameter about 1/2 the length of the snout, and situated slightly nearer angle of the mouth than to the end of the snout. Length of cleft of mouth about $2\frac{3}{4}$ in the length of the head. Snout pointed: anterior nasal tubes about 1/2 as long as the orbit. Gill-opening not quite so wide as the eye. Teeth—in old examples in one row, but in the young usually in two rows in both jaws. Colours—a light ground, blotched and marked all over with brown, or of a general brownish black.

Habitat.—Recorded from Tranquebar (Bl. Sch.), Indian Ocean, Australia, and tropical parts of the

Atlantic.

b.—Tail at least twice as long as trunk.

14. Muræna macrura, Plate CLXX, fig. 5.

Murana macrurus, Bleeker, Bant. p. 324; Günther, Catal. viii, p. 127.

Thyrsoidea longissima, Kaup, Apod. p. 82.

Thyrsoidea macrurus, Bleeker, Atl. Ich. iv, p. 111, t. clxvi, f. 2; Kner, Novara Fisch. p. 386.

Length of head from snout to gill-opening, 1/4 of the distance between the end of the snout and the anus: tail from $1\frac{3}{4}$ to twice as long as the trunk. Eyes—situated in the front 1/2 of the distance between the angle of the mouth and the end of the snout, about 2 diameters from end of snout. Teeth—pointed, those in the maxilla and mandibles in two rows; canines badly developed. Fins—the dorsal anteriorly is low and densely enveloped in skin, it commences midway between the gape of the mouth and the gill-opening. Colours—uniform brown, the fins tinged with black.

The example figured was from Malabar, and is of the variety longissima, Kaup, which has the body

comparatively longer than in macrura.

Habitat.—Seas of India to the Malay Archipelago. It attains upwards of 10 feet in length. This is the Seram pambu, Tamil, adverted to by Jerdon.

B.—Teeth in jaws pointed: globular on vomer.

15. Muræna thyrsoidea, Plate CLXXII, fig. 3.

Gymnothorax prosopeion, Bleeker, Atl. Ich. iv, p. 88, t. clxxxiii, f. 3.

Length of head $3\frac{1}{3}$ in the distance between the end of the snout and the vent: tail from 1/6 to 1/3 longer than the trunk. Eyes $-1\frac{1}{3}$ diameters from end of snout, which they are nearer to than the angle of the mouth. Anterior nasal tubes equal in length 2/3 of the vertical diameter of the eye. Length of cleft of mouth $3\frac{1}{3}$ in the length of the head. Gill-openings rather larger than the eye. Teeth—conical and biserial laterally on the maxilla: about 23 on either ramus of the mandibles: vomerine teeth globular and in 2 rows: no large canines: the mouth cannot be completely shut. Fins—dorsal more than 2/3 as high as the body. Colours—of a light brown covered all over with closely set purplish spots amongst which are light lines forming a net-work: gill-opening sometimes with a black mark around it: no white edge to fins. Bleeker shows a light lower edge to the anal fin.

Habitat.—Andamans to the Malay Archipelago, China and the Tonga islands. The example figured is

 $14\frac{1}{2}$ inches in length, and was from Port Blair.

16. Muræna picta, Plate CLXXII, fig. 4.

Moluk. p. 294, Mur. p. 47, and Ternate, p. 383.

Muræna Pfeifferi, Bleeker, Celebes, p. 173, and Mur. p. 72.

Sidera Pfeifferi and pantherina, Kaup, Apod. pp. 70, 71. Gymnothorax pantherinus, Bleeker, Batjan, p. 152.

Length of head $3\frac{3}{3}$ in the distance between the end of the snout and the vent: tail about as long as the trunk. Eyes—small, about 2 diameters from the end of the snout, and situated over about the centre of the cleft of mouth, which latter is about 1/3 of the length of the head: the mouth cannot be completely closed. Anterior nasal tube not quite so long as the vertical diameter of the orbit. Gill-opening about as large as the orbit. Teeth-maxillary and premaxillary teeth in a single row: the vomerine ones posteriorly rounded and generally anteriorly in a bifurcated row: the anterior 2 or 3 vomerine teeth are rather curved, sharp not subulate, and about the same size as those in the premaxillaries. Mandibular teeth in one row, except anteriorly where it is double. Colours—there are many different forms of colour, usually of a gray or grayish-yellow groundwork covered with black spots, which are connected together by a network of dark lines causing the fish to appear

Habitat.—East coast of Africa, Madagascar, Bourbon, and seas of India to the Malay Archipelago and beyond.

C.—Teeth generally obtuse or molariform.

17. Muræna zebra.

Gymnomuræna zebra, Shaw, Nat. Misc. p. 101; Richards. Erebus and Terror, Fish. p. 95; Kaup, Apodal Fish. p. 104, t. 14, f. 70.

Gymnothorax zebra, Bl. Schn. p. 528.

Gymnomuræna doliata, Lacépède, v, pp. 648, 649, pl. xix, f. 4. Muræna molendinaris, Benn. Proc. Zool. Soc. 1833, p. 32.

Murana zebra, Cuv. Règ. Anim.: Bleeker, Boeroe, p. 80, and Amboina, p. 93; Günther, Catal. viii, p. 128; Klunz. Fische Rothen Meer. 1871, p. 620.

Gymnomuræna fasciata, Kaup, Apodal Fish, p. 103, f. 69. Echidna zebra, Bleeker, Atl. Ich. iv, p. 81, t. clxxi, f. 1.

Length of head $6\frac{1}{2}$ to $7\frac{1}{2}$ in the distance between the end of the snort and the vent: tail 1/3 of the total length. Eyes—small, and rather nearer the end of the snout than to the angle of the mouth. Teeth—consist of bands of obtuse molars. Colours—of a rich dark brown, and ornamented with from 30 to 100 narrow white or yellow rings, which are sometimes incomplete.

Habitat.—Red Sea and East coast of Africa, through the seas of India to the Malay Archipelago and

the Pacific. It attains a large size.

18. Muræna nebulosa, Plate CLXXII, fig. 2.

Ahl, De Mur. et Ophichth. p. 5, t. i, f. 2; Günther, Catal. viii, p. 130; Klunz. Fische Roth. Meer. 1871, p. 618.

Muræna ophis, Rüpp. Atl. Fische, p. 116, t. 29, f. 2; Richard. Erebus and Terror, Fish. p. 93.

Thærodontis ophis, McClell. Cal. J. N. H. v, p. 217.

Muræna variegata, Richard. l. c. p. 94, pl. 47, fig. 11-16; Bleeker, Ich. Mol. p. 295, Mur. p. 47; Peters, Wiegm. Arch. 1855, p. 270.

Pacilophis variegata, Kaup, Apod. p. 98, f. 67; Kner, Novara Fische, p. 381.

Length of head $4\frac{1}{2}$ to $4\frac{2}{3}$ in the distance between the end of the snout and the vent: tail a little shorter than the trunk. Eyes—nearly 2 diameters from end of snout and situated midway between it and cleft of mouth, which last equals about 1/3 of the length of the head. Gill-opening rather smaller than the eye. Teeth—most of the teeth obtase or molariform. Fins—vertical ones rather well developed and commencing a little in front of gill-opening. Colours—brownish or olive, darkest along the back. A row of from 20 to 25 black blotches along the upper surface of the head and back extending on to the dorsal fin, and nearly as wide as the ground colour, there are some white spots in the centre of each. A similar row of blotches along the abdominal surface. Intermediate ground colour of fish covered with small black stars, spots or vermiculated Vertebræ, 65/57.

This fish is termed Saulinga Pám. Tel. according to Sir W. Elliot.

Habitat.—Red Sea, Madagascar, Bourbon, Seychelles Archipelago, through the Indian and Pacific Oceans. It is said to attain 5 feet in length.

19. Muræna polyzona, Plate CLXIX, fig. 3.

Richards. Voy. Sulphur, Zool. p. 112, pl. lv, f. 11-14, and Erebus and Terror, Fish. p. 95; Bleeker, Manado, p. 73; Jerdon, M. J. L. and Sc. 1851, p. 151; Gunther, Catal. viii, p. 129; Klunz. Fisch. Both. Meer. 1871, p. 617.

Digitized by Google

Length of head 1/4 of the distance between the end of the snout and the vent: tail about 1/3 longer than body. Eyes—of moderate size, placed about midway between angle of mouth and end of the snout. Length of cleft of mouth $3\frac{1}{2}$ in the length of the head. Gill-opening small, scarcely so large as the eye. Teeth—with rounded crowns, the form changing considerably with age. Fins—dorsal rudimentary, commencing a little behind the vertical from the branchial opening. Colours—deep brown, encircled with fine narrow, 25-30 (yellow) whole or half bands, which usually increase in width as they descend.

A beautiful figure, 17½ inches in length, marked, Búdidé pám, natural size, exists in Sir W. Elliot's collection of drawings of Madras fish.

Habitat.—Red Sea, through the seas of India to the Malay Archipelago and the Pacific.

20. Muræna nigra, Plate CLXXI, fig. 3.

Day, Proc. Zool. Soc. 1870, p. 702.

Length of head $4\frac{1}{2}$ in the distance between the end of the snout and the vent: tail nearly 1/2 of the total length. Eyes—situated nearer to the snout than to the angle of the mouth, small, diameter half that of the snout: anterior tubular nostril of moderate length. Gill-opening about as wide as the eye. Cleft of mouth equals 1/3 of length of the head: the mouth cannot be completely closed. Teeth—biserial, except in the mandible where there are three rows in some places, all are obtuse except the inner maxillary row, which are pointed and finer than the outer row: premaxillary and vomerine teeth of equal size and with globular heads: mandibles with about 20 teeth in either side. Fins—dorsal and anal moderately developed: the former commencing just behind a vertical line from the gill-opening, and half as high as the body. Colours—uniform black, no light edge to the fins.

Habitat.—Andamans. This specimen, 16 inches long, was discovered alive under a large stone at low

water at Port Blair.

Genus 10-Gymnomuræna, Lacépède.

Murænoblenna, Lacép.; Ichthyophis, Lesson: Uropterygius, Rüpp.: Channomuræna, Richardson.

Gill-openings of moderate width or narrow. Two pairs of nostrils on the upper surface of the snout, the posterior being a round foramen, or with a short tube. Teeth small, pointed, and numerous. Fins absent except a rudimentary one round the end of the tail. Scales absent.

Geographical distribution.—Indian and Pacific Oceans.

SYNOPSIS OF SPECIES.

1. Gymnomurana tigrina—Tail nearly twice as long as trunk. Brownish, with dark blotches. East coast of Africa, seas of India to the Malay Archipelago and beyond.

2. Gymnomurana marmorata—Tail rather longer than trunk. Gray marbled with arborescent dark lines. Andamans to the Malay Archipelago.

1. Gymnomuræna tigrina.

Ichthyophis tigrinus, Lesson, Mém. Soc. d'Hist. Nat. Paris, iv, p. 399, and Voy. Coq. Zool. ii, p. 129, Atl. Poiss. t. xii,: Swainson, Fishes, ii, p. 336; Richard. Erebus and Terror, Fish. p. 96; Bleeker, Ichthyoph. p. 463.

Gymnomurana tigrina, Bleeker, Atl. Ich. iv, p. 113, t. clxv, f. 3; Kner, Novara Fische, p. 307; Günther, Catal. viii, p. 133.

Length of head 41 in the distance between the end of the snout and the vent: tail nearly twice as long as the body. Eyes—small. Posterior nostril slightly tubular in the adult. Extent of cleft of mouth 21 in the length of the head. Teeth—no distinct canines: the maxillary and anterior mandibular ones in two rows. Colours—brownish, with various sized irregularly shaped or rounded black spots and blotches.

Habitat.—East coast of Africa, seas of India to the Malay Archipelago and beyond. There is an example in the British Museum from the Mauritius, 4 feet in length.

Uropterygius xanthopterus, Bleeker, Java, p. 350 (young).

Gymnomuræna macrocephalus, Bleeker, Mur. p. 54, and Atl. Ich. iv, p. 114, t. 165, f. 2 (young).
Gymnomuræna xanthopterus and micropterus, Bleeker, Atl. Ich. iv, p. 114, 115, t. 184, f. 4, and 164, fig. 2; Kner, Novara Fische, p. 388.

Length of head 4 to $4\frac{1}{2}$ in the distance between the end of the snout and the vent: tail rather longer than the trunk. Eyes—small, about $1\frac{1}{3}$ or $1\frac{2}{3}$ diameters from end of snout, to which it is nearer than to the angle of the mouth. Extent of cleft of mouth equal from $2\frac{1}{2}$ to $2\frac{3}{4}$ in the length of the head. The gill-opening wider than the eye. Anterior nasal tubes short, the posterior nostrils with a raised edge in adults. Teeth—pointed, in a band in either jaw, the inner row the larger: no large canines: in a single row in vomer, the anterior two of which are rather enlarged and accoular. Fins—the vertical fins only exist round the end of the tail, the fin rays being rudimentary. Colours—of a brownish gray marbled all over with arborescent dark lines. The variety G. xanthopterus has the fins yellow. Habitat.—Andamans to the Malay Archipelago. The example figured is 10·3 inches in length.

ORDER, IV-LOPHOBRANCHII, Curier.

Fishes having a dermal, segmental skeleton, with the opercular pieces reduced to a single plate. Gill-openings small: gills consisting of small rounded tufts attached to the branchial arches. Muscular system very slightly developed. Snout produced: mouth terminal, but small. Teeth absent. Air-vessel stated to be destitute of a pneumatic duct.

The fishes which comprise this order normally swim in a vertical position, the dorsal fin being the principal propeller, and which while in motion it rapidly undulates from end to end.

As respects the mode of propagating their species, Professor Canestrini considered a coitus occurs, when the ova are transferred from the female to the male, the latter fecundating them after they have entered the ovigerous sac. Kaup remarked that "in most of the species the males perform the function of hatching the eggs, which for that purpose are deposited up to the time of the evolution of the young, either between the ventrals (Solenostomus), or in tail pouches (Hippocampus), or in pouches on the breast and belly (Doryrhamphus), or in rows on the breast and belly (Nerophis), and are thus carried about by the fish." Dr. Günther, in his observations on Solenostoma cyanopterum, remarks, "Kaup states that in the males of Solenostoma paradoxum the egg pouch is formed by the union of the inner edge of the ventrals to the skin of the belly, and that in the females the ventrals are free as in other fish. All the specimens from Zanzibar which have been examined have the ventrals attached to the skin of the belly, and all of them are females: so that if the first part of Dr. Kaup's remarks prove to be true, both sexes in this species carry eggs. We may state that we have ascertained by dissection that specimens having eggs in the ventral rough have at the same time over in the eventral tained by dissection that specimens having eggs in the ventral pouch have at the same time ova in the ovaries scarcely less developed than those in the pouch."—(Fish. Zanz. p. 138.)

Fishes of this Order have been divided into two Families:-

Syngnathidee, with small gill-openings: one dorsal fin: no ventral; and some of the other fins may be absent.

Solenostomide, with wide gill-openings: two dorsal fins; and the fins well-developed.

FAMILY, I—SYNGNATHIDÆ, Kaup.

Gill-openings small, round, and situated at the posterior superior angle of the gill-cover. A single dorsal fin. Ventrals, and occasionally one or more of the other fins, absent.

SYNOPSIS OF INDIAN GENERA.

First group—Syngnathina.

Tail not prehensile: caudal fin usually present.

- A .- Humeral bones united: male with egg-pouch on tail: a caudal fin.
- 1. Syngnathus. Dorsal ridges of trunk and tail not continuous: dorsal fin opposite, or nearly so, to the
- vent: pectorals well developed, p. 677.

 2. Ichthyocampus. Dorsal ridges of trunk and tail continuous when distinct: dorsal fin opposite, or nearly so, to the vent: pectorals present, p. 679.
 - B.—Humeral bones united: male with egg-pouch on abdomen: pectoral and caudal fins absent.
 - 3. Doryichthys. Ridges on body very distinct: caudal fin not very long, p. 679.
- C .- Male with ova attached to the abdomen and no closed pouch: pectorals absent: caudal, when present, rudimentary.
 - 4. Nerophis. No adipose fins, p. 680.

Second group—HIPPOCAMPINA.

Tail prehensile: caudal fin absent.

- 5. Gastrotokeus. Body depressed, p. 681.
 6. Acentronura. Body compressed: occipital crest without a coronet, p. 681.
- 7. Hippocampus. Body compressed: occipital crest with a coronet, p. 681.

First group—Syngnathina.

Tail not prehensile: caudal fin usually present.

A.—Humeral bones united: male with egg-pouch on tail: a caudal fin.

Genus, 1-Syngnathus, Artedi.

Corythoichthys, Trachyrhamphus, and Halicampus, Kaup.

Body with more or less distinct ridges: the dorsal edge of the trunk not being continuous with that on its caudal portion: humeral bones firmly united into the breast ring. The operale may be entirely crossed by a distinct ridge, or it may be only at its base, or the ridge absent. Dorsal fin either opposite or nearly so to the vent: its base may be raised or not so: pectorals well developed: caudal present. An egg-pouch on the tail of the males, the eggs being covered by cutaneous folds.

Geographical distribution.—Tropical and temperate seas, some entering fresh waters.

SYNOPSIS OF INDIAN SPECIES.

A.—Bony ridge on opercle, when present, only along its base: base of dorsal fin elevated.

1. Syngnathus serratus, D. 25-27, Rings 21-25 + 45-47, Trunk 1/2 to 2/3 of total length. Snout less than 1/2 of length of head, and with a serrated crest. Body banded. Seas of India to China.

2. Syngnathus longirostris, D. 27, Rings 23 + 49? Snout more than 1/2 length of head and without a serrated crest. Body banded. Ceylon and Madras to China.

3. Syngnathus intermedius, D. 28, Rings 24-25 + 48-49. Snout 1/2 as long as head and without any crest. Body banded: dorsal fin spotted. Madras

crest. Body banded: dorsal fin spotted. Madras.

B.—A bony ridge entirely crossing the opercle.

4. Syngnathus spicifer, D. 23-27, Rings 15-16 + 39-42. Trunk 2/5 of the total length. Dark spots on lower jaw: body and dorsal in barred. Seas, estuaries, and fresh waters, from the Red Sea and East coast of Africa through the approximation of the state of the season Africa through the seas of India to the Malay Archipelago.

5. Syngnathus cyanospilos, D. 20-23, Rings 12-15 + 33-35. Body banded, each crossbar with a white posterior edge. East coast of Africa, seas of India to the Malay Archipelago.

A.—Bony ridge on opercle, when present, only at its base: base of dorsal fin elevated.

1. Syngnathus serratus, Plate CLXXIII, fig. 4.

Syngnathus typle, Russell, Fish. Vizag. i, p. 21 (not Linn.) and Goorahpoo subbookoo, pl. 30, f. 2. Syngnathus serratus, Schleg. Faun. Japon. Poiss. p. 272, pl. 120, fig. 4; Bleeker, Japan, p. 55; Günther, Catal. viii, p. 167.

Syngnathus subbookoo, Bleeker, Beng. p. 80.

Trachyrhamphus serratus, Kaup, Lophobr. p. 23; Dumeril, Hist. Poiss. ii, p. 538. Trachyrhamphus cultrirostris, Peters, Monatsber. Ak. Wiss. Berlin, 1869, p. 710 (young).

Kadil cudray and Cul-pamboo, Tamil.

D. 25-27, P. 17, A. 4, C. 6, Osseous rings 21-25 + 45-47.

Length of head from 5 to 6 in the distance between end of snout and vent: trunk from above 1/2 to nearly 2/3 of the total length. Eyes—large, situated in the middle of the length of the head. A spinate or serrated crest along the upper edge of the posterior 2/3 of the snout. Length of snout less than 1/2 of length of head: interorbital space broad, with the orbital edges prominent, smooth: occiput and nape with a median ridge: opercle finely striated. Body scarcely deeper than broad: shields without spines: vent nearly below the middle of the dorsal fin, the base of which is elevated, it stands on 5 or 6 rings, 2 of which are anterior to the anal ring: caudal fin extremely small: egg-pouch more than half as long as tail. Lateral-line—bent downwards and passes into the lower edge of the tail. Colours—light brown with light spots along the side, and the body banded in rings: tail fin black with a white lower edge: a dark mark at base of anterior dorsal rays; and a dark line along the middle of the fin.

Habitat.—Seas of India to China. The example figured, a male, was from Madras, where it is very

common.

2. Syngnathus longirostris, Plate CLXXIII, fig. 5.

Trachyrhamphus longirostris, Kaup, Lophob. p. 24; Dumeril. Hist. Poiss. ii, p. 538. Syngnathus longirostris and ? Ceylonensis, Günther, Catal. viii, pp. 167, 168.

D. 27, P. 18, A. 4. Osseous rings, 23 + 49 + x.

Length of head 34 in the distance between the end of the snout and the vent: the end of the tail is injured in the single example procured at Madras, but the length of the trunk from the end of the snout to the vent is scarcely more than 1/3 of the total length. Egg pouch not 1/2 as long as the tail. Eyes-1/4 of length of snout and situated in the posterior 1/2 of the distance between the end of the snout and base of the pectoral fin. Body deeper than broad. No elevated ridge along the upper surface of the snout. Length of snout

more than half the length of the head. Interorbital space nearly flat. A low and blunt ridge at the occiput and nape. Opercle covered with fine radiating lines. Vent below middle of the dorsal fin. Body prominent inferiorly from the sixth to the eleventh body rings. Fins—dorsal low, it commences on the third body ring before the one carrying the vent, it is situated on seven rings, and has its base elevated. Colours—grayish brown, with dark rings: under surface of snout light coloured with dark spots.

My unique Madras example (figured) has the comparatively thin body of S. Ceylonensis, Günther (example a), but has more osseous rings in the tail. It does not seem improbable that S. Zanzibarensis, Günther, may be partly this species, and perhaps example "c. Adult China. Presented by Vice-Admiral Sir E. Belcher," may be the second example which Kaup stated existed in the British Museum collection. Dumeril ii, p. 519, considers S. Zanzibarensis, Günther, identical with S. bicoarctatus, Bleeker.

Habitat .--? Ceylon, Madras and China.

3. Syngnathus intermedius, Plate CLXXIII, fig. 6.

Trachyrhamphus intermedius, Kaup, Loph. p. 24; Dumeril, Hist. Poiss. ii, p. 538. Syngnathus intermedius, Günther, Catal. viii, p. 168.

D. 28, P. 18, A. 4, C. 9. Osseous rings 24-25 + 48-49.

Length of head $3\frac{3}{4}$ to $4\frac{1}{4}$ in the distance between the end of the snout and the vent: the length of the trunk, between the end of the snout and the vent, equals $1\frac{2}{3}$ in the total length. Egg-pouch 2/5 of length of tail. Eyes—diameter 31 in the length of the snout and situated in the posterior 1/2 of the head. Body deeper than broad. Length of snout 1/2 of that of the head and without any elevated ridge along its upper surface except a projection above the nostrils. Interorbital space slightly concave, owing to the supraorbital ridges being well developed. A low and blunt projection on occiput continued as a sharper ridge along the nape. Opercle with fine radiating lines. Fins—dorsal of moderate height, it commences on the third body ring before the one carrying the vent, it is situated on 6 or 7 rings, having its base elevated. Length of caudal fin equal to 1/2 that of snout. Colours—grayish and banded: dorsal fin spotted.

Habitat—A pair captured at Madras: they appear to be identical with Syngnathus Ceylonensis, example

b. British Museum catalogue, from Zanzibar.

B.—A bony ridge entirely crossing the opercle.

4. Syngnathus spicifer, Plate CLXXIV, fig. 1.

Microphis tenuis, Blyth, Proc. As. Sc. Beng. 1858. p. 272. Ea-de or Lak-atha-dah or "Turtles tail," Andamanese.

D. 23-27, P. 16, A. 2, C. 8. Osseous rings 15-16 + 39-42.

Length of head $2\frac{2}{3}$ in the distance between the end of the snout and the vent: the length of the trunk Length of head $2\frac{\pi}{3}$ in the distance between the end of the shout and the vent: the length of the trunk from the end of shout to vent 2/5 of the total length. Eyes—nearly 1/6 of the length of the head, 3 diameters from end of shout. Gill-cover crossed by a raised longitudinal keel: an elevated ridge along the upper edge of the shout and extending to the nape. Interorbital space concave (due to the upper margin of the orbit being elevated), and which ends posteriorly in a ridge which is continued to the nape. Body compressed, higher than wide: ventral edge very prominent. Length of egg-pouch rather more than 1/2 that of the tail. Fins—the dorsal is situated on the first five rings of the caudal: the anal rays are minute and sometimes imperceptible. Rings with smooth edges, the division between one and the next but little apparent. Colours—generally light brownish, with a dark brown streak extending from the orbit to the angle of the mouth, and a second from the posterior angle of the eye over the opercle: a few black spots on under surface of the lower jaw: body inferiorly with fine brown bars. Dorsal fin barred with brown spots: caudal blackish with a light brown base.

Habitat.—Seas, estuaries, and fresh waters of Red Sea, East coast of Africa, India, and the Malay Archipelago: it ascends rivers high above the influence of the tides, even into fresh water. Grows to about

5 inches in length. The example figured was from the Andamans.

5. Syngnathus cyanospilos.

Bleeker, Nat. Tyds. Ned. Ind. vi, 1854, Banda, p. 114, and en. Pisc. p. 187; Dumeril, Hist. Poiss. ii, p. 555; Günther, Catal. viii, p. 170.

Syngnathus Mossambicus, Peters, Monats. Ak. Wiss. Berl. 1855, p. 465, and Flussfische v. Mossamb. p. 104, t. xx, f. 3.

Syngnathus Kuhlii, Kaup, Lophob. p. 34.

D. 20-23, P. 14, A. 4, C. 10. Osseous rings 12-15 + 33-35.

Length of head $8\frac{1}{4}$ in the total length, or $3\frac{1}{3}$ in the distance between the end of the snout and the vent: the length of the trunk $2\frac{3}{4}$ in the total length. Eyes—diameter 6 to $6\frac{1}{2}$ in the length of the head. Snout much longer than the postocular region, and equalling the distance from the hind edge of the eye to the middle of the pectoral fin. A low median ridge along the snout, crown, and nape: a second along the side of the head. Fins—dorsal on six rings commencing on the last body ring. Colours—body with irregular brown cross bars, each with a white posterior edge: black dots on the dorsal.

Habitat.—East coast of Africa, seas of India, to the Malay Archipelago.

Genus, 2--ICHTHYOCAMPUS, Kaup.

The ridges of the concave back and tail are continuous, and are continued (although sometimes very indistinctly) to the caudal fin. Dorsal fin nearly or quite opposite to the vent. Pectorals and caudal present. Males with an egg-pouch, having a cutaneous covering, situated on the tail.

Geographical distribution.—Seas of India to Australia.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Ichthyocampus carce, D. 23-26, Osseous rings 15-16+38-40. Brown, with milk-white spots on the body. Seas, estuaries, and fresh waters of India to the Malay Archipelago.

1. Ichthyocampus carce, Plate CLXXIV, fig. 2.

Syngnathus carce, Ham. Buch. Fish. Gang. pp. 13, 362; Gray and Hard. Ill. Ind. Zool. (from H.B.'s MSS.); Bleeker, Beng. pp. 80, 161.

Typhlus Ponticerianus, Bibron, Paris Mus. (Kaup.)

Ichthyocampus Ponticerianus, Kaup, Lophob. p. 31; Kner, Novara Fische, p. 391; Day, Fish. Malabar, p. 263; Dumeril, Hist. Poiss. ii, p. 540.

Ichthyocampus carce, Kaup, l. c. p. 30; Dumeril, Hist. Poiss. ii, p. 540; Günther, Catal. viii, p. 176.

D. 23-26, P. 17, A. 2, C. 6, Osseous rings 15-16 + 38-40.

Length of head $3\frac{1}{3}$ in the distance between the end of the snout and the vent: the distance between end of snout and vent is $2\frac{2}{3}$ in the total length. Eyes—diameter 1/6 of length of head, nearly 3 diameters from end of snout, and 1/3 of a diameter apart. Body higher than it is wide. Snout slightly elevated in its anterior third: interorbital space slightly concave, with a sharp low median ridge passing along the snout: another exists in the occipital region. A very sharp straight ridge crosses the opercle. Egg-pouch about 1/2 as long as the tail. Fins—the dorsal is situated on the second to the eighth caudal rings. Rings—with smooth edges. Colours—deep brown, with one—occasionally two—milk-white spots in the centre of each body ring along the infero-lateral ridge: the lower surface of the snout dotted with black spots: dorsal fin yellow: pectoral and condel leader colours, over greenish blue. caudal leaden-colour: eye greenish-blue.

Habitat.—Seas, estuaries, and fresh waters of India and Malay Archipelago; where it grows to about 5 inches in length.

B.—Humeral bones united: male with egg-pouch on abdomen: pectoral and caudal fins present.

Genus, 3-Doryichthys, Kaup.

Doryrhamphus, Cheroichthys, and Microphis, Kaup: Belonichthys, Peters.

Ridges on body well-developed: lateral-line interrupted or continued to the lower edge of the tail. Dorsal fin situated opposite the vent and of moderate length or elongated.

Geographical distribution.—Seas of the tropics, some species entering fresh waters.

SYNOPSIS OF SPECIES.

- 1. Doryichthys cunculus, D. 50, Osseous rings 17-18 + 25-27. Dorsal fin stands on 11 rings. Tidal rivers along the coasts of India.
 - Doryichthys Bleekeri, D. 40-45, Osseous rings 21 + 22. Dorsal fin stands on 9 rings. Malabar.
 Doryichthys deocata, D. 30, Osseous rings 16 + 32. Rivers of Bengal and Behar.

1. Doryichthys cunculus, Plate CLXXIV, fig. 4.

Syngnathus cunculus, Ham. Buch. Fish. Ganges, pp. 12, 362; Bleeker, Beng. p. 80.

Microphis cunculus, Kaup, Catal. Lopho. Fish. Brit. Mus. p. 64; Day, Fish. Malabar, p. 266; Dumeril, Hist. Poiss. ii, p. 591.

Doryichthys cunculus, Günther, Catal. viii, p. 181. Kunnur dant, "Crocodile's teeth," Ooriah.

D. 50, P. 16-18, A. 2, C. 8-9, Osseous rings 17-18 + 25-27.

Length of head 41 in the distance between the end of the snout and the vent: length of trunk from snout to vent about 1/2 of the total length. Eyes—of moderate size, situated in the middle of the length of

the head, and 3 diameters from the end of the snout. A fine ridge extends along the upper surface of the snout to between the eyes: an elevated ridge divides the gill-cover into two halves. Snout somewhat elevated. Edges of shields without spines. The lateral-line uninterrupted, it unites in the form of an arch with the lower border of the first caudal ring. Fins—dorsal fin stands on 11 rings, 2 of which are anterior to the anal ring. Colours—green superiorly, dirty white beneath: on the back several dusky lines intersect each other, forming a net-work: along either side a longitudinal spotted stripe: caudal reddish: eyes silvery: opercle burnished like silver.

In Orissa the natives asserted that these little pipe-fishes have some mysterious connection with the teeth of the crocodile, some of the fishermen believing them to be vivified teeth, others that they are rejected toothpicks.

Habitat.—Tidal rivers ascending far above tidal influence. I have taken them from rivers in Bengal and Orissa, from which latter locality the specimen figured was obtained; and it is said that Dussumier sent seven examples from Malabar to Paris. It attains 7 inches or more in length.

2. Doryichthys Bleekeri, Plate CLXXIV, fig. 3.

Microphis Bleekeri, Day, Fish. Malabar, p. 265; Dumeril, Hist. Poiss. ii, p. 599. Doryichthys Bleekeri, Günther, Catal. viii, p. 182.

D. 40-45, P. 21, A. 2, C. 9, Osseous rings 21 + 22.

Length of head $3\frac{1}{3}$ in the distance between the end of the snout and the vent: trunk from end of snout to vent nearly 2/3 of the total length. Eyes—slightly oval, diameter $7\frac{1}{2}$ in the length of the head, $4\frac{1}{2}$ diameters from end of snout, and 1/2 a diameter apart. The lateral-line posteriorly arches downwards and reaches the infero-lateral caudal ridge at the base of the ring behind the anal one. Snout compressed, curving slightly upwards at its extremity: opercle with a horizontal ridge along its centre, having five more ridges proceeding below it to its posterior and inferior margins: a ridge on the nape. Fins—the dorsal is placed upon 9 rings, the first of which is the anal ring: the pectoral wide and short: the caudal lanceolate and equal in length to half that of the snout. Rings—each very distinctly separated from the next, and ending in a moderately sharp spine posteriorly, causing the surface to feel quite rough to the finger passed from behind forwards. In the female there are sometimes two spines to the end of each ring, and they are much sharper and longer than in the male. Colours—a bright red line at the gills, and along the lateral-line, otherwise of a light brown with a dark line proceeding forward from the eye, and the under surface of the snout barred with brown: fins light brown.

Habitat.—Not rare in the Alwaye river at Cochin. Grows to at least 8 inches in length.

3. Doryichthys deocata.

Syngnathus deocata, Ham. Buch. Fish. Ganges, pp. 14, 363; Gray and Hard. Ill. Ind. Zool. (from H. B.'s MSS.); Bleeker, Beng. p. 80.

Microphis deocuta, Kaup, Lophob. p. 64; Dumeril, Hist. Poiss. ii, p. 590.

D. 30, P. 15, A. ? C. 17? Osseous rings 16+32.

Snout longer than in *D. cunculus*. Fins—dorsal stands on six rings, two of which belong to the body. Colours—generally brown: bright red under the lateral-line and dotted with blue. In Gray and Hardwicke the lower surface is red, vertically banded with darker stripes edged with blue, at the upper end of each dark stripe is a white dot or angular mark.

Habitat.—Rivers of Bengal and Behar.

C.—Male with ova attached to the abdomen and no closed pouch; pectorals absent: caudal, when present, rudimentary.

Genus, 4-Nerophis, Rafinesque.

Netasomata, Eichwald: Scyphius, Risso: Entelurus, A. Dumeril.

Body rounded and ridges when present very indistinct: the tail tapering to a point without possessing any or only a rudimental caudal fin. Dorsal fin of moderate length placed opposite to the vent: the pectorals absent. Ova attached to the loose integument of the abdomen in the males, and not covered by lateral cutaneous folds.

Geographical distribution.—Bombay, Atlantic and the coasts of Europe.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Nerophis Dumerilii, D. 37. Osseous rings 27 + 65. Bombay.

1. Nerophis Dumerilii.

Steindachner, Sitz. Ak. Wiss. Wien. 1868, lvii, p. 1002; Günther, Catal. viii, p. 191. Entelurus Dumerilii, Dumeril, Hist. Poiss. ii, p. 607.

D. 37, C. 7. Osseous rings 27 + 65.

Length of trunk from snout to vent 1/3 of the total length. Snout half as long as the head. Forehead

concave: an obtuse ridge above the opercle continued to the hind edge of the orbit. Fins-dorsal commences behind the twentieth ring: its base is on ten rings, 3 of which belong to the tail. Caudal rudimentary. Habitat .- Bombay.

Second group-HIPPOCAMPINA. Tail prehensile: caudal fin absent.

Genus 5-Gastrotokeus (Heckel) Kaup.

Syngnathoides and Solegnathus, Bleeker.

Body depressed, having smooth shields and a prehensile tail, which latter is not so long as the body. Dorsal fin of moderate length placed nearly opposite the vent: pectorals and anal present: caudal absent. The lateral-line passes along the edge of the abdomen. Ova imbedded in soft substance on the abdomen of the males, but there is no pouch formed of lateral cutaneous folds.

Geographical distribution.—East coast of Africa, seas of India to the Malay Archipelago, China, and Australia.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Gastrotokeus biaculeatus, D. 40-45. Osseous rings 16-18 + 45-55. Red Sea, East coast of Africa and seas of India to China and Australia.

1. Gastrotokeus biaculeatus, Plate CLXXIV, fig. 5.

Syngnathus biaculeatus, Bloch, t. 121; Bl. Schn. p. 515, t. 107; Shaw, v, p. 453; Richardson, Ich.

China, p. 202; Cantor, Catal. p. 387.

Syngnathus tetragonus, Gmel. Linn. p. 1453; Lacép. ii, p. 46.

Syngnathoides Blochii, Bleeker, Nat. Tyds. Ned. Ind. ii, Banda, p. 259.

Solenognathus Blochii, Bleeker, Verh. Bat. Gen. xxv. Trosk. p. 24.

Gastrotokeus biaculeatus, Kaup, Lophob. p. 19; Peters, Moss. Fische; Bleeker, En. Pisc. p. 189;

Dumeril, Hist. Poiss. ii, p. 528; Günther, Catal. viii, p. 194; Klunz. Fische Roth. Meer. 1871, p. 653.

D. 40-45, P. 17-23, A. 4. Osseous rings 16-18+45-55.

Length of head about 1/3 of the distance between the end of the snout and the vent: the tail shorter than the trunk. Eyes—situated in the posterior half of the distance between the end of the snout and the base of the pectoral fin. A well defined supraorbital spine above the hind edge of the eye: interorbital space concave. Occiput destitute of a coronet, but with a distinct blunt projection: usually a barbel-like filament on the mandible and in some examples cutaneous filaments exist on lower surface of jaws and on the body. Fins—dorsal situated on ten rings, commencing on the one anterior to the anal, or else on the anal ring. Anal fin situated in a depression: a projection covered with well-developed papille exists just in front of the vent. Colours—these vary in different localities. Pale green or brown superiorly, becoming of an orange or buff on the under surface, a light spot edged with very pale vermilion on the side of each body ring: in some, black spots are scattered along the sides of the lower surface of the body. Lower surface of the head with dark spots

Habitat.—Red Sea, East coast of Africa, seas of India to the Malay Archipelago, China, and Australia. It attains to at least 93 inches in length. The example figured was from the Malay Archipelago.

Genus, 6—Acentronura, Kaup.

Body rather compressed, with shields without tubercles, and a prehensile, finless tail: occiput compressed into a crest without any coronet. Dorsal fin with rather few rays: pectorals present. Ova carried by the males in a suc, which is situated below the tail and opening near the vent.

1. Acentronura gracillima, Plate CLXXVI, fig. 1.

Hippocampus gracillimus, Temm. and Schleg. Fauna Japon. Poiss, p. 274, t. cxx, f. 7. Acentronura gracillima, Kaup, Lophob. p. 18; Dumeril, Hist. Poiss. ii, p. 527; Günther, Catal. viii, p. 198.

D. 16-17, P. 15, A. 2. Osseous rings 13 + 41-45.

Tail a little longer than the body. Snout 2/5 of the length of the head. Occiput compressed into a crest, but without any coronet. Fins—the dorsal standing on four rings, two of which belong to the tail: its base not elevated. Colours-brownish, covered with small white dots, and likewise little brown markings which in the female almost form bands, especially across the ventral surface. A row of dark spots along the upper third of the dorsal fin, forming a band. The male is darker and of a bluish colour, with a milk-white spot on each body ring.

Two examples, neither exceeding 1.5 inches in length, were dredged by Mr. J. Wood-Mason, off the coast of the Andamans, at 35.40 fathoms. It appears to attain to 3 inches in length.

Genus 7-HIPPOCAMPUS, Leach.

Trunk compressed and somewhat elevated, having from 10 to 12 rings. The shields furnished with tubercles or spines. Occiput compressed and forming a coronet at its posterior superior angle, which is usually surmounted by

Digitized by Google

spines or knobs. Dorsal and pectoral fins present: the tail prehensile, finless, and longer than the trunk. Males furnished with an egg-sac situated below the tail and opening near the vent.

Geographical distribution.—These marine fishes are found generally distributed throughout tropical and temperate seas. Owing to their attaching themselves (by means of their prehensile tails) to floating substances and pieces of scaweed, or sticks which break from their moorings, these fishes are carried away for long distances by currents, causing the limits of their distribution to be very extensive.

These horse-fishes are difficult to distinguish one from another, owing to slight variations in the number of osseous rings, individual deviations in some of the proportions of the body as the length of the snout, and in the existence and development of the tubercles and the shape of the plates. The number of rays in the dorsal fin appears to be moderately constant.*

SYNOPSIS OF SPECIES.

1. Hippocampus trimaculatus, D. 19-20. Osseous rings 11+36. Coronet of moderate height or low. Burma to Pinang and China.

2. Hippocampus guttulatus, D. 16-17. Osseous rings 11 + 33. Coronet rather low. Red Sea, Indian Ocean to Japan and tropical parts of the Atlantic.

3. Hippocampus hystrix, D. 17-18. Osseous rings 11 + 36-37. Tubercles in the form of sharp spines. East coast of Africa, seas of India to Japan.

1. Hippocampus trimaculatus, Plate CLXXIV, fig. 7.

Leach, Zool. Misc. p. 104; Günther, Catal. viii, p. 204.

D. 19-20, P. 17, A. 4. Osseous rings 11 + 36.

Eyes—diameter 1/8 of the length of the head. Length of snout equals the distance between the front edge of the eye and the gill-opening. Tubercles variously developed, in some long and acute, in others low: coronet similarly high or low, with a tubercle anteriorly, and surrounded by 5 rudimentary or well-developed spines: a low supraorbital spine and one on either side of the throat, which are of about the same shape, pointed and curved backwards. Fins—dorsal situated upon the last 2 rings of the trunk, and the first of the tail. Spines -very diversified, exceedingly low in some examples, not so in others. Colours-pale yellow ochre: two rows of blackish spots along the dorsal fin, and occasionally three large brown blotches along the edge of the back on the first, fourth, and seventh body rings: in some there are numerous fine black dots over the body. Sometimes light marks exist on the side of the back, and the body is banded.

Habitat.-Andamans, Tenasserim to Pinang and the seas of China.

2. Hippocampus guttulatus, Plate CLXXIV, fig. 6.

D. 16-17 (18), P. 17, A. 4. Osseous rings 11 + 33.

Eyes—diameter 1/6 to 1/7 of the length of the head, the anterior margins of the orbits situated midway between the end of the snout and the posterior extremity of the head. There are two supraorbital spines directed backwards and outwards. The coronet is rather low, with from 4 to 6 blunt tubercles. The tubercles on the body and tail are generally obtuse. Fins—the dorsal fin stands on the last two body rings and the first two tail rings. Colours—vary, generally grayish marbled with darker and covered with light or dark spots: or brown with black spots or cross bands. Dorsal fin may have a dark intramarginal band with a white outer

* For the method in which the females introduce the eggs into the egg-carrying pouch of the male, see Fanzago, Atti Soc. Pad. 1874, p. 161.

Habitat.—Red Sea, Indian Ocean to Japan, also tropical parts of the Atlantic. It attains 11 or 12 inches in length.

3. Hippocampus hystrix, Plate CLXXVI, fig. 2.

Kaup, Lophob. p. 17, t. 2, f. 5; Guich. Fauna Reunion, Append. p. 30; Dumeril, Hist. Poiss. ii, p. 514; Günther, Catal. viii, p. 206.

D. 17-18, P. 16. Osseous rings 11 + 36-37.

Coronet high with 5 spines, and a tubercle anteriorly, in front of which is another spine. Snout slender, as long as the distance between the front margin of the orbit and the first nuchal spine: two strong spines above the posterior and one above the anterior margin of the orbit: 2 spines below the centre of the orbit, and one behind the middle of its posterior edge. All the tubercles (except those on the end of the tail) in the form of slender and pointed spines. Colours—gray, or yellowish white, with numerous brown and also smaller white dots: 6 or 7 light patches on the tail, covered with dark spots, and one or more similar spots on the body. Snout dark, with a light ring. Each spine black at the tip.

the body. Snout dark, with a light ring. Each spine black at the tip.

Habitat.—Zanzibar, Reunion, Aden, Andamans and Japan. An example from Aden in the Calcutta museum is 4.5 inches in length. Mr. Wood-Mason dredged up the specimen figured life-size, at the Andamans,

in 35 40 fathoms.

ORDER, V—PLECTOGNATHI, Cuvier.

Teleostean fishes with an incompletely ossified skeleton and few vertebrs. Gill-openings narrow, situated in front of the pectoral fins: gills pectinate. Head often large. Mouth narrow: the bones of the upper jaw mostly united, sometimes produced into the form of a beak. Teeth may be distinct in the jaws or absent. There may be a single soft-rayed dorsal fin belonging to the caudal portion of the vertebral column, and situated opposite the anal: while in some a rudimentary spinous dorsal is also present: ventrals, when existing, in the form of spines. Skin either smooth, or with rough scales, or ossified in the form of plates or Air-vessel destitute of a pneumatic duct.

Geographical distribution.—Mostly oceanic, but some are found in large rivers, and many in estuaries and tidal pieces of water in temperate and tropical portions of the globe.

SYNOPSIS OF FAMILIES.

- 1. Sclerodermi. Distinct teeth in the jaws.
- 2. Gymnodontes. Jaws modified into a beak.

Family, I—SCLERODERMI, Cuvier.

Body compressed or angular: snout somewhat produced. Distinct teeth in small numbers in the A barbel in one genus. The elements of a spinous dorsal and ventral fins generally present, but variously modified. Skin rough or spinate, or the scales in the form of a firm carapace.

Geographical distribution.—Marine fishes found in tropical and temperate regions.

SYNOPSIS OF INDIAN GENERA.

First group—TRIACANTHINA.

Body compressed: dermal covering in the form of small, rough, scale-like scutes. A spinous dorsal with from 4 to 6 spines: a pair of strong ventral spines articulated to the pelvic bones.

1. Triacanthus. Outer row of teeth cutting, p. 684.

Second group-Balistina.

Body compressed: dermal covering rough, or with movable scutes. Spinous dorsal with from 1 to 3 spines: ventrals, if present, consisting of a single pelvic projection.

- 2. Balistes. Three dorsal spines: no barbels, p. 686.
- Monacanthus. One or two dorsal spines: no barbels, p. 692.
 Anacanthus. A barbel present, p. 694.

Third group-OSTRACIONTINA.

Body angular with the dermal covering forming a carapace, leaving the snout and bases of the fins covered by skin. Spinous dorsal and ventral fins absent, except in the form of osseous protuberances.

5. Ostracion. Teeth small, slender and in a single row. Carapace closed behind the anal fin, p. 695.

First group-TRIACANTHINA.

Body compressed: dermal covering in the form of small, rough, scale-like scutes. A spinous dorsal with from 4 to 6 spines: a pair of strong ventral spines, articulated to the pelvic bones.

Genus, 1—TRIACANTHUS, Cuvier.

Body oblong, compressed, ending in a somewhat elongated caudal portion. Eyes lateral, high up, situated near the hind edge of head. Teeth in two rows in both jaws, the outer 10 in number, being incisor-like: the inner, from 2 to 4, being more molariform. First dorsal fin consisting of a long and strong spine, followed by from 3 to 5 smaller and weak ones: ventrals formed by a pair of strong spines articulated by a joint or ossified to the pelvic bones: caudal lobed. Scales minute and rough. Lateral-line present. Air-vessel strong.

In fishes of this genus, the proportions of the height of the body, the length of the head and extent of the spines vary with age, and also in individuals of the same species.

Geographical distribution.—From the shores of Beloochistan, through the seas of India to those of Australia.

