In French Guayana, or Cayenne, as it is commonly called, and the French West Indian island of Guadeloupe, the culture and preparation of annatto forms a recognised branch of industry, to which much attention is paid, and which is an important source of revenue to its promoters. It is stated that on Guadeloupe alone there are no less than forty-eight annatto plantations, covering an area of 528 hectares, and employing 1,044 labourers. The yield is a somewhat uncertain one, but the industry is apparently increasing; for while in 1870—379,400 kilos. were exported, the shipments for 1883 show a total of no less than 700,500 kilos. In Cayenne the annatto plantations are said to number no fewer than 563, covering 1,783 hectares, and yielding about 450,000 kilos prepared annatto annually. Notwithstanding complaints which have often been made about the adulteration to which French annatto is subjected, that variety appears to command a fairly steady sale. A common way of preparing it is said to be as follows:—The seeds, when taken from the pod are covered with hot water and thoroughly stirred, in order to separate the red colouring material—which forms the only really valuable portion—from the white core of the seed. After some days the mixture is passed through a sieve, which retains the now valueless seeds. It is then subjected to fermentation for another week, evaporated to a semi-liquid condition, and moulded in square cakes. These cakes, which are brown externally and reddish or yellowish inside, are dried in the shade and sent to the market, packed in banana leaves. The American Indians have a way of separating the colouring matter from the seeds by rubbing the latter between their oiled hands, and annatto thus obtained is much esteemed by artists as a colouring material, although it is rarely met with on the European markets, the Indians preparing it rather for decorating their own bodies than for commercial purposes. In Guadeloupe, we understand, an improved process of preparing annatto has been found to answer well. It consists simply in soaking the seed in cold instead of in hot water, passing the mixture through a sieve and drying it in the shade, without recourse to artificial heat. When evaporated to dryness, the residue is ground in a spice-mill. The annatto manufactured by this treatment is said to be five times as rich in colouring matter as that made by the hot water process. The Brazilian annatto, which is chiefly brought into commerce by way of Pará, is mostly prepared by Indians in the Amazon valley; but although the tree, or rather shrub, is very plentiful around the Indian villages, and produces fruit almost all the year round, the indolent habits of the natives render a regular supply almost out of the question. In Jamaica, St Lucia, and other British possessions in the West Indies the annatto plant flourishes luxuriantly up to an altitude of two thousand feet; but although it has been partly propagated by cultivation, there do not appear to be in the British Colonies any regular plantations of the shrub, and in order to encourage the industry, a recent *Kew Bulletin* has been devoted to the subject. Annatto is exported from the British possessions mainly in the form of cured seeds, of which Jamaica shipped 369,284 lb. in 1886. Dr. Macfadyen in his work on "The Flora of Jamaica" gives the following account of the method formerly used there:—

"Annatto is collected by pouring boiling water on the seeds in any convenient vessel. After stirring the whole, the water, with the farina suspended in it, is poured off, and this is repeated till only the naked seeds are left. The water, after some time, is finally poured off, leaving the annatto, which has settled at the bottom. The addition of an acid is said to hasten the process. The sediment is afterwards placed in shallow vessels and dried by evaporation in the shade. When it has acquired a proper consistence it is made into cakes or balls, and after being thoroughly dried is in a fit state to be sent to market."

From this description it will be seen that the usual method of preparing annatto has been substantially the same in all parts of the West Indies, and the circumstance that recently the unprepared seeds have been exported from the British Colonies to such a large extent is probably due to the fact that prepared annatto, when imported into the United States, the principal customer for the article, pays a heavy duty, whereas the seeds, being classified as raw material, are free. Considering, however, the enormous difference in price between the seeds and well-prepared roll or paste, there can be little doubt that a practical system of annatto preparation might eventually become a not inconsiderable, though necessarily a minor source of revenue to the colonial planter. The most rational process of extracting and preparing annatto, and the one which it would probably best pay planters to adopt seems to be that of Leblond. It consists of simply washing the seeds until they are entirely deprived of their colouring matter, to precipitate the latter by means of vinegar or lemon-juice, to boil it up in the ordinary manner, and to drain it in bags, as is done with indigo. Dyers who have used annatto prepared by Leblond's process state that its colouring power is at least four times in excess of that of ordinary commercial annatto, that it is required less solvent, gave less trouble in the copper, and furnished sopurer colour.

In Ceylon annatto is now very largely grown. It is supposed that the plant, which is undoubtedly of American origin, was introduced into the island by the Dutch colonists, who have also acclimatised it in Java whence shipments are now frequently forwarded to Europe. In Ceylon the annatto plant is grown up to an altitude of 3,000 feet, but it flourishes best in low-lying districts. Moist, warm situations, with an average temperature of 75° to 80° F. appear to suit it best, and an abundant rainfall is a *sine qua non* for its success. The plant can be easily propagated from the seed, which should be cleansed from its colouring material by means of tepid water, and dried in the shade. The seed may be placed in beds at distances of about four inches, and covered ½ inch deep with earth. The sowings may be protected by covering them with banana leaves, and should be kept moist. When the plants have attained a height of about 6 or 8 inches they may be transplanted, during the rainy season, at distances of from 10 to 20 feet apart. The plants usually commence to yield fruit in the third year of their growth. Cattle, [illegible] to eat the leaves, so the hilly pastures [illegible] advantage be selected for annatto-planting.

In a recent report on [illegible] by the United States Consul at Para, it is stated that the plant should be grown in full sunshine, but this [illegible] not tally with that of other authorities, who [illegible] that the plant grows best in shaded places. The [illegible]

ture requires very little care, and entails scarcely any expense, so that if the price of the seeds or paste should not be remunerative, little is lost by simply leaving the crop ungathered. Messrs. Fulwood & Bland, and S. G. Clements & Co., who are among the principal consumers of annatto, have given it as their opinion that annatto cultivation would be found to pay best if the Ceylon and Jamaica planters did not ship the seeds to this country, but only the prepared article, which should be manufactured with the utmost care, and might, in that case, speedily drive the French Indian annatto from the market. The seeds, if shipped at all, might be sent to the United States, where they can be imported duty free. Messrs. Clements & Co. mention that some time ago they purchased, through a firm of London brokers, some exceptionally fine annatto paste prepared in Ceylon, but subsequent lots received from that quarter showed a falling-off in quality, and upon inquiring for paste of the accustomed high standard, they were informed by their brokers that it was all shipped to America, where as much as 3*s.* 6*d.* per lb. was paid for it—a price which probably includes the duty.

The employment of annatto is considerable, although systematic cultivation on too extensive a scale would soon cause a glut in the market. Its chief use is as a colouring material for cheese, and butter, for which purpose it is well adapted (supposing these articles should be coloured at all), by reason of its innocuous character. We have heard it stated that a pound of annatto prepared by the cold-water process mentioned above is suffieient to colour 1,200 lb. of cheese. Probably a large quantity of annatto also finds employment in the American butterine industry. In Spanish-speaking countries, annatto is employed to impart colour and flavour to chocolate, soups, and rice, and the seeds, leaves, and roots of the plant are also used as condiments, dyeing materials, and, medicinally, as a febrifuge. Another use of annatto is as a dyeing material for cotton, silk, calico, and woollen fabrics to which it imparts a beautiful yellow hue, but it is said that the colour does not last. Annatto is mixed with yellow dyes in order to give them an orange shade. The addition of an alkali increases its solubility, and it is therefore generally mixed with at least its own weight of potash.—*Chemist and Druggist.*

A NEW use for the tobacco plant has been discovered in England. Its stems and waste, it is claimed, are equal to linen rags in the manufacture of paper. In that country tobacco waste costs less than $10 a ton, while linen rags are quoted at $55. There is no expense in assorting the former, and very little shrinkage, as against a loss of one-third of rags. The yearly tobacco waste is estimated by the census report of England at from 3,000,000 to 4,000,000 pounds. We cannot give the figures for the waste in this country, but compared with the above they must be immense, and the discovery of this new use for the refuse of the tobacco plant is of the greatest importance to us, as we manufacture a very large proportion of the paper supply of the world.—*Indian Agriculturist.*

THE CAMPHOR TRADE OF FORMOSA.—The American Consul at Amoy, in his last report, states that the statistics of the Chinese Customs authorities in Formosa indicate a constant dimunition in the production of crude camphor during the past two years, and the early extinction of that industry in the island. Since the termination of the Franco-Chinese war Formosa has been made a separate province and placed under the jurisdiction of a Governor-General, who has instituted many new taxes. Among his other fiscal measures is a Government monopoly of the camphor industry, which seems likely to hasten its extinction. The monopoly, the Consul says, appears to be a revival of the old "co-hong" system, and a restriction upon the foreign trade of Formosa, so far as the article camphor is concerned. Some intelligent foreigners regard this as but the first step by the native authorities to similar Government monopolies in other and more important articles of industry and trade that might cause irreparable injury to foreign commercial interests connected with the trade of Formosa—such, for instance, as the tea and sugar trade.—London *Times.*

INCREASED CONSUMPTION OF TEA IN BRITAIN.—In a paper read before the British Association, the great writer on statistics, Mr. Giffen, accounted for the fact that the percentage of improvement in the past decade had fallen when compared with the two previous decades, by stating that when a country got near the top, her rate of progress must necessarily become slower. Amongst the articles enumerated as showing a decreased rate of advance in consumption was tea. But as regards this article a turn for the better must have again commenced, for in the Report of the British Customs for 1886, an increase of duties collected out of proportion to the increase in population (the latter at the rate of 1,000 per diem) is accounted for as entirely due to the increased quantities of tea cleared for home consumption. This is an important and encouraging fact to put against the pessimist views we occasionally hear uttered as to the early prospect of tea being overdone and becoming a drug in the market. There should be no relaxation in the study of due economy in production and manufacture, but encouragement is to be derived from the fact that the use of tea is largely increasing and that the process is likely to be continued.

OBSERVATIONS ON COCONUT CULTIVATION.—Some persons heap rubbish &c. at the foot of trees and get good results for a time. By heaping rubbish at the foot of a tree, the stem gives off a number of adventitious roots, which feed on the loose new soil. Then the action of the proper roots gets diminished. This process will be all right while the heap of soil can be preserved round the stem. But it is liable to be washed down by the rain, and by that means the delicate adventitious roots dry up and become useless. A digging up round a tree could be done easily. In digging round a tree we must be careful not to cut off roots very near the stem, as then their functions will be stopped for a long time. I have lately seen a piece of coconut property where some of the trees looked very sickly and the leaves were dropping. On inquiring as to the cause I found that the trees have been dug round recently and the roots cut very near the stem. In digging round trees I think about 1½ foot from the stem should be left without disturbance. and the trench should be dug six to eight feet deep and as wide as possible, the wider the better. Others might have found by practice suitable dimensions for digging round trees; but I can say that this method is very effective. After digging round the trees and the soil being removed, the length of time the trenches are left without covering varies very much among different individuals. Some tie cattle or put manure and cover the trenches, two or three days after their being dug out. But I think if the trenches can be left without replacing the soil for a month or so, it will be very useful, as by that time atmospheric agencies would have turned a great deal of dormant plant-food into an active state. I know of some persons who are ignorant of scientific reasons, dig round their trees and leave them for a month or two and replace the soil without adding any manure and getting good results.—W. A. D. S.

TEA TASTING AND IMPROVED MANUFACTURE.

By Mr. A. M. Gepp.

(A Paper read at a Meeting of the Dimbula Planters' Association, 17th Sept. 1887.)

TEA TASTING.

It will, I fear, be somewhat difficult to render my Paper interesting as well as instructive on tea tasting proper, but still I shall try my best.

I may claim for my brother Tea Tasters that ours is not altogether a mushroom creation, though it may not be one of the noble professions. There is no doubt that the Chinese (the pioneers of tea) always taste their teas before submitting them to foreign competition in order to test their value, and they are as good if not better judges than the professional Chaazse or tea taster (derived from the Chinese word Cha). Shipments of tea in any quantity first commenced about the year 1835 and hence arose the need for the tea taster to be able to decide which were the best kinds of teas for the English market. It is not so absolutely a matter of necessity that the tea taster in China should "taste" his teas. The China teas have an aroma on the dry leaf by which you are in a great many instances able to decide the value. Bearing on this an amusing story is told of a Hankow Chaazse. When the new season's black leaf teas arrive at the shipping port of Hankow there used to be great anxiety displayed by foreign buyers to get the first samples of the new teas. Some of the new teas were brought down from the interior during the course of the night, and in order to "secure the early worm" the buyer arranged to have the samples sent in before daylight, of course lamp or candle light would be most deceptive for the purposes of examination, but the tea taster said: Maskee taste, maskee looksee, if can smell'em, then can buy. (Maskee-never mind.)

Tea tasting may be described as the art of being able to discriminate not only between good and bad tea but after a time to detect which are the kinds most suitable for the London market. I have no doubt of course that several of you gentlemen interchange samples, but say for instance that you have got a set of standard samples to live up to, as it were—then comes the trouble when you have finished your day's make. How can you be sure that your teas are equal to the standards. After the teas are graded it will not be difficult to have some idea as to whether your own teas are up to the samples as far as appearance goes, but unless you are able to taste tea you will still be very much in the dark. Say that your standards are strong, full flavoury teas, how can you know that your day's make is the same. A knowledge of tea tasting will enable you to test this. I honestly do not think that a tea taster can be self taught. He requires someone to point out the different flavours most suitable for the trade. One tea may be malty, another pungent, another thin but of an extremely delicate flavour, another strong and coarse. This latter characteristic does not of course come under the heading of fine teas, but from a buyer's point of view it may be by no means a tea that should be avoided at a certain price. The teas to be avoided are those which are thin, raw or much burnt. A tea taster ought to be able to say without tasting after looking at the infusions and the liquors whether the tea is good or not. A bright, coppery colour and all the leaves of an even colour, together with a bright, red liquor and yellowing towards the sides of the cup is an almost certain indication of good tea, whereas a dull unattractive liquor with black or brown infusions almost invariably indicates a common undesirable tea. Perhaps it may be interesting to describe the entire process of tea tasting for the benefit of those of my hearers who, though they may have tasted teas in a neighbour's factory, have not commenced making tea themselves and see no necessity for starting a Tea Tasting Room. The embryo tea taster having duly furnished himself with perhaps a dozen tasting pots and cups, scales, sandglass and spittoon, places his pots and cups in a row on his tasting table and proceeds to weigh up the same quantity of tea into each pot. During this time the kettle has been put on, soft not hard water should be used. In order to ensure a good tasting great care should be taken that the kettle boils as this is half the battle. The sandglass should be turned to run 5 to 6 minutes before the teas are turned out into the cups. After letting them drain for a little while the tea taster should go down his rows of pots and taking off the lids carefully note the aroma, in his own mind, or better still on paper, of each tea. Doubtless he will not be able to describe it, but he may recognize the same aroma on another tea. Then let him reverse the lids showing the infused leaves. He had better then examine each sample of the leaf and write down on a piece of paper the description of the tea, whether broken orange pekoe, broken pekoe, pekoe, pekoe souchong, souchong, congou, pekoe dust, or ordinary dust, with any peculiarity or characteristic he may detect, and in the same way with the liquors, carefully putting down what strikes him, whether the teas are burnt, sour, thin, strong, flavoury or pungent. I do not think it will be out of place to mention that in my system of teaching by correspondence which I am carrying out, I send my pupils a set of samples twice a week and get them to taste the teas themselves and send me their report which, having previously tasted the teas myself, I check by a report of my own and return their own as well for comparison.

IMPROVED MANUFACTURE.

I need hardly, I think, go into the question of manufacture generally. All you gentlemen know it more or less thoroughly, but I may be able perhaps to give a few hints which you may think useful.

Out of the various stages or processes that the green leaf has to go through after arriving at the factory none in my opinion is more important than a good wither and yet how difficult it is to get it in cold, rainy weather such as we have had. After a good wither, the green leaf receives the action of the roller more easily. The question of the length of time for rolling has been much debated, but I think ¾ of an hour for the 1st roll and then sift out the small leaf in the usual way and roll the large leaf for another ½ hour or so and again sift out, which will slightly increase your percentage of pekoe tips, and then roll again for a third time, about 20 minutes. This will soften any hard, coarse leaves you may meet with. The length of time required for a good ferment must be left to the direction of the tea maker, but I think there is a danger at the present time of underfermenting in order to give pungency; but it must not be forgotten that leaf which has not gone through the full chemical process is not so likely to keep. Proper fermentation, the leaf being a bright coppery colour, gives strength and pungency combined, whereas you sacrifice your strength by under fermenting.

As to the question of firing I would advise most strongly rather go to the extreme of overfiring than underfiring. An imperfectly fired tea will not keep, the liquor tastes thin and dull, but an overfired tea with a slight suspicion of being burnt will not unfrequently lose the fire during the voyage home and the flavour will develop.

It must also not be forgotten that the grocer at home has to keep his teas and he soon spots the kinds which have the best keeping properties and after all we have to study not only the original buyers of our teas in London but the retailer who eventually comes in contact with the consumer.

As regards sorting, the three principal grades of broken pekoe, pekoe and pekoe souchong seem most in favour with the home trade, unassorted having for the time at all events gone out of fashion. In conclusion I would caution you as to using too fine sieves for your grading. The coolly, in order to get as much tea to pass over through the meshes, is apt to smash and bruise the leaf against the wires and in consequence the leaf becomes grey; rather use the next largest to what you ordinarily do and steer clear of breaking up your rough leaves with a cutter. I need not refer to the [illegible] of each grade of your break, but the larger you can make each grade the greater the competition you will obtain in London

If not detaining you too long, I think that the following account of the process of Oolong making may not be uninteresting. Oolongs are, as you are doubtless aware, exported from China to America in considerable quantities. The tea when manufactured is of a brown and yellow colour, and for the finest teas the liquor is a pale, straw colour with an extremely delicate but pungent liquor. The coarser kinds have a reddish liquor, and are strong and rough flavoured.

Early in the year I wrote to a friend of mine in China who is largely engaged in the making of Oolongs and shipping them to America and he gave me the following account of the way the teas were manufactured:—

When the export of Ceylon teas reaches, as it may do in a few years' time, to 50 million lb. an additional outlet for your teas may be found not only useful but a matter of vital necessity. I will now read you what my friend says on the subject of Oolong making.

"I can only hope that you will forgive my negligence in not at least acknowledging your letter. With regard to Oolong making, it is very simple indeed.

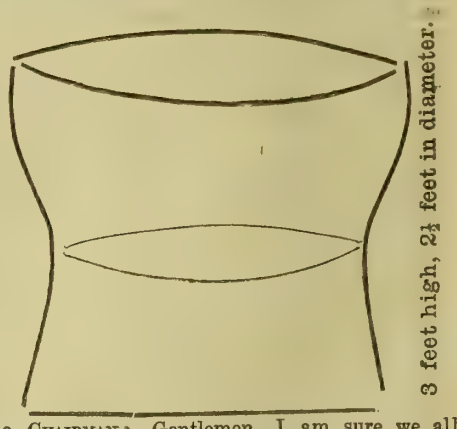
"1. Every 10 days when the new flushes make their appearance, leaves are picked say early in the morning and during the day from the tea bushes and are brought down to the factory in baskets.

"2. The baskets of tea leaves are then turned out on to large, round trays, and if the sun is out the trays are often exposed for a short time only, and whilst exposed a man or two (for as many as are required according to the number of trays) place their hands under the leaves and toss them into the air for 10 minutes and more. Sometimes they toss the whole of the tea in the tray up in the air catching the leaves again. This I call the natural absorbing process, or natural but rather hurried mode of withering the leaves. After tossing the leaves in the air for some time the trays and contents are placed on bamboo stands indoors, and during the morning and afternoon the same process of tossing and separating the leaves in the air is frequently repeated. It is not necessary to sun dry at all. Very often in rainy weather the absorbing goes on indoors in the way described, and in the course of the afternoon the leaves are ready to pass through the next process.

"3. When the leaves have had the moisture they contain gradually absorbed, and look drier than in their natural state and of lighter colour, then the pan-frying process must be gone through. The pans are all circular iron pans—regular Chinese cooking pans—about 3 feet in diameter and a foot deep. These pans are fitted into an earthen or brick wall or fireplace and under the convex side of the pan is fitted a fireplace. The pans are heated sufficiently strong to allow of your passing a handful of leaves into the concave pan very rapidly. You must arrange on the right side of the pan to have a basket of leaves partly withered by absorbing process. And on the left hand side of the pan you must have a smooth board, take care the board is scentless. You take a handful of leaves throw them into the pan and instantly give them a roll with the palm of your hand and pass them out on to the board when another man must give them a rapid twist by passing the palm of his hand over the fired leaves. When the green leaves are thrown into the hot pan they fry like anything else would, and whilst going through the instantaneous frying process the hand must give them a roll or twist; if this is not done *very rapidly* the teas will be overfired and will have a burnt, coarse flavour, and perhaps the quality will be taken out of the tea if they are choice flavoured. Well, after passing the leaves once through the pan and twisting them by a roll of the hand on the board they have once more to be pitched into the pans and passed through as rapidly as before and once more twisted on the board. The make and twist will all depend on the care taken in this process. It is not necessary that the green leaf when thrown into the pan should come out a totally black leaf in oolongs. Part of the leaf after frying might be black and another part yellow or golden coloured, which colours are liked in America, but if you fry for the London market the darker the leaf the better. The only thing is you must not fry the juices too long in the pan and take care the pan is not too hot, but still hot enough to frizzle the leaves.

"4. After passing through the pan fires and undergoing a twisting process by hand rolling, the teas must then be put through the basket firing process. In a large building, tiled-roofed and enclosed by walls having only doors and ventilators high up on the walls, also a roof ventilator or two so made that the hot air can escape, but no rain can enter, you dig round holes in the floor say 2 feet deep and 2½ feet in diameter, and you put brick sides in the interior of the holes just as if you were building a small brick chimney. Then raise *above the ground* of the building, each brick-hole about one foot more, and your fires are complete. A row of them will look like this

Recollect that the holes bricked all round must be 2 feet deep below and 1 foot above the ground. You can have, as I have, as many as 250 fires in one room, but if you only want to try it on a small scale one or two fires will do. We will suppose the fire holes are made, then the next thing you will require is a cylindrical shaped basket 2½ feet wide, same size as fireholes or a little larger and 3 feet high. Something like this ghost of a basket, which will show you also the sieve which rests midway down: the basket and on which the tea is placed."



The CHAIRMAN: Gentlemen, I am sure we all most heartily thank Mr. Gepp for having come here at a sacrifice of considerable time and expense, to deliver a lecture to which we all must have paid the greatest attention. I, therefore, propose that we tender him a cordial vote of thanks.

Mr. COTTAM: It is mentioned in that paper that the pans are made of iron. May I say that the pans in Assam and Japan are made of copper? They are generally made of copper: I never saw one of iron.

Mr. GEPP: I have seen them myself, the copper ones; but the tea-firing pans in China are always of iron.

Mr. COTTAM: That would only raise the question which would be the better— iron or copper pans? I think in a country like this, copper would be the better because it is not liable to rust.

Mr. GEPP: The action of the copper gives us green leaf. The iron pans are only used with regard to making Oolong tea.

Mr. COTTAM: Then do you think Oolong would be likely to form another kind of tea, if you use copper pans?

Mr. Gepp: That I won't undertake to say.

Mr. Sinclair seconded the vote of thanks to Mr. Gepp, which was carried with applause.

PLANTING IN MAURITIUS.

(From the *Mercantile Record*, Aug. 26th.)

The Weather and the Crop.—Most of the mills which had commenced manipulating, have been obliged to stop working, to begin again in the beginning of September; the canes not having yet arrived at full maturity. There has been received into the Town stores up to 20th instant about the same quantity of sugar as last year up to the same date; but it is probable that the next report will show a less amount as compared with that of last year, on account of the suspension of work to which we have just alluded.

Vanilla.—The market is always in the same situation and entirely bare of vanilla of good to fine quality. A few lots of inferior sorts were sold from R12 to R14 per kilo. The cropping is pushed on with great activity and, should the weather continue to be favourable to the preparation, we may expect the new crop to appear on the market in the latter part of next month. As we mentioned in our last, the outturn of the present crop will be superior in quantity to that of last year.

CHINA AND JAPAN TEA EXPORTS.

Those of our planting readers who are unacquainted with the exceptional character of the London tea trade, will naturally be surprized, that the prospects of an important decrease in this season's supply of China tea to England is having so little effect on the home market.

The fact is that a prospect which would have led to great excitement in the markets of other commodoties of general consumption has no effect on that for tea, owing to the trade being almost exclusively in the hands of the wholesale dealers and exporters.

No speculation in tea can take place with any chance of a profitable result: a speculator can of course buy as much as he likes at the public sales which are open to every one, but he cannot re-sell his purchases in the same way, because each lot he buys is known to the dealers and is "tabooed" by them.

He cannot re-sell to the retailers, for they, like the publicans, are under the thumbs of the capitalists from whom they buy on credit.

An outside speculator can only re-sell by private sale to the wholesale dealers or exporters, and they take care that he does not get much benefit from any advance in prices.

Speculators therefore keep clear of the tea market, but if they think well of prospects and wish to have a gamble in it, they can "bull" Indian Tea Companies' shares to their hearts' content.

Owing to the "Sauve qui peut" way in which Indian and China merchants rush their imports on the market the game is left in the hands of the wholesale dealers, and by the end of the year nearly the whole of the undelivered portion of the Indian and China supply for the following six months will be in their possession!

They will then probably begin to draw attention to the statistical position of China tea, and to enable them to work off their bonded stocks in a satisfactory manner will not object to pay higher prices for the dribblets which will be arriving at the tail end of the season.

The number of retailers who have capital or credit enough to be independent of the wholesale dealers is increasing so rapidly that it is just possible the hands of the wholesale dealers may be forced (if there has been no important recovery in the shipments) when the China exports begin as in ordinary years to indicate that the season is drawing to a close; and we may see a more decided improvement in the market than has been the case since the fact and cause of the decreased shipments were known in London. The co-operative stores and large retailers have got the thin end of the wedge into the preserves of the monopolists, and we hope in time the trade will be left more to its natural course than it now is.

The importers in the interests of the producers should do all they can to facilitate retail buying at auction: but instead of doing so they are allowing without remonstrance the wholesale dealers to make it even more difficult for the retailer to buy at public sales, by increasing the size of the lots or sampling breaks.

The wholesale dealers, during their thirty years' innings, have become wealthy and powerful, they will probably make a splendid coup out of their autumn purchases, because if the stock of China tea at the end of the year is thirty million pounds or more below that at the end of last year, it will not be a matter of so much indifference to the blender, as the prospect of it apparently is.

There is of course just the possibility, though it is now very improbable that the arrivals at the shipping ports, instead of decreasing as usual, will be double what they were last year during September, October and November, and ultimately there may not be any large deficiency in this season's supply of China tea.

A few weeks more will, however, decide the question. In the meantime, the receipts at the shipping ports continue to fall off, and the shipments to the United Kingdom are now 36¾ million pounds less than last year up to the 8th instant, as will be seen by the subjoined returns. When we wrote on this subject a fortnight ago the decrease was 32¾ millions of pounds. This continued decrease in the shipments was known in London fourteen days ago and the market is not affected by it, but until the end of the year it will suit the book of the trade to pooh-pooh and make light of the possibility of a decrease of 30 to 40 millions of pounds in the supply of Chinese tea having any effect on prices.

There is an increase in the stock at Foochow of about a million pounds compared with the last returns, but there is no increase at Hankow or Shanghai.

PLANTING IN NETHERLANDS INDIA.

(Translated for the Straits Times.)

For the present the Government has no intention of giving up the compulsory coffee cultivation in Java. So from this being the case, its con-

tinuance for an indefinite period is taken for granted, by the publication of a regulation, codifying all the rules and enactments bearing upon the subject. Every native cultivator, save priests, headmen, and officials within the coffee districts are bound each to plant and look after fifty coffee trees. They must themselves pick the berries and prepare them for market. The produce must be delivered to the Government at a fixed price. In these districts the produce of coffee trees planted by the people of their own accord, becomes liable to compulsory delivery to Government. In any case, the cultivators get a price far below the market value. With short crops the money they get becomes utterly disproportionate to the work performed on the plantations. The Minister for the Colonies comforts them with the assurance that he will not allow them to die of hunger in case the crop proves short. This is somewhat encouraging to them. A good shepherd shears his sheep but does not flay them.

The Surabaya *Courant* reports the arrival there of a heavy consignment of the Borneo cane now coming into prominence for enormous yields of sugar. The consignments come to the order of Fraser Eaton and Company. They were soon forwarded to the estates in the neighbourhood. The next season will show the result. Large stretches of land have already been planted with these canes of promise. In West Java, disease is prevalent among indigenous cane.

The new enactment regularising the compulsory Government coffee cultivation in Java, is not expected to improve matters much, from the difficulty of finding available land within easy distance of the villages. By law, no cultivator may be compelled to till coffee land beyond four miles from his home. The Government is not likely to get all the coffee the Javanese are forced to grow. The high prices now ruling prove too strong a temptation to pilfering. Government coffee finds its way into the hands of Chinese and others, who pay the cultivators twice the price the State gives them. In any case, the compulsory cultivation of coffee by the natives, however counter it may run to modern ideas is merely a labour tax which the State is as fully entitled to impose as a money one. Among people not flush of cash, taxation in labour proves a financial expedient admitting of revenue being drawn from the population without driving them into the clutches of money lenders, to whom they will infallibly have recourse under a ready money revenue demand.

The Surabaya *Courant* says that this year's Government Java coffee crop, will hardly total 300,000 piculs. In one district the yield has shrunk from 24,000 piculs two years ago to 2,100 this year. These figures augur a further rise in price.

INDIAN AND CEYLON TEA AVERAGE.—Messrs. Walker, Lambe and Co. in their monthly Indian and Ceylon tea report of September 1st, say:—"The good assortment of teas offered this month has stimulated the market and resulted in very satisfactory sales to both growers and importers. The prices realised for the finest parcels have been excessive but latterly a little irregularity in the bidding has been noticeable, and later invoices of favourite marks have hardly kept up their previous quality. Medium teas have been in good demand, and Pekoe Souchongs and Souchongs with good liquor have advanced steadily till within the last few days. Common teas are neglected and sell at low rates. The quality of Dooars and Terai invoices has fallen off, but from Assam good useful parcels are now coming forward. The Sylhet teas are still poor. During the present week the sales have become much heavier, nd with the large supplies at hand the market is likely to be tested. In China tea, however, there is a distinct recovery from the lowest prices established, which may in a measure assist our market. Ceylons have been in full supply this month, and sold readily at hardening rates. The advance has been in good teas, tippy Broken Pekoes and Pekoe Souchongs from 10d to 1s being much sought after. Even at today's quotations, however, they offer excellent value, a fact fully appreciated by the Trade as evidenced by the rapid deliveries. August Public Sales, 1887—68,506 Indian, 26.201 Ceylon.—*H. & C. Mail.*

COFFEE IN JAVA.—It will be seen from the Netherlands Indian news extracted in another column from the *Straits Times* that the Dutch Government, so far from giving up compulsory cultivation of coffee in Java, have published a new regulation which continues the system indefinitely. What the opinions of the Java papers on this subject are will be seen from the translations given. This year's coffee crop, it is now estimated, will hardly reach 300,000 piculs, the yield in one district alone having fallen in the last two years from 24,000 to 2,100 piculs.

WEATHER, CROPS AND PESTS UPCOUNTRY.—From a latter from Upper Dimbula of yesterday's date, we quote as follows:—

I think our weather means to change at last. The sun was struggling out all yesterday and there was very little rain, and this morning has begun without mist or rain. Last week was so awfully wet that some of Friday's leaf was only finished off yesterday. Our pruned tea is coming on very nicely up here: a few days' sun would make it shoot forward rapidly. We shall anyway have good pickings by the beginning of November. Still busy supplying. As I was going down yesterday a boy came to tell me he had killed a big snake near the coffee store; so I made him bring it, and I took it with me round my shoulders to show the ———. It measured 7 feet 6 inches unskinned, so I hope soon to get the 12 feet one that is lurking about somewhere. Last night I skinned my specimen and it was not an easy or an agreeable job. I washed my hands well after it. The green bug is rapidly diminishing and it has practically done no damage. The berries still remain sound and firm on the trees. But the bandicoots are a great nuisance to the tea. In one night they undermined and ate all the large roots of eight tea bushes near our bungalow here.

PLANTING MATTERS.—We fancy the correspondent who wrote us the other day, expressing a doubt if most tea planters would get 80 per cent of their estimates for this season, will turn out to be correct. For months back the weather has been unfavourable for flushing. For that very reason, no doubt, it has been favourable to the full and early maturing of coffee, and we hear of a large and early crop on a place in Lindula, where a slight picking has already been obtained. The long lull in the south-west monsoon has no doubt contributed to these results. On the other hand the violent recommencement of the monsoon wind, accompanied by heavy rain, is telling unfavourably on tea. A letter from Upper Dimbula of yesterday's date states:—

"My calculation for this month is 8,000, but I doubt if we'll get it if this dreadful weather goes on. We have had 4·79 inches in the last seven days against 4·40 for the whole of August. But Mr. —— is making the best of it, and is supplying part of the estate with fine tea plants. I was sorry to see the rats had made such ravages with the coffee primaries on the Wire Shoot Hill: but fortunately they nip mostly just beyond the fruit, so that the present crop will not suffer much, I think. There is a good deal of black bug about on the tea, but I do not fear that. We must try and fork the estate this year if we can."

No one seems to attach importance to black bug on tea. Green bug on coffee is very differently regarded. This formidable pest is stated to be indentical with the coccus which does most harm to fruit trees in English orchards.

OUR PALM TREES.

Both the Cocoanut and Palmyra trees are extensively grown in the Peninsula, but the contemptible remark cast in the teeth of every Jaffna man, who goes abroad that he is a *Panang kotte Chupee* points to the fact that the world is full of the idea that Jaffna is the land of the Palmyra. The produce of the Palmyra palm, is in fact, even now the food, yea, the main stay of the poor and a general failing of the crop is always attended with great hardship. The indiscriminate and wasteful felling of palmyra for export has always been viewed with great alarm, and if we might judge the present state of public feeling on the subject from the remarks made by a local contemporary, we should say that that alarm has by no means decreased. There is however one important fact which might serve to quiet our fears, namely, that the export of Palmyra timber to the Inports, has within the last few years been or but stopped by the exorbitant, nay prohibitive customs duty imposed on foreign palmyra timber by the authorities of the Madras Presidency. Many of those who were engaged in the Palmyra trade have had to give it up owing to the high rate of duty to which we have referred. The timber generally sent to India was of an inferior quality, and largely used there for scaffolding and other similar purposes. Since the increase of custom, duty the local merchants had to raise the price of the article in order to allow them a small margin of profit, but they found that the public demand for it fell off as there was other timber in the market of indigenous growth and of less value. We know of at least half a dozen palmyra timber traders who have been almost ruined in consequence of the excessively high rate of duty, and that the trade with India is greatly on the decline. We may therefore rest assured that the wasteful felling of Palmyra timber will cease in future.

As to the complaint that lands denuded of palmyra rees have been allowed to lie waste or converted into cocoanut gardens, we would remark that in the former case the inaction of the owners is culpable, and that it is well and good to disabuse them of the erroneous impression that the palmyra plantation would not pay in the long run, or that the labour bestowed upon it is not sufficiently remunerative. But in the latter case, that is to say where the palmyra is replaced or superseded by the cocoanut, we do not see why the practice should be disapproved of. We are of opinion that cocoanut is more paying than the palmyra, provided that the soil on which it is reared is good. There are indeed certain soils better suited for the palmyra than for the cocoanut, and on such soils it would be unwise to throw away money in planting cocoanuts, and there are those who in their rage for cocoanut planting have lost their money by laying it out on plantations ill-adapted for the cocoanut palm. The chief point to be kept in view in the cultivation of the two palms is the adaptability of the soil to each. And so long as this is not overlooked both may well keep their respective grounds with advantage to the people. The palmyra is the palm of the poor as the cocoanut is the palm of the rich, and while rich people are overrunning available waste and jungle lands in the Peninsula with cocoanut plantations the poor do not seem to be keeping pace in their cultivation of their favorite palm. But it is worthy of remark that the palmyra is a plant of spontaneous growth which will hold its own in spite of the woodman's axe and such incidental neglect in its cultivation as is noticeable.—"Ceylon Patriot."

THE GOLD REEFS OF MYSORE.

We have received from the Mysore Government a copy of Mr. Foote's report on the gold-bearing region of Mysore. The following notice in the *Pioneer* fairly indicates the leading characteristics of the report :—

Mr. R. B. Foote, Superintendent of the Geological Survey, has completed his survey of the auriferous tracts in Mysore, and the report he has submitted to the Dewan will be read with great interest. The mines of Mysore have not hitherto turned out the El Dorado which was expected six or eight years ago, and capitalists are beginning to have an uneasy feeling that their money might have been better invested where, though the promise was less alluring, the fulfilment was more safe. To such as these Mr. Foote's report will be to a certain extent re-assuring. He says nothing of monster nuggets or "lumps of gold," of which doubtless many imaginative shareholders have dreamt, and he notes several instances where surveyors who went before him have given exaggerated or utterly unfounded accounts of the material wealth of certain districts; but on the other hand, he found many workings were the reefs were fine and of very great promise. Generally his report may be said to bring out two things; first, that prospecting must in most cases be carried to a considerable depth before the value of the mines can be accurately gauged; and secondly, that the whole of the auriferous areas are deserving of close survey, as even the best of them are imperfectly known, and of what was known to the old miners in former generations much has been forgotten. In Mr. Foote's tour, which was for some reason or other very hurried, he chanced on no less than five sets of old working unknown to previous surveyors, and he suspects that many others exist in the wild and jungly tracts which abound in the hilly and mountanious parts of the country. Although the work of gold-prospecting left Mr. Foote little leisure to devote to any non-metalic minerals, he took some interesting notes on such as incidentally came in his way. One very beautiful variety of granite-gneiss eminently fitted for cutting and polishing on a large scale, he found about two miles east of Banavar. The rock he declares to be the handsomest he has seen in Mysore, and monoliths of large size could easily be quarriad. Again, the hills above Seringapatam are traversed by a great dyke porphyry of a warm brown colour. The stone in Mr. Foote's opinion is unequalled in Southern India, and, if highly polished, would rival the highly-prized porphyries of olden days. The dyke is fully a mile in length and of great thickness. Beds of marble of good quality were also found near Holgere. Mr. Foote, however, met with nothing to support the opinion to which previous surveyors—Mr. Lavelle in particular—had given currency, that emery, asbestos and kaolin existed of a quality and in quantities such as would warrant the investment of capital for their exploitation.

INDIA AND CHINA TEAS.

SIR,—I have read with much interest the instructive articles on Indian tea which have lately appeared in the columns of your Journal, and although the writer has quoted from reports open to him (which I consider exaggerated) of the capabilities of certain machines for withering and rolling leaf, his remarks in a general way—especially those relating to the history of the staple and its introduction into European markets—are reliable. The question he propounds towards the conclusion of his last article (No. V. in today's issue), viz., whether Indian and Ceylon growths do not possess too much of the active principles of tea and an excess of tannin injurious to the membranes of the stomach—both prejudicial to the nervous system"—is not a stranger to Indian and Ceylon tea planters. Its origin has been traced to those dealers who find it pays them best to introduce blends of cheap and inferior China teas, flavoured with Indians and Ceylons and until quite lately it has been a

serious obstacle to the introduction of pure Ceylon tea.

The question, however, has little importance when properly considered. If the active principles are found excessive when infused in the usual way, let a little more water be added—or, quite as simple, put less tea! Let people insist on getting the pure article, and blending it for themselves. When they learn to do so there will be little fear of the membranes of their stomachs suffering, and less of their paying for what they do not get.

I must also take exception to the statement that Ceylon tea quickly loses its flavour. It was only the other day that an eminent tea merchant in this town expressed to me a contrary opinion, which he assured me was based on a practical experiment of his own covering some five or six years.

In the interest of Ceylon tea planters, many of whom hail from this town and neighbourhood, and of whose number I am, I trust you will find space for this letter.—Yours, &c.,

R. B. ARTHUR.

104, Hamilton Place, Aug. 30th, 1887.

—*Aberdeen Journal.*

[Libels published by the Brokers interested in China tea, representing Indian tea as poison, long prejudiced the public in England, and this dishonest policy is still pursued in Australia.—ED.]

THE FORESTRY OF WEST AFRICA.

Sketch of the Forestry of West Africa with Particular Reference to its Principal Commercial Products. By ALFRED MOLONEY C. M. G., of the Government of the Colony of Lagos. (London: Sampson Low, Marston, Searle, and Rivington, 1887.)

This, as its title indicates, is intended to form a handbook to the economic plant-products of Western Africa. Although the author is Governor of a British colony in this region, his remarks are by no means confined to British possessions, but are intended to include all that is at present known of economic interest connected with the plants of Western Tropical Africa.

Following Prof. Oliver, the author deems it expedient to divide Western Tropical Africa into two principal geographical regions. The first, called Upper Guinea, includes the Western coast region from the River Senegal; on the north to Cape Lopez immediately south of the equator; the interior drained by rivers intermediate between these limits, and the small island of the Gulf, Fernando Po, Prince's Island, St. Thomas, and Annabon. The second region, called Lower Guinea, includes West Tropical Africa from Cape Lopez southward to the Tropic of Capricorn, including Congo, Angola, Benguela, and Mossamedes. Within the limits here indicated we have British possessions represented by "colonies" and "protected territories," and we have numerous possessions claimed by the French, Portuguese, Spanish, and German Governments, some of which have only lately been acquired in the European scramble for African territory. It is only right to mention that the term "possessions," as here applied, is somewhat a misnomer. There is little practically possessed, even by ourselves, except a slender coast-line: the interior is described as having no "territorial definiteness," and it is politically, no less than scientifically and commercially, unexplored. Capt. Moloney has wisely not attempted to treat separately of the economic products of these possessions. He has taken their present economic botanical productions in order of export value, and we find that these consist chiefly of palm oil, ground nuts, india-rubber, coffee, gum, dye-woods, cacao, cotton, fibres, and timbers. Palm oil, the produce of *Elæis guineensis*, a plant which covers immense tracts of country in Western Africa, is imported to this country to the value of nearly a million and a quarter annually. The yellow palm oil is obtained from the outside fleshy portion (sarcocarp) of the nut, while a white solid oil is obtained from the kernel. India-rubber is another West African product obtained chiefly from climbing vines belonging to the genus *Landolphia*. The author was one of the first to draw attention to the value of *Landolphia owariensis* as a rubber-plant, and it must be gratifying to him to find that the exports of "white African rubber," as the produce is called, have during the last four years risen from almost nothing to a value of nearly £36,000. What is known as "Yoruba" indigo derived from a large tree, *Lonchocarpus cyanescens*, has evidently a commercial value, but at present it is used to mix with butter or "shea" to make the negroes' hair a fashionable gray!

Numerous West African plants are cited as yielding either gum tragacanth, copal, frankincense, gum arabic, bdellium, or resin; what is called "ogea" gum, derived from an unknown tree, *Daniellia* sp., is used powdered on the body and as a perfume by women. The true frankincense-tree of Sierra Leone is *Daniellia thurifera*. Camwood, used largely as a dye, is derived from *Baphia nitida*; but although barwood is generally said to be derived from the same source, it fetches only one-sixth the price of the former. The medicinal properties possessed by numerous West African plants is a subject full of interest.

Various species of *Strophanthus*, the active principle of which was formerly used for poisoning arrows and is known to be of incalculable benefit in cardiac diseases, and the merits of the "miraculous berry" (*Sideroxylon dulcificum*) of the Akkrah and Adampe districts, which is credited with rendering the most sour and acid substances "intensely sweet," and of the "oro" plant of Sierra Leone, said to act as an irritant poison cumulative in its effects (which has been ascertained at Kew to be a species of *Euphorbia*), are among the numerous subjects requiring further investigation.

A most cursory glance at this book cannot fail to suggest the wonderful wealth both of botanical and industrial problems which are yet unsolved in connexion with West Tropical Africa. The "Flora of Tropical Africa," by Prof. Oliver, of which three volumes are published (the last in 1877) has made a beginning in the work of elucidating some of these problems; but in recent times few men have systematically pursued West African botany, and the entire absence of a resident botanist or of a properly-equipped botanical establishment in any of our West African colonies has left the plants of a most important region to be known only by the intermittent collections of travellers who have either perished there before their mission has been completed, or have hastened home to avoid the effects of the deadly climate.

Nearly 200 pages of Capt. Moloney's book are taken up with condensed notes and references to the economic plants of Western Africa arranged in natural orders according to the "Genera Plantarum" of Bentham and Hooker. To many people both in West Africa and at home these notes, brought together by the assistance of an officer connected with the Kew Museums, will prove of great value. In the appendices are given a copy of the instructions for collecting plants, seeds, and useful plant-products issued by the Royal Gardens, Kew; an ornithology of the Gambia, by Capt. Shelley; a list of Coleoptera and of diurnal Lepidoptera of the Gambia, by the same writer; and a list of reptiles, batrachians, and fishes collected at the Gambia by Capt. Moloney in 1884-85.

The book is well got up and clearly printed, but it has the unpardonable defect of being published without a good alphabetical index. This greatly detracts from its value as a book of reference. It, however, is the chief fault we have to find with a work full of interesting matter for the first time brought together, and evidently prepared with great care.—D. M.—*Nature.*

SLAVERY AND FREE LABOUR IN BRAZIL

are thus noticed in the *Rio News*:—

We understand that the Centro do Commercioe Lavoura is studying plans for promoting immigration to the province of Rio de Janeiro and for

realizing the transformation of labour. The ultimate objects are certainly good, but like nearly all such efforts in Brazil the means to be employed are altogether ill-timed and visionary. There is abundant labour in Brazil for all immediate requirements, but this is invariably overlooked for the untried assistance of the immigrant. Up to the present moment we have not seen one serious discussion or plan in regard to the future status of the freedmen in Brazil. There will be a million and more of them—all poor, homeless, friendless, and able to work. They will not die from cold and hunger in Brazil, for nature will be an indulgent mother to them all; but they will be vagabonds, idlers, beggars, thieves and assassins. What else can be expected. Without experience and knowledge of the world and with the vaguest ideas of what liberty and self-support mean, they are to be cast off and left to shift for themselves. No one thinks of providing colonies for them, no one thinks of arranging labour for them at fair wages, no one even dreams of providing them with homes upon the unsettled lands of the nation. They are accustomed to the climate and the methods of labor in vogue, but no one dreams of employing them; they are tractable and trustworthy, but no one cares to befriend them. It does not occur to their masters that the enforced labor of these people has enriched the country, and that there are but few families and fortunes that have not been built up on foundations laid by their humble hands. All this is forgotten. The slave is accused of being ungrateful; but where is the gratitude of his master? And where is the justice—to say nothing of the injustice of slavery itself—of expecting industry, ambition and good conduct from an ignorant, debased race thus treated? We firmly believe that kindness and generous treatment will retain a majority of the freedmen in the country and develop them into trustworthy laborers and orderly subjects. We are confident that Brazil has far more to hope from them than from the majority of the Italians which speculators are now introducing under the aid and protection of the State. If now the Centro wishes to do a really patriotic and beneficial work, let it turn its attention to this one great problem:—the establishment of the freedmen on the soil, in homes of their own, and with all the protection which law and the generous sentiments of the public can accord to them. Let them not be taken from under the lash of the master to be plundered and driven by magistrates and police and society, but let them be encouraged to labor for themselves, to educate their children, and to respect and obey wise and just laws.

PLANTING IN DELI.

(Translated for the Straits Times.)

Of late, heavy rains have been continuously falling in Deli. The tobacco crop runs every risk at turning out to be a poor one.

The news of the success attending Borneo tobacco in Holland and the favourable opinion entertained of that article by experts there, has opened the eyes of the [illegible] to the need for planters in the neighbouring Dutch colony doing their utmost to keep up the reputation for turning out excellent cover tobacco for cigar factories. The praises bestowed on the article brought to market by the British North Borneo Company shows that dangers threaten from that island. Five years will elapse before North Borneo can turn out tobacco in quantities large enough to [illegible] a formidable rival to Deli. [illegible] will [illegible] to [illegible] position and prospects, [illegible] the [illegible] competition. The Netherlands India Government too, should take warning by the direction the current of planting enterprise is setting in. Hitherto the Government in Deli has been rather working against the planters, in forgetfulness of the fact that the future prosperity of the colony depends on mutual co-operation now more called for than ever owing to North Borneo competition. The only way to meet it is for both the Government and planters to work together in developing to the utmost, the productive resources of Deli. The danger is heightened by the sundry points of resemblance between North Borneo and the East Coast of Sumatra. The most prominent is fertile land which awaits cultivation but with a scattered and indolent population. In both countries, European planting enterprise has to depend on imported labour—Chinese especially. In Deli, the Government has hardly done anything to encourage increase of population during the 20 years tobacco planting has been going on. Private enterprise has to meet requirements in this direction. In North Borneo, the Government has fostered and extended encouragement to immigration of a desirable kind. In Deli, the Government has neglected the duty of laying out the country, by making roads, opening out means of communication, and executing topographical surveys. Quite the contrary distinguishes the North Borneo authorities. They exert themselves to facilitate settlement by road making, &c. An efficient police organisation is still needed in Deli though a great improvement in this respect is manifest. The same branch of administration in North Borneo has more attention paid to it by the local Government. In Deli, official moves in these three directions are required to enable the Colony to attain that stage of advancement which its resources entitle it to reach.

PLANTING IN MANILA.

(Translated for the Straits Times.)

The *Comercio* having advised the mercantile community at Manila to take to the copra trade in the Carolines, a correspondent called attention to the difficulties in the way. It is admitted that with proper management the copra trade would yield remunerative returns but not in the Carolines, owing to their remoteness and scanty production.

The Philippine authorities are taking steps to promote the colonisation of the island of Palawan by encouraging emigration from the Philippines proper. An emigrant thither in arrears with taxes will be exempted from payment. Ordinary emigrants will be exempted from any taxes whatever for ten years. They and their familes will be entitled to free passages. Land will be given to them on condition of cultivating it on pain of forfeiture. The Government undertakes to supply them with rice and a small allowance of money daily for six months. The charges will be met out of local funds. These terms are liberal enough, but it remains to be seen whether they will attract settlers to that remote island.

ASSAM TEA.

The London merchants whose windows for the last six months have exhibited black pyramidal piles bisected by gigantic placards bearing the inscription "Jubilee Tea" have for once in a way committed themselves to an advertisement which is no more than the literal truth so far at least as a large portion of their stock is concerned. Though no one seems to have noticed the fact, Assam tea is one among the many more or less notable persons and things entitled to hold Jubilee synchronously with Her Gracious Majesty. The first experimental plantation, indeed, was made in Assam towards the latter end of 1835, but it was not till 1837 that the attempt met with any success, and it was then [illegible] that the first [illegible]. In that year [illegible] of Assam tea [illegible] in England [illegible], the [illegible] [illegible] with the product [illegible] judge from the experience of the last few years is destined to end in the complete [illegible]. It was

not, however, without a fierce and sustained fight that the leaf from the Assam Valley gained a footing in the market. The Assam Company, to which Government made over the plantations after the annexation of the Province in 1839, and which held the virtual monopoly for more than a decade, was rich enough, but its agents were utterly ignorant of the proper methods of cultivation. Blundering and waste were the result, and in a few years £200,000 of capital had been dissipated. The deepest darkness, however, was nearest the dawn; and even while the Company was on the verge of bankruptcy, profits began to flow in, and in 1852 the first genuine dividend was paid. From that date the success of the Assam Tea Industry was assured, and the pioneer Company, which forty years ago was practically insolvent, is at this day, after having divided among its shareholders over a million sterling, worth nearly half a million. In a sense, no doubt, the course of the industry has not been altogether untroubled. There was a time, in 1862-63-64, when the tea fever burnt almost as fiercely in India as did the gold fever some years earlier in Australia: when a man rashly threw up settled occupation in the Peninsula in the hope of shaking from the bushy green shrubs rapidly covering the valleys and hill-sides of Assam the riches which the pagoda tree no longer yielded; and when, as a natural consequence, disaster followed, and scores of card-built Companies fell to pieces, but excepting this instance of the commercial mania which comes as certainly to all undertakings with a future before them as the measles do to children, the record is one of steady progress. Unlike the wheat and seed trades the tea trade has not advanced by leaps and bounds; but neither has it like them been subject to backward lapses. Though the development has been slow, its almost unbroken continuity within the last twenty years is one of the best signs of the sureness of the foundation on which it rests.

The tremendous expansion which has taken place in the trade since the first tea seed was dibbled into the ground fifty years ago may best be seen by reference to a statement just submitted by the Assam Secretariat to the Provincial Government. There we find that at the close of 1886 there were in the Brahmaputra and Surma Valleys 883 tea gardens. These gardens comprise over 934,000 acres, but of this, the total tea-grant held by planters, only 204,000 acres are under actual cultivation. The rapid extension of recent years is evidenced by the fact that nearly one-sixth of the area under cultivation must have been added within the last four years, since we find 33,000 acres put down as under immature plants, which, with the Assam planters, means plants not four years old. Last year the total yield of tea from the gardens reached the large figure of 61 million pounds, 57 million pounds coming from the Brahmaputra Valley and 24 million from the Surma. As to the yield per acre, the returns available appear to be only approximately correct. Official statistics for 1886 put the yield in the Brahmaputra Valley at 385 lb. and in the Surma Valley 331lb.; or an average for the whole of Assam of 363 lb.; but the Indian Tea Association gives the average outturn 144 lb. an acre less, and this is probably nearer the truth. Cachar, Nowgong and Darrang are below the average for the whole Province, while Sibsagar, Sylhet, Goalpara and Lakhimpur are above. The case of the gardens in Kamrup and on the Khasi and Jaintia Hills is exceptional, for there the yield has been decreasing, and was so low last year that it is very doubtful whether some of the gardens will be able to go on. The area under tea in these districts, however, is but a very small fraction of the whole, and their influence is hardly felt in the total production of the Province. The highest yield is found in Lakhimpur, where the average last year was 508 lbs. per acre. Turning to the cost of production we have no certain information for all the gardens; but the average cost per lb., including sale charges, for 18 gardens in the Assam Valley and 23 gardens in the Surma Valley for the past two years, was about 8 annas for the former and about 7 annas for the latter Addressing the Society of Arts recently Mr. J. Berry White said he confidently anticipated that the crop of Indian tea in 1890 would be placed on the London market for a fraction under 6d. a lb.; but even if we allow a reduction of a penny a lb. in the cost of production for the next three years it is difficult to reconcile the statement with the above figures. Nevertheless the reduction in the cost of production is one of the most remarkable of the many changes which the fifty years have wrought. Labour is cheaper, the methods of cultivation and picking have improved, and the whole process of manufacture has been transformed by the introduction of machinery. All the most important parts of the manufacture, rolling, drying, sifting are done by machinery, mostly steam-drivers.

It is curious to note from the report above referred to that "all the Deputy Commissioners and those Managers who have expressed any opinion on the subject are unanimous in attributing the bad prices of last year to the supply being in excess of the demand." This theory of over-supply has been the companion of many an afflicted economist besides the tea-planter; but there was never an instance, perhaps, when there was less evidence in its support. The United Kingdom is almost the sole market for tea; but if we take the deliveries of tea there for the ten years between 1876 and 1885, we find they have increased by something less than one per cent annually, which is just about equal to the increase in population, and we find also that the increase in re-exports has been three times as large as the increase in imports. These figures show with sufficient clearness that to whatever the fall in prices is due the explanation does not lie over-production. The fact is, so far as the fall in Calcutta prices is concerned, the decrease must have taken place altogether irrespective of competition in China and Ceylon in obedience to the reduction in the cost of production. There is nothing more common than to hear planters express the fear that the same fate may overtake them as has overtaken the English wheat-growers. As Indian wheat has reduced prices below the cost of production in England, so it is thought the competition of China tea may reduce the price below the cost of production in India. The cases are, however, in no wise parallel. The India wheat-exporter has not felt the reduction in the gold price of wheat because it has in a great measure been counterbalanced by the fall in exchange; but every fall in the price of tea is felt equally by China and India. The conflict is thus reduced to a mere question of cost of production, and in this India must in the long run conquer. The enormous fall in the exports from China during the present year indicates that China growers have already been growing at a loss. All that Chinese competition has done or is likely to do is to prevent diminution in the cost of production being added to the planter's profits.—*Pioneer.*

COFFEE IN NORTH BORNEO is thus noticed in a report of the commerce of the settlement for six months:—The most satisfactory figures in the Return of Exports are perhaps those referring to Coffee and Pepper, proving that these industries have not only made a firm beginning but are already added to the Exports of the country.

DARVEL BAY.—At Silam the autumn Liberian Coffee is ripening fast and the prospect of a large crop is good. No leaf disease has appeared in the Experimental Garden since its commencement. The Coffee has been extended a few acres and the young plants look exceedingly healthy and strong. Pepper is being extended. One and a quarter acres have been felled and will shortly be planted. Cocoa is growing rapidly and is enormous in size for its age, pigs however, consume a deal of its fruit.—*British North Borneo Herald.*

THE EAST INDIA ASSOCIATION:

THE COMMERCIAL PRODUCTS OF ASSAM.

By O. WEYNTON.

Cajput—generally called caiaputer—the *Melaleuca cajeputi* of Roxburgh, is a small tree with a twisted, crooked stem scattered branches with a drooping tendency, similar to the weeping willow. It is rather sparsely distributed throughout the province—chiefly at the entrance of ravines, but to avoid an expensive search, may be procured either from Dacca, in Goalpara, under the Tipperah Hills near the station of Comilla, Jaintiapur, and, in fact, almost any locality where ruined temples abound, as in such places, in days gone by, it was carefully looked after, its medicinal properties being well known to the priests and native practitioners though they seldom extracted the oil, but used the hot, bruised leaves as applications in sprains, bruises and rheumatism. The tree takes three years to reach maturity, but slips may be planted close together so as to form a nursery, and until planted out in the permanent situation destined for them, may be constantly cropped (according to judgment) in that condition, so that returns may be had in eighteen months from the time of laying down the slips. The leaves are to be collected on a fine warm day, say from April to September, lightly rolled to break the cells, then chopped up fine, macerated in water for twelve hours; strained and the liquor distilled in a glass or enamelled still. The result will be a pure limpid oil with a light green or bluish tinge and an odour quite distinct—the caiaputer oil of chemists. It is apt to discolour if exposed to light, and should therefore be packed as soon as convenient, but, pending which, may be stored in large closely-covered earthern jars kept in a dry, dark place. There is considerable local demand for this oil, not only among the native population of Assam, but in both Munnipoor and Burmah, as also down country, and it is more than probable that the whole of one's out-turn, until it assumes large dimensions, could be profitably disposed of within the country. Once established, the cost of cultivation is but nominal, the preparation inexpensive, and the returns handsome. The plant may be grown on almost any soil above swamp-mark and scattered about in any unused plots of the grounds, placed in topes or groups sufficiently numerous to afford leaf for one day's systematic plucking—not isolated trees stuck about here, there and everywhere, necessitating an extensive roaming on the part of the gatherers.

Chaulmoogra—Gynocardia odorata, or the Ta-fung-yu of China, is a handsome tree supposed to be peculiar to the northern part of the Sylhet district—merely, I presume, as expressing the oil once formed one of the jail industries there; but it may be found in all ravines in which the primeval forest remains intact, in either of the mountain ranges from Gowhatti to the Brahma Khoond, and from the Laor River to the Khuboo Valley, as also in the deep semi-tropical forest gullies, in the Khassia, Garrow and N. Cachar hills. Were exploration safe, I have little doubt that it would be forthcoming in the northern ranges and Upper Burmah, as the expressed oil forms, under the name mentioned above, a large item of export from Laichung in Western China. Among the Chinese, Ta-fung-yu has for ages been regarded as a specific in syphilitic and kindred diseases, being, when mixed with ground cinnabar, applied externally to the parts affected, the pure oil used for injection; it possessed the property of disinfection, and drying without causing obstruction or any unsightly cicatrice; wounds and ulcers treated with it closing with an evenness that hardly leaves a trace behind. Chinese medical men asserting that treatment with Chaulmoogra entirely prevents the copper-coloured stain peculiar to the site of wounds caused by the diseases alluded to. Whether the whole of the therapeutic properties claimed for it would stand all tests, experience must decide, but all over the East, where cutaneous maladies, from leprosy down, are so prevalent, unbounded faith in its virtues exists, and so esteemed is it in Persia and the countries adjacent, that either at Shiraz or Bushire one rupee per ounce is readily paid by dealers from the interior for it. The water tetter, or ringworm from which new-comers from Europe to Assam almost universally suffer, rapidly yields to the mixture of chaulmoogra and cinnabar, and though mercury in any form is specially dangerous to deal with in warm climates, I have never yet heard of the slightest symptom of salivation arising from the use of the combination. In China a 6-grain pill made from the seed is sometimes given, but with what object I am unable to say, as the smallest quantity induces nausea and vomiting. The blossom appears in April and May, and the fruit, which takes the form of an oblong nut—not much dissimilar in shape to a Brazil nut—ripens towards the end of the rains, is smooth and of a greyish colour, yielding on cold pressure 10 per cent of rather thick resinous oil. Although it bears in the fifth or sixth year, the tree attains the size of a full-grown mango, so that wide planting is necessary, but beneath its shade other plants may be raised. The usual method of opening out the roots in March and heavily manuring with ash, stable dirt and pounded limestone will bring out a prodigious amount of blossom, but it is better not to resort to the practice yearly, until, at any rate, the tenth or twelfth season; every alternate year until then being as much forcing as the tree will bear with impunity. The cake, obtained as it is without heat to deprive it of all medicinal properties, may be ground into meal and used for poultices, being from its nauseating qualities unfitted for cattle feeding; although I have given it to pigs, who readily consumed it without any apparent deleterious effect. Chaulmoogra needs but an introduction in sufficient quantities to create a considerable demand, and its being a native remedy has, I opine, been the chief cause of its neglect among professional men who are apt to condemn all such without unprejudicially first giving their reputed merits a fair trial.

Dipterocarpus, or the tree that furnishes the *Gurjan* oil, or rather oily resin, is now difficult to find in the more accessible parts of Assam, but, as the intending settler of the present day will most likely have to locate himself in the veritable backwoods, it is very probable that some of these highly valuable trees that have escaped the jungle roamer may be found in his concession. Any native can point them out, but raising from seed, it must be borne in mind, must be undertaken in the interests of posterity, for the tree grows to a great altitude, generally shooting up to the height of forty feet ere throwing out branches. Those met with in the forest fit for tapping are presumedly some forty to fifty years old, and of late years the gatherers have not only been content to tap the trees to death, but have in many cases actually felled them, trying out the billets in so ruthless a manner that pitiable wholesale destruction has been wrought; still Gurjan is found, though one must go further afield for it, searching the hill ravines. It is very plentifully distributed in the deep valleys of the Looshai hills, and reported by the inhabitants to abound far in the interior, the crude resin finding its way to the markets on the Chittagong side of those hills; but a considerable number of untouched trees may be noticed in the valley of the Kopoli and also in the forest round about the Brahmakhoond. These localities are merely referred to as seed collecting centres, for to gather the sap from a tract of country so wide as that over which the dipterocarpus is distributed would prove not only too expensive, but might lead yourself and coolies into dangerous places. The seeds ripen in October, and should be sown as fresh as they can be procured—for they rapidly lose their germinating power. Raised in nurseries until the wood is sufficiently matured to bear transplanting, the young saplings may be placed out in the jungle and left to nature, a record of the date and site of planting being kept for the benefit of future generations, as the planter of dipterocarpus can hardly hope himself to reap the benefit of his own plantings. If one or more mature trees are found on the grant the rest may be ascertained any time from November to May in the following manner.—One or more oblong perpendicular [illegible] are made at a convenient distance from the ground—

two feet long by six inches broad—cutting well into the body of the tree through the bark; at the lower end a cup-like cavity must be scooped out of sufficient capacity to hold a fluid quart; fire is then introduced and kept up with charcoal for from two to three hours until the cavity is thoroughly well charred; on cooling the Gurjan commences to trickle out, needing baling night and morning; should there be a falling-off in the exudation, more charring will stimulate it, though the better plan will be to open a fresh hole on the opposite side of the tree, and thus working both alternately. The yield per annum from a fully matured tree—maturity being approximately indicated by a height of seventy feet and girth four feet from the base, of eighteen feet—was 346 pounds. Gurjan oil is the best varnish for all woods known throughout the East, and well rubbed into teak with the husk of coconut, gives a polish to that and other dark timber rivalling that shown by mahogany or walnut, while the surface oil applied in a similar manner to light-grained woods is attended with equally brillant results. Mixed with lampblack and applied to carved teak, a good many imitations of the celebrated Surat blackwood furniture are palmed off on the globe-trotting curiosity purchasers, but it looks equally well. Perhaps one of the most valuable preservatives of wood work is the combination of Gurjan and ground sulphate of copper, which, boiled to the consistency of the thick syrup, and applied hot to any timber—whether imbedded in the earth or not—effectually prevents the attack of white ants and borer, resisting also the exigencies of a damp climate, and would thus doubtless prove of value in the preservation of railway sleepers. As a cosmetic it imparts a delicate softness to the skin, but has a somewhat medicinal odour that would need eliminating or concealing with some counteracting perfume ere it found favour among such Europeans as indulge in those luxuries. Mixed with *neem* leaves it forms a most powerful poultice, and natives claim for it cetain medicinal qualities possessed by matico and copaiba, the details of which it is unnecessary to enter into.

Croton Oil.—Croton Tiglium, from which the croton oil is obtained, is found in all parts of the province, being more plentifully distributed in the drier districts. Though the family of the crotons is a numerous one, there is no difficulty in distinguishing the tiglium, which has the smallest leaf. The native name is *Jummul ghúti*. There being but a small demand for this oil only a limited area need be devoted to it, and as the plant is apt to spread it will require, occasionally, weeding out or otherwise keeping down. If, however, you elect to manufacture the oil, it will be as well to bear in mind that you are dealing with a most powerful irritant poison, which in any stage of preparation should not come in contact with the hands or other part of the body or even the clothing; the special press retained for its extraction should therefore be kept, and all manufacture conducted in a separate hut. The process of extraction is cold pressure between plates similar to those used in castor oil; when run off croton should stand for fifteen days, then filter through charcoal and pack in small bottles or tins. All refuse had better be burnt, and the plates and other paraphernalia scrubbed with ash lye with a long-handled brush kept especially for the purpose.

Many economic plants that now receive but passing attention ought to be brought either from the jungle or native homesteads and placed under observation, for many, used in their crude state, undoubtedly possess highly valuable properties that, owing to want of chemical knowledge, natives do not utilize to the full extent of such capabilities. Like the despised "old woman's" remedies in more civilized countries, unexpected valuable results are often obtained therefrom by painstaking chemical research. One's ears and eyes should be always open in Assam, and, given as natives are to romancing, there is generally some modicum of truth at the bottom of the wildest romance. The wealth of the province has by no means been thoroughly disclosed, for the simple reason that exhaustive explorations, either botanical, geological, or by naturalists, have never been attempted; but all investigations have been conducted in the most perfunctory manner; when one item was reported some one was sent to the particular locality to report upon that particular item, having done which his duties were considered at an end. Hence, Government incurred great expense in deputing the late Mr. Fortune to China to procure a deteriorated tea seed to plant in the land from which it had originally been taken nigh two thousand years before, though the history of its transport from Assam to the "Flowery Land" by a Buddhist pilgrim has formed a well-worn theme among the story-tellers of the Indian bazaars for ages past. Again, botanists were sent to South America to introduce cinchona and ipecacuanha, yet *Cinchona crispa* grows wild on the summit of the forest-clad cliffs that overlook the plains of Sylhet and Cachar at an elevation of some 1,500 feet, and ipecacuanha is found in abundance in the Larnai Valley within a dozen miles of Shillong. Nothing, therefore, should be considered too trivial for investigation, though neither of the latter plants referred to are likely to be attended with successful cultivation below the elevations indicated as their true *habitat*.

Pán, the well-known leaf of the betul vine masticated by all natives of India, seems never to have attracted that attention which its undoubted valuable qualities should ere this have commanded. When one reflects that men carrying heavy loads travel long distances in the hottest weather exposed to the ful blaze of a tropical sun or get through laborious tasks with no other sustenance than the mastication of this leaf, it is evident that it must contain some wonderfully stimulative properties well worth careful investigation; anyone can test these for himself, and although most natives use some half-dozen ingredients in conjuction with the leaf, a little consideration will show that such may be regarded merely in the same light as sauces with solid joints, and that in the juice of the pán leaf lies the stimulant. A leaf, taken when one is suffering slightly from the influence of the sun or fatigue, acts immediately as a restorative, quenching thirst and imparting an agreeable glow to the throat and regions of the face and head generally, without any deleterious *sequelæ*. Although it would not be possible to introduce the leaves themselves to Europe, and, in fact, their mastication would hardly find favour, an extract or tincture, if the properties noted could be retained therein, would not fail to be appreciated, especially among those with whom a non-intoxicating stimulant is a *desideratum*. Pán leaf, bruised, when applied to cuts and wounds arrests bleeding, cleanses from all suppuration, besides promoting granulation in the most ugly hurts; hence it is reasonable to infer that it must possess medicinal qualities that should recommend it to the notice of the faculty. It is needless to enter into details connected with the cultivation, as such may be seen in operation all over Assam, the favourite sites in the plains being the banks of rivers, but the best and most pungent leaves are those from vines planted in the limestone rifts in the hills. Shade is imperatively necessary, and, in the dry weather, systematic irrigation also, but the vine will not thrive under the drippings of dense umbrageous trees, and good drainage is essential to its well-being. The care bestowed upon it by such eminently careless cultivators in most respects, as Bengalis sufficiently indicates its delicate nature, as does the large area devoted to the raising of it, the remunerativeness of its culture.

The *Areca palm*, erroneously and almost universally called the betul-nut tree by Europeans, may be planted in any flat land, but not swamp, in and around the property at distances from 6 feet to 8 feet apart. The large demand for arecanuts all over India and the East renders the establishment of these plantations highly profitable, but as Europeans hitherto have been but "birds of passage" in Assam, none have cared to plant, hence the cultivation is almost entirely confined to natives. But when once rail communication with Chittagong gives the province its long-needed seaport, the demand for

arecanuts will form an important item in its exports, coastwise. The tree is best raised in nurseries, and may be planted out the following season. It attains a height of from 40 feet to sometimes 60 feet in the course of ten years, but bears the fifth, and although that may seem a long period to wait for returns. Once *in situ* no cultivation whatever is required, and the factory's appearance cannot fail to be greatly embellished by the presence of this most graceful of all the palms, which an eminent botanist has likened to "an arrow shot from Heaven."

Vanilla.—The terrestrial orchid that yields the aromatic pods of this spice, though better grown at 1000 feet or 2000 feet above sea-level, may, with care and attention to keeping the young roots clear of ants and other insects, be successfully raised in the plains and trained on the stems of the areca. When once it obtains a firm hold, little attention is needed, but should inclination to spread laterally be indicated, such should be encouraged and bamboos, hung by loops from palm-stem to palm-stem, will afford quite enough support for the ramifying tendrils. The bamboos must not be firmly lashed to the palm-stems, as the areca sways in response to the slightest breeze; thus a certain amount of play must be allowed for. The vanilla will bear well the third year, and the pods must be gathered as soon as they begin to change colour, or they will burst, then dried under an open shed, and are better exported in cases. Each should be wrapped in a piece of clean paper, but those who deem such a proceeding too elaborate may omit it.

Bael or *bel* is the fruit of a well-known tree that may with advantage be introduced from native gardens, but as the best is grown about Dacca, seed should be imported thence. Bael will yield in the seventh year, and, though its medicinal properties are little known in Europe, there is no doubt that it would make its way in public favour once brought prominently to notice. Its merits lie in the pulp contained in a hard calabash. The pulp, beaten up with sugar and strained through coarse muslin, has an undeniable regulating effect upon the bowels specially valuable when choleraic complaints manifest themselves. Anglo-Indian chemists manufacture a dried preparation of this fruit called "dhete ke bael," but much of the virtue of the pulp is lost during the process, and for export the form of preserve should invariably be adhered to. At the same time the fact should not be lost sight of that as it is a medicine rather than a condiment, sugar or other preservative used in the preparation should only be resorted to as sparingly as is consistent with the preservation of its therapeutic properties.

Nux Vomica, under the name of *Kuchela*, from the button-like seeds of which the alkaloid strychnine is obtained, is found growing wild in many parts of Assam, in such abundance in one part of Cachar as to give a name to an isolated block of lava-strewn rise, upon which a tea plantation has since been formed; there is no difficulty in obtaining it in any quantity, as all natives know it. Unless one is an adept in chemistry the extraction of the active principal need not to be undertaken, but the pods or seeds dried in the sun and packed in tea chests for export. If chemical action is resorted to, all utensils used must be kept securely locked up, as strychnine, it is almost needless to say, is a highly dangerous drug to leave about.

Neem.—The neem tree abounds, and the bruised leaves are much in request where strong drawing poultices are required, being specially useful about the mango season, when troublesome boils are so prevalent. An extract, distilled from the leaves, can be made that is of considerable value in stimulating the action of the milder applications, such as bread and linseed meal applications. Native practitioners make use of the neem for a variety of purposes, and as they are not by any means reticent in affording information, investigation and experiment may possibly result in adding another simple, though efficacious, remedy, to the British Pharmacopœia.

Doud-ka-putta is a quick-growing tree, allied to the acacias, the bruised leaves of which are applied to the water-rash, which nearly all new-comers to Assam suffer from; but as tamarind leaves have much the same effect, the *doud* may or may not possess any superior qualifications. However, this matter may readily be determined by experiment. A tincture or extract of such sent to an analytical chemist would soon answer the question.

Cassia.—*Cassia lignea* is indigenous to the hills, but whether it would flourish in the plains is not so certain, though the true cinnamon—a few plants—was successfully introduced into Sylhet twenty years since. If you are located in a hill ravine, a small experimental patch may be brought under plant at an elevation deemed suitable; for the cassia, though of much coarser flavour and inferior in other respects, bids fair, at no remote date, to outrival cinnamon either as a spice or oil producer, the general public being hardly competent to distinguish one from the other.—*Pharmaceutical Journal.*

PROCEEDINGS OF THE AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

STICK COVERED COCOONS.—Mr. J. Cleghorn, writing from Sarda, Rajshahye, sent some very curious caterpillars, covered with a cocoon or envelope of stalks of the grass on which they had been found feeding; they were examined by Mr. Wood-Mason, who reported on them as follows:—

"The curious bodies forwarded to the Society by Mr. Cleghorn are larva cases containing still living larvæ of a species of moth belonging to the family *Psychidæ* the *Sackträger* of German entomologists, so-called on account of the sacks which the larvæ build for the protection of their bodies, and in which they live, dragging the structures about with them from twig to twig, and from leaf to leaf, while they feed. The portable cases are constructed of silk, fortified on the outside with pieces of the food-plant. The pieces by which the cases before me are defended, are arranged in a succession of imbricated whorls, and they resemble bits of grass. The free ends of the pieces all point away from the mouth of the sack. The first or lowest whorl of pieces is at its hinder end, and the last or uppermost at its oral end. Each end is for a short distance devoid of defending pieces, and is open. The larvæ while feeding—and this they do chiefly during the night—keep hold of the case by means of the pair of legs at the hinder end of the body. When they have done feeding, or when they are alarmed, they retire into the case, suspending this by a few threads of silk to a twig, from which they hang suspended till feeding time returns, or the danger is past. They change to pupæ in the larva case, previously fastening this by its mouth to a twig much more securely than usual. The caterpillars that are destined to become male moths turn in their cases just before changing, so that their heads point to the opposite end of the case, from which the moths emerge, leaving their empty pupa skins projecting more than half way out of the cases. The males are winged and leave the case in quest of the females. These being devoid of all vestiges of wings, and of all but the nearest rudiments of feet and feelers, remain in the cases, and are there impregnated by the males.

"The transformations of the insect whose cases and larvæ are before me not having been observed, I am unable to tell you its specific name, or even to say for certain to what genus it belongs. It probably, however, belongs to the same genus as *Eumeta Cramerii*, one of the pests of the tea-plant, the bread, and several other plants. If any moths should emerge, they shall be determined, and their name communicated to you. The species of *Psychidæ* often remain in the larval state for many months.

"The allied *Eumeta Cramerii*, the larvæ of which bear the popular name of the tea caterpillar, attacks the bahul tree, the tea plant, a cereopsis, and one unknown to me (of which there is a luxurious growth

near the gate of the Bengal Club), and doubtless many other plants of use and ornament. As the species has an economic importance, perhaps the following account from my note-book, of the manner in which the cases inhabited by the larvæ and pupæ are built may prove of interest to the members, and possibly even some day be turnable to account in reducing the members of a pest, which often bares whole patches of tea bushes of the all important leaves before the planter becomes aware of its presence. The eggs are laid inside the 'faggot,' and the young caterpillars, as soon as they have cut out, leave the case and commence to walk about over its outer surface of their naked 'tails' borne erect as they go on their 3 pairs of thoracic legs, but after a short time they are seen to be covered as to their 'tails' by snow-white caps built up in the following manner of tiny particles of the whitish external covering of the dead and weathered babul spines of the parental dwelling. First, a half circle is formed of particles gnawed off for the purpose from the bark of the spines and arranged in a single row; by a turn of the front part of the body, the half circle is jerked on to the back of the tiny animal, which is at first but a mere animated speck, and the circle is completed; then a second circle is added in a similar manner to the first; then a third, and so on, till the whole body is covered. The particles are literally glued on one by one by a sticky secretion from the mouth, no doubt from the openings of the silk-glands, the joints being afterward strengthened by being smeared or spun over with more of the secretion. The case is at first a very loose and open affair, vacuities appearing here and there between the component particles of its walls, and allowing a fine silky matter to be seen; it is, in fact, a loosely and rather irregularly constructed net with minute particles of the bark of the dead babul spines interwoven in it. Having the constuction of its case carried, thus far the insect actively turns in it backwards and forwards for some time, for the purpose of consolidating it by drawing the particles closer and giving it a delicate silken lining; finally, it imperfectly closes the hinder end of the case, by tucking the edges in. The babul spines are attached as a defence to the outside at a later stage, and they form a truly efficient fortification."

Mr. Cleghorn mentioned that the natives of the district in cases of fever remove a caterpillar from its sack, and hang it in a muslin-bag round a patient's neck, "profuse perspiration is guaranteed."

OSTRICH FARMING IN SOUTH AFRICA.

The following letter has been addressed to the editor of the Melbourne *Argus*:—

Sir,—Seeing a paragraph in your valuable paper of the 10th inst, relating to the ostrich farming industry in the Cape taken from the *Cape Argus*, I should like to enlighten your readers a little more on the subject, if you will give this space in your useful paper. It is erroneous to suppose that good ostriches were sold for 5s. each, as good birds, even now with the depression, realise from £10 to £12 per pair. No doubt, if a competent judge had seen those ten ostriches that were sold in the Western Province for the small sum mentioned at per head, he would have announced them inferior and not worth keeping on a farm, owing to the worthless feathers they gave in return for their keep. There are some ostriches that grow such low-class feathers that the plucking is almost valueless, while on the other hand others grow superior quality, which always commands a high price. The wing feathers from an inferior bird yields say from 4 oz. to 5 oz. in weight, and worth at the rate of £1 per lb.; while a superior bird will give as much as 6 oz. from the wings, and worth from £12 to £14 per lb., at the market rates they are selling now in the Cape. These prices apply to feathers taken from the cock bird, and are called "white primes." The wing feathers of the hen bird are named feminas, and are worth about half the value of the "primes" and so on in proportion to the quality. The weight of feathers obtained from a good cock bird would be about 2 lb., divided into five different classes, as follows:—From the wings are taken three sorts, weighing 6 oz. primes, 2½ oz. fancy and mottled (usually termed byocks), and 2½ oz. long and medium blacks; in all, 11 oz. The tail generally yields 5 oz., and the short black feathers and floss taken from the breast and under the wings about 1 lb. Ostrich farming remains the most lucrative branch of farming at the present time in the Cape, and transactions in feathers have been large and important. The returns below, taken from the *Port Elizabeth Telegraph* of last mail, give some idea of the magnitude of business done at Algoa Bay alone. The sales at the ordinary auctions last March represented a value of £45,144, as compared with £25,868 for the same month last year, being an increase of £19,276. The total realised at the ordinary market for the first quarter of the current year was £100,858 as compared with £96,800 for the same period last year, the increase being £4,058. Some have an idea that feathers are going out of fashion, but if they were to see the large quantities shipped every week from Cape Town, Port Elizabeth, Mossell Bay, East London, and other ports, their ideas would be altered. The large parcels that are shipped to Paris, America, and other parts of the world show that feathers still hold their own against any ornament that is worn on the hat to make the fair sex look charming. I have had seven years' experience with ostriches and their feathers in Africa, and would like to return immediately. If I only could buy the birds I would choose to go farming with at 5s. each—the price of a goose—I should reckon in a few years to make a fortune, and instead of sleeping on goose feathers would have my pillows stuffed with "white primes." Apologising for taking up so much of your valuable space,—I am, &c.,

MELVILLE EDENBOROUGH.

Gordon-chambers.

THE GROWTHS of Corn and Potatoes of the United Kingdom are worth on an ave age over one hundred millions sterling per annum.—*Indian Gardener.*

THE NILAMBUR TEAK FOREST IN THE MADRAS PRESIDENCY is likely to be of enormous value, and we hope the planting of teak will be earnestly taken in hand in Ceylon, in view of the facts thus stated in the *Indian Agriculturist*:—

The position of Burman teak in the timber market, will, it is confidently predicted by experts, be greatly changed during the next decade. Already, in fact one may say for a long time past, the superiority of Madras teak over that obtained from the Burman forests has been so fully recognised, that it has been preferred by the Madras gun-carriage factory for the manufacture of their gun-carriages, to the Burman teak, even though the latter could be obtained and delivered at a much cheaper rate. This comparative cheapness is apparently its only recommendation, as the Anuamullai teak was found to have a splendid "breaking strain" as it is technically termed, and could resist shocks from discharges of gunpowder against which the Burman teak is powerless. A new rival has now, however come into the field in the shape of the Government teak plantations at Nilambur, and it is calculated that in ten years' time these plantations will be able to undersell Burman timber in the Madras market. The qualification of quality will in no way be below that of its Burman rival, in fact it has been found that there are natural teak trees growing in various parts of these plantations which have not yet come to maturity, although the roots are said to be one hundred and fifty years old. On examining the stumps of felled trees it has been found that in most cases these had been felled once before, and judging from the size of the old stem three feet from the ground, where the marks of felling can be seen, it appears probable that the tree had been eighty or 100 years old when first felled, while in one case where the annular rings of a felled tree were counted, it was found that they were sixty in number, this representing sixty years, this tree and others would be about one hundred and fifty years old. In this case there is a good prospect of the Burman teak being ousted from its position in the market.

A NEW SUGAR-CANE.

For some years, remarks a well-informed writer, efforts have been made to bring together into one collection all the different varieties of Sugar-canes which are known under cultivation in the Sugar-producing countries of the world. It would appear now that this object has in a great measure been accomplished in the extensive collections of Sugar-canes under experimental cultivation by the Department of Public Gardens and Plantations in Jamaica. The collection, as a whole, embraces about eighty varieties of canes, and it has been pronounced by a competent authority connected with the Department of Agriculture, Washington, "as probably the best collection of Sugar-canes ever gotten together."

As indicating the wide area from whence these canes have been obtained, it may be mentioned that the "Elephant" cane, so called from the size it attains under favourable circumstances, was obtained from Saigon, Cochin China; the Salangore cane is a native of the Malay Peninsula, where it is highly esteemed. The Tiboo cane is also East Indian, and is a productive cane of great merit. From Mauritius there come the Horne, the Mauritius, and the Barkley canes. From Queensland there are the Brisbane, the Green-Rose Ribbon, the Queensland, and the Hillii; while from the Pacific Islands (probably the home of the Sugar-cane) there are the Lahaina, the Cuban, the Pua-ole, and the Ko-Kea. The Lahaina cane is described in Hawaii (Sandwich Islands) as being the most universally esteemed of all canes, and everywhere, excepting at great elevations, it is planted to the almost total exclusion of other varieties. This cane has yielded as much as an average of 6 tons of Sugar per acre on areas as extensive as 100 acres, and 7½ tons per acre on an average over areas of 20 acres. The Pua-ole cane, another great favourite in Hawaii, is called the flowerless cane, because it never tassels, or throws out a flowering shoot. It is described as a soft, rich cane, yielding juice of high specific gravity, and especially adapted for cultivation at high altitudes. The Cuban, or Ko-Pake, in Hawaii, comes next to the Lahsina. It is rich in juice, rattoons well, grows rapidly and is entirely free from "cane itch." The Samuri cane is the favourite cane with the Sugar-planters of Fiji. It is hardy, grows rapidly and yields sugar freely. Of dark-rind canes, such as violet, purple, and black, there are numerous varieties. Many of these, such as the Egyptian and the Martinique, are admirably adapted for dry, arid regions, and grow luxuriantly where other canes would fail. Others, again, are adapted only as fodder plants, and are often grown for that purpose when grass is scarce. The Mamuri cane, of a dusky brown colour, is certainly a strange-looking cane. It would appear to be covered with a thin, dry bark, which marks it at once as a distinct and specialised variety. This is a hardy, slender cane, which would grow in the driest situations. Of striped canes there are very handsome specimens, such as the Green-Rose Ribbon and the Red Ribbon, which attract attention, and are likely to be great favourites with planters.