SYNOPSIS OF SPECIES.

1. Triacanthus brevirostris. Snout of moderate length: second dorsal spine of same length as third: length of base of anal 2/3 of length of head. A black blotch on first dorsal fin. Seas of India to the Malay Archipelago, and beyond.

2. Triacanthus strigilifer. Snout elongated: second dorsal spine three times as long as third: length of base of anal 1/2 of length of head. Yellow blotches and lines on body. Madras to Malay Archipelago and beyond.

B. vi, D. 5/22-25, P. 14, V. 1. A. 16-20, C. 12.

Length of head $4\frac{1}{2}$ to $4\frac{2}{3}$, of caudal $4\frac{1}{4}$ to $4\frac{3}{4}$, height of body $3\frac{1}{4}$ to $3\frac{1}{4}$ in the total length. Eyes high up, diameter 1/4 of length of head, $2\frac{1}{2}$ diameters from the end of snout and $1\frac{1}{3}$ apart. A considerable rise from the snout to the first dorsal fin, and an elevation opposite the orbits. Teeth—outer row in upper jaw consisting of 8 compressed cutting teeth, the inner row 6 in number rounded, and the two centre ones the longest: in the mandibles 10 in the outer and 2 in the inner row, smaller than but otherwise similar to those in the upper jaw. Fins—first dorsal spine very strong, longer than the head in the immature, of about equal length or shorter in the adult: second and third spines weak and of about equal length: dorsal fins together in the very young, not so in the adult. Anal highest anteriorly, its lower edge concave, the length of its base 2/3 of that of the head: ventral spine slightly shorter than that of the first dorsal: pectoral short and rounded: caudal deeply lobed. Colours—silvery, with a black spot on the first dorsal fin, and which extends a short distance on to the back: usually a dark supraorbital blotch.

Bennett observes that it is generally found in deep water, and rarely on the Southern coast of Ceylon: by the native fishers it is considered wholesome food. In India it is rejected, except by the lowest classes. Russell remarks that these fish are caught in such vast numbers after the month of May, as to injure the nets.

Triacanthus biaculeatus, Bloch, bears a considerable resemblance to this species, but has the snout much more elongated. Bleeker considered the relative height of the body in T. Nieuhofi, as greater than in T. brevirostris, and that it had a shorter and more obtuse head.

Habitat.—Seas of India to the Malay Archipelago, and beyond; attaining at least $9\frac{1}{2}$ inches in length.

2. Triacanthus strigilifer, Plate CLXXV, fig. 2.

Cantor, Catal. Mal. Fish, p. 363, pl. 9; Bleeker, Amboina, p. 97, and Atl. Ich. v, p. 89, t. cclxxix, f. 3; Jerdon, M. J. L. and Sc. 1851, p. 149; Günther, Catal. viii, p. 211.

Triacanthus longirostris, Hollard, Ann. Sc. Nat. 1854, i, p. 46, t. 2, f. 3.

Rama moolean, Tamil.

B. vi, D. 5/22, P. 14, V. 1, A. 15-16, C. 12.

Length of head 4 to 41, of caudal 5, height of body 31 in the total length. Eyes—high up, diameter $3\frac{1}{2}$ to $3\frac{3}{4}$ in the length of head, $2\frac{1}{3}$ diameters from end of snout and $1\frac{1}{4}$ apart. The upper profile between the eye and snout rather concave. Teeth—8 compressed and cutting ones form the outer row in upper jaw, whilst the inner row consists of 4 rounded ones: 10 similar ones in the outer and 2 in the inner row of the lower jaw. Fins—first dorsal spine very strong and longer than the head, the remaining ones weak: the second being more than 1/2 as long as the head, and 3 times as long as the third: fins otherwise similar to those of the last species, except that the length of the base of the anal is only about 1/2 of that of the head. Colours silvery, with some wide irregular yellow lines and blotches on the head and body.

Habitat.—Madras to the Malay Archipelago, China, and the Philippines. The example figured was

from Madras.

Second Group—Balistina.

Body compressed: dermal covering rough, or with movable scutes. Spinous dorsal with from 1 to 3 spines: ventrals, if present, consisting of a single pelvic projection.

Genus, 2-Balistes, sp. Artedi.

Balistapus, Tiles: Xenodon, Erythrodon and Pyrodon, Rüppell: Melichthys and Leinrus, Swainson: Balistapus, Kaup: Sub-genera, Parabalistes, Pseudobalistes, Canthidermis, Bleeker.

Branchiostegals six. Body compressed. Barbels absent. Sometimes a groove before the eyes. Upper jaw with a double series of incisor-like teeth, 8 in the outer, 6 in the inner row: mandibles with 8 similar teeth in one row: these teeth may be white, uneven, and more or less notched (Balistes): or white, even and incisor-like (Melichthys): or of a burnt sienna colour, with the supero-lateral pair projecting (Erythrodon). The first dorsal fin consisting of a strong spine succeeded by two weak ones: ventrals as an osseous appendage. There may or may not be oval, flattened, osseous, productions behind the gill-opening. Scales forming a carapace: in some species there are rows of spines or turbercles on the side of the free portion of the tail, which is either compressed or depressed.

Eating the flesh of these fishes occasions in places symptoms of most virulent poisoning. Dr. Mennier, at the Mauritius, considers that the poisonous flesh acts primarily on the nervous tissue of the stomach, occasioning violent spasms of that organ, and shortly afterwards of all the muscles of the body. The frame becomes racked with spasms, the tongue thickened, the eye fixed, the breathing laborious, and the patient expires in a paroxysm of extreme suffering. The first remedy to be given is a strong emetic, and subsequently oils and demulcents to allay irritability.

SYNOPSIS OF SPECIES.

A .- Free portion of the tail depressed.

1. Balistes stellatus, D. 3/26-27, A. 24-25, L. 1. 42-46, L. tr. 26.* Grayish green, with white spots and blotches, more or less disappearing with age. From the Red Sea through the Indian and Pacific oceans.

B.—Free portion of the tail compressed.

2. Balistes maculatus, D. 3/26-27, A. 24-25, L. l. 46-55, L. tr. 28. Teeth white, uneven, notched: cheeks scaled: a groove in front of eye: no osseous scutes behind gill-opening, or spines at side of tail. Bluish, spotted with lighter. Indian, Atlantic and Pacific oceans.

3. Balistes vetula, D. 3/30-32, A. 29, L. l. 61-63, L. tr. 37. Teeth white, uneven, notched: cheeks scaled: a groove before eye: osseous scutes behind gill-opening: no spines at side of tail. Two blue bands on side of head: a dark light-edged line below the eye, from which other lines radiate. Bluish bands on fins. Atlantic and Indian oceans.

4. Balistes niger, D. 3/26-28, A. 23-25, L. l. 45-47, L. tr. 23-26. Teeth white, uneven, notched: cheeks scaled: a groove before eye: osseous scutes behind gill-opening: 6 to 8 rows of small recurved spines at side of tail. Brown: yellow ring behind lips: caudal with light edges. Red Sea, seas of India to the Malay Archipelago.

5. Balistes mitis, D. 3/29-31, A. 26-28, L. 1. 55-65. Teeth white, uneven, notched: cheeks scaled: a groove before eye, osseous scates behind gill-opening: 7 or 8 rows of small round tubercles on scales of side. Brownish with a yellow ring round the mouth continued towards the pectoral fin. East coast of Africa, seas of India to the Malay Archipelago.

6. Balistes conspicillum, D. 3/25-26, A. 21-22, L. 1. 46. Teeth white, uneven, notched: checks scaled, a groove before eye: osseous scutes behind gill-opening: $2\frac{1}{3}$ rows of tubercles at side of tail. Dark, with large white spots on lower half of body: a white band between the eyes and round the snout: caudal white, with two black bands. Indian and Pacific oceans.

two black bands. Indian and Pacific oceans.

7. Balistes viridescens, D. 3/24-26, A. 23-24, L. l. 30-34, L. tr. 17. Teeth white, uneven, notched: cheeks scaled: a groove before eye: osseous scutes behind the gill-opening: $4\frac{1}{2}$ rows of recurved spines at side of tail. Brownish olive, with a yellow black-edged ring round the mouth: a dark band from eye to pectoral fin. Andamans to the Malay Archipelago.

8. Balistes fuscus, D. 3/25-26, A. 23-26, L. l. 45-55, L. tr. 27-31. Teeth white, uneven, notched: checks with stripes of tubercles a little apart: no spines at side of tail. Yellow, with irregular stripes and spots. Red Sea. East coast of Africa, seas of India to the Malay Archipelago.

Sea, East coast of Africa, seas of India to the Malay Archipelago.

9. Balistes flavimarginatus, D. 3/26-27, A. 23-24, L. l. 30-35, L. tr. 19-21. Teeth white, uneven, notched: a groove before eye: osseous scutes behind gill-opening: 4 to 6 rows of small spines on side of tail. Stone-colour, becoming buff on the chest: a dark spot on each scale: vertical fins with a dark band. Red Sea, Andamans to the Malay Archipelago.

* By L. tr. in this genus, is considered the number of rows of scales placed between the origin of the second dorsal and anal fins.

10. Balistes aculeatus, D. 3/24-25, A. 21-22, L. 1. 38-40, L. tr. 22. Teeth white, uneven, notched: no groove in front of eye: osseous scutes behind gill-opening: $2\frac{1}{2}$ rows of recurved spines on side of tail. Gray, with a dark blotch along the side of the body, obliquely banded with white; three blue lines pass from the eye to the base of the pectoral fin, and an orange one from the corner of the mouth. Red Sea, East coast of Africa, seas of India to the Malay Archipelago.

11. Balistes rectangulus, D. 3/23, A. 20-22, L. l. 42, L. tr. 24-28. Teeth white, uneven, notched: no groove in front of eye: osseous scutes behind gill-opening: $3\frac{1}{2}$ rows of spines on each side of the tail. A broad black blue-edged band from eye to anal fin: an angular black blue-edged band pointing forwards on the

side of the tail. East coast of Africa, seas of India to the Malay Archipelago and beyond.

12. Balistes undulatus, D. 3/25-26, A. 22, L. l. 40, L. tr. 23-26. Teeth white, uneven, notched: no groove in front of eye: osseous scutes behind the gill-opening: 2 rows of strong, recurved spines on either side of tail. Brownish, with concave yellow lines on body, and 2 or 3 round the mouth. Red Sea, East coast of

Africa, seas of India to the Malay Archipelago, and beyond.

13. Balistes erythrodon, D. 3/35, A. 30, L. 1. 33-35, L. tr. 17. Teeth brownish-red, in upper jaw the one on either side of the central pair projecting: osseous scutes behind gill-opening: slightly raised lines along caudal scales: caudal lobes elongated. Deep brown, with the posterior edge of the caudal nearly white. Red Sea, seas of India to the Malay Archipelago.

A.—Free portion of the tail depressed.

Leiurus stellatus, Blecker, Atl. Ich. v, p. 105, t. ccxv; Kner, Novara Fische, p. 398.

B. vi, D. 3/26-27, P. 15, A. 24-25, C. 13, L. I. 42-46, L. tr. 26.

Length of head $3\frac{3}{4}$ to $4\frac{1}{2}$, of caudal fin 5 to $5\frac{1}{4}$, height of body $2\frac{2}{3}$ to 3 in the total length. Eyes—diameter 2½ to 2¾ from the end of snout and 1½ apart: a groove in front of the eye. Teeth—uneven, notched. Tail posteriorly depressed. Fins-first dorsal commences slightly behind the orbit, its anterior spine strong, and 2/3 as long as the head. Ventral spine movable. Posterior edge of caudal concave, and the ends of the lobe often produced in adults. Soft dorsal and anal fins of moderate height. Scales—covering the cheeks: some enlarged scutes behind gill-opening. Two ridges on either side of tail in the adult, which in the young are formed of spines on the scales. Colours—generally gray, dashed with olive-green. Three large white blotches extend from the back some distance down the sides, the first at the base of first dorsal spine, the second between the two dorsal fins, and the third under the middle of the second dorsal: numerous small bluish spots scattered over the back, the lower half of the body being white, marked with light green bands and spots, or numerous yellow spots on the abdomen: 3 or 4 yellow lines run from the mouth towards the base of the pectoral fin. Pectoral yellow with a dark base. First dorsal nearly white, with irregular dark bands going upwards and backwards, and ending in a yellow blotch, between these are some shorter yellow bands having dark edges. Second dorsal diaphanous, with 7 or 8 tortuous and almost horizontal clive bands, the lowest of which are sometimes broken up into spots. Caudal light gray, with tortuous vertical white lines, most distinct in its posterior half. Anal light brown, with 5 vertical white bands. Young—an example 1 inch long, dredged at the Andamans, by Mr. J. Wood-Mason, is white, with a broad black interorbital band: black along the upper 1/3 of the sides with 4 white blotches which join over the back.

Bleeker places as perhaps belonging to this species, Balistes, Russell, Fish. Vizag. i, p. 15, and Lama Yellakah, pl. xxii, or Leinrus macrophthalmus, Swainson, Fishes ii, p. 326, or Balistes macrophthalmus, Bleeker, Beng. p. 78, and B. Yellaka (Cuv.) Jerdon, M. J. L. and Sc. 1851, p. 149.

Habitat.—Red Sea, East coast of Africa, and seas of India and throughout the Indian and Pacific

oceans. This is the commonest species of the genus at Madras, where it attains at least 2 feet in length.

B.—Free portion of the tail compressed.

2. Balistes maculatus, Plate CLXXVI, fig. 3.

Balistes oculatus, Gray and Hardw. Illus. Ind. Zool.; Bleeker, Atl. Ich. v, p. 121, t. cexviii, f. 2, Balistes Willughbeii, Bennett, Proc. Zool. Soc. i. p. 168, and in Beechey's Voy. Blossom, Zool. p. 68, t. xxi, f. 2.

Canthidermis oculatus, Swainson, Fishes, ii, p. 325.
Balistes angulosus, Quoy and Gaim. Voy. Urainie, Zool. p. 210; Hollard, l. c. p. 57.
Balistes azureus, Less. Voy. Coq. Zool. ii, p. 121, t. x, f. 2.

Balistes adspersus, Tschudi, Faun. Per. Pisc. p. 31.

Balistes conspicillum, Cantor, Catal. Mal. Fish. p. 344. (not Syn.)

Balistes longus, Gronov. ed. Gray, p. 37.

Balistes senticosus, Richards. Voy. Samarang, Fish. p. 23, pl. ix, f. 5-8; Bleeker, Nat. Tyds. Ned. Ind. v, p. 93.

Balistes longissimus, Hollard, l. c. 60, t. iii, f. 4.

Balistes sobaco and macrops, Poey, Cuba, pp. 324, 326.

B. vi, D. 3/26-27, P. 15, A. 24-25, C. 12, L. l. 46-55, L. tr. 28.

Length of head $3\frac{1}{3}$ to 4, of caudal fin $6\frac{1}{2}$ to 7, height of body $2\frac{1}{2}$ to 3 in the total length. Eyes—2 to $2\frac{1}{2}$ diameters from end of snout and 2 apart. A groove in front of eye. Teeth—uneven, notched. Fins first dorsal commences above the gill-opening, its anterior spine strong and nearly 1/2 as long as the head. Ventral spine usually movable. Posterior edge of caudal convex or undulated. Second dorsal and anal high anteriorly, especially in adults. Scales—cheeks entirely scaled: no osseous scates behind the gill-opening. Scales rough and granulated, but without spines or prominent tubercles except in the immature. bluish-black, young examples are covered with numerous light blue blotches, more especially in the lower half of the body, these spots are less numerous and larger in adults. Dorsal spine black. Eyes hazel.

Habitat.—Indian and Atlantic oceans, more especially in their tropical and subtropical portions:

also the Pacific and occasionally on the British coast. It is very common at Madras, attaining at least

16 inches in length.

3. Balistes vetula.

Linn. Syst. Nat. i, p. 406; Osbeck's Travels, p. 294; Bloch, t. 150; Bl. Schn. p. 470; Lacépède, i, p. 337; Less. Voy. Coq. Zool. ii, p. 113, t. ix, f. 2; Jenyns, Voy. Beagle, Fish. p. 155; Hollard, Ann. Sc. Nat. 1854, i, p. 305; Günther, Catal. viii, p. 215.

B. vi, D. 3/30-32, P. 16, A. 29, C. 12, L. 1. 50-60, L. tr. 35-37.

Length of head $3\frac{1}{2}$, and height of body $2\frac{1}{4}$ in the total length, excluding the caudal filaments. Eyes— 4 diameters from the end of snout and 11 diameters apart. A groove in front of the eye below the nostrils. Fins—first dorsal commences just behind the eye, its spine strong and half as long as the head. In adults the anterior dorsal rays and caudal lobes may be filamentous. Scales—cheeks entirely scaly: a patch of enlarged scutes behind the gill-opening. No spines or tubercles on the side of the tail. Colours—in the immature some oblique black lines go along the rows of scales. In the adult there are two curved blue dark-edged bands along the side of the head, and some narrow black ones between the eyes over the head, they are also continued below the eyes: caudal with its upper and lower edge blue, and a bluish band near its posterior extremity: transverse bluish bands on the dorsal and anal fins.

Habitat.—Coromandel coast of India and tropical parts of the Atlantic. An example in the Madras

museum is 15 inches in length.

B. vi, D. 3/26-28, P. 14, A. 23-25, C. 12, L. l. 45-47, L. tr. 23-26.

Length of head $3\frac{1}{2}$, of caudal fin $5\frac{1}{2}$, height of body $2\frac{1}{2}$ in the total length. Eyes—4 diameters from the end of the snout and $1\frac{1}{3}$ apart. A groove in front of the eye. Teeth—compressed and notched. Fins—first dorsal commences above the first third of the pectoral fin, its anterior spine strong, and 1/2 as long as the head. Ventral spine movable. Caudal truncated or undulated, second dorsal and anal of moderate height. Scales—entirely cover cheeks. Some osseous scutes behind the gill-opening: 6 to 8 rows of small recurved spines on the side of the tail. Colours—of a rich brown, lips yellow and a yellow ring behind the lips: caudal

dark, with a light upper and lower edge, and a white posterior extremity: second dorsal and anal yellow.

Habitat.—Red Sea, seas of India to the Malay Archipelago. The example figured (life-size) was from the Malay Archipelago, and for it I am indebted to Dr. Hubrecht, of Leyden.

B. vi, D. 3/29-31, P. 14, A. 26-28, C. 13, L. 1. 55-65.

Length of head $3\frac{1}{2}$, of caudal fin 6, height of body $2\frac{1}{4}$ in the total length. Eyes—diameter from $3\frac{1}{2}$ to $4\frac{1}{2}$ from the end of the snout, and $1\frac{1}{4}$ to $1\frac{1}{2}$ apart. A well marked groove in front of the eye. Teeth—8 in either jaw: compressed, notched, increasing in size anteriorly. Fins—first dorsal commences over the posterior edge of the orbit, its epine coarse, rather more than half of the length of the head: second dorsal and anal of moderate height. Caudal with its posterior edge sinuous or truncated. Scales—cover cheeks: some enlarged scutes behind the gill-opening: each scale in the caudal region with a round tubercle most distinct on 7 or 8 rows in the middle of the side. Colours—dull yellowish-brown: pectoral and ventral spine straw coloured, the other fins blackish with lighter bases, which posteriorly have a yellowish tint: ventral rays and membrane dark. A yellow band passes from round the mouth towards the base of the pectoral fin.

Habitat. - East coast of Africa, seas of India to the Malay Archipelago, and beyond.

B. vi, D. 3/25-26, P. 14, A. 20-22, C. 12, L. l. 44-54, L. tr. 27-31.

Length of head $3\frac{1}{2}$, of caudal fin 7 to 8, height of body $2\frac{1}{4}$ to $2\frac{2}{3}$ in the total length. Eyes—diameter 4 to $4\frac{1}{2}$ in the length of the snout. A groove in front of the eye. Teeth—white, compressed, notched. Fins— 4 to $4\frac{1}{2}$ in the length of the snout. A groove in front of the eye. Teeth—white, compressed, notched. Fins—first dorsal commences above the gill-opening: its spine coarse and about 1/2 as long as the head: second dorsal and anal rather low. Ventral spine short, movable. Caudal rounded. Scales—covering cheeks and snout: some osseous scutes behind the gill-opening: $2\frac{1}{3}$ or 2 whole and 2 half rows of tubercles on the side of the tail. Colours—brownish, with large round white or yellow blotches along the lower half of the body: below the first dorsal fin a light patch in which are numerous dark spots. A white band across the snout from eye to eye: a light ring round the mouth, with a narrow one behind it. Caudal fin with a dark band in its even fourth colored with white outer fourth edged with white.

Habitat. Indian and Pacific Oceans.

B. vi, D. 3/24-26, P. 14, A. 23-24, C. 12, L. 1. 30-34, L. tr. 17.

Length of head $3\frac{1}{3}$, of caudal fin 7, height of body $2\frac{1}{3}$ to $2\frac{1}{3}$ in the total length. Eyes—diameter $3\frac{1}{3}$ in length of snout, $1\frac{1}{2}$ diameters apart. A groove in front of the eye. Teeth—white, compressed, notched. Fins—first dorsal commences above the gill-opening, its spine coarse and about 1/2 as long as the head: soft dorsal and anal rather elevated. Ventral spine short. Caudal truncated or rounded. Scales—covering checks and snout: some osseous scutes behind the gill-opening. Four and a half rows of recurved spines on the side

Digitized by Google

of the tail. Colours—a light ring round the muzzle joining one from below, and dividing the black lip from a black band on the forehead: body brownish olive, each scale darkest in the centre: a wide blackish band from the eye to the base of the pectoral fin: vertical fins yellowish with dark margins, having sinuous lines on them: large blue blotches on the first dorsal fin, sometimes the base of the caudal is dark.

Habitat.—Red Sea, East coast of Africa, Andamans to the Malay Archipelago.

B. vi, D. 3/25-26, P. 14, A. 23-26, C. 12, L. 1. 45-55, L. tr. 27-31.

Length of head $3\frac{1}{2}$, of caudal fin 7, height of body $2\frac{1}{4}$ in the total length. Eyes— $2\frac{1}{2}$ diameters from the end of snout and 1 apart. Cheeks with naked grooves. Teeth—compressed and notched. Fins—dorsal commences above base of pectoral fin, its spine strong and 2/3 of the length of the head. Ventral spine movable. Caudal rounded in the young, truncate in the immature, deeply emarginate in the adult with the outer rays often prolonged. Second dorsal and anal fins well developed. Scales—those on the cheeks in the form of osseous tubercles, placed in rows at a short distance apart: some osseous scutes behind the gill-opening: no spines on the side of the tail. *Colours*—dull yellow, with vertical brown stripes and spots, which sometimes enclose spaces. Three dark narrow interorbital bands. Vertical fins spotted with dark in the young, with yellow in the adult. Old examples brown, with the vertical fins light edged.

Habitat.—Red Sea, East coast of Africa, seas of India to the Malay Archipelago. Th

The example figured

(life-size) was from Ceylon. It attains upwards of a foot and a half in length.

9. Balistes flavimarginatus,* Plate CLXXVIII, fig. 1.

Rüpp. Atl. Fische, p. 33, N. W. Fische, p. 54, t. xv, f. 1-2; Bleeker, Mol. p. 303, and Atl. Ich. v, p. 113, t. cexviii, f. 3, and t. cexxiv, f. 3; Peters, Fisch. Mossam. p. 276; Günther, Catal. viii, p. 223; Klunz. Fish. Roth. Meer. 1871, p. 626.

Melichthys marginatus, Swainson, Fishes, ii, p. 325.

Balistes Beeri, Bleeker, Celebes, p. 53.

B. vi, D. 3/26-27, P. 15, A. 23-24, C. 14, L. l. 30-35, L. tr. 19-21.

Length of head $3\frac{2}{3}$, of caudal fin $6\frac{2}{3}$, height of body $2\frac{1}{4}$ in the total length. Eyes— $3\frac{1}{2}$ diameters from end of snout and $1\frac{1}{2}$ apart. A groove in front of the eye. Teeth—compressed and notched. Fins—first dorsal commences above the gill-opening, its anterior spine stout. Ventral spine movable. Caudal rounded in the very young, truncated in the immature, deeply concave and having the lobes produced in adults. Second dorsal and anal well developed. Scales—anterior part of snout partly covered with tubercular rudimentary scales, in the adult the cheeks are not entirely scaled: a few scutes behind the gill-opening. Four to six rows of rather small recurved spines of the side of the tail. Colours—superiorly of a bluish stone, becoming lighter on the sides and below, where it becomes of a buff colour. The lower surface of mouth and chest orange, fading into yellow: immature with dark spots in the centre of some of the scales: vertical fins with a dark base and a light outer half along the centre of which is a dark band. Adults become of a nearly uniform colour.

Habitat.—Red Sea, Andamans to the Malay Archipelago. The largest example personally captured was 20 inches in length. Bulistes Brasiliensis, Bl. Schn. p. 470, is considered by Dr. Peters to be this species.

10. Balistes aculeatus, Plate CLXXVIII, fig. 3.

Linn. Syst. Nat. i, p. 406; Bloch. t. 149; Gmel. Linn. p. 1466; Bonn. Ich. p. 18, t. xi, f. 35; Bl. Schn. p. 465; Cuv. Règ. Anim.; Lacép. i, p. 367, t. xvii, f, 1; Swainson, Fishes, ii, p. 324; Bennett, Beechey's Voy. Blossom, Zool. p. 69, pl. xxii, f. 2; Jenyns, Voy. Beagle, Fish. p. 155; Bleeker, Balist. p. 15, and Atl. Balistes verrucosus, Bonn. Ich. p. 18.

* Amongst Sir Walter Elliott's drawings of fish from Madras, is a beautiful and as I believe unnamed Balistes: it is thus referred to by Jerdon (Madr. Journ. Lit. and Science, 1851, p. 149), "Balistes—? Varri korawa, Tamil. Greenish, with red longitudinal stripes: candal red and yellow." The figure is 8½ inches in length. A groove in front of snout. Fins—second dorsal and anal rather high anteriorly: caudal deeply lunated. Scales—cover cheeks. Colours—olive dashed with green along the back and sides, becoming light on the abdominal surface: four purplish bands along the cheek: numerous narrow purple bands extend obliquely along the whole length of the body, the superior ones ending along the dorsal profile, the inferior being broken up. Vertical fins bluich, with a dark band along the base of each: caudal light gray, with carmine outer edges and posteriorly carmine edged with yellow.

Balistes ornatissimus, Less. Voy. Coq. Poiss. i, p. 119, t. x, f. 1. Rhinecanthus ornatissimus, Swainson, Fishes, ii, p. 325. Balistes armatus, Cuv. Règ. Anim. Balistes striatus, Gronov. ed. Gray, p. 32. Balistrapus verrucosus, Kaup, Sclerod. p. 226. (not Linn.)

B. vi, D. 3/24-25, P. 14, A. 21-22, C. 12, L. l. 38-40, L. tr. 22.

Length of head $3\frac{1}{4}$, of caudal fin 7, height of body $2\frac{1}{4}$ in the total length. Eyes—5 diameters from the end of snout and $1\frac{1}{3}$ apart: no groove in front of eye. Teeth—compressed, notched, those in centre of lower jaw longer than those in the upper. Fins—first dorsal commences above the gill-opening, its anterior spine strong and about 1/2 as long as the head. Ventral spine movable. Caudal rounded in the young, undulated in the adult. Second dorsal and anal of moderate height. Scales—entirely cover the cheeks: some osseous scutes behind the gill-opening. Two and a half rows of recurved spines on the side of the tail. Colours—grayish, with a large dark blotch along the side of the body and extending to the anal fin. Four dark blue interocular bands divided by three black ones: three blue lines pass from the eye to the base of the pectoral, the two first being separated by a black band: an orange band goes from the angle of the mouth to the pectoral, the two first being separated by a black band: an orange band goes from the angle of the mouth to the same place: four or five oblique white bands pass from the middle of the body to the anal fin: caudal spines black and situated on a white base.

Habitat.—Red Sea, East coast of Africa, seas of India to the Malay Archipelago, and beyond.

B. vi, D. 3/23, P. 14, A. 20-22, C. 12, L. l. 42, L. tr. 24-28.

Length of head 3, of caudal fin 8, height of body 23 in the total length. Eyes-5 diameters from the end of snout and 2 apart. No groove in front of the eye. Teeth—compressed and notched. Fins—first dorsal commences above the gill-opening, its anterior spine strong, and 2/5 of the length of the head. Ventral spine movable. Caudal slightly rounded or cut nearly square. Second dorsal and anal of moderate height. Scales—entirely cover the cheeks: some osseous plates behind the gill-opening: 3½ rows of recurved spines. on either side of the tail. Colours—olive, a black band edged with blue passess from below the eye and widening is continued to the vent and along the anterior two-thirds of the base of the anal fin: in front of this band a yellow one, also having a blue outer edge, passes from the eye to the anterior portion of the base of the pectoral fin: another narrow black band edged with blue passes from behind the gill-opening towards the end of the soft dorsal: a black angular band edged with blue, the angle pointing forwards, exists on the free portion of the tail, extending forwards nearly to the middle of the base of the anal fin. Three very narrow black interocular bands, dividing four wider blue ones. A light blue band edged with black across the snout: fins light coloured, first dorsal bluish, with a light outer edge, which has a narrow brown base and a black outer margin: pectoral with a black base.

Habitat.—East coast of Africa, seas of India to the Malay Archipelago and beyond. The example figured (7½ inches in length) was from the Malay Archipelago, and for it I am indebted to Dr. Hubrecht, of Leyden.

B. vi, D. 3/25-26, P. 14, A. 22, C. 12, L. 1. 40, L. tr. 23-26.

Length of head $3\frac{3}{4}$, of caudal fin $6\frac{1}{5}$, height of body $2\frac{1}{5}$ in the total length. Eyes—high up and not above 1/2 a diameter from posterior end of head, 1½ diameters apart. No groove in front of eye. Fins—second dorsal and anal fins rather low, the corners rounded. Ventral spine movable. Posterior edge of caudal fin convex or undulated. Scales—cheeks entirely scaly: a patch of a few enlarged scutes behind the gill-opening: 4 to 6 strong spines on either side of the tail in two rows. Colours—brownish, with numerous undulating yellow lines from the eye and back to the anal and caudal fins: three or four likewise pass from the angle of the mouth and lips to between the ventral and anal fins: a dark band along the base of the second dorsal and anal: and a black margin to interspinous membrane between first and second dorsal spines. In some examples a black blotch exists at the side of the tail near the base of the caudal fin.

Habitat.—Red Sea, East coast of Africa, seas of India to the Malay Archipelago, and beyond. The

example figured (a skin 10 inches in length) was from the Andamans.

B. vi, D. 3/35, P. 14, A. 30, C. 12, L. l. 33-35, L. tr. 17.

Length of head $4\frac{1}{2}$, of caudal fin $3\frac{1}{3}$, height of body 3 in the total length. Eyes—3 diameters from end of snout and $1\frac{1}{2}$ apart. A shallow scaly groove in front of eye. Lower jaw projecting. Teeth—reddish-brown, strongly compressed, notched: the tooth on the side of the central pair in the upper jaw considerably projecting. Fins—first dorsal commences above the gill-opening, its spine strong and about 1/2 as long as the head. Ventral spines movable. Caudal deeply concave, with its outer rays prolonged. Second dorsal and anal elevated, especially anteriorly. Scales—cheeks entirely scaly: some enlarged scutes behind the gill-opening. Scales roughened, those along the middle of the body and tail with a small elevated tubercle on each, but no prominent spines. Colours—of a deep brown a black string after encircling the month goes to the base of the prominent spines. Colours—of a deep brown, a black stripe after encircling the mouth goes to the base of the Vertical fins nearly black, the caudal with a white posterior edge.

Habitat.—Red Sea, East coast of Africa, seas of India to the Malay Archipelago. The example figured

(life-size) was from Mangalore, where it was procured by Dr. Dobson.

Genus, 3-Monacanthus, Cuvier.

Alutarius, Cuv.: Stephanolepis, Gill: Chatodermis, Paramonacanthus, Amanses, Gray: Pseudomonacanthus, Liomonacanthus, Oxymonacanthus, Branchaluteres, Acanthaluteres, Ceratacanthus, Paraluteres, Pseudaluteres and Aluteres. Bleeker.

Body compressed. Barbels absent. Incisoriform teeth in both jaws, in two rows in the upper with six in the outer row, and a single row of six in the mandibles. The first dorsal fin composed of a spine which may be feeble or strong and merely rough, or provided posteriorly or laterally with barbs, occasionally a second rudimentary one: ventral fin, when present, reduced to a single osseous process, sometimes rudimentary and either movable or fixed. Scales minute and rough: cutaneous filaments present in some species: the side of the tail may be peculiarly armed in adult males, but less apparently so or not at all in the females. Vertebræ 7/11-14.

SYNOPSIS OF INDIAN SPECIES.

A.—Dorsal spine with only 2 rows of barbs, pointing backwards and downwards.

1. Monacanthus setifer, D. 1/28-34, A. 29-33. Second dorsal fin with its first ray prolonged. Brownish, marbled and streaked with darker. Indian and Atlantic Oceans.

2. Monacanthus choirocephalus, D. 1/28, A. 28-30. Fleshy tentacles over body. Seas of India to the Malay Archipelago.

B.—Dorsal spine rough but barbless.

3. Monacanthus monoceros, D. 1/46-48, A. 48-53. Snout moderately produced, with its upper profile

convex. Indian Ocean and Atlantic portions of tropical America.

4. Monacanthus scriptus, D. 1/44-48, A. 47-52. Snout produced with its upper profile concave. Indian Ocean.

A.—Dorsal spine with only 2 rows of barbs, pointing backwards and downwards.

1. Monacanthus setifer.

Monacanthus auratus, Castelnau, Poiss. Afr. Austr. p. 77.

B. vi, D. 1/28-34, P. 12, A. 29-33, C. 9.

Length of head $3\frac{1}{4}$ to $3\frac{2}{3}$, of caudal fin $4\frac{1}{2}$, height of body $2\frac{1}{3}$ to $2\frac{2}{3}$ in the total length. Eyes—situated in the posterior half of the head, 2 to $2\frac{1}{4}$ diameters from the end of snout. Body elevated. Fins—the first dorsal situated above the posterior portion of the eye, and at the highest point of the dorsal profile: the spine may be strong or weak, prolonged or not so. Second dorsal having its anterior ray occasionally with a filamentous prolongation. Ventral spine small, movable, attached to the abdominal membrane. Caudal rounded. Scales-present but small, the skin appears as if it were velvety. Colours-of a dull brown, with dark blotches and streaks: caudal fin with two dark vertical bands.

Habitat.—East coast of Africa, seas of India to China and Japan: also tropical and sub-tropical parts of the Atlantic.

2. Monacanthus choirocephalus, Plate CLXXIX, fig. 3.

Bleeker, Balist. p. 19, pl. ii, f. 4; Günther, Catal. viii, p. 242.

Paramonacanthus choirocephalus, Bleeker, Atl. Ich. v, p. 131, t. ccxxvii, f. 3.

B. vi, D. 1/28, P. 13, A. 28-30, C. 12

Length of head $3\frac{1}{2}$, of caudal fin 5, height of body $2\frac{1}{3}$ in the total length. Eyes—situated in the posterior half of the head over the gill-opening and below the dorsal spine: $2\frac{1}{4}$ diameters from the end of snout and 1 apart. Body rather elevated, profile from snout to first dorsal fin almost straight. The origin of the second dorsal fin is at nearly the highest point of the dorsal profile. Fins—dorsal spine situated over the last 1/2 of the eye, rather weak, rough anteriorly, and with a row of small barbs on either side of its posterior surface. Second dorsal and anal with the first few rays rather shorter than the succeeding ones. Ventral spine movable, without any enlarged spines at its termination. Caudal rounded, sometimes with a setiform prolongation of one of its upper rays. Scales—indistinctly visible, skin not very rough: numerous small fleshy tentacles on the sides of the body. Colours—of a gray stone-colour, with irregular and rather large block block here, two dork heads agrees the condel fin large black blotches: two dark bands across the caudal fin.

This species is not rare at Madras. It differs from the form described by Bleeker in having numerous fleshy appendages over the body.

Habitat.—Madras to the Malay Archipelago.

B.—Dorsal spine rough but barbless.

B. vi, D. 1/46-48, P. 14, A. 48-53, C. 12.

Length of head about 4, of caudal fin 8, height of body from 2\frac{3}{4} to 3\frac{3}{3} in the total length. Eyes - rather

small, situated between the upper end of gill-opening and first dorsal fin. Body oblong, snout moderately produced with its upper profile convex. Fins—vertical ones low: dorsal spine weak. Caudal truncated or very slightly convex. Colours—brownish or blackish, the fins yellow.

This fish "looks like a flounder at a distance, and has almost the same taste, but is not so fat,"

Habitat.—East coast of Africa, seas of India to the Malay Archipelago and Japan: Atlantic portions of tropical America. An example in the Madras museum is 15 inches in length. The specimen figured was from the Andaman Islands.

B. vi, D. 1/44-48, P. 15, A. 47-52, C. 12.

Length of head 4 to $4\frac{1}{4}$, of caudal fin $3\frac{1}{3}$ to $3\frac{2}{3}$, height of body $4\frac{1}{4}$ in the total length. Eyes—of moderate size, situated between the upper end of the gill-opening and the first dorsal fin. Body oblong, snout produced, with its upper profile concave. Teeth—8, compressed and pointed. Fins—vertical ones low, dorsal spine weak and of moderate length. No ventral spine. Caudal wedge-shaped. Colours—buff, covered with small brown spots and blue lines.

Habitat.—Red Sea, East coast of Africa, seas of India to the Malay Archipelago, and beyond: attaining

at least two feet in length. The example figured (stuffed) 12 inches long, was from Madras.

Genus, 4—Anacanthus, Gray.

Psilocephalus, Swainson: Pogonognathus, Bleeker.

Body compressed, elongated. A fleshy barbel below the symphysis of the lower jaw. Incisoriform teeth in both jaws, in two rows in the upper and one row in the lower jaw. The first dorsal in the form of a single flexible spine: the second and the anal with many rays: ventral fin absent. Body covered with fine asperities. Vertebræ 29-30.

Geographical distribution.—Seas of India to the Malay Archipelago, and beyond.

Anacanthus barbatus, Gray, Zool. Misc. 1831, p. 8; Günther, Catal. viii, p. 255.

Crassi kola and Watamoo kola, Tamil.

B. iii, D. 1/49-52, P. 10, A. 57-64, C. 12.

Length of the head about 1/3 of that of the body excluding the caudal fin. Eyes-high up, behind and above the branchial opening. Body strongly compressed, with a fleshy barbel below the symphysis of the lower jaw. In the male there is a skinny prolongation from the throat and continued nearly as far as the anal fin, it is supported by a prolongation of the pelvic bone. Fins—second dorsal and anal low: caudal wedge-shaped, its central rays the longest. Colours—dull brown or gray, fins yellow, the caudal with about six vertical or angular dark bands not so wide as the ground colour.

Habitat.—Seas of India to the Malay Archipelago. Is very common at Madras, especially the young.

It attains at least 10 inches in length.

Third group—OSTRACIONTINA.

Body angular, with the dermal covering forming a carapace, leaving the snout and bases of the fins covered by skin. Spinous dorsal and ventral fins absent, except in the form of osseous protuberances.

Genus, 5-OSTRACION, Artedi.

Leetophrys, Tetrosomus and Rhinesomus, Swains.: Acanthostracion, Bleeker: Cibotion, Kaup.

Branchiostegals six. Body shortened and angular, with the integuments modified into a solid carapace composed of angular osseous plates in juxtaposition with one another, but leaving the snout, bases of the fins, and the hind portion of the tail, covered by soft skin. They may be destitute of spines or have them variously situated. The carapace from three to five ridged, and closed behind the anal fin. Mouth small, premaxillaries and maxillaries coalescent. Teeth slender and in one row. A single spineless dorsal fin placed opposite the anal. Ventrals absent.

These fishes with their hard, box-like outer covering and angular form are easily recognised, and although the species differ widely amongst themselves, the intermediate forms preclude the possibility of subdividing them into Genera.* The spines observed on some of the species vary with the age of the individual.

SYNOPSIS OF SPECIES.

a.—Carapace 3-ridged, with or without spines.

1. Ostracion turritus. A compressed triangular dorsal, also a supraorbital spine: each ventral ridge with 4 spines. A blue spot in each scute. Red Sea, seas of India to the Malay Archipelago.

b.—Carapace 4 or 5-ridged, spineless.

2. Ostracion cubicus. No median dorsal ridge. A blue black-edged ocellus in the centre of most of the Red Sea, seas of India to the Malay Archipelago, and beyond.

3. Ostracion punctatus. No median dorsal ridge. Numerous white dots, sometimes confluent into

East coast of Africa, seas of India to the Malay Archipelago, and beyond.

4. Ostracion nasus. A median dorsal ridge. Black spots irregularly scattered over the body. Seas of India to the Malay Archipelago, and the Pacific.

c.—Carapace 4-ridged, spines present.

5. Ostracion cornutus. A supraorbital forwardly directed spine, and a similar one directed backwards at the posterior extremity of each ventral ridge. Blue and black spots on body and tail. Red Sea, seas of India to the Malay Archipelago, and beyond.

a.—Carapace 3-ridged, with or without spines.

1. Ostracion turritus, Plate CLXXXI, fig. 4.

Carapace 3-ridged, the superior or dorsal ridge being elevated and superiorly compressed into a sharp Carapace 3-ridged, the superior or dorsal ridge being elevated and superiorly compressed into a sharp triangular spine. Each lateral or ventral ridge well developed, and armed with 4 triangular, flattened and strong spines directed backwards. Body about as wide as high, being of a triangular shape, the apex being above. The carapace forms a moderately broad bridge across the back of the tail. A compressed supraorbital spine directed upwards or a little backwards. Teeth—12 in the upper and 8 in the lower jaw, conical, weak, and of a brownish colour. Fins—dorsal and anal highest anteriorly: caudal rounded or truncated. Scutes—from 9 to 11 from the gill-opening to the tail, 9 or 10 transversely: and about 11 across the ventral surface. Colours—olive brown, with 3 badly marked dark bands in the lower 1/3 of the body, and a fourth just behind with two dark vertical bands, one at its base, the other at its outer extremity. The young have several dark blotches and bands over various parts of the body, and a ridge extends from the orbit to the upper part of the blotches and bands over various parts of the body, and a ridge extends from the orbit to the upper part of the bridge over the tail.

Habitat.—Red Sea, East coast of Africa, seas of India to the Malay Archipelago, and reported from

* Except Genus Aracana, Gray, which I consider to be distinct, the carapace remaining unclosed behind the anal fin, whereas it is closed in the various species of Ostracion.

New York. The example figured (life-size) was from Madras, where it abounds. It attains at least 9 inches in length.

b.—Carapace, 4 or 5-ridged, spineless.

Ostracion tesserula, Bleeker, Mol. p. 305 (not Cantor).

D. 10, P. 10, A. 10, C. 10.

Carapace 4-ridged and spineless: ridges blunt, but the ventral more prominent than the dorsal ones. Body about as wide as high: back convex, but without any distinctly raised ridge along the median line. The carapace forms a broad bridge across the back of the tail. Interorbital space concave. Teeth—about 10 in either jaw, conical, weak, and of a reddish-brown colour. Fins—dorsal and anal highest anteriorly: caudal truncated and equal to about 1/5 of the total length. Scutes—about 10 between the gill-opening and the tail, 5 or 6 transversely: and 5 or 6 across the ventral surface. Colours—brownish, with a single blue black-edged ocellus in the centre of most of the scutes: sometimes these spots are absent from some parts of the body: on the head they are frequently black, and have more than one spot on each scute. On the abdomen the spots may be white, with or without black marks: or the spots may be black or even absent. The fins yellowish and covered with black spots or immaculate.

Habitat.—Red Sea, East coast of Africa, seas of India to the Malay Archipelago, and beyond. It attains

at least 18 inches in length.

D. 9, P. 10, A. 10, C. 10.

Carapace 4-ridged and spineless: ridges blunt, but the ventral more prominent than the dorsal ones. Body not quite so high as wide: back rather convex, but without any ridge along the median line. The carapace forms a moderately broad bridge across the back of the tail: superior profile of snout concave. Interorbital space concave, sometimes flat. Teeth—about 10 in either jaw, conical, weak, and of a reddishbrown colour. Fins—dorsal and anal highest anteriorly: caudal truncated and equal to nearly 1/5 of the total length. Scutes—about 10 across the ventral surface. Colours—reddish-brown, covered with numerous

white dots, which are sometimes confluent into lines.

Habitat.—East coast of Africa, seas of India to the Malay Archipelago, and beyond. The example figured (life-size) was from the Malay Archipelago, and I am indebted for it to Dr. Hubrecht, of Leyden.

Ostracion nasus.

Bloch, t. cxxxviii; Bl. Schn. p. 500; Bonn. Ich. p. 23; Lacépède, i, p. 458; Cuv. Règn. Anim.; Swainson, Fishes, ii, p. 323; Bleeker, Balist. p. 33, t. vii, f. 15, and Atl. Ich. v, p. 36, t. ccii, f. 5 (young), and t. cciv, f. 2 (adult); Hollard, Ann. Sc. Nat. 1857, vii, p. 161; Day, Fish. Malabar, p. 253; Günther, Catal. viii, p. 263.

Ostracium tesserula, Cantor, Catal. Mal. Fish. p. 367, pl. viii, f. 2, 3.

D. 9, P. 10, A. 9, C. 10.

Carapace 5-ridged and spineless: ridges rather sharp. Body wider inferiorly than high: a distinct ridge along the median line of the back. The carapace forms a broad bridge across the back of the tail: interorbital space concave, more especially in the adult when a hump exists above the mouth. Teeth-about

12 in the upper and 10 in the lower jaw, weak, pointed, and of a reddish-brown colour. Fins—dorsal and anal highest anteriorly: caudal rounded, and about 1/5 of the total length. Scutes—11 to 12 between the branchial opening and the base of the caudal fin: and 6 or 7 transversely: 7 or 8 across the ventral surface. Colours—greenish yellow, with small irregularly scattered round black spots, or one in the centre or at the side of each scute: abdomen whitish: black spots on the tail and caudal fin. The young are bright orange-yellow, with numerous black spots along the sides, and which are not situated in the centre of the scutes, some black spots also exist over the caudal and on the base of the pectoral fins: the fins are yellowish, the abdominal surface of a whitish yellow. Pupil golden.

Habitat.—Seas of India to the Malay Archipelago and the Pacific. I procured two young ones at Cochin,

but have not obtained the adult. It attains to at least $8\frac{1}{2}$ inches in length.

c.—Carapace 4-ridged, spines present.

5. Ostracion cornutus, Plate CLXXVI, fig. 4.

Linn. Syst. Nat. p. 409; Bloch, t. 133; Gmel. Linn. p. 1443; Bl. Schn. p. 500; Lacép. i, p. 470; Shaw, Zool. v, p. 223, t. clxx; Temm. and Schleg. Fauna Japon. Martoo-plachee, Tamil.

D. 9, P. 11, A. 9, C. 10.

Carapace 4-ridged and forming a bridge across the back of the tail. A long anteriorly directed and conical supraorbital spine: and each ventral ridge terminates posteriorly with another somewhat similar one. Dorsal ridge rather elevated about the middle of its length with a low ridge, but no spine. Interorbital space very concave. Teeth—about 8 or 10 in either jaw, conical and weak. Fins—dorsal and anal highest anteriorly: caudal truncated and equal to about 1/2 the total length. Scates—about 10 between the gill-opening and the tail, 5 or 6 transversely: and 7 across the ventral surface. Colours—carapace of a light brown, with round blue spots all over it in moderate numbers, about one on each scute, some, however, being destitute of any. Caudal blue spotted.

Amongst Sir W. Elliot's drawings is one of a variety of this species of a yellowish colour with light spots, whilst the spines are excessively elongated. It was captured at Waltair, April 1850.

Habitat.—Red Sea, East coast of Africa, seas of India, to the Malay Archipelago, and beyond.

FAMILY, II—GYMNODONTES, Cuvier.

Body more or less short. Some possess the means of dilating an elastic portion of the cosophagus, or an abdominal sac, with air: or this power may be entirely wanting. Bones of the upper and lower jaw in the form of a beak, having a cutting edge, and being covered with a layer of ivory-like substance in which a median suture may be present or absent. A spineless dorsal, anal and caudal exist: pectorals present: ventrals absent. Dermal covering modified into small or large spines or laminæ. Pelvic bones and air-vessel present or absent.

Most of the Indian forms of fishes included in this family are reputed to be highly indigestible as food or even virulently poisonous.

SYNOPSIS OF INDIAN GENERA.

First Group-TRIODONTINA.

Tail and caudal fin distinct. Abdomen dilatable into a large compressed sac, which is supported by an elongated pelvic bone. Air-vessel present.

1. Triodon. The upper jaw divided by a median suture: the lower jaw entire, p. 698.

Second group-Tetrodontina.

Tail and caudal fin distinct. A portion of the esophagus dilatable and may be distended with air. No pelvic bone. Air-vessel present.

A .- Jaws with a median suture.

- 2. Xenopterus. Dorsal and anal fins with many rays, p. 699.
- 3. Tetrodon. Dorsal and anal fins with few rays, p. 699.

B.—Jaws without any median suture.

4. Diodon. A simple nasal tentacle having a pair of lateral orifices. Body covered with stiff movable spines, p. 708.

First group—TRIODONTINA.

Tail and caudal fin distinct. Abdomen dilatable into a large compressed sac, which is supported by an elongated pelvic bone. Air-vessel present.

Genus, 1—Triodon (Reinw.), Cuvier.

Branchiostegals six. The upper jaw with, the lower without, a median suture. Two separate nasal orifices on either side. Tail elongated, terminating in a bilobed fin: dorsal and anal with few rays. Abdomen possessing a large sac, the upper portion of which can be dilated with air, whilst it is kept distended by elongated pelvic bones. The dermal covering consisting of spinate, osseous lamine, which are not imbricate. Air-vessel present.

Geographical distribution.—The single species of this genus at present recorded, has been taken in the seas of India and the Malay Archipelago.

Triodon bursarius.

(Reinw.) Cuv. Règn. Anim.; Griffith in Cuv. An. King. x, pl. x; Bleeker, Blootk. p. 20, and Atl. Ich. v, p. 84, t. ccxiv, f. 1; Günther, Catal. viii, p. 270.

Triodon macropterus, Less. Voy. Coq. Zool. pl. iv.

B. vi, D. 10-11, P. 15-16, A. 9-10, C. 18.

Length of head 4 to $4\frac{1}{2}$, of caudal fin 7 in the total length. Eyes—situated in the posterior half of the head. Interorbital space rather concave. Fins—dorsal situated in the last half of the distance between the eye and the base of the caudal fin, and slightly in advance of the anal, both are highest anteriorly: caudal emarginate. Colours—dull brown, a large, irregularly shaped, black yellow- or blue-edged spot is present on the upper portion of the sac. Fins yellow.

Habitat.—Seas of India to the Malay Archipelago. It attains at least 21 inches in length.

Second group—Tetrodontina.

Tail and caudal fin distinct. A portion of the esophagus dilatable and may be distended with air. No pelvic bone. Air-vessel present.

A.— Jaws with a median suture.

Genus, 2—Xenopterus (Bibron), Duméril.

Chonerhinus, Bleeker.

Branchiostegals five. Back rounded: jaws divided by a median suture. Nostrils funnel shaped with fringed margins. Dorsal and anal fins with many rays (23 to 38). Parts of the body covered with fine dermal spines, having double or treble roots.

These fishes, like the Tetrodons, are able to inflate their bodies with air and float on the water, abdomen uppermost. They ascend large rivers, far above tidal influence. In some parts of Burma they are eaten, but their bites are dreaded, and the Burmese assert that where they abound should anyone fall into the water they attack him in droves, and almost immediately cause death by biting pieces out of his body. They readily take a bait either of a piece of meat or a small fish.

Xenopterus naritus, Plate CLXXXII, fig. 1.

Tetraodon nuritus, Richardson, Voy. Samarang, Fish. p. 18, pl. viii (adult); Cantor, Mal. Fish. p. 383, pl. x (young); Bleeker, Blootk. p. 21, and Borneo, p. 439.

Tetrodon grandispina, Van der Hoeven, Handb. Dierk. 2nd Edit. ii, p. 275.

Xenopterus Bellangeri (Bibron), Duméril, Rev. Zool. 1855, p. 281.

Chonerhinus naritus, Bleeker, En. Pisc. Arch. Ind. p. 202, and Atl. Ich. v, p. 77, t. cexi, f. 2; Blyth, J. A. S. of Beng. 1860, p. 173.
Xenopterus naritus, Günther, Catal. viii, p. 271.

B. v, D. 32-38, P. 19, A. 28-32, C. 12.

Length of head rather more than its distance from the base of the dorsal fin. Eyes—rather small: interorbital space broad and flat. Lips thick and fringed. Teeth—the lower a little larger than the upper pair. Fins—the length of the base of the dorsal exceeds the length of the head, it is highest in the middle, but its highest point is not equal to that of the body: anal similar to but rather smaller than the dorsal: caudal slightly emarginate. Spines—with 2 or 3 roots, large, rather widely separated, situated between the eye and base of the pectoral fin, above which they are continued a short distance : also present for a short distance behind that fin and along the abdominal surface nearly as far as the vent. Colours—pale yellow, darkest along the back and in the lower 2/3 of the dorsal fin.

Habitat.—Through the rivers and estuaries of Burma to the Malay Archipelago.

Genus, 3-Tetrodon,* Linnœus.

Leisomus, Lagocephalus, Cirrhisomus and Psilonotus, Swainson: Kolacanthus, Gray: Prilonotus and Anchisomus, Kaup: Tropidichthys, Bleeker: Promécocéphale, Dilobomycterè, Amblyrhynchote, Geneion, Catophorhyngue, Batrachops, Rhynchote (Bibron) Duméril: Rhynchotus, Apsicophalus, Brachycephalus, Hollard.

Back broad, or compressed into a ridge. Either jaw with a median suture. Should a conspicuous nasal organ exist: there may be two on either side in a papilla (Tetraodon, Bleeker): or a single tubular one (Crayracion, Bleeker): or an imperforate one having a fringed edge and the body spiny (Chelonodon, Müller): or a simple round cavity and the body smooth (Monotretus, Bib.): or two imperforate tentacles on either side (Arothron, Müll.): or the nasal organs may be inconspicuous, and the back compressed into a keel (Anosmius, Peters). Dorsal and anal fins with few rays. Body wholly or partially covered with fine dermal spines, or such may be absent. There may be a more or less distinct fold along the lower part of the tail, and very apparent nasal organs (Gastrophysus, Müll.): or should the fold be absent, but the body be spinate and the nasal organs very distinct (Cheilichthys, Mull.): or the fold be absent and the skin smooth (Liosaccus, Günther). A portion of the asophagus dilatable and able to be distended with air. Air-vessel present and horse-shoe shaped.

The Tetrodons are termed Kuddul mah-cutchee, or "Sea Frogs" by the natives of Malabar, on account of the noise they make when captured: although they are occasionally eaten by the lower classes, they are said to occasion indigestion, so are usually avoided, while all of them emit an odour the reverse of agreeable. The native doctors sometimes prescribe them in cases of lung affections. The Burmese in some districts consider these fishes to be poisonous, but in other localities they eat them, being very careful to first remove the gall-bladder, which they assert occasions all the poisonous symptoms. The Japanese eat one species as a means of enabling them to commit suicide. The Andamanese eat these fishes, as I personally witnessed: they appeared rather to prefer them to some of the better kinds. Hamilton Buchanan observed the fishes of this genus are eaten by the poor, but are considered as indifferent food. Bleeker remarked on their poisonous qualities at Batavia, where some species are prohibited from being sold: he enumerates T. oblongus and T. reticularis as very venomous, T. stellatus as venomous, but says that T. lunaris is eaten. Cantor likewise

* Kappa, Tel.: Plachee, Tam. Globe or puff fishes.

Digitized by Google

remarked that due to their poisonous nature they are even objected to as manure in Malayan countries. In Egypt exists a poisonous Tetrodon, whilst at the Cape of Good Hope eating a spotted Tetrodon has caused so many deaths amongt the sailors in harbour, that they are specially warned against employing them as food.

The colours of these fishes are subject to considerable variation: thus (as in T. stellatus), abdominal bands may be seen in the young (T. lineatus), but absent or only slightly marked in the adult: but the young also may be destitute of these bands. Spots may be present or absent, as in a variety of T. nigropunctatus there are no spots.

The extent of the spines may vary in the same species of the fish, thus in T. nigropunctatus some examples may be almost entirely covered with well marked spines, or such may almost be concealed in the skin, or even be nearly absent.

Geographical distribution.—Tropical and sub-tropical seas entering estuaries, whilst some few are found in fresh waters.

SYNOPSIS OF INDIAN SPECIES.

A.-Back broad: nasal organs conspicuous.

a.—Two nasal openings on either side, situated in a single and prominent papilla (Tetraodon, Bleeker).

- 1. A fold of skin along the lower part of the side of the tail (Gastrophysus, Müller).
- 1. Tetrodon inermis. Very soft spines on the abdominal surface only, and not extending to vent. A dull band from eye to tail, above this plumbaceous, below silvery white. Seas of India to Japan.

- Tetrodon lunaris. Spines along the back to the dorsal fin, and along the abdomen. Silvery.
 Tetrodon sceleratus. Spines along the back to the dorsal fin, also along the abdomen. Greenish superiorly, with brown spots: a triangular white spot before the eye. Red Sea to the Malay Archipelgo, and
- 4. Tetrodon hypselogenion. Spines of moderate size, rather wide asunder, going from eye to dorsal fin, along abdominal surface to vent, and also behind pectoral fin. Yellowish brown, with light or white spots on the back, and white on the sides and below: from 3 to 5 vertical bands below the eye: caudal barred. Red Sea
- 5. Tetrodon oblongus. Two-rooted spines from nostrils to dorsal fin: a few on cheeks, and numerous on abdomen as far as vent. Brown bands from back down the white sides: round or oval white spots on head and back. Seas of India to China, and beyond.
 - $b.{--}A$ fringed but single, unperforated, nasal cavity with a fringed edge: body spiny.
- 6. Tetrodon patoca. Three or 4-rooted spines from nostril to dorsal fin, inferiorly to the vent. Brown superiorly with many round or oval white spots. Seas of India to China.
 - c.—A simple and circular nasal cavity: body spineless (Monotretus, Bibron).
- 7. Tetrodon cutcutia. A light interorbital band: a black ocellus on the side anterior to the dorsal fin: reticulated all over: caudal fin tipped with carmine. Fresh waters of Orissa, Bengal and Assam.
 - d.—Two solid tentucles, one on each side of an impervious nasal fossa (Arothron, Müller).
- 8. Tetrodon immaculatus. Small spines cover the body, except snout and posterior half of the tail: interorbital space broad Without spots or lines: or with parallel lines on the body, or spots on the head. Red Sea to the Malay Archipelago, and beyond.

9. Tetrodon nigropunctatus. Spines small, usually covering the entire body; interorbital space narrow. Brownish, more or less covered with black spots: vent in a black spot. Red Sea to the Malay Archipelago,

and beyond.

10. Tetrodon stellatus. Spines small, covering the body. Brownish, with dark spots placed closely together on the back and upper portion of the sides: vent in a black spot: the young with black semi-circular abdominal bands. Red Sea to the Malay Archipelago, and beyond.

11. Tetrodon reticularis. Spines small, covering the body. Body superiorly gray or brown, becoming white below: with concave black bands which are continued round the eye: white spots on back: caudal

reticulated with black. Seas of India to the Malay Archipelago and New Guinea.

12. Tetrodon hispidus. Spines small, those on abdomen with 2 or 3 roots, they cover the body to the base of the caudal fin. Brown along the back with bluish-white spots, and one or two light bands round the orbit and also round the base of the pectoral fin. Sometimes lines or spots of black on the abdomen, but not ascending on to the cheeks. Red Sea to the Malay Archipelago, and beyond.

13. Tetrodon leopardus. Two-rooted and widely separated spines from eye to dorsal fin, also along the abdominal surface to the vent: dark along the back with round white spots: a light interorbital band: reticulated black lines enclosing spaces on the dorsal and caudal fine. Some of India.

reticulated black lines enclosing spaces on the dorsal and caudal fins. Seas of India.

14. Tetrodon viridipunctatus. Two-rooted and widely separated spines from eyes nearly to dorsal fin, and inferiorly as far as anus. Back dark green, with emerald green spots: a light interorbital band with a central prolongation backwards: a second transverse band over the back: four black spots under throat: caudal and

anal dark edged. Cochin.

15. Tetrodon fluviatilis. Two-rooted and widely separated spines from eye to the base of the dorsal fin, and along the abdomen as far as the vent. Greenish olive superiorly, becoming light on the sides and below. Large black blotches along the sides, and two or more light bands cross between the eyes and over the back. Seas and estuaries of India to the Malay Archipelago, and beyond.

c.—Nasal organs inconspicuous: back compressed into a keel (Anosmius, Peters).

16. Tetrodon margaritatus. Spines minute, but usually cover the body. Dull reddish, becoming lighter beneath. Blue bands and spots on the head, and blue spots on the body: caudal fin with or without similar spots. Red Sea to the Malay Archipelago, and beyond.

A.—Back broad: nasal organs conspicuous.

a. Two nasal openings on either side, situated in a single and prominent papilla: a fold of skin along the lower part of the side of the tail (Gastrophysus).

1. Tetrodon inermis, Plate CLXXX, fig. 1.

Tetraodon inermis, Temm. and Schleg. Fauna Japon. p. 278, t. cxxii, f. 2.

B. v, D. 12-13, P. 19, A. 11, C. 10.

Length of head equals its distance from the base of the dorsal fin. Eyes—rather large and situated nearer the gill-opening than the end of the snout. Interorbital space broad, equalling $1\frac{1}{3}$ diameters of the eye. Teeth—in the two jaws of about the same size. Fins—dorsal with its anterior rays the longest, situated in the last third of the distance between the nostrils and base of the caudal fin, its height is rather above twice the length of its base: anal of similar size and shape. Caudal emarginate. Spines-if they can be so termed, are soft and widely separated, they only exist along the abdominal surface, not extending so far as the vent. A moderately well marked fold of skin along the side of the tail. Skin on the summit of the head with short longitudinal ruge. Colours—Upper surface of head and back plumbaceous: a broad dull brown band passes from the eye nearly to the tail, beneath which it is silvery white. Gill-opening black internally: dorsal fin dark in its upper 2/3: caudal dark in its last half, margined with white.

Habitat.—Seas of India to Japan. The example figured was from Madras, where it attains at least

17.5 inches in length.

2. Tetrodon lunaris, Plate CLXXXII, fig. 2.

Tetrodon lunaris, Bl. Schn. p. 505; Temm. and Schleg. Faun. Japon. Poiss. p. 277, pl. 122, fig. 1; Rüpp. N.W. Fisch. p. 59; Cant. Mal. Fish. p. 378; Bleek. Beng. p. 78, and Atl. Kappa koorawah, Tel.: Cha-mo-dah, Andamanese.

B. v. D. 12-14, P. 16-19, A. 11-12, C. 10.

Length of the head equal to or rather less than the distance between it and the base of the dorsal fin. Eyes—rather large, and situated much nearer gill-opening than to the end of the snout: interorbital space flat and equal to $1\frac{1}{2}$ diameters of the eye. Teeth—in jaws of about the same size. Fins—dorsal with its anterior rays the longest, situated in the last third of the distance between the front edge or middle of the eye and the base of the caudal fin: anal similar to dorsal. Caudal emarginate. Spines—small, entirely covering the back, or only anteriorly from opposite the front margin of the eyes: abdomen similarly protected: snout, sides and tail spineless. Colours—Green sh-olive above, sides and abdomen of a white satin, having a yellowish line from the eye to the centre of the car dal fin: end of caudal dark with a light outer edge.

Habitat.—Red Sea, seas of India to the Malay Archipelago, and beyond: attaining at least a foot in

length. The example figured was from Madras. The fry are common in the Hooghly.

3. Tetrodon sceleratus.

(Forster) Gmel. Linn. i, p. 1444; Bl. Schn. p. 506; Lacép. i, pp. 476, 508; Günther, Catal. viii, p. 726; Klunz. Fish. Roth. Meer. 1871, p. 640.

Tetraodon bicolor, Brevoort, Not. Japan. Fish. p. 283.

B. v. D. 10-12, P. 16-17, A. 9-11, C. 11.

Length of head equals about 2/3 of its distance from the base of the dorsal fin. Eyes—nearly two diameters from the end of snout. Tail depressed. Fins—dorsal situated in the anterior third of the total length excluding the caudal fin, the latter, which is emarginate, being 1/6 to 1/7 of its total length. Spines—head and back with fine spines, none on the sides, but some with three roots present along the abdominal surface to a short distance behind the base of the anal fin. Colours—olive-green superiorly with some brown spots: whitish laterally and below, with a silvery longitudinal band: a triangular white spot in front of the eye: a brown band round the mandibles, and which is sometimes continued along the side below the silvery lateral band: gill-openings black.

Habitat.—Red Sea, East coast of Africa, seas of India to the Malay Archipelago, and beyond: attaining

at least $2\frac{1}{3}$ feet in length.

4. Tetrodon hypselogenion, Plate CLXXXIII, fig. 5.

B. v. D. 8-9, P. 16, A. 8, C. 10.

Length of head equals its distance from the base of the dorsal fin. Eyes-situated rather behind the middle of the length of the head. The osseous interorbital space very much narrower than the shortest diameter of the eye. Teeth—of about the same size in both jaws. Fins—dorsal situated in the hind third of the distance between the front edge of the eye and the base of the caudal fin, the length of its base is only 2/5 of its height, its anterior rays the highest: anal of similar form. Caudal slightly emarginate, the outer rays being the longest, its height being $4\frac{1}{2}$ in that of the total. Spines—of moderate size and rather widely separated, they commence on the dorsal profile from a slight distance posterior to the eyes and are continued half the distance or even more to the base of the dorsal fin: they are also continued along the abdominal surface almost to the vent: some are likewise present on the sides behind the pectoral fin. Colours—of a yellowish-brown, becoming white stained with yellow beneath: the colour of the back being often sharply defined from the white of the sides: the whole of the upper surface covered with light dots, which have usually dark edges: from three to five vertical bars under the eye. Caudal with about seven vertical bands most distinct in its upper lobe.

Habitat.—Red Sea, and East coast of Africa to the Malay Archipelago, and Australia. It attains about six inches in length. The example figure was from Madras, where it is common.

D. 12, P. 17, A. 10, C. 10.

Length of the head equals its distance from the base of the dorsal fin. Eyes-in or a little before the middle of the length of the head, and small in adults: the interorbital space nearly flat and very broad in adults, in which it exceeds the length of the snout. Teeth—the lower a little larger than the upper pair. Fins—dorsal with its central ray somewhat the highest, it is situated in the last third of the distance between the front edge of the eye and the base of the caudal fin, its height equals about twice the length of its base: anal beneath the dorsal and of similar shape and size. Caudal truncated. Spines - with two roots and present on the back from the nostrils to the dorsal fin: a few on the lower part of the cheeks and numerous along the abdominal surface almost as far as the vent. Colours—of a light brownish along the back, becoming white tinged with yellow on the sides and beneath. Bands of dark brown pass from the back down the sides to the middle of the body enclosing light spaces of irregular sizes and shapes or round spots. From the snout to the dorsal fin round or oval light spots predominate. Occasionally a few bars descend from the eye over the cheek. Fins yellow stained with orange, sometimes a black shoulder spot.

Habitat.—Seas of India to the Malay Archipelago, China, Japan, and the South Sea. The example

figured was from Madras.

b. A fringed but single unperforated nasal cavity, with a fringed edge: body spined (Chelonodon, Müller).

D. 10-11, P. 18, A. 8-10, C. 10-11.

Length of head is rather less than its distance from the base of the dorsal fin. Eyes—situated in about the middle of the length of the head, interorbital space broad. Teeth—of about the same size in either jaw. -dorsal and anal rounded, the caudal (which is from $4\frac{1}{2}$ to $5\frac{1}{2}$ in the total length) truncate. Height of dorsal fin equals the length of the head excluding the snout. Spines—small, with three or four roots, extending from a short distance behind the nostrils to the base of the dorsal fin: inferiorly they extend over the chest nearly as high as the base of the pectoral fin and posteriorly to the vent. Colours—upper half brown or black with numerous round or oval white spots, sides and abdomen silvery, a yellowish tinge dividing the dark back from the white side. Caudal in the young stained dark in its outer half. The caudal fin is rather longer, the back is darker, the light spots smaller and more distinct in examples from Calcutta than in those from the sea. In some, especially marine forms and immature specimens, two to three distinct dark bands descend from the back to the middle of the sides, and a fourth passes across the head.

Habitat.—From Sind through the seas of India to China, attaining at least 13 inches in length. It is

very common along the Coromandel coast of India.

c. A simple and circular nasal cavity: body spineless (Monotretus, Bibron).

7. Tetrodon cutcutia, Plate CLXXXII, fig. 5.

B. v, D. 10-11, P. 21, A. 10, C. 7.

Length of head equals its distance from the base of the dorsal fin, caudal fin 6 in the total length. Eyes—slightly behind the middle of length of head: interorbital space flat and broad. Nostril a single orifice, situated in a very short simple tube. Fins—dorsal situated in the posterior 1/3 of the distance between the front edge of the eye and the base of the caudal fin: all the fins rounded. Spines—entirely absent. Colours greenish yellow above, becoming white on the abdomen. A light band passes from eye to eye. A large black ocellus, surrounded by a light edge, on the side anterior the origin of the dorsal and anal fins. The whole of the back marked with dark greenish reticulations enclosing lighter spaces: fins grayish: caudal tipped with carmine: a red spot on the throat.

Habitat.—Fresh waters of Orissa, Bengal and Assam. It attains about $3\frac{1}{2}$ inches in length. The

example figured was from Orissa.

d.—Two solid nasal tentacles, one on each side of an impervious nasal fossa (Arothron, Müller).

8. Tetrodon immaculatus, Plate CLXXXIII, fig. 4.

D. 9-10, P. 17-18, A. 8-10, C. 9-10.

Length of head equals its distance from the base of the dorsal fin. Eyes—situated in about the middle of the length of the head, the interorbital space broad and flat. Teeth—of about equal size in both jaws. Fins -rounded, the dorsal is situated in the last third of the total length excluding the caudal fin, its height equals about 1/2 the length of the head. Caudal rather elongated, being equal to 1/4 of the total length. Spines—small, covering the body except the snout and the posterior half of the tail. Colours—greenish superiorly: brownish along the middle of the side, and dirty white below: upper and lower edges as well as the end of the caudal black. In some there is a white spot over the eye: occasionally there are several parallel grayish longitudinal bands on the sides. In some examples all the spines are white.

Habitat.—From the Red Sea, through the seas of India to the Malay Archipelago, and beyond:

attaining at least 12 inches in length.

9. Tetrodon nigropunctatus, Plate CLXXX, fig. 4.

Bl. Schn. p. 507; Günther, Catal. viii, p. 293; Klunz. Fische Roth. Meer. 1871, p. 643.

Arothron melanorhynchus, Bleeker, Halmah. p. 111, and En. Pisc. p. 201. Crayracion nigropunctatus, Bleeker, Atl. Ich. v, p. 74, t. ccvi, f. 4.

B. v, D. 10, P. 18, A. 9, C. 9.

Length of head nearly equals its distance from the base of the dorsal fin. Eyes—rather small, about two diameters from the end of the snout and about three apart: interorbital space nearly flat, and the osseous portion less than two diameters of the eye wide. Teeth-of about the same size in both jaws. Fins-dorsal situated in the last fourth of the body excluding the caudal fin: it and the anal are rounded. Caudal rounded and equal to about 1/5 of the total length. Spines—small, and usually cover the entire body, they are either much projecting or almost concealed in the skin: the extent over which they extend also varies, in fact they appear to be absent in some examples. *Colours*—brown above, becoming lighter on the sides and beneath: some scattered black dots over the body, and the vent in a black spot: the snout and round the mouth black or very dark brown: the spots in some examples are absent. In one variety termed citrinella, Günther, l. c. the entire body is of a beautiful lemon colour. Besides the scattered spots on the sides, there are some irregular small and large black spots on the back: one large blotch round the base of the dorsal fin, which

also is black. A large round black spot round the eye and gill-opening. (Günther, l. c.)

Habitat.—Red Sea, and East coast of Africa, through the seas of India to the Malay Archipelago, and beyond. It attains at least to nine inches in length. The example figured (life-size) was from Madras.

B. v, D. 11, P. 18-21, A. 11-12, C. 11.

Length of head equals its distance from the base of the dorsal fin. Eyes-rather above two diameters Length of head equals its distance from the base of the dorsal in. Eyes—rather above two diameters from the end of the snout, and $2\frac{1}{2}$ apart: interorbital space nearly flat and the osseous portion extending the whole distance. Teeth—of about the same size in both jaws. Fins—dorsal situated in the last 1/4 of the distance between the end of the snout and the base of the caudal fin, which is rounded and about 1/6 of the total length. Spines—small, extended all over the body, from just behind the lips almost to the base of the caudal fin. Air-vessel—horse-shoe shaped. Colours—generally of a brownish-yellow tint along the back: the whole of the back and sides as low as the lower level of the pectoral covered with brown spots divided by yellowish-white lines above, but further apart lower down. Caudal spotted: dorsal and anal dark: pectoral vellowish often with a black base margined by a white line also a black streak below its base inferior to which yellowish, often with a black base margined by a white line, also a black streak below its base inferior to which are three black blotches: anus in a black ring: lower lip black, yellow at the angle, inside of mouth and tongue black.

In the variety lineatus there are concave black bands on the abdomen, which however, are not constant in their direction, often become confluent and are usually lost in adults.

Owing to its reputed poisonous quality it is forbidden to sell this fish at Batavia.

Habilat.—Red Sea, East coast of Africa, seas of India to the Malay Archipelago and beyond, attaining at least two feet in length. The example figured (eight inches long) was from Madras.

11. Tetrodon reticularis, Plate CLXXX, fig. 5.

Paatha, Mal.: Ko-pud-dah, Andamanese.

D. 10-11, P. 19, A. 10-11, C. 10-11, Vert. 8/10.

Length of head equals its distance from the base of the dorsal fin. Eyes-situated in about the middle of the length of the head, the interorbital space broad and flat. Teeth- of about the same size in either jaw.

Digitized by GOO

Fins-rounded, the dorsal situated in the last fourth of its total length excluding the caudal fin, its height somewhat exceeds half the length of the head. Length of caudal fin equal to $4\frac{1}{2}$ in the total length. Spines small, cover the entire body except the forepart of the snout. Colours—upper surface of the body deep gray or brown, becoming white below: with from eight to ten longitudinal black stripes, which, under the eye, as well as round the mouth and pectoral fin, are concave: on the back are darker blotches anteriorly (where blackish bands surround spots of white or gray), it is chequered with black posteriorly: caudal reticulated with black on a white ground. In the young the bands on the cheek are wanting.

Bleeker observes that this species is deemed poisonous in the Malay Archipelago.

Habitat.—Seas of India to the Malay Archipelago and New Guinea. It attains at least seventeen inches in length.

Arothron laterna, Bleek. En. Pisc. p. 200.

Crayracion implutus, Bleeker, Atl. Ich. v, p. 71.

Crayracion laterna, Bleeker, Atl. Ich. v, t. ccv, f. 3.

B. v, D. 10, P. 17-18, A. 10-11, C. 11.

Length of head equals its distance from the base of the dorsal fin. Eyes—of moderate or rather small size, from $2\frac{1}{2}$ to 3 diameters from the end of snout, and 3 apart: orbit prominent and interorbital space concave, upper profile of snout rather concave. Fins—rounded: caudal about 1/5 of the total length. Spines—small, those on the abdomen with two or three roots, they cover the body from the snout to a short distance behind the base of the dorsal fin. In some examples they appear not to extend so far, as Jenyns described the *T. implutus* with its "body everywhere smooth except the middle of the abdomen from underneath the pectorals to the vent, and not very prickly here." Colours-Brown superiorly, with a moderate number of bluish-white spots: one or two bluish-white bands sometimes exists round the orbit, another well-marked one round the gill-opening and pectoral fin: sometimes there are lines or spots of black on the abdomen, but they do not ascend to the cheeks: some have several black blotches along either side of the abdomen, or bands descending on to it.

Bleeker observes that the superior pharyngeal bone in this species has its summit of moderate size, a little obtuse, and armed with many rows of small teeth, whereas in T. reticularis the summit of this bone is obtuse and rounded without visible teeth, but divided by numerous transverse ridges.

Cantor's type of T. bondarus (a painted skin), is in the British Museum, and is unquestionably this species, and must have been coloured almost identically to the example figured pl. clxxxii, f. 2.

Hubitat.—From the Red Sea through the seas of India to the Malay Archipelago, and beyond. Attaining at least twenty inches in length. The example figured (life size) was from Madras.

13. Tetrodon leopardus, Plate CLXXX, fig. 2.

? Tetraodon, Russell, Fish. Vizag. i, p. 19 and Bondaroo kappa, pl. xxvii; Jerdon, M. J. L. & Sc., 1851, p. 150. B. v, D. 11, P. 18, A. 8-9, C. 11.

Length of head equals its distance to the base of the dorsal fin. Eyes—of moderate size, $1\frac{1}{2}$ diameters apart and the same distance from the end of the snout: interorbital space flat. Teeth-about the same size in both jaws. Fins—dorsal highest in front, situated in the last third of the distance between the front edge of the eye and the base of the caudal fin: anal similar to dorsal. Caudal rounded and $4\frac{2}{3}$ in the total length. Spines—two rooted, widely separated along the back, extending from the front edge of the eyes to the dorsal fin: inferiorly they are closer together and reach to the vent. Colours—Olive superiorly, extending two-thirds of the distance down the sides, with an interrupted black network surrounding white spots: three black cross bands, one over the head, with a V-shaped light interorbital band posterior to it: the second, above the pectoral fin: the posterior one from the base of the dorsal. Reticulated narrow black lines enclosing large white spots on the caudal and dorsal fins, the latter having likewise a narrow black basal band.

Russell's description of T. bondaroo kappa corresponds in colour to the one here described, but the spines resemble T. reticularis. It is open to question whether one species is not merely a variety of the other differing in colour, and also in the extent to which the body is spined.

Habitat.—Seas of India.

14. Tetrodon viridipunctatus, Plate CLXXVI, fig. 5.

Leiodon viridipunctatus, Day, Proc. Zool. Soc. 1865, p. 315, and Fishes of Malabar, p. 258, pl. 20, f. 2. Tetrodon viridipunctatus, Günther, Catal. viii, p. 289.

B. v, D. 12, P. 18, A. 11, C. 11.

Length of head equals its distance from the base of the dorsal fin: caudal fin 1/5 of the total length. Eyes—diameter 1/5 of length of head, rather nearer to gill-opening than to the end of the snout. Nostrils two solid tentacles.* Fins—all are rounded. Spines—two-rooted, short, some distance asunder, they commence from the occiput, and pass along the back two-thirds of the way to the commencement of the dorsal fin: none on the sides. Inferiorly they begin below the orbit, surround the lower and posterior margin of the pectoral fin, and are continued backwards as far as the anus. Colours—back light green: abdomen silvery-white: back and sides covered with emerald green spots: a bar of the same colour passes across the vertex from one eye to the other, and also goes backwards in the median line towards a second irregular band of the same colour, which passes across the back more posteriorly. Eye brown, with a golden rim surrounding the iris. Caudal and anal tipped with black: dorsal yellowish: four black spots under the throat.

Habitat.—Cochin on the Malabar coast.

15. Tetrodon fluviatilis, Plate CLXXXIII, fig. 1.

Tetrodon fluviatilis, Ham. Buch. Fish. Ganges, pp. 6, 362, pl. xxx, fig. 1; Swainson, Fishes ii, p. 328; Bleeker, Beng. p. 78; Günther, Catal. viii, p. 292; Steind. Sitz. Ak. Wein. 1870, lxi, p. 640, t. v, f. 2.

B. v, D. 14-16, P. 22, A. 12-13, C. 11,

Length of head equals its distance from the base of the dorsal fin. Eyes—rather large, and from $1\frac{1}{2}$ to 2 diameters from end of snout: the interorbital space broad and slightly convex. Teeth—of about the same size in both jaws. Fins—dorsal situated in the last third of the distance between the eye and base of caudal fin. Caudal fin truncated, its length being 1/4 of the total. Spines—with two roots, widely separated, concealed in the skin, and extending from the hind edge of the eyes to the base of the dorsal fin, also over checks and abdomen as far as the vent. Colours—greenish-olive superiorly, becoming white along the sides and below: back and sides with large black blotches, leaving very little of the ground colour apparent: one or two irregular light bands, one crossing between the eyes, another between the pectorals, and often one or two more over the back: abdomen covered with round or angular black spots and blotches much wider than the ground colour, sometimes it is quite black beneath: fins yellowish, end of caudal stained dark and sometimes with black spots.

According to Blecker, examples from the Malay Archipelago, have fewer rays than those from India, he gives D. 12-14, A. 11-12.

Habitat.—Seas and estuaries of India to the Malay Archipelago, and beyond. It attains at least 61 inches in length.

e. Nusal organs inconspicuous: back compressed into a keel (Anosmius, Peters).

16. Tetrodon margaritatus.

* The single example being stuffed, the nostrils had become dried, and the figure and description formerly given are erroneous as regards this character, as I have ascertained after macerating the specimen some weeks in spirit. 4 x 2

Digitized by GO

PLECTOGNATHI.

Rhynchotus margaritatus (Bibron) Duméril. Rev. Zool. 1855, p. 282. Tropidichthys margaritatus and Bennetti, Bleeker, Amboina, pp. 500, 504.

Anosmius Bennetti and margaritatus, Bleeker, en. Pisc. pp. 202, 203.

Psilonotus Bennetti, Bleeker, Ternate, p. 230, and Sumatra, p. 66.

Canthogaster ocellatus and margaritatus, Bleeker, Atl. Ich. v, pp. 80, 81. Psilonotus ocellatus and margaritatus, Bleeker, Atl. Ich. v, t. ccxiv, f. 4, and t. ccxiii, f. 5. B. v, D. 9-10, P. 14-16, A. 9, C. 11.

Length of head equal to its distance from the base of the dorsal fin. Eyes—rather high up and in the posterior half of the length of the head. Upper profile of snout rather concave. Fins—dorsal situated in almost the last fourth of the total length excluding the caudal fin, which last is rather convex and from 4½ to 5 in the total length. Spines—minute, and generally covering the entire body, but occasionally deficient from the caudal portion. Colours—of a dull reddish, becoming light beneath, fins yellow. The body is variously marked: in T. margaritatus, there is a black blue-edged occllus on either side of the dorsal fin: horizontal blue lines round the eye and on the posterior portion of the body, elsewhere there are small yellow dark-edged ocelli, which are even on the caudal fin. In T. papua the black dorsal spot is also present: the oblique bands on the snout become nearly horizontal and a blue band passes to the vent: also angular bands on the tail: body and cheeks covered with small blue, black-edged spots. In T. Bennetti, a black dorsal spot also exists. Bluish vertical bands on snout and one along the middle of the throat: angular bands on the tail. Bluish spots on the body, smallest on the sides of the head.

A very good figure of this species exists amongst Sir W. Elliot's drawings of Madras fish, which is referred to by Jerdon as "Karoom palasi, Tamil. Not common at Madras." (M. J. L. and Sc. 1851, p. 150.)

Habitat.—Red Sea, East coast of Africa, seas of India to the Malay Archipelago, and beyond.

B.—Jaws without any median suture.

Genus-Diodon (Linnœus), Cuvier.

Paradiodon, Bleeker.

Body nearly globular. Jaws without median suture. Nasal tentacle simple, with a pair of lateral openings. Body covered with stiff and erectile dermal spines, each having a pair of lateral roots. A portion of the exophagus dilatable, and can be distended with air. No pelvic bones. Air-vessel present.

Geographical Distribution.—Tropical Seas to the Cape of Good Hope.

In the Museum at Calcutta were two examples, but without labels, of the Diodon spinosissimus; and as the British Museum contains a specimen from Siam, it is not unlikely that it is found in the seas of India. The D. novemmaculatus, Bleeker, is also probably a visitor to India.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Diodon hystrix. Body covered with short spines, longest on the sides and behind the pectoral fins. Numerous blue or brown round spots. Tropical seas.

1. Diodon hystrix, Plate CLXXIX, fig. 4.

Hystrix piscis, Clusius, Exot. vi, c. 23; Jonston, Nat. Hist. Pisc. t. xlv, f. 4; Willugh. Hist. Pisc. t. i, f. 5.

Reversus Indicus, Aldrov. Pisc. iii, p. 113, t. xv, f. 12; Jonston, l. c. t. iii, f. l.

Diodon hystrix, Linn. Syst. Nat. i, p. 413; Bris. Barnev. Rev. Zool. 1846, p. 141, Bloch, t. cxxvi;

Jerdon. M. J. Lit. and Soc. 1851, p. 150; Günther, Catal. viii, p. 306; Klunz. Fische Roth. Meer. 1871, p. 647. Diodon atringa, Bloch, t. cxxv; Bl. Schn. p. 511; Lacép. i. t. xxv, f. 3 and ii, pp. 1, 3; Rüpp. Sench. Mus. Fische, p. 35: Kaup, Wiegm. Arch. 1855, p. 227 (not Linn.); Bleeker, En. Pisc. p. 203.

Diodon plumieri, Lacép. i, t. iii, f. 3 and ii, pp. 1, 10. Diodon brachiatus, Bl. Schn. p. 513.

Diodon punctatus, Cuvier, Mem. Mus. Hist. Nat. iv, p. 132; Bleeker, Blootk. p. 19.

Holocanthus hystrix, Gronov. ed. Gray, p. 27. Paradiodon hystrix, Bleeker, Atl. Ich. v, p. 56, t. cevii, f. 2.

Moollu plachay, Tamil.

Body covered with coarse spines, which are longest on the sides of the body behind the pectoral fin, where they become about 3/4 the length of that fin: they are dilated at their bases and usually with a pair of basal grooves. Two or three pairs of immovable spines at the upper and lower sides of the tail. Colours—the whole of the fish (except the ventral surface) of a light brown covered with round blue or brown spots, rarely above one to the base of a single spine. The fins similarly spotted.

Habitat.—From the Red Sea through the seas of India to the Malay Archipelago and the Pacific. The example figured (11 inches in length) was brought from the Andamans by J. Wood-Mason, Esq., of the

Calcutta Museum. This fish attains a large size: one in the British Museum is $2\frac{1}{3}$ feet in length.

SUB-CLASS, II—CHONDROPTERYGII.

Elasmobranchii, Buonaparte.

Skeleton cartilaginous: no cranial sutures. From one to seven gill-openings: the gills are attached by their outer edges to the skin, and there usually exists an intervening gill-opening with an external orifice between each: none or only a rudimentary gill cover. Three series of valves at the bulbus arteriosus. Optic nerves, although united, do not decussate. Body with vertical and paired fins, the posterior pair abdominal: caudal with an elongated upper lobe. Intestines with a spiral valve. Male sex with prehensile organs attached to the vertical fins. Ovaries containing large ova, which are fertilised, and sometimes likewise developed internally. Embryo with external deciduous gills. No air-vessel.

This sub-class as at present constituted * is divided into two orders, the first of which does not appear to have representatives in India.

I. Holocephala. With only one external gill-opening and a rudimentary cartilaginous gill-cover:

four branchial clefts inside gill-cavity. The palatal and maxillary apparatus coalescent with the skull.

II. Plagiostomata. With five to seven external gill-openings, and no cartilaginous gill-cover. Jaws distinct from the skull.

ORDER—PLAGIOSTOMATA.

Body more or less cylindrical or depressed: the trunk may or may not pass into the tail. From five to seven gill-openings, which may be lateral or inferior. Jaws distinct from the skull.

This order has been sub-divided as follows:-

Sub-order I—Selachoidei or Sharks. Trunk gradually passing into the tail. Gill-openings lateral. Sub-order II—Batoidei or Skates and Rays. Gill-openings ventral, p. 727.

SUB-ORDER, I—SELACHOIDEI.

Body more or less cylindrical, gradually merging into the tail. Gill-openings lateral.

Geographical distribution.—Sharks are found in the seas and estuaries of temperate and tropical regions: some ascend rivers even far beyond the influence of the tides. Not only sharks but saw-fishes occasionally reside in fresh-water lakes, when their return to the sea has been cut off. Professor Meyer (Nature, Dec. 30th, 1875), remarks on this subject, "an accurate comparison (between marine and fresh-water forms), Professor Meyer (Nature, showed no difference at all, and therefore the changed conditions seem to have had no influence on the external features of the species.'

The sub-order Selachoidei, has been sub-divided into nine families, the following only of which have been recorded from the seas of India.

SYNOPSIS OF FAMILIES.

I. CARCHARIIDÆ. A nictitating membrane to eye: two dorsals and an anal fin, p. 710.

II. LAMNIDE. No nictitating membrane to eye: two dorsals and an anal fin: nostrils not confluent with mouth, which last is inferior. Spiracles absent or minute, p. 722.

III. NOTIDANIDE. No nictitating membrane to eye: only one dorsal fin and an anal, p. 723.

IV. Scylling. No nictitating membrane to eye: two dorsals and an anal fin. Mouth inferior. Teeth small, several rows being generally in use at the same time, p. 724.

* I here omit the consideration as to whether the Ganoids and Dipnoids should be included with the Chondropterygii into one sub-class, Paleichthes, as proposed. Likewise I have continued to term this sub-class Chondropterygii instead of Elasmobranchii, as is now generally adopted by anatomists. I do so because the former designation has the priority.

FAMILY, I—CARCHARIIDÆ.

The snout may be produced longitudinally or laterally. Spiracles absent or present. Eye with a nictitating membrane. A small pit may or may not exist above the root of the tail, and a groove at the angle of the mouth may be present or absent. Mouth crescentic, inferior. Teeth may be erect or oblique, with a single cusp, having smooth or serrated edges: or they may be small, the cusps being obsolete: or with one in the centre and one or two lateral ones. The first dorsal fin, destitute of a spine, is placed opposite the interspace between the pectoral and ventral: anal fin present.

Sharks are found all along the coasts of India, but their carrying off human prey is not a common occurrence. The most savage species appear to be the ground sharks of the rivers, as Carcharias Gangeticus, which seldom loses an opportunity of attacking the bather. The Galeocerdo Rayneri, is likewise dreaded along the coast or in the harbours. Though stationed several years at Cochin, I could only ascertain a single instance of a living human being having been carried off by these fishes. The most frequent accidents occurring are after the fish has been hooked and lifted into the fisherman's boat: or else while entangled in a net when attempts are made to seize it or cut it adrift. Corpses are almost immediately attacked by sharks.

In some years they are much more numerous than in others, and this is due to the presence or absence of shoals of smaller fish, as sardines (see Clupea longiceps, p. 637).

Sharks and rays are captured to a large extent both for the oil which is obtained from their livers, and on account of the flesh of those of medium size, which is salted and sold to the poor.* Their fins likewise are exported to China, where due to the gelatine contained in them, they are in request for making soups, while the skins of some forms are employed as shagreen for scabbards of swords. In most localities they are captured by baits secured to a rough hook, which is attached to a chain: but off the coasts of Sind shark nets of strong twine or string are used, and which are capable of holding these fishes at least up to 20 or 30 feet in length (see p. 718).

SYNOPSIS OF GENERA.

First group—Carcharina.

Snout produced longitudinally. Teeth erect or oblique, with a single cusp, which has smooth or serrated edges.

a.—A pit at the base of caudal fin.

1. Carcharias. No spiracles, p. 710.

2. Hemigaleus. Spiracles minute or small. Teeth serrated or notched in the upper jaw. Distinct labial folds, p. 717.

3. Galeocerdo. Spiracles small Teeth serrated in both jaws. Caudal fin with a double notch, p. 718.

Second group—ZYGÆNIINA.

Head produced laterally into the shape of a hammer. Nostrils on front edge of head. Teeth oblique, with a single cusp, having sharp smooth edges.

4. Zygæna. Spiracles absent, p. 719.

Third group-Mustelina.

Teeth small, having a central and one or two smaller lateral cusps, or such may be obtuse.

5. Triænodon. No spiracles. A pit at the root of the caudal fin, p. 720.

6. Mustelus. Spiracles small: labial folds well developed. Teeth obtuse. No pit at base of caudal fin, p. 720.

First group—Carcharina.

Snout produced longitudinally. Teeth erect or oblique, with a single cusp, which has smooth or serrated edges.

a.—A pit at the base of caudal fin.

Genus, 1.—CARCHARIAS, Müller and Henle.

Scoliodon, Aprion or Aprinodon, Physodon, Hypoprion, Prionodon, Müller and Henle: Prionace, Cantor: Eulamia, Isogomphodon, Lamiopsis, Platypodon, Hypoprionodon, Isoplagiodon and Cynocephalus, Gill.

* The Seedees (Africans) in Bombsy buy small ones as their usual food.

No spiracles. A pit before the root of the caudal fin. Snout longitudinally produced. Mouth crescentic: the labial fold or groove rarely extends beyond the angle of the mouth. Teeth erect or oblique with a sharp more or less compressed cusp, sometimes triangular, the edges of which may be serrated or smooth. The first dorsal fin, destitute of a spine, is placed opposite the interspace between the pectoral and ventral: caudal with a distinct lower

Respecting the colours in these fishes, it must not be forgotten that black spots or marks on the fins frequently become fainter in examples which have been preserved some time in spirit, more especially if removed from the alcohol and permitted to dry.

The fishes constituting this large and widely distributed Genus have been subdivided by some authors into several genera, by others into the like number of sub-genera or divisions, which latter course is the one I have adopted.

a .- Teeth with smooth edges: all oblique and without swollen bases (Scoliodon).

1. Carcharias laticaulus. Pectoral fin not reaching to below dorsal: length of base of anal nearly

- equalling its distance from the ventral: second dorsal posterior to base of anal. Groove at angle of mouth not extending on to the upper jaw. Indian Ocean to the Malay Archipelago, and beyond.