In the West Indies generally the favourite canes are the Otaheite, the transparent, Mort Blanc, and the Bourbon. These may be said to yield the bulk of Cuban and West Indian Sugars, but several others are being tried, with the view of testing their capabilities for different soils and climate. As the Sugar-cane has lost the power of producing seed from which plants may be raised, it is now entirely propagated by shoots or pieces of the stem, which are furnished with eyes at every joint. These eyes give rise to new plants, which necessarily must be identical with the parent plant, and keep true for an indefinite period. The importance of introducing new canes, and so testing the highest producing powers of the land, in these days of low prices and keen competition, is self-evident. From the supplement to the *Jamaica Gazette* we find that the collection of canes abovementioned sent to the New Orleans Exposition has lately been carefully tested by Dr. Crampton, chemist, attached to the Bureau of Chemistry Department, Washington, D. C. Planters in the West Indies would do well to procure these analyses, and carefully consider whether some of these new canes do not offer them advantages in a cultural and economic sense superior to the old. We may add that a full description of these canes was given in the last report of the Director of the Botanical Department, Jamaica, and Dr. Crampton's analyses are intended to supplement these descriptions, and give Sugar planters every possible information on the subject.—*Food.*

THE CULTIVATION OF A WOOD FOR TEA BOXES.

Dr. H. Meyer, Lecturer on Forest Botany at the University of Munich, has recently published the results of his inquiries as to Forest Cultivation, in a tour of some months which he made through the northern part of India. Being informed of the scarcity of indigenous wood suitable for Tea boxes, he directed his particular attention to this subject, and he has come to the conclusion, taking soil, climate, and other contingent matters into full consideration, that the quickest, cheapest, surest means of providing for a future suitable supply of wood for Tea-boxes, in this country, would be to cultivate the *Cryptomeria* (Japanese *suji*), or, as Dr. Meyer calls it, *Sequoia Japonica*, for the Hills round Darjeeling, and the *Paulownia imperialis* (or the Japanese *Kiri*) for the plains, Terai, and lower hills of the N. W. P. and the Punjab. It may be argued that the proper persons to give attention to and advice on this subject are the Forest Department, and no doubt the matter will be taken up by them, but it is within the ability of any planter to create for himself timber reserves, and the doing so will be found by no means unprofitable.

In Japan, the *Suji* (Japanese cedar) is largely cultivated all over the whole empire, and it is also found in a wild state. It forms a splendid mass of forest in many districts, and grows to the height of 150 feet, with a girth of 6 feet and more. The tree is said to be a native of China. At any rate from that country the first seed was brought to Darjeeling by Mr. Fortune. A few trees only were at the time planted, but the kindly way in which they have taken to the hill, soil, and climate, shows the adaptability of the place to their cultivation, and it is to be hoped, now that the value and suitability of the wood for tea boxes is established, it will induce a considerable extension of cultivation.

In Japan itself, the wood is highly prized, and very extensively used. It grows in all situations and soils,—in damp villages as well as on high mountain slopes, and is one of the commonest and also one of the most useful of Japanese timber-trees. The sapwood is whitish yellow, from 2 to 3 inches broad, and is, when beams or boards are wanted, generally not removed from the dark-reddish sometimes black-bluish, striped heart-wood. The wood is very light and soft, and easily manipulated; and may be used for all kinds of carpentry besides Tea-boxes. For propagation of the *Suji*, the terminal piece of every branch is used, 1½ to 2 feet long. The plantation in the ground must be made before or at the beginning of the rainy season, the cuttings being put 3 to 5 inches deep in the soil. This method is much preferred to sowing, the young seedling being tender and easily killed by frost. Although, of course, the tree takes many years to arrive at maturity, its commercial value is none the less ascertainable at any stage, and a tea estate possessing a reserve of this timber, in almost any stage of growth, would possess a marketable commodity of ascertainable value.

In planting, scarcely 4 feet should be left apart, for only in a dense growth does the *Suji* soon lose its branches, and produce a clean, straight, and valuable bole.

There is another timber-yielding tree, the wood of which is suitable for Tea-boxes,—the *Paulownia imperialis* (called *kiri* in Japanese), but it does not grow well in the wet climate of the Eastern Himalayas. The wood of *Paulownia* is largely used in Japan, not only for tea boxes, but for boxes and furniture of every kind. One peculiarity in the cultivation of this

tree is, that when the seedlings are two years old, they are cut off close to the ground, and the new shoots grow straight up to a height of 10 feet or more without a branch, in a single year.

When the tree attains a girth of from 3 to 4 feet, the timber is available for use for Tea-boxes. In Japan, the tree is sawn off, every 8 or 10 years, very close to the ground, and the new shoots grow straight up to a height of 10 feet or more, without a branch in a single year.

Dr. Meyer, who supplies us with all this information, offers to provide the Forest Department with seeds from Japan, and we trust that his offer will be availed of, and the seeds distributed to such as are willing to experiment with them.

It would be no small thing gained if we could grow in the Terai and hill districts of India a wood more suitable for Tea-boxes than that we now possess, and although, perhaps, it may seem a long time to look forward to for the realization of any personal advantage from such cultivation, yet the land thus planted with wood of an unaltering value, would always be by so much enhanced in saleable merit.

We commend the subject to the attention of owners of tea properties, who may find thus, in time, their timber land even more valuable than the land under the tea itself.—*Indian Tea Gazette.*

THE ROYAL BOTANIC GARDEN, CALCUTTA.

The annual report on these gardens for the past year opens with the following interesting retrospect of a hundred years' work. Dr. George King, the superintendent, writes:—

"It may not be inappropriate to begin the hundredth annual report of the garden by giving a brief account of its history, which is, to a very great extent, a history of Indian Botany.

"1. The suggestion to form a Botanic Garden here was first made to the Government in Calcutta in June 1786, by Colonel Robert Kyd, then Superintendent of the Hon'ble Company's Dockyard at Kidderpore. The proposal was favourably entertained by the Governor-General, and its adoption was recommended to the Supreme Board in London during the same month, practical effect being given to it during the following year by the selection, as a site, of a large piece of land immediately below Colonel Kyd's private garden at Shalimar. This piece of land, besides the Botanic Garden as it is now limited, included about fifty acres which form part of the grounds of the present Engineering College. Colonel Kyd was himself an ardent horticulturist, and he had brought together in his private garden at Shalimar a large collection of exotic plants, chiefly from the Straits. He was, therefore, very appropriately appointed the first Superintendent of the Botanic Garden which had been founded at his suggestion. Colonel Kyd continued to perform the duties of Superintendent until his death in 1793. On Colonel Kyd's death Government decided to put the garden under the charge of a special officer who should have no other duty. Dr. William Roxburgh, the Company's Botanist in Madras, was therefore transferred from that Presidency, and was installed at Seebpore in November 1793. No better selection than that of Dr. Roxburgh, could have been made. Dr. Roxburgh, for many years prior to his transfer, had been engaged in studying the then little-known Flora of the Northern Circars in the Madras Presidency. He was a most ardent and enthusiastic botanist, and a good gardener. Dr. Roxburgh continued to be Superintendent until 1814, when he was obliged to proceed to the Cape on account of his health. From the Cape he went on to St. Helena, and from thence to England, where he died during the following year. Dr. Roxburgh was the first botanist who attempted to draw up a systematic account of the plants of India. During his busy life in this country he prepared a *Flora Indica*, which contained systematic descriptions of all the indigenous plants knows to him, as well as of many exotics then in cultivation in the neighbourhood of Calcutta. The manuscript of this work he took with him when he left India, intending to publish it during his residence in England. His death prevented the execution of this plan; and with the exception of the first volume, which was printed with some additions and interpolations by Drs. Wallich and Carey, in 1820, the book remained unpublised until 1832. In the latter year it was printed, exactly as the author had left it, by the piety of his sons, Captains James and Bruce Roxburgh, neither of whom was a botanist. This book is the basis of all subsequent Indian Botanical works. It is an admirable production: the descriptions are accurate and graphic, and its authorship justly entitles Roxburgh to his title of the Father of Indian Botany. Until the year 1872, when the publication of the "Flora of British India" was begun by the distinguished botanist, Sir Joseph Hooker, Roxburgh's was the only single book through which a knowledge of Indian plants could be acquired. A second edition of this excellent manual was issued by Mr. C. B. Clarke in 1874 at a merely nominal price, Mr. Clarke's desire being to put the book within the reach of the poorest student. Besides the *Flora Indica*, Roxburgh published, at the expense of the Honourable Company, in three large folio volumes, his *Plantæ Coromandelianæ*, being descriptions with figurse of three hundred of the most striking plants of the Coromandel Coast. Dr. Roxburgh was immediately succeeded in the Superintendentship of the Garden by Dr. Francis Buchanan (afterwards Hamilton), who at the time was on special duty in connection with an extended enquiry into the agriculture of India and in the collection of materials for a Gazetteer. Dr. Hamilton, who was an accomplished botanist and zoologist, collected a vast mass of material, part of which was published in his own name, but the bulk of which, after many years' suppression, was published under the title of "Montgomery Martin's History: Topography and Statistics of Eastern India." Dr. Buchanan-Hamilton held charge of the garden for only a short time, and he was succeeded in 1817 by Dr. Nathaniel Wallich, lately Surgeon to the Danish Settlement at Serampore. Dr. Wallich was an able and most energetic botanist; and, during the earlier part of his term of office, he organised collecting expeditions into the remote and then little known regions of Kumaon, Nepal, Silhet, Tenasserim, Penang and Singapore. Dr. Wallich in fact undertook a botanical survey of a large part of the Indian Empire. The materials (in the shape of dried specimens of plants) thus accumulated were taken by Dr. Wallich to London, and, after being named there by himself and by other botanists, they were distributed in numbered collections to the leading botanical institutions in Europe. In this great distribution, Dr. Wallich included the collections of several other botanists which had been made over to him for the purpose. The liberality with which these specimens were given away was so extreme, that in the garden report for the year 1843, we find Dr. Griffith (who had been appointed to officiate for Dr. Wallich during his absence in England) complaining that the herbarium had been completely denuded of every specimen collected during the first fifty years of the existence of the garden. Besides distributing this enormous collection, Dr. Wallich was enabled through the munificence of the Honourable Company, to publish, under the title *Plantæ Asiaticæ Rariores*, three superb volumes illustrated by coloured figures of a high degree of excellence. Dr. Wallich retired in 1846 and died in 1854. During the lengthened absences of Dr. Wallich in Europe, his place at the garden was filled by Dr. W. Griffith, whose premature death deprived Botanical Science of one of its ablest and most industrious votaries. Dr. Griffith's extensive notes and numerous drawings were, after his death, published by Government in nine volumes. Dr. Wallich was succeeded by Dr. Hugh Falconer. Dr. Falconer was a Palæontologist, well known by his researches on the Sivalik Fossil Mammalia. In 1850 he left the country on account of ill-health, and was succeeded as Superintendent by Dr. Thomas Thomson, a traveller and botanist of much ability, the coadjutor of Sir Josep

Hooker in the collection and distribution of an extensive and well known herbarium of East Indian plants, and the joint author of the first volume of a new *Flora Indica*. Dr. Thomson retired in 1861, and was succeeded by Dr. Thomas Anderson, whose untimely death in 1870 was caused by disease contracted during his efforts for the introduction of the quinine-yielding Cinchonas into the Sikkim Himalaya. For the two years subsequent to Dr. Anderson's departure from India, Mr. C. B. Clarke acted as Superintendent, and during his incumbency he began the series of botanical publications which has earned for him so high a scientific reputation.

"2. From the first foundation of the garden, it was understood that it was to be made a source of botanical information for the possessions of the Company, and at the same time a centre to which exotic plants of economic interest could be imported for experimental cultivation, and from which, in turn, they could be issued for distribution in the Company's possessions. It was also intended to assist in introducing indigenous Indian products to new markets. It was intended that it should not only be a botanical, but also a horticultural and agricultural garden. The preceding paragraph shows how the botanical work laid out for the garden has been accomplished. But the economic side has by no means been neglected. At first, great hopes were entertained that the spices which rendered the trade of the Company with the Moluccas and other of the Malayan Islands so valuable, might be cultivated in Bengal. The earliest efforts of Colonel Kyd were therefore directed to the introduction of the trees which yield nutmegs, cloves, and cinnamon, and of the pepper vines. It was, however, speedily proved that the climate of Northern India is quite unsuited to these equatorial species. The equatorial fruits, such as mangosteen, langsat, dukko and bread-fruit, were also tried with a similar result; and so were the temperate fruits of Europe. In fact, no small part of the benefits conferred on the country by the garden in its early days was the demonstration by practical experiment that certain natural products, many of them of a most desirable kind, cannot be grown in Bengal; much money and bootless effort being thus saved to the country. The introduction of exotic timber trees also received early attention; and in the garden there still remain a few of the original mahogany trees introduced in these early years. The introduction of tea was one of the items put down in Colonel Kyd's original programme; and in the final establishment of what has now become one of the most important industries in Nothern India, the garden bore a most important part. Potatoe growing was introduced through its agency, and the cultivation of the quinine-yielding Cinchona of the Andes, was initiated and carried to a successful issue under the direction of superintendents of the garden. In the improvement of Indian cotton, and in the introduction both of that and of jute to the markets of Europe, the garden authorities worked cordially hand in hand with the Agri-Horticultural Society of India, with what success it is unnecessary to point out. By the introduction of some of the best kinds of sugarcane from the West Indies, and the dissemination of these to all parts of the country, a considerable improvement was effected both in the quality and quantity of the sugar crop of the country. In this matter also the Agri-Horticultural Society worked hand in hand with the garden authorities. Very soon after the establishment of the Society just mentioned, a considerable piece of land in the garden was made over to it rent-free, and on this land the Society conducted the greater part of its operations for forty years. In fact, it was not until the year 1872 that the Society's garden was transferred to its present site in Alipore. It is unnecessary to discuss in detail the numerous experiments in the cultivation of economic plants which have been conducted in the garden since its beginning. A few of the products tried may simply be mentioned. Chief among these are flax, hemp, tobacco, henbane, vanilla, coffee (American and Liberian), cocoa, ipecacuanha, aloes, sarsaparilla, jalap, Indiarubber, cardamoms, tapioca, and coca. As regards horticulture, it may suffice to say that a large proportion of the kinds of exotic plants now found in private gardens in India has been introduced in to the country through the agency of this garden, and that the improved methods of cultivation which now obtain were to a great extent initiated here.

"3. In 1820 about fifty acres of land belonging to the garden were made over by Government to the Society for the Propagation of Christian Knowledge, and on this land the Society founded the institution so long known as Bishop's College, but since 1880 (owing to its re-transfer to Government) as the Government Engineering College. In the year 1864 the garden was devastated by a cyclonic storm of extraordinary violence, which either uprooted or broke to pieces the majority of the trees in it and by blowing down all the plant-houses, hopelessly crushed their contents. The few trees which escaped on that occasion were sadly reduced in number by a second cyclone which passed over the garden in 1867; and at the present time almost the only trees dating from before 1867 are the great banyan and a smaller tree of the same sort, some peepuls and country almonds, about twenty mahogany trees and some palms. It is almost a pity that the occasion of its destruction by these cyclones was not taken to remove the garden to a site on the Calcutta side of the Hooghly. For although there are certain advantages in the garden being so remote from the town, there can be little doubt that the balance is in favour of a site more easily accessible to the residents of Calcutta. The destruction of all shade which resulted from the removal of the trees, allowed the inveterate weed known popularly as ooloo grass, and botanically as *Imperata cylindrica*, to take possession of the whole of the ground not occupied by roads or flower borders; so that when I took charge of the garden in 1871 it presented rather a sorry appearance. The liberality of the local Government under whose control it soon thereafter passed, has made it possible for me to lay out the garden entirely anew. The whole of its area has since that date been treated for landscape effects, sheets of ornamental water having been formed, and, with the earth so obtained, undulations having been thrown up. New roads and footpaths have also been made; a building for the Herbarium and three handsome conservatories for the more delicate kinds of living plants have been erected; nursery buildings have been put up; and the garden staff have been furnished with comfortable houses.

"4. Botanically the most important feature in the garden is its Herbarium, or collection of dried plants. As has already been explained, all the collections prior to Dr. Wallich's visit to England in 1828 were distributed by him to scientific institutions abroad. The commencement of the present collection dates, therefore, from his return to India in 1832. It consists of plants contributed by almost every worker at Botany in India since that date and of considerable contributions from Botanists in Europe. It is first and foremost an Indian Herbarium, but the plants of South-Eastern Asia, of Japan, of Persia, and of Asia Minor are fairly well represented. Those of Europe are also excellently represented; but in African and American plants the collection is comparatively poor. Constant communication and interchange of specimens have been kept up for the last fifty years with the great national collection at Kew; and to the distinguished Directors of that institution, Sir William Hooker and his son and successor Sir Joseph, the Calcutta Herbarium is indebted for invaluable contributions. Interchanges have also been kept up with other European Botanic Institutions, such as the Herbarium of the British Museum, of the Jardin des Plantes, Paris, the Imperial Gardens at St. Petersburg and Berlin, the Royal Botanic Garden at Buitenzorg in Java, at Peradeniya in Ceylon, and at Saharanpore; and with many other institutions. Amongst the private contributors in past times, from

whom the Herbarium has received the most valuable collections, must be mentioned, Vicary, Edgeworth, Griffith, Wight, Simons, Law, Gibson, Stocks, Dulzell, Kurz, Miquel, and Maingay. The most important contributions received during recent years have been duly mentioned in my annual reports.

"5. The year which ended on 31st March last presented little of novelty. No new works were undertaken in the garden, and the time of the staff was occupied in the ordinary routine of cultivation. The show of orchids was unusually fine, and the general condition of the plants, both in the conservatories and out of doors, was satisfactory.

"6. The collection of dried plants received several valuable additions during the year. Chief amongst these was a set of the plants collected by Dr. Aitchison during the Afghan Boundary Commission. Dr. Aitchison's collections were taken by himself direct to Kew, whence after having been also named and numbered, a set was issued to Calcutta. From Kew were also received a named set of plants collected by Dr. Giles during the Gilgit Expedition; and a quantity of plants collected some years ago by Dr. G. Watt while he was on duty with the Commission appointed to settle the boundary between Munipore and Burmah. From Kew were also received a quantity of interesting specimens made by various collectors in the Malayan Peninsula, in Singapore and in Penang. For all these contributions from Kew we are indebted to the good offices of Mr. Thiselton Dyer, its present distinguished Director. Dr. Regel of the Imperial Garden St. Petersburg presented a large number of most interesting plants from the Russian possessions in Central Asia. Three excellent named collections from Natal were presented by Mr. Medley Wood of the Botanic Garden, Durban. From Mexico, Mr. Pringle sent four hundred named species; and from New Guinea Mr. H. O. Forbes forwarded a large box filled with dried plants. Of contributions received from within the limits of India I have to acknowledge—from Sikkim, a quantity of plants from Mr. G. Gammie, as also a collection made by a Bhootea employed by Mr. Pantling in the Lachen valley, from the Khasia Hills, many fine things, chiefly trees from Mr. Gustav Mann; from the Naga Hills a fine collection made during his short residence there by Dr. D. Prain, now Curator of the Herbarium; from the North-Western Himalaya some interesting plants sent by Mr. J. F. Duthie, of Saharanpore, and by Colonel H. Collett, C. B.; from Manbhoom a collection made by Reverend J. Campbell, and from Southern India a few most interesting plants from Mr. J. S. Gamble Conservator of Forests.

"7. During the month of November last the Herbarium was visited, for the purpose of study, by the Reverend Father Scortechini, the Government Botanist of Perak, who had been deputed by Sir H. Low, the British Administrator of that State, to proceed to Calcutta in order to name and arrange his collections of Peark plants. It was Father Scortechini's intention to have remained here for three or four months; but unfortunately he died shortly after his arrival. During the year there was issued from the press the first part of a monograph of Indo-Malayan species of Ficus, in which I have been engaged for some time.

"8. I have to acknowledge, with thanks, the assistance freely afforded whenever asked, by the Indian Assistant in the Kew Herbarium, Mr. W. Botting Hemsley. Mr. Hemsley, with the permission of the Director, Mr. Thiselton Dyer, is always ready to settle any knotty point in nomenclature, or to check any doubtful identification—a kind of work that can only be done with accuracy in a perfectly equipped Herbarium like that of Kew.

"9. The interchange and distribution of plants and seeds has gone on actively during the year. Of plants, 8,064 were received against 46,109 given out. Of seeds, 503 packets were received and 2,534 distributed. The names of all donors and recipients will be found in the appendices to this report.

"10. The Lloyd Botanic Garden at Darjeeling has during the year been under the charge of Mr. W. Kennedy. And the Municipality having agreed to continue the vegetable garden which lies wedged in between the Botanic Garden and the grounds of the Sanitarium, that garden also has been under Mr. Kennedy's care. At one time the Municipality threatened to convert the vegetable garden into a bazaar; at another they resolved to turn it into a washing place for the dobies of the station. Its maintenance as a sightly spot is a matter which concerns not only the Municipality, but the visitors who frequent Darjeeling, and the patients in the Sanitarium. It is well, therefore, that both these proposals have, for a time at least, been shelved. I regret to have to report that the acclimatised English potatoes turned out badly, the product having been tasteless and waxy. This was also the experience of private growers.—*Indian Agriculturist.*

VENEZUELA: EXPORTS FROM CIUDAD BOLIVAR.—Among the exports from Ciudad Bolivar in the year 1886, the following articles occupy a prominent place. Tonquin beans alone forming about four-fifths of the total quantity of drugs shipped.

To	Balsam Copaiba.	Cinchona Bark.	India-rubber.	Simaruba.	Tonquin Beans.
Trinidad	.. 2,900	...	10,254	...	111,967
New York	.. 4,172	4,004	13,824	3,216	63,144
Hamburg	.. 276	1,302	...	1,290	...
Total lbs.	7,438	5,306	24,078	4,506	175,111

PLANTING ON THE NILGIRIS.—Many healthy signs of improvement are showing themselves in our coffee districts. The long run of good prices for the berry that have ruled and are still ruling in the London market, and the bright prospects for the future, consequent upon the abolition of the import duty in the United States, and the reduction of the same in British ports, are conducing to a prosperous state of things here. It is cheering to learn of several extensions of coffee estates now going on in the Wynaad, for it tells us plainly that the "croakers" who have croaked for years past, are now effectually silenced. It will be useless now for any one to try to depreciate coffee-planting as an investment—the public know better. Confidence is being rapidly restored. Very few of those who have estates are now-a-days willing to sell; and in one or two instances where sales have been effected, the prices are such as would a few years' back, been termed "very high" but are looked upon as "very fair." Coffee planting in Southern India has seen its worst days. Planters now are *planters* and not merely superintendents. Coffee-trees are now made not only to grow, but to grow well. The soil, the wood, the blossom, and the berry, are all cared for by experienced men, who act upon a system that combines science with nature. "Bumper" crops also are looked on with less anxiety than formerly, and planters are satisfied when they get a good outturn from their outlay of capital and labour. Another good sign of the times is that the Supreme Government are showing an anxiety to further the planting interests. A circular has been sent to all the tea planters, informing them of the anxiety of the Governor-General to learn what facilities are needed to give fair scope to them, and asking them for full and free statements of the existing obstacles of the same. What may be gained by the tea planter, must to a great extent also benefit the coffee planter, for if concessions in the shape of increased facilities of communication, and easier land tenure, and other advantages are made to the one, they cannot be withheld from the other. If the Government of India at last wakes up to the great importance of encouraging in every possible legitimate way, the possession of land in this country by Europeans and their descendants, and the utilization of such land to its utmost extent, not only will planters be benefitted, but every class in British India. Of British capital there is enough and to spare—waiting for a profitable outlet. Of British enterprise and pluck there is also a redundance, waiting and looking about for a profitable field of employment. Money, and brains and sinews all await if the Indian Government can turn a portion of the stream on to some of the fertile fields of India.—*Nilgiri Express.*

Correspondence.

To the Editor of the "Ceylon Observer."

CULTIVATION OF THE SUNFLOWER (*HELIANTHUS ANNUUS*).

Farmer's Cottage, Bandaragama, 1st Sept. 1887.

SIR,—The composite family to which this useful plant belongs is the largest in the vegetable kingdom, and at the same time one of the best defined and most esily recognized.

On inquiring into the use made of this plant, we were given to understand that it is raised chiefly for the yield of a useful oil, as does the fruit of Madia sativa. But it is also of use for many other purposes. In the market places of the larger towns we often heard the people eating the seeds, which when boiled in water, taste like the boiled Indian corn. In some other districts the seeds are employed with great success in fattening poultry; they are also said to increase the number of eggs more than any other kind of grain. The dried leaves are given to cattle in place of straw; and the withered stalks are said to produce a considerable quantity of alkali.

Jerusalem artichokes are the tubers of a *Helianthus*, allied to the sunflower. These are both American herbs, now common everywhere in our gardens.—Yours faithgully

J. A. GNO. RODRIGO, *A. I.*

SYSTEMATIC "PUSHING" OF CEYLON TEA AND THE RESULTS: MR. RUTHERFORD'S RECOMMENDATION TO PERSEVERE AND CONTRIBUTE GENERALLY.

Nuwara Eliya, 23rd September.

DEAR SIR,—At the risk of being considered too importunate in continually urging upon tea planters how advantageous it is to their interests to subscribe to every means of pushing and advertizing Ceylon tea, I would desire, with your permission, to again bring the matter before them. I do so because I have met men who are growing and manufacturing tea and who tell me they cannot *afford* to be continually subscribing to these Exhibitions.*

I am afraid those men have never considered the subject sufficiently, or they would see, that although the little we subscribe is the veritable sprat to catch the whale, we fortunately, however, *do* catch the whale.

It is admitted by nearly every dealer and broker in Ceylon teas in London that there is nothing special in our teas that makes them sell at a higher average price than Indians, but that we maintain a 1d per lb. advantage, solely on account of the way our teas are pushed and brought before the notice of the tea-drinking public. To show what has been done in the county of Kinross, I quote from a letter received by this mail from Mr. David Reid who has been appointed to act on the Glasgow Exhibition Committee for Ceylon teas:—"As to the policy of Ceylon tea planters spending money in bringing their tea to the public notice at such Exhibitions as Liverpool, Glasgow, etc., I am much impressed with the advantages of this way of bringing Ceylon tea to the notice of the British tea drinker. Ceylon tea planters have done fairly well so far in bringing their teas to notice, but they must keep on working vigorously in that way if they are to displace the China teas as I drive it out of the British Isles. Great results sometimes flow from apparently small causes and some of these results are rather puzzling. I will give you an example from my own county. A few years ago Ceylon tea was absolutely unknown, and even in 1885 not a grocer in the place kept it. I was told by the largest grocer here that there was now more Ceylon tea sold in the County of Kinross than all other kinds put together. I cannot vouch for the truth of this, but certainly a great quantity of Ceylon tea is sold. Now I attribute a great deal of this to the action of Messrs. W. G. Inglis and John Tyndall who have sold it here, and yet between them they do not sell one per cent of the Ceylon tea drunk in this country. When the grocers found that good Ceylon tea was being sold here at reasonable prices, they had to get Ceylon tea to keep their customers. The reason I mention this case, which has come under my notice, is that I think the exhibiting and selling of good tea at these Exhibitions will produce much greater results than will show."

This is only the evidence of one man on the subject, but we hear the same story from every quarter, viz. that the good done in the interest of the Ceylon planter by the judicious pushing of Ceylon tea is incalculable. Now, to those planters who are doubtful of the good done by Exhibitions and by other means taken to push our teas, and who hang back from subscribing, and to the Government, who I hold should subscribe penny for penny with the planter, I would point out wherein we so greatly benefit. If this pushing and advertizing of our teas will this year maintain our average at 1d. above their intrinsic value as compared with Indian teas, then on the estimated crop of the year 1887-8 this means an *extra* profit of £90,000 sterling or R1,200,000, all of which money comes back to the colony. When it is put in this light surely everyone interested (both planters and the Government) will subscribe liberally to all means brought forward, under proper auspices, for the representation of our teas. If the planters *annually* subscribed R20,000 for this object and Government supplemented this amount, it would only be doing what *ought* to be done by both parties in their own interests.

It is, I think, a great pity that we are not likely to be represented at Melbourne with our teas, as it is an opportunity lost and one which may not occur again for some time. Glasgow was brought forward early in the day, and we have men at home ready to begin work whenever they are advised that the money will be forthcoming. Had the Association funds at their back to take up the work of pushing the representation of Ceylon teas whenever opportunity offered, a great deal more might be done. It is impossible to know even approximately what will be subscribed, and I therefore think (as it is fairly certain we will get sufficient funds for Glasgow) that it would be better to make sure of one Exhibition being done well than two badly. The Glasgow Exhibition was chosen, for the reason that Mr. Thos. North Christie had made certain arrangements in the event of the planters taking it up, and it was considered desirable that having *done* London and Liverpool we might as well finish our efforts in Great Britain by attacking the northern counties. After this Exhibition our teas should be thoroughly well-known over the length and breadth of the land, and we can then afford to leave the working out of our interests in the hands of the many friends of Ceylon who are pushing the sale of our teas in every town and village in the British Isles.

Next year I would suggest that we begin our colonial or foreign crusade, and year after year

* Unless there are further lists to appear, very few seem to have joined in subscribing tea for Mr. J. L. Shand.—ED.

go on from field to field conquering as we go. However, to enable us to make an "Ever Victorious Tea Fight" against China we must have funds. Up to this time planters have not spent £1,000 on pushing the tea enterprize, but I do not think I am far out in saying that what they have spent, aided by the good offices of many friends, will (if we take the sales of teas season 1884-85 to 1887-88 as having an increased value of 1d per lb.) bring back to the colony no less an *extra* sum than £180,000. With such a result it surely offers every encouragement to planters to push more than ever and Government to assist them in bringing their teas before the notice of every nation.

There were, at the end of 1886, 900 estates growing tea in Ceylon, and the crop this year 1887-88 will be about 22¼ millions of lb., or say an average for each estate of 25,000 lb. Surely in a country like Ceylon a sum of R20,000 might easily be raised annually for *our own benefit*. No better investment can be made by the tea planter and the Government at the present moment than the advertizing of Ceylon tea. The burden should be as far as possible equally distributed and every grower ought to recognize that what is done in the interest of Ceylon tea *generally* is done in his particular interest also. No man in Ceylon is true to his fellow labourers, or indeed is justified in growing tea in this island, unless he gives support to that which is for the good of those who cultivate the same product as himself. It is by united effort we will win in the struggle for our existence in the tea world. Our efforts should not be by fits and spasmodic starts, but be a long pull, a strong pull and a pull altogether. Money and energy will do what is required, and if every planter will see the necessity of subscribing not only to the Glasgow Exhibition but to a general fund for future efforts, the thing will be done.

Let it be an axiom among us all, that we subscribe R1 (one rupee) for every 1,000 lb. of tea we turn out of the factory for the next few years, which sum should be paid every 6 months to the Planters' Association, and we would soon have funds enough for our purpose. This would only come to one-tenth of a cent per lb. of tea, and if this returns to you (not 1d per lb. as I believe it does at present) but one farthing per lb. extra, you will have made a very handsome profit on your small outlay, and again I say your little sprat will have caught a very big whale.

The subscription should be looked upon as a *voluntary tax* if I may be allowed the expression, and I would suggest, and hope it may become a recognized duty of every tea proprietor that he pay into the Association for the purpose I have mentioned R1 for every 1,000 lb. of tea he produces.

It would be well if this subject were prominently brought forward before every District Association to obtain the views of the whole body of planters on the subject, and superintendents or agents might in the meantime lay the matter before absent proprietors. Should general support be given to the creating of such a fund somewhat on the basis proposed and the Parent Association ratified the general desire, we could then approach Government on the subject of obtaining their aid. It could be pointed out that this year from the good effects of the Colonial and Liverpool Exhibitions and other means taken to push our staple there will, in all probability, be fully R1,200,000 returned to the island in the shape of *extra* profits; and that as tea planters who have saved the island from utter and absolute commercial ruin, we are entitled to receive every possible assistance at the hands of Government. H. K. RUTHERFORD.

ANALYSES OF GREEN TEA LEAF.

Planters' Association of Ceylon,
Kandy, 27th Sept. 1887.

SIR,—I beg to enclose for publication copy of correspondence with reference to green tea leaf analyses laid before the Committee of the Association at a recent meeting.—Yours faithfully,
A. PHILIP, Secretary.

Colombo, 20th July 1887.

H. K. Rutherford, Esq., Nuwara Eliya.

Dear Sir,—I have pleasure in handing you the enclosed list of determinations of certain constituents in four samples of green tea leaf received from Torwood estate. I am sorry I cannot afford the time necessary to prosecute the investigation: indeed, owing to excess of other work, I have not been able to do anything to the last three samples received.

I should state that the samples were not all treated exactly alike. I had not made such analyses before, and therefore altered my methods of working somewhat as experience suggested. Two of the samples were dried first in the sun, and afterwards in an oven, and two, on account of wet weather, were dried in the oven at once without a preliminary drying in the sun.

When these facts are taken into consideration, I think the result of the investigation so far, is to show that the tea on Torwood estate is very rich in the alkaloid theine or caffeine at least as compared with tea after it leaves the factory, and of a pretty uniform composition. In the case of No. 4 the filtration of the aqueous extract was very slow, extending over several days. I think the leaves had got somewhat stewed from not being turned over often enough in the oven. I fancy, if the leaves had been well dried in the sun, I should have, in this case, got a closer approximation to the other results as regards amount of aqueous extract, and matter insoluble in water. I should like to have determined the amount of tannin in the samples, but the necessary chemicals for Löwenthal's process could not be obtained in Colombo. I have been waiting to receive these from England, and may possibly still add this determination to the other results.—I am, yours truly, (Sd.) M. COCHRAN.

Determination of certain constituents in four samples of tea received from Torwood estate from April to June 1887:—

	Moisture.	Aqueous Extract.	Insoluble in Water.*	Theine.*	Soluble Ash.*	Insoluble Ash.*	Total Ash.*
(1) Recd 16th April...	75·66	49·91	50·09	5·66	3·59	1·66	5·25†
(2) Recd. 3rd May ..	78·19	47·77	52·23	5·64	3·62	1·83	5·45
(3) Recd. 16th May..	77·36	47·71	52·29	5·14	3·48	1 78	5·26
(4) Recd. 2nd June..	76·50	44·89	55·11	5·13	3·70	1·62	5·32

(Signed) M. COCHRAN, F. C. S., Analyst.

* Percentage of dried leaf.

† Expressed in percentage of total ash: potash 41·96, phosphoric acid 16·04, and lime 10·24.

Colombo, 30th July 1887.

H. K. Rutherford, Esq., Nuwara Eliya.

Dear Sir—In reply to yours of 29th inst. I would undertake to give monthly analyses of green tea leaf, and I would do my best to overtake fortnightly analyses without positively binding myself to the latter. I would make the following determinations, which I think would be sufficient for all practical purposes for R30 for each analysis.

Moisture; Extractive matter; Insoluble matter; Theine matter; Tannin; Total ash; Ash soluble in water; Ash insoluble in water; Ash insoluble in acid; Potash; Phosphoric acid; Lime.

If the last 3 items were not determined, the fee would be R20 for each analysis.—Yours truly,
(Signed) M. COCHRAN.

Apples.—It is stated that by a careful analysis it has been found that Apples contain a larger amount of phosphorus or brain food than any other fruit or vegetable, and on this account they are very important to sedentary men who work with their brain rather than muscles. They also contain the acids which are needed every day, especially for sedentary men, the action of whose liver is sluggish, to eliminate effete matters, which, if retained in the system, produce inaction of the brain, and indeed of the whole system, causing jaundice, sleepiness, scurvy, and troublesome disease of the skin.—*Indian Gardener.*

Mr. Cochran's Analysis of Green Tea Leaves is interesting but confessedly tentative and to a certain extent incomplete, so that we must look for full and fully reliable information to the results of the further analyses likely to be made. A question will arise in many minds how far the sun-drying and oven-baking processes described by Mr. Cochran as preliminaries to his chemical examination assimilated the *green* leaves to the condition of the roasted tea of the breakfast table? The large proportions of potash, phosphoric acid and theine obtained are striking. In the case of dried Ceylon tea, results obtained at Melbourne were as follows, being the averages of 26 specimens analyzed :—

PEKOE.

Mineral ash	4·71
Extract	45·60
Soluble salts	3·16
Theine (only)	1·81

PEKOE SOUCHONG.

Mineral ash	4·78
Extract	45·11
Soluble salts	1·06
Theine (only).. ..	3·81

SOUCHONG.

Mineral ash	4·72
Extract	43·68
Soluble salts	3·10
Theine (only)	1·79

It will thus be seen that, if Mr. Cochran's results are fully reliable the proportion of the element of theine, which is the characteristic constituent of tea, is very considerably lessened by the process of manufacture from green leaf to dry. There are other differences, such as the division into soluble and insoluble ash, and the somewhat higher total in the case of the green leaf. The proportion of potash takes us somewhat by surprise. It is equal to the average of that salt in coffee.

Analyses of Cinchona Bark.—At the annual meeting of the British Pharmaceutical Conference, held in Manchester on Aug. 29th, we learn from the *Pharmaceutical Journal* that, "in a communication on Quinological Work in the Madras Cinchona Plantations, Mr. David Hooper supplied another convenient summary of results obtained in further experiments carried out by him in his capacity of quinologist to the Madras Government. The first series of twelve analyses referred to showed that bark from trees of the same age and growing in the same situation might vary in alkaloidal strength, the figures ranging from 1·75 per cent to 3·90 per cent of quinine, and from none to 0·16 per cent of quinidine. It also seems probable that there is no advantage in raising only one stem from a coppiced tree. Bark from the same twelve trees, examined in each consecutive month, showed that in the six months next following the original stripping there was a decrease of alkaloids in the bark left, as if the tree had suffered in this respect from the shock of the operation; but in the seventh month recovery had well set in, and by the twelfth the bark was richer than it had been a year before. Incidentally it was also observed that March is the month in which cinchona bark appears to be richest in alkaloids. Some further experiments as to the effect of manuring cinchona trees seems to show that bone manure and cattle manure are best suited for the purpose, though the improvement of the bark in quinine was in no case more than 14·58 per cent. Another experiment as to the extent to which renewal of bark can be profitably carried appears to show that the maximum in the case of a hybrid Ledger plant had been reached with the third year's renewal, although the fourth renewal still resulted in a rich bark."

Improved Tea Machinery.—About two years ago a lively correspondence took place in these columns upon the manufacture of tea on "scientific" principles. Messrs. A. and J. Main & Co., of Glasgow, it will be remembered, took a prominent part therein. Since that time Messrs. A. and J. Main & Co., in conjunction with their co-patentee Mr. Dick, have been engaged in making elaborate experiments, both at home and at a tea garden in India, with the view of perfecting certain machinery for the realisation of their views. Last year Mr. Dick went to India with a full set of specially constructed machinery; and after making a series of careful experiments and observations upon a tea garden, he returned home feeling sure that only some minor changes in the appliances were necessary to bring success within measurable distance. The necessary mechanical changes were made, and Mr. Dick returned to India to complete his experiments. We are glad to learn that a telegram has this week been received from him, to the effect that his trials this season have proved "satisfactory." This subject is one which cannot of course be exhausted in a telegram, so for fuller particulars we must await the arrival of detailed information by letter. Meantime, we understand that the scope of Messrs. Main and Dick's experiments cover the withering of the green leaf, in any weather, in a brief space of time without injury—if not with advantage—to the quality of the tea, consequently the results of their experiments will be of the greatest interest to all concerned in the production of tea.—*H. and C. Mail.*

Adulteration in Spices :—What One of the Agricultural Department Chemists Found Out.—Washington. D. C., March 30.—The report of the chemists of the Department of Agriculture on food adulteration in this country is being prepared. That portion relating to spices and condiments, prepared by Clifford Richardson is already completed. Mr. Richardson's investigations show that no other kinds of human food are adulterated to such an extent. Of twenty samples of ground cloves examined, only two were pure. The others had suffered the extraction of the essential oils, and had been polluted by the addition of clove-stems, allspice, and husks of various kinds. Of eight samples of Cayenne pepper only one was pure. Of ten samples of mustard, none was pure, though several had only suffered the loss of their fixed oil; the others contained quantities of wheat-flour, the spurious matter being in some cases two-thirds of the compounds. This made it necessary to add tumeric acid (harmless) to restore the mustard color. Of ten samples of allspice only eight were pure. Four samples of cassia were all pure. Of ten samples of ginger, four were pure. Only one out of thirteen samples of black pepper was found to be what it purported to be. A specimen sent from Baltimore to a man who had an army contract was almost entirely spurious. Cayenne pepper, black pepper, husks, and mustard hulls were used to give flavour and pungency, while "body" was supplied by ground bean and rice and color by charcoal. Two samples of white pepper out of five were pure; two samples of three out of five were pure; and of three samples of nutmeg examined, all were pure. Mr. Richardson believes that the poor paid governs the amount of adulteration in spices. Usually when he demanded a pure article of a first-class grocer he got it.

CEYLON UPCOUNTRY PLANTING REPORT.

THE SOIL FOR TEA—TEA ON MARIAWATTE—SIGNS OF THE N.-E. MONSOON—THE IDEAL COOLY.

26th Sept. 1887.

The question which has been regarded as unanswerable has frequently been asked: Where will tea not grow? And men with peculiar experiences have affirmed that they have known the tap-root penetrate a cement floor, push its way with ease through the hardest cabook and flourish on an old macadamized cart-road, where the plants had simply been dibbled in. Nowadays we are all learning that where the best soil is, is the best home for tea, and that willing as the plant may be even in untoward surroundings, that willingness may be overstrained. There are a goodly number of acres growing our new product—that would have been better fallow. Already in some cases it has become a question, whether it would not be wise to abandon, and I have heard of one place in the Matale district, where, after a three years' trial, this extreme course has actually been recommended. What makes the example more peculiar is that the soil has the appearance of good tea soil, deep chocolate colour and considerable depth. And yet the tea refuses to thrive.

Spite of the general experience of the unsuitability of the past season for tea, I learn that at Mariawatte there is every prospect of the highest record of that fruitful garden being outstripped by this year's returns. Other places in the same locality are doing well, and want only time to make a name for themselves.

The weather is hot and dry and feels like the N.-E., while the wind still blows steadily from the S.-W. The clouds, however, are banking up higher and higher nightly, and many signs of the coming change are daily manifesting themselves.

Work on estates is rather difficult to find, owing to the supply of labour being more than equal to the demand, this especially in regard to men. What to do with them is at times a sore puzzle, especially when the ground is hard and no digging or manuring can be done. The cooly of the future is the man whose personal charms will attract and attach to him two wives at the very least, and who during the slack seasons on estates will scorn to ask his employer for six days' work, or even the half of it, preferring to live upon the labour of his helpmates, than by the sweat of his own face. This may seem an ideal cooly, but he is n't: he can easily be found, and it is the kind we have got to encourage! PEPPERCORN.

PLANTING IN NETHERLANDS INDIA.

(*Translated for the Straits Times.*)

Among sugar growers in Java the impression seems to be gaining ground, that matters have reached that point where mending becomes probable. Hopes of coping successfully with falling prices by a cheaper outturn of sugar have been aroused by the satisfactory results attending trials with the so-called diffusion method. That process of sugar making has stood the test of repeated experimenting, triumphantly. Its general adoption is expected to admit of the planters making head against beet root competition. Others pin their hopes of improvement on growing the new Bornean cane, now becoming famous for fabulous yields of rich juice. These new canes and the diffusion process are hailed by the sugar interest as powerful allies in the contest with the bounty-fed article. In Europe also the diffusion process is in high favour with beet sugar makers. The method consists in doing away with crushing altogether. The cane is sliced into small discs. The slices are soaked in water until all the saccharine particles are drawn out.

THE SCALE INSECTS IN NEW ZEALAND.

The New Zealand Departments of State Forests and Agriculture have published a work entitled, "An account of the Insects Noxious to Agriculture and Plants in New Zealand," in which the natural history of the scale insects is described, and the insects in their various stages are delineated. The author of this well-timed publication is Mr. W. M. Maskell, F. R. M. S., registrar of the University of New Zealand. By way of preface, Mr. Maskell leads his readers to infer that New Zealand has rather more than a fair share of insect pests, and especially of those known as scale insects. From time to time papers have been read on these subjects to the New Zealand Institute, and others are to be found in European and American works not accessible to the general reader. "It was thought, therefore that the time had arrived when the information which might be useful to gardeners and tree-growers, as well as to students, might be brought together in a compendious form, and the present volume is an attempt towards this." A second volume will be required to render the work complete, there being many well-known pests other than those coming under the denomination of scale insects whose natural history would certainly fill another volume. "For example, the 'Pine-blight' (Kermaphis), the 'American blight' (Ercosoma), the 'black leech' (Tenthredo), the cabbage caterpillar, the turnip fly, the various aphides on roses, geraniums, &c., the grass-grub (Odontria), the codlin moth, the borers, weevils, wire worms, and a number of others," might be enumerated, and we venture to think that more than one volume will be needed to treat these additional invaders of the orchard and garden in as comprehensive a manner as Mr. Maskell has treated the coccids. These, as he rightly observes, constitute one of the most general as well as the most noxious, families of plant parasites in climates such as those of New Zealand and Australia, excepting certain cold portions. The plates, we are told, have been prepared with a double object; first that gardeners and tree-growers may be able easily to recognise the kind of insect which may happen to be damaging their plants; and secondly that the student who desires to know more of this curious family may have enough details indicated to guide him in his investigation. For the first purpose the figures have been coloured as near to nature as possible; for the second a few anatomical details have been introduced. The plates do great credit to all concerned in their production. There are no less than 23 whole-page plates, and on some of them from a dozen to three dozen diagrams are given; the descriptions appear on the opposite pages. The work which commences with the indispensable "glossary of terms and phrases" consists of six chapters, in which are dealt with the character, life history and metamorphoses of coccididæ, their products (honeydew and black fungus). Next follow chapters on checks to the increase of coccididæ, parasites, &c., remedies against coccididæ; catalogues of insects and diagnosis of species; their division into groups; an index of plants and the coccididæ attacking each, and an index of genera and species. Whilst it is certain that this work will be sought by agricultural and horticultural students, those actually engaged in the business of fruit growing should certainly make themselves familiar with its contents. The New Zealand authorities have shown judicious liberality in announcing that copies can be obtained from the Government printer at the low price of 5s each.—*Australasian.*

THE BRAZILIAN NUT TREE, a native of the country the name of which it bears, grows to an average height of seventy-five feet. The fruit resembles a cocoa-nut, and is about a third larger. Each ball contains from twelve to twenty nuts, three-cornered in shape and nicely packed together. During the season of their falling it is dangerous to enter the forest without a shield, as the force of their descent is sufficient to knock down the stronges t man.—*Indian Gardener.*

GEOLOGY OF CEYLON.

A correspondent, evidently a new arrival, asks us about a work to consult on the geology of the island. He is specially interested in the Jaffna Peninsula, where red soil resting on a coral base has puzzled so many observers. Our correspondent has a theory as to the origin of this soil, which we shall not anticipate him in stating. It differs from received opinions. We must ask our correspondent to accept a reply through the columns of the *Observer*, which may be of some use and interest to others also.

There is no separate publication on the geology of Ceylon, and we can but repeat the hope so frequently expressed by us, that ere long a member of the Indian Geological Survey —one of the most extended and most complete in the world, and the results of which have been embodied in three separate manuals, the latest of which, on the gem minerals has just reached us,—that an officer who has gained experience in the course of this survey may be borrowed to examine and report on the geology of this island.

This first real attempt to describe the geology of Ceylon was made by Dr. John Davy, a brother of the celebrated philosopher, Sir Humphry Davy, and himself an accomplished scientist. He served here on the medical staff in the early part of the century and embodied his observations on our rocks and minerals and mineral waters in a paper contributed to the transactions of the British Geological Society. He subsequently included it, with such improvements and additions as we deemed necessary, in his book on the interior of Ceylon. Of course the science of geology has greatly advanced in the sixty years which have elapsed since Davy wrote, especially in a knowledge of the laws which have produced and are still producing the metamorphic rocks, but although Davy's theories have been improved upon in some respects and a good many additions made to the facts recorded by him, his observations on the rocks and minerals of Ceylon have formed the groundwork of nearly every attempt made since then to give an idea of our geology and mineralogy.

Our correspondent will feel the truth of this statement, if, after reading the chapters on the subject in Davy's book, he subsequently peruses those in Pridham's work (a boiling down of previous works on Ceylon and so of considerable value) and in the book on Ceylon by an officer of the Ceylon Rifles, a book of which it may almost be said that it "fell stillborn from the press." The Rev. Dr. Macvicar, the first Chaplain of the Scotch Church in Ceylon, made some interesting observations on the geology of Ceylon, but the first and only attempt to give, in a separate paper, a comprehensive account of the geology of our island was made by Dr. George Gardner, Superintendent of the Peradeniya Gardens. The paper forms an appendix to the late Mr. George Lee's translation of the French version of Ribeiro's account of Ceylon, published at Colombo.

Sir J. Emerson Tennent, in writing his great work on Ceylon, besides having access to all previous works had the advantage of personal intercourse with Macvicar, Gardner and other observers in systematizing the results of his explorations. In addition to all this he availed himself of the results of a partial survey and reports made by Dr. Gygax, a Swiss scientist who happened to be in the island and was employed by Lord Torrington's Government. The result of the whole is a very interesting summary of the geology and mineralogy of Ceylon in what is still *the* great book on Ceylon, although Tennent, over-sanguine about a theory which would have been grand had it been well founded instead of wild and baseless, allowed himself to be misled by Gygax (himself in some inexplicable manner deceived) into asserting the presence, in connection with millions of tons of iron ore, of anthracite in such quantity that it could be laid down in Colombo at 18s per ton! It became the duty of the writer of this article, in preparing for the transactions of the local Asiatic Society the fullest and most complete account of the mineral graphite or plumbago ever yet written, conclusively to show that no trace of anthracite is to be found in Ceylon, while all the probabilities are against coal in any shape existing in our formations. Let our correspondent observe the caution thus given, in reading the latest attempt at summing up the main facts in the geology of this island, contained in the account of Ceylon given by Mr. J. F. Dickson in the new edition of the *Encyclopædia Britannica*. Scattered in various periodicals, especially in the transactions of the local Asiatic Society, are a number of interesting papers by Dr. Kelaart on upcountry laterite, by the late Mr. Oswald Brodie on salt formations, and, of special value a more complete and more correct list of the minerals of Ceylon than that of Gygax, by Mr. Alexander Dixon. This recent and careful observer saw no trace of coal in any shape, although he noticed slight indications of tin and copper. As yet, however, our only economic mineral of consequence is plumbago, of which in its purest carbon form the island has almost a practical monopoly. Dr. Trimen, in a paper on the botany of Ceylon, glances at some interesting theories connected with its old-world geological history.—In a compilation of articles from the *Observer* and other source, "All about Gold and Gems," a new edition of which is about to be published at the *Observer* Office, there is a mass of information about the mineral wealth of Ceylon in the mountains, plains and marine banks of the island.—In this sketch we have not, of course, included all fugitive articles or chance writers on the geology of Ceylon, and we were about to claim that we thought we had omitted no work or writer of importance, when we recollected he "Circular Notes" of that most accomplished but perhaps somewhat imaginative geologist, the late Mr. Campbell of Islay.

Such generally being the information available, we may add that the accepted theory is that the dynamic forces which originally raised Ceylon "from out the azure main" are still at work, and that a slow, very slow process of upheaval is going on. We cannot tell what the rock are "all the way down," or to the centre of our globe, but our obvious foundation rock is primitive granite. It is not only our lowest but our highest formation, for it has in some places been so projected as to form the rocky domes and pinnacles of nature's temples on our mountain tops. Granite, grey and red, with porphyry and sienite, occasionally even amongst our most prevalent formation, gneiss

which overlies the granite. The igneous rock, according to the received theory, pushed up the stratified rock, gneiss, from the ocean in which it had slowly formed, the gneiss in its turn pushing up beds of crystalline limestone (dolomite), which had formed, also in the ocean, over the surface of the gneiss. These are our three principal and primitive rocks, gneiss being king of all. Indeed, some have held the view that true granite where in contact with its allied rock, has been compelled to enter on the metamorphic processes, which have given gneiss such protean shapes, colours and conditions. While granite is being metamorphosed into gneiss at one end of the scale, gneiss decaying from the action of the atmosphere on superabundant felspar, is, at the other forming new combinations, and giving us the valuable laterite locally known as cabook (sometimes called iron clay); good as blocks for building purposes, as gravel for road material, and as it is further acted on by the atmosphere and man's agency, the foundation of our most fertile soils. The characteristics of this curious product of gneiss will be thoroughly discussed and settled before the discussion on its failure as a foundation for the Maligakanda reservoir closes. We may just notice in passing that while the red colour produced by peroxide of iron distinguishes some of our very richest soils, oxides of iron in other shapes are charged with the strangely contrasted barrenness which distinguishes our upland patanas (mountain prairies or savannahs) from the rich forests from which they are in most cases so sharply divided. The superabundant iron in Ceylon was formerly utilized by the natives, many furnaces and much slag being scattered over the land, but now the imported metal has put an end to all local manufacture. Felspar, besides leading to the decay of gneiss and its transmutation into laterite, is the origin of the beds of kaolin or China clay, pretty common in our hill system, and also of the very pretty but not intrinsically valuable moonstone, with its semi-pearly lustre. The more kaolin in the rock, the more potash in the soil. When coffee was our great cultivation the quantity of lime contained in our gneiss-derived soils was deemed deficient either for fertilizing purposes or for keeping the clay soils mechanically free. But for tea cultivation the stiffness of our clayey soils and the large proportion of ferruginous constituents in them are not disadvantageous. The strong taproot of the tea plant opens up the stiff clay subsoil, while the presence of iron in quantity not deemed beneficial for coffee, seems to suit tea admirably. The mineral constituents of our soils and the proportions of humus and other organic matter vary considerably, but of late years the tendency of opinion is that the fertility of our Ceylon soils, especially those of the mountain region (about one-sixth of the whole), has been considerably underestimated. Tea, at any rate, seems to grow well in all localities, where the rainfall exceeds 70 inches per annum. The disintegrating and denuding effect of the tropical heat and violent monsoon rains on our mountain gneiss formation is very marked, and the slow rise from below believed to be going on is quite necessary to preserve the equilibrium. Curiously enough the presence of garnets in our gneiss, and much of it is excessively garnetiferous, seems to promote decay as much as excess of felspar does. Large and most beautiful hard specimens of rock sparkling with garnets were obtained from the centre of the great slip which recently took place on the railway. As a gem, the red garnet is not found so as to be of special value, but "cinnamon stones" are amongst the common precious stones of the island. The fine blue sapphires for which Ceylon is so famous, rubies (the same stones only differently coloured) and most of our gems are derived from decomposed gneiss, being crystallized clay generally, but our second primitive rock, the crystalline limestone, is in some cases as at Matale and in Uva, bright with spinel sapphires. The mountain limestone is generally too largely composed of magnesia to be of good quality for building or agricultural purposes, but in some places it exists as an almost pure carbonate of lime, fit to be usefully polished into marble, and burnt into lime for whitewash and cement or as a soil fertilizer. Our harder forms of gneiss can also be beautifully polished; for instance that quarried at Mahara for the grand Colombo Breakwater. A polished column in the Museum, in which grey, black and green tints are harmoniously combined, is much and deservedly admired. Equally beautiful, when properly polished, are specimens of the red granite or granitic gneiss which is found a few miles distant from this quarry south of Henaratgoda. Swallow and bat caves exist in the gneiss formations, as well as in the limestone, but nitre forms chiefly in the limestone caves, we believe. The soils of the regions of outlying hills, standing in small ranges and detached masses, beyond, sometimes far distant from the limits of the mountain zone, differ essentially from very poor in some portions of the south-west to very rich in the north and east. Between the vast boulder of Dambulla for instance and the hill of Mihintale near Anuradhapura, the soil is rich to a degree, wanting only irrigation water to restore it to its ancient fertility. Tennent's theory is that Sigiri, Mihintale and other detached hills were "shot up" as they stand, when our mountain system, with the centre of activity near Adam's Peak, was upheaved. Mr. Campbell, in looking from Dambulla rock over the vast eastern and north-central plain, imagined the action of an ancient ocean striking against the cave rock. But during a recent tour in this region we looked in vain for traces of marine remains, and our inclination is to regard Sigiri, Mihintale and the mysterious range of Ritigala as the surviving remnants of a mountain and hill system which once covered the larger portions of the island, the rich soil of Nuwarakalawiya being the result of the decomposition of the softer gneissic rocks. Our theory must be taken at what it may be deemed worth. Other theories, while questioning any closer junction with the Indian continent than now exists, represent Ceylon as having been part of a region which stretched to the Maldives on the one hand and to Sumatra on the other. Tradition on the other hand points to vast subsidences. Populous places which have left no trace are stated to have been submerged off the west coast of Ceylon, while the Basses Rocks, on the south-east coast of the island, are supposed, apparently with good reason, to be the remains of a greater Lanka then now exists. There is a sudden sinking of the sea bottom to great depths at Trincomalee on the east coast and also in the Gulf of Mannar, supposed to indicate ancient earthquake action and subsidence. There is, apparently, no evidence of *recent* volcanic action in Ceylon, and the hot wells which exist are said by some to be due to the chemical action of subterranean vegetation, rather than to any volcanic products. But here we are on doubtful ground. Basalt seems certainly to exist in Ceylon, but in a very altered condition. We have already noticed the existence of veins of plumbago. It is

found generally in association with quartz, and its great purity is due to the fact that in this island, unlike the conditions in India, it is scarcely ever found in association with and contaminated by lime. Gold in the form of dust is widely distributed. It was gathered in the rivers from far back in antiquity, and Australian diggers, a generation ago, created a "rush" to the Mahaoya. More fever than gold was the result, but it seems pretty certain that deep digging into the quartz reefs near the sources of this river in Dolosbage, as well as in other places (notably Ratnapura, where small nuggets have been gathered), would give profitable results to skilful miners backed by capitalists. Meantime the true wealth of Ceylon is in its soil, under the influence of its genial climate.

The vast mass of Ceylon consists of primary rocks or soil and alluvial matter derived from their decay. Our recent formations consist, we believe, we may say, exclusively of various forms of what geologists term breccia. This formation, or rather re-formation, of existing material and of foreign material driven on our shores by currents (which specially abound off Ceylon, reaching our island in some cases from far off Australia) is confined almost exclusively to the sea coast. The only marked exception is in the case of the recently elevated northern end of the island, where in a sketch map Tennent represents the "Madrepore" region as extending southwards as far as a straight line from Mannar to Mullaittivu would include, while, going well inland from Mannar, it stretches along the north-west shore until it comes to a point opposite the island of Karaittivu and the principal pearl banks. The total area thus shown compares in size with the mountain system, but we cannot help suspecting it is somewhat exaggerated, for during a recent journey nothing struck us more than the absolute disappearance of any trace of marine formations or products at a short distance inland from Mannar. On the bund of the Giant's Tank, for instance, there are some blocks of coral breccia. But they are as markedly of distant as the gneiss is of local origin, the latter rock being abundant in the river close by. One of the most curious and valuable forms of breccia in the island is that which forms on the sea-shore north of the Kelani river, near Colombo, and which, beautifully stratified, as grey, yellow, or black ferruginous sand predominates, forms cliffs rising to twelve feet high in some cases. This rock, which can be absolutely seen in the process of daily formation, and which yet yields a valuable building material (Pamunagama stone), is from its highly arenaceous character, naturally enough, known popularly as sandstone. Its constituents include not only the sea shore-sand and matters carried by and deposited from currents, but detritus brought down by the rivers and driven on the shores by the monsoon waves. Fragments may be found in this formation, not only of all the materials—quartz, mica hornblende and felspar,—of our primitive rocks, but also of the precious stones which exist in the alluvium through which the rivers, after escaping from the mountains run. We quoted recently, from Mr. Haly's Museum Report, a notice of some curious breccias found by him on the shores of the bay in which our chief pearl banks are situated. This we now requote:—

Opposite Karaittivu the coast is particularly interesting, and I explored it as far as Kudramalai point, and collected specimens of the formations, duplicates of which have been sent to Berlin with a short description of the coast. The specimens I procured were, first, a kind of laterite, of which fragments that had fallen in the sea became hardened, and acquired a polish, showing the constituents of the rock very clearly. The most remarkable circumstance about the fragments is, that they are full of pieces of shell. I had little time at my disposal for thoroughly examining the formation, but as far as I could see, there was no trace of fossil shells to be found in the cliffs themselves. Whether they really do exist in the cliffs, or whether the fragments are first broken up and then mixed with the broken shells, and reunited by the action of the water, I cannot say, and I trust the Berlin geologists will be able to inform us. Secondly, fragments of the upper part of some lofty limestone cliffs, most peculiarly weathered these cliffs look like coarse sandstone, but the application of acid reveals their true character. Thirdly, fossil shells, all of one species, from the base of these cliffs. These are undoubtedly true fossils. Fourthly, specimens of the limestone, as it crops up through the beach. Fifthly, specimens of raised beach at few feet above the sea-level—a conglomorate of recent shells and corals. Sixthly, specimens of shells from the forest soil resting on this raised beach; it is in some parts ten ft. or more in thickness, and is full of shells of the same species as are now living on the surface. Seventhly, specimens of the same soil hardened by the action of the sea, and again worn by exposure to the atmosphere. Pottery and recent fresh water shells are sculptured out in the most delicate manner by the gradual wearing away of the hardened earth. Numerous specimens of recent marine shells are found in the lower part of the forest soil, and also immense quantities of pearl-oyster shells mixed with pottery, showing that a pearl-fishery existed here in very ancient times.

We also quote our own remark on Mr. Haly's statement:—

"As to the curious formations and re-formations found by Mr. Haly on the shores opposite the pearl banks, we venture to predict that the *savants* in Berlin will decide that the rocks were first comminuted by attrition and then glued together, with shells intermixed by the large quantities of carbonate of lime in the sea water, the mineral mentioned being that, without abundance of which present, pearl shells in millions of millions during countless generations could not have been formed."

We may also refer our correspondent to our recent article, in which we traced the mud which so bounds near Puttalam and is filling one lagoon after another on the north-western coast, to currents from Southern India, sweeping round and striking on to our coasts. To currents such as these are attributed the shifting sheets and "dunes" of sand and even the red soil which overlie the so-called madrepore formation of the Jaffna Peninsula. That formation in geological parlance is as much a breccia as is the "sandstone" near Colombo. But the Jaffna breccia, blocks of which also make good building material, are composed almost exclusively of carbonate of lime, while the soil which overlies them is largely siliceous. If the geological theory is correct, only the coral foundation is of local origin, the sand and the arable soil being contributions from the coast of Coromandel, borne across the strait between Point Calimere and Point Pedro by bountiful currents. The origin of the limestone breccia seems obvious enough. The sea-water off the northern coast of Ceylon (and the same is true of the southern coast between Galle and Matara) must be permeated with carbonate of lime, and the coarl insects (polyparia) are now, as they have been for countless age, incessantly at work*

* When resident at Point Pedro we were able occasionally to see these curious creatures at work on their stony skeletons or abodes. They were covered with a slime of jelly-like carbonate of lime, which they were depositing on strictly mathematical lines, their up and down motion in the process reminding us of that of a saw, rising out of and sinking into a pit

elaborating this substance into beatiful shapes, from immense masses of brain coral, almost solid, to the most exquisite traceried branch corals, the hues of which in the water are varied and brillant, including green and gold and loveliest pink shades. From the violence of the waves and by processes of natural decomposition which doubtless accompany certain stages of life in the zoophytes, the corals thus formed have been broken up, comminuted by attrition and finally agglutinated together by the abundant carbonate of lime into breccia, into which dead and broken shells also entered. Gradually the fragments solidified into the form in which the "madrepore" now exists, and the elevating process already alluded to having raised portions of this formation to or a little above the surface of the sea, the theory is that currents carrying sand and soil from the coast of India did the rest. Our correspondent entertains a different opinion regarding the origin of the red soil of Jaffna, and we shall be very glad to publish his views, if he will furnish them for information and discussion. In 1846-47, the late Rev. R. H. Hoisington sent us several analyses of Jaffna soil, amongst the rest that of the hills of white-ants, and if the records of Batticotta Seminary are searched we think it highly probable that copies of the analyses will be found included. Thers is a natural formation of salt near the marine stream (haunted by crocodiles) at Tondaimannar, about seven miles west from Point Pedro. We do not recollect seeing evidences of the presence of oxide of iron in connection with this formation, but we know that when we sent Mr. Steele, when he was Assistant Agent at Hambantota, a notice of the great Sambur Salt Lake in Rajputana, showing that deep red contrasted with the silvery white crystals of the salt, Mr. Steele stated that the effect of peroxide of iron was also visible in the salt "lewayas" of Hambantota; which by the way are in the neighbourhood of drifting sand "dunes" as formidable as those on the north-east coast of Ceylon. Our correspondent will, of course, direct his attention to the limestone caves at Alvai, a little inland from Point Pedro, in which it is supposed is the source of the fresh water which bubbles up in the sea nea Kankesanturai. He will also study Tennent's extraodinary theory (founded on a popular belief), that besides fresh water seeking the sea (as is natural) in the Jaffna "madrepore" formation, the sea water goes inland, *against* natural laws, the substratum of salt water at bottom of the Puttur well forcing up the fresh! A paper dealing fully with the peculiar physical conditions of the Jaffna coral formations, overlaid by Indian sand (and soil?), could not fail to be very interesting.

Dr. John Davy was himself never able to visit Jaffna, but he analyzed specimens of rock and soil received from his friend Mr. Finlayson, and this is what he wrote:—

This limestone contains numerous shells: it is generally grey or light-brown, very fine-grained and compact, and breaks with a conchoidal fracture. The specimens I have tried, have been very nearly pure carbonate of lime, exhibiting slight traces of the presence of vegetable or animal matter, and containing a little water. It is not confined to the island of Jaffnapatam; it occurs in the district on the mainland, and has been observed by Mr. Finlayson as far as Palweryenkatte, where he found it with coral rock, in a salt-water lake, at a little distance from the sea, with which the lake communicates in the rainy season. Where it occurs, the whole of the country is similar level, without hills or even hillocks and elevated a very few feet only above the surface of the sea, by which, at no very remote period, there is good reason to suppose, it was once covered. The retiring of the sea from this district does not admits of a doubt. It is evident within the memory of man; many individuals recollect the waves breaking where their spray now seldom reaches: Nor is it less evident, perhaps from the nature of the land as described, and from the circumstance of coral rock being found mixed with the limestone rock several miles from the sea. It is always more easy to observe the phenomena of nature, than to point out their causes, especially in geological changes, such as the present, which are not watched in the act, and are noticed only when completely accomplished. Minute enquiry, on the spot, it is very likely, might afford a clue to an explanation of the formation of this rock, which, in all probability, is still going on in the shallows of the adjoining seas, and along the shores of Jaffnapatam. Its formation, it may be conjectured, may be connected with coral which abounds greatly in the narrow sea, between Ceylon and the continent of India, to such an extent, indeed, that most, if not all the islets in that sea, are composed of it. The difficulty is to find the cause of the solution of calcareous matter in some places, and its precipitation in others adjoining. Perhaps, in the deeper, cooler water it is dissolved, and in the warmer, shallow water it is precipitated. The solution is aided, perhaps, by the presence of a little carbonic acid, and the precipitation is assisted or produced by the escape of the acid gas. This is mere conjecture, but of that kind that it admits of being tried by the test of experiment.

Again, writing of Ceylon soils, he remarked:—

The most striking instance to be adduced, of soil destitute of calcareous matter, and incumbent on a bed of coral, is the common soil of the coral island Delft, off the coast of Jaffnapatam, celebrated for its excellent pasturage. It is a dirty-yellow, very fine sand, slightly cohering which consists, in its dried state, of

95.0	silicious sand coloured by iron, with perhaps a very little alumine
2.5	vegetable matter
2.5	water
100.0	

Nor hardly less remarkable are some of the soils of Jaffnapatam, for which as well as those of Delft, I am indebted to my friend, Mr. Finlayson. Two instances may be mentioned,—one of a soil of a tobacco field, which is manured by means of sheep, like turnip-ground in England; the other of rice-ground, which receives no manure, but is carefully irrigated. The tobacco soil, of a reddish-brown colour, collected when perhaps partially exhausted, the crop not having been long taken off the ground, consisted of

95.5	silicious sand, coloured by iron with a few particles of calcareous matter
2.0	vegetable matter
2.5	water
100.0	

The rice soil, of a light grey colour, containing a good deal of straw in a finely divided state, consisted of

95.5	silicious sand, with traces of iron, carbonate of lime and alumine
2.5	vegetable matter
2.0	water
100.0	

It seems extraordinary that in slands, the foundations of which are calcareous, there should be so little calcareous matter, and so large a proportion of silicious matter, in the soil. It is a subject deserving of minute inquiry on the spot; perhaps, the fine silicious sand is drifted there by strong winds from a

distance*; and perhaps, as already hinted, the calcareous matter is washed out in process of long time by the action of the heavy periodical rains.

It will be seen that Davy referred the origin of the siliceous soil superimposed on the limestone base, to wind instead of water currents. As there is an interval of only 40 miles between Point Calimere on the Coromandel Coast and Point Pedro in Ceylon, and as the wind currents in the north-east monsoon are exceedingly powerful, aerial currents may certainly have done their part in supplying Jaffna with soil.—Dr. George Gardner was able to personally visit Jaffna: he wrote in 1847, about a third of a century after Davy had recorded the facts and opinions we have quoted, and this is what he said of the geology of the Peninsula:—

Passing over all those series of rocks to which the names of secondary and tertiary have been given, none of which are known to exist in Ceylon, we come to those very modern ones called post-tertiary, which are being formed at the present day, and which either shew themselves in the shape of elevated terraces of shells, or in a more solid form arising from the agglutination of particles of sand and fragments of such coralines and shells as still inhabit the surrounding seas. Such elevated shell banks, and such rocks are to be met with in several places along the coast. Thus the greater part of the Peninsula of Jaffna is formed of them, and I have likewise noticed their existence at Galle and at Belligam. The study of these modern formations is of peculiar interest to the Geologist, as they are fraught with important analogies as to the process of nature in more ancient times. At Jaffna the lower portions of this breccial rock is quarried for building purposes. It is compact in its structure, but abounds in very perfect remains of shells and corals, and in its general structure resembles very much the same kind of rock in which human remains have been found on the north-east coast of the main land of Guadaloupe. Along the shores of the lagoon which separates the main land from the peninsula of Jaffna, and but little elevated above the present sea level, the formation of this rock may be seen in various states of progress towards solidification. Some specimens which I collected there consist of nearly an entire mass of small shells similar to those which are still found abundantly alive within the present tidal range, and are beautiful examples of the manner in which those limestone rocks of the secondary strata which are so full of the remains of shells and other marine animals, have been formed.

Finally we quote from the work of Sir Emerson Tennent:—

The land has for ages been slowly rising from the sea, and terraces abounding in marine shells imbedded in agglutinated sand occur in situations far above high water mark. Immediately inland from Point de Galle, the surface soil rests on a stratum of decomposing coral; and sea shells are found at a considerable distance from the shore. Further north at Madampe, between Chilaw and Negombo, the shells of pearl oysters and other bivalves are turned up by the plough more than ten miles from the sea.

These recent formations present themselves in a still more striking form in the north of the island, the greater portion of which may be regarded as the conjoint production of the coral polypi, and the currents, which for the greater portion of the year set impetuously towards the south. Coming laden with alluvial matter collected along the coast of Coromandel, and meeting with obstacles south of Point Calimere, they have deposited their burthens on the coral reefs round Point Pedro; and these gradually raised above the sea-level, and covered deeply by sand drifts, have formed the peninsula of Jaffna and the plains that trend westward till they unite with the narrow causeway of Adam's Bridge—itself raised by the same agencies, and annually added to by the influences of the tides and monsoons.(*)

On the north-west side of the island, where the currents are checked by the obstruction of Adam's Bridge, and still water prevails in the Gulf of Manaar, these deposits have profusely heaped, and the low sandy plains have been proportionally extended; whilst on the south and east, where the current sweeps unimpeded along the coast, the line of the shore is bold and occasionally rocky.

NORTHERN PROVINCE.—*Coral Formation.*—But the principal scene of the most recent formations is the extreme north of the island, with the adjoining peninsula of Jaffna. Here the coral rocks abound far above high-water mark, and extend across the island where the land has been gradually upraised, from the eastern to the western shore. The fortifications of Jaffna were built by the Dutch, from blocks of breccia quarried far from the sea, and still exhibit, in their worn surface, the outline of the shells and corallines of which they mainly consist. The roads, in the absence of more solid substances, are metalled with the same material; as the only other rock which occurs is a description of loose conglomerate, similar to that at Adam's Bridge and Manaar.

The phenomenon of the gradual upheaval of these strata is sufficiently attested by the position in which they appear, and their altitude above high-water mark; but, in close contiguity with them, an equally striking evidence presents itself in the fact that, at various points of the western coast, between the island of Manaar and Karativoe, the natives, in addition to fishing for chank shells † in the sea, dig them up in large quantities from beneath the soil on the adjacent shores, in which they are deeply imbedded. ‡

The sand, which covers a vast extent of the peninsula of Jaffna, and in which the cocoanut and palmyra-palm grow freely, has been carried by the currents from the coast of India, and either flung upon the northern beach in the winter months, or driven into the lake during the south west monsoon, and thence washed on shore by the ripple, and distributed by the wind.

The arable soil of Jaffna is generally of a deep red colour, from admixture of iron, and, being largely composed of lime from the comminuted coral, it is susceptible of the highest cultivation, and produces crops of great luxuriance. This tillage is carried on exclusively by irrigation from innumerable wells, into which the water rises fresh through the madrepore and sand; there being no streams in the districts, unless those percolations can be so called which make their way under-ground, and rise thorough the sands on the margin of the sea at low water.

Tennent talks of the subterranean water rising fresh through the coral, but we submit that much of the good effect of the numerous irrigation wells by means of which the Jaffna Peninsula is cultivated like a garden, is due to the fertiliz-

---

* There are very many instances of sand being carried to a great distance by the wind. On our voyage from India, approaching Table Bay, at the Cape of Good Hope, the S. E. wind blowing strongly off land, was so impregnated with a subtle sand, like that of Delft, that it proved very troublesome even three and four miles off the shore.

* The barrier known as Adam's Bridge, which obstructs the navigation of the channel between Ceylon and Ramnad, consists of several parallel ledges of conglomerate and sandstone, hard at the surface, and growing coarse and soft as it descends till it rests on a bank of sand, apparently accumulated by the influence of the currents at the change of the monsoons. See an *Essay* by Captain Stewart *on the Paumben Passage*. Colombo, 1837. See Vol. II. p. 554.

† *Turbinella rapa*, formerly known as *Voluta gravis*, used by the people of India to be sawn into bangles and armlets.

‡ In 1814 an anchor was found under the soil at the north-western point of Jaffna, of such size and weight as to show that it must have belonged to a ship of much greater tonnage than any which the depth of water would permit to navigate the channel at the present day.

ing salts of lime brought up in the ola baskets with the irrigation water.—We trust the information we have thus brought together may be useful to our corrspondant and others, but a regular scientific survey of and report on our rocks and minerals is a desideratum still to be supplied. For instance, the recived opinion is, founded on the fact that there are no lakes amongst the mountains of Ceylon that none ever existed. We hold strongly, contra, that the Plain of Nuwara Eliya is the bed of an ancient lake whence, when the barriers were worn away or broken up, the waters escaped into Uva on the eastern side; into Dimbula on the western. There are other similar localities amidst our mountains, and the valley of Maturata is so narrow and its sides so steep that it resembles the formations called canyons, down which rivers tumble over sheer precipices into the Yosemite valley in California. We cannot help thinking that captured water, long retained but finally breaking the barriers which confined it, has had something to do with this formation and similar ones in our Ceylon mountain system.

While we are writing a specimen of rock is brought to us taken at a depth of 170 feet, from the borings which are going on at Mannar, with the hope of finding a perennial supply of water at that truly penal station, where, what with glare and heat, the paucity of rain and the absence of good water, life must be very difficult to live. The hard rock to which the borings have reached, after passing through much soft breccia, is of course the underlying gneiss, which crops up at Pulaverayenkadu on the Ceylon mainland and in the island of Remesvaram and which is conspicuous in the beds of the Kalaru and other rivers which enter the sea near Mannar. At present the supply of fresh water for the residents of Mannar is obtained from a couple of wells dug in the sand, about two miles distant, the rail water caught in the old Fort reservoir being of very small account. A plentiful supply of good water would make all the difference in the world, and we trust Government will not grudge a substantial vote, say R1,000, instead of first R250, and then R120, which have been allowed. Many a convict in our jails has better prospects of life and ahealth than persons condemned to live at Mannar, and as we are so careful about he health and life of our prisoners, we ought to xtend at least equal privileges to honest people ondemned to live at a place on which nature has largely laid her ban in the shape of drought and fever.

TEA PLANTING IN CEYLON.

(*The Field*, August 27th.)

Noticing an article in the *Citizen* upon the Tea Enterprize in Ceylon, which gives full and detailed estimates both of expenditure and returns from a block of 300 acres, it may interest your readers to lay before them the result of seven years' experience of tea-planting in that island. We say tea-planting, although it must be owned that the experience commenced with coffee. It is often the way with the would-be money-making world to be willing to rush into any investment so long as it be sought after by the crowd The public always like to back the favorite. People tell one in a superior way that it never answers to be a pioneer, that it is more prudent to wait and see the result of other people's investments before making the plunge oneself, and that they do not like to put their money into a sinking ship. All this is quite true, but they forget that there are such things as ships which cannot sink. They may be laden with timber and become water logged and even abandoned; these will be tossed about for some days or weeks, but in the end some steamer will find them and take them into the nearest port, where their cargo may fetch its full value after all. So it is with many industries and countries. They may be down in their luck, but, for all that, if they are timber-laden by having a good climate and rainfall, good soil, or diligent inhabitants, it is contrary to experience that they should remain for ever in this hopeless condition. This is exactly the case with the island of Ceylon at the present time.

After forty years of comparative prosperity, and after five years of doubt and uncertainty, coffee has been found a complete failure. Men who have never swerved from the belief that they could pull it round by generous cultivation have been ruined by dozens, and had in many instances to seek the protection of the Bankruptcy Court. Private people at home, tempted by favorable reports and a high rate of interest, advanced thousands of pounds upon mortgage, and received for a longish time ten, and even twelve, per cent, for their money.

Then came the bad crops in succession, endless attacks of leaf disease (*Hemileia vastatrix*) and "bug," followed by the dying-out of the coffee trees themselves at last, causing abandonment of the properties. Proprietors of estates, who had lived for years in England upon the fine profits accruing to them from their Ceylon properties, in many cases came out to the island themselves, imagining that the disasters were owing to the reckless expenditure and gross mismanagement. Others, who had without interruption enjoyed for ten or fifteen years an income derived entirely from coffee, began to find that, instead of a profit, there was a heavy loss year after year, and that the expenditure of the estate exceeded the value of the crop by four or five thousand pounds. In some instances, these proprietors became so disgusted as to write out ordering all expenditure to be stopped, and that the estate be sold at once for whatever it would fetch.

A case, the full particulars of which were known to all residing in the district, occurred in Kotmalie. One of the oldest and finest properties there belonged to a gentleman who had for many years resided comfortably in England. About five years ago the crop failed for the first time to cover the expenditure. No doubt he thought that this had been occasioned by an abnormal season, and that, so far from its occurring again, it would probably give rise to an unusually heavy crop the succeeding year. Judge of his unpleasant surprize when, instead of this, a far heavier loss was announced, followed by reports that the entire aspect of the estate was altering rapidly, that the trees had lost their vigorous, "laurely" colour, and were becoming sickly, or were denuded of leaves by wind and leaf-disease. The year following brought a still greater loss, and worse reports, which even advised the abandonment of certain fields on the estate. This estate, which had been yielding an average profit during ten years of over £5,000 per annum, and could have been sold for £45,000, was one morning advertised for sale, the price being £1,000. For two or three months the property remained abandoned, when one day two planters rode over to look at it. Within a week they purchased it.

A month after that an Indian tea planter, happening to see the estate, examined well its soil, and found out its climate and rainfall from the books. He wanted to buy it, but found it was too late. Going straight to the present proprietors, he offered £1,000 for a half share, and, upon being refused, he paid this money and accepted a third share.

They have now opened up most of the land in tea, which will be in bearing in another eighteen months. They have refused £10,000 for the place, which is valued at present at £15,000. Now, this is not a solitary case, or a solitary chance. In every one of the thirty coffee districts are abandoned estates, with a climate and rainfall perfect for the growth of the tea plant, with ruined proprietors, and with a bad name. Yet no one will buy now; they will wait for the rush. When the general public considers the investment good, then they will follow the crowd, and will be eager to buy. But when that time comes the land will be run up to an abnormal value, which they will perhaps hasten to pay, and which may counteract any profits made for a long time. It may be as well to state here that I do not own an acre of land in Ceylon, either directly or indirectly, nor am I a mortgagee. After a residence of seven years, I have left the island for good having business to attend to in England.

Ceylon tea is a proved success, and is being planted by thousands of acres each season. In another two years land will be at its full value. Any one going out now with even a few thousand pounds may very well buy an estate which will yield them by no means a contemptible income after three or four years' work. The island is at present the water-logged ship, and the few investors are the men in boats, who are saving what little they can from the wreck. The news will not take long to travel, and then will come the tug-boat in the shape of the public at large to bid for all the available land. Ceylon has been at its very lowest ebb, and is now improving rapidly. Its climate in the hills is well nigh perfection for Europeans, and its labor supply and rainfall exactly what is required for the successful cultivation of tea. A man, a little ahead of the swarm of investors who will follow him, may now buy land before it is run up to its full value. Month after month the use of Ceylon tea is increasing, and its price already beats both Indian and China, just as Plantation coffee used always to fetch higher prices than either Mocha or Brazil.

It is so much a cry now-a-days to know what young men are to do after leaving school if they have not sufficient brains or application to pass successfully through the ordeal of competitive examinations, that any suggestion may be useful. Some young men tell their parents honestly and plainly that they cannot stand the wear and tear of the cramming necessary now even for Woolwich and Sandhurst. Many wish an out-door life, and in Ceylon they will have one. Work is hard, but in no way derogatory. Up before the sun, one has to muster the coolies and send them off to their respective works of lining, holing, planting, weeding, or pruning, as the case may be. Within half an hour after eating a very light meal, called "early tea," one follows the labor, and for four hours superintends their work or walks round the estate to see that everything is in order, that the night's rain has not choked drains or ravines, and that no small land-slip has occurred. Pretty tired and hot after all this exercise, the bath at ten o'clock will be found a luxury which was never equally appreciated in England and after that the appetite one has for a solid breakfast would surprise our quiet-going relations. The rounds of the work must be done again between 2 and 4 p. m., at which time the coolies cease work for the day, and one's time is one's own to spend in shooting snipe or hares, visiting neighbours' bungalows to play tennis, or in some districts even cricket. Dinner at 7 and bed at 9 p. m. is the usual time, for one requires a good night's rest after the amount of open air exercise taken throughout the day.

As there seems to be some misapprehension about the amount of sport and big game shooting obtaining in Ceylon, it is as well to say that this has to be followed chiefly in the "low-country." In most of the higher districts the larg st game are elk (Sambhur deer) and red deer, both of which are hunted most enthusiastically by dogs and men They are seldom shot for this reason. Wild pig, mouse deer, hares, jungle-fowl, spur-fowl, and snipe complete the list, and most excellent sport can be enjoyed by those whose legs are sturdy.

A. O. W. B.

THE SAO PAULO *Diario Mercantil* of the 26th ult. contains a letter from the new Paranapanema district, praising its great advantages, especially for coffee cultivation, and giving a partial list of the planters who have recently procured large tracts of land for coffee plantations.—*Rio News.*

CINCHONA BARK is thus noticed in the report of a meeting of the Wynaad Planters' Association held on Sept. 7th :—In answer to Mr. Guard's letter, members stated that their experience agreed that in uprooting cinchona the root bark was one third of the stem. Read Mr. Hooper's analysis of Ledger Bark from Erimaculla supplied by Mr. Lamb. The following figures show the result of shading and covering.