 2. Carcharias acutus. Pectoral fin reaching to below origin of dorsal: length of base of anal nearly equalling half its distance from the ventral: second dorsal over end of base of anal. Groove at angle of mouth not extending on to the upper jaw. Red Sea, seas of India to the Malay Archipelago, and beyond.

 3. Carcharias Walbeehmii. A well marked groove at the angle of the mouth extending a short distance along both jaws. The distance between the end of the snout and the mouth equals the interspace between the outer margins of the nostrils. Seas of India to the Malay Archipelago, and Japan.
- b. Teeth with smooth edges: those in the centre of the lower jaw smaller than those at the side, the latter being swollen at their bases and having an oblique and narrow cusp. Upper teeth flat and oblique (Physodon).
- 4. Carcharias Mülleri. Snout elongated: end of base of first dorsal above origin of the ventral: second dorsal small and posterior to the base of anal. Bengal.
- c. Teeth with smooth edges: all narrow and standing on a broad base, the upper being erect or slightly oblique: the lower being erect (Aprionodon).
- 5. Carcharias acutidens. Second dorsal as large as the anal and nearly equal in size to the first dorsal. Nostril with a distinct valve inferiorly. Teeth $\frac{2}{2}\frac{7}{7}-\frac{2}{2}\frac{9}{9}$. Red Sea, East coast of Africa, seas of India.
- 6. Carcharias tricuspidatus. Second dorsal nearly as large as the first. Teeth \(\frac{32}{34}\)\(\frac{2}{34}\) with a distinct basal cusp on either side. Coasts of Sind to Australia.
 - d. Teeth with smooth edges, except the bases of the upper ones which are serrated (Hypoprion).
- 7. Carcharias Macloti. Snout pointed. The bases of the teeth in the upper jaw serrated on both sides. Seas of India to New Guinea.
- 8. Carcharias hemiodon. Snout rounded. Only the outer sides of the bases of the upper teeth serrated. Seas of India.
 - e. Some or all the teeth serrated both on their bases and on their cusps (Prionodon).
- 9. Carcharias sorrah. Teeth in both jaws serrated. Gill openings wider than the orbit. Seas of India to the Malay Archipelago.
 - 10. Carcharias Dussumieri. Teeth in both jaws serrated. Second dorsal not much smaller than the anal.

Fins darkish with light edges. Seas of India to the Malay Archipelago.

- 11. Carcharias Gangeticus. Snout obtuse. Teeth in both jaws serrated. Seas of India to Japan: it ascends rivers.
- 12. Carcharias melanopterus. Teeth in both jaws serrated. All the fins black edged. Seas of India to the Malay Archipelago, and beyond.
- 13. Carcharias Bleekeri. Fins, except the first dorsal, with black extremities. East coast of Africa and seas of India.
- 14. Carcharias Ellioti. Teeth coarsely serrated in upper jaw: awl-shaped in lower, some with a basal cusp. Seas of India.
- 15. Carcharias menisorrah. Upper teeth serrated: second dorsal opposite the anal. A black spot on second dorsal. Seas of India.
- 16. Carcharias limbatus. Teeth serrated and on rather a broad base: lower more slender. Ends of some of the fins black. Seas of India and beyond.
- 17. Carcharias Temminckii. Teeth in both jaws slender and from thirty-six to forty in number. India.

a. Teeth with smooth edges: all oblique and without swollen bases (Scoliodon).

1. Carcharias laticaudus. Plate CLXXXVIII, fig. 1.

? Squalus, Russell, Fish. Vizag. i, p. 9, and Pala-sorrah, pl. xiv.
Carcharias (Scoliodon) laticaudus, Mull. and Henle, Plagios. p. 28, t. viii; Bleeker, Beng. p. 80; Duméril, Hist. Nat. Poiss. i, p. 343; Kner, Nov. F. p. 414.

Carcharias (Prionodon) palasorrah (Cuvier), Bleeker, Beng. p. 80.
Carcharias (Scoliodon) macrorhynchus, Bleeker, Plagios. p. 31, t. i, f. 1; Duméril, l. c. p. 343.

Carcharias laticaudus, Günther, Catal. viii, p. 358.

Dun-da-nee, Sind.: Nullian sorrah, Tel.

Length of preoral portion of snout exceeding the width of the mouth by 1/5, and equal to or slightly above the distance between the eye and the first gill opening (it is still longer in the immature): the groove at the angle of the mouth scarcely extends on to the upper jaw. Nostrils very much nearer mouth than the end the angle of the mouth scarcely extends on to the upper jaw. Nostrils very much nearer mouth than the end of snout. Teeth—Those in upper jaw rather oblique not swollen at their bases: those in the lower jaw very oblique especially near the symphysis: none are serrated. Fins—The length of the base of the anal fin is nearly or quite equal to its distance from the ventral, especially in the immature: the pectoral does not extend so far as to below the origin of the dorsal, its posterior edge is nearly straight, its internal edge 1/3 of the length of its outer. The caudal equals $3\frac{2}{3}$ to 1/4 of the total length, but is rather longer in adults than in the immature. Colour—Uniform gray superiorly, white beneath: the pectoral of a deep gray, having a white outer edge, as have also the ventral and anal, posterior portion of caudal fin dark gray or nearly black.

Habitat.—Seas of India to the Malay Archipelago and beyond. It attains at least two feet in length. Habitat.—Seas of India to the Malay Archipelago and beyond. It attains at least two feet in length.

2. Carcharias acutus. Plate CLXXXVIII, fig. 2.

Rüppell, N. W. Fische, p. 65, t. xviii, f. 4; Günther, Catal. viii, p. 358. Squalus Russellii, Gray and Hardw. Ill. Ind. Zool.

Carcharias (Scoliodon) acutus, Müll. and Henle, Plagiost. p. 29; Richards. Ich. China, p. 194; Cantor, Catal. Mal. Fish. p. 399; Bleeker, Plagiost. p. 30; Duméril, Hist. Nat. Poiss. i, p. 345; Kner, Novara F. p. 414; Klunz. F. R. M. 1871, p. 655.

Purrooway sorrah, Tam. : Parl sorrah, Mal.: Sem sorrah, Tel.

Length of preoral portion of snout 1/4 longer than the gape of the mouth, and equal to or slightly less than the distance between the eye and the gill-opening: a groove at the angle of the mouth not, or but slightly extending on to the upper jaw. Nostrils nearer to mouth than to the end of the snout. Teeth—the upper and lower ones oblique without swollen bases and none serrated. Fins—The length of the base of the anal fin is one half, or less, than its distance from the ventral: the pectoral extends to at least below the origin of the dorsal, its posterior edge is concave, and its internal edge about 2/5 the length of its outer: second dorsal small, situated over the posterior half of the anal. Length of caudal fin about $3\frac{1}{2}$ to $3\frac{2}{3}$ in the total length. Colours—Gray or bronze above, white below: fins gray, the posterior edge of pectoral, outer edges of ventral, and and posterior half of caudal, white: upper edge of caudal dark, as is also its posterior lobe.

Habitat.—Red Sea, seas of India to the Malay Archipelago, and beyond: said on the Malabar Coast to attain a considerable size, but the largest I obtained was twenty-nine inches in length. The example figured

(eleven inches long) was from Madras.

3. Carcharias Walbeehmii. Plate CLXXXV, fig. 2.

Carcharias (Scoliodon) Walbeehmii, Bleeker, Nat. Tyds. Ned. Ind. x, p. 353. Carcharias Walbeehmii, Günther, Catal. viii, p. 359.

Ei-dah, Andamanese.

Length of the preoral portion of the snout exceeding the width of the mouth by nearly 1/3, and equalling the distance between the eye and the second gill-opening. A well marked groove at the angle of the mouth extending on to both the upper jaw and along a portion of the mandible. Nostrils rather nearer the mouth than to the end of the snout, the distance between the outer edges of the nostrils equal to the extent between them and the end of the snout. Teeth—oblique and flat in both jaws without any serrature. Fins—the pectoral extends to nearly beneath the middle of the first dorsal fin, it has its posterior edge rather concave, and its inner edge equals 1/3 of the length of its outer: second dorsal rather small, with its posterior lobe produced, it is situated over the last half of the anal. Length of the base of the anal equal to 2/5 of its distance from the base of the ventral, caudal fin 2/7 of the total length. Colours—light brown superiorly becoming dull white beneath. Fins gray and mostly with light outer edges.

Habitat.—Seas of India to the Malay Archipelago and Japan. The example figured (a male, twenty-five

inches long) was from Malabar.

b. Teeth with smooth edges, those in the centre of the lower jaw smaller than those at the side: the latter being swollen at their bases and having an oblique and narrow cusp: upper teeth flat and oblique (Physodon).

4. Carcharias Mülleri.

Müller and Henle, Plagios. p. 30, t. xix, f. 1 (teeth); Bleeker, Beng. p. 80; Duméril, Hist. Nat. Poiss. i, p. 347; Günther, Catal. viii, p. 360.

Snout elongated and pointed. Nostrils nearer the angle of the mouth than to the end of the snout. Mouth nearly as long as wide. Fins—the end of the base of the first dorsal situated opposite the origin of the ventral: second dorsal very small and commencing above the last third of the base of the anal. Pectoral extends to below the origin of the first dorsal. Colours—brownish, becoming lighter beneath: fins a little darker.

Habitat.—Bengal.

c. Teeth with smooth edges: all narrow and standing on a broad base, the upper being erect or slightly oblique: the lower being erect (Aprionodon).

5. Carcharias acutidens, Plate CLXXXIX, fig. 1.

Rüppell, N.W. Fische, p. 65. t. xviii, fig. 3; Günther, Catal. viii, p. 361; Klunz. Fische Roth. Meer. 1871, p. 657.

Carcharias (Aprion) acutidens, Müller and Henle, Plagios. p. 33. Carcharias (Aprionodon) acutidens, Duméril, Hist. Nat. Poiss. i, p. 349.

Snout obtuse and rounded, the length of its preoral portion equal to 2/3 of the width of the mouth and much less than the distance between the eye and the first gill-opening. Nostrils rather nearer mouth than to the end of the snout. A very short groove at the angle of the mouth not extending on to the upper jaw. Eye small. Gill-openings much wider than the orbit. No trace of any spiracle. $Teeth-\frac{2}{2}\frac{7}{7}-\frac{2}{2}\frac{9}{7}$, those in both jaws rather slender, erect, or oblique, and with the bases rather swollen, none serrated. Fins—the base of the first dorsal situated midway between the inner angle of the pectoral and the commencement of the ventral: second dorsal nearly as large as the first, situated above but rather larger than the anal. Caudal fin $4\frac{1}{2}$ in the total length. Pectoral falciform, its inner edge $3\frac{1}{4}$ times in its outer, it reaches to beneath the middle of the base of the first dorsal. A well-developed pit before the base of the caudal fin. Colours—of a dull reddish brown, becoming lightest on the sides and beneath.

Habitat.—Red Sea, coasts of Sind and the Indian Ocean. The example figured is nearly four feet in length, but I have obtained specimens up to six feet.

6. Carcharias tricuspidatus, Plate CLXXXVI, fig. 1.

Odontaspis Americanus, Günther, Catal. viii, p. 392 (part).

Length of preoral portion of the snout equal to half the width of the mouth, and not equal to half the distance between the eye and the first gill-opening: no groove at the angle of the mouth. Nostrils nearer to the mouth than to the end of the snout. Gill-openings much wider than the orbit. $Teeth - \frac{3}{3} \frac{2}{0} \frac{3}{3} \frac{1}{4}$, very large, awl-shaped, smooth except at the base, where there exists a small basal cusp on either side. The fourth tooth on either side of the symphysis of the upper jaw very much smaller than those next to it: the central tooth on either side of the symphysis of the mandibles slender. The last few lateral rows in either jaw small. Fins—pectoral reaching to below the base of the first dorsal: its inner edge 1/5 of the length of its outer. First dorsal very slightly larger than the second, its base situated nearer to the ventral than to the pectoral. The second dorsal slightly in advance of and about the same size as the anal: length of base of anal equals its distance from the ventral. Caudal fin $3\frac{1}{2}$ in the total length. Colours—brown superiorly, becoming dull white beneath.

I obtained several examples of this large shark at Kurrachee and from the coast of Beloochistan, none of which were less than twelve feet in length, while all had a pit at the root of the caudal fin.

Habitat.—Seas of Sind, where they abound—attaining at least twenty feet in length; one on board a native craft measuring that length. The example figured (a skin) is 12 feet 3 inches in length. The teeth are depicted the natural size. A specimen, $10\frac{1}{2}$ feet long, from South Australia is in the British Museum: also several jaws.

d. Teeth with smooth edges except the bases of the upper ones which are serrated (Hypoprion).

7. Carcharias macloti, Plate CLXXXVIII, fig. 2.

? Squalus, Russell, Fish. Vizag. i, p. 9, and Sorra kowah, pl. xv. Carcharias (Hypoprion) macloti, Müll. and Henle, Plagios. p. 34, t. x; Duméril, Hist. N. Poiss. i, p. 350. Carcharias macloti, Günther, Catal. viii, p. 362.

Pala sorrah, Tel

Length of the preoral portion of the snout exceeding the width of the mouth by 1/3 and equalling the

Digitized by GOO

distance between the eye and the second gill-opening. A short groove at the angle of the mouth, not extending on to the upper jaw. Nostrils nearer to the opening of the mouth than to the end of the snout. Teeth—the bases of those in the upper jaw denticulated on both sides: those in the lower jaw erect, with smooth edges and a broad base. Fins—the length of the base of the anal is equal to about twice its distance from the base of the ventral: the pectoral extends to nearly as far as to below the hind edge of the first dorsal, its posterior margin reneral. one pectoral extends to hearty as lat as to below one find edge of the first dotsal, its posterior margin length of its outer edge; caudal 3½ to 3½ in the total length. Colours—gray or brown, becoming dull white beneath: the fins gray, the caudal nearly black in its posterior helf; outer helf of first dotsal doubt, posterior helf; outer helf of first dotsal doubt, posterior and market with a light of some helf of first dotsal doubt, posterior and market with a light of some helf. posterior half: outer half of first dorsal dark: pectoral and ventral with a light edge.

Habitat.—Seas of India to New Guinea. The longest example obtained in Malabar, was a little over

twenty inches.

8. Carcharias hemiodon.

Carcharias (Hypoprion) hemiodon, Müll. and Henle, Plagios. p. 35, t. xix, f. 2 (teeth); Bleeker, Beng. p. 80; Duméril, Hist. Nat. Poiss. i, p. 351.

Hypoprionodon hemiodon, Gill, Ann. Lyc. Nat. Hist. New York, vii, p. 409.

Carcharias hemiodon, Günther, Catal. viii, p. 362.

Snout obtusely rounded: the distance between the end of the snout and the mouth equals the interspace between the outer angles of the nostrils. No groove at the angle of the mouth. Teeth—in the upper jaw oblique, with the outer side of their bases serrated. Fins—the pectoral reaches to below the middle of the first dorsal: the second dorsal commences opposite to or rather behind the origin of the base of the anal. Caudal fin equal to $4\frac{1}{3}$ in the total length. Colours—gray, becoming lighter beneath.

Habitat.—Seas of India, ascending rivers as the Hooghly at Calcutta.

e. Some or all the teeth serrated both on their bases and on their cusps (Prionodon).

9. Carcharias sorrah, Plate CLXXXV, fig. 1.

Carcharias (Prionodon) sorrah, Müll. and Henle, p. 45, t. xvi; Bleeker, Plagios. p. 39 and Bengal, p. 80; Kner, Novara Fische, p. 414; Duméril, Hist. Nat. Poiss. i, p. 368.

Isoplagiodon sorrah, Gill, Ann. Lyc. Nat. Hist. New York, vii, p. 410.

Carcharias sorrah, Günther, Catal. viii, p. 367.

Length of the preoral portion of the snout about equal to the width of the mouth and nearly equal to the distance between the eye and the first gill-opening. No groove at the angle of the mouth. Nostrils about midway between end of snout and mouth. Gill-openings rather wider than the orbit. $Teeth-\frac{2}{3}\frac{5}{5}$, those in the upper jaw oblique, serrated, and with a toothed notch on their outer edge: those on lower jaw a little oblique, rather narrow, situated on a broad base and serrated. Fins—pectoral falciform, extending to beneath the hind third of the base of the first dorsal fin, its internal margin equalling about 1/4 or 2/7 of its outer. Origin of first dorsal slightly posterior to the base of the pectoral, and not extending to above the ventral. The second dorsal smaller than and slightly posterior to the origin of the anal, the latter rather nearer the caudal than the ventral. Caudal fin $3\frac{1}{4}$ in the total length. Colours—dull brown superiorly, and whitish beneath: fins gray, lower caudal lobe and pectorals with black extremities.

Habitat.—Seas of India to the Malay Archipelago. The example figured (18 inches long) was one of Bleeker's specimens received from Dr. Hubrecht, of the Leyden Museum. I captured one of similar size at

Mangalore, but which is now in a bad state owing to its having had a quantity of salt enclosed with it.

10. Carcharias Dussumieri, Plate CLXXXVII, fig. 2.

Carcharias (Prionodon) Dussumieri, (Valenciennes) Müll. and Henle, Plagios. p. 47, t. xix, f. 8; Bleeker, Beng. p. 80; Richards. Ich. China, p. 194; Kner, Novara Fische, p. 414; Duméril, Hist. Nat. Poiss. i, p. 370. Carcharias (Prionodon) Javanicus, Bleeker, Plagiost. p. 38; Duméril, l. c. p. 369. Carcharias Dussumieri, Gunther, Catal. viii, p. 367.

Length of the preoral portion of the snout very slightly exceeding the width of the mouth, and equalling the distance between the eye and the first gill-opening. A very short groove at the angle of the mouth, and only slightly extending on to the upper jaw. Nostrils nearer the opening of the mouth than to the end of the snout. Gill-openings wider than the orbit. Teeth—25, those of the upper jaw oblique and serrated, having a notch on the outer side: those in the mandibles smaller, oblique, narrow, serrated, and with a broad base. Fins—pectoral extends to the hind edge of the base of the first dorsal, its posterior margin is slightly concave, its internal margin equals 2/5 of the length of its outer edge. Origin of the first dorsal a very slight distance behind the base of the pectoral, and its base not extending to above the ventral. The second dorsal slightly smaller than the anal. The length of the caudal equals $3\frac{2}{3}$ in the total length. Colours gray or dull brown, becoming white beneath: fins gray with white outer edges: upper two-thirds of second dorsal blackish.

Habitat.—Seas of India to the Malay Archipelago. The example figured was from Malabar.

11. Carcharias Gangeticus, Plate CLXXXVII, fig. 1.

Carcharias (Prionodon) Gangeticus, Müll. and Henle, Plagios. p. 39, t. xiii; Bleeker, Beng. p. 80; Duméril, Hist. Nat. Poiss. i, p. 359.

Carcharias (Prionodon) Japonicus, Temm. and Schleg. Faun. Japon, Poiss. p. 302, t. cxxxiii. Squalus (Carcharias) Gangeticus, Blyth, J. A. S. of Beng. 1860, p. 36. Carcharias Gangeticus, Günther, Catal. viii, p. 367, and Ann. Nat. Hist. 1874, p. 36.

Length of the preoral portion of the snout only 2/3 of the width of the mouth, and equalling half of the interspace between the eye and the middle gill-opening: a very slight groove at the angle of the mouth. Nostrils in the front half of the distance between the end of the snout and the mouth. Gill-openings wider than the orbit. Teeth—twenty-seven to thirty in either jaw, all being serrated: the superior ones almost triangular, their outer edge with a notch, very distinct in the immature, but becoming almost lost with age: those in the lower jaw narrow, erect, and having broad bases. Fins—pectoral elongated, falciform, and extends to beneath the middle of the first dorsal: its internal margin 2/7 of the length of its outer. Origin of the first dorsal slightly posterior to the hind edge of the base of the pectoral, its base not extending to above the ventral. The second dorsal of about the same size as the anal, the latter nearer the caudal than the ventral. Length of the caudal 2/7 of the total length. Scales—small and with rough edges: they are hardly above 1/2 the size of those in C. melanopterus. Colours—gray superiorly, becoming dull white beneath. Fins gray, the pectoral, ventral, and anal with light edges: posterior portion of caudal rather dark.

This is one of the most ferocious of Indian sharks, and frequently attacks bathers even in the Hooghly at Calcutta,* where it is so dreaded that a reward is offered for each that is captured. I have taken it at Cuttack.

The example figured (18 inches long) was from Bombay, and the teeth are exceedingly minute, but under the microscope the notch in the upper teeth and the serrations are visible.

Habitat.—Seas of India to Japan, ascending rivers to above tidal influence. It attains at least seven feet in length. Also recorded from Bagdad.

12. Carcharias melanopterus, Plate CLXXXV, fig. 3.

? Carcharias melanopterus, Quoy and Gaim. Voy. Uran. Zool. p. 194, pl. 43, figs. 1 and 2; Rüpp. N.W. Fische, p. 63; Günther, Catal. viii, p. 369: Klunz. F. R. Meer. 1871, p. 658.

Carcharias (Prionodon) melanopterus, Müll. and Henle, p. 43, pl. 19, fig. 5 (teeth); Bleek. Plag. p. 33; Richards. Ich. China, pp. 194, 317; Duméril, Hist. Poiss, i, p. 365; Kner, Novara Fische, p. 415.

Carcharias (Prionodon) melanopterus, Cant. Mal. Fish, p. 400.

Carcharias (Prionodon) Henlei, Bleek. Nat. Tyds. Ned. Ind. iv, p. 507.

? Carcharias (Prionodon) brachyrhynchus, Bleek. Act. Soc. Sc. Indo-Neerl. vi, p. 206; Duméril, Hist. Poiss in 364. Poiss. i, p. 364.

Length of the preoral portion of the snout two-thirds the width of the mouth and considerably less than the distance between the eye and the first gill-opening: a very short groove at the angle of the jaws. Nostrils nearer to the extremity of the snout than to the end of the mouth. Snout rounded and very obtuse. Teeth— $\frac{24-25}{24-25}(\frac{31}{31})$, the upper broad, flattened, oblique, with a very slight notch or rather concavity on the outer side and serrated: the lower much narrower, pointed, on a broad base and also serrated, these serrations being generally minute, sometimes only on one side of the tooth and are occasionally wanting, especially in the lower jaw. Fins—pectoral falciform, extending to beneath the middle or even hind edge of the base of the dorsal, its outer edge three times as long as its internal one. Base of first dorsal a little nearer the pectoral than its posterior end is to the ventral. Second opposite and similar to the anal. Length of caudal 3\frac{3}{4} to 4\frac{1}{4} in the total length.† Scales—comparatively large, lineated, but with almost smooth edges. Colours—brown or bluish-gray superiorly, fading to dull white beneath; ends of all the fins deep black. Iris gray, stained darker superiorly. It may be remarked, as showing the size to which this species attains, that the liver of one at the Government fish-oil factory at Calicut weighed 270lbs.

Habitat. - Seas of India to the Malay Archipelago, and beyond. The example figured (42 inches long), a female, was from the Andamans. This form is very common, having from 24 to 25 teeth only in each jaw.

C. melanopterus, is variously named by the natives: thus Sir W. Elliot received examples termed Caval sorrah, Nella vekal sorrah, Raman sorrah, Mukhan sorrah, Boka sorrah, and Ran sorrah.

13. Carcharias Bleekeri.

Carcharias (Prionodon) Bleekeri, Duméril, Hist. Nat. Poiss. i, p. 367. Carcharias bleekeri, Günther, Catal. viii, p. 370.

* Sir Joseph Fayrer informs me that in a case brought to his hospital at Calcutta, the shark not only divided the soft parts down to the thigh bone in a native, but even made a deep groove on the neck of the femur.

† In Quoy and Gaimard's figure the length of the caudal fin is shown as 3½ in the total: but Duméril (l. c.) observes that the "caudale formant à peu près le quart de la longueur totale," and also that the types are in the Museum. 4 T 2

Length of the preoral portion of the snout equal to the width of the mouth. Nostrils midway between the end of the snout and the mouth. $Teeth-\frac{2}{2}\frac{5}{3}$, the upper triangular with a slightly notched outer border: the lower nearly erect, narrow, and on a broad base. Fins—the dorsal commences a short distance behind the angle of the pectoral: second dorsal opposite to, nearly as long as, but lower than the anal, and elongated posteriorly. Pectoral with its upper edge $4\frac{1}{2}$ to 5 times as long as its lower: caudal 1/4 of the total length. Colours—a deep black spot at the lower edge of the end of the pectoral fin: a second at the end of the inferior lobe of the caudal: no black spot on the first dorsal.

The example or rather remnants of the skin, head, and fins of a "half-grown male," which were shown me at the British Museum, as this species from the Seychelles, give eight inches as the distance from the snout to the first gill-opening; the fish when entire would therefore have been about four feet long. The example is very similar to C. limbatus.

Habitat.—East coast of Africa, Seas of India.

14. Carcharias Ellioti, Plate CLXXXIX, fig. 2.

Length of the preoral portion of the snout equal to the width of the mouth, but less than the distance between the eye and the first gill-opening. A well-developed labial groove along the outer side of the maxilla, and a slight one on the mandible. Eyes rather small. Nostrils rather nearer mouth than to the end of the snout. Gill-openings much wider than the orbit. No trace of any spiracle. $Teeth = \frac{2}{3}\frac{4}{0} \cdot \frac{2}{3}\frac{4}{4}$, the upper nearly triangular without any notch or basal enlargement, very coarsely serrated on both edges: those in the mandible obliquely erect, awl-shaped, becoming smaller and more triangular at the angle of the mouth; the awl-shaped ones have a cusp at either side of the base, below which the outer edge has a few serrations: the external triangular ones are serrated externally. Fins—the first dorsal commences just behind the root of the pectoral, its base being nearer to it than to the ventral: second dorsal smaller than the first, but larger than the anal, before which it commences. Pectoral falciform, its internal margin 1/3 of the length of its outer, the fin reaches to beneath the end of the base of the dorsal. Anal below the last two-thirds of the second dorsal. Caudal 33 in the total length: a well-developed pit before its base. Colours—gray superiorly, becoming nearly white beneath.

This species is the one referred to by Jerdon, M. J. L. and Sc. 1851, p. 148.

Habitat.—Seas of India. The example figured (a skin nearly six feet in length) was from Kurrachee, where it is not uncommon. A very good figure of it exists among Sir Walter Elliot's drawings of Madras fish. It is stated to be termed Puducan or Adugu-pal sorrah, Tamil; and Pal sorrah at Vizagapatam.

15. Carcharias menisorrah, Plate CLXXXIV, fig. 1.

Carcharias (Prionodon) menisorrah, Müll. and Henle, Plagios. p. 46, t. xvii; Bleeker, Plagios. p. 35, t. i, f. 3; Duméril, Hist. Nat. Poiss. i, p. 369.

Carcharias menisorrah, Günther, Catal. viii, p. 371; Klunz. Fisch. Roth. Meer. 1871, p. 660.

Carcharias Malabaricus, Day, Jour. Linn. Society, i, 1871, p. 529.

Karamoottee sorrah and Ciga sorrah, Tel.

Preoral portion of snout nearly or quite as long as the mouth is wide: the width of the head equals the distance from the angle of the mouth to the end of the snout. A very small groove at the angle of the mouth extending a short distance on to the upper jaw. Teeth-twenty-eight in the upper jaw, they are oblique, triangular, notched externally, and serrated in the whole extent of their cusps: lower teeth ercet, slender, lanceolate, not serrated and having broad bases. Fins—pectoral not so long as head, one fifth longer than broad at its extremity, it is scarcely emarginate, its inner margin equals about half the length of the onter: base of the second dorsal slightly more than half of that of the first dorsal, it is opposite the anal, and almost as large as it. Posterior end of the dorsal fin is at an equal distance from the ventrals as its anterior end is from the root of the pectoral. Upper edge of the caudal almost straight, its length being slightly more than the interval between its base and the origin of the ventral. Colours—gray above, white below: upper half of the second dorsal deep black. In Müller and Henle, and in Günther's Catalogue the black is omitted, so it may occasionally be absent: it is adverted to by Bleeker, and also present in a fine specimen I have received from Leyden labelled by Dr. Bleeker.

Habitat.—Řed Sea to the Malay Archipelago. The example figured (nineteen inches in length) was from Calicut. It attains twelve feet or more in length.

16. Carcharias limbatus, Plate CLXXXIV, fig. 2.

Wien. 1867, lvi, p. 356.

Digitized by Google

Carcharias limbatus, Günther, Catal. viii, p. 373. Carcharias Ehrenbergi, Klunz. Fisch. R. Meer. 1871, p. 661.

Length of preoral portion of the snout about equal to the width of the mouth, and is slightly less than the distance between the eye and the first gill-opening: a short groove at the angle of the mouth scarcely extending on to the upper jaw. Eyes—small: gill-openings about twice the size of the eye. Teeth—erect, somewhat constricted above the base, which is broad, the upper broader than those in the lower jaw, although both are of somewhat similar shape: both serrated, but most distinctly in the upper jaw: in the young the teeth in the mandibles usually appear to have smooth edges, but under the microscope* the rudiments of serrations are perceptible. Fins—the length of the base of the anal is equal to about 2/3 of its extent from the base of the ventral: the pectoral extends to below or even to beyond the hind edge of the dorsal fin: its posterior edge is slightly concave: its internal edge is equal to from 3 to $3\frac{1}{3}$ in its outer. Dorsal commences over the inner angle of the base of the pectoral: second dorsal arises above or slightly posterior to the origin of the anal, than which it is somewhat smaller. Length of caudal $3\frac{1}{3}$ to $3\frac{1}{2}$ in that of the total. Colours—gray superiorly, becoming white on the sides and beneath. Fins dark gray: in the immature (as the example figured) the outer extremity of pectoral, lobe of caudal, and the margins of the fins, dark black: ventral and anal white edged. As age advances, as at two feet, the second dorsal becomes black tipped and the anal has a darker edge.

Habitat.—The example figured (16.8 inches long) was from the Malabar coast of India. It attains at least six feet in length. It is very common along the sea borders of India, and appears to frequent the tropical parts of the Atlantic, the Pacific coast of Central America, and to extend through the Indian Ocean.

17. Carcharias Temminckii.

Carcharias (Prionodon) Temminckii, Müll. and Henle, Plagios. p. 48, t. xviii. Squalus (Carcharias) Temminckii, Blyth, Journ. As. Soc. of Bengal, 1860, p. 36. Lamiopsis Temminckii, Gill, Ann. Lyc. Nat. Hist. New York, vii, p. 410. Carcharias temminckii, Günther, Catal. viii, p. 374.

Length of the preoral portion of the snout equals about 4/5 the width of the mouth. Nostrils nearer to the mouth than to the end of the snout. $Tecth = \frac{3.6-3.8}{3.8-\frac{1}{4}.8}$, upper rather narrow with a broad base, erect and scrrated: the lower erect, entire, awl-shaped: the teeth near the outer angle of the jaws very small. Fins—first dorsal inserted midway between the roots of the pectoral and ventral fins: pectoral with its upper edge nearly three times that of the lower. Second dorsal opposite anal, and nearly as large as the first. Colours—uniform.

Habitat.—Seas of India.

Genus, 2-Hemigaleus, Bleeker.

Chanogaleus, Gill.

Spiracles minute and behind the eye. Membrana nictitans present. A pit before the root of the caudal fin both above and below. Snout longitudinally produced. Mouth crescentic, with labial folds. Teeth in the upper jaw denticulated, not so in the lower. The first dorsal fin, which is destitute of a spine, is placed opposite the interspace between the pectoral and ventral: caudal with a single notch.

These fishes have been divided from Carcharias on account of the existence of a rudimentary spiracle behind the eye, and likewise by the labial folds being developed in all known species but which is rare in Carcharias (see C. Walbeehmii, p. 712).

Habitat.—Coromandel coast of India to the Malay Archipelago.

1. Hemigaleus Balfouri, Plate CLXXXV, fig. 4.

Length of the preoral portion of the snout slightly exceeding the width of the mouth, and not quite equalling the distance between the eye and the first gill-opening. Spiracle minute, situated about 1/2 a diameter of the eye posterior to the orbit. A groove at the angle of the mouth extending some distance along either jaw. Nostrils situated nearer to the mouth than to the end of the snout. The distance between the outer angles of the nostrils equal to the width of the mouth. Gill-openings at least twice the width of the orbit. Teeth—2.4, those in the upper jaw smooth, notched externally, or with about three denticulations along the outer side of the base: those on the lower jaw of a slightly smaller size, erect and smooth. Fins—pectoral falciform, extending to below the first third of the base of the dorsal fin, its internal nearly equalling 1/3 of its outer margin. First dorsal (with about 24 rays) having its base almost midway between the end of the base of the pectoral and the origin of the ventral fins. Second dorsal (with about fifteen rays) commencing slightly in advance of the anal, the length of its base equal to rather above 1/2 of that of the first dorsal, while it is rather larger than the anal. Caudal fin equal to about 5 in the total length, and with a distinct pit at its root. Colours—dark brown, fins gray, the second dorsal with a dark summit.

* I have examined one example this size in which none of the teeth were apparantly serrated, but if placed under 2-inch power of the microscope serrations are observed to be commencing, the edges of the cusp being crenulated. The black marks on the dorsals, pectoral and caudal, were well marked, but they were absent from the ventral and anal.

The example figured is from Sir Walter Elliot's collection, and was obtained at Waltair, on the Coromandel coast. It is a male 32.5 inches in length. I take this opportunity of dedicating this new fish to Surgeon-General E. Balfour, late of the Madras Medical Service, the scientific founder of the Madras Museum, and who first directed my attention to collecting the fishes of India.

Habitat.—Coromandel coast of India.

Genus, 3-GALEOCERDO, Müller and Henle.

Spiracles small. Membrana nictitans present. Mouth crescentic. Teeth oblique, serrated on either edge, and with a deep notch on the outer margin. The first dorsal spineless, placed opposite the interspace between the pectoral and ventral fins: caudal with a double notch. A pit on the tail, both above and below, at the base of the caudal fin.

Sharks of this genus are much dreaded in India, the native fishermen distinguishing between those forms with long awl-shaped but smooth-edged teeth, from others having elongated or triangular cusps with serrated edges. The former can be captured by lines and even by nets: but the latter immediately cut through nets and sever lines, rendering it necessary to attach the hooks to chains. Sharks seem to prefer their food a little high, and therefore the natives bury the bait in the ground for a day or more before baiting their hooks with it.

Geographical distribution. - Seas of the Tropics, also of temperate and Arctic regions.

SYNOPSIS OF SPECIES.

1. Galeocerdo Rayneri. Caudal fin $3\frac{1}{2}$ to 4 in the total length. Teeth $\frac{2}{3}\frac{3}{3}$, denticulated, and of equal size in both jaws. With dark spots. Indian and Australian seas.

2. Galeocerdo tigrinus. Caudal fin 3 to $3\frac{1}{4}$ in the total length. Teeth denticulated, and rather smaller in the lower than in the upper jaw. Red Sea, Indian Ocean to Japan, and beyond.

1. Galeocerdo Rayneri, Plate CLXXXVII, fig. 3.

Galeocerdo tigrinus, Gray, Chondrop. p. 54; Blyth, J. A. S. of Beng. 1860, p. 36. Galeocerdo Rayneri, McDonald and Barron, Proc. Zool. Soc. 1868, p. 368, pl. xxxii; Günther, Catal. viii, p. 377.

Wulluven sorrah, Tam.: Kettalam sorrah, Tel.

Length of preoral portion of the snout much less than the width of the mouth. A groove at the angle of the mouth extending some distance along the side of the maxilla: nostrils nearer the end of the snout than the mouth. Gill-openings not so wide as the orbit. Spiracle small. Eye—rather large. Teeth—23/23, large, of equal size in both jaws, compressed and serrated in their whole extent in both jaws, as well as notched externally above the base. Fins—pectoral extends to beneath the anterior third of the first dorsal, it is falciform in shape. Origin of first dorsal a short distance behind the base of the pectoral, but nearer to that fin than to the ventral, which latter is midway between the hind edge of the first dorsal and the origin of the anal. Second dorsal above the anal, the two being of about equal size. Length of the caudal $3\frac{1}{4}$ to 4 in the total length, apparently comparatively decreasing in length with age. Colours—dark gray superiorly, becoming dull white beneath; cheeks and lower surface of the snout yellowish. Body, from a short distance behind the gill-openings, with numerous large black spots and vertical bars. Fins gray, the first dorsal with irregular vertical bands.

This fish attains to a considerable size in the Indian seas, where it is not very numerous. It is exceedingly fierce; and Jerdon remarks that it is very cunning and swells itself out so as to appear like a floating mass of animal substance, and having thus decoyed its prey it immediately attacks it. It eats everything, even seasnakes. Sir W. Elliot observes that he obtained an example of this voracious shark 12 ft. 4 in. long. In its stomach were the remains of fish of various sizes and several shin-bones of beef partially digested. Another example, $8\frac{1}{4}$ feet long, had the remains of a sea-snake ($Hydrus\ nigrocinctus$) and of a siluroid fish. A fine pair of jaws of this species (15 inches across the gape), from Kurrachee, exists in the British Museum; it is labelled $Carcharius\ fisciatus\ ?$.

Habitat.—Indian and Australian Seas; attaining upwards of twelve feet in length.

2. Galeocerdo tigrinus.

? Galeus maculatus, Ranzani, Nov. Comm. Ac. Bonom. iv, 1840, p. 68, t. viii.

Galeocerdo tigrinus, Müll. and Henle, Plagios. p. 59, t. xxiii; Bleeker, Beng. p. 80; Gill, Pro. Ac. Nat. Sc. Phil. 1864, p. 263; Duméril, Hist. Nat. Poiss. i, p. 393; Günther, Catal. viii, p. 378; Klunz. Fisch. Roth.

Meer. 1871, p. 663.

Galeocerdo maculatus, Poey, Repert, Fis.-nat. Cuba, 1868, p. 453.

Length of the preoral portion of the snout equal to 1/2 the width of the mouth and slightly less than the distance between the inner angles of the nostrils. A long labial fold along the edge of the upper jaw. Teeth—in lower jaw not so large as those in the upper, denticulated in both jaws, and the denticulations at the base of each cusp also serrated, more especially in the lower jaw. Fins—the first dorsal commences above the angle of

the pectoral: second dorsal arises slightly in advance of the anal. Caudal 3 to $3\frac{1}{4}$ in the total length, and considerably (one-third) exceeding the length of the interspace between the two dorsal fins. Colours—gray superiorly, becoming slightly lighter on the sides and beneath. Numerous brown or dark gray spots over the body.

Habitat.—Red Sea, seas of India to Japan, and beyond.

Second group-Zygænina.

Head produced laterally into the shape of a hammer. Nostrils on front edge of head. Teeth oblique, with a single cusp, having sharp and smooth edges.

Genus, 4-ZYGÆNA,* Cuvier.

Cestracion Klein: Cestrorhinus, Blainv.: Sphyrna (Raf.), Müll. and Henle: Eusphyrna and Reniceps, Gill.

The anterior portion of the head is broad, flattened, and laterally elongated, with the eyes situated at its lateral extremities and the nostrils at its fore border. A membrana nictitans present. Spiracles absent. Mouth crescentic. Teeth similar in both jaws, oblique and notched. The first dorsal fin spineless, situated above the interspace between the pectoral and the ventral: caudal with one notch, and a pit at the commencement of the fin.

This genus of sharks is reputed to be very dangerous in some localities. The young are captured along the shores of India in large numbers.

SYNOPSIS OF SPECIES.

1. Zygæna Blochii. Each lateral expansion of the side of the head two or three times as long as broad. Indian Ocean.

2. Zygæna malleus. The length of the hind edge of each lateral expansion of the head nearly or quite

equal to its width near the eye. Tropical and temperate seas.

3. Zygwna tudes. Anterior edge of head curved but not continuous with the lateral one: the length of the hind edge of each lateral expansion is less than its width near the eyes. Tropical and temperate seas.

1. Zygæna Blochii, Plate CLXXXIV, fig. 4.

Cuv. Règne Anim: Val. Mém. Mus. ix, p. 227, t. xi, f. 2: Bennett, Life of Raffles, p. 694: Cantor, Quart. Med. Journ. Cal. 1837, and Trans. Med. and Phys. Soc. Cal. viii, pt. 2, Appendix, p. ccxi, and Ann. and Mag.

1845, xvi, p. 372; Ginther, Catal. viii, p. 380.

Koman sorrah, Tam.: Sappa sorrah, Tel.

Each lateral expansion of the side of the head from twice to thrice as long as broad, and with a deep groove along the anterior edge, reaching externally nearly as far as the orbit. The posterior edge of the lateral expansion about as long as its anterior edge, while the external edge is nearly straight. Nostril much nearer the expansion about as long as its anterior edge, while the external edge is nearly straight. Nostril much nearer the mouth than the eye. Eyes—situated near the upper angle of the external edge of the lobe of the head. Teeth—oblique, externally notched and smooth in their entire extent. Fins—the dorsal arises slightly behind the base of the pectoral, extending nearly half way to above the ventral: second dorsal arising above the posterior half of the anal, than which it is much smaller. Colours—of a deep gray or brownish-gray, becoming lighter beneath: the fins are usually of a slightly deeper colour than the body.

This is the commonest form on the Malabar coast of India, where the fishermen consider it attains to a very large size. Blyth found it to be also the most common species of the genus on the coast of Bengal, observing that it rarely exceeded four feet in length.

Habitat.—Seas of India to the Malay Archipelago, and beyond. The example figured (17.5 inches long)

came from Malabar.

Cestracion tudes, Duméril, Hist. Nat. Poiss. i, p. 384.

Anterior edge of head curved, but the front margin is not continuous with the lateral one: the length of its hind margin less than its width near the eye. Eyes—situated just below the junction of the anterior and outer edges of the snout. Nostril close to the eye, and a groove running along the anterior edge of the head. Teeth-oblique, with a notched outer edge. Fins-dorsal arises above the hind margin of the inner edge of the pectoral fin, its height equals the length of the pectoral: second dorsal over the hind half of the anal: length of the base of the anal extends 2/3 of the distance to the ventral: caudal 3 to $3\frac{1}{3}$ in the total length. Colours—Gray, becoming lighter beneath: first dorsal fin very dark, the upper portion of the second dorsal and the lower caudal lobe deep black in newly captured examples, the colour fading after they have been some time in spirit. One example, captured at Cochin, Dec. 27th, 1872, besides the black marks on the fins mentioned, had the hind edge of the dorsal and the end of the pectorals dark.

Habitat.—Mediterranean, Indian Ocean and Archipelago, also tropical parts of the Atlantic. It attains several feet in length.

Third group—Mustelina.

Teeth small, having a central, and one or two smaller lateral cusps: or the teeth may be obtuse.

Genus, 5—TRIENODON, Müller and Henle.

No spiracles. Membrana nictitans present. Mouth crescentic, with a pit behind its angle. Teeth numerous in both jaws and consisting of one central cusp and a smaller lateral one on either side. First dorsal spineless placed opposite the interspace between the pectoral and ventral jins. Lower cawlal lobe distinct. A pit at the root of the caudal fin.

Triænodon obtusus, Plate CLXXXIX, fig. 3.

Snout short and rounded, the distance between the mouth and the end of the snout equals about 1/2 the width of the mouth. Nostrils nearer end of snout than the mouth, each with a flap. Eye of moderate size. Gill-openings rather wider than the orbit. No spiracle. Teeth—with one central and a small lateral cusp on either side. Fins—the first dorsal commences behind the inner angle of the pectoral and its base does not extend to above the ventral. Second dorsal not quite 1/2 as large as the first and situated above the anal. Pectoral reaches to below the middle of the first dorsal: caudal fin nearly 1/4 of the total length. Coloursdark above, becoming lighter beneath.

This species is allied to T. obesus, Rüppell, but its first dorsal fin is more advanced, and its second dorsal considerably smaller than shown in Rüppell's figure or the examples in the British Museum.

Habitat.—One example, nineteen inches in length, was obtained at Kurrachee: it is a young male.

Genus, 6—Mustelus, Cuvier.

Small spiracles behind the eyes. Mouth crescentic, with long labial folds. Membrana nictitans present. Teeth small, numerous, similar in both jaws, pavement like, obtuse or with indistinct cusps. The first dorsal fin spineless, situated above the interspace between the pectoral and ventral: the second nearly as large as the first: caudal without a distinct lower lobe, and no pit at the commencement of the fin.

Geographical distribution.—Seas of tropical and temperate regions. Not recorded from the Red Sea.

Mustelus manazo, Plate CLXXXVI, fig. 3.

Mustelus vulgaris, Temm. and Schleg. Fauna Japon, Poiss. p. 303, t. cxxxiv. Mustelus manazo, Bleeker, Japan, p. 126; Gunther, Catal. viii, p. 387. Pa sorrah, Tel.

Snout produced and pointed, the length of its preoral portion equalling the width of the mouth (or 1/4 more in the fœtus), which latter is somewhat angular. A well-developed labial fold at the angles of the mouth: membrana nictitans very distinct. Spiracle behind and much smaller than the eye. Teeth—rhombic, and destitute of any distinct cusp. Fins—the first dorsal arises opposite the posterior end of the base of the pectoral, and does not extend to above the anal: the second dorsal smaller than the first, but the length of the bases of the two about the same. Pectoral reaches to below centre of first dorsal: anal commences beneath the posterior half of the second dorsal and is smaller than it. Caudal equal to $4\frac{1}{3}$ in the total length, its lower lobe moderately developed and notched. Colours—reddish gray superiorly, becoming dull white beneath. Posterior moderately developed and notched. Colours—reddish gray superiorly, becoming dull white beneath. Posterior extremity of the caudal of a dark colour.

Habitat.—Seas of India to Japan. I obtained a female (16.5 inches in length) at Kurrachee, and which had several young inside. The one figured, from the same place, is 27 inches in length.

FAMILY, II—LAMNIDÆ.

Spiracles, if present, minute. No membrana nictitans. Mouth inferior and crescentic. Nostrils not communicating with the mouth. First dorsal spineless, and placed opposite the interspace between the pectoral and ventral fins: an anal fin present.

I have (p. 713) described a shark, Carcharias tricuspidatus, the teeth of which so closely resemble those seen in Odontaspis, that specimens have been erroneously referred not only to that Genus but to the O. Americanus. The absence or presence of the pit at the root of the caudal fin is one character which at once distinguishes the two forms, for if they were identical species the character of the pit at the base of the caudal fin as a distinguishing guide would have to be given up, not only as a generic but even as a specific character.

Genus 1—LAMNA, Cuvier.

Oxyrhina, Agassiz.

Spiracles, if present, minute. No membrana nictitans. Mouth wide. Gill-openings large. Teeth large, awl-shaped, smooth or sometimes with a small lateral basal cusp on either side. The first dorsal fin spineless, placed opposite the interspace between the bases of the pectoral and ventral fins. Lower caudal lobe large. A keel along the side of the tail. A pit at the base of the caudal fin.

Oxyrhina punctata, Duméril, l. c. p. 409.

Lamna spallanzanii, Günther, Catal. viii, p. 390; Klunz. Fische Roth. Meer. 1871, p. 669.