	Natural. 5 years old	Renewed not covered. 6 mnths.	Renewed not covered. 12 mnths.	Renewed and covered. 6 mnths.	Renewed and covered. 12 mnths.

*Equal to Crystallized Sulphate of Quinine ...	5·42°/°	3·75°/°	4·82°/°	5·34°/°	7·37°/°

Members stated that Ledger trees did not stand shaving well and the Honorary Secretary was requested to write and request Mr. Lamb to give his experience as to the effect of shaving and the number of trees operated on.

CEYLON TEA IN THE MELBOURNE EXHIBITION.

All that was possible at the time (and much of what was accomplished was most useful and important) was done for Ceylon tea at the Exhibition of 1880-81. With the valuable aid of Messrs. Henty & Co., and especially Mr. Oswald Moody, a series of reports and careful analyses were secured and published, which, added to the list of prizes awarded, attracted attention to the new competitor in the tea market, not in Australia alone, but in Britain and over the whole tea-drinking world. Side by side with Mr. James Inglis (now Minister of Public Instruction in New South Wales) the Ceylon Commissioner fought the battle of pure Indian and Ceylon teas against the vested interests which had profited and still wished to profit exorbitantly by dealing in post-and-rails" and adulterated stuff from Foochow, the animus and the abuse which had to be encountered were intense beyond conception. Nevertheless, Ceylon tea would have found a market in Australia to a much greater extent than has yet been the case, amongst those who could afford to give a good price for a good article, but for the fact that up till recently and even until now, to a great extent, Britain offered a far better market for all that Ceylon could produce. Taste in Australia has been generally formed on the coarser and cheaper Foochow teas, with a proportion of the finer kinds, and although Indian and Ceylon teas could compete successfully as to quality, they could not at first in price, and it is well-known that many of the earlier invoices were purchased in Melbourne to be shipped to London. It was perhaps a pity that the Ceylon Commissioner was not on that occasion authorized to give "afternoon tea" after the example set by India. But we doubt if the results would have greatly differed from what they have been. It is not quality but price alone which prevents larger quantities of Ceylon as well as Indian teas being used in Australia, where, after all, the consumption in a year is only 20 millions of pounds, if so much, against a total approaching 200,000,000 lb. in Britain. But as our production is augmented, prices are likely to go down, and in view of the importance of cultivating fresh markets, we quite agree with Mr. Wm. Mackenzie in the importance he attaches to the approaching Centenary Exhibition at Melbourne as an occasion for pushing our teas. Although there can be no regular representation of the colony and of our varied productions, there can yet be a Ceylon Tea House, where our pure and fine flavoured product can be sold not only in the chest and in the packet but in the cup. Arrangements for such a purpose ought not to be costly, and if planters generally appreciated the importance of the results which are likely to follow such efforts, we do not see why funds *and tea* for both Glasgow (on a big scale) and Melbourne on a more moderate standing should not be collected. Mr. Mackenzie feels so strongly on the subject that he wants to fight Mr. Rutherford. But we trust that instead of the Highlander "drawing his skene dhu and sticking it in the bowels" of the lowlander, to the accompaniment of the orthodox "warlike howls," the two will "rush into each other's arms and swear on eternal friendship," over an agreement founded on the mottoes "Let Glasgow flourish" and "Advance Australia." Mr. Rutherford's partner, Mr. Reid, will represent him at Glasgow, and what better representative could he and other tea planters have in Melbourne than Mackenzie, Laird of Nahalma, himself? Glasgow is good, but "both are best."

CINCHONA BARK: CEYLON, INDIA, AND JAVA.

(From *Lewis & Peat's Circular*, Sept. 9th.)

Our supply from the East during the year has exceeded that of the previous year, and the reports of a great reduction from Ceylon have not been verified in the results.

Quantity (in pounds) offered since 1st January to date:—

	Ceylon.	East India.	Java.	Total.
1887 ..	8,917,790 ..	1,359,890 ..	359,730 ..	10,637,410
1886 ..	9,457,762 ..	702,614 ..	301,477 ..	10,461,853
1885 ..	7,890,702 ..	495,738 ..	95,659 ..	8,482,099
1884 ..	6,214,686 ..	404,000 ..	86,144 ..	6,704,830

We expect the shipment from Ceylon from September, 1886 to October, 1887 will total million 13¾ pounds against 15½ million pounds the previous 12 months, the quality, however, is fully 15 per cent richer this year—average about 2½ per cent of Quinine.

Since 7th June, 1887, the sales of Ceylon show the following results:—

3d per lb. and under ..	.. 239,710 lb.
Over 3d up to 6d per lb.	..1,206,460 ,,
Over 6d up to 1s per lb.	.. 763,740 ,,
Over 1s per lb.. ..	.. 90,585 ,,
Total ..	..2,300,495 ,,

We intimated a year ago that in our idea the limit of our capacity to absorb Cinchona had been reached, and, that if our supply were increased, we should have as a consequence lower prices. The continued depression and low rates for nearly all produce has contributed to this, and the continued forced sales by speculators of Sulphate of Quinine, has added to it.

Consequently, although the deliveries are so large and the price so unremunerative as not to stimulate production in new plantations to any large extent, prices are today one-third lower than a year ago; the unit averaging about 2d. Manufacturers have had an unprofitable time owing to the great competition, and the stocks of both Bark and Quinine are still far too large, though that of South and Central Americans kind shews a large falling off; a large portion is of inferior quality. Some considerable quantity had been offered in auction during this year.

Imports from Ceylon have been of good average quality and generally well packed. *Root* has sold readily and well; Spokeshavings also, but quills and young branch and twigs have generally sold very badly.

Reports of probable serious decrease in the supply from Ceylon, owing to the uprooting of Cinchona to make room for Tea, continue to be circulated. A year hence we may speak as to the facts regarding this.

The supply from Java has increased 50 per cent, but we don't think the richness of the Bark is increasing: the average is nearly 3 per cent of Quinine. Shipments in 1886-7 2,426,530 lb. against 1,665,800 lb. in 1885-6, against 1,300,000 lb. in 1884-5.

Central America has forwarded small lots of old cuttings which have been realised at very disastrous prices, and we hear we cannot except any appreciable quantity thence at anything near the currency of the last few years. Holders have, however, been ready sellers of old import. The stock of these varieties shews a very great reduction.

Bolivia increases her supply from Plantations and of rich cultivated Bark.

India, Darjeeling and the Wynaad and Neilgheries have sent nearly double the quantity of the previous year, but low rates may not tempt to stimulate them further; the average percentage of Quinine is about 2½.

From West Indies and Africa (St. Thomas) there have been a few small parcels.

We repeat that the Stocks of the world are in London, and that New York and France have very little Stock.

The consumption of Sulphate of Quinine has been large—we think larger than in any previous year—though, probably, stocks are everywhere rather large too, as happily there has been no great epidemic or war to take off the surplus. Many have very sanguine views as to the wants of China in the near future, as that country appears to be opening up so rapidly to Western civilization.

The Statistics on the other side will be of interest, and we beg reference to our regular fortnightly Prices Current on this article.

The following figures will be of interest, and we believe they are fairly accurate :—

	Ceylon	E. I.	Java
From September 1886 to 30th Aug. 1887	13,230,780 lb.	1,604,830 lb.	593,642 lb. offered in auction—Total 15,429,252 pounds, against
From September 1885 to 7th Sept. 1886	12,812,970 lb.	963,980 lb.	401,182 lb. —Total 14,177,132 pounds.

Stocks in packages all sorts Cinchona and medicinal Barks, Ceylon and E. I. all places, Central America, Bolivia, Lima, &c.

	1887		1886	1885
Of which Ceylon and E. I. amount to say	*61,283 pkgs.		†69,291 pkgs.	†72,717 pkgs.
At say 240 lb. each—	19,078 "	4,578,720 lb.	9,291 "	2,229,840 lb. 4,717 " 1,132,080 lb.
Leaving S. A. Barks a large part off market	42,205 "		60,000 "	68,000 "

AGRICULTURE IN MANILA.

(Translated for the Straits Times.)

The Caroline islands, the possession of which so nearly brought on a war between Spain and Germany, turn out to be a worthless acquisition for the present.

Their only recommendation lies in the group becoming of commanding importance, in the event of the completion of the Panama Canal. The *Comercio* having suggested that the Carolines might offer a field for Spanish commercial enterprise in the direction of copra dealing, a correspondent throws cold water on the scheme. He points out that the islands in question bear none of the characteristics of a land of promise. The islands themselves, small and insignificant, stand no comparison with the many isles of the Philippines. The coconut palm only grows on the sea shore of the Carolines. Spaniards in the Philippines, in his opinion, would do well to shun the Carolines as a copra-yielding field of enterprise. The distance alone is a standing discouragement. The islands are remote indeed. Steam communication with them does not exist. Communication by sailing vessels is unfrequent and irregular. The matter was lately put fairly to the test by an employee of the General Tobacco Company who was specially deputed there to start some kind of business venture. He soon found out the hopelessness of setting about anything of the kind. The impossibility of competing with the British and German traders there came quickly home to him. Of them, there were even too many for the little trade that happened to be going. The revenue of the Carolines offers so few prospects of elasticity, that they bid fair to be a burden on the Philippines for many a year.

Manila hemp, besides being useful for ropes, has been also found serviceable for making paper. In Spain, paper has actually been made from it, and turned to account for newspapers. At Madrid, the refuse portion of the fibres has been successfully utilised for the purpose. The paper produced is rather brown in colour, but seems to answer press requirements fairly well. It only remains for enterprising individuals to start mills in the hemp yielding provinces for supplying both the Philippine and Spanish Press with paper. The matter is important enough for inquiry.

SIZE OF SAMPLING BREAKS OF TEA.

TO THE EDITOR OF THE "HOME AND COLONIAL MAIL."

Sir,—You are no doubt aware there has been a conference on this subject between the representatives of the buyers and sellers, at which it was decided to pass over all lots of tea in public sale under 12 chests, 18 half-chests, and 30 boxes, and sell them at the end of the day. Whilst some members of the conference would have been in favour of raising these limits even higher, I think the compromise which has been arrived at will, for the present, meet the general convenience.

But before the question gets out of sight, I should like to place before your readers the result of a very careful analysis of last week's catalogues in regard to the average number of packages in each break.

The total number of packages offered was as follows:—Indian tea, 971 breaks; 22,136 chests; 2,452 half-chests; 227 boxes. Ceylon tea, 310 breaks; 2,613 chests; 2,415 half-chests; 54 boxes. Java tea, 34 breaks; 1,140 chests. China Congou tea, 75 breaks; 10,907 half-chests.

Of the above 971 breaks of Indian tea, 21 were under 8 packages; 353 were on garden account, averaging 29 packages to the break; and 597 were Calcutta bought tea, averaging 24·4 packages to the break.

Of the 310 breaks of Ceylon tea, 90 were under 8 packages and consequently omitted, and the 220 large breaks averaged 22·1 packages to the break, but as almost one-half consisted of half-chests, the average quantity of tea to each break was only about 1,600 lb. as against 2,700 lb. Indian on garden account and 2,300 lb. Calcutta bought. The latter is smaller on account of splitting up the breaks in Calcutta.

The Java teas were all packed in chests, and averaged about 3,350 lb. to the break, whilst the China averaged 10,150 lb.

In view of these figures it behoves the Indian and Ceylon planters to bestir themselves in the direction of sending larger breaks.

It seems to ordinary minds a curious fact that with all the resources of British enterprise the results are so far behind China in this matter; the deliveries of Indian teas are now about equal to those from China, and if the trade is ultimately to double its present proportions the existing arrangements must give place to better.

This subject will be periodically brought before the Committee of Wholesale Dealers, who will narrowly watch the effect of the increase in the size of the breaks, and I believe the time is not far distant when the imports from India and Ceylon will so grow in importance that a further increase in the limit of small lots will be imperatively necessary in order that the large breaks may receive fair attention at the hands of buyers generally.—Yours, &c., R. SEDGWICK, Hon. Sec.

London Wholesale Tea Dealers' Association.
3, Great Tower Street, E. C., Sept. 7th, 1887.

[The question still remains, however, whether the smaller lots do not suit the smaller tea buyers and so obtain better prices?—ED.]

TEA LEAF CROPPER.

The latest addition of machinery to the production of tea is one which has often been projected by planters, but which, so far as we know, has never till now been carried to completion. The "Swinburne Cropper," which is simple in construction, though an ingenious and not inelegant machine, is designed to supersede hand plucking altogether on Indian tea gardens, and there can be no doubt that if it fulfils its purpose it will be by far the most important invention which has yet been applied to tea production. The *prima facie* objection to machine plucking is the possible injury which the plants may suffer from the somewhat drastic treatment; but the inventor who has tried the system on his own gardens in Assam for two seasons, asserts that so far from this danger being a real one, the bushes are actually strengthened by systematic pruning. The machine is calculated to do the work of about ten coolies, being worked by one, and as very little skill or practice is required in its manipulation there should be no difficulty in its general introduction. The blades of the cutter are so arranged as to be incapable of taking off more of the flush than is necessary to make good tea, and as the surface is reduced by the process to a perfect level, it follows that on the second pruning all the leaves must be of the same age. The leaf is therefore more homogeneous, and the quality consequently improved, while the quantity, according to Mr. Swinburne's experiments, is not diminished. The operation is likened to the clipping of garden hedgerows with shears, when the bushes are rendered even more luxuriant than they would be in a state of nature, from the fact of the strength of the plants, which has a tendency to concentrate in particular branches, being distributed evenly over the whole surface. The only difference between the effect of the shears and the "Cropper" being that the latter automatically makes the surface an exact level, an effect which could not of course be obtained by any amount of care with unassisted manual labour. In order for a planter to ascertain the value of the invention it would only be necessary to try the experiment on about half-an-acre for one season, and the machine is in actual operation on some gardens at the present time. It would, of course, be impossible for us to predict with any certainty the ultimate success of an invention which can only be tested by individual experience; but, as far as we can judge, there seems every chance of its successful operation. Should the machine answer the expectations of the inventor there can be no doubt that it will be of incalculable service to the Indian planter, as by appreciably diminishing the cost of tea production, it would give him another chance over his Chinese competitor.—*South of India Observer.*

AN INSECT ENEMY OF FRUIT TREES.—From the *Australian Times and Anglo-New Zealander* of Sept. 9th we learn that at the meeting of the British Association at Manhester:—

In the Biology section, Professor Riley contributed a paper on "Icerya Purchari," an insect injurious to fruit trees. The species of which he wrote is the most polyphagous of coccids, living on a great variety of plants, and thriving particularly on acacia, lime, lemon, orange, quince, pomegranate, and walnut. It is capable of motion at all stages of development after hatching, and can survive without food for a long period. These characteristics have rendered it the most grievous enemy which the fruit grower has to contend with in Australia, New Zealand, South Africa and California. It is believed to have originated in Australia, and to have been introduced into other parts of the world upon living plants. This icerya, on account of the protection offered by its fluted waxy ovisac, and of its other characteristics, is one of the most difficult of all insects to control, as few insecticides will reach the eggs. These difficulties have been surmounted in California by judicious spraying of kerosene emulsions and of resin soaps, as well as by a combination of gases under a portable tent.

PHOSPHATE OF LIME AS AN INSECTICIDE.—Aphides, or plant lice, are marvellously abounding owing to the drought. These insects are to the invertebrata what rabbits are among the mammalia. They depend for their specific existence on their marvellous fecundity. Seven generations of aphides can be produced asexually. Ten become a thousand, and a thousand a great nation. In the last number of the *Agricultural Gazette* there appears a paragraph which is worth quoting for the benefit of all those who have dealings with aphides. A Mr. Barlow says that, having a field of turnips much infested with "fly," he tried the experiment of dusting a few of the plants with superphosphate of lime, and he found that it completely destroyed the insect pest. He then had the whole field dusted, and the result was the entire annihilation of the "fly." The experiment was carried a step further in a horticultural direction. Some fine pansies in his garden were much infested with slugs. They got notice to quit by the application of the phosphate dust, and were all ejected accordingly. Those who have ears to hear let them hear.—From *Science Notes* in the *Australasian*. [The great point is that, after acting as an insecticide, phosphate of lime will fertilize the soil.—ED.]

THE CONSUMPTION OF TEA AND SUGAR.—This month "facts and figures," especially figures, are very much to the fore. Mr. R. Giffen, that master of statistics of all kinds, in his inaugural address at Manchester, on Thursday, as president of the Economic, Science, and Statistics Section of the British Association, gave figures to show that the rate of commercial progress has not been so great in the United Kingdom during the last ten years as in the preceding twenty years. Having referred to the production of coal and of pig iron, he said: "As to the consumption of tea and sugar, which are again commonly appealed to as significant of general material progress, what we find as regards tea is that the consumption per head rises between 1855 and 1865 from 2·3 lb. to 3·3 lb., or 43 per cent.; between 1865 and 1875 from 3·3 lb. to 4·4 lb., or 33 per cent.; and between 1875 to 1885 from 4·4 lb. to 5 lb., or 13½ per cent. In Sugar the progression is, in the first period from 30·61 lb. to 39·8 lb. per head, or 30 per cent; in the second period from 39·8 lb. to 62·7 lb., or 58 per cent.; and in the third period from 62·7 lb to 74·3 lb., 19 per cent. only. In the last ten years in both cases the rate of increase is less than in the twenty years before.—*H. & C. Mail.* [In the latest years of the decade, however, the rate of increase has risen considerably.—ED.]

Correspondence.

To the Editor of the "Ceylon Observer."

CACAO AND ARABIAN COFFEE IN WATAGAMA DISTRICT.

Frankland, Watagama, 2nd Sept. 1887.

DEAR SIR,—By this post I send you 2 cacao leaves which I believe are the largest yet sent you. No. 1 is 2 feet 1½ inch long and 10½ inches broad. No. 2, is 1 foot 10 inches long and 11 inches broad. At the Matale Show the cacao pods from Goonambil estate, Watagama, were certainly the largest. As regards your correspondent who says cacao trees with large leaves do not bear much crop, let him come here and see. Large dark green leaves show health in tree and strength in soil with sufficient moisture and shade. The gold medal being awarded at Matale Exhibition to Goonambil estate for best collection of estate produce, I cannot understand why that *one* medal was not given by His Excellency while many other medals of minor account were delivered. This was not fair to our district. I cannot say who was or is answerable for this. Lands are being opened this year in our district for tea and cacao and Arabic coffee on this estate is still in good heart and giving good crop. Green bug is checked from doing much harm,—Yours faithfully.

J. HOLLOWAY.

MESSRS. WM. JAMES AND HENRY THOMPSON ON THE NEW ARRANGEMENTS REGARDING BREAKS OF TEA.

London, 38, Mincing Lane, 7th Sept. 1887.

SIR,—We think it will be useful to planters if you will consent to being the means of their being informed of the change in the rule regulating the sale of "small breaks" which was agreed upon at a meeting of the Trade held last week.

You are doubtless aware that for some time the Trade has been face to face with the difficulty of compassing the work involved in valuing the number of samples offered day after day, and with the hindrance to their business caused by the length of time which they are compelled to pass in the auction room. To meet these difficulties it was arranged some time ago that "small breaks," *i.e.*, parcels containing less than 8 chests or half-chests, or 20 boxes should be sold (under the hammer) at the conclusion of the sales. Under this arrangement the large buyers were able to retire when the sale of the larger parcels was over, leaving the smaller buyers to compete for the small lots.

The great increase in supplies, however, both from India and Ceylon, has so accentuated the difficulty of conducting business, that the buyers asked the sellers to raise the limits for the size of breaks, and proposed that all parcels of less than 12 chests, 20 half-chests or 50 boxes, whether from India or Ceylon, should be classed as small breaks, and sold at the end of the auction. This was discussed at a joint meeting of representatives of the Trade Association, with the result that the sellers agreed to make the limits for Indian tea 12 chests, 18 half-chests and 30 boxes, but at our instance it was agreed that until the 31st December the limit for *half-chests of Ceylon* should be 12; after that date limits for both Indian and Ceylon to be the same. No alteration has been made in the rules as to sampling, so that everyone who wills can procure them from the warehouse as before.

The object of the buyers in pressing for this change was, of course, two-fold. 1. To shorten the time which they must spend in the auction room. 2.—To stimulate producers to make fewer and larger breaks. We, however, know the difficulty with which managers of young or small estates have to contend in making good sized parcels, and in common with our brother-brokers we have tried to impress this upon the Trade. To some extent we have succeeded: but we desire to impress upon producers that it is to their own interest to assist the Trade by taking all reasonable steps to avoid the shipment of small lots. It is not a question of patience or convenience, but of the physical impossibility of dealing during the hours of daylight with the number of samples now offered—and, of the loss to the seller whose samples have been passed over in favour of something more attractive.

To the suggestion that the difficulty can be met by sending all Ceylon tea unsorted, we prefer the alternative—for many good reasons—of continuing assortment but reducing it to three kinds; and where the yield is too small to give a full-sized break of any kind, to keep back the chests packed for a subsequent shipment. In such cases we advise that each day's manufacture be packed off at once as made, and not stored, but the bulking when necessary done here. Every consideration should be secondary to putting tea on the market in high condition, and although "factory bulking" where the yield is large and accommodation and appliances are adequate is preferable, we advise the alternative plan where circumstances are otherwise.—Yours faithfully,

WM. JAS. & H. THOMPSON.

PUSHING CEYLON TEA: GLASGOW BY ALL MEANS, BUT ALSO MELBOURNE.

Nahalma, September 27th.

SIR,—All interested in tea must have read with pleasure Mr. Rutherford's appeal for funds to push our produce in different markets. His facts and arguments ought to convince every planter that it is his duty as well as his interest to come forward and aid in the efforts being made to bring our teas into notice. Help and hearty co-operation should come from all. Let no one hang back because his mite is so small that it cannot affect the issue.

I am at one with Mr. Rutherford and the Committees of the Nuwara Eliya and Dimbula meetings in recommending support to the Glasgow Exhibition. But I join issue with them in overlooking the Melbourne Show. This, the best opportunity we may ever have of opening up a large market where we have no friends, and where dealers and importers are our enemies, is either quietly shelved or postponed for various and curious reasons.

Mr. Rutherford says:—"It is a great pity we are not likely to be represented at Melbourne, as it is an opportunity lost which may not occur again for some time"; "Glasgow was brought forward early in the day, and we have men at home ready to begin work whenever they are advised that the money will be forthcoming"; "the Glasgow Exhibition was chosen (by whom, pray?) for the reason that Mr. Christie had made arrangements in the event of planters taking it up, and it was considered desirable that, having done London and Liverpool, we might as well finish our efforts in Britain by attacking the northern countries." Also that on account of the uncertainty as to amount of funds, although "fairly certain there will be enough for Glasgow, it would be better to do one Exhibition well than two badly."

Next year, Mr. Rutherford recommends we should begin our Colonial and Foreign crusade.

These extracts fairly sum up Mr. Rutherford's reasons for supporting Glasgow and throwing over Melbourne. Mr. Rutherford has shown how much

has been done in a small country *i. e.* Scotland by private efforts in a few years. He has also shown how small a contribution *pro rata* on our shipments would suffer to provide an annual fund for pushing our teas.

The points where I join issue with Mr. Rutherford are, first, in his doubt as to the success of the appeal for funds, which would make him postpone action *from the right time* until an indefinite next year. I believe, were it not for a certain lukewarmness towards Melbourne in some leaing planting circles, it would be quite possible to raise money sufficient for both Exhibitions. I have more faith in my brother planters than Mr. Rutherford has, but the example he sets them by contenting himself with *pity for Melbourne* until *after the fair*, will certainly be fatal unless others with different views and convictions come to the rescue.

2nd. Mr. Rutherford would 'do' Glasgow not because it is the best field of operations, but because it was early in the field, because Mr. Christie has made certain arrangements, and because having done London and Liverpool, it was considered desirable, &c.

Such weak reasons, for what to me appears a misdirection of funds, [Oh! ED.] are almost enough to deter subscribers from coming forward, who, seeing that there is none to waste, naturally desire their money to be turned to the best account. Now, we know that, besides having done London and Liverpool, every corner of Britain is being canvassed most thoroughly; and it certainly seems more rational that (while helping at Glasgow) we should mainly direct our efforts to the wide field which is practically untouched, where we have not already done the two chief cities (at the time of the last Melbourne Exhibition Ceylon tea was in its infancy), and where we have no friends helping us as the business of their lives.

3rd. Mr. Rutherford would postpone to next year all action in the colonies, admitting, however, that such an opportunity as the present may not occur soon again, that there will be no exhibition again for years probably, and certainly none comparable to the "Centenary," I should like to know how we are to carry out the colonial crusade? By fitful efforts in each town, with vested interests against us! Or should we not rather take advantage of such an opportunity as brings, practically, all men and women of Australia to one centre, *bent upon seeing and testing new notions, fashions and products?*

If planters do not subscribe towards this object, it must be because they find cold water thrown upon it by those who generally lead in such matters. But let the men of leading and standing throw off the coldness towards the best chance we have ever had, or may have, in our generation: let them clear themselves of indifference, prejudice, preconceived partiality; let them cease to shelve the object *with pity*, or postpone it to an impossible future, and to mislead their districts with plausible pretexts, and go heartily into the work of advocating representation at Melbourne, and the end will be achieved. Their (and all our) pockets will benefit even if the oracles are found for once to be wrong!

Let our old allies—the merchants and bankers—be asked to assist; their liberality has always been conspicuous in every good cause. Let the THREE English papers (the "Examiner," in honor of Mr. Barber) be asked to publish daily lists of subscriptions, as a more rapid and certain method of exciting emulation and enthusiasm than circulating lists in the different districts.

I have been asked not to divide the country on this matter. I have no desire to do so, but at the same time I object to Planters Association officials taking it upon themselves to *quiet the country* by assuring it that it is enough to "do" the coming Exhibition this year, while the opportunity for "doing" the right one slips past. I feel confident that energetic action, on the part of the leaders, will ensure success; and, failing success, I would call upon them to give an account of their stewardship at the meeting in Nuwara Eliya on the 15th proximo.

Let us all, in the words of Mr. Rutherford, "subscribe to the sprat, to catch the whale."

For Nahalma and self, I promise R250 to a *joint fund* for the Exhibitions. If we start by being afraid that there will not be funds for both, depend upon it we shall not be disappointed. Failure surely attends such a start. But for the attitude already assumed by those entrusted with the planters' interests in such matters, I would have bet Mr. Rutherford R250 (*to go to the fund*) that money sufficient would have been forthcoming.

WILLIAM MACKENZIE.

EXHIBITIONS AND "COMMERCIAL SAMPLES" OF TEA.

28th Sept. 1887.

DEAR SIR,—The Matale exhibition appears from your special report to have been an unqualified success and the different estate products better represented than was the case in the Kandy exhibition in May last. Blackstone has at last had to take second place; this is a matter for congratulation as indicating that planters are fully alive to the importance of manufacturing finer teas and that a spirit of emulation has been aroused by the same mark gaining the gold medal at two successive exhibitions. There is no doubt the success of the recipient at the Matale show will stimulate others to compete for the coveted prize, and it might be well to have a proper definition of the term "Commercial Samples," as it occurs to some that until this is done many will be deterred from competing.

A discussion took place at the late Kandy exhibition as to the smallest lot from which a *bona fide* commercial sample could be drawn. One planter had it "that as one cwt. of coffee or cacao could be made into a shipment, that quantity of either product would be sufficient."

Another "believed that it could even be cut finer and so long as an actual shipment was made the weight was immaterial." Indeed, this authority concluded by saying: "One may select 25 lb. of say coffee, send home 5 to constitute the shipment and exhibit 20." This shows the elastic nature of the phrase "*bona fide* commercial samples."

As a means of remedying this and giving all an equal chance something like the following might as regards tea be submitted for the consideration of next year's exhibition committee:—

I.—Let all samples be drawn from a break or invoice of not less than 1,000 lb. of each of three grades.

II.—The samples to be drawn by a Colombo tea broker appointed by the committee, who would be furnished with a letter from the exhibitor authorizing him to draw the samples from a break on arrival in Colombo.

III.—The samples might be taken any time within three months and up to ten days of the opening of the exhibition.

IV.—Samples would be at once sealed and numbered. A corresponding number placed on an envelope which would contain the name of the estate. The envelope to be opened only after the tea was judged and the prizes awarded.

It is a comparatively simple matter to make a few hundred pounds of a superior class of tea by plucking a fine flush off the best bushes on the estate, withering, rolling and fermenting care-

fully and sorting with sieves of a very small mesh, but the invoice should be at least one of 3,000 lb. to be a test of what an estate can produce and what should be considered a purely commercial tea.—Yours faithfully, S

MR. WM. MACKENZIE'S PROPOSAL FOR PUSHING CEYLON TEA IN AUSTRALIA.

No. I.

"Call you that backing of your friends?
A plague upon such backing."

Henry IV.

Nuwara Eliya, 1st Oct. 1887.

SIR,—I am glad to hear that well-known voice once again crying from out the wilderness of the lowcountry, to the denizens of the mountains, to come out and help as one man to push Ceylon tea at the Melbourne Exhibition. The voice is not one of sweet seductive wooing, but sounds like the outpourings of a spirit terrible in his wrath if his behests be not obeyed.

With what sneers and withering scorn does he not write of the "men of leading on the Planters' Association Committee"; accusing them of "coldness and indifference" to his scheme, "prejudice and preconceived partiality" for the Glasgow foundling. He opens his extraordinary letter of fire, by saying "I am at one with Mr. Rutherford and the Committees of the Nuwara Eliya and Dimbula meetings in recommending support to the Glasgow Exhibition."

After having, I presume, quaffed a creaming bumper of "Nahalma" broken pekoe, and before the fumes are off, or the Pambagama cock has time to mount the "midden" and crow, Mr. Mackenzie startles us by denying his opening sentence, when he states that he considers subscribing to the Glasgow Exhibition "*a misdirection of funds*"! He says the Committee have thrown cold water on the Melbourne proposal, and that my example will be fatal unless others with different convictions come to the rescue. He then proceeds to turn a tap of boiling water on us; places us on the fire; and leaving us to simmer there—disappears.

There is not a line in Mr. Mackenzie's letter to show us "*how to do it*"; and, if he is to do any good, he had better come up here on the 15th, and give us a lead over, and I promise to give him Exhibitions enough.

I do not believe there is a single man on the Planters' Association Committee present at the Nuwara Eliya meeting who would not gladly support both the Glasgow and Melbourne Exhibitions. For myself I would go further and add Brussels.

Mr. Mackenzie's statements, that the Committee wish to "shelve Melbourne"; are "misleading their districts"; and have "assumed an attitude" hostile to the Melbourne Exhibition, will I should say not be accepted by any member of the Committee. It is quite competent for any member of the Association to bring the subject before the general meeting on the 15th instant, when, it is to be hoped, we will see such enthusiasm that will leave no doubt as to funds being forthcoming.

The whole matter is one of funds. Mr. Mackenzie, I regret to see, does not touch at the root and essence of my letter on the subject, but confines himself to abusing the Committee.

Were the scheme I proposed adopted, of creating a fund, we would always be in a position to know what we could, and what we could not, do. As things are, the Committee could not possibly take upon itself the onus of advocating the expenditure of, say, R14,000 for the two exhibitions without knowing where the money was to come from. Personally, I will go shoulder to shoulder with those who desire to push tea at the two Exhibitions, and am prepared to subscribe on the basis of the scheme I sketched out. That is, if R14,000 be the sum required for these two Exhibitions, I would subscribe on my proportion of the island's crop of 22¼ millions, and this would be at the rate of 63c per 1,000 lb of tea.

Mr. Mackenzie says he has more faith in planters subscribing than I evidently have. I have faith in the same men coming forward again and again to subscribe, and of a few converts, but it is more difficult making planters believe in the good done by Exhibitions than he seems to be aware of. Will he be surprized to learn that, although every district was canvassed and both newspapers strongly advocated support being given to Mr. J.L. Shand at the Liverpool Exhibition, the value of the tea subscribed did not amount to more than £150!

The value of the Ceylon crop (the greater portion of which was sold in Great Britain) for the same year amounted to £600,000. Comment is needless.

My motto is "Support *everything* but let *all* pay."

H. K. RUTHERFORD.

No. II.

Goatfell, 1st Oct. 1887.

SIR,—I had already put my pen to paper to express my concurrence with Mr. Rutherford's opinion that it is a great pity nothing has been done towards representing Ceylon tea at the forthcoming Melbourne Exhibition; and now that Mr. Mackenzie has taken up the subject, I am the more strongly inclined to write in favour of some action being taken to secure such a splendid opportunity of advertizing our teas.

I think Mr. Mackenzie does Mr. Rutherford some injustice, and, no doubt, the latter gentleman will disclaim any intention of throwing cold water upon any scheme projected for the benefit of Ceylon tea-growers. The object, however, for which I write, is to urge upon all interested (and who in Ceylon is not?) to make every possible effort to get our teas introduced into the Australian market; and as the Exhibition will afford such a grand opportunity, it certainly ought not to be let slip. Comparatively little has as yet been done towards introducing Ceylon tea into Australia, and in saying this, I do not lose sight of the efforts put forth at the Melbourne Exhibition of 1880-81, efforts which, I feel bound to say, were very largely successful, but which have not since been adequately followed up; the development of any trade having been left almost entirely to the private enterprise of individuals with insufficient means to carry on what must prove at best a very tough fight against vested interests.*

Compared with the number of individuals who through their connections with the United Kingdom have done so much to advertize Ceylon tea at home, the number who are connected similarly with the Australian colonies is very small indeed, and therefore it is not to be supposed that the tea can be advertized in the same way to any great extent in Australia, and consequently if we would obtain a market there, some additional means must be adopted. I believe a Ceylon Tea House selling tea in the cup would answer the purpose of advertisement to a great extent; but I do not think this would be sufficient. Tea must be put directly into the hands of consumers, even brought to their very doors, if results are to be attained in the immediate future.

* This, and, as we explained, the demand for Ceylon for all that Ceylon could produce at prices which the Australians would not pay. Prices have now come nearer the Australian level.—ED.

It is now seven years since the last Melbourne Exhibition, and I would go so far as to say that not in one household out of ten throughout Australia has Ceylon tea been heard of, far less seen and tasted. To prove that I do not write without a degree of authority, I may mention that in 1881 I visited a large proportion of the towns in the Colony of Victoria, my business being principally with the retail tradesmen; and I took every opportunity of furthering the interests of Ceylon tea, although, as Mr. Mackenzie says, it was only in its infancy then; and I feel perfectly certain that had I known as much about tea as I have learned since, I could have sold it in quantity, and in all probability would now be engaged in selling it instead of producing it.

I am now only repeating views which I have expressed in your columns before. Let me again suggest what I consider the most likely *modus operandi* to secure our object. Establish agencies in Melbourne and other principal towns with sufficient funds and stocks of tea to carry on the business, and let them employ canvassers, men who would carry samples and take orders from house to house, not only in towns, but throughout the stations in the "Bush"; being paid by a liberal commission, and being allowed to take other commissions excepting tea. A man cannot push a new line at his own risk on a 5 per cent commission, as I know from experience. There seems to be great difficulty in getting support to any Syndicate or other scheme formed for the benefit of those who have invested capital in tea property, but I believe the time is not very far distant whem this question will come to be quite equal in importance to that of labour supply; and then no stone will be left unturned to find outlets for the millions of lb. of tea we shall want to export.

As yet there is but a proportion of those who will erelong be interested in the tea market who are in a position to subscribe in kind towards the present object; but all who have tea planted or even only in nurseries as yet should feel called upon to support a scheme which will ultimately benefit all alike. CHAS. M. HENRY.

THE PUSHING OF CEYLON TEA: MR. SCOVELL BRINGS UP HIS FORCES FOR THE BATTLE.

Nawalapitiya, 2nd Oct. 1887.

SIR,—In May of last year I wrote to the Planters' Association and the press urging the great importance of some co-operative action being taken to assist in the opening up of new markets for our teas, and the general and systematic advertising of our produce. Mr. Rutherford followed this up with a carefully prepared scheme, which, however, did not receive the general support it merited, partly and from the fact that contributions of *tea* not *money* formed the basis of the proposed operations, but mainly, I think, because *prices* then ruling for our teas both in London and Colombo apparently lulled men into a position of false security.

My remark made at that time that the matter of systematic pushing of our tea "was one which, involving some trouble, we are apt to neglect until the necessity for action is *forced* upon us," has been emphasized by subsequent events, and I feel sure that all interested in this most important question must be glad to see the powerful and opportune appeals for action in this direction which have recently appeared in the papers from such men as Mr. Rutherford and Mr. Mackenzie.

It is maintained by brokers and others that our teas at the present moment command an enhanced value directly and solely traceable to the energetic way in which they have been placed before the public; and that this is so, is doubtless due to our having such men as Mr. Rutherford in our midst and Mr. Shand and others at home, to take the initiative in such matters. To *maintain*, however, our position in the great "tea-fight" of the world, it behoves us not to rest contented (as some would seem to advocate) with the small though good beginning we have made, but with our increasing shipments it becomes increasingly desirable that we should be in a position to give ready support to, and take advantage of, any well-considered proposal and favourable opportunity which may come before us for pushing and advertising our teas, *under proper auspices*. If general and pro-rata contributions to this object are annually made, in some such way as Mr. Rutherford suggests, even for a time and to such an extent as would step by step enable our teas to be advertised in most of the important railway stations and towns of the colonies and elsewhere, and by these and other opportunities as they present themselves help to maintain prices, it will be to the manifest benefit of all in Ceylon, down to the veriest "goyiya." Such a "voluntary tax" from all growers must however take some little time to carry out *thoroughly*, as all interested in the matter must hope to see done; in the meantime I quite concur in what Mr. Mackenzie says regarding the importance of losing no time in our efforts to raise a "joint fund" sufficient to enable us to be represented at the forthcoming Melbourne Exhibition. The "Centenary" affords us an opportunity of obtaining a footing to benefit us for all time in the vast Southern Colonies with their enormously increasing population, the advantages of which can scarcely be exaggerated and which as Mr. Rutherford says may not occur again for some time. In the hope therefore that general and *prompt* contributions will be made to a joint-fund, I shall be glad to subscribe a R200 "sprat to catch a whale."—I am, sir, yours faithfully,

ARTHUR E. SCOVELL.

GIGANTIC CACAO LEAVES.—The leaves sent by Mr. Holloway put the other big cacao leaves entirely in the shade. One is 2 ft. by 10 in., and the other 1 ft. 10 in. by 10½ in.!

INDIAN TEA IN AUSTRALIA.—The *Pioneer*, in reviewing the trade of India, remarks:—"It is especially disappointing to find that the exports of Indian tea, for which it was hoped there would be a great field in Australia, declined in value, no doubt only by a small amount but sufficiently to show that the article is not making its way in the colonies." It is possible, of course, that the export of the previous year was too large to be taken off. Australia is talked of as the land of gold, but in truth the proportion of the people rich enough to afford Indian tea is restricted.

FIJIAN TEA is thus noticed in the Sydney letter of the *British Trade Journal* of Aug. 1st:—It might interest the tea trade section of your readers as well as tea-drinkers to be told that the first instalment of Fijian tea ever offered publicly in this market was sold at auction four days ago, the price realised being 1s 11½d to 1s 2d, duty paid, the said duty being 3d per lb. This sample of pekoes came from the Alpha Estate, Tavileri. With the present revolution in the British fancy as regards China teas, and the increasing demand for Indian and Ceylon sorts, it will be interesting to watch, should, as at present appears probable, this new Fijian industry blossom into any proportions, how far the Australian taste will go in patronizing it. As in London, so here at present, Indian teas are growing favourites, and Fijian may yet work its way in time in like manner.

INDIAN EXPERIENCES.

(*Continued from page* 258.)

With the object of counteracting the deplorable state of things referred to in my last letter, Tea and Chinchona have been planted to a considerable extent both on fresh land and between the lines of the gradually perishing Coffee trees. I have been recently informed on the best authority, that in this district of the Ouchterlony Valley and the neighbouring one of Goodalore, from eight to ten millions of Chinchona trees are being cultivated at the present time, mostly of the Succirubra and Calisaya species, and large quantities of bark are now being forwarded to the London markets. The revenue derived from this source will doubtless help to diminish the deficit caused by the Coffee crop failures, but it is highly problematical whether this source of revenue will long be maintained in the face of rapidly falling prices for all kinds of barks in the markets of the world, owing to over-production in India, Ceylon, and Java by artificial cultivation. The cultivation of Tea would appear to be the planter's sheet anchor for the future, to which he is now turning his attention. It has been amply demonstrated that Tea of excellent quality can be produced in India at similar elevations to the Valley under notice, and that it fetches a fair price in the home markets; and as the Tea shrub has been found to possess a much hardier constitution than that of either Coffee or Chinchona, it follows that its cultivation would be likely to prove of a more permanent nature than either of the last named plants. It is, therefore, to be hoped that the land in the Ouchterlony Valley will not be abandoned to the growth of noxious underwood, but that under the operation of intelligent and scientific cultivation, land that was once clothed with the finest Coffee plantations of the south of India, may, ere many years have passed, be occupied with the Tea shrub.

I visited the Ouchterlony Valley on many occasions during my sojourn in India, and at each visit was more and more charmed with the appearance of the Coffee plantations and the wonderful beauty of the surrounding heights crowned with the everlasting verdure of the forests, from which issued lovely and ample streams of the purest water, which intersected the Coffee estates in their course to the river beyond, and turning many a water wheel on their way. Unlike many Coffee districts, there was ample water here of the purest and best description for all purposes, and yet I never knew the planters turn it to account in the way of irrigation, even in seasons of the greatest drought.

Possessing a delightful climate equally enjoyable to the Englishman and the native of India—a soil, at once of the greatest depth and richest description, capable of producing not only Coffee of the finest description, but also English vegetables of every kind in abundance and of excellent quality, as well as Apples, Peaches, Oranges, Loquats, Limes, Shaddocks, Pine Apples, Pears, and other fruits, and numberless English flowers—this delightful valley seemed to have been set apart by Nature either to be left alone for ever in its pristine beauty of forest and stream, to be the home of the elephant, the bison, the tiger, and the innumerable wild animals and birds that inhabited its forests, or to be changed into a Garden of Eden by the skill and industry of intelligent man, for the permanent benefit of his kind. Instead of that it has run imminent risk of being changed from its primitive grandeur into a pestilential wilderness by the hands of the land speculator hastening to be rich. No better tract of country could be conceived for the settlement of small landholders, both European and native, where by dint of highly cultivating the naturally fertile soil, marvellous crops might have been raised, not only of Coffee, but of many kinds of fruits and vegetables, for the wants of the cultivators and for sale. In no part of the world, I imagine—certainly in no part of Southern India—has the system of speculative husbandry or land jobbing succeeded for any great length of time. If Government, instead of countenancing any such system, had from the first ostered and encouraged the settlement of small landholders, both native and European, in the various Coffee districts of the Presidency of Madras, it would not only have greatly benefited cultivators of the land in general, but it would have been the means, most assuredly, of permanently upholding the land revenue of Government, and instead of the thousands of acres in every district, once covered with Coffee, but now converted into noxious thorny scrub, we should have had well cultivated districts comprised of small but highly cultivated and remunerative holdings, supporting a large population, where, at the present moment, not a soul exists.