Snout pointed, angle of the mouth about midway between the nostril and the first gill-opening. Gill-openings very wide. $\frac{13}{13}$ on either side, awl-shaped, with sharp but entire lateral edges, and destitute of basal cusps: the third on either side of the symphysis of the upper jaw smaller than those on either side of it. Fins—the base of the first dorsal rather nearer the pectoral than the ventral fin. Pectoral falciform, its inner being one-fourth of the length of its outer margin. Second dorsal and anal small, situated opposite one another. The keel on the side of the tail commences anterior to the base of the second dorsal and anal fins. Colours—gray, becoming lighter beneath.

Habitat.—Red Sea and Indian Ocean, also the Atlantic and Mediterranean. The figure is from one of

Sir W. Elliot's drawings, which was taken from an example captured at Madras. It attains to a very

large size.

FAMILY, III—NOTIDANIDÆ.

Spiracles small and on the side of the neck. No membrana nictitans. Gill-openings six or seven. A single spineless dorsal fin placed nearly opposite to the anal: lower caudal lobe present. No pit at the root of the caudal fin.

Genus, 1-Notidanus, Cuvier.

Hexanchus and Heptanchus, Rafin.: Monopterhinus, pt. Blainv.

Spiracles small and on the side of the neck. No membrana nicitians. Mouth crescentic. No labial fold. Gill-openings six or seven, and wide. Teeth in the upper jaw consisting of one or two pairs that are awl-shaped, followed by six broader ones, which have one strong and several smaller cusps. In the lower jaw six large comb-like ones on either side, and some smaller lateral ones. A single, spineless, dorsal fin placed opposite the anal: lower caulal lobe present. No pit at the root of the caudal fin.

Geographical distribution.—Seas of tropical and temperate regions.

Notidanus Indicus, Plate CLXXXIX, fig. 4.

Cuv. Règn. Anim.: Agassiz, Poiss. Foss. iii, pp. 92, 217, t. E. f. 1 (teeth); Günther, Catal. viii, p. 398.

Heptanchus maculatus, Girard, U. St. Pacif. Exp. Fish. p. 367.

Notorhynchus borealis, Gill, l. c. 1864, p. 150.

Snout rounded and obtuse. Cleft of mouth wider than deep. Teeth—opposite the symphysis of the upper jaw is a tooth having a single cusp, those on either side being stronger and denticulated. The central tooth in the lower jaw has no median, but two or three lateral cusps on either side. Colours—gray, with dark blotches and marks.

Sir W. Elliot obtained an example at Madras, and had a figure taken of it.

Habitat.—Seas of India and South Africa to California. The figure is from a stuffed example in the British Museum, about $4\frac{1}{2}$ feet in length.

Digitized by Google

FAMILY, IV—SCYLLIIDÆ.

Spiracles present. Eye without any nictitating membrane. Mouth inferior. Teeth small, several rows being generally in use. The first dorsal fin spineless, placed above or behind the ventrals: an anal present, which may be in front of, below, or behind the second dorsal.

SYNOPSIS OF INDIAN GENERA.

A.—Nasal and buccal cavities separate.

1. Scyllium. The upper edge of the caudal fin smooth.

B.—Nasal and buccal cavities confluent.

- 2. Ginglymostoma. Small spiracles behind the eyes. The second dorsal and anal fins are nearly opposite one another, p. 725.
 - 3. Stegostoma. Snout obtuse. Caudal portion of body and fin very long, p. 725.
- 4. Chiloscyllium. No appendages on the head. Spiracles below the eye and well developed. Anal fin some distance posterior to the second dorsal, p. 726.

A.—Nasal and buccal cavities separate.

Genus, 1-Scyllium, Cuvier.

Scylliorhinus, Halælurus, Poroderma, and Cephaloscyllium, Gill.

Spiracles behind the eye. Nasal and buccal cavities distinct. Teeth small, in several rows: usually with a central and one or two lateral cusps. Origin of anal fin in advance of that of the second dorsal: upper edge of caudal not serrated.

These sharks, or "dog fishes," do not attain to any large size, but are much dreaded by fishermen, as they get entangled in their nets, from which great injury occurs. Their eggs are similar to those of the Rays. Habitat.—Tropical and temperate seas.

SYNOPSIS OF SPECIES.

1. Scyllium marmoratum. Nasal valves confluent with a single transverse uninterrupted flap and a well-developed labial fold. Brown spots, bands, or ocelli. Seas of India to the Malay Archipelago, and beyond.

2. Scyllium Capense. Nasal valves not confluent and separated from one another by a considerable interspace. Dark, lighter beneath. Seas of India to the Cape.

1. Scyllium marmoratum, Plate CXC, fig. 2.

Bennett, Life of Sir S. Raffles, p. 693; Günther, Catal. viii, p. 400.

Scyllium maculatum, Gray and Hardw. Ind. Zool.; Richards. Ich. China, p. 193; Müller and Henle, Plagios. p. 5, t. vii; Cantor, Catal. Mal. Fish. p. 391; Bleeker, Plagios. p. 16, and Beng. p. 80; Duméril, Hist. Nat. Poiss. i, p. 319; Kner, Nov. Fisc. p. 412 (not Bl. Sch.).

Length of the snout equals the width of the mouth. Nasal valves confluent in the form of a single broad flap, with a free posterior edge, and no cirrus. A well developed labial fold. Gill-openings as wide as the orbit. Teeth—small. Fins—first dorsal commences just behind the ventral: the second dorsal slightly larger than the first and has the anal beneath its anterior 1/2 or 2/3. Colours—of a tawny brown, becoming lighter beneath. Lines of spots, some of which occasionally become confluent, exist along the body: there may also be bands or ocelli.

This species, so far as I am aware, does not appear to be common in India, where I never met with an

Habitat.—Seas of India to the Malay Archipelago. The figure is taken from Hardwicke's type of Scyllium maculatum, 18 inches in length, and still in the British Museum.

5. Scyllium Capense, Plate CXC, fig. 1.

Müller and Henle, Plagiost. p. 11; Duméril, Hist. Nat. Poiss. i, p. 320; Günther, Catal. viii, p. 404.

Snout obtuse. Nasal valves distinct, separated from one another by a considerable interspace, and having no prominent cirrus. No labial fold to the upper jaw, but a short one on the lower. Gill-openings narrow, not so wide as the orbit. Teeth-minute. Fins-the first dorsal is inserted rather nearer the anal than to the base of the ventral: the second dorsal situated entirely behind the anal. Colours-brown, lightest beneath. Body with light vertical bands and some white blotches.

Habitat.—The only reason for recording this as an Indian species is due to an example at the British Museum being thus marked, and from which the figure is taken. It is stuffed and about 40 inches in length.

B.—Nasal and buccal cavities confluent.

Genus, 2—GINGLYMOSTOMA, Müller and Henle.

Nebrius, Rüppell.

A minute spiracle behind the eye which also is minute. A quadrangular flap formed before the mouth by the conjoined nasal valves, and which has a free cirrus on either side. A superior and an inferior lip, the latter not extending across the symphysis. Nasal and buccal cavities confluent. Teeth either in many rows with a strong median and one or two smaller lateral cusps: or else in merely about three rows of which the foremost only is in use, and each tooth with a convex and serrated edge. Fourth and fifth gill-openings situated close together. Dorsal fins spineless, the first above or behind the ventrals, the second rather in advance of or opposite to the anal.

Habitat.—Red Sea, Indian Ocean to the Malay Archipelago; also tropical parts of the Atlantic.

1. Ginglymostoma Mülleri.

Ginglymostoma concolor, Müll. and Henl. Plagios. p. 22, t. vi (not Rüppell); Bleeker, Beng. p. 80; Duméril, Hist. Nat. Poiss. i, p. 334.

Ginglymostoma Mülleri, Günther, Catal. viii, p. 408; Klunz. Fisch. R. Meer. 1871, p. 670.

Snout very short, its length not equalling the width of the mouth. Nasal cirrus short, reaching to the edge of the upper lip. Teeth—in many rows, each with a large central cusp, and three or four lateral ones on either side. Fins—first dorsal opposite the ventral, angles of all the paired fins pointed: second dorsal slightly in advance of the anal, but rather smaller than it or than the first dorsal. Caudal nearly 1/3 of the total length.

Habitat.—India. Said to attain $8\frac{1}{2}$ feet in length.

Genus, 3—Stegostoma. Müller and Henle.

Spiracles about the size of the small eye behind which they are situated. Fourth and fifth gill-openings close together. Nasal and buccal cavities confluent. Snout obtuse: upper lip thick with a cirrus on either side. A well-developed labial fold round the angle of the mouth. Teeth small, sometimes trilobed, the dental plate being almost quadrangular. Two spineless dorsal fins, the first above the ventral, the second anterior to the anal, which is near the caudal, the latter being very elongate.

Geographical distribution.—From the Red Sea and East coast of Africa, through the seas of India to the Malay Archipelago, and Formosa.

Pollee-makum, Komrasi and Oorookoolti sorrah, also Potrava (when young) Tel.; Corungun sorrah, "monkey-mouthed shark," Tam.

Head as broad as long. Eye-small, with the spiracle just behind it. Upper lip very thick, like a quadrangular pad, with a barbel on either side. A distinct labial fold round the angle of the mouth, which is slightly nearer the eye than to the end of the snout. Teeth—small, and trilobed. Fins—the origin of the first dorsal is a little posterior to the base of the ventral, it is about as high in front as its base is long, and larger than the second dorsal, which commences a short distance behind it and anterior to the anal. Caudal fin very long, being about 1/2 of the total length and with notch near its lower extremity. A low median, tubercular dorsal ridge, and sometimes another on either side of dorsal fin. Colours- (young) white or buff, which are in the form of markings, the fish appearing black, with narrow white lines or bands across the head and body, between which are white spots: these take on various forms in different examples. Adults—tawny, or with more or less transverse bands of rounded spots, the colour of the fish being brownish.

The favourite food of this fish is Molluscs and Crustacea.

Habitat.—Red Sea, East coast of Africa, seas of India to the Malay Archipelago, and beyond; attaining at least 6 feet in length. It is common at Madras, where the example figured (12 inches long) was captured.

Genus, 4—CHILOSCYLLIUM, Müll. and Henle.

Hemiscyllium, Müll. and Henle.

Spiracle below the eye. Fourth and fifth gill-openings close together. Nasal and buccal cavities confluent: nasal valve with a barbel. Lower lip continuous or interrupted in the centre. Teeth small, triangular, with or destitute of, lateral cusps. Two spineless dorsal fins, the first above or behind the ventrals, the second considerably anterior to the anal, which is near the caudal.

Geographical distribution.—Seas of India to the Malay Archipelago, and Australia.

SYNOPSIS OF INDIVIDUAL SPECIES.

1. Chiloscyllium Indicum-Lower lip with the labial fold uninterrupted: angle of mouth nearer eye than end of snout. Dark cross-bands, sometimes enclosing white spots: or even uniform brown. Seas of India to the Malay Archipelago, and beyond.

Chiloscullium indicum, Günther, Catal. viii, p. 411.

Corungun sorrah, Tam.; Ettee, Mal.: Poos-hee, Belooch.

Head rather depressed and flatter inferiorly than superiorly. Eyes—small, with the spiracle (which is of about the same size) below and slightly posterior to it. Lips surround the mouth, the lower labial fold being continuous: the mouth at its angle 1/3 nearer the eye than to the end of the snout, which is obtuse. Nasal valve with an elongated barbel. Teeth—small, triangular, with lateral cusps. Fins—the origin of the first dorsal is just posterior to the base of the ventral, anteriorly it is slightly higher than long at its base, which latter distance equals the length between the two dorsal fins, both of which have their anterior and upper edges rounded: the second fin being somewhat smaller than the first and ending some distance anterior to the origin of the anal. Anal notched, terminating close to the caudal fin, which is also notched posteriorly, and about $5\frac{1}{2}$ in the total length. From one to three smooth or tubercular ridges may exist along the back, or such may be entirely absent. Colours—these vary exceedingly: they are usually gray with dark, or even black, cross-bands, which may or may not include white spots: sometimes the cross-bands break up into spots or bands, having dark edges: or the fish is simply of a reddish brown colour.

Habitat.—Seas of India to the Malay Archipelago, and beyond.

SUB-ORDER, II—BATOIDEI.

Spiracles present: gill-openings in five pairs, and on the ventral surface of the body. Body depressed, forming, due to largely-developed pectoral fins, a more or less flat disk, and having usually a thin and slender tail. Dorsal fin, when present, in the caudal portion of the body: anal absent.

Skates and rays exist in enormous numbers in the Indian seas, where they attain to a great size, and some are dreaded by fishermen because of the wounds inflicted by their caudal spines, while others cause great injury to the oysters. Skates are gregarious, and may suddenly arrive to the dismay of the owner of an oyster bed, as they appear to remain so long as any molluses are to be obtained. Rays lie concealed in the sand, and are reputed to be able to suddenly encircle fish or prey swimming above them with their long whip-like tails, and then wound them with their serrated tail spine. Their skins were formerly valuable as shagreen, being considered superior to those of sharks, owing to the scales being of somewhat larger dimensions. Irrespective of being employed for shagreen, they are occasionally used as rasps or sand-paper, to give the first surface to wood or horn which it is desired to polish. Their fins are exported along with those of the sharks to China, where they are used for soups, while from their livers an oil is extracted.

The thin horny cases, inside which are the feetal rays, are more square in form and comparatively

The thin horny cases, inside which are the feetal rays, are more square in form and comparatively smaller than what are observed among the sharks. Many of these cases are square, with a horn-like projection from each corner.

SYNOPSIS OF FAMILIES.

I. Pristide. A flattened snout, having lateral teeth, rendering it saw-like, p. 728.

II. RHINOBATIDE. Pectoral fins not continued to the snout. Trunk gradually passing into the tail, which has two dorsals and a caudal fin, p. 730.

III. TORPEDINIDE. Trunk a broad smooth disk. Usually dorsal and caudal fins. An electric

organ, p. 733.

IV. RAJIDÆ. Trunk a broad and generally a rough disk. Pectoral fins extend on to the snout. A fold

along either side of the tail: no serrated caudal spine. No electric organ, p. 735.

V. TRYGONIDÆ. Pectoral fins extend on to and are confluent at the snout. No fold along side of tail:

which latter is usually armed with a serrated spine, p. 736.

VI. MYLIOBATIDE. Pectoral fins do not extend on to the side of the head: snout with a detached pair of fins, p. 742.

FAMILY, I—PRISTIDÆ.

Saw-fishes.

Snout much produced, flattened, and having a saw-like appearance, due to the existence of large teeth on its lateral edges.

Dr. J. E. Gray (Proc. Zool. Soc. 1864,* p. 163), described the endoskeleton of one of these teeth forming the saw, but without recognising from whence it had been derived. Professor Kölliker having examined the same specimen microscopically, ascertained it to be part of the endoskeleton of a Plagiostome. The endoskeleton of a tooth of the saw consists of from three to five hollow tubes, tapering towards their extremity, and covered with an osseous deposit which is perforated with fine holes. These teeth vary both in size and number in the same species, rendering them unsuitable as specific, but admissible as individual distinctions.

Great injuries are inflicted by these fishes, which strike sideways with their formidable snouts; and although not personally a witness to the fact, I have been informed on native authority, that large ones have been known to cut a bather entirely in two. The largest example I saw was off the coast of Sind (Pristis zysron): it measured over 16 feet, the rostrum being 4 ft. 2 in. in length. A P. cuspidatus, 14 feet long, captured at Calicut, was found to have a liver weighing 185 lbs. which was taken to the oil factory when I was present.

At Gwadur, on the Meckran coast, I found that the fishermen of all religions presented the saws of these fishes at a small temple, where they were hung up inside or piled round the outside. The priest was expected to pray for success in their takes and a safe return to shore. At the Andaman Islands the Aborigines wishing to make a suitable offering to Mr. Homfray, their superintendent, attacked an enormous saw-fish, which they harpooned, and eventually secured at the risk of their lives. They presented him with the rostrum.

Geographical distribution.—Seas of tropical and temperate regions. The Family consists of a single Genus.

Genus, 1—Pristis, Latham.

Body elongated and depressed. Gill-openings inferior and of moderate width. Spiracle wide and posterior to the eye, which latter has no nicitating membrane. Nostrils inferior. Teeth minute and obtuse. Dorsal fin spineless, the first quite or nearly opposite the ventrals: front edge of pectoral free.

SYNOPSIS OF SPECIES.

A.—Caudal fin with a distinct lower lobe.

1. Pristis cuspidatus-From twenty-three to thirty-five pairs of broad teeth on the snout, but none present on its basal fourth or fifth: in the young their hinder edge is barbed. Dorsal fin arises behind the root of the ventral: caudal with a lower lobe. Seas of India to the Malay Archipelago, ascending rivers.

B.—Caudal fin without any distinct lower lobe.

- 2. Pristis Perrotteti—From seventeen to twenty pairs of teeth on the rostrum, commencing at its base. Dorsal fin almost entirely in advance of ventrals. No distinct lower caudal lobe. Tropical seas, entering
- 3. Pristis Zysron-From twenty-five to thirty-two pairs of teeth on the rostrum, commencing near its base. Dorsal fin almost entirely posterior to the ventrals. No lower caudal lobe. Seas of India to the Malay Archipelago.

A .- Caudal fin with a distinct lower lobe.

Rostrum narrow and of about the same width throughout, armed with from twenty-three to thirty-five

* See Myriosteon Higginsii Ann. and Mag. Nat. Hist. 1870, v, p. 366.

pairs of broad teeth, those on one side (generally the right) often exceeding in number those on the other. This teething is absent in the fœtus, while in the immature it only exists in the anterior 3/4 of the snout, and in the adult a considerable portion of the base is unarmed. Usually the anterior six pairs of teeth are opposite one another, and the posterior teeth in the immature are mostly barbed behind. Mouth transverse, with a membranous valve (fringed in the young) behind the teeth in the upper jaw, and with a deep notch near the symphysis. The pupil is transverse, with a semi-circular flap above and another below; these flaps are easily raised, depressed, or expanded, according to the stimulus of light received, which they can partially or entirely exclude: lens very soft. Spiracles large, nearly transverse, posterior to the eyes, half a diameter of the eye in width. Nostrils situated about one-and-a-half transverse lengths from the mouth: they have long triangular narrow valves in their upper, and a hemlike one at their lower margins: their distance asunder posteriorly equals their length, and is twice as much anteriorly. Teeth—small, longer than broad. Fins—the first dorsal commences just behind the ventral: the second dorsal midway between the posterior extremity of the first dorsal and the base of the caudal. The two dorsals are of equal size, their upper margins concave, and the posterior lobe of each produced. Posterior margin of the caudal deeply excavated so as to form two lobes. A keel passes along the tail, dividing the lateral from the abdominal surfaces. Colours—grayish-yellow above, whitish beneath. Iris golden, with a black edge.

Habitat.—Seas of India to the Malay Archipelago: ascending rivers. Attaining 20 feet and upwards in

Habitat.—Seas of India to the Malay Archipelago: ascending rivers. Attaining 20 feet and upwards in length. The flesh is equally esteemed with that of the sharks. The fins are prepared and sent to China: oil is extracted from the livers, whilst the skins are useful for sword scabbards or for smoothing down wood. The example figured, a little over 3 feet in length, was from Madras.

B.—Caudal fin without any distinct lower lobe.

2. Pristis Perrotteti, Plate CXCI, fig. 1.

? Pristis microdon, Latham, Trans. Linn. Soc. 1794, ii, p. 280, t. xxvi, f. 4 (rostrum).
Pristis Perrotteti, Müll. and Henle, Plagios. p. 108; Duméril, Hist. Nat. Poiss. i, p. 474; Günther, Catal. viii, p. 436.

Pristis antiquorum, Costa, Fauna Regn. Nap. Pesc. t. viii, ix; Blyth, J. A. S. of Beng. 1860, p. 36. Pristis microdon, Bleeker, Beng. p. 80, and Plagios. p. 54.

Rostrum of moderate breadth, rather narrow anteriorly, armed with from seventeen to twenty pairs of teeth, mostly of about the same number on either side, and commencing at the base of the snout: the first four pairs being opposite one another, and the breadth of the base of each anteriorly being about equal to 1/3 of the interspace. Spiracles placed very obliquely, from 1 to 1½ diameters behind the orbit Teeth—larger than in P. cuspidatus or P. zysron, oval, longer than broad. Fins—the first dorsal almost entirely in advance of the ventral: second dorsal commences nearly midway between the posterior extremity of the first dorsal and the base of the candal: these two fins are of about equal size: inferior margin of caudal with a faint indication of a lobe. Colours—reddish-brown superiorly, becoming dull-white along the abdominal surface: iris golden, with a black edge.

Blyth observes, l. c. Pristis antiquorum, Latham: "Small individuals are not unfrequently brought to the Bazaar." As I could find in the Calcutta Museum only several small stuffed examples of P. Perrotteti without labels, and none of P. antiquorum, I consider Mr. Blyth to have alluded to this species. Dr. Günther remarks that "there is no possibility of distinguishing those (isolated rostra) of Pristis antiquorum from those of P. Perrotteti."

Habitat.—Tropical seas, entering rivers. In the Mahanuddee river it ascends at least forty miles from the sea, far beyond influence of the tides and salt water, where I obtained it to 4 ft. in length. In Orissa it is only eaten by the sweepers and the very lowest castes.

3. Pristis zysron, Plate CXCI, fig. 2.

Bleeker, Plagios. p. 55; Duméril, Hist. Nat. Poiss. i, p. 479; Günther, Catal. viii, p. 438. Pristis dubius, Bleeker, Plagios. p. 56; Duméril, Hist. Nat. Poiss. i, p. 478. ? Pristis pectinatus, Klunz. Fische Roth. Meer. 1871, p. 673.

Vella sorrah, Tamil.

Rostrum intermediate in width between *P. cuspidatus* and *P. Perrotteti*, of about the same breadth throughout, and armed with from twenty-five to thirty-two pairs of teeth, of mostly the same number on either side: they commence just anterior to the base of the snout, the posterior ones are much further apart than the anterior ones. *Teeth*—intermediate in size between *P. cuspidatus* and *P. Perrotteti*. *Fins*—first dorsal almost entirely behind the ventrals: second dorsal, as large or larger than the first, is situated rather near to the root of the caudal to which its posterior lobe almost reaches: caudal without a lower lobe. *Colours*—sandy-brown, becoming lighter beneath.

This species is perhaps more common in the seas of India than P. cuspidatus. It is especially abundant along the Meckran and Sind coasts, where it is much dreaded.

Habitat.—Seas of India to the Malay Archipelago. Attaining at least 20 ft. in length. The example figured (thirty-four inches long) was from Madras.

Digitized by Google

FAMILY, II—RHINOBATIDÆ.

The disk slightly dilated laterally: the rayed portion of the pectoral fin not continued on to the snout. Tail thickened, moderately elongated, and with a longitudinal fold along either side. Two well-developed dorsal likewise a caudal fin. No electric organs.

These fishes are very destructive amongst marine crustacea and molluscs: and are said to live in large droves. Owing to the great injury done by them to the beds of pearl oysters at Ceylon, it was proposed to enclose such with stakes to prevent their ingress.

Geographical distribution.—Tropical and temperate seas.

SYNOPSIS OF INDIAN GENERA.

Rhynchobatus. Two dorsal fins, the anterior opposite the ventrals, p. 730.
 Rhinobatus. Two dorsal fins, the anterior situated far behind the ventrals, p. 731.

Genus, 1-RHYNCHOBATUS, Müller and Henle.

Rhina, sp. and Rhinobatus, sp. Bl. Schn.: Rhamphobatis, Gill.

Body depressed and elongated. Gill-openings inferior, narrow, and internal to the base of the pectoral fin. Spiracles wide and behind the eyes, which latter have no nictitating membrane: snout rather elongated and acute: nostrils inferior, oblique, wide slits. Teeth obtuse, ridged: the dentary plate having an undulated surface. Dorsal fins spincless, the first apposite the ventrals: front edge of pectoral free, not extending to the head: caudal with a well-marked lower lobe.

Geographical distribution.—From the Red Sea and East coast of Africa through the seas of India to the Malay Archipelago and China.

SYNOPSIS OF SPECIES.

- 1. Rhynchobatus ancylostomus. Snout broad, having a semi-circular outline. Rows of large tubercles and spines on head and trunk. Brown. From the East coast of Africa through seas of India to the Malay Archipelago
- 2. Rhynchobatus Djeddensis. Snout elongated: few tubercles or spines on head or body. A black shoulder spots and numerous white spots on upper surface. Red Sea to the Malay Archipelago, and beyond.

1. Rhynchobatus ancylostomus, Plate CXCIII, fig. 3.

Manu ulava, "mud skate," or Nalla dindi, Tel.

Snout very broad with a semi-circular outline. It has longitudinal rows of tubercles, one on either side of the head above the eyes continued on to the shoulders, and a median one along the back, with two short lateral ones between this last and the pectoral fin: a few round the front edge of the eye and below the spiracle. Teeth—77/75. Twenty-two vertical rows in the centre of the upper and twenty-seven in the centre of the lower jaw. The dental surface deeply undulated, with one large median and a smaller lateral elevation in the lower jaw and with corresponding emarginations in the upper. The teeth are largest on the summit of each elevation: all are obtusely rounded with several longitudinal ridges across each. Colours—of a dull brown, lighter beneath: the body and sometimes the fins covered with whitish spots: occasionally some tortuous black lines.

Habitat.—From the East coast of Africa through the seas of India to the Malay Archipelago and China. The figure is taken from an example sent by Dr. Jerdon from Madras to the British Museum: its length was 6 ft. 10 in.; and inside it were found the remains of great numbers of crustacea of many kinds. The natives assert that it swims slowly just above the bottom of the sea not far from the shore, picking up what it finds.

Ulavi, or Tipi Ulavi, Tel.

Snout elongated, the distance between the mouth and end of snout equals 1/4 to 1/5 of the entire length excluding the caudal fin, being shortest in adults. Eyes—rather large: the spiracle close behind the orbit. Teeth—oval, wider than broad with a horizontal cusp across the centre of each: 40-42/40-42, twenty to twenty-five vertical rows across the middle of both jaws. Dental plate with a central and a smaller lateral elevation, corresponding emarginations exist in the upper jaw. Fins—the first dorsal commences opposite the centre of the base of the ventral. The second dorsal is half nearer to the base of the caudal than to the posterior extremity of the first dorsal; it is smaller than the latter fin; but its shape is the same. Scales-minute, of irregular shapes and sizes, keeled: a number of tubercles, directed backwards, exist in rows in some parts of the body: a supraorbital row extends from the anterior margin of the orbit round its upper edge to above the spiracle: a second passes from a central point between the termination of the last two and proceeds along the back to the base of the first dorsal, the tubercles on it being much further apart than in the other lines: from slightly behind the commencement of the dorsal line of spines is a short diverging row on either side, also a row on the shoulder, and two or three spines on the scapula. The lateral keel commences a little above the termination of the ventrals. Colours—the immature are dull-gray above, whitish sometimes tinged with red beneath. A dark or black band on the upper eyelid and a dark spot beneath on either side of the snout: also there is usually, but not invariably, a black spot at the root of the pectoral, which may have several small white ones round it. The body and sometimes the pectoral fin is spotted with whitish, or light gray. Iris golden. The adult is of a dull-gray above and lighter on the abdomen.

The young are captured along the Coromandel coast in large numbers about the month of March.

Habitat.—Red Sea and East coast of Africa, seas of India to the Malay Archipelago, and beyond. Its flesh is considered nourishing whether eaten salted or fresh, and oil from its liver is much esteemed. It grows to at least six feet in length.

Genus, 2-RHINOBATUS, sp. Bl. Schn.

Syrrhina, Müll. and Henle.

Body depressed and elongated. Spiracles wide and behind the eyes. Snout elongated, the cranial cartilage being produced and the interval between it and the pectoral fin being filled by a membrane. Nostrils oblique and wide: the anterior nasal valves not confluent. Teeth obtuse, ridged. Dorsal fins spineless: both far behind the ventral: no lower caudal lobe.

Geographical distribution.—Tropical and sub-tropical seas. They are exceedingly numerous along the coast of India, and prefer a sandy to a muddy bottom.

SYNOPSIS OF SPECIES.

Rhinobatus halavi. Snout rather obtuse: a few blunted spines along the middle of the back. Mediterranean, West coast of Africa, Red Sea, and seas of India to the Malay Archipelago.

Rhinobatus granulatus. Snout elongated: a row of spines along the middle of the back. Seas of India

to the Malay Archipelago and Australia.

Rhinobatus Thouini. Nostrils very large, their distance apart at the base being less than 1/2 their length. Red Sea, seas of India to the Malay Archipelago.

Snout rather obtuse, its length equalling 7 to 8 in the total. The width of the interorbital space equals $2\frac{1}{4}$ to $2\frac{1}{3}$ in the length of the snout. Anterior nasal valve not dilated laterally. The distance between the

Digitized by Google

outer angles of the nostrils equals 11/4 in the preoral length of the snout: the length of the nostrils about equals the distance their bases are asunder. Rostral ridges divergent posteriorly, becoming confluent in their anterior half or 2/3. Teeth—transversely oval with a slight ridge along the centre: the width of the plate above the symphysis of both jaws being 1/8 of its length: 70/66 rows of teeth: and fifteen vertical rows in the median line in either jaw. The dental plate almost straight. Fins—The two dorsals of about the same size, their distance asunder equalling the interspace between the second dorsal and base of the caudal: the latter being $7\frac{1}{2}$ to $8\frac{1}{2}$ in the total length. Scales—are somewhat trefoil-shaped and flattened, being rather largest along the median line of the back, which, however, is not spined, although a few tubercles almost form spines. Colours—reddish gray superiorly becoming white beneath: fins and spout with a reddish time. Colours—reddish-gray superiorly, becoming white beneath: fins and snout with a reddish tinge. Large examples have occasionally black blotches over them.

Habitat.—From the Mediterranean, West coast of Africa and Cape of Good Hope: also from the Red Sea through the seas of India to the Malay Archipelago and China. It attains at least six feet in length.

The example figured was from Mangalore.

2. Rhinobatus granulatus, Plate CXCII, fig. 2.

Rhinobatus typus, Bennett, Life of Sir S. Raffles, p. 694.

Pur-run-qun, Tamil; Cun-da-ree, Sind.; Gna-man-haing, Burmese.

Snout elongate, its length being from $4\frac{1}{2}$ to $5\frac{1}{2}$ in the total, and as a rule being longest in the immature: the width of the interorbital space varies from $2\frac{1}{2}$ to $3\frac{1}{2}$ in the length of the snout. Anterior nasal valve with no lateral dilatation. The distance between the external angles of the nostrils equals about 2/3 or 3/5 in the

preoral portion of the snout: the two rostral ridges narrow and closely approximating in their anterior half or two-thirds: mouth transverse. Teeth—42/32, dental plate with a central and lateral elevation in the lower, with corresponding depressions in the upper jaw: 20/22 vertical rows in the upper and 13 in the lower jaw opposite the symphysis. Scales—tubercles on the back, and a row of compressed spines along its middle, which become obsolete with age: some spines on the edge of the orbit and on the shoulder. In the young a row likewise along either side of the upper edge of rostral ridge. Colours—reddish-gray superiorly, becoming dullwhite beneath.

Habitat.—Seas of India to the Malay Archipelago and Australia. It attains at least seven feet in length. The example figured was from Malabar.

3. Rhinobatus Thouini, Plate CXC, fig. 4.

Raie Thouin, Lacépède, i, p. 134, pl. i, f. 3-5.

Raja Thouiniana, Shaw, Zool. v. 2, p. 318, pl. exlvii, f. 2. Rhinobatus Thouini, Müller and Henle, Plagiost. p. 120; Duméril, Hist. Nat. Poissons, i, p. 500, pl. x, f. 2 (snout): Günther, Catal. viii, p. 442.

Rhinobatus ligonifer, Cantor, Catal. p. 415, pl. xiv; Bleeker, Plagiost. p. 59.

Snout of moderate extent, equalling five or six in the total length: the width of the interorbital space equals $2\frac{3}{4}$ in the length of the snout. Anterior nasal valves not dilated laterally. The distance between the outer angles of the nostrils equals 2/3 of the length of the preoral portion of the snout: the length of the nostrils is more than twice the extent their bases are apart. Mouth straight. Rostral ridges confluent in almost their entire length. Teeth—small, upwards of one hundred rows in either jaw. Fins—the two dorsals of about the same size, high and pointed, the first if laid flat nearly reaching the base of the second dorsal: caudal $6\frac{1}{2}$ in the total. Scales—skin granulated with a row of compressed spines along the middle of the back and smaller ones over the shoulders and above the eyes. Colours—brown, becoming yellowish-white beneath.

Habitat.—From the Red Sea (Duméril, l. c.) through those of India to the Malay Archipelago.

This species attains to 6½ feet in length, according to Bleeker. The example figured is a skin 4½ feet long from the Andamans, and the only specimen I procured in the East.

FAMILY, III—TORPEDINIDÆ.

Trunk broad and disk smooth. Anterior nasal valves confluent and forming a quadrangular flap. Tail with a rayed dorsal (except in Temera) and caudal fin: also a longitudinal fold along either side. An electric organ* situated between the pectoral fin and the head.

Geographical distribution.—Tropical, sub-tropical and temperate seas. In India they do not appear to be used as food.

SYNOPSIS OF GENERA.

Two dorsal fins: spiracles immediately behind the eyes, p. 733.

One dorsal fin, p. 733. 2. Astrape.

Genus, 1-NARCINE, Henle.

Disk distinct from the tail, which has a lateral fold on either side and is longer than the disk. Spiracles close behind the eyes: nasal valves confluent, forming a quadrangular flap. Teeth nearly flat, with a central point. Two dorsal fins, the anterior behind the ventrals and usually smaller than the posterior. An electric apparatus present.

Geographical distribution.—Tropical and sub-tropical seas.

Nat. Poiss. i. p. 518 Nat. Poiss. i, p. 518.

Outline of disk somewhat rounded, while it is broader than long: along the side of the tail is a broad skinny keel reaching the base of the caudal fin. Caudal portion of fish rather longer than the body. Nasal valves confluent, forming a quadrangular skinny flap which is rather elongated in the middle. Spiracle just behind the orbit and not tuberculated on the edge. Teeth-flattened anteriorly, the internal ones with a small median cusp: the dental plate only embraces the central half of either jaw, the lips being thickened and continuous at the angles. The form of the dental plate varies, being either angular in the mandible the angle pointing downwards or similar to what obtains in the upper jaw. Fins—the anterior dorsal usually commences just behind the ventrals but occasionally over their posterior extremity, it is somewhat smaller than the posterior: in the young its apex forms an angle, which in the adult becomes rounded. The distance between the two dorsals equals that between the posterior dorsal and the caudal. The size and shape of the two dorsals is similar. Caudal with its hinder edge rounded and confluent with the inferior. Colours—body and fins reddish-brown above, with numerous irregularly sized chocolate-coloured spots: lower surface white. Pupil triangular, apex below. Iris golden. In the immature the spots have a white margin. Some examples are marked all over with large brown blotches much wider than the ground colours. In others no spots at all These differences in colour do not depend on sex, age, or locality.

Habitut.—Seas of India and the Malay Archipelago. It attains at least eighteen inches in length. "Out of the water they may be handled with impunity."—Cantor.

Genus, II—ASTRAPE, Müller and Henle.

Tail with a fold on either side. Spiracles close behind the eyes, which last are minute. Nasal valves confluent, forming a large quadrangular flap. Teeth flattened or with a central elevation, the dental plate extending slightly beyond the outer edge of the jaws. A single dorsal fin on the tail: caudal well developed. An electric apparatus on the side of the head between it and the pectoral fin.

Geographical distribution.—Seas of India to the Malay Archipelago and China, also the Cape of Good Hope and Madagascar.

* For a description of the peculiar "Appareil folliculaire nerveux" of the Torpedo not possessed by other Plagiostomata nor by Gymnotus or Melapterurus, &c., see Boll. in Arch. Anat. Phys. Berl. 1875; and on the immunity of this fish from a self-inflicted shock, J. Steiner, Arch. Anat. Phys. 1874.

Malabar, p. 276; Günther, Cat. viii, p. 454.

Astrape Japonica, Schleg. Faun. Japon. Poiss. p. 307, pl. cxl.

Disk rounded, as wide as long, extending posteriorly to over the anterior margins of the ventrals. Length of tail shorter than that of the body: a low keel along its lateral edge. Snout short. Spiracles smooth, close to and much larger than the eyes: vent slightly nearer to the head than to the posterior extremity of the caudal fin. Tecth—pointed with tetragonal bases; they slightly project beyond the margin of the jaws. Fins—ventrals with their angles acute in the young, rounded in the adult. Caudal rounded, its upper and lower portions confluent. Colours—Dull reddish-olive above, whitish below. A white spot near either side of the posterior end of the head of the head of the ventral, and generally a third at the root of the caudal, wentral with a white seder. caudal: ventral with a white edge.

Habitat.—Seas of India to the Malay Archipelago, China and Japan. It attains at least ten inches in

length. The one figured (life size) was from Madras.

FAMILY, IV—RAJIDÆ.

Disk broad, rhombic: tubercules or spines usually present. The pectorals extend to the snout. Tail with a longitudinal fold on either side. No serrated caudal spine. Electric organs absent.

Yarrell remarks:—"Spines on the upper surface of the males occur in the different species of Skate with smooth skins, and are entirely independent of those spinous productions of the cuticle which distinguish two British species." Darwin* observes of these spines, "they are only temporarily developed during the breeding season." This phenomenon, so far as I am aware, has not been observed amongst the various forms of Indian skates or rays.

Geographical distribution.—Seas of both hemispheres, but more numerous in the northern, it possesses but few representatives along the coasts of India.

Genus, 1-PLATYRHINA, Müller and Henle.

Disk rhombic, with a fold on either side: tail distinct. Nasal valves distinct. Two dorsal fins on the tail: caudal well developed: ventrals separated one from the other. Body covered with rough asperities and spines.

Geographical distribution.—Seas of India to China and Japan.

Platyrhina Schönleinii.

Müll. and Henle, Plagios. p. 125, t. xliv; Duméril, Hist. Nat. Poiss. i, p. 577; Günther, Catal. viii, p. 471.

Disk sub-circular: snout obtuse: tail as long as the disk. Dental plate undulating: three elevations in the lower and three corresponding depressions in the upper jaw. Nostrils wide apart. A row of strong spines and also smaller lateral ones along the median line of the back and tail: some more along the edge of the orbit and on the shoulder. Colours—brown, covered with light blotches, said sometimes to have dark cross bands and large dark spots.

Habitat.—Coromandel coast of India. The example described, a male, $27\frac{1}{2}$ inches in length, was in the Madras Museum.

• "Descent of Man," p. 331.

FAMILY, V-TRYGONIDÆ.

Disk wide: the pectorals are continued to the extremity of the snout where they become confluent. Tail long and slender without any lateral folds. Vertical fins, if present, imperfectly developed, or instead they may be modified into a serrated spine.

The forms with armed tails occasion exceedingly dangerous injuries, not only due to their jagged nature, but apparently also to the presence of some irritating foreign substance which becomes carried into the wound.

Geographical distribution.—Tropical and temperate seas.

SYNOPSIS OF GENERA.

 Urogymnus—Tail long and spineless. Body densely covered with tubercles, p. 736.
 Trygon—Tail long, armed with a serrated spine. Teeth flattened, p. 736.
 Teniura—Tail long, armed with a serrated spine, and having a broad lower cutaneous fold continued to its termination, p. 740.

4. Pteroplatea-Body very broad, tail very short and armed with a serrated spine. Teeth with from one to three cusps, p. 741.

Genus, 1-UROGYMNUS, Müller and Henle.

Anacanthus, Ehren.: Rhachinotus, Cantor.

Disk sub-circular: tail long and distinct, destitute of any spine, but with a narrow inferior fold: pectorals united anteriorly. Teeth flattened. Body covered with osseous tubercles, amongst which are sharp conical spines.

Geographical distribution.-From the Red Sea and East coast of Africa, throughout the seas of India to the Malay Archipelago.

Urogymnus asperrimus, Plate CXCV, fig. 1.

Raja asperrima and ? Africana, Bl. Schn. p. 367.
Anucanthus asperrimus and ? Africana, Müll. and Henle, Plagios. p. 157.

Rhachinotus Africanus, Cantor, Catal. Mal. Fish. p. 422; Bleeker, Nat. Tyds. Ned. Ind. 1853, iv, p. 64. Urogymnus asperrimus, and Africanus, Gray, Cat. Chond. p. 115; Dumeril, Hist. Nat. Poiss. i, pp. 580, 581; Günther, Catal. viii, p. 472; Klunz. Fische Roth. Meer. 1871, p. 64.

Disk nearly as wide as long: snout scarcely projecting. Body densely covered with small heart-shaped scales, between which are numerous thorns which are generally erect, and are continued posteriorly to the first fifth of the tail, where they cease. On the pectoral fins are numerous small conical spines, irrespective of those over the body amongst the tubercles. Colours-greenish above, white beneath.

A fine example, 2 feet across the disk, exists in the Madras Museum.* Habitat.—Red Sea, East coast of Africa, seas of India to the Malay Archipelago.

Genus, 2—Trygon, Adanson.

Himantura, Himitrygon and Hypolophus, Müll. and Henle: Paratrygon, Duméril.

Disk oval or rhomboidal: tail elongated and tapering. Nasul valves coalescent, forming a quadrangular flap. Teeth flattened or with a central point or transverse ridge. Pectoral fins united anteriorly: tail destitute of a fin, or if with a cutaneous fold, such does not extend to its extremity: it is armed superiorly with one or two lanceolate spines serrated on both sides. Body smooth or with tubercles.

In this Genus the colours in individuals of the same species are subject to considerable variation, and this not entirely due to age. The character of the tubercles and their extent have also been (as I think erroneously) employed to characterize some species, thus one, Trygon chindrakee (Cuv.) Bleeker or T. nuda, Gunther, is a form without tubercles or spines, except on the tail. T. polylepis, Bleeker, has small tubercles in the interobital space, a narrow band along the back with a few indistinct enlarged ones, but none on the tail. T. walqa, Müll. and Henle, has the interorbital space and back covered with small tubercles, but no larger ones in the median line, but a series of short spines between the root of the tail and the larger spine. Now all

* I must here remark that, when referring to the specimens of fish in the Madras Museum, I allude to what were there in 1873, as since then the Curator (under, I presume, orders from Government) has given away some of the finest examples.

these forms with every intermediate variation, occur, and the smooth body usually confined to the young may be persistent in the adult.

The various species of this extensive Genus may be sub-divided as follows:—

A.—Dental laminæ transverse: if undulating, slightly so: no caudal cutaneous fold (Himantura).

1. Trygon uarnak—Snout rather pointed. Tail very long. One or more large tubercles in middle of Brown or spotted. Red Sea, Indian Ocean to Malay Archipelago: also African coast.

2. Trygon marginatus—Tail twice as long as disk. A row of pointed tubercles on the back which is

spined all over. Hooghly at Calcutta.

3. Trygon Bleekeri—Snout very pointed. Tail three to four times as long as disk. A central and several smaller tubercles on the back. Bengal.

- 4. Trygon walga—Snout pointed. Tail rather longer than disk. Tubercles variously disposed. Red Sea, seas of India to the Malay Archipelago.
 - B.—Dental laminæ transverse: if undulating, slightly so. Tail with a cutaneous fold (Trygon).
- 5. Trygon Bennettii-Snout pointed. Tail three times as long as disk. Tubercles few. Red Sea, seas of India to China.
- 6. Trygon Kuhlii-Tail 1/2 longer than disk. Body nearly smooth. Blue ocelli on upper surface.

- East coast of Africa, seas of India to the Malay Archipelago.

 7. Trygon imbricata—Tail scarcely as long as body. Tubercles few. Seas of India.

 8. Trygon zugei—Snout very pointed and produced. A few tubercles in median line of back. Seas of India to the Malay Archipelago, China, and Japan.
 - C.—Lower dental lamina somewhat pointed, the upper being angularly bent for its reception (Hypolophus).
- 9. Trygon sephen-A broad fold along lower surface of tail. Upper part of body covered with flat tubercles. Red Sea, East coast of Africa, seas of India to the Malay Archipelago.
 - A.—Dental laminæ transverse; if undulating, slightly so: no caudal cutaneous fold (Himantura).

Trygon Ellioti, Blyth, Journ. As. Soc. Beng. 1860, p. 41.

Sona kah tiriki, Tam.: Puli tenke, Tel.

Disk about as broad as long, snout pointed and rather prominent: tail from three to four times as long as the body. Iris with a well-developed superior flap. Teeth—dental laminæ undulating. Fins—no cutaneous folds on the tail which is armed with a serrated spine situated about 1/2 the length of the disk from the root of the tail. Tubercles-vary in different specimens, absent in the very young: in those with a disk of about 6 inches across there are two or three rows of widely separated oval tubercles on either side of the head, internal to the eyes, and meeting on the occiput: from thence towards the scapula is a single row of larger and more widely separated ones. In the middle of the back three large closely approximating scales or tubercles, the centre one heart-shaped, the anterior round, and the posterior almost heart-shaped. In some specimens of a large size, there are also numerous distant thorns on the tail which may disappear with age. In specimens with a disk of 3 feet across, the head, back, and sides are covered with smooth, roundish scales, having intermediate smaller ones. Colours—vary according to age: up to the period when the breadth of the disk is about 9 inches the body is of a yellowish brown, darkest along the back, and the abdomen white: a short distance beyond the commencement of the tail it is irregularly annulated with alternate narrow light brown, and broad or narrow dark-brown rings. As its age increases, black spots commonly appear on the body, and when it has attained the width of 3 feet across its disk it is light brown or greenish-olive, covered with lighter and in some almost white spots, or reticulated with white lines, whilst the anterior extremity of the tail also shows the remains of the rings. The adult is uniformly brownish or greenish-olive. Iris golden. Occasionally there are light spots on the posterior portion of the disk, as shown in the figure (T. Gerrandi. Gray, or T. macrurus, Bleeker).

Digitized by Google

In the cold season, as about October, these fish are frequently perceived springing out of the water for

some distance. They devour large quantities of small fish, crustacea, molluscs, &c.

Habitat.—Red Sea, seas and estuaries of India to the Malay Archipelago, and China, also the Cape of Good Hope. The immature are frequently captured in the back waters, and wounds from their caudal spines are much dreaded. In one instance, an old man was admitted into the Civil Hospital in Cochin for mortification of the arm, due to a wound inflicted by one of these fish, which he attempted to drag out of the sea into a boat: it wound its tail round his arm, and dragged its spine through the muscles nearly down to the bone. They attain a large size, as 5 feet or more across the disk.

2. Trygon marginatus.

Blyth, Journal Asiatic Soc. of Bengal, 1860, p. 38; Duméril, Hist. Nat. Poiss. i, p. 588. ? Trygon atrocissimus, Blyth, l. c. p. 39.

Disk slightly broader than long, tail from 1/2 longer to nearly twice as long as the disk. The width of the interorbital space equals the length of the snout. Tubercles sparsely set all over the upper surface, but a little larger along the median line, where they appear like small limpets: an irregular row of pointed tubercles on either side of the middle line of the back: tail tuberculated as far as its spine, but destitute of any fin. Colours-gray above; buffy-white below, with a dark border, except in front.

In all the examples examined by Blyth, the caudal spine had been removed, as is usually done by fishermen. T. atrocissimus, is founded on some pieces of tails of a Trygon, in which the spine is present; it

may be that the two species are identical.

Habitat.—Hooghly at Calcutta. I examined one of the examples in which the disk was 16 inches across and 15 long; but Blyth says one specimen was 52, another 60, inches across the disk, and the tubercles were extended on to the edge of the disk and even to its under surface. This would therefore appear to be a result of age.

3. Trygon Bleekeri, Plate CXCV, fig. 3.

Blyth, Proc. Asi. Soc. of Bengal, 1860, p. 41; Duméril, Hist. Nat. Poiss. i, p. 593; Günther, Catal. viii, p. 475.

Tail from three to four times as long as the disk. Snout prolonged and pointed. Width of interorbital space equal to 1/2 or 1/3 in the length of the snout anterior to the eye. A large round tubercle in the middle of the back, and commonly three smaller triangularly disposed before it, and three similarly placed behind it. Tubercles sometimes present along the upper surface of the tail to the caudal spine, from whence, in adults, they are continued to its extremity. Colours—"Brown above and below, with a narrow white median longitudinal patch on the abdomen."—Blyth. The example figured is brown above with margins of the disk

Habitat.—Bengal. Blyth observes, length of one 25 inches to base of tail, the tail 72 inches: of another 15 and 56 inches. The example figured is 8 inches across the disk.

Trygon immunis, Bennett, Life of Sir S. Raffles, p. 694.

Disk about as broad as long, with the snout pointed and acutely projecting, more so in some examples than in others. Eyes smaller in the adult than in the young. Interorbital space concave. Teeth—small, having a transverse elevated ridge along each. Dental lamina undulated. Fins—no cutaneous folds on the tail, the length of which is rather longer than the disk. One or two (sometimes more) large serrated spines on the tail at the companion of its area. on the tail at the commencement of its second third, between this and the base of the tail exists a median line of about seven short spines. Scales—interorbital space, and for a varying width along the middle of the back and also on the tail exist numerous fine tubercles which usually have no larger ones, but in some examples there is one on the centre of the shoulder, in others a few more anterior to it. Neither the number, size, character, nor extent of the distribution of the tubercles and spines depends on age or sex, adults even may be without any of either. In one example (a male) the band of tubercles along the back is very narrow, a row of large ones exists in the median line. row of large ones exists in the median line of the scapular region, and four along the back of the tail. This

would be intermediate between T. walga and T. polylepis. Another example has a row of small spines all along the first third of the back of the tail, and a moderately sized rather compressed median scapular spine with six smaller ones anterior to it: a very wide band of tubercles exists along the back. One example has the smaller caudal spine very well developed, a very narrow row of tubercles along the back, and a central scapular tubercle. Another has only a few small tubercles and one central spine in the scapular region, some between the eyes, and some fine spines between the base of the tail and the two large spines. Young ones are often destitute of tubercles or armature except the caudal spines, and this immature character may be seen in some adults. Colours—dull gray or brown superiorly, white beneath.

Blyth observes, the males are larger than the females and have proportionately longer tails: very commonly the second caudal spine (more especially of the females) does not extend beyond the first one. Some have a small lanceolated tubercle on the centre of the dorsal surface, others two or more, even to a series of five or six along the median line. This species is so very often brought in pairs to the bazaar, a male and a female, that I cannot help suspecting that it lives in pairs, the two being commonly taken together.

Habitat.—From the Red Sca, through the seas of India to the Malay Archipelago.

B.—Dental laminæ transverse; if undulating, usually slightly so: tail with an upper or lower cutaneous fold (Trygon).

Trygon Bennettii.

Müll. and Henle, Plagios. p. 160, t. lii; Richards. Ich. China, p. 197; Duméril, Hist. Nat. Poiss. i, p. 595; Günther, Catal. viii, p. 480. Trygon carnea, Richards. Ich. China, p, 197.

Disk about as broad as long: tail about three times as long as disk, and with a low cutaneous fold along its inferior surface. Snout somewhat pointed. Eyes are nearer together than to the end of the snout. A tubercle in the middle of the back in adults, with some flat ones around it, and which extend backwards to the caudal spine: but the young are quite smooth. Colours—of a pale fleshy-red which becomes almost white in parts, the tail becoming darker near its extremity.

Habitat.—Seas of India to China and beyond.

6. Trygon Kuhlii, Plate CXCIII, fig. 2.

Müller and Henle, Plagios. p. 160, pl. 50; Temm. and Schleg. Fauna Japon, Poiss. p. 308; Bleeker, Plagios. p. 73, and Beng. p. 82; Duméril, Hist. Nat. Poiss. i, p. 603; Günther, Catal. viii, p. 479.

Disk broader than long: tail about one-half longer than the disk. Snout somewhat obtuse, its length equal to or slightly exceeding the breadth of the interorbital space. Two appendages on the floor of the mouth. equal to or slightly exceeding the breadth of the interorbital space. Two appendages on the floor of the mouth. Teeth—dental plate more undulated in the upper than in the lower jaw. Fins—a cutaneous fold along the tail both above and below, caudal spine well developed. Colours—superiorly of a dull brown, covered with numerous small black spots and larger rounded blue ocelli, each having a rather dark outer edge.

Habitat.—East coast of Africa, seas of India to the Malay Archipelago. A very good coloured illustration (a male) exists amongst Sir Walter Elliot's drawings of Madras fish, $5\frac{1}{4}$ inches across the disk: it was termed Kunnoo tirike and Shemen tenkee, Tel. The example figured is 5 inches across the disk, and was

obtained in Madras.

7. Trygon imbricata.

Raja imbricata, Bl. Schn. p. 366.

Trygon imbricata, Müll. and Henle, Plagios. p. 164; Duméril, Hist. Nat. Poiss. i, p. 606; Günther, Catal. viii, p. 481.

Disk as broad as long, snout produced and pointed: tail scarcely as long as the body, with low upper and inferior cutaneous folds. Small tubercles on the nape and back, with a row of conical spines along the shoulder and back: while along the tail as far as the spine are large tubercles intermixed with smaller ones.

This is said to be Bl. Schneider's imbricata, which has been referred by Cantor to T. walga, from which it appears to differ in possessing a low cutaneous fold both along the upper and lower border of the tail.

Habitat.—Coromandel coast of India.

8. Trygon zugei, Plate CXC, fig. 3.

Müll. and Henle, Plagios. p. 165, t. liii; Temm. and Schleg. Fauna Japon, Poiss. p. 309; Richards, Ich. China, p. 197; Cantor, Catal. Mal. Fish. p. 426; Bleeker, Plagios. p. 68, and Beng. p. 32; Duméril, Hist. Nat. Poiss. i, p. 606; Günther, Catal. viii, p. 481.

Trygon Crozieri, Blyth, J. A. S. of Beng. 1860, p. 45; Duméril, l. c. p. 597.

Chumbara kah, Tam.

Disk about as broad as long, with the snout very much produced and acutely pointed, its length being about 1/3 of that of the disk: tail equal to 12 or twice the length of the disk. Eyes small: interorbital space concave. Teeth-dental laminæ undulated. Fins-a distinct cutaneous fold along the lower surface of the

Digitized by Google

tail, commencing opposite the base of the spine, there is likewise a fold along the upper surface of the tail. A strong and long spine, serrated in its last third, situated in about the commencement of the second quarter of the tail, and anterior to it a row of small spines, the body otherwise smooth. In some examples a row of tubercles exists along the median line of the back. Colours—dull brown superiorly, the edge of the fins black.

Habitat.—From the seas of India to the Malay Archipelago, and Japan. The example figured (7 inches

across the disk) is a male from Madras.

C.—Lower dental lamina somewhat pointed, the upper being angularly bent for its reception (Hypolophus).

9. Trygon sephen, Plate CXCV, fig. 2.

Raja sephen, Forsk. Descr. An. p. 17; Gm. Linn. i, p. 1508; Lacép. i, p. 123; Bl. Schn. p. 364. Raja, Russell, Fish. Vizag. i, p. 2, and Wolga tenkee, pl. iii.

Raja sancur, Ham. Buch. Fish. Ganges, p. 2.

Trygon Forskalii, Rüpp. Atl. Fische, p. 53, taf. 13, fig. 2.

Hypolophus sephen, Müll. and Henle, p. 170; Bleek. Beng. p. 82, and Plag. p. 77; Cant. Mal. Fish. p. 429; Blyth, J. A. S. of Beng. 1860, p. 37; Duméril, Hist. Nat. Poiss. i, p. 616; Day, Fish. Malabar, p. 279. Adavalan tiriki, Tamil: Volugiri tenkee, Tel.

Disk rather broader than long: the length of the tail three to four times that of the body. Snout more obtuse in adults. Teeth—lower dental laminæ somewhat pointed, the upper angularly bent for its reception: The angle of the strategy and $\frac{20}{20}$ vertically opposite the symphysis, they are all flattened, those in the centre of the upper jaw being the smallest. Fins—tail with a broad lower cutaneous fold: there may be one or two serrated spines situated rather behind its anterior third. Scales—upper surface of the head and body and base of tail covered by thick, concave, or flat-headed, several-sided tubercles. In the scapular region and central line of the back are two in the young, and three in the adult, of large, smooth, approximating tubercles, the middle and largest of which is usually oval, the second in size posterior and heart-shaped, the anterior or smallest round or heart-shaped. Colours—the upper surface of the immature is reddish-brown: but in the adult lead-coloured, becoming black in the posterior two-thirds of the tail. Some examples have a row of black blotches near their outer margin.

Habitat.—Red Sea, through the seas of India to the Malay Archipelago, and beyond. This fish grows to a large size. The jaws in the figure were from an example 5 ft. 10 in. across the disk. In its stomach were found crustacea, molluses, &c. It is most common during the south-west monsoon, when it approaches the shore. From the skin of its back some of the "shagreen" of commerce used to be prepared. Wounds inflicted by the spine of its tail are considered dangerous.

Genus, 3—TENIURA, Müller and Henle.

Disk oral or rhomboidal: tail elongated and tapering. Nasal valves coalescent, forming a quadraugular flap. Pectoral fins united anteriorly: tail with a broad lower cutaneous fold continued to its extremity. Body and tail either smooth or furnished with tubercles.

Geographical distribution.—From the Red Sea and East coast of Africa through the seas of India to the Malay Archipelago and tropical America.

1. Tæniura melanospilos.

Blecker, Nat. Tyds. Ned. Ind. 1853, iv, p. 513; Duméril, Hist. Nat. Poiss. i, p. 620; Günther, Catal. viii, p. 484.

Jiluga tirike, Tel.

Disk rather broader than long: its upper surface smooth. Tail very thick at its base with two strong flattened elongated spines (upper 91, lower 51 inches long) servated externally. From opposite these spines on the lower surface of the tail commences a broad, cutaneous fold, and which is continued to the extremity of the tail, and on its surface are numerous tubercles of the same character as on the tail. The figure appears to have been mislaid and the colours are not noted.

The foregoing description is compiled from Sir W. Elliot's and Dr. Jerdon's notes of two examples captured in 1853 off the Coromandel coast, where they were said by the fishermen to be very rare. The tail of one with the spines intact has been preserved. One of the examples had its disk 4 ft. 11 in. long and 5 ft. 11 in. broad, its tail, however, was absent: the other was 8 ft. 11 in. in its total length, and its disk 4 ft. 1 in. long by 5 ft. 11 in. wide. Inside its stomach were found the remains of some small crabs and a squilla. It is, however, expressly stated that the body was smooth, but the tail covered with rough tubercles, all of which have a stellated base.

Habitat.—Coromandel coast of India and Batavia.

Genus, 4-PTEROPLATEA, Müll. and Henle.

Ætoptatea, Müll. and Henle.

Body at least twice as broad as long: tail thin, generally shorter than the body, with or without a rudimentary fin, but having a serrated spine: spiracles with or without a tentacle: nasal valves confluent, and forming a quadrangular flap. No papilla at bottom of the mouth. Teeth with from one to three cusps. Pectoral fins united in front. Skin smooth or tubercular.

Geographical distribution.—Tropical and temperate seas.

A .- Tail finless.

Pteroplatea annulata, Swainson, Fishes, ii, p. 319.

Dasyatis microura, Blyth, J. A. S. of Beng. 1860, p. 37.

Peroom tiriki, Tamil.: Tappu cooti, Tel.

Disk about twice as wide as long: tail as long as disk in young, but shorter in adults. No tentacle to spiracle. Teeth—with a single pointed cusp. Fins—one or two small spines on caudal fin. Skin smooth. Colours—Reddish-brown: tail annulated with white and brown: superiorly in the centre of each light ring, there is generally a brown spot. The young are covered all over with small brown spots. A figure exists amongst Sir Walter Elliot's drawings of Madras fish of an example covered all over with light round spots.

Habitat.—Seas of India to the Malay Archipelago, and beyond. Jerdon obtained one in which the disk

was 6 feet across and 3 feet long.

FAMILY, VI-MYLIOBATIDÆ.

Pectoral fins large, developed along the sides of the body occasioning the latter to appear very broad: these fins are not present on the sides of the head, but re-appear at the end of the snout as a pair of detached fins.

SYNOPSIS OF GENERA.

A.—Teeth large, flattened, tessellated.

- 1. Myliobatis. Fins on head meet in the form of a soft appendage in front of snout. Teeth in several series, the middle ones being the broadest, p. 742.
 - 2. Attobatis. With only one series of very broad teeth, p. 743.
 - 3. Rhinoptera. Fins on either side of snout form a lobe, p. 743.
 - B.—Teeth small: cephalic fins forming an appendage on either side of snout.

 - 4. Dicerobatis. Teeth in both jaws, p. 744.
 5. Ceratoptera. Teeth only in the lower jaw, p. 745.

A.—Teeth large, flattened, tessellated.

Genus, 1-Myliobatis, Cuvier.

Head distinct from disk: snout with a soft prolongation, internally supported by fin rays: nasal valves coalescent, forming a quadrangular flap. Teeth hexagonal, flat, the central ones being broader than long: the external rows narrow. Tail very long and whip-like, having a dorsal fin near its base, and usually a serrated spine posterior to it. Body smooth or tuberculated superiorly.

Geographical distribution.—Tropical and temperate seas.

SYNOPSIS OF SPECIES.

1. Myliobatus Nieuhofii. Body smooth. No caudal spine. The young with five blue cross-bands on

the upper surface, but which disappear with age. Seas of India to the Malay Archipelago, and Japan.

2. Myliobatis maculata. A row of small tubercles in the median line of the scapular region. No caudal spine. Ocelli with brown margins in posterior half of the upper surface of disk.

1. Myliobatis Nieuhofii.

Raja Nieuhofii, Bl. Schn. p. 364.

L. & Sc. 1851, p. 149; Kner, Novar. Fische, p. 421; Duméril, Hist. Nat. Poiss. i, p. 638; Günther, Catal. viii, p. 491.

Tuppa koollee or Chuppa tirike, Tamil.

Disk about twice as broad as long: tail about three times as long as disk. Fleshy prolongation of snout short; no horn on orbit. Body smooth. Fins-dorsal situated at commencement of base of tail, opposite the end of the insertion of the ventrals: no spines posterior to it. Colours—olive superiorly, tinged externally with a reddish hue and a dark outer margin to the disk. The young have about seven blue bands across the disk and two more between or close to the eyes. As the fish increases in size, first the bands on the head disappear and finally those on the body.

Habitat.—Seas of India to the Malay Archipelago and Japan. Two good illustrations of this species,

from Madras, exist amongst Sir Walter Elliot's drawings.

2. Myliobatis maculata.

Gray and Hardw. Illust. Indian, Zool.; Müller and Henle, Plagios. p. 178; Bleeker, Plagios. p. 84, and Beng. p. 82; Richards. Ich. China, p. 198; Gray, Catal. Chond. Fish. p. 129; Duméril, Hist. Nat. Poiss. i, p. 639; Günther, Catal. viii, p. 490.

Disk about twice as wide as long: tail more than three times as long as the disk. Fleshy prolongation of snout short, no horn on orbit. Body with a row of small tubercles along the median line of the back in the scapular region. Fins—dorsal situated at the commencement of the base of the tail, behind the end of the insertion of the ventrals: no spine posterior to it. Colours—greenish-brown, with round blue spots in the posterior half of the disk. Tail white with black rings.

Habitat.—Seas of India to the Malay Archipelago.

Genus, 2—ÆTOBATIS, Müll. and Henle.

Stoasodon, Cantor.

Head distinct from disk: snout with a soft prolongation, internally supported by fin rays. Nasal valves usually distinct, each forming a long flap, or such may be united into one quadrangular flap. Teeth hexagonal, broad, flat, with the lower dental laminæ projecting beyond the upper. Tail very long and whip-like: dorsal fin present near its base, and a serrated spine posterior to it.

Geographical distribution.—Seas of the tropics.

Aëlobatis laticeps, Gill, Ann. Lyc. Nat. Hist. New York, viii, p. 137.

Eel-tenkee, Tel.: Currooway tiriki, Tam.: Ra-ta-charm-dah, Andam.

The comparative proportions of this fish vary greatly with age: the distance from the mouth to the anus equals about half the width of the disk. Nasal valves in some examples separate, each forming a long flap,* in other examples the valves unite and forming a quadrangular flap the lower edge of which is fringed: the spiracle wider than orbit. Teeth—broad, flat, and in a single row, those in the lower jaw may be angularly bent or nearly straight: the lower dental plate projects beyond that in the upper jaw. Fins—the dorsal arises opposite the base or centre of the ventral, the latter fin being about three times as long as broad. Tail three or four times as long as the body, triangular in shape as far as the spine, which is serrated and situated just behind the termination of the dorsal fin: beyond the spine the tail is compressed; in this, as well as in some other species there is occasionally a second spine on the caudal a little behind the root of the first. Scales—body smooth. Colours—grayish-olive, sometimes greenish-olive or leaden-gray above, and usually covered from beyond the occiput with numerous dirty-white or bluish spots edged with black: abdominal surface white: tail black. Iris golden-green, teeth greenish-yellow. In the immature the back is of a deep leaden colour, and the spots hardly apparent.

Habitat.—Red Sea, seas and estuaries of India to the Malay Archipelago, and beyond. Eaten by the natives. Is captured to upwards of 6 feet in width.

Genus, 3—RHINOPTERA, Kuhl.

Mylorina and Micromesus, Gill.

Head distinct from the disk, but with a pair of rayed appendages on the lower edge of the snout. Nasal valves confluent, forming a broad flap. Teeth broad, flat, in five or more rows, the central ones being the broadest. Tail whip-like, with a dorsal fin and a serrated spine posterior to it.

Geographical distribution.—Tropical and contiguous seas.

SYNOPSIS OF SPECIES.

 Rhinoptera adspersa. Nine series of teeth in upper jaw, and seven in the lower. Seas of India.
 Rhinoptera Javanica. Seven rows of teeth in each jaw, the three central series being much the longest. Seas of India to the Malay Archipelago.

* The protruding angular portion of the dental laminæ of the lower jaw appears liable to be broken off, and it is in such examples that it seems that the notch in the united nasal valves is wanting.

1. Rhinoptera adspersa.

Müll. and Henle, Plagios. p. 183; Bleeker, Beng. p. 82; Jerdon, M. J. L. and Sc. 1851, p. 149; Duméril, Hist. Nat. Poiss. i, p. 648; Günther, Catal. viii, p. 494. Mutta tirke, Tamil.

Disk about twice as wide as long: tail about three times as long as disk. Notch on snout shallow. Teeth—nine rows in the upper and seven in the lower jaw, the teeth in the central row of the upper jaw $2\frac{1}{2}$ to three times wider than in the antero-posterior direction, but not so wide as those in the next row. Fins—dorsal situated at the base of the tail, and immediately behind it a strong serrated spine. Upper surface of body covered with fine stellate tubercles. Colours—greenish brown superiorly, becoming lighter at the edges of the disk.

Amongst Sir Walter Elliot's illustrations of Madras fish are two of this species, the largest being 9 inches across the disk.

Habitat.—Seas of India.

2. Rhinoptera Javanica, Plate CXCV, fig. 4 (teeth).

Müller and Henle, Plagiost. p. 182, t. lviii; Bleeker, Plagiost. p. 89; Duméril, Hist. Nat. Poiss. i, p. 647; Günther, Catal. viii, p. 494.

Rhinoptera affinis, Bleeker, Nat. Verp. Holl. Maatsch. Wet. Haarlem, 1863, Guinee, p. 19.

Disk from about $1\frac{2}{3}$ to twice as broad as long: tail nearly twice as long as disk. Notch on snout shallow. Teeth—seven rows in either jaws, those in the central row being four or five times wider than in the antero-posterior direction, and rather more than twice as wide as the row on either side. The outer rows are hexagonal and narrow. Those in the lower jaw rather narrower than those in the upper. Fins—dorsal, situated at the base of the tail, and immediately behind it a serrated spine. Colours—greenish superiorly, white beneath.

The teeth figured are from a large example captured at Kurrachee. Habitat.—Seas of India to the Malay Archipelago.

B.—Teeth small: cephalic fins forming an appendage on either side of snout.

Genus, 4—DICEROBATIS, Blainville.

Cephaloptera and Mobula, A. Duméril.

Pectoral fin not extended on to the sides of the head, which latter is truncated in front, whilst on either side is a forwardly-pointing horn-like projection, which is internally supported by fin rays. Nostrils not confluent. Teeth in jaws very small, flat, or tuberculated, and in many rows. Tail whip-like, with a dorsal fin situated above and between the ventrals, armed with or destitute of a serrated spine.

The designation Sea-devils, has been given by some authors to fishes belonging to this and the succeeding Genus: it is also frequently applied to several other forms of armed Rays, and fishes which inflict dangerous wounds.

Geographical distribution.—Tropical and temperate seas.

SYNOPSIS OF SPECIES.

- 1. Dicerobatis eregoodoo. Teeth numerous in both jaws. Seas of India to the Malay Archipelago.
- 2. Dicerobatis Kuhlii. Teeth \(\frac{3}{34} \frac{3}{36}\). East coast of Africa, seas of India to the Malay Archipelago.

1. Dicerobatis eregoodoo, Plate CXCIII, fig. 1.

Raja, Russell, Fish. Vizag. i, p. 5, and Eregoodoo tenkee, pl. ix. Cephaloptera eregoodo-tenkee, Cuvier, Règne Anim.

Dicerobatis eregoodoo, Bleeker, Beng. p. 82; Cantor, Catal. Mal. Fish, p. 438; Jerdon, M. J. L. & Sc., 1851, p. 149; Günther, Catal. viii, p. 497. Cephaloptera eregoodoo, Duméril, Hist. Nat. Poiss. i, p. 655.

Disk about twice as broad as long: tail in the young $1\frac{1}{2}$ times the length of the body, but in adults only a little more than 1/2 the same length. Body smooth. The horns or cephalic portion of the pectoral fin have a convoluted appearance, and "are used by the animal to draw its prey into its mouth, which opens like a huge cavern between them. The fishermen say they see them swimming slowly along, with their mouth open and flapping these great sails inwards, drawing in the smaller crustacea on which it feeds" (Sir W. Elliot, MS.). Teeth-small, like flattened, quadrangular tubercles as broad as wide in adults, twice as broad in the young, with a backwardly directed point: $\frac{3+0}{3+6}$, in a jaw twelve inches across the gape taken from an example upwards of eighteen feet across the disk, and $\frac{2+0}{3+6}$ vertical rows opposite the symphysis. In a pair of jaws, from an example captured at Kurrachee, four inches across the jaws there are $\frac{3+0}{2+4}$. Cantor found in an example thirty

inches across the disk $\frac{50}{60}$, and six or seven vertical rows. It may therefore be supposed that the number increases with age, and perhaps alters in shape. The band of teeth reach nearly to the angle of the mouth. *Fins*—no spine on the tail posterior to the dorsal fin. *Colours*—of a deep purplish superiorly: white beneath.

Amongst Sir Walter Elliot's notes on these fishes is an account of a large female example of this species, 16 ft. 9 in. across the disk, which at first broke the net but was eventually captured, Oct. 8th, 1850; subsequently, May 12th, 1853, a male was taken near the same place 18 ft. 8 in. across the disk. It is observed that only the stump of a tail remained in the female, this appendage being very liable to injury and seldom found perfect in adults.

Habitat.—Seas of India to the Malay Archipelago: attaining to 18 feet and upwards across the disk. The example is figured from Jerdon's specimen in the British Museum, 34 inches across the disk.

2. Dicerobatus Kuhlii.

Cephaloptera Kuhlii, Müller and Henle, p. 185, t. lix, f. 1; Bleeker, Amboina, p. 6, and Beng. p. 82; Duméril, Hist. Nat. Poiss. i, p. 654.

Dicerobatis Kuhlii, Günther, Catal. viii, p. 497.

Disk more than twice as wide as long: tail not so long as the disk. Body and tail smooth. Teeth—wider than broad: $\frac{3.4-3.8}{3.4-3.8}$ series, the band ceasing some distance from the angle of the mouth. Colours—brown or greenish.

Habitat. - From the East coast of Africa through the seas of India to the Malay Archipelago.

Genus, 5—CERATOPTERA, Müller and Henle.

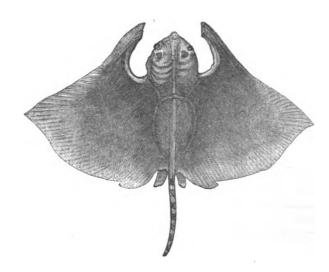

Head truncated anteriorly, free from the pectoral fin, a portion of which latter, however, exists in the form of a horn-like appendage on either side of the head. Mouth wide and anterior. Teeth small and only in the lower jaw. Tail elongated and slender, with a dorsal fin situated on its base, but without any spine.

Habitat.—Tropical and temperate seas.

Ceratoptera Ehrenbergii.

Müller and Henle, Plagiost. p. 187; Günther, Catal. viii, p. 498. Kotuwa tirike, Tamil.

Amongst Sir Walter Elliot's figures of Madras fish is one of which the woodcut is a reduced copy. The original is 6 in. across the disk, and is termed Cephaloptera, and the Tamil name is also given. I can only surmise that it is this species and identical with the unpublished plate of the "Symbolæ Physicæ" adverted to in the British Museum Catalogue, named Cephaloptera stelligera, and in which the horns are bent horizontally inwards.

CORRIGENDA. ADDENDA AND

Page 1, 20 lines from top, for "and thoracic" read "or thoracic."

Page 1, last line, for "Trachinide" read "Ophiocephalide."

Page 2, Serrangs Waandersi is not identical with Bleeker's species, which I have had the opportunity of examining. Bleeker has renamed it Epinephelus Dayi, Atl. Ich. viii, p. 47, but that name having been previously given to another species by the same author, I propose the term Serranus Coromandelicus.

Page 13, Serranus Merra. Bleeker considered some confusion must have occured in Bloch's collection.

and that he mixed up two species, and therefore this form had better still be termed S. Gilberti.

Page 14, Serranus Hexagonatus, add to synonyms "Serranus stellans, Richardson, An. Nat. Hist. 1842.

Page 17, Serranus diacanthus, add to synonyms "Epinephelus Dayi, Bleeker, Rev. Ep. p. 105."
Page 27, line 1, for "Labrus punctatus" read "Labrus punctulatus."
Page 27, line 25, for "Genus, 5—Anthias" read "Aprion," omit synonyms, while it should be placed at

Page 27, line 29, after "Preopercle" insert "entire with a single ridge or finely."
Page 27, line 31, for "from nine to eleven" read "ten to eleven."
Page 27, line 38, for "Anthias multidens" read "Aprion multidens." The species closely resembles A. pristipoma, Bleeker.

Page 32, line 1, LUTIANUS ERYTHROPTERUS. I think the late Dr. Bleeker may be right when suggesting that some error may have occurred amongst Bloch's type specimens, and this fish should be Lutianus annularis.

PRIACANTHUS HOLOCENTRUM.

Bleeker, Perc. p. 48; Günther, Catal. i, p. 220.

B. vi, D. $\frac{10}{12-13}$, P. 17, V. 1/5, A. $\frac{3}{12-13}$, C. 16, L. 1. $\frac{50}{565}$, L. tr. 10/36.

Length of head $3\frac{1}{3}$, of caudal fin $6\frac{3}{4}$, height of body $3\frac{1}{3}$ in the total length. Eyes—diameter $2\frac{1}{2}$ in the length of the head, 1/2 a diameter from the end of snout, and about 2/3 of a diameter apart. The maxilla reaches posteriorly to beneath the first third of the orbit. Preorbital and first suborbital bones serrated inferiorly: both limbs of the preopercle serrated, and also possessing a long, flat spine at its angle equal in length to more than 1/2 a diameter of the orbit. Two opercular spines. Subopercle serrated. A shoulder spine. Fins—dorsal spines of moderate strength, roughened on one side, the second 2/3 the height of the last, which is the longest, and equal to $1\frac{1}{3}$ diameters of the orbit: rayed portion of the fin rather higher and angular. Pectoral nearly 1/2 as long as the head. Ventral just reaches the commencement of the anal. Third anal spine the longest, the two first being serrated anteriorly, while the rays are also rugose. Caudal truncated. Free portion of the tail as high at its base as it is long. Scales—smallest on the head and above the lateralline, they extend superiorly as far as the snout. Colours-rose-coloured superiorly, becoming nearly white on the sides and beneath: ventral fins spotted with brown: a dark edge to dorsal and anal fins.

Habitat.—Madras to the Malay Archipelago. Amongst Sir W. Elliot's illustrations of Coromandel fish exists this species; but I did not obtain examples until lately, when Dr. Keess, of Madras, sent me several.

Page 51, add to synonyms of Ambassis ranga "Chanda (Ambassis) ruconius, McClelland, Cal. Journ. Nat. Hist. ii, p. 586."

Page 55, add

Ambassis thermalis.

Cuv. and Val. iii, p. 493; Günther, Catal. i, p. 225.

D. $7 \mid \frac{1}{9}$, ∇ . 1/5, A. $\frac{3}{8}$.

Height of body not quite 1/3 of the total length excluding the caudal fin. Scales—large. Colours greenish, with a silvery lateral band. A blackish longitudinal streak along each caudal lobe.

Habitat.—Warm springs of Cannia, in Ceylon.

Page 59, "APOGON ENDEKATENIA" unite as one species with "APOGON FASCIATUS," p. 60.
Page 65, Note, "APOGON QUINQUEVITATUS=GLYPHISODON RAHTI;" Blyth, J. A. S. of Beng. 1860, p. 111.
Page 73, "Pristipoma hasta," add to synonyms "Pristipoma nageb, Rüppell, N. W. Fische, p. 124, t. xxx, f. 2."

* When I commenced this work it was not my intention to have given references to wherever each species was adverted to by different naturalists, but to restrict such to those who have published well-known treatises on ichthyology, or might more strictly be termed Indian authors. After the Serrani had been printed, the late Dr. Bleeker persuaded me to give a fuller list of references, pointing out for one reason as that I had omitted S. stellans from my list of synonyms of S. hexagonatus, it had appeared to him that I believed such to be different species. Acting on his advice, I propose here adding the more important synonyms which are not recorded in the text.

Page 78, DIAGRAMMA LINEATUM. The two varieties especially alluded to are species. The form described is, albovittatum. The lineatum has D. $\frac{1}{18}$ - $\frac{1}{20}$, L. l. $\frac{9.0-1.00}{70-700}$, L. tr. 13/27. To the colours given add, "base of pectoral and anal sometimes with dark blotches."

Page 83, DIAGRAMMA PUNCTATUM. Since the article on this fish was published the late Dr. Bleeker

showed me his entire series, and how D. pictum is the young of D. punctatum.

Page 96, at line 13 from the bottom, after "Inferior pharyngeal bones firmly united by a suture" add "in some but not in all species."

Page 98, Gerres setifer, to "Habitat" add "the sea at Madras," as I have received a specimen from that locality collected by Dr. Keess.

Page 101, 13 lines from bottom, for "taniatus" read "multitaniatus."

Page 105, to synonyms of "Chatodon Mertensii" add "C. chrysurus, Desjardin, 3rd Report of Soc. Hist.

Nat. de Maurice. C. xanthurus, Bleeker, Amboina, p. 53."

Page 106, under "Chatodon guttatissimus" insert "C. miliaris, Quoy and Gaim. Uranie, Zool. 1824, p. 380, p. 181, f. 6; Cuv. and Val. vii, p. 26; Voy. Bonite, Poiss. p. 163, t. ii, f. 2; Günther, Catal. ii, p. 31, and Page Val. Soc. 1871 p. 679

p. 380, pl. 18th, f. 6; Cuv. and Val. Vii, p. 26; Voy. Bonite, Poiss. p. 103, t. ii, f. 2; Gunther, Catal. ii, p. 31, and Proc. Zool. Soc. 1871, p. 658.

Page 107, under "Chectodon vittatus" insert, as a synonym, "C. Layardi, Blyth, Kelaart's Fauna Zeylon. Appendix." The type of which, 3 inches long, is in the Calcutta Museum.

Page 148, for "Genus, 1—Sebastes, Cuv. and Val." insert "Myriodon, Barneville;" for "no groove on occiput, usually a few small spines: preopercle armed," insert "Opercle spinate: preopercle denticulated, with spinous teeth on the lower limb directed forward."

For SEBASTES STOLICZKE read MYRIODON WAIGIENSIS.

Scorpana waigiensis, Quoy and Gaim. Voy. Freyc. Zool. p. 324, pl. lviii, f. 1.

Centropistes scorpænoides, Cuv. and Val. iii, p. 48.

Myriodon scorpænoides, Bris. de Barnv. Rev. Zool. 1847, p. 130.

Its range extends to the Malay Archipelago and Australia.

Page 148, 7 lines from bottom of page, erase "Scorpæna cyanostigma, Bleeker, which has only eight rows of scales above the lateral-line.'

Page 149, for "Scorpena Haplodactylus" insert "Scorpena Bleekeri," and erase the synonyms. Bleeker observed, S. haplodactylus has the upper as well as the lower pectoral rays simple.

Page 152, under "Genus Pterois" add synonym "Pseudomonopterus, Klein."

Page 158, under "Genus Micropus," add synonym "Trachidermis, Heckel."

Page 237, above "Genus PSENES" insert "FAMILY NOMBIDE."

Page 242, 8 lines from bottom, for "mars" read "marks."

Page 251. Scomber loo, Cuv. and Val. is not identical with S. microlepidotus. Dr. Bleeker gave me an example of the former from the Malay Archipelago. It may be distinguished by the anterior portion of the adipose lid of the eye passing downwards, and becoming attached to the upper edge of the preorbital and to that of the succeeding bone of the suborbital ring.

Page 255. Caranx nigripinnis. Two examples have lately been received from Madras, each having

Page 255. Caranz nigripulus. 2.00 Salap.

Page 260, under "Genus Uranoscopus" insert as a synonym, "Nematagnus, Gill."

Page 264, under "Sillago domina" place "Cheilodipterus panijus, Ham. Buch. Fish. Ganges, pp. 57, 367.

Page 286, under "Gobius viridipunctutus" add synonym "Gobius chlorostigma, Bleeker, Blen. en Gob. p. 27.

Page 287, for "Gobius cyanosmos" read "Gobius cyanomos."

Page 294, 3 lines from bottom, for "Plate LXVII" read "Plate LXVI."

SICYDIUM GRISEUM.

Day, Journal Linnean Society, Zool. xiii, p. 140.

B. iv, D. 6 $\left| \frac{1}{10} \right|$, P. 17, V. 6, A. 11, C. 13, L. 1. 80, L. tr. 25.

Length of head $5\frac{1}{2}$, of caudal fin $6\frac{1}{2}$, height of body 6 in the total length. Eyes—diameter 4 in the length of the head, rather above 1 diameter from the end of snout, and $1\frac{1}{2}$ apart. Body subcylindrical: upper surface of the head flat, its greatest width equalling its length. Cleft of the mouth extending to below the first third of the eye. Lower jaw placed horizontally. Lips thick, the edge of the upper coarsely fringed. Snout not overhanging the mouth. No barbels. Teeth—in the upper jaw in a single row, small, closely set and implanted in the gums. The outer row in the lower jaw, horizontal, posterior to them and opposite the symphysis are two strong, recurved, canines. Fins—dorsal spines filiform, and projecting beyond the metherate: and all rounded. Scales—strongly etenoid of irregular sizes and shapes and in irregular rows. membrane: candal rounded. Scales—strongly ctenoid, of irregular sizes and shapes, and in irregular rows: they extend forwards to nearly as far as the eyes: none on the sides of the head. Colours—brownish, with eight or nine rings of a darker tint encircling the body, and wider than the ground colour. Fins—dark, most deeply so at their edges.

Habitat.—South Canara, where I procured two examples in fresh water, the largest being 3 inches. They were mislaid until after p. 299 had been printed.

THE END.

G. NORMAN AND SON, PRINTERS, MAIDEN LANE, COVENT GARDEN, LONDON.

SUPPLEMENT, OCTOBER, 1888.

During the ten years which have elapsed since the publication of my "Fishes of India," many new piscine forms have been obtained from both the seas and fresh waters of that portion of Asia. Extended investigations among specimens in European museums have likewise shown me that some species which I formerly considered as undescribed, had no title to that designation, while several of my new species have been redescribed as novelties in the Proceedings of Societies, in scientific journals or other publications. I am also indebted to Mr. Thurston of the Madras Museum, and Mr. Haly of the Colombo Museum, for some new Indian forms. I have likewise had the opportunity of consulting the volume of beautiful coloured drawings of Burmese fishes with their descriptions by the late Col. Tickell, several of which I have included in the present supplement.

As it is now proposed to re-issue my work in a more portable size, one better suited for travellers and collectors, and in which it would be very inconvenient, on account of the necessary space it would require, to embrace the entire synonymy of every species, I have considered it advisable to complete the original work to the present date. By this means the references would be available for those who are concerned in working out each species, for doubtless a vast number of Indian fishes still remain to be discovered.

Pseudolates cavifrons. Alleyn and Macleay, Pro. Lin. Soc. N. S. W. i, p. 262, pl. iii.

Page 9. Cromileptes altivelis. Add to synonyms as varieties.

Serranus striolatus, Günther and Playfair, Fish. Zanzibar, p. 11, pl. iii, f. 2. gibbosus, Bonlenger, Proc. Zool. Soc. 1887, page 654.

The chief structural reason why these two varieties have been separated from the original form appears to be in consequence of the comparatively low spinous dorsal fin: and the colours in which last S. striolatus and S. gibbosus likewise differ. S. striolatus has its third and fourth dorsal spines, said to be the longest (both are broken in the single example) and fourth dorsal spines, said to be the longest (both are broken in the single example) and one-third the length of the head (thus differing from S. altivelis). In the figure, the third spine is one-fourth longer than the last, which, however, exceeds the penultimate one (which is also broken), while it is more than half the height of the longest dorsal ray (1.4 to 2.4). The height of the soft portion of the dorsal and anal fins equals that of altivelis, but the pectoral is shorter. In colours it has fifteen or more rows of short brown streaks and numerous brown spots on the head and body. The single skin is 19 inches in length.

Serranus gibbosus. The unique specimen has been preserved in spirit, and is 15 inches in length. The third dorsal spine is longer than the last, which is one-third shorter than the longest ray. Its colours are an advance from striolatus towards altivelis, it being generally brown with spots or blotches of a larger size than in striolatus, some of which are surrounded by a light ring, but having a tendency to form about seventeen lines along

I think these two new species cannot be specifically separated, but may be varieties of altivelis, which latter has not been recorded from the Red Sea, nor known to extend to Muscat or Zanzibar. If, therefore, they are varieties, they are evidently outlying specimens which show a variation in the length of the dorsal spines from what obtains in those captured more to the east. The pectoral fin appears rather short in *striolatus*, but more of the normal length in *gibbosus*, whereas in all the number of scales appears to be

Digitized by Google

The figure of Serranus altivelis in Cuv. and Val. ii, pl. xxxv, shows the spines of the dorsal fin increasing in length to the last which is delineated nearly twice as long as the second. Cantor, "Malayan Fishes," found these spines from the third to be of nearly equal length. Blecker shows them slightly, but gradually increasing to the last, which is figured one-fifth longer than the third. I have observed them more corresponding with Cantor's description, but all have been small specimens. Still the foregoing show that differences do exist in the length of these spines, that augmenting from the third to the last is not universally carried out in the same way. In altivelis the length of the third dorsal spine is about $\frac{1}{2}$ of that of the head, in the larger gibbosus 15 inches long it is $2\frac{1}{9}$, and in the still larger striolatus $\frac{1}{3}$.

Page 21. Serranus morrhua. Add to synonymy.

Serranus præopercularis, Boulenger, P. Z. S. 1887, p. 654.

As I have remarked, and likewise figured, the young of this species has broad white bands, whereas, as it becomes older, it is brown with narrow black lines, which were the original borders of the white bands. In the Paris Museum is a young specimen in which there are dark spots along these lines, while among these percoid fishes longitudinal dark bands or lines have a tendency to become spots, and finally disappear, as horizontal bands have to fade away. In Klunzinger's figure, F.R.M. t. i, f. 2, three brown bands radiate from the eye and become four curved ones on the body, the first going to the eighth dorsal spine, the second to the fifth ray, while between them are blotches, spots or markings of the same colour. The fifth dorsal spine is shown the longest, and as equalling a little more than $1\frac{1}{3}$ the length of the orbit. Among Sir W. Elliot's drawings is one of this fish 1·1 inches long, it has a strong spine at the angle of the preopercle and another on the subopercle.

Serranus preopercularis is represented by two specimens from the Persian Gulf, one 12 inches, the other 24 inches in length. The number of spines, rays and scales, as well as the form are similar to the type, but instead of black lines there are black dots along the sides rather irregularly disposed, and least numerous in the larger specimen. If, however, the smaller one be examined, the radiating lines from the eye, although indistinct, are still perceptible, giving a certain clue to what the markings had been in the young, or those of the young of the S. morrhua.

Serranus latifusciatus, Schlegel, Fauna Japon. Pisces, p. 6; Day, Proc. Zool. Soc. 1888,

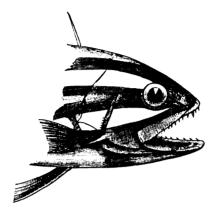

page 259.

Having been shown the types of Schlegel's fish at Leyden, I found the two specifically

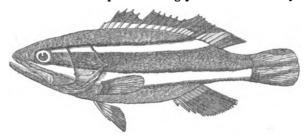

Having been shown the types of Schlegel's fish at Leyden, I found the two specifically identical.

The earlier stages of growth in all fishes are interesting, more especially as they may be one means of deciding the original forms from which certain genera have probably been developed. It is, therefore, very desirable that all such should be recorded as discovered, even if merely as an incentive to further research. In 1867, I obtained

some small specimens of a remarkable percoid form at Madras that I termed *Priacanthichthys Madraspatensis*, but which are the young of *Serranus latifasciatus*. I have figured below in outline the head and contiguous parts of the body three times the natural size, from a specimen 1.6 inches long.

In this instance we see a preoperculum with a strong serrated spine at its angle somewhat as observed in the genus *Priacanthus*, the development of which, and the rate at which it becomes atrophied with age being most probably factors in the amount of protuberance at that spot in older fish. There is likewise a small spine on the sub-opercle, while it is very peculiar that the ventral spine is strongly serrated internally similar to a siluroid.

This figure is from a specimen sent by Mr. Thurston from Madras, and delineated the natural size, 3 inches long, but in which the fifth dorsal spine is abnormally shortened, giving somewhat the appearance of two spinous dorsal fins. The serrated spine at the angle of the preopercle is now only represented by coarse denticulations, the ventral spine is smooth, and the fish has assumed the form it subsequently retains. The colours are not yet similar to those of the adult, the bands along the body change as described under Serranus morrhua and the black bands on the caudal fin are eventually represented by more or less black spots (see Plate V, fig. 4).

SERRANUS POLLENI.

Epinephelus polleni, Bleeker, Fish. Reunion Versl. Kon. Akad. Wet. 2nd Rks. ii, p. 336, and Poisson Madagascar et Reunion, p. 19, t. vii.

B. vii, D. $\frac{9}{15-16}$, P. 17, V. 1/5, A. 3/9, C. 17, L. l. 115-120.

Length of head $3\frac{1}{2}$, of caudal fin 7, height of body $3\frac{2}{3}$ in the total length. Eyes—diameter 6 in the length of the head, $1\frac{1}{3}$ diameters from the end of the snout. Preopercle serrated, most coarsely so along its lower edge. The posterior edge of the maxilla reaches to somewhat behind the hind edge of the orbit. Teeth—canines somewhat large. Fins—dorsal spines increasing in length to the fourth, the posterior ones four-fifths as high as the rayed portion of the fin, which latter is rounded posteriorly. Second anal spine somewhat the longest. Caudal fin slightly rounded. Scales—9 or 10 rows between the base of the sixth dorsal spine and the lateral-line. Colours—closely approaching those of Serranus boenack, being generally reddish brown, with 5 or 6 narrow blue lines on the head passing backwards, 10 or 12 horizontal blue lines along the body, those in the upper third being interrupted and contorted, some ending on the soft portion of the dorsal fin, while others similarly end on the caudal and anal fins. A horizontal narrow blue band along the centre of the dorsal fin, and a narrow blue edging to the soft portion, 2 or 3 blue bands taking a semi-horizontal direction on the anal fin. Caudal externally edged with reddish brown.

Digitized by Goo

An example from the Isle of France exists in the National Museum; another is in the Paris Museum, received from M. Lienard, of the Mauritius, and the coloured figure of a Madras specimen termed Sembarra punnee, Pam., exists in the late Sir Walter Elliot's collection made at Madras.

Page 24. Serranus guttatus.

It has been my belief that this is a variety of the S. hemistictus, the latter wanting the cross bands. S. guttatus was figured in colours in the Fische de Sudsee by the late Mr. Ford, and as the specimen was superior to mine I requested him to employ the same fish for my uncoloured representation. He did so, but the bands had faded, and now the Südsce figure is referred to as S. guttatus, mine as S. hemistictus. As both were from the identical specimen by the same artist, it affords an additional argument that they are varieties of one species.

Centopristis pristopoma, Klunzinger, Fisc. Roth. Meer, p. 16.

Add Genus. Aphareus, Cuv. and Val.

Branchiostegal's seven, pseudobranchiæ. Body oblong. Cleft of mouth wide and oblique, the lower jaw the longer. Preopercle and preorbital entire. Canines absent, palate edentulous. A single dorsal fin, with the front portion the highest, spines (10-12) feeble: caudal forked. Scales small. Air-bladder simple. A respiratory cavity behind the branchiæ. Pyloric appendages few.

APHAREUS RUTILANS. Page 27.

Aphareus rutilans, Cuv. and Val. vi, p. 490; Rüppell, N.W.F. p. 121; Bleeker, Amboina, p. 52, and Atl. Ich. vii, Perc. t. xxi, f. 2; Günther, Catal. i, p. 386; Klunz. F.R.M.

Aphareus furcatus, Bleeker, Atl. Ich. viii, p. 80.