There are not wanting indications that the Government of India are becoming alive to the very unsatisfactory state of agriculture in the country, especially with regard to the Coffee, Tea, and Chinchona industries, undertaken to such a large extent by Europeans, and the time may not be far distant when facilities may be afforded settlers of small means to obtain small holdings, which would be almost certain by right cultivation to prove both remunerative to themselves and to the State. The idea that India is but ill adapted to the English constitution is, I think, exploded; at least it is my belief from an experience of seventeen years, that with due care the average Englishman is as likely to live as long and enjoy life quite as much on any of the hill tracts of South India as in any part of his native land.—PLANTER.—*Journal of Horticulture.*

NEW ZEALAND.

The geographical position of Auckland is latitude 36° 5′ south, and longitude 174° 50′ east. Situated as it is on two magnificent harbours the summer-heat is tempered with pleasant sea breezes, while the winters are very mild; and, being subject to no extremes of heat or cold, the climate is, by almost universal testimony, considered to be one of the best in the world.

Meteorological observations, extending over a period of fifteen years, give the following average results:—Mean barometer, 29·939; mean temperature in shade, 59°·6; total rainfall, 44·651. Number of days on which rain fell, 187. During the month (May), which corresponds with November in Great Britain, a good deal of cool wet weather was experienced. The state of the weather to-day (May 21) is—barometer, 29·888; thermometer in complete shade, 58°; under verandah, with roof subject to sun's rays, 58°.

Vegetation makes very rapid growth when moisture is plentiful. The climate somewhat resembles that of Great Britain, though the mean annual temperature is some degrees higher, but more equable, and is very favourable for agricultuarl purposes. Instruction in agriculture and botany are subjects now taught in the Auckland University, and, considering the importance of such instruction in a colony where so much depends upon agriculture and fruit cultivation, it is highly probable that a considerable number of students will avail themselves of the instruction now offered, and in after life be induced to engage in agriculture or kindred pursuits. As an instance of the rapidity with which land may be brought under cultivation and crops obtained, I may mention that I have today seen some Potatoes, fine large tubers of the Hobart variety, which were grown by some new settlers at Hokianga, on land which in the middle of December last was covered with bush. Fine crops of Water Melons, Vegetable Marrows, and Pumpkins grown on the same block of land, have also been sent in to market. It is no uncommon thing here to see Pumpkins of a variety named Iron Bark, weighing from 100 to 115 lb.; and Vegetable Marrows, 20 to 24 inches in length.

Auckland is well supplied with all kinds of European vegetables, the greater portion being grown by Chinese gardeners, of whom there are a good many located in the district. A poll-tax of £10 per head is levied by the Government on all Chinamen landed in the colony.

For some months past I have daily had an opportunity of observing the progress made by a party of

four Chinamen, who have taken a block of about 3 acres of land for market gardening, and I could not fail to notice the systematic and workmanlike manner in which they proceeded in breaking up, laying out, and planting the different beds, every available yard of land being utilised. Their method of planting out some of the crops in rows would, perhaps, not suit the eye of the head of the culinary department of a well-organised establishment at home, for the Chinese, so far as I have observed, do not include garden lines among their implements, they nevertheless succeed in producing heavy crops of good marketable vegetables.

Fruit is plentiful here at present, a steamer having just arrived from Fiji and the South Sea Islands with a cargo of fruit in good condition. The principal kinds brought are Oranges, Limes, Pineapples, Figs, Cocoanuts, Bananas, and Pea-nuts, or earth-nuts (Arachis hypogæa).

The juvenile fraternity in the vicinity of the wharf hail with delight the arrival of an island steamer with a cargo of fruit, and they are quickly alongside the steamer on the off-chance of making a haul.

Among the more rare kinds of fruit I noticed fine specimens of the Bread-fruit tree (Artocarpus incisa), the Japanese Persimmon, also some Walnuts and Chestnuts; the three last-mentioned kinds were the produce of plants growing in Auckland district.

The following are the prices realised by public auction for a portion of the fruit cargo above referred to:—Seven hundred bunches of Bananas were sold for 2*s.* 6*d.* to 3*s.* 6*d.* each; forty crates Pine-apples, 4*s.* 9*d.* to 5*s.* 9*d.* per dozen; forty sacks Coconuts, 7*s.* 3*d.* to 7*s.* 9*d.*; fifteen sacks Earth-nuts, 2*d.* per pound; twenty sacks Walnuts, 5½*d.*; 1000 boxes of Figs fetched 6*s.* 6*d.* per dozen.

I have during the past year visited two exhibitions held by the Auckland Horticultural Society. The exhibits of fruit, especially Apples, for size, quality and variety, I have never seen equalled at any exhibition in England. This morning I examined some fine specimens of Apples, the produce of trees planted on Maori land thirty years ago. The trees, it is said, have never been pruned or received any care whatever, are still growing in quite a wild state, surrounded with "titree," and produce abundant and excellent crops of fruit every year.

A few days ago Maoris were offering for sale here a stock of the "Kumara," a kind of sweet Potato (Convolvulus chrysorrhizus), of which there are several varieties cultivated, the tubers differing in shape and colour just as in the Potato. The "Kumara" forms one of the principal articles of vegetable food of the Maoris.

I believe attempts were made some years ago by Sir Joseph Hooker of Kew, to introduce the "Kumara" into England, but I have never learned with what success.—EDGAR SPOONER, Auckland, May 21. (See *Gardeners' Chronicle*, 1883, vol. xx., p. 601.)—*Gardeners' Chronicle.*

WARAS: ITS COMPOSITION AND RELATION TO KAMALA.

BY DAVID HOOPER, F.C.S.

Within the last four years waras or wars has been the subject of various notes in the *Pharmaceutical Journal*, in which its history, histology, and botany have been discussed by several pharmacologists. The present paper is a supplement to what has already appeared, insomuch as it deals with some chemical and technical experiments with the authenticated drug of Southern India, and critically compares it with the kamala of the Pharmacopœias.

Source and Collection.—The plant which yields the red glands known as waras is *Flemingia Grahamiana* (W. and A.), a small leguminous undershrub growing on the northerly slopes of the Nilgiri plateau, as well as in other districts of India. The sample that came to my hands was from above the Gudalm ghaut, and collected by Mr. M. A. Lawson, Government Botanist in the Madras Presidency. Mr. Lawson has studied the species of *Flemingia* afforded by this part of India, and concludes that *F. rhodocarpa* of Baker is not specifically distinct from *F. Grahamiana*. The fruits ripen in November, towards the close of the north-east monsoon, when they are covered with the peculiar red glands. The drug is collected by cutting off the clusters of pods from the ends of the branches and laying them in the sun to dry for one or two days. They are placed upon boards or paper, as during the process of drying much of the powder falls, and would be lost unless such a precaution were taken. The pods are then pressed or rubbed together by hand over sieves. The powder is mixed with hairs, stones and pieces of stalk; it is readily removed from these impurities by finally passing it through a fine muslin or lawn sieve. Although the plant occurs pretty frequently in Southern India, very little seems to be known by the natives of its colouring or medicinal properties, and from inquiries made of Canarese traders north of the Nilgiris and Tamil people to the south, no information could be gleaned of its glands being a marketable article; but at a recent exhibition of the Agri-horticultural Society at Madras some of the powder was shown by a native dyer.

Terminology.—Waras, warus, wurrus, wurrhus, wors, wars, vars and huars are some of the names which have been applied at different times to the glands from Flemingia pods, and like most Eastern words, when translated into English characters, are variously written with an endeavour to represent the foreign accent. Daniel Hanbury, in 'Science Papers,' gives the Urdu or Hindustani name of the drug as used by the merchants at Aden, and renders the English equivalent as "waras." This word is distinctly bisyllabic in pronunciation; it signifies the "saffron"-like colour of the pigment, and, as Hanbury states, very probably originated with the Muhammadans of India. "Waras" has always been used by the authorities at Kew in their reports and correspondence, but Professor Flückiger and Dr. Dymock resent uniformity in this respect by continuing to employ the term "wars."

Characters and Tests.—Waras is a granular, mobile powder of a deep purplish-red colour, and without any marked odour or taste. Under the microscope it is in the form of cylindrical or subconical grains with oblong resin-cells arranged in stories in the interior. The powder ignites like lycopodium when thrown into the flame of a lamp. The specific gravity is 1·37. It is insoluble in cold water; when mixed together it at first floats on the surface, and if left in contact, it slowly becomes wetted, and sinks. If, however, it is rubbed up in a mortar before added to the water, or if it is boiled in it the glands become broken and a bright yellow emulsion is formed; if this emulsion is allowed to stand the resinous matter will subside and leave a yellow, sweetish solution. The greater portion of waras is dissolved by ether and warm alcohol, the resulting solution being of a bright orange-red colour; when treated with caustic alkalies the solution is intensely red. It sinks in oil of turpentine, imparting a slight colour to it after a time. When rubbed up in a mortar with water and the mixture submitted to distillation, an odour between that of caraway and lemon was observed in the distillate, and a greasy film in the receiver indicated traces of a volatile oil as its source. Heated in a crucible, it at first blackened, giving off aromatic vapours, then intumesced and evolved inflammable gases which burnt with smoky flame; when the charred mass was destroyed by prolonged ignition a residue was left of a grey-coloured ash consisting mainly of finely divided sand.

Chemical Composition.—The resinous colouring matter which constitutes the chief part of waras has a brittle consistence; it is of a deep garnet-red colour in bulk, and orange-red when observed in thin strata. It is soluble in ether, alcohol, benzol, chloroform, carbon disulphide, acetic acid, and in solutions of potash, soda, ammonia and the alkaline carbonates. It forms soluble compounds with lime and magnesia. It is precipitated from its solutions in the alkalie s

by acids in an apparently unaltered condition. Sulphuric acid dissolves it in the cold. Heated with nitric acid it rapidly oxidizes, yielding yellow-coloured products and a resin soluble in alcohol. A solution in spirit is partially precipitated by acetate of lead. Diluted alcohol appears to separate it into two resins; a soluble one of a yellow colour, and an insoluble one of a deep red. Heated with potash or soda an odour of citron is evolved. An ethereal solution of the resin allowed to evaporate spontaneously deposits a mass of crystals. The crystals are of a lighter colour than that of the surrounding red resin examined microscopically they appear as crops of acicular prisms radiating from a common centre. Ether and other liquids were added with a view to remove the crystals from the resin or *vice versâ*, but but all the volatile solvents tried resulted in forming a solution of both, and this rendered the separation an insuperable difficulty.

Besides the resinous and crystalline principles of waras, there is a volatile oil, already noticed, albuminous and saccharine matters soluble in water, and an amount of ash rarely falling below 5 per cent.

* * *

Waras as a Dye-Stuff.—A dye-bath was made of waras, with solution of alum and sodium and potash-sium carbonates, and in the boiling liquor were separately immersed pieces of silk, wool, linen and cotton. The colour formed on the silk was a brilliant orange-brown, of a much superior tint than that on the wool, while the linen and cotton were of a dull brown, and became fainter when washed. The colour being adapted for an animal fabric, as silk, more than for vegetable tissues, is another indication of its alliance to kamala, an article used in India and elsewhere essentially as a dye for silk.

To obtain a more valuable testimony to its artistic use Mr. Lawson forwarded a large sample of waras to Sir Joseph Hooker, and from him it was sent to Mr. Thomas Wardle, the well-known silk dyer, of Leek, Staffordshire. Mr. Wardle, made several experiments with the dye upon mulberry silk, Tassar silk and wool, and reports as follows:—"This substance contains only a small amount of colouring matter compared with the vegetable yellow dyes of commerce, and no colours can be obtained from it which will bear comparison in depth and richness with those of kamala, for which, it is stated in 'Kew Report' for 1880 it is used as a substitute, and which is certainly a very much more valuable dye-stuff. As far as my observations have gone waras is inferior to kamala in permanence, as regards the action of light. The colour produced by waras is easily turned brown by alkaline solutions, whilst kamala is only slightly reddened. Both dyes, however, resist the action of acids very well. Waras is a suitable dye for silk more than for wool, and it is useless as a dye for cotton. I have tried it on cotton with most of my mordants, as well as without mordant, and the result is only a very pale shade of yellow."

Sir Joseph Hooker, on receiving the specimens of China silk dyed with waras by Mr. Wardle, stated that they showed great delicacy of tint, and he did not see why the dye, the use of which in India from an indigenous source appears to have been previously unknown, should not have at least a local interest.

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

PARIS, September 10.

There is a race of cattle in France, which is making most remarkable progress and merits the attention of importers—the *Charolaise*, called sometimes the "Nivernais." It is over a century since its amelioration has been taken in hand, and with astonishing success recalling in this sense the onward march of the Angus in the Lowlands of Scotland. The nursery ground of the Charolaise, or it may be styled the French Durham, is in and around the department of the Saone-et-Loire, a part of ancient Burgundy. Perhaps the climate, soil, and rich herbage have done as much for the race as positive selection. The climate is mild, rather humid than dry; the soil is fertile, generally a calcareous or a sandy clay permeable, and particularly favorable for the growth of first class clovers and grasses; the undulatory character of the land, and the superior advantages of being well watered. The pasturages, in point of richness and abundance, yield in nothing to those of Normandy. The Charolaise was the race of cattle which supplied the butchers of Lyons with the fine, rich, juicy meat for which they were so long celebrated.

When Bakewelle, Colling, Tomkins, &c., improved the Durham and Hereford, or the splendid ovine races Dishley, Southdown, &c., what did they do? They only introduced the improved breeds into those places contiguous to where they had been ameliorated, but above all where climate, quality, and abundance of herbage existed.

However, each breed has its place. The race Charolaise is also special to the districts of Nivernais and the Cher. It possesses the precious aptitude for easy and economic fatting, as well as for work; and the ameliorations while changing conformation have conserved the animal's rich nature, sobriety, rusticity, aptitude for work, and putting up of flesh. Under the head of milking qualities much is to be desired. There has been a prejudice against crossing the Charolaise with the Durham; after the second generation the animals display better conformation, but the new blood has been found to weaken the rusticity of the race, injure fecundity, and generally diminish aptitude for heavy and sustained work. It is not the less a fact notwithstanding that where the Charolaise has been crossed with a Durham bull, and when meat was only the end of the stock breeder, the result was satisfactory.

The Nièvre, where the Charolaise also flourishes, is one of the ten departments of France richest in cattle. Yet when Arthur Young visited that locality in 1788, it was the most backward part of the centre of France. It was then the custom to import bulls and cows from Switzerland, but it was only in 1719 that a Charolais farmer named Mathieu gave the first impulse to the selection of the breed of cattle now so famous. He imparted an impulsion to the rearing of cattle on a great scale to supply Lyons with rich juicy beef, for the race put up flesh and fat with remarkable rapidity. The new race spread quickly into the neighboring departments, and led to converting the cold calcareous lands into pasturages, while raising their value from fr. 5 to 20 fr. an acre. The Charolaise was found to be peculiarly excellent for fattening on pastures, and the latter were easily prepared—everywhere that the soil wanted hands or its humidity was an obstacle to lucrative culture.

Several points of the original Charolaise remain today unchanged, such as the hide which is uniformly white or of a cream shade. The body is thick and cylindrical, resting on legs short and but little voluminous; the head is short but broad, and the nostrils well open. The line of the back is perfectly straight; the lumbar regions wide, the buttocks thick and rounded behind, while the tail is planted low. By the native fineness of its qualities the Charolaise is admirably predisposed for

amelioration, especially in precocity. This M. Louis Massè has demonstrated since 1822. His principles were liberal, even high feeding of the young stock both in summer and winter, and the giving extreme care to those selected for breeding. It was by consanguinous selections or breeding that the race attained its present pre-eminence. M. Massè never imported a bull, he reared all his own. He patronized no Durhams as he had perfected the Charolaise before the short-horns were introduced into France.

The characteristics of the Charolais are a short, broad, conical head, with wide respiratory organs; the horns are round, small, ivory-white pointing outwards, and with a tendency to turn up at the tip; the eyes are large, prominent, lively, albeit mild; the ears are broad, raised, and possessing little hair; the back straight, and well-covered with muscle; the loins wide, thick, and short; the sides lengthy and well-arched; the thighs highly developed; the tail short, fine at the end, and not much covered with hair. The limbs are very elegant well-set, and about one-third of the height of the body; there is an absence of all angularities; the skin is mean thickness, of remarkable suppleness, covered with fine lustrous, but not plentiful hair. The butcher qualities are extremely well developed. At one year old, the height of the animal is 45 inches, at six years old 57 inches. A Charolais fat ox, aged between 5 and 6 years, yields 8 cwts. of prime meat.

The Charolais is not a race celebrated for milking qualities; the greatest yield does not exceed 8 to 10 quarts per day, and 6 gallons are necessary to produce 2¼ lb. of butter. The calf does not consume more than the half of its mother's milk. Careful housing and unstinted feeding of the stock during their first winter compose the secret of the amelioration of the breed. The bullocks are trained to work when 30 months old, and the heifers are delivered at two years to the bulls so as to have first calf in the current of the third year. Independently of their mother's milk, the calves suck twice a day, they also receive a supplement of food consisting of roots, meals, and choice hay as soon as they can use it. They generally wean themselves preferring the herbage to the teat. Some calves teat up to 7 or 8 months. It should not be forgotten that the Charolaise race is appreciated for its working qualities, and these qualities suffer as the butcher's ideal of precocity is approached.

It is said that the Durham failed in the Nivernais, because the pastures were not rich enough, and the transitions of temperature too trying. It was found too, that the crossings between the Durham and the Charolaise, after the fourth generation rapidly degenerated. The Charolaise, in conclusion, possesses the great advantage of thriving well on poor, rough pasturages, and the cows are remarkable for their fecundity. The race has its special Herd Book.

The "Black Rot" has not made its appearance so far in the Medoc vineyards—the Claret region of France. In the district of Vendée another grape malady has been recognised quite independent of the black-rot. On a bunch of grapes, often a third, and even the moiety of the berries, are dried—grilled in fact, while the other moiety remains green, but the berries fall like ripe pears on the slightest touch of the hand. The berries strewing the ground, are shrivelled and decayed. On examining the berries thus spontaneously fallen, they will be found to be profoundly changed, presenting a brown spot, slightly hollow, and the cells dried up into filaments of fungi. It is also a mushroom, *Coniothyrium diplodiella*, which is the cause of this fresh scourge, and for which there is no remedy. Doubts exist as to whether the phylloxera has penetrated into Algeria. Finer grapes—white varieties—have never been supplied to the Paris market than what the growers of Algeria have been sending since six weeks. It is said, that with the view of securing a soft flavor and agreeable bouquet for the wines of Algeria, proprietors intend to adopt henceforth the plan of pressing the grapes in the vat by men's feet, and not by cylinders. When the latter are employed, the seeds or pips of the grapes, on being crushed, impart an unpleasant sharpness and rawness to the wine.

Professor Duclaux of the Agronomic Institute has corroborated the experiments of Professor Soxhlet of Germany, relative to the action of light and air, on the fatty matters of milk, in the end to prevent the deterioration and rancidity of butter. When a morsel of butter, quite fresh, is melted and filtered into a tube, it loses in a few days, often in 24 hours its natural flavor, and acquires the taste of tallow. This is due to the oxydation of the volatile matters which give to the butter its taste and aroma. At the same time the coloring matter of the butter whether natural or artificial, also disappears, the butter becoming paler, and so changing gradually inwards. The change is not due to light alone, but to the slow and penetrating action of oxygen—the air only gradually making its way inwards. The oxydation develops cabonic acid, and destroys the volatile acids. Fresh cream contains 7 per cent of the latter; after two months' exposure to the air in the shade the percentage falls to 3½. Keep butter from contact with light and air is the only practical conclusion so far.

Parmesan cheese when grated—and an ingenious machine has lately been invented for this purpose—is much employed in cookery. Signor Rava of the Liodi Dairy School, remarks, that the milk for Parmesan cheese must have a certain degree of acidity, only inferior to that which produces coagulation at boiling point. In milk thus acidified, it requires to be less heated, but exacts more rennet. Whole milk will be longer preserved fresh, as the temperature is lower, hence cool milk in order to secure a good deal of butter, and at same time to possess the creamed milk in the best conditions to make cheese.

Holland possesses 900,000 milch cows: one-third of this total meet the native wants for milk and butter, so that the milk of the remaining 600,000 is manufactured into butter and cheese for exportation. If a cow yields 660 gallons of milk producing 220 lb. of butter, business must be brisk. Frise produces the finest butter. In 1885 Holland exported 34,000 ton of cheese of all kinds, from the Edam and Gouda to the Leyden stuffed with cloves and caraway seeds. Holland may be considered as the head quarters of artificial butter, of which Napoleon III. may be viewed as the real inventor. Since he delegated in 1886 M. Mège-Mouriez to study the preparation of a substance for the navyand the working classes that might replace butter.

In 1869, Mège-Mouriez took out his first patent in England, but it was only in 1873 that he really commenced the industrial preparation of *Margarine*. When beef fat is deprived of its membranes it is chopped and placed in a boiler: one ton of suet to 66 gallons of water, 2½ lb. of Carbonate of potash and the minced stomachs of sheep or pigs are added, when the mass after 24 hours' ebullition separates into stearine and oleo-margarine. The liquid is run off into linen sacs; but as the stearine requiring a higher temperture to melt, it remains in the sacs, and is employed to make candles: the oleo-margarine exudes is collected in tin vases, and when cooled, washed and moulded, is sold as margarine.

When destined for simili-butter the margarine is mixed with ground-nut oil in the proportion of 5 to 30 per cent, following the season: to ten parts of this mixture are added four of uncreamed milk, and the chopped raw udder—ocasionally of cows. The whole is rapidly whisked for two hours in a churn, and the "butter," when taken off is cloured as usual. A quantity of real butter is added according as a superior quality of the artificial article is demanded. The product is nutritious, only its fabricants generally desire to pawn it off as veritable butter. It is subjected in Paris to the same tax as the latter. Holland takes nearly all the fat of the Paris slaughter-houses, and sends it back as artificial butter but so marked.

The recent rains have had but little effect on the beet harvest: the yield of roots, and their saccharine richness will be less this season by a good one-third. Fa

mer sare, however, more interested in the proposed Congress for the discussion of the sugar bounties. French farmers allege that Germany and Austria—why not too Russia, possessing peculiar natural advantages for the culture of sugar beet—would kill the sugar industry in France if the bounties were withdrawn.

A new variety of tares or vetches is being successfully tried. It comes from Hungary, and is called *Vicia multiplicata*. It is sown in August at the rate of 141 lb. per acre, mixed with 56 lb. of rye. In the early days of May it yields rich and abundant cuttings; the vigorous aftermath of the vetches is allowed to produce seed.

After a sow has littered, several farmers have the teeth of the young pigs examined, and whenever any of them are unusually long and pointed, cut or file them down on a level with the jaw-bone. This prevents the young when sucking from biting the mother, that, which often drives the latter to devour them. It is a wise precaution to leave the bedding in soft straw, cut into lengths of five inches so as not to penetrate the eyes of the young, nor adhere to the teats of the mother. If the straw be too long or too plentiful, the litter may be smothered. Some hog-rearers run a rest in wood 12 inches high and 9 from the wall of the cot round the latter, so that the sow on lying down cannot crush the young.

A SKETCH OF BRAZIL.

BY JAMES W. WELLS,

M. Inst. C. E., F.R.G.S., Corresp. M. Soc. de Geographia de Rio de Janeiro.

Being some remarks upon the Commerce and Industries, the Railways, the Sugar Factories, the Finances, Slavery, and Immigration and the immediate future of the country.

The seaboard of Brazil is 4,922 miles in length, and as this runs from north to south it will easily be perceived what a variety of productions the soils and climates of so many degrees of latitude must necessarily produce, and this being so, it has caused the export trade of the country to be divided into several distinct groups, for although there is a certain amount of intercostal traffic, practically, these groups are really independent of each other. In order to more fully carry out my meaning, I will specify these various groups of exporters.

No. 1.—Pará, the northern terminus of the Brazilian coast trade, for there is no steam coast communication whatever north of this port, not even to the neighbouring Guianas—is the head-quarters of the great india-rubber trade, and all the productions of the great Amazons Valley. Forming a more or less connected link of mercantile interests with Pará, are the markets of Maranhao and Ceará.

No. 2 group, comprising Pernambuco and Bahia, with their adjoining minor coast cities of Natal, Parahyba, Maceio, and Aracaju, is as essentially distinct from the Para trade as though these respective centres were in different countries.

No. 3 group comprises Rio de Janeiro and Santos and their adjoining coast cities.

No. 4 group represents Rio Grande do Sul and the other southern seaports.

The export trade of these four groups naturally consists of the chief local productions, the nature of which serves to indicate the character of the country. They are as follows:—

I will mention them in their order of importance, in the trade of each group.

No. 1.—India-rubber, Brazil nuts, medicinal balsams, herbs and roots, cotton, cabinet woods, cocoa, and sugar and hides from the southern cities.

No. 2.—Sugar, cotton, tobacco, hides, and a little of cabinet woods and piassaba fibre.

No. 3.—Mainly coffee, with a little sugar.

No. 4.—Tallow, hides, horns, bones, grease, and jerked beef.

Thus it will be observed how different to each other are the chief items of exportation of these four essentially distinct mercantile sections of Brazilian trade, and, as a matter of fact, the heads of houses in each of these divisions have usually formed their opinion of Brazil according to their individual local experiences, and thus it is that many an old merchant of Brazil will form a pessimist or an optimist view of the future, or even present career of the country, accordingly as he may be biassed by the fortune or misfortune of his particular trade. And it would be really puzzling to an outsider to listen to the enunciated views of a triumvirate of old Brazilian merchants composed of an india-rubber merchant from Pará, a sugar merchant from Pernambuco and a coffee merchant from Rio de Janeiro, and consequently I can only conclude, that it is through the ups and downs of these various sections of the mercantile community, that there exists such a clash of opinions with regard to the welfare, progress and probable future of the country.

I will now give the statistics of the imports and exports of Brazil for the past three years. In order to make their values more readily appreciable, I have reduced the currency in round numbers to sterling at an average rate of exchange, 21 pence the milreis.

Year.	Imports.	Exports.	Surplus.
1883	£16,053,000	£17,364,000	£1,311,000
1884	£16,801,900	£18,753,000	£1,951,100
1885	£14,261,300	£19,596,800	£5,331,500

Table showing the annual value in milreis of the chief articles of export, at the end of each decade from 1841 to 1881.

	1841.	1851.	1861.
Coffee	17,804:438$	32,603:951$	72,919:389$
Sugar	11,892:224	15,779:045	10,299:739
Indiarubrer	198:203	1,046:610	3,402:335
Cotton	3,919:997	5,995:905	4,581:948
Tobacco	652:984	1,702:927	2,376:435
Totals	34,467:846	56,828:438	93,579:847

	1871.	1881.
Coffee	84,503:900$	126,134:000
Sugar	23,308:818	25,935:000
Indiarubrer	7,501:491	11,855:700
Cotton	24,423:928	5,114:600
Tobacco	6,349:294	7,553:600
Totals	146,087:440	176,593:000

The considerable increase of the exports of cotton in 1871 was owing to the high prices of this product during the American Civil War. Now although there are yet vast quantities of cotton plants in the distant interior, the present prices are not sufficiently remunerative to compensate the great cost of transporting the cotton long journeys by mules, over rough and rugged trails. The plants, like many another production of the interior, await the advent of railways.

The total length of the railways in traffic and in construction represented 59 distinct railways—27 of which were worked at a profit, 14 at a loss, the returns of 9 were unpublished and 9 were yet in construction.

Of the railways that are able to pay a dividend about 5 per cent. from profits derived from traffic and independently of guarantees, they are still only 9. Of this number, 1 belongs to the State, 1 to an English company and 7 to native companies.

In such an essentially agricultural country as Brazil is, it can easily be understood how the returns of the various railways must necessarily vary from year to year in accordance with the good or the bad crop seasons. The latter part of the last year and the present new year have been times exceptionally favourable to railway interests in Brazil on account of the great coffee crop in the south and the equally great sugar crop in the north. In São Paulo the railways have been so congested with coffee that the means have been insufficient to carry it, and in many parts, the planters have had to revert to the old time mule troops to get their crops to market.

The generality of railways in Brazil have been constructed to supply the wants of quite local requirements, but there are a few that have much more ambitious objects in view, and in order to form an idea of the probable course of the future trans-continental railways, I will specify them.

THE SLAVE QUESTION AND IMMIGRATION.

The number of registered slaves in Brazil in 1883 was 1,346,648; in 1884, 1,240,846, and in 1885, 1,133,228. Now the number must be considerably under a million, or more than one-third less than the number three years ago.

Thus it will be seen that slavery in Brazil can only last a very few years more, and the abolitionists will certainly not rest until the whole of the empire is liberated from this curse to the country. And even now there are many large districts and municipalities that joyfully boast of having freed the last slave within their boundaries.

I have often heard in Brazil—an opinion expressed by English residents—that the final extinction of slavery will be the death blow to the profitable cultivation of coffee, an article that at present constitutes the main strength and wealth of the country. It is believed that the freed negroes and their descendants will not work, and that it will be impossible to obtain free labourers in sufficient numbers and at such wages as will ensure a profit to the planter. This idea was, of course, derived from knowing the disastrous results that ensued in Jamaica after the sudden emancipation of the slaves there, and before any time had been allowed to substitute another system of labour. To say that such results will or will not eventually occur in Brazil is only to make a hypothetical assertion, and a supposition that it will do so, I am not disposed to endorse for the following reasons:—

1st. My experience on the coast and in the interior has proved to me that the free black man (the blacker he is the better) is by a long way a far more valuable citizen of Brazil than the ordinary white-brown matuto (peasant). In the interior, whenever I came across some rare example of thrift and industry, in nine cases out of ten it was the work of a family of negroes. The best muleteer I ever had was a negro; the best navvies I have ever employed on works were negroes; the most industrious farmers I have met with were negroes, and the most intelligent mechanic I have ever employed in Brazil was also a negro.

2nd. On many of the great coffee estates the planters are wisely training their blacks to habits of industry, by limiting their hours of work, and paying them wages for extra work, providing them with comfortable quarters, well lighted, clean, and commodious and by giving each family a plot of ground where, by working in their off time, they can acquire money, and even free themselves if they so desire. The result will be that when the time for a general emancipation occurs, these blacks will naturally prefer to follow the comfortable lives they have become habituated to—a life that many and many of our poor farm labourers would envy. Unfortunately these wise planters are few in number, and in the generality of plantations I am afraid the lot of the poor black is a very hard one.

3rd. In north Brazil, where the emancipation movement has made greater progress than in Rio de Janeiro and Minas Geraes, it is now a matter of fact that labour is cheaper and more plentiful than it was say ten years ago, and where large sugar planters have informed me that they now prefer their free to their former slave labour.

4th. One more reason I will quote, and that is the most important, for it is a demonstration of a successful effort to entirely substitute slaves by another system.

In 1885 an important coffee planter and a member of the House of Deputies, explained to his attentive auditors in the House how he thought he had solved this problem. After selling some of his slaves and freeing others he contracted with a number of families some Portuguese, some Brazilian, to squat on his estate. He provided house, ground, plants,—some bearing, some developing,—advanced provisions, superintended general operations and the disposal of the crops. The labourers, on their part, cultivated the soil, collected the crops and worked in the mill house when required. The net proceeds were divided equally between the two parties, and each was satisfied and contented. It is practically a co-operative association of capital and labour, where it is to the labourer's advantage to exert himself to the utmost.

Having thus briefly sketched a few reasons for not endorsing the pessimist's views of the disastrous consequences to Brazil of the extinction of slavery (I could easily quote other reasons, but time will not permit) I will now say a few words on immigration.

Amidst such varieties of soil and climate as the vast territory of Brazil offers, it is perfectly admissible that many natural conditions must necessarily exist that are favourable to the requirements of the emigrant from the crowded old world. Such conditions do exist, but without better communications and an alteration of certain social difficulties, immigration on any large scale in Brazil must result in failure—that is, immigration of poor labourers unaccompanied by capital. They might certainly substitute the million of slaves and work with the planters on co-operative principles. But this is not what I especially allude to in speaking of immigration. I refer more particularly to a means of populating the vast undeveloped areas even of the coast districts, and then of the great interior—verily a world in itself.

The Government of Brazil has long since recognised the necessity for a great progress of the country in a spontaneous influx of immigrants, and during the past twenty years the State has not only granted concessions of large tracts of lands and other favours, but has also actually expended about 4,000,000*l.* sterling in promoting the acquisition of settlers, unfortunately not only with very sterile results, but also in many cases with most disastrous failures that brought ruin and misery upon numerous poor misguided people.

The past non-success of immigration in Brazil can be traced to a variety of causes, amongst which the not by any means least important is the physical configuration of the country, a circumstance that has rendered the development of communications with the distant interior both difficult and costly. In the Argentine Republic this great obstacle does not exist, for there we find an immense and practically flat area, threaded by thousands of miles of great navigable rivers, all converging to a common outlet at Buenos Ayres. These great advantages are of immense importance in the settlement of a new country, for the most outlying borderland has thus a means of obtaining a road to a market for produce, and great lengths of railways can be laid down at a relatively inexpensive outlay.

In Brazil, excepting the Amazons Valley and in Maranhão, there practically exist the reverse of these advantages. In these two exceptions large flat areas and riverine systems are found somewhat similar to Argentine Republic, but although the soil and the rich vegetation is all that can be desired, the climate, without being absolutely a deterrent to white labour, is certainly far less amenable than that of the Southern Republic. In the other parts of the Brazilian coast, say from Cape Frio to the Province of Santa Catharina, the seaboard contains some of the greatest elevations of the country, and although the beautiful climate and many fertile tracts of these highlands and of the tablelands of Minas Geraes, Sao Paulo, Paraná and Rio Grande do Sul are so well adapted to a white settler, the physical configuration of the country has hitherto caused the extension of Railways to be a slow and costly progress. The coast regions of this section of Brazil are the sea face of the great Brazilian tableland, the approach to which is generally rugged and mountainous. The summit is a series of great undulations or earth waves, and the land and rivers drain towards the interior and find an outlet in the River Plate. Over these vast regions the only communications were formerly merely rough bridle paths and it can be easily comprehended what a gigantic mistake it was to induce a crowd of poor impecunious immigrants to go so far inland where they were left helpless to feed on the grass like cattle, whilst their crops had time to grow, even if they had spirit and energy sufficient to plant, and yet if they had been able to raise any crops, their value would have been consumed in a long and weary march to a market.

But every year these physical difficulties are disappearing with the spread of railways that at vari-

ous points along this southern coast have climbed the steep sea wall, and are spreading their ramifications slowly but surely far and wide over this fair land. In Sao Paulo is especially noticeable the great benefits derived from a network of railways, built where they were wanted, and not as in some parts of Brazil where they were not required. The construction of these Sao Paulo railways has certainly induced immigration, for more settlers now flock to this province than to any other.

Yet another obstacle is apparent, under existing circumstances, to the spontaneous adoption of even this southern section of Brazil by any of the streams of emigrants from Europe, and that is, that the immediate coast regions are in the hands of large proprietors who unprofitably occupy areas far larger than the requirements of a modern system of agriculture demand (for plough and manure is dispensed with except in rare cases). These proprietors are naturally anxious to welcome the immigrant, not however as an independent settler or small farmer, but as a laborer to substitute his slaves. This the immigrant naturally does not want; he looks rather for independence and a possible fortune, results that are not likely to occur so long as he wastes his best years in working for small wages or on the perhaps doubtful co-operative system. For although this system may have great advantages to an impecunious immigrant, it cannot be acceptable to one with a moderate capital.

I have lately heard of a new feature in the colonization of Brazil, and that is the purchase of a large tract of land in Paraná by a syndicate of British capitalists, I can heartily congratulate them upon their wisdom. This is essentially what is required, foreign capital in combination with foreign labour will render the immigrants to such a colony independent of the paternal but cumbersome care of the Government and also of the "old man of the mountain," the old great landed proprietor. I anticipate eventually great success to this enterprise.

At present the total immigration in Brazil is between 20,000 to 25,000 per annum, a mere drop in the ocean to so vast a territory. These people consist mainly of Portuguese, Italians, Germans, Austrians, Spaniards, Poles, in the proportion respectively of 87, 59, 12, 6, 6, 4,

THE IMMEDIATE FUTURE OF BRAZIL.

The best estimation of the future of any country can only be a surmise, but if the calculations are based upon facts that warrant the drawn conclusions they must necessarily carry with them a certain amount of faith. At the same time, there are many erroneous ideas with regard to Brazil that must be dissipated before considering such a theme.

Fristly. The general idea of Brazil is that it is a vast and universally fertile land. Secondly. That it has a very hot tropical and unhealthy climate generally. Both of these ideas are wrong, for with regard to the former, the larger part of Brazil is covered with comparatively desert savannahs of grass or scrub, well watered, certainly, but unfit for anything except pastoral purposes. This fact detracts the value of a very considerable portion of the huge country; still, even discounting these wastes, there are many, many wild and uncultivated sections of the country that offer a very fair soil, but not by any means exceptionally so. As to the climate, I maintain that no part of the tropics is to be comprised to Brazil for general mildness and healthiness. On the coast yellow fever and agues occasionally appear, and in some of the great riverine valleys, insect pests and intermittent fevers quite prohibit any settlement by white folks, yet away from land-locked parts of the coast and the lowlands of the interior there are vast regions where the climate is all that a human being could desire. Even in many parts of the great Amazons river the climate is perfectly healthy and enjoyable.

Now the population, of about 13,000,000 of inhabitants must not be estimated as a wholly productive factor, for when the whole exports of the country are only 20,000,000$, it will be seen that there is something wrong, and really fully one-half of this population must be dismissed from one's calculations as a non-productive element, at any rate for the present, for this half is scattered so thinly over the vast area of the interior, that the people have to vegetate as the trees around them, they neither export nor import, for the way to the coast is long and weary, and prohibitively costly.

A casual visitor to the interior would be hastily disposed to condemn these country people as the personification of indolence, and be disposed to attribute the cause to the enervating effects of a hot climate. But a long experience with these people leads one to draw other conclusions. I attribute two main causes to the production of this state of apparent enervation and degeneration of races, namely, slavery and want of communications. One of the ill-effects of slavery, that has been coeval with its existence in every country (and that is especially rampant in Brazil), is the destruction of the dignity of manual labour that, by carrying with it a sense of odium or even disgrace, has naturally done much to undermine the natural forces of a once energetic race. I will give an example of how this feeling pervades even the educated classes that ought to know better. On one occasion, when I was directing some public works, I took off my coat and rolled up my sleeves to show the native bricklayers, what was my idea of bricklaying, and how I wanted it done. In consequence of this my assistants, young Brazilian engineers, promptly dropped the courteous appellative of Senhor Doutor that they had hitherto addressed me by, and I became thenceforth simply Senhor Wells. I had lost caste. But much of this false shame is wearing away, for now many a Brazilian gentleman can be seen carrying a parcel in the street, an action that formerly would have been looked upon with absolute horror. The want of communications to markets for local surplus productions has also largerly contributed to foster the lethargy of the people, by destroying all stimulus to work for something beyond actual necessities. Yet beneath this indolent exterior, I have found on many and many an occasion with these people a latent power of endurance and a capacity for excessively hard work—not fitfully, but day after day, week after week, and month after month, sustained under heat, privations, and insect pests, without a murmur—that is really surprising and only proves what these people will do for those who know how to handle them.

Therefore, when these facts are considered it will readily be admitted. I believe, what a change will take place, socially and commercially, when slavery is finished, immigrants arrive, and railways reach the interior. Immigration and railways are indispensable, but one without the other will only produce failure.

Amongst those people who are rather misty in their geography, it is customary to speak of Brazil, or the Brazils as they call it, as one of those South American Republics. It is hardly necessary for me to say that it is the only monarchy on the Continent (if we except British and Dutch Guiana), but it has generally existed calmly in a peaceful vortex surrounded by a whirl of revolutions in the neighbouring republics. In Brazil there is, like in every monarchy, a republican party and also a separatist party, but the influential people of the empire are so compromised in the stability of the State (whatever political changes may take place) that it is to their own advantage to see that the foreign credit of the country is not jeopardised, for the internal debt of the country is more than three times that of the foreign debt a factor of security to the foreign bondholder that no other South American State can show.

One of the most important results that I anticipate will ensue from the construction of the great inland railways will be discoveries of gold, silver and diamonds. It is true that the old Portuguese colonists did do an immense amount of mining and were extremely successful (in 1753 a fleet arrived in Lisbon from Rio with bullion to the value of £3,000,000 sterling), and yet when one traces on a map of Brazil the districts that at best were only superficially explored and sees the vast areas of Brazil yet unknown, well, one cannot but think that there are as yet "as good fish in the

sea as ever were caught," or in other words, there are probably as rich mines yet waiting for discovery in Brazil as ever were worked. I believe the time will yet come for a gold rush to Brazil, that will lead eventually to its being peopled and developed as California, Australia, and Southern Africa have been.

In this necessarily compressed review of matters, Brazilian, I have not been able to enter so fully or so clearly into a explanation of the purport of what I had to say, but I will conclude by stating that I do strongly and emphatically believe in a great and prosperous future career of this vast empire of 3,207,800 square miles. Troubles may come, but troubles will go, and Brazil will flourish for—well, a very long time.—*Chamber of Commerce Journal.*

TEA ANALYSES: VARYING RESULTS.