B. viii, D. $\frac{10-19}{9-11}$ P. 16, V. 1/5, A. $\frac{3}{8}$, C. 17, L. 1. 65-70, Cec. pyl. 5.

Length of head 4, of caudal fin $3\frac{1}{2}$ to $3\frac{2}{3}$, height of body $4\frac{3}{4}$ to 5 in the total length. Eyes—diameter 4 in the length of the head, $1\frac{1}{4}$ diameters from the end of the snout and 1 apart. Teeth—anteriorly in two or three rows, in a single row posteriorly. Fins—fourth and fifth dorsal spines the highest in the fin; last dorsal and anal rays prolonged to twice the length of the penultimate ones; caudal deeply forked. Colours-rosey, darkest along the back, with a yellow blotch between each ray of the dorsal fin near their bases; caudal lobes with dark tips.

Blecker considered this species to be identical with Labrus furcatus, Lacép., or Aphareus cærulescens, Cuv. and Val.

Habitat.—Red Sea to the Malay Archipelago. Obtained at Ceylon by Mr. Haly.

Page 28. Add Grammistes punctatus.

Cuv. and Val. vi, p. 504; Günther, Fische d. Südsee, 1875, p. 11, t. ii, f. B; Bleeker, Fish. Madagascar, 1874, p. 24, t. xiii, and Atl. Ich. vii, p. 69, Perc. t. lix, f. 5.

B. vi, D. $7/\frac{1}{12}$, P. 16, V. 1/5, A. 11, C. 17.

Length of head $3\frac{1}{3}$, of candal fin 7, height of body 4 in the total length. Eyes—high up, diameter $5\frac{1}{2}$ in the length of the head, about $\frac{1}{2}$ a diameter apart. Lower jaw the Vertical limb of preopercle with spinate denticulations: three spines on opercle. A barbel, rather longer than one diameter of the eye, at the symphysis of the lower jaw. Teeth—generic. Scales—small, imbedded in mucus. Colours—grayish-brown, with small white dots.

A third species, with 7 or 8 dorsal spines and a more elongated body, has been found at the Seychelles, and appears to be G. compressus, Lienard.

Forskal's species appears to be identical with Holocentrus Bengalensis, Bloch, but the variety he mentions with a black lateral blotch is H. quinquelinearis, Bloch, and is certainly a distinct species, the latter differing, irrespective of colouring, in many important points from the former, for its preopercular notch is deeper, its eye larger, its snout more rounded, &c. In some specimens the bands on the side are red, not blue.

Length of head $3\frac{1}{2}$, of caudal fin $4\frac{1}{4}$ to $4\frac{1}{2}$, height of body 3 to $3\frac{1}{4}$ in the total length. Eyes— $3\frac{1}{2}$ to 4 diameters in the length of the head, 1 diameter from the end of the snout, and 1 apart. Upper profile of head very convex. Lower jaw the longer. Vertical limb of preopercle with a deep notch to receive a large interopercular knob, and its lower edge serrated. Fins—dorsal and anal with their soft parts pointed, pectoral long, reaching the anal. Caudal emarginate. Colours—adult, of a grayish-black, immature, dark purplish, nearly black (belly bluish), with several light spots along the base of the dorsal fin. A light band along the middle of the body and tail fin. Another from the eye over the jaws, and a third down the opercle. Fins dark, the posterior ends of dorsal and anal fins light-coloured. Caudal lobes tipped with white.

Bleeker considered that Lutianus nigra to be distinct from L. macolor.

Habitat.—Red Sea, East Coast of Africa, Navigator Islands to the Malay Archipelago, and Mr. Haly in 1887 had an example sent from the Maldives to the Ceylon Museum.

Length of head 4, of caudal fin $4\frac{1}{2}$, height of body $3\frac{1}{4}$ in the total length. Eyes—diameter one-third of the length of the head, 2/3 of a diameter from the end of the snout, and the same distance apart. Lower jaw the longer. Cleft of mouth very oblique: the maxilla reaches to beneath the front edge of the orbit. Preorbital with seven strong teeth along its lower edge: a spine at the posterior-superior angle of the orbit. Vertical limb of preopercle entire: its horizontal double edge serrated the lower most coarsely so. Sub- and inter-opercles entire. Teeth—villiform in jaws, vomer, and palate, a small central band at the root of the tongue. Fins—second spine of the dorsal longest and equal to $4\frac{3}{4}$ in the total length, and 2/3 the height of the body below it. Ventrals reach the vent: pectoral reaches to above the third anal spine, which latter is longer and weaker than the second, but half shorter than the third dorsal spine. Scales—two to three rows along the cheeks. Lateral-line—curves to near the middle of the soft dorsal, when it becomes straight, it is uninterrupted. Colours—silvery, with a burnished lateral band. Interspinous membrane between the second and third dorsal spines spotted with black.

Habitat.—Sea at Madras, from which Mr. Thurston has sent me one specimen 4 inches long, to the Malay Archipelago and Cook's Islands.

Length of head $3\frac{1}{4}$, of caudal fin $5\frac{1}{4}$, height of body $2\frac{1}{5}$ in the total length. Eyes—diameter $3\frac{1}{3}$ in the length of the head, $\frac{3}{4}$ of a diameter from the end of the snout, and 1 apart. A very slight rise from the snout to the base of the dorsal fin. Snout a little elevated: upper jaw slightly the longer, and extending posteriorly to below the last third of the orbit. Both limbs of the preopercle serrated, the vertical one finely and evenly, the angle rather coarsely and the lower limb more irregularly: shoulder scale serrated. Teeth—villiform ones in jaws, also present on vomer and palate. Fins—Dorsal spines strong, the two first short, the third slightly the longest, and equal in length to the head behind the middle of the eyes, and nearly half the height of the body below it: the rays of the second dorsal as long as the longest dorsal spine and one-fourth longer than those of the anal fin. Pectoral reaches to above the anal spines, and the ventral nearly as far. Caudal somewhat square at its extremity. Lateral-line very slightly curved, becoming straight on the free portion of the tail: its tubes simple with a basal expansion on each side. Colours—greyish, darkest along the back and a dark band behind the base of the second dorsal fin: an oval black spot nearly as large as the orbit and surrounded by a narrow yellow ring exists below the lateral line and under the first dorsal fin. Vertical fins black, caudal yellowish.

Habitat.—Madras, from which Museum I have been lent by Mr. Thurston, a specimen 3 inches long.

Page 62. Apogon bifasciatus. Add synonym.

Apogon maximus, Boulenger, P. Z. S. 1887, p. 655.

Some very fine examples, in which the black spots are unusually large, were received from the Persian Gulf and thus named. The third and fourth dorsal spines are only half the length of the head, the eye is naturally smaller than in recorded specimens, and the maxilla extends to below the middle of the eye. These fish reach to about 10 inches in length.

Length of head 3 to $3\frac{1}{4}$, of caudal fin $5\frac{1}{2}$, height of body $3\frac{1}{4}$ in the total length. Eyes—diameter $\frac{1}{4}$ of length of head, nearly 1 diameter from the end of the snout, and $\frac{3}{4}$ to 1 diameter apart. Lower jaw very slightly the longer. The maxilla reaches to slightly behind the hind edge of the eye. The posterior edge of the preopercle finely serrated except in a small portion of its lower part. A considerable rise from the snout to the base of the first dorsal fin. Fins—first dorsal spine one-third the length of the second, which is equal to the third and about $2\frac{1}{2}$ in the length of the head; second dorsal somewhat higher than the first. Caudal rounded. Scales—finely ctenoid. Colours—pale horn above and below, with a slight golden tinge on the opercles: caudal and ventral both having a dark hind edge. A round black spot at the root of the caudal fin.

Habitat.—Col. Tickell procured two examples at Akyab (see figure 4.2 inches long,

"scale 10/16," p. 215, MSS.) and it seems to be identical with Cantor's fish.

Length of head $3\frac{1}{2}$ to 4, of caudal fin 7, height of body $3\frac{1}{2}$ in the total length. Eyes diameter $2\frac{1}{3}$ to $3\frac{1}{4}$ in the length of the head, $1\frac{1}{3}$ diameters from the end of the snout, and 1 apart. The maxilla reaches nearly to be neath the front edge of the eye. Vertical limb of preopercle serrated. Fins—dorsal spines slightly higher than the rays, the second to the fourth being of about the same length, and the longest in the fin, while each is about equal to one-third of the height of the body; second anal spine the longest and strongest. Scales—ctenoid. Colours—silvery with horizontal grayish or brownish bands, the upper of which are wider than the ground colour, these bands unite anteriorly over the nape and snout, while the upper ones end posteriorly at the base of the dorsal fin. Fins yellowish, the dorsal, caudal and anal with some dark bands and spots and dark outer

A specimen $7\frac{1}{2}$ inches long received from Madras through the kindness of Mr. Thurston, has D 10, which is very interesting, as showing how great a variation in the number of spines and rays may exist, for the usual numbers are D 12-13 o.

Habitat.—From the East Coast of Africa, to Ceylon, Madras, and the Malay Archipelago to 380": and in the British Museum to 143 inches.

Page 81. DIAGRAMMA GRISEUM. Add synonym.

Diagramma jayakari, Boulenger, P. Z. S. 1887, p. 656.

This differs from the types in having one more spine and ray in the dorsal fin, or D 13/22, but Mr. Thurston has lately sent me a specimen from Madras with D 12/22. Some error occurred in Mr. Boulenger's description, for if "the greatest depth of the soft dorsal equals the length of the longest spine, or seven-eighths the depth of the body," this fin would be enormously developed. However, we are also informed that the longest dorsal spine is "not quite one-third the length of the head," and it is manifestly improbable that any Diagramma would have the length of its head equalling nearly three times the height of the body when that height is "thrice and two-fifths in the total length." In fact the

form is similar to that figured as D. griseum, C.V.

In the "Fishes of Zanzibar" it was pointed out that D. griseum was subject to variations in colour, and one was figured showing four whitish curved cross bands. There is no genus of Asiatic marine fishes with more variation in the colour of individual specimens and local races than shown in that of Diagramma. While I stated that in the young some sinuous and narrow light blue lines exist over the snout and cheeks, and also several sinuous blue lines taking an oblique direction from the head upwards, and which extend to nearly the length of the body.

FAMILY—MALACANTHIDÆ, Günther.

Branchiostegals from five to six: pseudobranchiæ present. Gill-openings wide, the membranes united beneath the throat. Gills four, with a slit behind the fourth. Body elongated and compressed ips thick. A posterior canine tooth in the premaxillaries. Dorsal and anal fins with many rays, the first few of the former not being articulated. Ventrals thoracic with one spine and five rays. Scales small, and finely etenoid. Air-bladder simple. Pyloric appendages absent.

Genus 1. MALACANTHUS, Cuv.

Cleft of mouth horizontal, with the jaws equal anteriorly. Opercle with a spine: pre-opercle entire. Eyes lateral. Villiform teeth in the jaws, having an outer band of stronger ones: palate toothless. A long continuous dorsal fin with the first four to six rays not articulated.

Habitat.—Tropical seas.

Page 138. Pagrus spinifer. Add synonym.

Pagrus ruber, Boulenger, Proc. Zool. Soc. 1887, page 658.

Mr. Boulenger has instituted a new species from the Persian Gulf having "a protuberance between and in front of the eyes;" of the dorsal spines the "third longest, compressed and curved, its length one-third to one-fourth the depth of the body," being apparently considered sufficient to characterize it. In Cuv. and Val. we are told that in Pagrus spinifer the third dorsal spine is 2/3 the height of the body, and the fourth about the same length. If, however, a large number of specimens are brought together it becomes at once apparent that this difference in the length of the dorsal spines is almost entirely owing to the age and size of the example. In two young specimens from Sind, each 3 inches long, the filamentosus prolongation reached the caudal fin, but as age increases the comparative length of these filaments diminishes. The largest of Mr. Boulenger's two specimens is 19 inches long, its third dorsal spine is 1.8 inches or 105 in the total length; while the smaller example is 13 inches long, and its third dorsal spine 1.7 inches long or $7\frac{11}{17}$ in the total. In two small specimens, 7 and 7.4 inches respectively in length sent to the British Museum by Colonel Playfair, the length of the prolonged rays is absolutely greater than in the larger examples. In a Madras specimen 4.8 inches long the third dorsal spine is 2 inches long, or 2\frac{1}{4} in the total length; and in a larger example 9 inches long the third dorsal spine is 18 inches long, or 1/5 of the total length, while the frontal protuberance is well developed. I figured an intermediate sized one in which this spine was about $3\frac{1}{2}$ in the total length or 2/3 of the height of the body. It is no doubt true that in the young considerable variations are seen in the length of these rays, which prolongations become absorbed with age. The two types of P. ruber are somewhat large specimens, but if we examine the foregoing figures we see as follows respecting the third dorsal spine, at 19 inches it equals $10^{\frac{5}{9}}$, at 13 inches $7^{\frac{11}{17}}$, at 9 inches 5, at 7 inches $3^{\frac{1}{2}}$, at 4.8 inches $2\frac{1}{4}$ in the total length.

Equula dentex, Peters, Fish. Moss. p. 246 (not C. V.).

Length of head $3\frac{1}{2}$ to 4, of caudal fin 5, height of body $2\frac{1}{4}$ to $2\frac{1}{2}$ in. of the total length. Eye—diameter $\frac{1}{3}$ of the length of the head, 2/3 of a diameter from the end of the snout. Teeth—canines of moderate size. Fins—first dorsal higher than the second. Colours—body grayish, with some dark lines passing along the rows of scales, light-coloured on the

chest; dorsal, anal, and ventral fins nearly black, caudal of a dull yellow.

Habitat.—Red Sea, Madras to the Malay Archipelago. A coloured figure named Psani paré, Tamil, exists among the late Sir W. Elliot's drawings.

Length of head $3\frac{1}{2}$, of caudal fin $7\frac{1}{4}$, height of body 7 in the total length. Eyes—diameter $3\frac{1}{2}$ to $4\frac{1}{2}$ in the length of the head, $1\frac{1}{2}$ diameters from the end of the snout, and 1 apart. Snout more pointed than in S. microlepidotus. Teeth—in jaws stronger than in the last species, and well developed on the vomer and palatines. Colours—similar to those in the last species, with the addition of two or more rows of dark spots along the back and also some transverse streaks.

Habitat.—Persian Gulf to Japan.

Page 263. Add Percis Cylindrica.

Day, Proc. Zool. Soc. 1888, p. 260.

B. vi, D. 5/21, P. 15, V. 1/5, A. 17-18, C. 15, L. 1. 44, L. tr. $2\frac{1}{2}/9$.

Length of head 4, of caudal fin $5\frac{1}{2}$, height of body $5\frac{1}{4}$ in the total length. Eyes—diameter $3\frac{1}{4}$ in the length of the head, I diameter from the end of the snout, and $\frac{1}{4}$ of a diameter apart. The greatest width of the head equals its length, excluding the snout. Cleft of mouth very slightly oblique: lower jaw a little the longer: the posterior extremity of the maxilla reaches to beneath the first third of the orbit. The greatest depth of the preorbital equals one-third of the diameter of the eye. All the opercles entire: a well-marked spine on the opercle and another on the subopercle, no shoulder spine. Teeth—two enlarged ones on either side, above the symphysis of the lower jaw: fine ones on the vomer. Fins—second dorsal spine the longest, equalling three-fourths of the diameter of the eye. Pectoral nearly as long as the head. Ventral one-fourth longer than the head, reaching the base of the seventh anal ray. Caudal slightly rounded. Colours—reddish-brown, with five wide and dark vertical bands, extending from the back to the lower surface, these bands being darkest at their edges and disappearing about the middle of the body, where there are also some dark spots. A brown occllus at the upper part of the base of the caudal fin, which has some brown spots on it. Numerous brown spots on the snout and upper surface of the head and checks, some on the upper edge of the eye, where there are two dark narrow bands. Ventrals white. First dorsal fin nearly black between the spines: soft dorsal and anal with fine dots between the rays.

Habitat.—Two small specimens from the Andamans.

Page 264. For Sillago domina read S. Panijius. Add synonym. Cheilodipterus panijius, Ham. Buch, Fish Ganges, pp. 57, 367.

Page 267. For Pseudochromis xanthochir read S. fuscus. Add synonym.

Bleeker, Atl. Ich. ix, Sciænidæ, t. v, f. 4.

Col. Tickell figured two varieties of a species of this genus taken at Saddle Island, off Kyouk Phoo. He gave the D. 22, A. 13-14, and stated that the scales were large. The one he termed Malacocanthus coccinicauda being of dark burnt umber colour, becoming a little purplish below. Fins pale brown. Dorsal rays vermilion. Anal with a pale red band along its centre. Caudal deep carmine. The second, M. bicolor, had the anterior half of its body yellow olive-green, its posterior half superiorly including eyes, dorsal, caudal, and anal fins sepia, upper and lower margins and angle of caudal whitish gray. Pectoral and ventral yellowish. A row of small irregular spots of a smalt colour along the middle of the posterior half of the body.

Page 278. Add Genus 2-Trigla, Artedia

Hoplonotus, Guichenot.

Branchiostegals seven: pseudobranchiæ present. Head parallelopiped, with its superior and lateral surfaces bony. Villiform teeth in both jaws, and usually on the vomer, but none on the palatines. Two dorsal fins, the first being of less extent than the second: three free filaments at the base of the pectoral fin. Air-bladder well developed, generally provided with lateral muscles, and sometimes partially divided internally by partitions. Pyloric appendages few or in moderate numbers.

Geographical distribution.—Coasts of Europe, and one species extending across the North Atlantic to the western shores of North America. To the south it passes round the west coast of Africa from the Atlantic to the Indian Ocean, and one species has been obtained in the Persian Gulf on one hand, and also in Japan; consequently it is here inserted as Indian.

1. TRIGLA HEMISTICTA.

B. vii, D. 7/11-12, P. 11 + iii, V. 1/5, A. 11-12, C. 16.

Length of head about 3, of caudal fin $5\frac{1}{2}$, height of body $5\frac{1}{2}$ in the total length. Eyes— $1\frac{1}{2}$ diameters from the end of the snout, and $1\frac{1}{4}$ apart. Profile from upper edge of orbit to the snout scarcely concave. Preorbital produced anteriorly into a flattened spine; two spines on the preopercle, the upper the larger. Opercle ending posteriorly in a strong spine equalling the diameter of the orbit; shoulder bone with two spines. Teeth—villiform. Fins—dorsal spines strong, the third and fourth the longest. A bony plate along the base of the dorsal fin, wider in small than in large examples. Pectoral reaches to above the third anal ray, three free appendages. Scales—small. Colours—upper part of body rosy, with numerous small rounded or oblong black spots: lower half of body white. First dorsal with a large black oblong blotch and a row of small round black dots along the middle of the second dorsal: inter-radial membrane of pectoral bluish-black.

Habitat.—An example 9 inches long has been obtained from Muscat, the species has likewise been brought from Japan.

Page 278. Genus 3-Peristethus, Kaup.

Branchiostegals seven: pseudobranchiæ present. Head parallelopiped in shape, the sides and upper surface cuirassed with bone: the preorbital prolonged anteriorly into a flat projecting process. One or more barbels on the lower jaw. Teeth absent. One or two dorsal fins, the posterior of which is most developed. Two free pectoral appendages. Body covered with bony, scale-like plates. Pyloric appendages few, or in moderate numbers. Air-bladder present.

Geographical distribution.—From the south coast of Britain to the Mediterranean, also from the Atlantic and Indian Oceans to China. It has likewise been obtained at the Sandwich Islands in the South Pacific Ocean.

Peristethus, Haly, The Taprobanian, vol. i, 1886, p. 165.

B. vii, D. 7/15, V. 1/5, A. 15, L. 1. 34.

"Preorbital processes short, their length being contained $3\frac{1}{2}$ times between their extremity and the anterior margin of the orbit. A pair of spines on the occiput, on either side of which is a low ridge terminated by a small spine. Anterior vertical plates longer than broad. The opercular ridge forms a strong spine. Lower jaw with barbels. Colours—uniform red."

Habitat.—A single specimen taken at Galle in deep water in April, 1883.

Page 279. DACTYLOPTERUS ORIENTALIS. Add synonym.

Corystion orientalis, Bleeker, Waigou, 1868, p. 3.

Page 284. Among Sir W. Elliot's and Dr. T. C. Jerdon's MS. illustrations of Indian fishes are several undescribed gobies, but as the notes respecting them have been lost, I can merely give such details as are shown on the drawings; the subject of scales and teething being omitted, must be ascertained by future observers. No specific names are attached, as the descriptions are merely for the purpose of directing the attention of collectors to the forms.

Page 284. Gobius ?

Natsuli, Jerdon.

D. $6/\frac{1}{13}$, A. 13.

Length of head $4\frac{2}{3}$, of caudal fin 6, height of body 6 in the total length. Eyes—rather high up, diameter $4\frac{1}{2}$ in the length of the head, $1\frac{1}{4}$ diameters from the end of the snout. Cleft of mouth oblique, lower jaw somewhat the longer. Teeth? Fins—spines and rays somewhat filamentous, and of about equal height, nearly equalling that of the body. Caudal rounded. Scales? Colours—of a light buff, with a row of oval brown spots along the middle of the body, and several scattered smaller ones above; among these are interspersed many small yellowish-red dots. First dorsal fin with a row of orange spots along its base and a dark outer margin. Second dorsal with a similar row of orange spots along its base, a dark band along its centre, and a dark outer edge. Ventrals black. Anal with two orange bands and a dark outer edge. Caudal with 6 or 7 narrow vertical brown or orange bands, and a dark outer edge.

Habitat.-Madras, to 4 inches in length.

Page 284.

Gobius?

D. 7/13, A. 13.

Length of head 6, of candal fin $4\frac{1}{3}$, height of body 7 in the total length. Eyes—very high up and of moderate size. Fins—dorsal with a short interspace, somewhat higher than the body. Pectoral longer than the head, candal somewhat lanceolate. Colours—buff, becoming pink beneath, a row of cloudy spots along the middle of the sides, and indistinct bands. Numerous fine black dots on the back. A black mark under the eye. A black spot on the last two dorsal spines, both dorsal fins and upper half of caudal spotted. A dark base to the pectoral fin.

Habitat.—Adyar River near Madras, to 2.8 inches in length.

The other two forms are as follows:—No. 1, elongated, height about one-twelfth of its length. Eyes high up. Pectoral fin short. Caudal lanceolate. Buff-coloured, becoming white beneath. Fins immaculate, except the caudal which is irregularly spotted. Madras. No. 2. Height 8 in its total length. Eyes high up. Pectoral fin longer than the head. Caudal lanceolate, light brown, irregularly banded: two dark bands from the eye: a large black spot on the upper portion of the first dorsal fin: caudal irregularly spotted. In another figure a black occllated spot may be present on the hind edge of the last dorsal rays; while in a third the spot on the first dorsal is absent.

Page 284. Add Gobius Gymnocephalus.

B. v, D. $6/\frac{1}{18-19}$, P. 17, V. 1/5, A. $\frac{1}{19}$, C, 13.

Length of head 6, of caudal fin $4\frac{1}{4}$, height of body 8 to 9 times in the total length. Eyes—high up, diameter $4\frac{1}{2}$ in the length of the head, $\frac{3}{4}$ of a diameter from the end of the snout, and placed close together. Head higher than broad: snout obtuse: cleft of mouth oblique, the maxilla reaching to below the hind edge of the eye. Teeth—canines in both jaws. Fins—dorsal spines flexible, nearly as high as the body: caudal lanceolate. Scales—minute. Colours—greenish stone colour, becoming lightest beneath: three or four vertical bands on the body and another on the nape, with indistinct narrow intermediate ones. Dorsal fins darkish, unspotted: caudal also dark and reddish externally, said to have several

Anal with a narrow and nearly central band along its extent, which blue and red streaks. is red externally and blue inferiorly.

Habitat.—Madras to the Malay Archipelago. Jerdon's figure is 6.4 inches in length. He has likewise the figure of another fish with much the same proportions, but the number of rays is not enumerated. He termed it Natsi candai, Tam. Body of a light colour, four horizontal narrow red lines along the first and three along the second dorsal fin, two along the anal which has likewise a dark outer edge. Three narrow red vertical bands down the base of the caudal fin, which has an outer dark margin.

B. v, D. $6/\frac{1}{10}$, P. 22, V. 1/5, A. 10, C. 14, L. 1. 30, L. tr. 8.

Length of head $4\frac{3}{4}$, of caudal fin $4\frac{2}{3}$, height of body $5\frac{1}{2}$ in the total length. Eyes—upper margin near the dorsal profile, diameter $4\frac{1}{4}$ in the length of the head, $1\frac{1}{4}$ diameter from the end of the snout and 1 apart. Head $\frac{1}{3}$ wider than long, while its height equals its length without the snout. An oblique rise from snout to eyes, from whence the dorsal profile is nearly straight: the width of the body equals \(\frac{3}{4}\) of its height. Upper jaw slightly the longer, cleft of mouth rather oblique, the posterior extremity of the maxilla hardly reaching to beneath the front edge of the eye. A single row of warts across the cheeks No barbels. Teeth-villiform with an outer enlarged row, and a small canine in either jaw. Fins-First dorsal separated by a short interspace from the base of the second dorsal, its spines flexible, the longest equalling the height of the body below it: the last rays of the second dorsal somewhat prolonged, \(\frac{1}{4}\) longer than the dorsal spines, and reaching to the base of the caudal fin. Pectoral as long as the head, its upper edge straight, its lower rays the shortest, some of its upper rays silk-like. Ventral reaches vent; anal similar to second dorsal; caudal wedge-shaped. Scales—strongly ctenoid and angular, anterior to the dorsal fin comparatively small, there being 11 rows between the posterior edge of the orbit and the first dorsal spine: 8 rows between the bases of the second dorsal and anal, none on the head. Colours-slatey-grey, with 5 rows of dark and interrupted narrow brown bands in the anterior portion of the body, becoming brown spots from the pectoral fin on the base of which are two well-marked brown blotches. Numerous small blue spots on the body: first dorsal with brown spots: ventral black, and with a dark outer edge.

Habitat—One specimen $4\frac{1}{3}$ inches long, sent by Mr. Thurston from Madras.

Page 291. Add Gobius Microlepis.

B. v, D. $6/\frac{1}{12}$, P. 22, V. 1/5, A. $\frac{1}{13}$, C. 17, L. l. 50.

Length of head 6, of caudal fin 3 to $3\frac{1}{4}$, height of body from $7\frac{1}{3}$ to 9 in the total length. Eyes—high up, and placed rather close together; diameter, 4 in the length of the head, and about 1 diameter from the end of the snout. Cleft of mouth oblique, lower jaw the longer, the maxilla reaches to below the hind edge of the eye. Snout obtuse. Teethin a single row without canine, those in the upper jaw a little longer and further apart than those in the lower jaw. Fins—both dorsals higher than the body, in some examples the fifth ray of the first dorsal fin has a filamentous prolongation. Caudal lanceolate. Colours -greenish or brownish-buff, with some clouded spots on the back and sides, a black dot at the edge of most of the scales: sometimes a black spot at the base of the caudal fin. Fine dark spots on the rays of the dorsal fins; anal and caudal stained dark, especially externally.

Habitat.—Madras, to the Malay Archipelago and China.

B. v, D. 6/11, P. 15, V. 1/5, A. 10, C. 14, L. 1. 22, L. tr. 6.

Length of head $4\frac{1}{2}$, of caudal fin $4\frac{1}{2}$, height of body $5\frac{1}{2}$ in the total length. Eyes—

diameter 3 in the length of the head, $\frac{1}{2}$ a diameter from the end of the snout and placed close together. The greatest width of the head equals $\frac{2}{3}$ of its length, while its height equals its length excluding the snout. Anterior profile of head somewhat obtuse. Cleft of mouth oblique, lower jaw slightly the longer: the posterior extremity of the maxilla reaches to beneath the first third of the eye. Preopercle spineless, and no warts on the head. Teeth—in villiform rows, none enlarged. Fins—dorsal spines of moderate strength, the longest nearly half the length of the head. Pectoral as long as the head, some of its rays fine and silk-like: caudal pointed. Scales—finely ctenoid, none on the head: eleven rows between the occiput and front edge of the dorsal fin. Colours—yellowish with a few dark spots on the body and a dark band from the eye to the snout, also a dark mark on the opercle. Upper half of eye black. Dorsal, anal and caudal fins with a gray outer edging: ventrals white.

Habitat.—A small species from Madras.

B. v, D 6/12, P. 19, V. 1/5, A. 11, C. 14, L. 1. 56, L. tr. 16.

Length of head $5\frac{1}{2}$, of caudal fin $7\frac{1}{4}$, height of body 7 in the total length. Eyes—upper margin on dorsal profile, diameter $4\frac{1}{2}$ in the length of the head, $1\frac{1}{2}$ diameters from the end of the snout, and 2 apart. Body subcylindrical. Interorbital space nearly flat, snout obtuse and rounded, an oblique fall from orbit to it. Upper jaw the longer and overhung by the snout: cleft of mouth nearly horizontal: the maxilla reaches to below the middle of the eye. Lips thick. No warts, barbels or scales on the head. Teeth—in maxilla, in a single external movable row in the gums, directed almost horizontally, and a single inner row of longer pointed and curved ones, these two rows being divided by a considerable interspace: a large recurved canine on either side of symphysis of the lower jaw: in a single row of much smaller teeth in the upper jaw. Fins—spines of first dorsal ending in filamentous prolongations, but the longest is not quite so high as the body below it. A considerable interspace between the first and second dorsal fins, the rays of the latter are equal to about half the height of the body, and similar to the anal. Ventral does not extend half way to the anus. Caudal rounded at the extremity, its central rays somewhat the longest. Pectoral as long as the head, excluding the snout. Scales—strongly ctenoid, the exposed portion above twice as high as wide, and rounded, about 19 rows from occiput to first dorsal fin, the first few anterior rows somewhat small, the remainder on the body of about the same size. Colours—greenish brown, a black interorbital band which is continued from the eye to the angle of the mouth: some dark vertical bands on the body: a dark outer edge to ventral and anal, also a dark band to outer edge of caudal, margined externally with white, which is widest at the angles.

Habitat—Ceylon, from whence Mr. Haly has sent me an example 3 inches long.

Page 310. ELEOTRIS MACROLEPIDOTA.

This fish is not *E. hoedtii*, &c. Bleeker, as observed in Günther's "Fische der Südsee," ii, p. 185, as the type at Berlin (No. 2155) has D. $7/\frac{1}{5}$, A. $\frac{1}{10}$, the last ray in both being almost double, and therefore counted as two by Bloch. L. l. 30, L. tr. 13-14, and from 26 to 28 scales between the snout and first dorsal fin.

B. vi, D. 6/12, P. 21, V. 6, A. 13, C. 13, L. 1. 80, L. tr. 16.

Length of head $4\frac{1}{2}$, of caudal fin $4\frac{2}{3}$, height of body $5\frac{1}{2}$ in the total length. Eyes—high up, diameter $3\frac{1}{2}$ in the length of the head, 1 diameter from the end of the snont. Height of head $\frac{2}{3}$ of its length: interorbital space narrow. Cleft of mouth somewhat oblique, the maxilla extends posteriorly to beneath the middle of the eye. Teeth—rather large, in single row in the upper jaw with two small lateral canines: in two or three rows in the centre of the lower jaw, separated from the single lateral row by two large recurved canines.

Fins—dorsal spines thin, flexible and equal in height to the body below them, second dorsal and anal of similar height and one-third lower than the first dorsal. Pectoral nearly as long as the head. Caudal rounded with its central rays somewhat the longest. Scales—ctenoid in the posterior portion of the body, where they are larger than in the anterior portion, and small on the surface of the head: none on the cheeks. Colourswhitish with five wide and light chestnut bands descending from the back, each of which has a black outer edge: another over the nape is without dark edges. Caudal fin brown, with a broad yellowish black-bordered vertical band down its centre. A dark horizontal band running along the cheeks below the eye. Dorsal fins light brown with white outer edges, a large black white-edged blotch in the posterior half of the first dorsal fin, and a second but smaller one at the termination of the second dorsal, which last fin is white at

Habitat.-Madras. A skin from Sir W. Elliot's collection is 3.2 inches in length, but it is in a bad condition. A coloured drawing was made when the fish was fresh.

Page 323. Add

FAMILY—TRICHONOTIDÆ, Günther.

Branchiostegals seven: pseudobranchiæ. Gill-openings wide. Body elongated, sub-cylindrical. The infraorbital ring of bones does not articulate with the preopercle. Teeth mostly villiform. One or two dorsal fins occupying almost the entire length of the back, when there are two, the first is short and the anal similar to the second dorsal. Fin rays branched. Ventrals jugular with one spine and five rays. No prominent papilla near the vent. Scales cycloid of moderate size. Air-bladder and pyloric appendages absent.

> The fishes of this family have been variously located. A species of HEMEROCETES was placed by Forster and also by Schneider among the Callionymidæ, and near which Cuv. and Val. considered it should be located. Dr. Günther (Catal. Fishes Brit. Museum, ii, p. 225) observed that it "is not an Acanthopterygian fish, all its fin rays being articulated." Subsequently he remarked (l. c. iii, 1861, p. 484), that the affinities of these fishes are very obscure, and instituted an Acanthopterygian family for their reception. observing that the ventral fin had one spine and five rays, he placed it between the Ophiocephalidæ and Cepolidæ, and in 1880 he located it among the Acanthopterygii Blenniiformes. Steindachner, in 1867, suggested that a species he described might possibly be a type of labroids, but the example was too small to examine the pharyngeal

Geographical distribution.—Small fishes of the seas and coasts of India, and the Malay Archipelago to New Zealand.

Genus V.—Trichonotus, Bl. Schn.

Head depressed and pointed, with the lower jaw the longer. Cleft of mouth deep, almost horizontal, the lower jaw the longer. Eyes of moderate size, closely approximating. Conical teeth in jaws, vomer, and palatine bones. One long dorsal fin, the first few rays may be elongated, or else slightly detached.

Habitat.—Andamans to the Malay Archipelago.

1. Trichonotus setigerus.

Bl. Schn. p. 179, t. xxxix; Cuv. and Val. xii, p. 316; Bleeker, Celebes, v, p. 251; Günther, Catal. iv, p. 484.

5 K

Trichonotus polyophthalmus, Bleeker, Ceram. iii, p. 243 (female).

B. vii, D. $\frac{2}{4.5}$, P. 11, V. 1/5, A. 37, C. 13, L.l. 58, L. tr. 6.

Length of head 4, of caudal fin $6\frac{1}{4}$, height of body 10 in the total length. Eyes—diameter $\frac{1}{4}$ of the length of the head, 1 diameter from the end of the snout, and placed close together, so that they are directed somewhat upwards. Teeth—a single row in the jaws, vomer and palatines, being somewhat enlarged in the intermaxillaries. Fins—owing to the small size of the example, it is difficult to count the number of rays. The dorsal commences above the axil of the pectoral, its two first rays are not elongated (? age or sex), but slightly divided from the remainder of the fin.

Habitat.—This example, measuring a little over $1\frac{1}{2}$ inches in length, was obtained at the Andamans.

Page 324. Add CEPOLA INDICA.

B. vi, D. plus quam 90, P. 17. A. plus quam 90.

Length of head 8, height of body 8 in the total length. Eyes—diameter $3\frac{1}{4}$ in the length of the head, $\frac{1}{2}$ a diameter from the end of the snout, and 2/3 of a diameter apart. Cleft of mouth oblique, the maxilla reaches posteriorly to beneath the middle of the eye. A strong spine at the angle of the preopercle, one on the vertical limb above it, and four on the horizontal limb. Teeth—in a single row in both jaws, a small curved canine in an outer row in the lower jaw, also one in upper but not in a separate row. Fins—the dorsal commences on a line slightly posterior to the orbit, its rays are unbranched, they increase in height to the sixth, which is 2/3 that of the body below it, from whence they gradually decrease and join with the caudal, there appear to be over 100 rays. Anal begins beneath the ninth dorsal spine, and has nearly as many rays as the dorsal, it is conjoined to the caudal, the latter being pointed. Scales—small but distinct, they appear as if forming horizontal ridges, cheeks scaled, none on the opercles. Lateral-line—commences from above the middle of the upper margin of the opercle, then ascends to close to dorsal fin and becomes obsolete after first third of the body. Colours—of brick-dust red, dorsal and anal fins with dark outer edges, an oval black spot between eighth and eleventh dorsal rays.

Habitat.—Madras, from whence Mr. Thurston has sent me one specimen 8 inches long.

Page 325. For Blennius leopardus read Salarias brevis. Add synonym.

Day, Proc. Zool. Soc. 1888, p. 262.

B. vi, D. 40, P. 13, V. 3, A. 27, C. 10.

Length of head $4\frac{3}{4}$, of caudal fin $6\frac{3}{4}$, height of body 6 in the total length. Eyes—diameter $2\frac{2}{3}$ in the length of the head, $\frac{2}{3}$ of a diameter from the end of the snout, and the same distance apart. The greatest width of the head equals half its length: the maxilla reaches to below the first third of the orbit. Snout somewhat broad and rounded in front, the upper jaw a little the longer. No tentacles on the head. Teeth—an exceedingly large recurved canine on either side of the lower jaw, and a much smaller one in the upper, while about 14 teeth exist in a single row in each jaw between the canines. Fins—dorsal commences midway between the eye and hind edge of the opercles, and does not extend quite so far as the caudal fin, the height of its longest rays equals two-thirds of that of the body, and rather more than those in the anal fin, which latter is not united to the caudal. Colours—with about ten broad vertical bands extending from the base of the dorsal to the anal fins, separated from one another by a very narrow light line.

Dorsal and anal fins externally black edged, and the membrane studded with fine brown spots. Caudal light-coloured.

Habitat.—Ceylon, one specimen $1\frac{1}{2}$ inches in length.

Day, Proc. Zool. Soc. 1888, p. 263.

B. vi, D. 13/20, P. 14, V. 2, A. 23, C. 12.

Length of head 1/5, height of body 1/5 of the total length. Eyes—situated high up near the dorsal profile, diameter 1/4 of the length of the head, 1 diameter from the end of the snout and also apart. Body strongly compressed, profile from above the orbits to the end of the snout oblique. The height of the head equals its length excluding the snout. The posterior extremity of the maxilla reaches to beneath the front edge of the eye. No tentacles or crest on the head. Teeth—large, well developed, posterior canines. Fins—dorsal not notched, but becoming higher posteriorly where the longest rays equal half the height of the body: anal not quite so high as soft dorsal: dorsal, anal, and caudal rays unbranched. The dorsal and anal fins not quite connected to the caudal. Colours—olivaceous, four wide brown bands on the head, the three anterior of which encircle it, about twelve vertical bands on the body, more or less distinct, but most so at the base of the dorsal fin. Dorsal fin with a dark mark along its anterior two-thirds: anal blackedged, each ray tipped with pure white. In one there appears to be marks of some narrow, horizontal bands having existed along the front half of the body.

Habitat.—Three specimens up to $2\frac{1}{2}$ inches in length from Kurrachee in Sind.

Page 331. Add SALARIAS CRUENTIPINNIS.

Tickell, Fishes, p. 313, MSS. with a figure.

B. vi, D. 13/13, V. 2, A. 17.

Length of head 5, of caudal fin $5\frac{1}{2}$, height of body 4 in the total length. Eyes—high up near the dorsal profile. Body compressed: the profile from the eyes to the mouth almost vertical: the posterior extremity of the maxilla reaches to beneath the hind edge of the eye. No crest on the head: a bifurcated supraorbital tentacle and a fringed nasal one. Fins—dorsal not notched, and posteriorly continued on to the caudal fin, its spinous portion equal to three-fourths the height of the body and rather more than its soft part. Anal lower than the dorsal, its posterior rays the longest. Colours—rich vinous olive sepia: a large patch of pale yellowish-brown from the angle of the lips to the lower edge of the subopercle. Caudal fin of the same colour as the body, with the three outer rays above and below tawny. Dorsal fin dusky, its basal half blackish, external half of anterior 17 rays carmine, of the 9 posterior rays black. Anal fin dusky with a carmine band along its centre, and externally with a carmine and black edging. Pectoral paler than the body with its lower rays tinged with carmine.

Habitat.—Saddle Island, off Kyoukphoo in Arracan. The specimen was 2.8 inches in length.

Page 332. Add SALARIAS NEILLI.

Day, Proc. Zool. Soc. 1888, p. 263.

B. vi, D. 12/17, P. 13, V. 2, A. 19, C. 10.

Length of head $4\frac{1}{2}$, height of body $4\frac{1}{2}$ of the total length. Eyes—situated high up near the dorsal profile, 4 diameters in the length of the head, 1 diameter from the end of the snout and half a diameter apart. Frontal profile very steep, the head as high as it is long, the maxilla reaches to beneath the last third of the eye. A fringed supraorbital tentacle about twice as long as the eye, a small fringed one at the nostril, no crest on the head. Teeth—in a single row fixed, a very large curved canine posteriorly in the lower jaw and a smaller curved one in the upper. Fins—spinous portion of dorsal fin lower than the rayed part, the notch between the two portions well marked, the longest dorsal rays are equal to half the height of the body of the fish, neither the dorsal nor anal fins are attached to the caudal, which latter is somewhat wedge-shaped and its rays are branched. Colours—olive with seven or eight short dark bands descending from the dorsal fin down the first third of the body. Some dark bands radiate from the eye: a large black blotch below and somewhat behind the orbit. Two semicircular brown bands across the lower surface of the mandibles. Fins darker than the body.

I have named this fish after A. Brisbane Neill, Esq., to whom I am under great obligations for the valuable assistance he has always afforded me in my publications. Habitat.—Kurrachee in Sind, out of ten specimens the longest is $2\frac{1}{4}$ inches.

B. vi, D. 12/19-21, P. 14, V. 2, A. 23-24, C. 13.

Length of head 7, of caudal fin 7, height of body 7 to $7\frac{1}{2}$ in the total length. Eyeshigh up, diameter $\frac{1}{4}$ of the length of the head, $1\frac{1}{2}$ diameters from end of snout, which is very slightly oblique. The maxilla extends to somewhat beyond the hind edge of the orbit. A crest on the summit of the head, a fringed tentacle above the orbit and another at the nostrils. Teeth—small canines in the lower jaw. Fins—dorsal fin deeply notched almost to its base, while posteriorly it is continuous with the caudal: its anterior portion two-thirds as high as the body, and its posterior at least one-third higher: caudal rounded, its central rays being the longest. Colours—stone-colour along the back, becoming violet on the side and beneath: darker bands from the back, sometimes arranged in pairs. Anterior dorsal reddish-violet, with several undulating narrow white lines and sometimes a small black blotch between the first and second spine. Second dorsal with the white bands taking an oblique direction upwards and backwards: bluish marks or spots in its outer fourth. Caudal and anal with their outer thirds brownish.

Habitat.—Aden, the east coast of India to the Malay Archipelago.

Salarias bicolor, Tickell, MSS. with a figure.

D. 11/17, V. 2, A. 18.

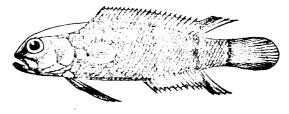

Length of head 5, of caudal fin 5, height of body 6 in the total length as shown by the figure, snout not overhanging the mouth, no crest on head, tentacles were not observed. First—first dorsal as high as the body below it and separated by a deep notch from the second dorsal, which last is not confluent with the caudal. Colours-anterior half of the body so far as to the origin of second dorsal fin of a deep blue (smalt), posterior half carmine-orange. Dorsal fins sepia tinged with smalt, base of second dorsal orange: caudal and anal orange tipped and margined with sepia: pectoral smalt: ventrals whitish.

Habitat.—A specimen 1% inches long from Saddle Island, Kyoukphyoo, Arracan.

Page 336. Add-Genus Acanthochinus, Jenyns.

Six branchiostegals: pseudobranchiæ. Body elongate. Cleft of mouth of moderate width. Gills united beneath the throat. Teeth in jaws, vomer and palate. Dorsal fin single, occupying most of the length of the back, it is chiefly composed of spines: anal long, and having more spines than rays. Ventral jugular consisting of one spine and three rays: caudal distinct. Scales cycloid: lateral-line present or absent. No air-bladder.

Geographical distribution.—Coasts of India and New Zealand.

1. Acanthoclinus indicus.

Day, Proc. Zool, Soc. 1888, p. 264.

B. vi, D. 21/4, P. 16, V. 1/3, A. 10/4, C. 17, L. 1. 40, L. tr. 14.

Length of head 4, of caudal fin 5, height of body 3 in the total length. Eyes—diameter 1/5 of the length of the head, I diameter from the end of the snout, and \(\frac{3}{4}\) of a diameter apart. Cleft of mouth somewhat oblique, the maxilla reaching posteriorly to beneath the hind third of the orbit. Two strong opercular spines. Teeth—in jaws, vomer, and palate. Fins—dorsal spines strong, the fins not united with the caudal: pectorals rounded: ventrals long and inserted slightly in front of the base of the pectoral: caudal rounded. Scales—cycloid. Lateral-line—absent. Colours—brownish-black with a milk-white band commencing on the front end of the dorsal fin, and extending to the snout: a white band over the free portion of the tail: a white spot at the base of the pectoral fin: one on either side of the base of the mandibles, one on the isthmus. The posterior half of the ventral fin, also a ring round the vent, white: as well as the tip of the caudal fin.

Habitat.—Madras, where one example, an inch long, was captured.

Page 336. Add Genus-Cristiceps, Cuv. and Val.

Branchiostegals six: pseudobranchiæ. Body elongate covered with small or rudimentary scales. Gill-opening wide. Cleft of mouth of moderate width, snout short. Usually some tentacles on the head. Fine teeth on the jaws and vomer. Two separate dorsal fins, the anterior being composed of three spines, the posterior with many rays, the majority of which are spines. Ventral jugular with one spine and two or three rays. Pyloric appendages absent. Viviparous.

Habitat.—Mediterranean, Ceylon to the Malay Archipelago, coasts and rivers of Australia and Tasmania.

Cristiceps halei.

B. vi, D. $3/\frac{2.7}{4}$, P. 13, V. $\frac{1}{2}$, A. $\frac{2}{16}$, C. 14.

Length of head $4\frac{1}{6}$, of caudal fin 7, height of body $4\frac{3}{4}$ in the total length. Eyes— 4 diameters in the length of the head, 1 diameter from the end of the snout and nearly 1 apart. A broad-fringed supraorbital tentacle and a short simple one on the snout. Teeth—fine in the jaws and on the vomer, none on the palatines or tongue. Fins—first dorsal commences above a vertical line from the hind edge of the eye, and its spines are higher than the front ones in the second dorsal fin, it is not confluent with the caudal. All the pectoral rays unbranched, anal commences below about the eighth spine of the second dorsal: anal with two spines fifteen unbranched and four divided rays. Caudal wedge-shaped. Scales—rudimentary. Lateral-line—with a rather strong curve anteriorly. Colours—brownish-yellow with a white mark behind the lower half of the orbit, and some irregularly-shaped similar markings on the occiput and gill-covers, two more at the base of the pectoral fin, a row of about 12 below the base of the spinous dorsal fin, and two more badly developed rows along the sides of the body, of which the three largest are behind the pectoral fin and are longer than wide.

Habitat.—Colombo, where it was obtained by Mr. Haly, who is doing such good work among the Ceylon fishes and after whom I have named the single specimen obtained, and which is figured life size.

Page 337. XIPHASIA SETIFER. Add synonyms.

B. vi, D. 128-129 (233?), P. 13, V. 3, A. 115-116, C. 12.

Length of head 16, of candal fin 32 in the total length. Eyes— $3\frac{2}{3}$ in the length of the head, from ½ to ¾ of a diameter apart and I diameter from the end of the snout: upper profile of the head rounded. The upper jaw slightly the longer. Teeth—a single row of closely set, recurved, cardiform teeth in the lower jaw, and with a large lateral canine on either side, which is received into a groove in the roof of the mouth. Teeth in the upper jaw similar in size and number to those in the lower, except that the lateral

canines, although present, are merely half the size of those in the mandibles. Finsthe dorsal commences above or slightly before the orbits, and extends posteriorly to the root of the caudal fin to which it is not joined: the anal begins beneath the seventeenth dorsal ray and similarly reaches the root of the caudal fin. The rays of both fins are simple, unbranched, and higher than the body. In the Australian examples the caudal fin was distinct with no elongated central ray, but this last was observed by Jerdon at Madras. Colours—alternate bands of dark and light ash: the fins opaline: the dorsal with a black and narrow white-edged margin, becoming widened anteriorly into blotches.

Habitat.—Coromandel coast of India, and New South Wales, possibly Madagascar, and probably the South Sea. It attains at least 14 feet in length. Jerdon observed, "said to be venomous."

D. $4/\frac{1}{8}$, P. 14, V. 1/5, A. $\frac{3}{9}$, C. 15, L. 1. 38, L. tr. 12-13.

Length of head from $4\frac{1}{4}$ to $4\frac{1}{2}$, of caudal fin $4\frac{1}{4}$, height of body $4\frac{1}{4}$ in the total length. Eyes—diameter $\frac{1}{4}$ of the length of the head, nearly 1 diameter from the end of the snout and $1\frac{1}{2}$ diameters apart. The greatest width of the head equals its length behind the last third of the eye. Eye with a narrow posterior adipose lid. Interorbital space flat. Upper lip rather thick: preorbital scaleless, moderately curved and serrated: the end of the maxilla visible. The mandibular bones form an obtuse angle: the uncurved space on the chin is broadly lanceolate. About 25 rows of scales between the snout and the origin of the dorsal fin. Fins—first dorsal higher than the second, its spines of moderate strength, the height of the first being equal to the width of the head: the fin commences above the tenth scale of the lateral-line, the second dorsal above the twenty-first: the pectoral reaches the eleventh scale. Soft dorsal and anal fins scaled, the latter commencing very slightly in advance of the vertical of the former. The lowest depth of the free portion of the tail equal to $2\frac{1}{4}$ in the length of the head. Scales—no elongated one in the axil, one along the base of the first dorsal, also at the ventral: the scales on the back from in front of the first dorsal fin form a sort of keel for some little distance. Colours—golden around the eye, no black pectoral spot.

Habitat.—Red Sea and seas of India.

Length of head 4 to $4\frac{1}{2}$, of caudal fin 5, height of body a little over half of the total length. Eyes—diameter 2/5 of the length of the head, half a diameter from the end of the snout. Preopercle rather coarsely servated. Scales—lateral-line ceases below the soft dorsal fin, but is continued in the middle of the free portion of the tail, as one or two holes in each scale. Colours—deep brown, vertical fins dark, becoming black at their edges. A white spot at the nape, which is sometimes wanting, a second above the lateralline below the middle of the dorsal fin.

Habitat.—Red Sea, and east coast of Africa to Polynesia. In Sir Emerson Tennent's account of Ceylon, Dr. Günther gave this species as existing there, which has been confirmed by Haly (Taprobanian, i, 1886, p. 166) who states it to be common at Colombo.

Length of head 4, of caudal fin 5, height of body $2\frac{1}{4}$ in the total length. Eyes—diameter $3\frac{1}{2}$ in the length of the head, 1 diameter from the end of the snout. The depth of the anterior portion of the suborbital ring of bones equals that of the preorbital. Teeth—narrow compressed. Fins—dorsal spines rather short, increasing in length posteriorly, the soft portion of dorsal and anal somewhat rounded, caudal slightly emarginate. Lateral-line—ceases below hind edge of dorsal spines. Colours—neutral sepia or dusky, with a greenish tinge beneath: fins black or a little diluted at their bases. Scales edged darker.

Habitat.—Red Sea, east coast of Africa, Burma to the Malay Archipelago.

Page 391. Add Genus—Xiphochilus, Bleeker.

Branchiosteyals six: pseudobranchiæ present. Body oblong: head scaled and nearly as high as long: snout obtuse, upper lip thin and can be almost hidden under the preorbital. Both limbs of the preopercle are destitute of scales. Four canine teeth anteriorly in both jaws, while the lateral teeth are soldered into an osseous ridge: a posterior canine tooth present. Fins having the following numbers of rays, $D^{1} \cdot \frac{1}{9-8} \cdot A$. Scales large, 28 or 29 along the lateral-line. No scales along the bases of the fins. Lateral-line continuous.

XIPHOCHILUS ROBUSTUS.

Günther, Catal. iv, p. 98; Klunz. F. R. M. 1871, p. 110.

B. vi, D. $\frac{1}{9}$ $\frac{1}{8}$ A. $\frac{3}{10}$, L.l. 29, L. tr. 3/9.

The following is from Dr. Günther's description:—Height of body nearly 33, length of head 32 in the total length. Head nearly as high as long: snout obtuse. Preorbital higher than the orbit, preopercle not serrated. Teeth—four strong canines in either jaw, the outer ones of the mandibles being turned outwards, an obtuse osseous ridge round the edge of the jaws in which teeth are scarcely distinct. Fins—Dorsal spines strong, the last being the longest and equalling one-third the length of the head, the soft dorsal and anal reach the root of the caudal, the last being rounded. Colours—yellowish red, a yellow band along the basal half of the anal and middle of the dorsal fin.

Habitat.—One specimen 12 inches long, obtained in Ceylon by Mr. Haly (Taprobanian, i, p. 165), and one in the British Museum is from the Mauritius: also Red Sea.

Page 392. Add Cossyphus BILUNULATUS.

Labrus bilunulatus, Lacép. iii, pp. 454, 526, pl. xxxi.

Cossyphus bilunulatus, Cuv. and Val. xiii, p. 121; Bleeker, Amboina, ix, p. 4, and Atl. Ich. i, p. 101, t. xxxviii, f. 3; Günther, Catal. iv, p. 105.

B. vi, D. $\frac{12}{10}$, P. 16, V. $\frac{1}{5}$, A. $\frac{3}{12}$, C. 14, L. l. 34.

Length of head $3\frac{2}{3}$, of caudal fin about $6\frac{1}{2}$, height of body $3\frac{1}{4}$ in the total length. Eyes—diameter $5\frac{1}{2}$ in the length of the head, and 2 diameters from the end of the snout. Preopercle finely serrated, and scaled. Fins—caudal emarginate, the outer rays being produced. Colours—reddish with light or yellow stripes and a large black blotch below the hind edge of the soft dorsal fin and over the commencement of the free portion of the tail. Two black lines on the head, one from the snout through the eye, the second from the angle of the mouth to the subopercle. A black blotch between the first three dorsal spines. Habitat.—Isle de France, Ceylon (Haly) to the Malay Archipelago. This fish is considered by some to be identical with C. micrurus, Lacép. C. chabrolii, Lesson, C. maldat, Cuv. and Val. and Labrus spilonotus, Bennett.

Page 394. Add Cheilinus undulatus.

Rüpp. N.W. Fische, p. 20, t. vi, f. 2; Cuv. and Val. xiv, p. 108; Bleeker, Atl. Ich. i. p. 68, Labroidei, t. xxvi, f. 3; Günther, Catal. iv, p. 129; Klunz. F. R. M. 1871, p. 112. Crassilabrus undulatus, Swainson, Fish, ii, p. 225.

B. v, D. $\frac{8-9}{10}$, P. 12, V. 1/5, A. $\frac{3}{8}$, C. 11, L. l. 22-23, Vert. 9/14.

Length of head $3\frac{1}{3}$, of caudal fin $5\frac{1}{2}$, height of body about 3 in the total length. Eyes—diameter 1/6 of the length of the head and situated in about the middle of its length. Head slightly longer than high, and having a hump in some old specimens. Lower jaw slightly the longer: lips thick. Fins—ventrals not quite so long as pectorals: caudal rounded. Scales—two or three rows of scales on the cheeks. Lateral-line—tubes not branched. Colours—Bluish green, with the anterior half of the body below the lateral-line reddish, as are also the cheeks. Two narrow dark bands pass from the eye to the snout, between which is a yellow one: two similar bands pass backwards from the eye. Many narrow red and yellow lines on the head and chest, and dark undulating bands on the fins, outer edge of caudal yellow.

Habitat.—Red Sea, Zanzibar, Ceylon (Haly) to the Malay Archipelago.

Page 398. Add PLATYGLOSSUS METAGER.

Julis metager, Tickell, Fish. MSS. p. 322, c. fig.

B. vi, D. $\frac{9}{13}$, V. 1/5, A. $\frac{3}{12}$.

Length of head $4\frac{3}{4}$, of caudal fin 7, height of body $3\frac{1}{6}$ in the total length, according to the figure. Eyes—diameter $4\frac{1}{2}$ in the length of the head, $1\frac{3}{3}$ diameters from the end of the snout. Body compressed, the form of the dorsal and abdominal profiles about equally convex. Teeth—the posterior canine said to be large. Fins—dorsal moderately elevated,

equal in its highest portion to about one-third the height of the body, and similar to the anal. Caudal rounded. Colours—body and fins of a deep olive bistre, the body longitudinally striated with about thirteen lines of sepia. An elongated patch of a black colour, and having a grayish white margin filling up the middle half of the dorsal fin from the eleventh to the fifteenth ray. Caudal tawny with a wide central and vertical brown band. Young.—Caudal tawny white with the band of pale Indian red.

Habitat.—The larger example which is figured, is a little over 4 inches in length; both

were taken on November 27th, 1862, at Saddle Island off Kyoukphyoo.

Page 400. Add Platyglossus Javanicus.

B. vi, D. $\frac{9}{12}$, P. 15, V. 1/5, A. $\frac{3}{12}$, C. 12, L. 1. 28.

Length of head $3\frac{2}{3}$, of caudal fin 6, height of body $4\frac{1}{4}$ to $4\frac{1}{2}$ in the total length. Eyes—diameter 4 in the length of the head, $1\frac{2}{3}$ diameters from the end of the snout, and $\frac{3}{4}$ to 1 diameter apart. Fins-spines of dorsal fin not so high as the rays: caudal rounded. Colours-of a brownish red becoming silvery along the abdomen, a vertical blue band or spot behind the upper half of the orbit: some oblique red streaks on the head: a black spot superiorly at the base of the pectoral fin. Dorsal fin reddish with two or three rows of round yellowish spots, caudal of a similar colour but the spots irregularly disposed. Anal fin reddish.

Habitat.—Singapore and Colombo (Haly, Taprobanian, i, p. 165).

Add PLATYGLOSSUS ROSEUS.

Page 401. Day., Proc. Zool. Soc. 1888, p. 264.

B. vi, D. $\frac{9}{12}$, P. 14, V. 1/5, A. $\frac{9}{12}$, C. 14, L. l. 28, L. tr. $\frac{21}{10}$ Length of head $4\frac{1}{3}$, of caudal fin $6\frac{1}{4}$, height of body $3\frac{3}{4}$ in the total length. Eyes—diameter $\frac{1}{4}$ length of head, $1\frac{1}{4}$ diameters from the end of snout and 1 apart. The greatest width of the head equals half its length. Teeth—a posterior canine. Fins—caudal slightly rounded: the length of the pectoral equals that of the head behind the middle of the eye: outer ventral ray somewhat elongated. Scales-none on the head, those on chest smaller than on the body. Colours—in a spirit specimen rosy, with a large black spot behind the middle of the eye and a small one between the two first dorsal spines: two narrow light bands pass from the eye to the snout : a broad orange band along the suborbital ring of bones: body with dark and narrow horizontal bands in its anterior half, while seven dark and wider bands pass from the back down the sides. A narrow light band goes from the eye to the middle of the base of the caudal fin. Basal third of caudal fin somewhat dark, with its outer edges light.

Habitat.-Kurrachee in Sind.

Page 408. Add Coris Halei.

Coris, sp. Haly, Taprobanian, i, 1886, p. 165.

B. vi, D. $\frac{9}{12}$, V. 1/5, A. $\frac{3}{12}$, L. l. 75, L. tr. 3/27.

"Height of body 33 of the total length, the length of head 1. Fins—anterior dorsal spine elevated, and equal to the height of the body. Colours—body vinous-red, barred by eleven purplish-gray stripes: each scale with a spot of brilliant emerald green. Head orange, with violet, red-bordered stripes radiating from the eye, two of these unite to form a broad band descending from the fourth dorsal spine, past the eye and the mouth to the subopercle. A broad red band on the edge of the opercles. Dorsal fin red gray, with an orange band covered with small blue spots: anal vinous-red, with an orange border and covered with small blue spots. Caudal dark gray with large blue, black-edged spots."

Habitat.—Ccylon. A somewhat allied species seems to exist in Coris Bleekeri, Hubrecht,
Ann. and Mag. Nat. Hist. 1876 (4) xvii, p. 214.

Add Pseuboscarus bataviensis. Page 413.

Scarus bataviensis, Bleeker, Java, iv, p. 342.

B. v, D. $\frac{9}{10}$, P. 14, V. 1/5, A. $\frac{3}{5}$, C. 13, L. 1. 25.

Length of head 4, height of body $3\frac{1}{4}$ in the total length. Eyes—diameter 6 in the length of the head, $2\frac{1}{4}$ diameters from the end of the snout. Teeth—two small ones at the corner of either jaw. Fins-the dorsal spines of about the same length equalling one-

Digitized by Google

fourth of that of the body beneath. Caudal nearly square in the young, the outer rays produced in old examples. Scales—two rows on the cheeks, none covering the lower limb of the preopercle. Colours—head superiorly Indian red, extending to snout and throat, becoming gradually more diluted over the belly: golden green on cheeks and opercles. Eye surrounded by emerald green, passing downwards in two stripes to the upper lip and chin, a second short one behind the chin: two short branches from the hind edge of the orbit. Body olive green becoming paler below. Dorsal fin banded as follows from summit to base, cobalt, deep vinous-red, emerald green, vinous-red and cobalt. Pectoral pale orange. Ventral rosy with its outer ray blue: anal banded as follows from outer edge to base, cobalt, rose, cobalt, red and cobalt. Caudal venetian red, its upper and lower edges and three vertical bands cobalt. Every scale red at its base.

Habitat.—Arracan to the Malay Archipelago.

Page 413. Add Pseudoscarus dussumieri.

? Scarus dussumieri, Cuv. and Val. xiv, p. 252; Blecker, Batav. p. 404. Pseudoscarus dussumieri, Blecker, Scar. 1861, p. 13, and Atl. Ich. i, p. 46, t. viii, f. 1; Günther, Catal. iv, p. 224.

B. v, D. $\frac{9}{10}$, P. 15, V. 1/5, A. $\frac{3}{9}$, C. 13, L. 1. 25.

Length of head $3\frac{2}{3}$, of caudal fin $6\frac{1}{2}$ in the total length. Eyes—diameter $6\frac{1}{3}$ in the length of the head, and 3 diameters from the end of the snout. Teeth—small ones at the corner of either jaw. Fins—dorsal spines slightly increasing in length posteriorly and not so high as the rays: caudal emarginate except in the young. Scales—two rows on the cheeks and two scales on the preopercular limb. Colours—carulean blue, with the lower edge of the body pale rose: the centre of every scale on the blue portion being gall-stone green, as is also the upper portion of the head. Carulean blue bands and marks are round the orbit also radiating from it towards the forehead, the angle of the mouth, and irregularly over the cheeks. A blue band across the upper lip and another a short distance behind the lower one. Dorsal and anal fins of an orange gall-stone, having a carulean blue basal, and a second outer band. Caudal of a similar colour with its outer rays blue, and three broken vertical blue bands on its outer half. Pectoral rays as follows: the upper blue, the succeeding four gall-stone orange, the remainder hyaline. Ventral outer ray blue, the rest hyaline with the outer halves of the second and third rays orange gall-stone.

Habitat.—Red Sea, Persian Gulf, Arracan to the Malay Archipelago.

Page 419. Add 2. Brotula jerdoni.

D. 126, V. 1, A. 95.

Length of head 6, height of body $5\frac{3}{4}$ in the total length. Eyes—in figure, diameter $3\frac{1}{2}$ in the length of the head, and $\frac{3}{4}$ of a diameter from the end of the snout. Fins—dorsal commences over the base of the pectoral, vertical ones confluent. Colours—lilac along the back becoming white beneath, a black band from the eye to the angle of the subopercle, a second from above the eye passes downwards to the base of the pectoral, which fin it crosses obliquely, a third black band commences on the occiput but soon divides into two, the upper branch going along the base of the dorsal fin, and the lower passing down a short distance and then running parallel to the first. Fins yellowish, three large round black spots edged with white along the upper half of the dorsal fin, which has a dark margin, as has also the anal, which, however, is externally edged with white.

Habitat.—Taken at Madras in August, and among Sir. W. Elliot's and Jerdon's illustrations is one 5.4 inches in length.

Page 419. 3. Brotula multibarbata.

? Brotula multibarbata, Schlegel, Fauna Japon. Poiss. p. 251, pl. exi, f. 2; Günther, Catalog. iv, p. 371.

Generates ferruginosus, Tickell, MSS. with a figure.

D. C. and A. 165 (186), V. 2.

Height of body 5 (4 to 41), length of head $5\frac{1}{2}$ in the total length. Upper jaw the longer. The maxilla extends to below the hind edge of the eye, opercle ending in a spine. Barbels—both jaws with three on either side. Fins—dorsal commences above the base of the pectoral, all the vertical fins confluent. Colours—reddish or vinous burnt umber becoming nearly white below. Vertical fins a little darker edged with black having an outer red margin.

Habitat.—Col. Tickell procured one 4.9 inches long at Saddle Island off Kyoukphoo in Arracan in 1862, it is not so deep as shown in Schlegel's figure: Jerdon also procured

one 8 inches long at Madras, the depth of which to the total length was still less, being only one-seventh: a good figure of it exists.

Page 419. Add Genus-Fierasfer, Cuv.

Echiodon, Thompson: Diaphasia, Lowe: Oxybeles, Richardson: Porobronchus (young), Kaup.

Branchiostegals seven, pseudobranchive absent. Body terminating in a long and tapering tail. Gill-opening wide, the membranes united beneath the throat, but not attached to the isthmus. Gills four. The upper jaw overlapping the lower. No barbels. Cardiform teeth in the jaws, vomer, and palatines, while canines may likewise be present. Vertical fins continuous, ventrals absent. Vent under the throat. Scales, if present, minute. Air-bladder present. Pyloric appendages absent.

FIERASFER HOMEI.

Oxybeles homei, Richards. Voy. Erebus and Terror, Fishes, p. 44, pl. xliv, fig. 7-18.

" brandesii, Bleeker, Verh. Bat. Gen. xxiv, Chironec. p. 24 and Nat. Tyds. Ned. Ind. i, p. 276, f. 1-3.

Fierasjer homei, Kaup, Apodal Fish, p. 158; Günther, Catal. iv, p. 382.

Length of head $7\frac{1}{2}$, height of body 12 in the total length. Eyes—diameter $\frac{1}{4}$ of the length of the head, half a diameter from the end of the snout, and I diameter apart. The greatest width of the head $\frac{1}{5}$ of its length. Snout rounded. The upper jaw the longer: the maxilla reaching to behind the posterior edge of the eye. Teeth—in the upper jaw in a rather widely-set, recurved row, and a canine-form one near the centre of the jaws: an outer row of small teeth. In two rows in the lower jaw the outer being the larger and somewhat curved, they are largest near the symphysis: 2 or 3 rows on the palatines: 2 large ones, placed one before the other on the vomer, and surrounded by smaller teeth. Vent in front of a line from the base of the pectoral fin. Scales—absent. Fins—vertical ones enveloped in skin: the dorsal commencing the length of the head behind the front edge of the eyes: the anal beginning behind the vent. Pectoral as long as the head behind the eyes. Colours—yellowish-red, a silvery band going from the upper edge of the opercles along the first fourth of the body: opercles silvery: end of tail with some black reticulations.

Habitat.—An example 4.8 inches long received from Madras. It is found in the Malay Archipelago and the Australian Seas.

Page 450. Add Leiocassis fluviatilis.

Duxordia fluviatilis, Tickell, MSS. p. 338, c. fig.

B. vi, $D_{\frac{1}{7}}/0$, P. 1/7, V. 6, A. 11, C. 18.

Length of head $4\frac{1}{4}$, of caudal fin $5\frac{1}{4}$, height of body 5 in the total length. Eyes—rather small, high up and in the anterior half of the head. The greatest width of the head equals two-thirds of its length. There is a moderate rise from the snout to the base of the dorsal fin. Upper jaw the longer, upper surface of head smooth. Barbels—a maxillary pair reaching to the posterior edge of the orbit, no others were detected. Teeth—in an uninterrupted villiform band across the palate. Fins—dorsal spine smooth and nearly as long as the fourth ray which is 4/5 as high as the body below it. Adipose dorsal rather long, commencing a short distance behind the base of the rayed fin. Pectoral spine denticulated internally. Caudal forked. Colours—yellowish horny with darker shades of olive brown on the snout and along the back, also some cloudy markings. A large black blotch on the lateral-line above the anal fin, another between the pectoral and first dorsal. Tip of dorsal and ends of both caudal lobes black.

Habitat.—Col. Tickell obtained four examples, the largest 31 inches long from the Anin, a stream rising near Weywoon, Wagroo in the Tenasserim Provinces.

Page 474. Add Genus-Akysis, Bleeker.

Body somewhat elongated: head broad, and covered with soft skin. Gill-openings of moderate width, the membranes stretching across the isthmus, and being slightly notched posteriorly. Mouth terminal: the upper jaw slightly the longer. Nostrils, the anterior one with slightly tubular edges, posterior with a barbel before it. Barbels eight. Eyes small. Villiform teeth in the jaws, none on the palate. A short dorsal fin with one spine and five rays: pectorals horizontal: ventral with six rays: caudal emarginate or forked. Lateral-line present. Skin tubercular.

Geographical distribution.—From the Tenasserim Provinces to the Malay Archipelago.

3 L Z

AKYSIS PICTUS.

Günther, Ann. and Mag. N. H. (5) xi, p. 1883, p. 138.

D. $\frac{1}{6}/0$, P. 1/7, V. 6, A. 9.

Head broader than deep. Eyes—wide apart, and twice as distant from the gill-opening as from the end of the snout. The distance of the anterior nostrils apart equals about half the length of the snout, while the interspace between the anterior and posterior nostrils equals half that present between the front pair. Barbels—nasal half as long as the head, the maxillary reaching to the origin of the dorsal fin, the outer mandibular ones to the axil of the pectoral, while the inner ones are shorter. Fins—dorsal commences midway between the snout and the adipose fin, its spine comparatively strong. Anal arises nearer the root of the caudal than that of the pectoral. Caudal emarginate: pectoral extending a little beyond the origin of the dorsal, its spine strong and entire: ventrals reaching the vent. Colours—head grayish with minute black spots, body anteriorly black which is contracted into an irregular band that runs along the middle of the posterior part of the body and tail. Dorsal fin with a black band covering all but its front corner and upper edge: caudal and pectoral banded.

Habitat.—Tenasserim to 45 millim long.

Page 475. Olyra Longicauda. Add synonym.
Olyra elongata, Günther, Annals and Mag. Nat. Hist. p.

Page 503. Add Family-GALAXIDE.

Body more or less elongated: abdomen rounded. Pseudobranchiæ absent. Edge of upper jaw mainly formed by the premaxillaries. Dorsal fin opposite to the anal, no adipose fin. Air-bladder large and simple. Pyloric appendages few. The ova pass into the abdominal cavity before exclusion.

Genus 1.—GALAXIAS, Cuvier.

Mesites, Jenyns.

Definition as in family. Conical teeth in both jaws, vomer and palatine bones, and large ones on the tonque.

Habitat.—Southern portion of South America, Australia, New Zealand, and observed to live in fresh waters: this Indian form was from the littoral district.

GALAXIAS INDICUS.

B. ix, D. 13, P. 10, V. 8, A. 18, C. 15.

Length of head $8\frac{1}{2}$, of caudal fin $8\frac{1}{4}$, height of body 11 in the total length. Eyes— $3\frac{1}{2}$ diameters in the length of the head and $1\frac{1}{4}$ from the end of the snout. Body elongated and flattened, with a rounded abdomen. Teeth—fine conical ones in the lower jaw, vomer and palatine bones, and some larger ones on the tongue. Fins—ventral well developed and arising midway between the hind edge of the eye and the posterior extremity of the base of the anal fin. Dorsal fin commences opposite the origin of the anal, and in about the commencement of the last third of the total length it is highest in front, and the extent of free portion of the tail behind it equals about $1\frac{1}{2}$ in the length of its base. Caudal forked.

Habitat.—Littoral districts of Bengal and Madras, attaining about 2 inches in length.

Among the drawings of the late Sir Walter Elliot is one of a small fish, a little over 1 inch in length, and a magnified copy nearly four times that size. It was taken at Waltair, April 8th, 1853. Its form is deeper than the foregoing, while it has D. 17, A. 24. No ventral fins are shown, and the vent is placed in the centre of the length of the body. Dorsal fin commences slightly in advance of the anal and in the commencement of last third of the total length: caudal forked. Colours—a row of black spots along the edge of the abdomen. Sufficient details are not given to render one able to decide on the position it should hold. In the absence of ventral fins, which may have been overlooked, it somewhat approaches the Leucopsarion Petersii of Hilgendorf.

Page 520. Add Exocetus altipinnis.

Cav. and Val. xix, p. 109, pl. 560; Bleeker, Atl. Ich. vi, Scomb. t. i, f. 3 (ventrals too short); Day, Proc. Zool. Soc. 1888, page

Exocætus katopron, Bleeker, Atl. Ich. vi, p. 72.

B. xi, D. 13, P. 14-15, V. 6, A. 10, C. 14, L. l. 52; L. tr. 7-8/2.

Length of head $5\frac{1}{4}$ to $5\frac{1}{2}$, of caudal fin $4\frac{3}{4}$ to 5, height of body 7 to $7\frac{1}{2}$ in the total length. Eyes—diameter $2\frac{3}{4}$ in the length of the head, $\frac{2}{3}$ of a diameter from the end of the smout, and rather more than 1 apart. Interorbital space flat or rather concave. Barbels—absent. Teeth—rudimentary. Fins—dorsal commences between the hind edge of the orbit and the end of the lower caudal lobe, anteriorly it is two-thirds as high as the body. Ventrals commence midway between the hind edge of the eye and the base of the caudal fin, reaching to the end of the base of the anal. Anal begins on a line below the middle of the dorsal fin. Scales—28 rows between the occiput and the base of the dorsal fin. Colours—bluish, becoming silvery along the abdomen: pectoral nearly black with the first ray white, and an oblique wide white band crossing from its outer edge to a little in front of its base. In one specimen the ventral is black tipped: caudal grayish.

Habitat.—Two specimens up to $11\frac{1}{2}$ inches long received from Bombay: it extends to the Malay Archipelago.

Page 549. CIRRHINA FULUNGEE. Add synonym.

Gobio angrioides, Jerdon.

Page 551. Scaphiodon irregularis. Add synonym.

Cirrhina afghana, Günther, Trans. Linn. Soc. 1887.

Not only does this fish differ from those of the genus Cirrhina in the character of its mouth, but it likewise possesses a serrated osseous ray in the dorsal fin.

Page 564. BARBUS TOR.

This species is found in Ceylon, according to Haly.

Page 582. Add Genus-Acanthonotus, Tickell (MSS.).

Mouth arched, anterior: barbels absent, eyes without adipose lids. Dorsal fin rather short, commencing slightly anterior to the root of the ventral, its osseous ray being strong, serrated and preceded at its base by a small forwardly-directed spine: anal short. Scales large, no enlarged row at base of anal fin. Lateral-line complete and continued to opposite the centre of the base of the caudal.

1. ACANTHONOTUS ARGENTEUS.

Tickell, MSS. page 49, with a figure.

D. 9 $(\frac{1}{8})$, P. 14, V. 8, A. 7, C. 18, L. 1. 30.

Length of head as delineated 6, of caudal fin $3\frac{2}{3}$, height of body $3\frac{1}{3}$ in the total length. Eyes—diameter $3\frac{1}{4}$ in the length of the head, I diameter from the end of the snort. Snort blunt, rather overhanging the mouth, body compressed: profile with a considerable rise from snort to base of dorsal fin. Fins—dorsal spine strong and posteriorly serrated, caudal deeply forked, its lobes acutely pointed. A small horizontal spine in front of the dorsal fin pointing forwards and scarcely protruding from beneath the skin. Lateral-line—complete. Colours—brilliant silvery with lilac and blue shades and a tinge of olive-yellow on the back. Dorsal fin orange-scarlet superiorly bordered with black except on the last two rays, the other fins lemon-yellow. Dorsal ridge black in its upper portion.

Habitat.—Very common in the streams of the interior of the Tenasserim district, the largest obtained being about 5.4 inches in length.

Page 587. Add Rohtee cunna.

Abramis cunma, Tickell, MSS. p. 53, c. fig.

B. iii, D. 12 $\binom{3}{9}$, P. 13, V. 19, A. 30, C. 18, L. l. 44.

Length of head $5\frac{1}{2}$, of caudal fin $4\frac{1}{4}$, height of body 3 in the total length. Eyes—diameter 3 in the length of the head, 1 diameter from the end of the snout and also apart. Profile over nape slightly concave, a considerable rise from snout to base of dorsal fin: snout somewhat obtuse, upper jaw the longer. Fins—dorsal anteriorly two-thirds as high as the body below it, commencing somewhat nearer the snout than the base of the caudal

fin, its spine weak and longer than the head, not serrated. Caudal deeply forked, lower lobe somewhat the longer. Lateral-line-strongly marked in its first four scales. Colours-olive, superiorly becoming silvery on the sides and below: a brassy tinge along the lateral-line and over the cheeks and gill-covers. Fins amber: dorsal and caudal with a narrow black edge.

Habitat.—Colonel Tickell procured it at Moulmein, where he found it to be common. His figure is 5½ inches long.

Page 652. Family Chirocentride. After "intestinal canal short," add "and furnished with spiral folds."

Page 679. Add Syngnathus conspicillatus.

Syngnathus fasciatus, Gray, Ind. Zool. c. fig. (not Risso).

conspicillatus, Jenyns, Voy. Beagle, Fish. p. 147, pl. xxvii, f. 4; Günther, Catal. viii, p. 174.

Syngnathus hamatopterus, Bleeker, Nat. Tyds. Ned. Ind. ii, p. 258. Corythoichthys fasciatus, Kaup, Lophob. p. 25; Kner, Novara Fisch. p. 391.

D. 29-32, P. 14, A. 3, C. 10, osseous rings 16-17 + 34-37.

Length of head about $10\frac{1}{9}$ in the total length: tail portion more than twice as long as that of the body. Snout slender. The upper profile of the head rises abruptly above the eyes. Opercle crossed by a ridge: a median ridge on the occiput and nuchal shields: a supraorbital ridge which is continued along each side of the crown. Body slightly deeper than broad, ridges well developed: egg pouch not quite half so long as the tail. Fins—the dorsal commences on the anal or first caudal ring. Colours—trunk grayish-brown, with deep brown interrupted transverse bands, and sometimes large white intermediate spots. Fine brown lines on the head, and a band below the eye over the lower side of the opercle. Dorsal fin a little spotted.

Habitat.—From the east coast of Africa to the Pacific Ocean. The Colombo Museum possesses five specimens procured from Jaffna in the northern portion of Ceylon (Haly, Taprobanian i, 1886, p. 165).

Page 692. Add Balistes Buniva.

Balistes niger, Osbeck, Voy. China, ii, p. 93 (not Linn.); Bl. taf. 152, f. 2; Bl. Schn. p. 472; Lacép. i, p. 370, pl. xviii, f. 1; Richards. Voy. Samarang Fishes, p. 21, pl. vi, fig. 1-4, and Ich. China, p. 201; Günther, Fish Zanzibar, p. 135, pl. xix, f. 1. Balistes bunica, Lacép. v, p. 669, pl. xxi, f. 1; Günther, Catal. viii, p. 227.

" pictus, Poey, Proc. Ac. Nat. Sc. Phil. 1863, p. 180.

B. vi, D. 2-3/31-33, P. 15, A. 28-30, L. 1, 53 (65 Bleeker).

Length of head 4, of caudal fin 8, height of body nearly half of the total length. Eyes-5 diameters in the length of the head, and $3\frac{1}{2}$ from the end of the snout: a groove before the eye. Teeth—white, even, and incisor-like. Fins—first spine of dorsal fin very strong: caudal posteriorly with an S-shaped outline, in old specimens the lobes are slightly produced. Scales—enlarged osseous plates behind the gill-opening. Seven or eight raised and spiny lines on the side of the tail. Colours—black with a raised white line along the bases of both the second dorsal and anal fins.

Habitat.—Tropical parts of Atlantic, Indian, and Pacific Oceans. It has been captured in Zanzibar (Playfair) and Ceylon (Haly), where it appears to be common.

Page 693. Add Monacanthus tormentosus.

Balistes tormentosus, Linn. Syst. Nat. i, p. 405; Gronov. ed. Gray, p. 34; La Cépède, i, pp. 333, 359.

Monacanthus tormentosus, Cuv. Regne Anim: Bleeker, Atl. Ich. v, p. 127, Balistes pl. vi, fig. i, male, and pl. xvi, fig. i, female: Günther, Catal. viii, p. 238.

B. vi, D-1/26-29, P. 11, A. 25-27, C. 10.

Length of head 4, of caudal fin $5\frac{1}{4}$, height of body $2\frac{1}{2}$ in the total length. Eyes situated high up in the posterior half of the head over the gill-opening and 2 diameters from the end of the snout. Body somewhat elevated, profile from snout to first dorsal

fin somewhat concave. Fins-Dorsal spine situated over the hind quarter of the eye, strong and about as long as the head, armed posteriorly with a double row of recurved spines. Ventral spine movable with small curved spines posteriorly, second dorsal and anal fins low: caudal rounded. Scales—small, each with 4 or 5 marginal spines, while the male on either side of the tail has a long patch of short setiform spines sometimes absent from the female. Some short fleshy tentaches on the side of the body. Colours—brown, spotted and marbled with black, a light band along the anterior half of the body. Caudal fin with two dark vertical bands.

Habitat.—Obtained by Mr. Haly in August, 1888, at Karativoe, Ceylon; is found in the Malay Archipelago, Chinese and Australian seas.

Page 708. The Colombo Museum sustained a great loss during my absence last year: a small sun-fish, Orthagoriscus, was brought for sale, but was unfortunately rejected (Haly, in the Taprobanian, vol. ii, 1888, p. 165). This may have been the widely ranging O. mola not uncommon off the British coast, and which has been taken in New South Wales, &c., and of which Klunzinger seems to have obtained a specimen in the Red Sea: or it may be the form found at Amboina which was described and figured by Bleeker in 1873 as O. oxyuropterus: or possibly a nondescript.

Page 709. Add Diodon Maculatus.

Diodon tacheté, Lacép. ii, p. 13.

" novem-maculatus, Cuvier, c. fig.; Bleeker, Nat. Tyds. Ned. Ind. iii, p. 567.

" quadri-maculatus, Bleeker, l. c. p. 58, pl. viii, f. 2. Diodon maculatus, Günther, Cat. viii, p. 307.

B. vi, D. 2/13, P. 23, A. 2/12, C. 7.

Length of head $2\frac{3}{4}$ to $3\frac{1}{2}$ in the length of the body. Eyes—diameter $3\frac{1}{2}$ to 4 in the length of the head. Sometimes tentacles above the orbit and on the lower side of the head, and on the back. Spines of varying lengths, from 16 to 19 between the snout and the dorsal fin: there are generally only two or three posterior to the dorsal fin. The roots of these spines are long and strong, and have a distinct ridge along their basal portions. Colours—large black yellow-edged blotches on the body of various shapes, and often small black spots. The large black spots are in some cases badly defined.

Habitat -Tropical portions of the Atlantic, Indian Ocean, and Archipelago, also the Pacific. Found in the Gulf of Manaar by Sir Walter Elliot, and in Ceylon by Haly.

Page 716. Add Carcharias Murrayi.

Günther, Ann. Mag. Nat. Hist. (5), xi, p. 137.

Snout short and obtuse: the distance between the mouth and the end of the snout being less than that between the inner angles of the nostrils. Nostrils nearly midway between the end of the snout and the mouth. Teeth—in the upper jaw of moderate size, the anterior equilateral, rather longer than broad, those on the side oblique, with their posterior edges concave, and both sides finely serrated: twenty-nine rows in the lower jaw, lanceolate, their edges smooth, with a broad base, two-rooted, and some with an additional minute Fins—first dorsal commences opposite the axil of the pectoral: the second only one-third of the size of the first, but larger than the anal, which is small: origin of anal behind that of the second dorsal. Pectoral large, exceeding the distance between the first gill-opening and the end of the snout, the length of its hind margin only one-fourth of that of its outer. Caudal of moderate size, rather more than the distance between the two dorsal fins. Colours—uniform, top of first dorsal may have been black.

Habitat.—Kurrachee, where an example 6 feet 8 inches long was captured. The specimen is stuffed, and not in a good condition. It is very closely allied to C. ellioti, from which it differs in the smaller size of the second dorsal and anal fins, but is probably only a variety.

Add Zygena Mokarran. Page 720.

Rüppell, N. W. Fisch. 1835, p. 66, t. xvii, t. 3; Günther, Catal. viii, p. 383; Day, Ann. and Mag. N. H. (5) xx, 1887, p. 389.

Sphyrna mokarran, Müll. and Henle, Plagios. p. 54.

Zygena dissimilis, Murray, Annal. and Mag. N. H. (5) xx, 1887, p. 304.

Anterior edge of head nearly straight, and forming a more or less right angle with its lateral margin. Length of the hind edge of one of the lobes equal to or rather exceeding its width near the eye. Eyes—nostrils near them: but no groove running along the front edge of the head. Teeth—oblique, as broad at their base as long, with an indistinct lateral notch, and serrated on both edges. Colours—brownish gray, becoming white beneath.

Habitat.—Red Sea to Kurrachee where one, a little over 10 feet in length, was captured in April, 1884.

Page 722. Add LAMNA GÜNTHERI, Murray.

Murray, Ann. and Mag. Nat. Hist. (5), xiii, p. 349.

Said to differ from L. spallanzanii in having $\frac{2}{2}\frac{2}{5}$ teeth on either side, and the dorsal fin being a little further behind the base of the pectoral.

By an error in transcribing (Ann. and Mag. Nat. Hist. 1887) I placed this shark instead of Carcharias murrayi, Günther, as a synonym to Carcharias ellioti. It occurred owing to having noted, after having examined the type that Murray's shark from Kurrachee, that it seemed to be identical with Elliot's shark from the coasts of India.

Habitat.-Kurrachee.

Page 722. Add Genus 2—Odontaspis, Agassiz.

Triglochis, Müller and Henle.

Spiracles minute and above the angle of the mouth. No nictitating membrane. Mouthwide and crescent-shaped. Teeth large, awl-shaped, and with one or two cusps at the base. Gillopenings of moderate size. Two spineless dorsal fins, the first opposite the interspace between the pectoral and ventral: the second dorsal and anal not much smaller than the first dorsal. A pit present or absent at the root of the caudal fin.

Geographical distribution.—Temperate and tropical seas.

1. Odontaspis tricuspidatus.

Carcharias tricuspidatus, Day, Fish. India, p. 713, pl. clxxxvi, fig. 1.

Dundance, Sind.

This fish was formerly placed as a Carcharias, owing to the presence of a pit at the root of the caudal fin as observed at page 722.

. Genus 3.—Alopias, Rafinesque.

Mouth crescentic. No membrana nictitans to the eye. Spiracles minute, close behind the orbit. Teeth of rather small size, flattened and triangular, having smooth edges. Gillopenings of medium size. The first dorsal fin spineless, inserted above the interspace between the pectoral and ventral fins: the second dorsal above the interspace between the ventral and anal, the latter being small. Caudal very long, with a pit at its commencement. No keel on the side of the tail.

1. ALOPIAS VULPES.

Squalus vulpes, Gmel. Linn. p. 1496; Lacépède, i, p. 267; Bl. Schn. p. 127.

Carcharias vulpes, Cuv. Règne Anim.

Alopias vulpes, Bonap. Fauna Ital. Pesc. iii, p. 66, c. fig.; Müller and Henle, p. 74, pl. xxxv, f. 1 (teeth); Gray, Catal. Chond. p. 64; Day, Fish. Great Britain and Ireland, ii, p. 300 (see synon.).

Alopecias vulpes, Yarrell, Brit. Fish. (ed. 3), ii, p. 512, c. fig.; Günther, Catal. viii, p. 393.

Body fusiform, gradually decreasing in size to the caudal fin, the great length of which is about half of the total. Eyes—rather large. Nostrils beneath and nearer the anterior border of the mouth than the end of the snout. Gill-opening of median size, the last two being over the pectoral fin. Teeth—about $\frac{22}{19} + \frac{22}{19}$, the third or fourth tooth on either side of the centre of the upper jaw smaller than the others.

Habitat.—Atlantic Ocean on both shores. One from the Cape of Good Hope is in the Paris Museum, and Mr. Haly in the Tabrobanian, 1886, i, p. 167, records one 8 ft. 8 in. in length from Ceylon, having been procured from the Colombo market, February, 1884, where it was quite unknown to the fishermen. It is also found in the Mediterranean, and has been obtained from San Francisco Bay, California, and New Zealand.

Page 723. Add

FAMILY—RHINODONTIDÆ.

Spiricales minute: no nictitating membrane. Gill-openings wide. Two spineless dorsal fins, the origin of the first somewhat in advance of the ventrals: the second small, placed nearly opposite the anal: lower caudal lobe well developed. A keel along the side of the tail. A pit at the root of the caudal fin.

Genus 1.—RHINODON, Smith.

Definition as in the family. Mouth and nostrils near the extremity of the snout. Teeth small and conical. Gill-rakers similar to those of the basking-shark of Northern seas.

Geographical distribution.—Ceylon and Seychelles to the Cape of Good Hope. Specimens are said to have exceeded fifty and even seventy feet in length. It is a harmless form.

RHINODON TYPICUS.

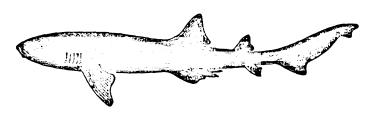

Smith, Illus. S. African Fish, pl. 26; Müller and Heule, p. 77, t. xxxv, f. 2 (teeth);

Dumeril, Elasm. p. 428; Haly, Ann. and Mag. N. H. (5), xii, p. 48.

Snout broad, flat, and short. Eyes—small. Upper jaw with a long labial fold.

Colours—brownish white dots and narrow transverse lines.

Habitat.—One example recorded from the west coast of Ceylon.

Page 725. Add 2. GINGLYMOSTOMA CONCOLOR.

Nebrius concolor, Rüpp. N. W. Fische, p. 62, t. xvii, f. 2.
Ginglymostoma concolor, Cantor, Mal. Fish. p. 395; Günther, Catal. viii, p. 409; Klunz.

Synopsis F. R. M. 1871, p. 672.

Ginglymostoma rüppellii, Blecker, Verh. Bat. Gen. xxiv, Plagios. p. 91; Dumeril, Elasm. p. 334.

Snout short. The nasal cirrus nearly reaches the lower lip. Teeth-in three rows, with one central and four or five lateral cusps, having serrated edges. Fins—dorsal, pectoral, and anal fins with pointed angles. Second dorsal much smaller than the first, and placed nearly opposite to but larger than the anal. Caudal fin one-third of the total length.

Habitat.—Red Sea, through those of India to the Malay Archipelago.

Page 729. Add 4. Pristis pectinatus.

Latham, Trans. Linn. Soc. 1794, ii, p. 278, pl. xxvi, f. 2 (snout); Bl. Schn. p. 351, pl. lxx, f. 1; Müll. and Henle, p. 109; Blyth, Journ. As. Soc. Beng. 1860, p. 36; Duméril, Elasmobranchs, p. 475; Günther, Catal. viii, p. 437; Klunz. Synop. F. R. M. 1871,

Squalus scie, Lacép. i, p. 286, pl. viii.

Rostrum nearly twice as wide at its base as at its termination, armed with from 24 to 27 pairs of teeth which are generally long and somewhat strong and not placed opposite one another, while they may be directed somewhat posteriorly. Anteriorly the interspace between each tooth equals about the width of their base, but among the most posterior ones it becomes double that distance. Fins-first dorsal commences opposite the ventral, the second dorsal about of equal size to the first. No lower candal lobe. Colourssandy-brown becoming lighter beneath.

Habitat.—Red Sea, through the Indian Ocean.

Page 732. Add RHINOBATUS COLUMNÆ.

Rhinobatus (Syrrhina) columnæ, Müller and Henle, p. 113: Duméril, Elasm. p. 486. annulatus, Müll. and Hen. p. 116: Smith, Illus. Zool. S. Afri. Pisces, pl. xvi : Duméril, l. c. p. 487.

Digitized by Google

Raja rhinobatus, Gronov. ed. Gray, p. 10.

Rhinobatus (Syrrhina) polyophthalmus, Bleeker, Japan, p. 129.

Snout rather elongated: the distance between the outer angles of the nostrils equals two-fifths of the extent preoral portion of the snout. Anterior nasal valve is connected to a fold of skin passing towards the median line and so nearly joins that of the opposite side. The upper vortral ridges are convergent in front. Back finely granular with a medium row of small tubercles. Colours—brown, young examples have a white snout.

Habitat.—Mediterranean and the Indian and Atlantic Oceans.

Page 745. Erase Genus CERATOPTERA.

Ceratoptera ehrenbergii.

The figure must, I think, refer to an abnormal condition of Astrape dipterygia, as I find such a form of monstrosity more common among European rays and skates than I had formerly reason for supposing.

Page 729. Add

SUB-CLASS—LEPTOCARDII.

Skeleton semicartilaginous and notochordal: destitute of jaws or ribs. Brain absent. Blood colourless and distributed by pulsating sinuses. Respiratory and abdominal cavities confluent: numerous branchial clefts and the water discharged by an opening in front of the vent.

FAMILY I.—CIRROSTOMI.

An elongated compressed body, having a low and rayless dorsal fin, continued round the tail past the vent to the respiratory opening. Mouth a longitudinal slit on the inferior surface, and with cirri. Eyes rudimentary. Vent near the end of the tail.

Genus 1—Branchiostoma, Costa.

Amphioxus, Yarrell.

Definition as in the family.

One or more species of this genus are common around the waters of India, Burma, Ceylon, and the Andaman Islands.