We draw attention to Mr. Cochran s interesting letter, further explaining the results of his recent analyses of green tea leaves. The conclusion forced on us is, that it would be of importance that planters should have before them the results of analyses of teas grown at varying elevations, and, above all, that such analyses should be spread over each season and every month of the year. For it is now obvious that not only do the constituents of tea differ according to soil and elevation, but that they are most extensively affected by the meteorological conditions of season. We believe we are correct in saying that in proportion to the percentages present of theine and potash, so is the value of well manufactured tea, and Kellner's analyses have proved conclusively that, while those constituents are most abundant in warm, genial summer weather, they are reduced to exceedingly minute proportions by the cold of winter. The experiments having been made in Northern India, where the extremes of summer heat and winter cold are much more marked than in Ceylon, it is, of course, probable that the contrasts between the results of analyses in May and November, may not present such violent differences in Ceylon as was the case in India. But there can be no doubt, that similar variations will be here shown, for we know without the aid of chemistry, by the tests of the London market, that our teas gathered in cold, droughty, windy weather have sold at lower prices and evoked very different opinions amongst brokers, than those gathered and manufactured in warm, mildly moist conditions of the atmosphere. The scientific conclusions resulting from such analyses as those of Kellner, the results of which Mr. Cochran placed before us in Ceylon, and those which Mr. Cochran himself has made or may make, possess a purely technical interest of no small value. But we need scarcely point out to intelligent planting readers the importance of the results in a practical and cultivator's point of view. There seems no reason why careful pruning and other treatment of tea plants should not be successful in inducing the heaviest possible yields of leaf in those months which have been proved by scientific and practical tests to give the largest proportions to the vegetation of theine, potash and phosphoric acid, on which the economic and commercial value of the tea leaf so largely depend. Mr. Cochran feeling certain of the correctness of his process for ascertaining the proportion of theine (the crystals of which are very beautiful, largely resembling those of quinine), it is obvious that further analyses are required to settle the question whether the Torwood proportion is normal or, from certain causes, exceptional. Indeed, there is no reason why, if Mr. Cochran's attention were specially directed to the matter, the result of a series of analyses might not be to enable planters so to modify the processes of withering and fermenting as to *retain* in the dried leaf a larger percentage than is at present done, of the theine and potash, which are evidently in large proportion in the green leaf, and which perhaps (?) may be carbonized in the great heat of the roasting process.

MR. COCHRAN ON THE ANALYSIS OF GREEN TEA LEAVES.

Colombo, 4th October 1887.

DEAR SIR,—I shall be glad if you will allow me to refer to your remarks of 28th September on my analyses of green tea leaf. First, as regards the drying operations,—these were necessary, in order that the leaves might be reduced to a fine state of division, suitable for the application of solvents. To avoid as far as possible chemical change being produced in the leaves, the drying was conducted at a temperature below 160° F. except in the case of sample No. 4, during the drying of which the temperature for some time was considerably above this limit. The powdered and sifted product had a fine olive green colour. I think any method of treating the leaves which did not involve a preliminary drying operation would be impracticable.

Again, as to the amount of theine formed in Torwood estate tea leaves, I do not wonder that you were surprised. No one could have been more surprised than I was myself at the result of this determination, nevertheless I have confidence in the results obtained. The theine, as reported, was obtained in a state so nearly pure, that when a weighed quantity was placed in a watch-glass covered by another inverted and well fitting watch-glass, and placed on the sand, bath over a small flame, from 93 to 95 per cent of the theine placed on the lower glass was recovered in the upper glass as a sublimate of pure crystallized theine. Moreover, when the alkaloid was dissolved in various menstrua, and crystallized on the slide of the microscope, it yielded the aggregations of clear, colourless, sharply defined needle-shaped crystals characteristic of the genuine article. After all, though the percentage of theine was uncommonly high, it was not unprecedentedly so; thus Peligot obtained in different teas the following amounts of theine—2·7, 3·5, 4·1 and even 6·21 per cent. The process followed by me was the same as that used by O. Kellner, who appears to be the only chemist who has recorded systematic analyses of green tea leaf during different months. He made twelve analyses during six months from May to November, and found the percentage of theine to vary from 2·85 by a gradual decrease to 1 per cent. I am not aware whether the tea upon which he experimented, was high-grown or low-grown.

In the Melbourne assays quoted by you, "mineral ash" is necessarily lower than my "total ash" as the former means total ash minus carbonic acid. In the Melbourne assays, also, the term soluble salts does not quite answer to my "soluble ash."

The latter is the portion of total ash that is soluble in water, the former is the ash obtained by evaporating to dryness the aqueous extract, and igniting the solid residue. Hence soluble salts are sometimes reported as "ash of aqueous extract."

The potash in the total ash of Torwood estate tea, plucked in the middle of April, agrees very closely with that found by Kellner in tea plucked in the end of May. In the beginning of May, Kellner found nearly three times as much potash as was present at the end of November, his figures calculated upon "pure ash," *i. e.*, ash without carbonic acid, being May 15th, 49·06 per cent, November 30th, 17·31 per cent. M. COCHRAN.

P. S.—I send you a sample of the theine, obtained from the green leaves of Torwood estate tea, crystallized from water on the slide of a miscroscope.

M. C.

GREEN BUG (LECANIUM VIRIDE).

SIR,—There is now no doubt whatever that this pest has made its appearance amongst us, and it spreads so rapidly that on estates where it was first noticed only two months ago, there is now scarcely a tree that has not got it more or less. At first sight the green scale bug does not appear to do much damage, but after a time a black fungus appearance forms on the leaf, just like the old black bug, and then the trees begin to suffer and the crop falls off. A meeting of a few planters was held at the school room, Coonoor, last Monday evening 20th instant, to consider the best way of eradicating the pest. Mr. W. H. Gerrard, who has just returned from Ceylon, was present and gave a description of the terrible devastation this new pest has wrought there. On Hallacarry and Glenburnie estates several remedies had been tried, but without much success, the Manager had imported *red ants*, which were certainly feasting on the bug; he believed in castor oil shade being of great use. On Benhope, carbolic lime had been freely and carefully applied, and it had certainly checked the spread. On Runnymede, the green bug was discovered about three weeks ago on ten trees only in the middle of a fine field of coffee, the Superintendent, Mr. George Brown, immediately set to work and applied his own remedies and apparently with such success that on the 20th instant last, when five gentlemen visited the estate, Mr. W. H. Gerrard amongst them, and inspected the trees most carefully, one solitary insect alone was found! Other isolated trees had been attacked and treated in like manner and with like success. The bug had completely disappeared from trees that had been treated; they are constantly visited and watched. It was resolved by all present at the meeting to do their utmost to eradicate the pest, and that the best plan was to treat the trees affected the instant they were discovered. The following is the treatment Mr. George Brown, adopted on Runnymede, and it is made public for the benefit of the community. Kerosine oil and water, 1 part oil to 30 parts water.

Wood ashes containing lime and saltpetre

75 parts wood ashes.
20 parts lime.
5 parts finely powdered saltpetre.

The tree is first syringed with the oil and water, then whilst wet the wood ash, &c., is thrown well up under the leaves and dusted over every part of the tree—after 2 or 3 days, if there is any sign of the bug remaining, it is repeated.—THOMAS STANES, Coonoor.—*M. Mail.*

INDIAN AND CEYLON TEA.

Indian tea has at last, we learn, got the better of Chinese in the deliveries to London. It has been gradually drawing nearer its former all-powerful competitor, and in the first quarter of this year it managed to pass it; fifty-one pounds of tea out of every 100 lb. brought into the metropolis being from India. This sudden advance on the part of the Indian teas, combined with the fact that the China crop of tea is 30 millions of pounds short may perhaps lead a great many people to believe that the Chinese leaf has now run its race, and come to the end of its tether. Those who are of this opinion would do well not to ignore past facts too hastily, and hurriedly invest in shares in tea without knowing the facts regarding production and consumption. "A Tea Grower" states the case plainly in a letter to the *Englishman*, dated 8th instant, he writes:—

"I think it would be advisable for investors in tea property to look facts in the face.

"The Indian tea crop this year is estimated at eighty-five million lb., and the Ceylon at seventeen million lb. making a total of one hundred and two million lb.

"Suppose the English market takes seven million lb. a month, this will make eighty-four million lb. per year, leaving eighteen million lb. to be placed against China's deficiency.

"Next year India will produce one hundred million lb., and Ceylon forty million lb., making a grand total of one hundred and forty million lb. Where are the drinkers of Indian tea to come from.

"Investors must bear in mind that, though the consumption of Indian tea is advancing yet the consumption of Indian and China tea has not advanced one iota, and that, if prices advance, China will again flood the English market with cheap teas."—*Indian Agriculturist*, Sept. 17th.

[The writer in the *Englishman* is too pessimistic. He exaggerates the production of India and Ceylon and violates truth in stating that consumption has not advanced an iota. The advance in the consumption of tea has, in truth, been very great and the advance is still going on, though not at the rate of ten years ago. The consumption in Britain is now fully 5 lb. per caput and if peace can be preserved, we have no doubt the rate of 6 lb. a head will speedily be reached. Still the opening of new markets is of great importance.—ED.]

A MARKET FOR INDIAN TEA.

TO THE EDITOR.

SIR,—However gratifying it may be for our tea-planters to learn that 'Indian tea is steadily making its way in public favour,' the phrase partakes too much of the stereotyped order, and those most deeply concerned in the matter would like to see more energetic measures adopted in pushing the retail trade in Europe, America and the Colonies. I am willing to accord all due praise to the Indian Tea District Association, in their endeavours both here and in London; and the fact that nearly 24,000 lb. weight was disposed of in small packages at the "Colinderies," should stimulate the London branch of the Association to increased exertions. They should not confine themselves to retailing their tea at fashionable resorts only, but adopt measures to bring it to the notice of the small purchasers in the neighbourhood of the quarters inhabited by the labouring population, in the large towns in the United Kingdom, as also in the agricultural districts. In the latter particularly, the demand for good, coarse rough tea is spreading, owing largely to the efforts of temperance advocates. Statistics compiled during the past two winters, when the pinch of trade depression was felt in its greatest severity, show that the increase in the consumption of tea was far in excess of that of beer and other intoxicants; and city missionaries tell us that in many poverty-stricken one-room homes the wretchedly paid match-box makers and steamstresses took no other stimulant throughout their labour. Experience has proved to them the overwhelmingly superior sustaining powers of tea,—even of the cheap China Kaisows and Monings—over the once vaunted ale or porter.

The Association in London would, I think, do well to drop the position of wholesale merchants, and would better serve the interests they represent, by enlarging the scope of their operations and opening tea-bars similar to those known as "Lockhart's," at which not only properly made tea should be procurable, but packets priced as low as a penny, should be had. Dock labourers and others who live from hand to mouth, and who inhabit the poorer lodging-houses, are the greatest and most profitable customers of the small grocers in the East End, and other centres of poverty in London. These petty tradesmen derive a steady lucrative business in penny and even half-penny screws of tea, and as the customers of such, as per latest returns, number something like 2,000,000, it is certain that there is a market in this direction almost unopened to Indian producers. True, the present retailers have an established footing, but as they retail none but the cheap, weak varieties mentioned above, the introduction of the strong pungent sustaining [illegible] our planters could supply, might be trusted speedily to make a way for itself. A clergyman at the East End of London computes the average consumption among the classes I have mentioned, to be at the rate of half an ounce per head per diem, or something over 62,000 lb. a day. Even if our planters could

secure but half that custom, and were satisfied with a profit of but 2 annas per lb. for all bulked teas below pekoe-souchong such a trade would prove remunerative, and if the scheme were expanded throughout the country, it is quite within the reasonable bounds of possibility that this trade might be doubled.

Of course, all this means the expenditure of money, and situated as the greater portion of the tea interest is at present, funds I fear, are not available, and as the tea must be put within reach of the class of customers to be secured at a very low rate it will not bear half-a-dozen profits. But the initial cost need not exceed £1,000; and as I believe I am correct in stating that "Lockharts" established their business upon the principle of devoting the profits of one shop, as they matured, to defraying the cost of opening others, the adopting of a similar plan by the Tea Association should, if properly conducted, prove equally successful. Lockhart's business is assuming quite gigantic proportions. Then, with regard to the country trade among farmers and small holders, it must be prosecuted, not by the ordinary 'traveller of the day,' but by veritable pedlar's carts or trucks and though the idea may provoke ridicule among some, the comfortable incomes derived by itinerant vendors of articles of daily consumption, who supply requirements at the very door of the customers, in our outlying villages and agricultural districts generally tend to prove that the country trade would prove as profitable as the town one, even though it were necessary, in the latter case, at the outset, to distribute samples gratuitously. Both ideas are not new, but were sketched out, much on the same lines as I have indicated, so far back as 1871, and again urged upon the tea community in the *Statesman*, eight years later. At any rate, with increasing yield from our plantations—though the roaming a-field to Australia, America, and elsewhere, for fresh markets is commendable enough,—those entrusted with promoting the increase of the consumption of India tea would do well not to ignore the markets afforded by the neighbourhoods I have drawn attention to.—TEA-PLANTER.—*Indian Agriculturist*, Sept. 24th.

TOMATOES.

"Apples of Paradise!" say the Germans; "love-apples" say the English and Italians. Why "love" apples? who has ever explained? whilst the Paradisian theory has its reason. There exist old prints of the sixteenth century in Germany in which Eve is represented on tiptoe trying to reach a bough of tomatoes twining round a very tall oak, and certain Teutonic doctors of that age have affirmed that this *Paradiesapfel* was none other than the apple of our fate.

Be it so; it has remained for us miserable sinners one of the most universal agents of gastronomy. The tomato is absolutely an element of *perfection*, for there is scarcely anything that it does not complete. Only, you must know what to do with it; which is precisely what very few people do. In the first place you must wait for it, for a half-ripe *pomme d'amour* is a squashy and an unwholesome thing Unless in Spain or in Provence, your tomato is as capricious as a *pasteque*, and depends on all the accidents of climate. It is essentially a sun-absorbent, and is capable of no end of vagaries if its direct contact with Phœbus be intercepted or if the muddy rains of northern lands have presumed to wash its ruddy face. It comes from Persia, and hankers after its old birthplace. Spain and Provence are its genuine homes in Europe, because it is best pleased with bleak heat, which you can enjoy to your heart's content in either region.

When "contrairy," as it shows itself nine times out of ten in what are termed temperate atmospheres, it is addicted to taking you in in an extremely provoking manner. It will lie to all appearance lovingly enough upon the trellised wall to which it clings, and turn to you a nice plump, shining, crimson cushion that suggests a triumphal adaptation to the proper "stuffing;" but when you have detached it from its resting-place you find that it has only been turning on its protector a hard, knobby, yellow surface, indicative of a sour and discontented disposition. Throw it away—there is nothing to be made of it—and send for the "real thing" (by express train, mind) either from Seville or Vaucluse. It will arrive with its bloom on it, as do figs now from Marseilles—none of the "shine taken out of it."

Now granted you have got it, what—in your rough imperfect science of the treatments of the divine fruit—what are you, or what is your cook, going to do with it? Boil it probably, fancying that with a few herbs etc., it will make itself into "sauce;" for that is the word with which heathens profane the virtue of the tomato. "Mostly employed in sauces"—that is copied textually from several of their abominably heretical books. The tomato is no adjunct, but a substantive, an esculent, standing by itself and requiring due homage to be paid to it by the creature who has the honour of eating it.

There are two modes of adapting the use of the tomato to man—the hot and the cold. For the latter the Spaniard is supreme; but the Provençal alone knows how to dress it hot. The people of Bordeaux (where all the women are born cooks) imagine they can supply you with a dish of stuffed tomatoes. It is a mistake. Firstly, their soft, often hazy, south-western climate does not furnish the fruit; secondly, they have not the oil; and thirdly, they have not the "trick" of it. No! there are a few things for which you must go to Provence (of which Messer Francesco Petrarca—a rare gourmet in his day—was well aware). You must go to Aix for its oil, to Barbantane for its asparagus, to Cavaillon for its aubergines and its melons—those Sir John Falstaffs of the kitchen-garden; to the Fontaine de Vaucluse for its eels and its fat *becque-figues*; but to Avignon for its *tomatoes farcies*. This dish is the business of a day. First take a shallow copper *tourtière* and see how many tomatoes of equal size will fit into it, very close together. Next take out each tomato, cut off one-third of the upper part, and put it (face downwards) into a plate upon a pinch of strewn salt. Leave the fruit for about three hours, until all the acid juice shall have exuded. This prevents the stupid complaint of ignoramuses, that "tomatoes are unwholesome, and they are afraid of them." When all the "vice" has been taken out of them, range your "apples" in the *tourtière*, with a teaspoonful of oil at the bottom to keep them moist and then delicately apply to each one a light covering of the forcemeat described below introducing the wee-est portion of it into the orifices of the cut fruit. When this is complete, set it on a charcoal-fire covered over with ashes, and let it stew gently till it is ready to serve. The time usually required is two hours or two hours and a half.

The "stuffing" consists of yolk and white of eggs boiled hard, of tarragon and chervil, of bread-crumbs (sifted), of an onion or two (cooked), of a spice of garlic, the whole well chopped and mixed together (not till it is a paste), and at last having some grated Gruyère cheese (*de première qualité*) added on to it. All this "stuffing" must be so delicately spread over the tomatoes that it forms a manner of light crust; and previously to being carried to table it must be cunningly "browned" by a very skilful hand. The whole time of its stewing it has to be unremittingly watched; for if it gets dry oil must be gently dropped in, and if a danger

of wet shows itself it must be obviated by a pinch of the finely grated cheese. It is a *plat* calling forth every quality of a first-rate cook; but when it succeeds it amply justifies the high reputation of the Provençal *chefs*.

It has been said, Spain knows of the tomato when cold. Yes, and for a model *gaspacho* you had better go to Malaga or Seville, for the sun is the prime ingredient. Take several fine tomatoes, and as many fine ripe red *pimientos dulces*, and, when your tomatoes are well drained, cut them all into large (not too thin) slices, add a cucmber in transparently shaved pieces, some of the creamy sweet-onion (uncooked), and as much garlic as you can bear. To this add salt, pepper (real pepper from the Isles), and oil, with a fair squeeze of lemon (gathered fresh); and you shall then taste of a dish such as the Spanish saying assures you will make you "indifferent as to whether you live or die." It is pretty certain that this is the inspiriting food of which those truculent smugglers are partaking in that famous third act of poor Bizet's "Carmen."

Though the Iberian is not born of his mother with a sauce-ladle in his hand, there are culinary feats he can perform: one is an omelette, in which Spain equals Austria (the Austrian in that particular thoroughly outshining the Gaul). There was once a woman in Pampeluna, in a dingy smoky *fonda*—it was years ago. She was *muy gruesa*—a mountain of a woman—and ferocious in her ways and sharp-spoken; but she did know so thoroughly the secrets of a *Huevos revueltos con tomates*, that it was worth basely cringing to her to obtain as many of them as might be digested.

Well, let it be repeated: the tomato is a grand creation if you know what to do with it. And as an ornament? Go south, and you will soon learn what that means. See it in summer and autumn in the straggling *pueblos* of the Basque frontiers, filling the untrimmed wild cottage gardens with light, as though the sun himself had been playing football therein with red balls of fire; see it climbing about the rough porches of the peasants' huts of stone; and ask yourself whether even the grape-vine of Italy could replace it. However, it is altogether a fierce plant, and should be spared the sufferings of a "moderate temperature." Now that we are cobwebbed over with rails why not use some of them to bring this apple of Paradise to Covent-garden Market?—*St. James's Budget*.

PLANTING IN NETHERLANDS INDIA.

(*Translated for the "Straits Times."*)

The coffee crop in Java this year bears every appearance of being a very short one. In some parts of the island, the planters have to keep a sharp look out not only after leaf disease but also tigers as well. For instance the province of Malang so swarms with beasts of prey that people go armed into the coffee estates. Once an employee, when inspecting an estate along with the manager, was suddenly sprung upon by a royal tiger. The monster had miscalculated the distance. Its intended prey, stooping in time, came off wholly unhurt. The manager who happened to have a gun with him forthwith brought the tiger down with a couple of shots.

The *Locomotief* is assured by a correspondent that the first 15 bales of tobacco from Brtish North Borneo consigned by Mr. Persyn fetched a fair price at Amsterdam. Experts formed a favourable opinion of its quality, flavour, colour, and strength. These satisfactory results have resulted in a great demand for land in Borneo. Several Companies have been formed in Holland and Germany for the purpose.

The Government Java coffee crop has fallen greatly below expectations. The estimate for this year has come down to 227,000 piculs. The native cultivators who grow the berry from compulsion will suffer heavily from this amazingly short crop, unless the Government makes it somewhat good by giving a heavier price for the article.

The persons despatched by Fraser Eaton & Co. to West Borneo, have returned to Surabaya with heavy consignments of the new famous variety of cane known by the name of *tebu keong*. Their return voyage by steamer was rather dangerous owing to the Master becoming mad. Should the Borneo cane stand the test of cultivation, that island will come into greater prominence than ever for plantation enterprise.

OUR FRUIT PRODUCTION.

Jaffna has a reputation if not for the wealth, at least for the superior quality of her fruit production. The Jaffna mango is acknowledged to be the best of all mangoes produced in Ceylon. Pridham acknowledges it and attributes it to the hot climate and calcareous soil of Jaffna. There may be—there are larger quantities produced in Colombo, but even the fruiterers there have to cry out "Yapana ambe! yapana ambe!" if they are to find a ready sale for their stock. All Europeans acknowledge this, and it is fact which has come within our own knowledge that Europeans who have been long residents of Colombo or Galle develop the most keen appetite for the Jaffna mango, whenever they happen to be visiting Jaffna during the mango season.

The most exhaustive and voluminous writer on Ceylon—the late Sir James Emerson Tennent—was of the same opinion, and alluding generally to the soil of the Peninsula observed:—

"The arable soil of Jaffna is generally of a deep red colour, from admixture of iron, and being largely composed of lime from the comminutated coral, it is susceptible of the highest cultivation and produces crops of great luxuriance."

The late Mr. Dyke, who was second only to the late Mr. William Ferguson in his knowledge of the trees and fruits of the Northern Province, had the highest possible opinion of the Jaffna mango. He knew the villages and the particular gardens in which grew trees producing the best variety of fruits, and by means of grafts obtained from them and carefully nurtured in the "Old Park" (late Kachcheri Garden) he distributed plants throughout other villages—a system which it is deeply to be regretted, has not been kept up since that gentleman's death. Not content with the Jaffna varieties of the mango, he did the same in regard to varieties procured from Colombo. Many enterprising Natives availed themselves of this chance to stock their orchards with different varieties of the mango tree. The Jaffna varieties numbered from 1 to 16 and the Colombo varieties from 16 to 34, if our information is correct; so that in Mr. Dyke's garden alone, there were no less than 34 varieties, of the mango; and all the European Residents of Jaffna were welcome to the enjoyment of this luscious fruit during the season.

We would next refer to Jaffna grapes as of a variety not procurable in any other part of Ceylon for its deliciousness. This may be an exotic introduced by the Dutch, if not by their predecessors—the Portuguese. But by whomsoever introduced, there was a time when most houses in the Pettah had their grape-vine bowers. The grape season was anxiously looked for by speculators and, long before they were ripe, there they were, with money in their purses to pay for the whole crop in advance according to an approximate estimate; the difference being paid when the crop was gathered and weighed out. The price varied from six pence to a shilling per lb. according to the competition existing. The speculators had already, before the grapes were ripe, engaged relays of coolies and posted them at the several stage [illegible]

route to Colombo; and no sooner were the grapes gathered and weighed out, than they were put in wicker baskets of Navanture manufacture, provided with an amplitude of airing, which baskets being suspended to Pingoes, the coolies hastened on in their laborious and often hazardous journey, proceeding more at the pace of the lamplighter than either the tappal runner or the baggage bearer of the present day—the owner of the whole concern accompanying them and travelling like one of them. Arrived at Colombo, they often succeeded in realizing from 2 shillings to 4 shillings per lb. The lower rate was accepted only when the grapes had signs of rot or decay about them. Otherwise they generally realized their 4 shillings, and at times even 5 shillings the lb. Is there anything equal to this exciting trade at the present time? We positively say no. In the first place the vine-bowers are no-where. They have disappeared as in a vision or a dream. Time was when the propritors of vine-bowers were themselves also the speculators, as in the case of the late Mr. Nicholas Bowdewyn. By small trade between Jaffna and Colombo he had acquired large wealth. Part of this he laid out in houses in the Pettah, of which he was possessed of less than 6 in different most eligible sites. In all these houses, there were vine-bowers. The average yield of each of these bowers was from £15 to £25 an year, which was capable of being trebled, if not quadrupled, by being sent to Colombo on his own account. Consequently, he often made the journey to Colombo, notwithstanding the terror of elephants and other beasts. But how many vine-bowers are there at the present day in the Pettah? Not one worth the name. How is it in the several country villages where the red-soil predominates? There are less than nothing at all. Why then speak of other fruit trees, if the mango and the grape fare so badly? There are oranges, pomegranates, pineapples, anonas, melons, cucumbers, and other fruits, which if only largely produced will find a ready market in Colombo, now that Colombo is being daily visited by the steam ships of all the world.—"Jaffna Patriot," Sept. 30th.

CEYLON UPCOUNTRY PLANTING REPORT.

INSECT ENEMIES—THE DROUGHT AND THE CACAO CROPS —BUG—A MODEL BROKER'S CIRCULAR.

10th Oct. 1887.

During the last few years the Ceylon planter has had his fill of vegetable pests. He has a wholesome horror of all kinds of blights, fungi, and creeping things, and when he finds an insect in any number feeding on a promising cultivated product, in the voracious manner which as a rule distinguishes that low-bred creation, his imagination wakens up at once. The less he knows of the new-comer, the more easily does he build up the record of its future, and foreshadows its conquering career. It has appalling potentialities: down its greedy maw he can see disappear in mournful procession all the fruits of his labours and the hopes he has rested on: the creature grows into a veritable "Jabberwock" and pursues him into the land of dreams. It has even a wider empire. A new poochie has been known to flutter such calm surfaces as scientific authorities. This was especially noticeable during the cacao scare: for a man to appear at that time say at the Peradeniya Gardens bent on entomological enquiry, and armed with specimens, sent a shiver through the whole staff. Borers, sucking bugs, fly and other abominations had been too much for the placid atmosphere of exact knowledge, especially when they came in with a rush, and an excited planter at the tail of each of them. Of late I have had my eye on an insect which, in those days, would have caused no end of a stir. I have seen it on cacao, devouring the foliage at an amazing rate. I have also watched its career on the tea bush, and I have heard of it infesting forest trees. It is a worm inside of a vegetable casing, a kind of house which it carries with it. When on the lower surface of a leaf it hangs straight down, when on the upper it stands straight up. It seems to be capable of spinning a kind of web, and it can riddle a hole in a leaf in no time. In appearance it is like a periwinkle shell—the long tapering kind—and it can move from place to place with considerable ease. In the "Lepidoptera of Ceylon" it is classed in the genus *Aprata*, and according to Moore it rejoices in the name of *Manatha albipes*. It spreads slowly, but I know of one tea estate where last year R200 were expended in keeping it down, which sum has had to be doubled this. It was that significant fact set me inquiring further into its manners and habits, and how best to fight it. Those who ought to know speak rather highly of it as a pest. To destroy it, just give the infested tree a shake, that will cause the insects all to hang down. Then pass a lighted bunch of grass quickly through the branches, and as the vegetable coating over the worm is very inflammable it will readily take fire and the insect will be destroyed. This is the best time to operate; but even supposing it is allowed to fulfil its mission and bursts into a moth, its natural enemies, in the shape of birds and other things would soon reduce the numbers, were there a tendency to increase beyond the normal rate.

The croton caterpillar which so scourged that plant last year, as to leave in many places nothing but bare boughs, is hardly to be seen this season. The havoc which crows, birds, fowls, frogs, ants and other things made with the moth, with perhaps the addition of climatic effects, have certainly checked the increase. A similar result is confidently looked for of the *Manatha albipes*, should it multiply to the position of a pest. All the same, it is better not to give it the chance, and whether children be sent to pick the worm off, or the fire be applied, it will be the part of wisdom to keep the worm always in its right place.

The drought, which happily has now broken up, has been especially rough on Dumbara. The cacao has suffered considerably, although perhaps not so much as might have been expected. Still it has been severe enough to affect the coming crop, and I have heard your estimate of this product for the coming year set down as much too high.

Bug is retiring to an obscure life in the jungle, and let us hope it will stay there. Patches of trees can be seen perfectly black with it. All the same, it has not left the coffee, but hangs about it as unwelcome as "the man in possession."

What a model circular that is issued by Messrs. Wilson & Co. the other day? Planters and others are much indebted to that firm for the pains it has taken to make it so interesting and so complete.

PEPPERCORN.

DELI TAMIL IMMIGRATION.

(From the *Straits Times*, September 24th.)

The Netherlands Indian Government has once more taken up the subject of Tamil coolie immigration from India to Deli. The question has been under consideration for years, and the Deli planting commuity has made no small stir about the matter, but, so far, without success. By last advices from Java, the proposals before the authorities there to meet the end in view have at last taken definite shape. Suggestions have been forwarded to the Dutch Home Government respecting the steps to be taken in British India for the purpose of concluding a convention regulating the emigration of Tamils to the East

Coast of Sumatra. The Netherlands Indian Government proposes to send the Consul General at Singapore on a mission for the purpose accompanied by a Controller from the East Coast Sumatra. The expense of the mission falls upon the Home finances. It is evident that the success of the mission depends upon the tact and energy of the commissioners selected. Planters in Deli now feel more than ever the need for depending on other labourers than Chinese. The latter have become scarce and dear owing to the action of the coolie brokers in the Straits, who find it to their interest to keep up the price of labour. The brokers form a ring and dictate their own terms to the planters. The latter, at one time, combined against them, but had to give in owing to some of their number breaking word and squaring matters with the brokers. A regular supply of cheap labour is acknowledged to be of vital importance to planting enterprise in the pioneering days of a Colony. One need not be thoroughly versed in planting matters to understand what will be the fate of estates which have no command of labour, or can secure it with difficulty. Planters on the East Coast of Sumatra have to struggle with these hindrances. Hence, no wonder they longingly look forward to the conclusion of a coolie convention with the Indian Government. Such a state of things urgently calls for remedy. Difficulties have always attended the emigration of coolies from India. Their migration to Deli was looked upon with disfavour by the Indian Government, owing to the Dutch authorities refusing to allow the appointment of a British official as their Protector in that colony. A compromise in the direction of appointing a Dutch official acquainted with the Tamil language as Protector proved impracticable, owing to nobody with that qualification being available. Considering that the Indian Government has insisted on a Protector of Indian immigrants even in the Straits Settlements, it cannot be expected to waive this requirement in a foreign colony where their interests stand in greater need of safeguarding. Planters in Deli have had good reason to complain of Government neglect of their interests in this respect. As far back as 1884, the subject was brought under the notice of the Governor General of Netherlands, India, who promised at the time to do everything in his power to further the end in view. It is not till now, that action has been taken in the direction of moving the Home Government in Holland. The difficulty lies in giving the Indian Government satisfactory security that its subjects will meet with justice and fair dealing. In bygone years, in the early days of tobacco growing in Deli, that colony enjoyed an evil repute for lawlessness and harshness towards coolies. Nowadays matters have vastly improved in this respect. When common sense and sound judgment are once brought to bear on the subject, the difficulties in the way of a convention will soon vanish. It is to be hoped that the Netherlands Government will see their way to come to some arrangement admitting of the stationing of a Coolie Protector in Deli. Anything short of this will doom the mission to failure.

PLANTING IN DELI.

(Translated for the Straits Times.)

A correspondent of the *Java Bode* has been spying out the land in Deli. He is not at all favourably impressed by Government arrangements there which seem to be mainly directed to levying taxes. The encouragement of planting enterprise turns out to be a matter of secondary importance. The first glimpse of the country caught by a traveller voyaging thither, does not convey a taking idea of the land of promise. Labuan Deli, the first coast port called at is nothing more or less than a Chinese village in the midst of mud, filth and all uncleanness. Fever stricken wretches creep about the shore. The houses stand in a swamp giving out pestilential exhalations too strong for the feeble vegetation to absorb. A railway soon takes one from this seat of disease to Medan higher up. This town yet in its infancy bids fair to attain large dimensions as time rolls on. Building operations are proceeding apace. Carpenters, masons, and bricklayers display intense activity. Buildings are rising up on all sides. A railway station forms a prominent feature in the view. Hotels and Government buildings meet the gaze. Outside the town, a racecourse adds to its attractions in the eyes of sportsmen of whom there is no lack there. Further inland, tobacco estates dot the country. Their produce bears brands that rejoice the hearts of brokers in the Amsterdam markets, and bring prices averaging sometimes two and a quarter guilders per pound. They yield dividends bringing joy and gladness to shareholders. Many of them belong to a few powerful companies. They set to work with that preponderance and dominating influence which, according to nineteenth century ideas, give every right to expect high market quotations. Singular to say, it is just these companies which pay employees the worst. They make a point of engaging young fellows of no experience in Holland and Germany, who think it a great thing to draw a salary of eighty guilders or marks as the case may be. When too late they discover that a wage of that amount hardly keeps them going. In their agreement, increases of pay early are stipulated for, but these enhancements go upon the same economical principle which counselled getting them out on low salaries. However high may be the dividend earned by these companies, thanks to the energy, activity, and conscientiousness of their employees, the latter are none the better for them. On the other hand, on private estates, it is no rarity to find book-keepers and assistants who engaged at 100 to 150 dollars a month, draw a salary of $200 on entering their third year of service. Sometimes, harsh judgments are passed upon these assistants calling in question their conduct. Sweeping condemnation is passed upon them, in forgetfulness of the fact that a batch of individuals, take them from whatever class of society one likes, will show the usual admixture of good and bad characters. Formerly, in the early days of tobacco growing when, from the absence of effective police arrangements, a tight hand had to be kept over the coolies, the assistants exercised rigour and strictness bordering upon ill-treatment and even cruelty. Nowadays, when law and order are more vigorously enforced, such instances of estate despotism have become rarer. An assistant's situation is no sinecure, especially for those who have to serve under hard masters. In that case, they must be in the fields and store-houses, work or no work, from early in the morning to 11 a.m. After a short spell, they turn to again in the fierce heat from one to six o'clock. Some masters treat their European employees but little better than coolies. Others even grudge them the time spent in eating. They set spies upon them, and even keep watch on their movements in the fields with telescopes. Many more, however, treat their employees with every kindness and indulgence. But when sickness or fever overtakes a European on the East Coast of Sumatra, he is in a very bad case indeed. Few estates lie so high among hills that they present the advantages of a sanitarium. Batavia

and the Java highlands can only be reached by an expensive voyage. The nearest health resort is the Crag, at Penang. Even that falls short of requirements.

DOES TEA PAY?

The question as to whether tea pays—whether it may be looked on as a profitable investment, would probably be answered promptly in the negative by most people. Everyone connected with the tea industry is always ready to join in a Jeremiad on the subject, and to cry "Ichabod." Managers, agents, shareholders, and proprietors all alike lament the glorious past, when "rupee averages" were by no means exceptional, and when "going into tea" was thought to be synonymous with being in a fair way to retire with a competency within a reasonable number of years; and when "making a fortune" out of it was quite within the bounds of probability. Now, they say, all is changed. Prices have fallen so much that a small managing proprietor may slave all his days in an unhealthy climate, and never get more than a bare subsistence out of his garden. Companies, through the voices of their agents or directors, insist on the stern necessity of more economical working: shareholders bewail dividends growing small by degrees and beautifully less; and grow restive, and carp at direction and management, goaded thereunto by the diminishing value of their shares. Assistants growl over the futility of asking for salaries commensurate with their own ideas of the value of their services; and managers are apt to use unparliamentary language if the subject of their commission is touched on. Agents, who are popularly supposed by managers on the one hand, and shareholders on the other, to absorb a large proportion of whatever is to be made of out of tea, shake their heads and look gloomily mysterious over the question: and if they refuse to commit themselves to a decided opinion on the prospects of tea, give one thoroughly to understand that they at least obtain a small advantage only; and even selling brokers, who would seem to stand secure to make nothing but a profit out of tea, selling it at so much a chest, do not admit that their life is an ideally happy one. The cry of over production, so far from carrying doubt and dismal foreboding in its ring should be to them tidings of comfort and joy. The more tea produced, the more chests to sell. Yet there is no one to be found who will raise a cheerful strain on the subject.

It is worth while to consider this chronic despondency on the subject of tea, and endeavour to ascertain if it may not be due in a great measure to a habit of looking at the dark side of the picture. It must be borne in mind that in no business or profession is success assured. Merchants and tradesmen do well or ill,—make fortunes, derive only a subsistence, or absolutely fail,—according to circumstances and their individual capacities. Professional men are in the same category. For one successful doctor, lawyer, or engineer who rises to the top of his profession and makes a big income, retiring eventually with a fortune, there are many who can just manage to make a decent livelihood; more with whom it is a constant hand to mouth struggle for existence; and others again who cannot manage to keep afloat, but sink in the struggle;—the stream of life flows over their heads, and their place knows them no more.

Anyone who would seek to deduce from the failure of a few merchants, or the nonsuccess of sundry professional men, that such a business or profession was, "played out," and no longer a profitable business to engage in or a promising career to embark on, would at once be looked on as foolish and illogical; generalizing recklessly from a few exceptional data. Yet the gloomy view taken so generally of tea rests on no better basis. A few companies here and there pay no dividends; the market value of shares of a good many concerns has depreciated. Private planters can no longer realize rapid fortunes by opening out, floating a company to take over their gardens at a huge profit, and retiring on the proceeds. And hence the wail that floats on the air;—tea is no longer a profitable investment: tea planting is a career no young man who can obtain anything else to do should embark on; and in short, "the planter's life is not a happy one."

But the fact is that, 20 years or so ago tea was a speculation, a "fevered dream of wealth." Now it has come down to the level of its surroundings and is an every day, prosaic, ordinary business, subject to the hard necessities of every other business in which competition is keen, and wherein things have to be very closely looked after to show a profit at the end of the year. That it pays as well if not a trifle better, than most other kinds of businessis we think capable of demonstration. Take the results of the working of twenty-four tea companies registered in London as published in our issue of 23rd August, of the twenty-four concerns, nine paid a dividend of ten per cent and upwards; eight more paid five per cent and upwards; while five paid no dividend at all. But even of the non-dividend paying companies only two actually worked at a loss; the other three show considerable profits, £3-16-3, £2-5-3 and £1-14-10 per acre,—and that on large areas. In one case the profits,—some £15,000,—made out of tea are absorbed by the losses on other business done by the same concern: in the other two cases the surplus, about £9,500, and £3,600, goes to pay off interest and loans incurred in former years as the result of a combination of bad seasons and bad management. Here we have 22 out of 24 companies making handsome profits; in two cases fifteen and eighteen per cent. Seventeen out of the twenty-four pay five per cent and upwards. We are inclined to think that five per cent and more up to eighteen per cent for one's money is pretty good in this present Jubilee year of grace, as times go. The three companies noted above as working at a profit but paying no dividend, owing to outside causes or former misfortunes, each show a profit of five per cent or more. Thus we have 20 out of 24 concerns registered in London paying 5 per cent and upwards. The table published in our issue of the 30th August gives particulars of twenty of these London tea companies, including the dividends paid for the last six years. A study of this will also go to prove that tea, properly managed, is very far from being a non-paying investment. A comparison of the share lists in the daily papers will help to bear out our assertion that tea pays as well as most other business. There are 75 commercial companies and 110 Tea Companies quoted. Of the 75 commercial companies, 32 pay no dividend: of the 110 tea companies, 41 pay no dividend. Only 57 per cent of the commercial companies can show a dividend for 1886, while 63 per cent of the tea companies make the hearts of their shareholders glad. Of the forty-three dividend paying commercial companies seven or sixteen per cent pay in two figures, ten per cent and upwards; while eighteen per cent of the tea companies pay ten per cent and upwards. The highest dividend in the former is 15 per cent in the latter 28 per cent. These figures are not very impressive perhaps, but they are certainly in favour of tea.

Again, how many of the companies that pay no dividend are really working at a profit? We would venture to say that at least three-fourths of the non-dividend paying concerns are really making a profit of five per cent and upwards; but this profit unfortunately is swallowed up by interest on old debts or on advances for current expenditure, and in other ways, so that none of it finds its way into the pocket of the shareholder. Where a company has a heavy interest charge on an old debt incurred in former years, and has besides to hypothecate the season's crop for money at twelve per cent. for current expenditure, the shareholders stand a very poor chance of getting anything out of the gardens. In such cases it is worth their while to consider whether it would not be better for them to become their own creditors in some way; to advance the money required themselves, whether on preference shares, debentures, or in any other way that seems best to them, instead of leaving the company to raise money at high interest elsewhere. They would

thus be sure of getting whatever profit might be made out of their gardens, in one shape or other; instead of allowing it to be absorbed by outside capitalists while their original shares went dividendless for years, and steadily depreciated in value till they became an utterly unmarketable commodity.

Reviewing the foregoing, however, it seems to us that it may be fairly concluded that tea *does* pay, at least as well as if not better than most other kinds of business; and that the gloomy and despondent view so often taken of tea planting and tea as an investment is due more to a bad habit of looking only on the reverse of the picture and a wilful closing of the eyes to the bright side of it, than to a careful consideration of the real facts, and a comparison with the state of other industries.—*Indian Planters' Gazette.*

PEPPER ADULTERATION.

The various prosecutions in the spring for the sale of adulterated Pepper have had a very satisfactory effect upon the London deliveries, which for the first thirty-five weeks of this year were 5,442 tons, against 5,013 tons in 1886. These figures are for Black and White Peppers together, and indeed this is the proper way to regard the statistics of the trade, because, owing to decortication here, the use of the two kinds is now inextricably mixed up. It was pointed out that the retail Grocers would not knowingly have bought adulterated Peppers, and thus have compromised their good name for what yielded no appreciable profit. They were simply tempted by low prices, and did not know of the existence of the adulteration. They are now on their guard, however, and hence the improved demand for real Pepper. The wholesale houses are also taking steps in the direction of increased caution, by more careful selection, the rejection of doubtful samples, grinding their own Pepper, &c. It is particularly satisfactory to notice that the adulteration of White Pepper with Long Pepper appears to have received a very severe blow. Long Pepper has fallen 20s. per cwt., or about one-third of its then value, since the spring, owing undoubtedly to the prosecutions for its use with White Pepper. At the great fall that has taken place, its use with White Pepper would give a profit of 6d for every pound of Long Pepper that could be mixed with White Pepper, so that the temptation to those fraudulently disposed is very great. Fortunately, however, the taste and smell of Long Pepper cannot be disguised, so that the adulteration is readily to be detected. As it is probable that the practice of adulterating Pepper is as yet only dormant, and might very readily be revived, the actual cost of the lowest ground samples which the Grocers could safely sell may be useful. The present market value of good heavy Penang, which is supposed to contain from 8 to 12 per cent of dust, is 6¾d to 7d per lb.; and adding ¾d per lb. for the cost of grinding, this would bring its present first cost to 7½d per lb. Those who bought a little time back, can, however, sell with a profit at that quotation. The lowest cost of ground common White Penang, taken in the same way, is 10¾d. In this case the market is lower than it has been. It is also satisfactory to notice that the demand for genuine Ground Ginger is increasing, since the recent prosecution for the use of spent Ginger for adulterating Pepper.—*Produce Markets' Review.*

COCONUT CULTIVATION IN CEYLON.

Siyane Korale, 30th Sept. 1887.

We are having strange weather just now. One feels as if he has imperceptibly glided into the middle of the N.-E. months with chilly mornings and grillingly hot days. What completes the delusion is that the Peak is clearly visible.

Complaints are rife on all sides that coconuts are very small-sized in this and the previous season, and that it won't pay planters to dry their nuts owing to a couple hundred or so of nuts more being required to make a candy of copra. Coconuts have been selling cheaper since July than I have ever known before in my limited experience in the Korale. As the property I supervise is young, and the crop small, it was always deemed expedient to sell the nuts rather than turn them into copra, as small parcels of copra are not affected by mill-owners. No offers being made recently for my nuts, whereas in former years active competition prevailed, the only course left was to convert them into copra. The result was encouraging both as regards the outturn of copra and the price obtained for it—1,150 nuts went to the candy of copra and the price obtained for the article clean and well dried was the same as that ruling for the best kinds. In this instance at least the fallacy was exploded that the vehicle in which copra reaches Colombo determines its price. I sent in neither boat nor cart copra, yet the price I obtained for it was equal to the best boat-copra. Let planters take encouragement from my experience. They can rest assured that for clean, well-dried copra they will obtain top-prices in either of the German houses owning mills.

The Hapitigam planting prophet raises a wail in your issue of the 10th instant that he is discredited, and that his neighbours "know better than I do, what to do, and how to do it." He must not be surprised at this, the result of his affected superiority to all coconut planters, and to his laying down dictums without adducing reasons in support of them. Now to his system of cultivation as enunciated by him "for the tenth time" to enlighten a perverse and stiff necked generation of planters. He starts with a plantation five years old, and he requires that the tree should have "at least 2 feet of clear stem, and a head of not less than twenty green leaves." Impractical as usual to begin with, for the planter is not only required to measure the stem of every individual tree on his plantation, but to count the number of *green* leaves each tree is carrying! for, mind you, the bone dust he uses for a plantation having these his two essential requirements "is not a suitable manure for young plants, or weak or dwarfed trees of any age," so that not only must the measure of the tree's stem and the number of leaves it is carrying be ascertained, but when applying the manure the planter must stop short of the roots of young plants and dwarfed and weak trees; for the bone dust is sown broad cast, it must be remembered. Let us now regard his system from an agricultural point of view. A coconut tree under ordinary circumstances does not come into bearing till it is between eight or ten years old, so that to force it into bearing in the fifth or sixth year is to induce precosity which is inconsistent with longevity and is harmful to the constitution of the tree. I would regard a man who practised this system as either ignorant of agriculture, or as being eminently selfish in leaving to his heirs a worn out property. Bone dust is regarded as a highly stimulating manure, and is used with caution for even trees in bearing, as its use once commenced must always be persisted in. What will be the result I ask of its use on young trees forced into premature bearing? What is the object besides of manuring? In sound and practical agriculture it is to return to the soil the elements of fertility removed from it by crops. According to my ideas of agriculture, all that is necessary for a tree till it reaches the bearing stage, is to encourage its *growth* by loosening the soil. Given a well-grown, healthy tree and you can do what you like with it to make productive. Your correspondent uses four cwt. of bone dust sown broad-cast for an acre of land *i.e.*, about 6 lb. per tree counting 75 trees to the acre. Is not that an extremely large dose especially for young trees? Besides, most of the manure will be wasted when sown broad-cast, for trees of five years of age can hardly be expected to have sent roots all over the ground, except perhaps in exceptional localities with rich, free soil. In practice it will be found that the feeding roots are found almost exclusively round the tree and well within shelter of its branches, and a practical Welsh gardener told us years ago that the fibrous roots round the stem of a tree supply it with fruit-forming materials, while the larger roots which spread further away supply materials for the formation of

wood and leaf Bone. dust being a phosphatic manure is a fruit-former, therefore all that is applied beyond the reach of the fruit-forming roots in literally thrown away.

I cannot understand your correspondent's objection to manure being applied within four feet of the stem or to its being applied in holes or trenches. Perhaps if he gives his reasons I may be able to appreciate the force of his objections. As for myself I think a shallow hole or trench from 18 inches from the stem to 6 or 7 feet form it a splendid receptacle for manure, as the bulk or of the feeding roots will be found within that area. If holes or trenches are tabooed how is bulky manure to be applied, and how husks and branches? Surely not in the form of ashes, for science has proved by repeated and crucial tests that it is not good husbandry "to burn any refuse that will rot in the soil." Your correspondent advocates digging in of manure within 6 or 7 inches of the surface, for the coconut is a surface-feeder and any food presented to it must be placed where most easily available. All very good and true I say, but slightly contradictory of a previous utterance when he advocates constant stirring of the soil with the plough, for "disturbing the roots is a matter of no consequence" and he wants no mains within nine inches of the surface.

I ask in no spirit of carping criticism, but with a desire for information, what is the meaning of the word "fallow" as used by your correspondent in his frequent communications on coconut planting? If the land is dirty, I keep it in fallow for twelve months.

GREEN BUG.

Sir,—In your issue of the 24th instant there appears a short letter by Mr. Thomas Stanes, of Coonoor, from which it appears that what coffee planters on these hills have of late begun to fear is a fact, and this notorious pest, that has devastated so many estates in Ceylon, is fairly in our midst. Mr. Stanes kindly makes known to the public the ingredients of a mixture which has done good as applied on the Runnymede Estate. If all of us follow the example thus set, and make public the results of experiments, valuable data will doubtless be shortly forthcoming. The "green bug" made its appearance on Adderley over a year ago, and there is every reason to suppose that it has been more or less on other places for a long time; but it has not been recognised till quite lately. At the beginning it kept to guavas, and to a tree of the ficus tribe called in Canarese "*Kad Goni.*" The Coorg orange trees in the fruit garden were then attacked, and this and last season's crops have been almost entirely destroyed. Subsequently the Atti trees began to get covered with it; and here and there it is now to be seen on the coffee. To my mind it does not seem to be very fond of coffee, at present; but what it may do in the future it is impossible to tell. It shows its patiality for the following trees in a diminishing degree in the order named:—Guava, Orange, Atti (*ficus racemosa*), other varieties of the fig tribe, certain jungle trees, the "Nérel" (*Nága Maram Tam.*) coffee, and C. Succirubra. As to the last I have only noticed one Cinchona tree on which the bug was to be seen. The Jack appears never to be touched. It is an open question whether the Atties do good, by attracting the bug to themselves, away from the coffee; or harm, by attracting this pest to the estate. I most reluctantly admit that my own opinion is that they must, and cannot but do harm. For they form great breeding places all over the estate, and although for the time being, the bug may keep to them in preference, I fear that it would cease to do so with the disappearance of green leaves and shoots. It is a terrible dilemma that we are in; extermination—if it be possible—cannot be carried out, unless every Atti tree on the estate so soon as attacked, is cut down and burnt. And this is the tree that we have so carefully reared, and brought up for shade!! If vigorous measures are decided upon, then I feel sure that all trees which attract the green bug must at once be cut down, chopped up, and burned. In the case of Atties, shade could be raised again, and quickly, by suckers from the stumps. Meanwhile a smart maistry could be appointed with a sufficient gang of picked coolies to apply whatever mixture may prove to be best, whatever required. And I think a strong incentive, to search out in every nook and corner for infested trees, ought to be offered to the maistry say R50 to be paid to him six months hence, if by that time, through his exertions, the "green bug" shall have disappeared. These suggestions I offer, and doubtless other planters will be able to improve upon them.—R. H. MORRIS.—Adderley Estate, 26th Sept.—*Madras Mail*, Oct. 1st.

THE CHINA TEA CROP.—It is a significant fact that the crop this year is 27,000,000 lb. short of former production. The only inference is, that the Chinese agriculturist is finding that there are more profitable local crops, the inferior quality of late years having rendered shipments unprofitable.—*Indian Tea Gazette.*

COCONUT PEARLS.—Referring to the letter of Dr. Sydney J. Hickson, published in your paper of June 16th last (p. 157), I have the pleasure to communicate to you that I have a collection of fourteen coconut pearls (one of them I myself found in 1866 at Holontalo, North Celebes, in the endosperm of the seed of the coconut); two melati pearls (*Jasminium sambae*); one tjampaka pearl (*Michelia longifolia*), found in the flowers, according to the natives. One of the coconut pearls has a pear-shaped form, the length being 28 mm. The common name amongst the natives for this kind of pearls is mustika.—J. G. F. RIEDEL, Utrecht, September 6th.—*Nature.*

TEA ADULTERATION.—So much has been heard about the wonderful excellence of Russian tea and its great superiority to the article which is retailed in England, that it is rather surprising (says the *British Medical Journal*) to read in the *Peterburgskia Vedomosti* that a large number of analyses made in the Sanitary (Analytical) Station of the St. Petersburg Vratchebnaia Obshtchina led to the conclusion that adulteration of tea has attained enormous dimensions in the nothern capital of Russia. Some specimens, sold at 1 rouble 20 kopecks (about 2s 6d,) contained only 15 to 20 per cent of genuine leaves, the remaining 85 or 80 per cent consisting of various admixtures, including such an injurious substance as the leaves and flowers of epilobium angustifolium, or the French willow-herb (Russian, Kapor skytchai or Ivan-tchai).—*Globe.*

COCONUT OIL AS A SOAP MATERIAL is thus noticed in an article on the manufacture of soap in the *Indian Engineer*:—

"The importation of palm and coconut oils added an important variety to the list of soaps, particularly of toilet soaps, the former being a useful and pleasant material, improving all soaps into which it enters; which cannot, however, be said of coconut oil as it retains a rancid odour which it seems impossible to remove, and which is to most people objectionable, so that it should be used sparingly. On the other hand, it has many good qualities, giving soap a fine appearance and in use giving a copious lather. It has also properties peculiar to itself; thus, it saponifies only in strong lyes, and will dissolve in salt water, and is often called 'marine' soap. It will also retain a large percentage of water without impairing its solidity or appearance. These properties it in some degree imparts to other soaps to which it may be added, and it has been the means of much sophistication and adulteration, which has given to purchasers an idea of inferior quality, yet to some it is a favourite because of the richness of its lather.

FRUIT AT COONOOR.

Coonoor has always been famous for the growth of fruit trees. Oranges, apples, plums, peaches, nectarines, &c., thrive luxuriantly and fruit freely. The grounds of the three Hotels in the station, Gray's, Glenview and Hill Grove, are well stocked, and visitors who have the good fortune to secure accommodation at these comfortable and picturesquely situated establishments can enjoy the fruit fresh, or prepared in delicious marmalades or preserves. The owners of these orchards, who spare no expense and attend assiduously to the condition of the grounds have wisely adopted the precaution of annually planting a number of young trees, by which means they avoid the inconvenience and disappointment of trees dying out from age or disease. Either or both have lately become epidemic. Orange trees which a few years back we saw loaded with the most tempting and luscious fruit are now leafless and without a blossom, the process of decay or disease having set in without a single instance of recovery, that we are aware of. The past season has proved similarly inimical to apple trees. Some fine pippins which but a year or two ago yielded several bushels of fruit have gone completely out, the cause not being discoverable. It is suspected to be in the soil, which to all appearance is well drained and rich in plant food The Orleans plum does admirably, and the dwarf plantain is said to come to maturity and freely ripen at the greatest elevation in the station. There is no doubt that the successful cultivation of fruit in Coonoor, making every allowance for the advantage of a higher temperature, is in a large degree owing to a greater amount of intelligent attention bestowed upon the subject by the residents of that station—attention which we should be glad to see emulated by those engaged in fruit culture in Ootacamund.—*Nilgiri Express.*

A FEW NOTES ON RED SPIDER.

Red spider is a pest with an appropriate adjective. It does much damage to tea, especially when it attacks the first young shoots of the season. Low *jat* plants and plants that have been early pruned are most subject to its ravages. The best preventive for it is to keep the plants in a healthy state, *i. e.*, in soil that is conducive to vigorous growth, and having the sap channels clear, so that the reciprocal action of the root and top is allowed to go on freely. I have seen various means taken to check red spider after it has attacked the bushes, and the most effective that I know of is plastering the plants with a mixture of clay and cow-dung half-and-half. The *chokra-log* are best adapted for this work. Holes are dug in convenient places near the tea, and in these the mixture is made to about the consistency of cream. Each boy has a *harri* which he fills and carries to the side of a bush to be done, then, holding the *harri* on his left knee by the left hand, and with a bunch of stiff grass in his right hand he dips this into the mixture and throws it with a jerky motion over all the plants till not a particle of green can be seen. This should be done in dry weather. If the weather continues dry the clay and cow-dung on the bushes will soon smother the red spider and in a few days it will crack and fall off in scales. When rain comes on before the plastering has had the desired effect, there is still the benefit that the plants will derive from the cow-dung being washed down to their roots to put against the labour expended. Lime is not good for this sort of plastering. It is too adhesive, remains too long on the bushes, and interferes prejudicially with the natural functions of the leaves.

I have seen flour used for this work too. A large consignment was imported for the coolies, but they got tired of it and it was allowed to go bad and eventually it was mixed with mud and used for plastering to kill red spider. It killed the insects where applied, but, like lime, it proved prejudicial to the plants.

Mud, without cow-dung, is of no use unless rain comes on before it has properly dried and the labour expended is lost. There is nothing like the clay and cow-dung mixture, for, in applying it, if you are not killing red spider, you are manuring the bushes.—*Indian Planters' Gazette.*

QUINOLOGICAL WORK IN THE MADRAS CINCHONA PLANTATION.

BY DAVID HOOPER, F.C.S.

[*Abstract.*]

1. *Analysis of Crown Barks.*—Twelve stems of different size, &c., were taken and analysed so as to show how trees of the same age and growing in the same situation vary in alkaloidal strength. The results were tabulated, and it was seen that the quinine ranges from 3·90 per cent to 1·75 per cent; the quinidine from 0·16 per cent to an entire absence in two cases. The results bear directly on the practice of coppicing, and it seems quite probable that there is no advantage in raising one stem only from a coppiced tree, as two or three stems have equally rich bark. But it would be erroneous to suppose that any great advantage would be gained by growing three stems from one stool, except where the neighbouring trees are inferior in vigour of growth. The results also show that very little dependence can be placed upon the appearance of a tree as indicating its market value.

The same trees were again analysed a year later, and the results summed up show that for six months after the trees were stripped the alkaloids decreased, but increased in the subsequent six months, the one counterbalancing the other.

2. *Manures.*—Cattle, stable, lime and stable, and bone manures were each distributed on a piece of ground divided into five portions, the fifth being left in its natural state. The barks were harvested a year afterwards, and the result of the harvest proved that the amount of bark per tree was highest in the portion containing cattle manure, and the next that from prepared bones, but the quantities of bark from the stable and lime and stable manured portions did not materially exceed the amount of natural bark from the unmanured trees.

3. *Lime in Cinchona.*—A twenty-year old *Cinchona succirubra* was incinerated, and quicklime amounting to 7½ oz. obtained from it. It was distributed as follows:—

	oz.
Bark of stem and root	4·74
Bark of branches and twigs	1·04
Leaves	·44
Wood of stem and root	1·28
	7·50

4. *Renewal of Ledgers.*—Under this heading Mr. Hooper shows the effects of renewal upon the alkaloidal value of Ledger barks. The total alkaloids remain practically the same, but the quinine had increased from 1·35 per cent in the original to 3·87 per cent in the third renewal, decreasing, however, to 3·03 in the fourth.

5. *The Influence of Prolonged Covering* is to increase the amount of alkaloids, but analysis shows that it is a mistake to keep the covering on longer than three years; after that there is a decrease.

Mr. Hooper concluded his paper by the following:—

Analyses of Rarer Species of Cinchona.

—*Chemist and Druggist.*

INDIAN HEMP—WILD AND CULTIVATED—AND ITS PRODUCTS

are thus noticed in the *Pioneer*:—We said the other day in connection with provincial excise that the local Government has explained to the Board of Revenue that their proposals with regard to the hemp plant ignore the distinction between *bhang* and *ganja*. To avoid misconception it may be useful to give the exact words used in the correspondence to which we referred. "In many districts," wrote the Board, "the hemp plant (from which *charas*, *ganja*, and *bhang* are prepared) grows wild in great profusion, but is not known to be used for the manufacture of drugs; whereas in other districts, under apparently similar conditions, *e.g.*, Farukhabad and Bahraich, large quantities of *bhang* are manufactured for local and export sale. It is a question whether the time has not arrived for restricting the cultivation of the hemp plant and the manufacture of the drugs therefrom, as is done in Bengal and the Central Provinces." On this the Government remarked:—"A recommendation is made by the Fyzabad Excise Officer that cultivation of the hemp plant should be prohibited and the drug contractor empowered to destroy the wild plant. The Board are inclined to think that some action of this kind may now be required in these Provinces. But much clearer evidence as to the extensive culture of the hemp plant in the North-Western Provinces or Oudh is necessary before the proposal can be entertained, nor should the distinction between *bhang*, *ganja*, and *charas* be overlooked. The former is a comparatively harmless decoction from the leaves of the wild hemp, which grows freely in many districts, which cannot be made into *ganja*, and which it would be utterly impossible to extirpate by enactment. The cultivated plant from which *ganja* is made in Bengal and the Central Provinces requires, it is believed, somewhat different climatic conditions from those obtaining in these Provinces. The sole question, therefore, is whether any attempts to cultivate the *ganja* plant in these Provinces are increasing, and on this point the opinion of the Commissioner of Excise should be obtained."

The interpretation put by us on these passages was that the Board, through ignorance of the distinction between the wild hemp plant, which produces only *bhang*, and the cultivated special variety of the Rajshahye district from which alone *ganja* is made, proposed to take measures generally against the hemp plant in these Provinces with the object of checking the internal manufacture of *ganja*; and that the Government pointed out the futility of this by explaining that the common wild hemp of these Provinces does not produce *ganja*. We understand, however, that the Board was not guilty of this lapse and that all it meant was that the cultivation of the special *ganja*-producing variety should be restricted. Our error seems to have been shared by the Government, for the whole gist of the remarks recorded by it on the Board's proposal is that wild hemp alone is at present found to any appreciable extent in these Provinces, and that it is unnecessary to restrict *its* growth or cultivation, insomuch as it does not produce either *charas* or *ganja*. The misinterpretation of the Board's meaning is excusable on account of the ambiguous wording of the passage. The opening sentences refer exclusively to the general prevalence of the wild plant in the province, and contain no allegation that the cultivation of *ganja* is at present attempted here as in the Rajshahye district. As the Board would not be likely to propose to restrict what does not exist, it was not unnatural to attribute to it the intention of proceeding against the wild variety, the prevalence and use of which it had just been deploring. We are glad, however, to learn that this was not the Board's meaning, and that what it did wish to do was to prohibit cultivation of the *ganja*-producing variety, even though the cultivation as not yet been attempted in these Provinces and was likely to be impracticable. This would indeed [illegible] the forelock. We apologise sincerely to the Board for having imputed ignorance to it; but we fail to see that its proposal, when put into clear language, has any particular meaning. If the authoritative accounts of *ganja* cultivation (such for instance, as are contained in the statistical history of Bogra or Rajshahye, or in Baboo Hem Chandra Kar's report) be examined, it becomes clear that *ganja* can only be successfully produced on particular soils, by expensive and special methods of cultivation, and by cultivators possessing traditional knowledge of the habits and formation of the plant. The drug is obtained from the immature flowers and floral envelopes of the female plant, which in the cultivated variety and under special conditions contain a sort of resinous juice. To create or increase the quantity of resin is the art of the *ganja* cultivator in Rajshahye and Bogra, and we can assert from personal knowledge that the hereditary aptitude of the particular castes cultivating the plant is very marked. In the Doab the most that the Board can point to is an occasional hemp plant or two growing in a man's garden, often for the sake of ornament, which in loose language may be said to be cultivated, but is to all intents and purposes the wild variety growing under normal conditions, which can be readily distinguished from its congener, the cultivated plant of Bengal, and which will not yield marketable *ganja*, still less *charas*. Of the "drugs" which the Board imply are made in these Provinces, the only one which has any real existence is *bhang*. This is obtained by gathering and drying the leaves of the common wild hemp, which the Board correctly say grows in profusion in the northern districts. The Board, however, it is understood, do not propose to interfere with its growth: indeed, interference with it would be as little feasible as interference with the wild *datoura* plant. The Board's proposal is restricted to the few plants occasionally found within the enclosure of a cultivator's garden, which will not yield decent *ganja*, and which may yield an infintesimally small amount of *bhang*. There may be some point in the proposal which has escaped our notice, but, as far as we understand it, it seems uncalled for by the present conditions under which hemp grows in these Provinces. *Nec Deus intersit nisi nodus vindice dignus.* The knot in the present case is almost too small to be seen.

THE CHINESE FAN PALM (LIVISTONA SINENSIS) AND ITS USES.

In the report of the superintendent of the Botanical and Afforestation Department of Hong Kong for 1886, the following interesting facts are given on the cultivation of the Chinese Fan palm *(Livistona sinensis*, Mart.), for the manufacture of fans.

The Rev. B. C. Henry, who has travelled much in the Kivangtung province, says in his book "Ling Nam," that the palm district extends about twenty miles from east to west, and ten miles from north to south. It appears that fan palm cultivation is confined to the San Ui district. In reference to this, Mr. Henry says "That the limitation of this industry is a matter of necessity and not of choice, is proved by attempts made at various times to cultivate the palm in other places, attempts that have always resulted in failure."

Judging from the appearance of the country in travelling through the delta, the reputed failure of the palm when its cultivation has been attempted in other places than the San Ui district could scarcely be attributed to soil, as everywhere this had much the same appearance of richness and constituency. Knowing the immense influence which winds have on the growth and success of not only delicate plants, but also on the hardiest of trees, it is possible that the uninterrupted sweep of certain winds over the flat land of the delta, combined with some other minor uncongenial circumstances, may be the cause of the failure of the palm for commercial purposes. The San Ui district is protected by lofty hills to the north and westward, which possibly afford the conditions of shelter that the palm requires for the development of perfect leaves suitable for the manufacture of fans.

The palm plantations are situated on flat alluvia lands, about six to ten feet above the water of the rivers, and creeks which run through the delta, and they are intersected with numerous open canals or ditches four feet wide or more, for carrying off the surplus water in the rainy season, and for retaining it, by means of wooden sluices fixed on the banks which surround the plantations or fields for purposes of irrigation.

The land is not wholly given up to palm cultivation, but other crops, as bananas, plantains, papays, oranges, peaches, ginger, betel-pepper plant, and various vegetables occupy shares of the ground.

The cultivation of the palm and the manufacture of fans from its leaves is a most important industry. According to Mr. Henry, the manufacture of the fans after the leaves have been cut gives employment to about one hundred firms, and from ten to twenty thousand people. When the plantations are made, the young seedlings are placed at various distances apart, in order that different kinds of leaves, which are produced from plants growing at close and wider distances asunder, may be obtained for the manufacture of fans, for which thick or thin, or large or small leaves are required.

"The most perfect plantation which I saw was about half a mile in length, and about a quarter of a mile in width. It was drained by means of open canals as above described. The main body of plants were in perfectly straight rows, and they were exactly 4 feet 4 inches apart; the stems were from 2 feet to 4 feet high, and they bore about six fully developed and perfect leaves, the pelicles (stems) of which were 5 feet long, and the blade or leaf itself 3 feet long. Next to, and surrounding the main body of palms, about 100 feet wide of smaller palms, which were growing at only 2 feet from each other. The stems were but 1 foot high, they bore the same number of leaves (six) as the other plants, but, unlike them, half the number of leaves were bad. The leaves and their stems were each 1 foot shorter than those on the larger plants, and the pelicles were much more slender. Outside of this belt, and on the extreme margin of the plantation, there was a second belt which, however, was very narrow. It consisted of only three rows of palms, the plants being very close together, only 1 foot 4 inches apart. None of the leaves on this belt appeared good enough for fan manufacture.

"The inner belt of plants was intended, by reason of thicker planting, to serve as a screen to protect the main plantation from the damaging effects of winds, while at the same time it affords finer leaves for smaller fans. The marginal and closely planted belt was placed on the river bank to serve as a fence to keep intruders out of the plantation. For this purpose the palm, while in a young state, and when planted together, is well adapted; the spines on the pelioles presenting a barrier sufficiently offensive to the bare, stockingless, and shoeless legs and feet of the Chinese cooly. The long, straight vistas, the regularity of the planting, and the canopy of the verdant leaves overhead, produce on the visitor a delightful impression which is worth travelling some distance to experience.

"Other plantations contained palms of all ages. Some had trees upwards of a hundred years old, according to the assertions of natives, but these plantations always contained trees of mixed ages, young plants having been constantly added to take the place of older ones as they died out, or were blown down by winds. The old trees were always of a very stunted appearance, a condition which would naturally ensue from the continued lopping of its leaves. A parasitical fungus or lichen covered these old trunks, and gave them the appearance of having been whitewashed. The tallest trees seen were only about twelve feet high, but they were said to be upwards of a hundred years old. The leaves on these old trees are larger and stouter than those on young plants, and the stems of the leaves are only about a foot long. The palm begins to yield leaves suitable for fans when it is about six years old. The first cutting of leaves takes place early in the year, and the leaves which are somewhat damaged by the winterly winds and consequently of inferior quality, are used for thatch in the construction of the 'matsheds' which are too extensively used for temporary purposes in China.

"Leaves for fan making are obtained in April, one, two, or three leaves being taken from each plant, and the process is continued each month until November, when, I was informed, cutting is discontinued for a few months. The leaves are taken from the plantations to a clear space covered with short grass turf. Here each leaf has a thin piece of bamboo placed across the blade where it is joined on the stem. Each end of the bamboo is secured in its place by the loose end of a segment of the leaf being dexterously bound round it. The bamboo prevents the leaf curling up while it is drying. The leaves are then laid out singly on the turf to dry in the sun, and collected and stacked at night. The process is continued daily until the leaves are quite dry, when they are either sent off direct to the town to be made into fans, or they are stacked for a time until the manufacturers are ready to receive them."

The manufactory of the fans is carried on chiefly in the town of the San Ui, but there are also some establishments in the country where this is done. The dried leaves are subjected to a process of blanching by means of sulphur. They are then straightened and rendered shapely by being held and manipulated over a charcoal fire. The operator, as he finishes the fans, places them one by one on each other, making a heap on the floor; the heap is firmly pressed down by the weight of the operator, who stands on a board placed on top of the heap while he is working at succeeding fans. When a heap of twenty or thirty fans have been thus treated, they are removed, and another series is begun. The next process is sewing on the bindings at the edge of the fans, this is done by women and children, chiefly at their own homes, and the fans returned, when finished, to the manufacturer. The more expensive fitting of horn and bamboo handles is done at Canton. The portion of the stalk which is not required as a handle for the fan is not wasted; it is composed of a fibrous material that is utilised in making short lengths of rope used as slings to suspend baskets from carrying poles. Around the stem, as bases of the leaf stalks, there is a quantity of fibrous substance, somewhat resembling coir fibre; this is carefully collected, and also used for making ropes.—*Journal of the Society of Arts.*

THE CULTIVATION OF THE CASTOR OIL PLANT.*

According to a common saying the castor oil plant can be grown wherever Indian corn will grow. Yet this saying does not quite correspond with the facts, because, while it may accompany corn northwards as an ornamental plant, if the locality is favourable, its profitable cultivation is only possible in certain zones. In the United States, for instance, the northern limit is about the middle of Iowa, and as far as altitude is concerned, the castor oil shrub remains from 2000 to 3000 feet below the level at which corn may still be raised. The castor oil plant is not a food-plant like corn; its only value lies in its yield of oil; and the warmer its place of growth the more oil will it yield. Hence it would be folly to expect large profits (if any at all) from the cultivation of the castor oil plant in unsuitable localities.

The question of the applicability of any given locality for this cultivation, however, depends for answer upon still other conditions, besides atmospheric temperature. It is necessary to take into account the available moisture. In many parts of the sub-tropical zone the coldest period arrives at the close of the rainy season, which corresponds to the winter. This cold period must be allowed to elapse completely

* Extract from 'Die Tropische Agriculture. Ein Handbuch für Pflanzer and Kaufleute.' von H[illegible] Semler in San Francisco. Vol. II., 8vo, Wismar, 1887. From the *American Druggist*, June.

before sowing can take place. For neither corn nor the castor oil shrub can stand the slightest frost, and their seed rot in the ground unless the latter is thoroughly warm. This condition is not fulfilled until after the rainy season is over. Of course, where natural rainfall is defective, artificial irrigation may be used, but this is never as effective as the former.

Before starting any plantation of the castor oil plant, the amount of available moisture, either natural or artificial, must be thoroughly studied.

The castor oil plant requires a very rich soil, if it is to yield an ample crop, as may be seen from the following composition of the ash of the seeds:—

Lime	88·38
Magnesia	7·33
Oxide of iron	0·89
Phosphoric acid	38·65
Sulphuric acid	2·21
Chlorine	0·89
Potassa	29·52
Soda	8·75
	100·00

Attention is called to the large amount of potassa, and particularly to the extraordinarily high percentage of phosphoric acid. The plant also requires a copious supply of nitrogen. Unless the cultivation is started on virgin soil manuring can scarcely be avoided, though it would be useless to expect everything from artificial enrichment of the soil. The latter must be naturally adapted to it. It must, besides, be neither too loose nor too dense; neither stiff clay nor loose sand answers the purpose. A clayey-sand or sandy-clay bottom or alluvial ground is most conducive, provided it is of sufficient depth and porosity.

While it would be the most rational method to ascertain the capabilities and requirements of a soil by a chemical analysis of it, made from time to time—and this should be done if at all possible—yet in many cases this will be impracticable. It is, therefore, of advantage to know a manuring compound which is likely to furnish all the required constituents, without doing harm by the presence of one or another in excess. Such a compound is produced by a mixture of

Cotton seed	750 parts.
Stable manure	750 „
Superphosphates	500 „

If cotton seed cannot be obtained, the following may be used:—

Cotton seed meal...	500 parts.
Stable manure	1000 „
Superphosphate	500 „

These substances are to be made into a heap under cover, and to be thoroughly moistened, in order to prevent overheating and to promote fermentation. After six weeks the mixture may be applied to the fields, from 1000 to 3000 pounds per acre, according as may be required. The soil must be turned deep as the roots of the shrub penetrate to a considerable depth.

When the soil has been properly prepared sowing may commence. This should be done in the beginning of the rainy season, except where frosts are to be expected near its end, in which case the beginning of the hot season must be awaited. The next question to be decided is which variety is most suitable for the locality. If the common species be employed, which usually grows to the height of about 8 feet in the sub-tropics, the plants must be placed at intervals of 4 feet in all directions. Under the tropics the shrub grows 2 or 3 feet higher; the distance here must be 5 feet. If a still higher variety is chosen (such as *Ricinus sanguineus*), the distance should be extended to 8 feet.

In planting out on a large field, supposing the distance between the plants is determined at 5 feet, it is advisable to leave a space of 7 feet after every five rows of 5 feet apart, but only in one direction. This wider passage facilitates the harvesting.

The seed-beans are soaked for twelve hours in luke-warm water, then laid in pairs in the market places, and covered with earth 1 inch high. As soon as the plants are 3 to 5 inches high, the weaker of the two plantlets is pulled out at every place. Sometimes four beans are planted at a time, and the two weakest ones pulled out, but this is not to be recommended. If economy of space is necessary, it is better to put the plants closer together, rather than to duplicate them in one place.

The field requires only a repeated loosening of the soil with the cultivator, not with the plough, as this penetrates too deep and injures the roots. Hence even the cultivator must be adjusted at a rather slight depth. How often this operation should be performed depends on the weather. Four repetitions are usually sufficient. Of course, the soil in the immediate vicinity of the plant must be loosened with the hoe or rake.

So far as known to the author, the castor oil plant is only attacked by one insect, the same as infests the tobacco plant; all other insects shun it. In fact, the presence of the shrub appears to be a good agent to repel insects of all kinds. For this reason, probably, it is customary in some tropical districts to surround the field with several rows of castor oil plants, a practice that appears to deserve imitation.

When the pods ripen, they turn brown, hard and brittle, and begin to burst. All pods do not ripen on the plant at the same time, but the ripening process proceeds from below upwards. Hence the harvesting must be done in several instalments. For this purpose it is quite customary to use a sort of sled, drawn by a docile horse or other animal, which is guided through the wider passages of the field, while the ripe capsules are collected at either side of it and thrown into the box of the sled. A smooth ground is previously prepared at a suitable place in the neighbourhood, and surrounded by a board fence 4 to 5 feet high. Upon this place, which must be exposed the greater part of the day to the hot rays of the sun, the capsules are piled to a depth of 3 to 4 inches, and turned over with a shovel once each day. With favourable weather, the capsules burst completely in four or five days. In order to separate still adhering seeds, a very light roller, drawn by an unshod horse, is rolled several times over the ground, the capsules being turned over before each new circuit.

The capsules and beans are then put in one heap, and the latter separated from the former by a winnower or by means of throwing with a shovel.

The ground having been cleared, it is ready for the next crop, and this is continued until the harvest is over. The shrubs are then cut down and put in the compost heap.

The clean beans are finally put in bags, and sold to the miller.

In the East Indies the oil is extracted by crushing the beans between two rollers, the mass is packed into hempen sacks, and expressed by a screw-press. The oil is mixed with water, and the latter raised to boiling. This causes the impurities to rise to the top. The oil is next strained, bleached by exposure to the sun, and transferred into casks. In Oudh, the crushed beans are boiled with water, and the oil which rises to the surface gradually dipped off.

In the United States, the usual process followed is to expose the beans in an oven for an hour to a dry heat, which has been found to facilitate the extraction of the oil. They are next transferred (in bags) to a strong screw-press, and the oil, as it runs out, immediately mixed with an equal measure of water. The mixture is boiled for an hour, which causes the coagulation and separation of the albuminoids contained in the oil. After cooling, the oil is drawn off and transferred to large zinc tanks, in which it remains eight hours. Finally, it is exposed to the sun to bleach. One hundred pounds of beans yield about 18 quarts of oil. The finest oil is obtained by a process, which, according to the author, is only partially known. The beans are first passed through rollers in which their peel or skin is taken off, which contains an oil of disagreeable taste. They are then crushed, and either cold-pressed or extracted with alcohol. The oil is finally purified by contact with

acids, and the final product is a fine, clear, nearly colourless oil, almost devoid of odour and taste.—*Pharmaceutical Journal.*

CONTRIBUTIONS TO THE KNOWLEDGE OF CATHA LEAVES.

BY PROFESSOR FLÜCKIGER AND J. E. GEROCK.

Catha edulis, Forskal, is a glabrous tree or shrub, widely distributed in the interior of eastern Africa from Abyssinia to Port Natal * which appears also to be largely cultivated throughout those regions as well as in the southern districts of Arabia.

The first scientific notice of catha is due to the Swedish botanist Peter Forskal who died in Arabia, in July, 1768, after having explored the flora of that country and lower Egypt. The statement referring to Catha will be found in the 'Flora Aegyptiaco-arabica,' Haviniae, 1775, p. 63, edited by Carsten Niebuhr.

The short account of Forskal is as follows:—

"Catha. Arbor. Rami alterni, axillares; ramuli virides, annui, articulati. Folia bipoll. ovato-lanceolata, serrata, glabra, plana, nitida, patentia, rigida, opposita; in ramis magnis alterna. Petiolus superne planus, brevis . . . . Pericarpium, capsula oblongo-cylindrica, trilocularis, monosperma in quovis loculo.

"Arab. 'Giat' vel 'Kat.'

"In Yemen colitur iisdem hortis cum caffea. Stipitibus plantatur.

"Arabes folia avide edunt, multum earum vires venditantes, qui copiosius comederit, vel totam vigilet noctem; asseverant quoque pestem ea loca non intrare, ubi haec colitur arbor: et hominem ramum cathae in sinu gestantem, tuto posse inter infectos peste versari. Gustus tamen foliorum tantam virtutem indicare non videtur."

Catha edulis is now the prevailing name, although we are not aware of Forskal's having bestowed it on the plant, which was described by Richard under the name of *Catha Forskalii*. The specific name of "edulis" would appear to be partly due to Vahl, who termed the plant *Celastrus edulis* in his 'Symbolæ botanicæ,' i. (Havniae, 1790), 21.

According to Bentham and Hooker, 'Genera Plantarum,' i. (1862—1867) 361, there is but one species known of the genus *Catha*; the same is Baillon's opinion in his 'Dictionnaire de Botanique,' vol ii., p. 655. So we may quote the diagnosis of the former work as an excellent diagnosis of the plant:—

"Calyx 5-lobus, parvus. Petala 5, erecto-patentia. Stamina 5, margini disci inserta, filamentis subulatis; antherae late didymae. Discus tenuis, margine undulato. Ovarium ovoideum, disco immersum, liberum, 3-loculare; stylus brevis, crassus, stigmatibus 3 brevibus, liberis v. basi connatis; ovula in loculis gemina, e basi erecta. Capsula lineari-oblonga, 3-gona, loculicide 3-valvis, 1-3-sperma, septo medio perassatis. Semina immatura medio septo hinc late alato, compressa, testa minute tuberculata, foramine dilatato intero. Frutex glaberrimus, ramulis cinereis. Folia opposita, petiolata, lanceolata, coriacea, grosse serrata. Stipulae e cilius paucis . . . ."

Among modern travellers who became acquainted with kat in its native countries we may quote the following:—

P. E. Botta,† in 1837, found catha much in use, and largely and most carefully cultivated in the mountains of south-western Yemen, in the mountainous district of Saber, between 13° and 14° N. lat. Botta was presented by one of the Sheikhs of the country with a bundle of branches of kat, according to the rules of politeness of that people. He ascertained that the leaves when chewed had an agreeable, exciting action, which imparted the desire to spend the night rather in quiet conversation than in sleep. Botta expressly states that he thought extremely pleasant that kind of excitation and the lovely dreams provoked by the use of kat. He gives an account of its virtues much resembling those of coca leaves; in Yemen kat affords the same relief, chiefly to messengers while on hard journeys, as coca does in the Cordilleras.

Every visitor being presented, in good houses, with twigs of kat, chews the leaves and throws on the floor of the reception room not only the stalks, but also these parts of the leaves which he has not swallowed. Botta, nevertheless, speaks in high terms of the green bundles of catha and their agreeable smell; he says that the leaves are strongly inebriating when freshly cut, but the intoxication does not last for a long time.

In the 'Flora' of Regensburg, xxiv., part 2 (1841), p. 662, Ch. F. Hochstetter, describing some new African genera, suppose kat to belong to an undescribed plant, and, therefore, mentioned it under the name of *Trigonotheca serrata* in the following terms:—

"Frutex foliis oppositis simplicibus lanceolatis in petiolum brevem attenuatis obtuse serratis glaberrimis luridis discoloribus . . . . . Colitur ad oppidum vel pagum Abba Gerima, prope Adaua et in provincia Schiré nomine abyssinico Tschat, folia crude a Muhammedanis comeduntur et infusione aquæ ferventis potum sapidum Theae instar praebent."

In his exploration of Abyssinia and Shoa, Major, Harris,* 1841-1843, repeatedly met with khat (chaat) or kath. He stated that the shrub or little tree, not exceeding 12 feet in height, was extensively cultivated in Shoa and the neighbouring countries of Kat and Kaffa (about 5° to 10° N. lat.), although it is indigenous in the western mountains, in a region of from 5000 to 8000 feet above the level of the sea, where the temperature, on an average, varies from about 15° to 16° (60° F.) The leaves of the kat are either chewed by the people or boiled with milk or water so as to take the infusion. † They also make a drink of it by adding honey; it is bitter and stimulating, and prevents sleeping if taken in excess.

In Abyssinia catha was again met with by the French expedition of Lefebvre, Petit et Quartin-Dillon, 1839-1843. The botanic results of that expedition being edited by A. Richard, this botanist devoted a page to *Catha Forskalii*, as he termed the tree, in the 'Partie Botanique,' tome iv. (Paris, 1847), 134. Among synonyms bestowed upon Forskal's catha, Hochstetter's name of *Trigonotheca* is shown by Richard to be due solely to the author's not having been aware of Forskal's description.

We need borrow only the following lines from Richard:—

". . . . fol. opposit. rarius alternis . . . . Crescit ad pagum Abba-Gerima, prope Adaua, ubi colitur (Quartin-Dillon et Schimper), et in provincia Choa (Ant. Petit et Rocher d'Héricourt)

"Nomina vernacula, Tschut, Tohat, Tohaï."

In another French account of Abyssinia, a few years later, kat will be found under the name of *Celastrus Tsaad*, Ferret et Galinier; the tree is in fact closely allied to *Celastrus* as already noticed by Vahl. The following account in the botanical results of that expedition‡ is of some interest:—

"Grand arbrisseau qui est appelé Tchaad, cultivé à Abbagarima et dans le Chire. Les Mahometans, comme à Moka, mangent les feuilles crues ce qui les enivre légèrement. Les feuilles, préparées à la manière du thé, donnent une infusion assez agreable à boire."

* 'The Highlands of Ethiopia and Embassy to Shoa.' By Major W. Cornwallis Harris, of the Hon. E. I. Comp Engineers. London, 1844. We have before us only the excellent German translation by Kraft von Kallinger), 2 vols. Stuttgart, 1844-1846. The short remarks on kat will be found in vol. ii., p. 300, and in the Appendix, pp. 34 and 174.

† In a short notice of the British Vice-Consul at Hodeidah, *Pharm. Journ.*, xvii. (1857), 6, it is expressly stated that the Arabs do not make a decoction from kat.

‡ Ferret et Galinier, 'Voyage en Abyssinie,' iv. 1847, 109.

* Oliver, 'Flora of Tropical Africa,' i., 361.

† 'Relation d'un voyage dans l'Yemen, entrepris en 73.' Paris, 1841, pp. 45, 84, 99

"Les feuilles du sommet des rameaux sont parfaitement opposées, un très-léger bourrelet transversal passe du pétiole d'un coté du remeau au pétiole de l'autre coté. La base des rameaux offre des feuilles, alternes, ordinairement assez rapprochées, deux par deux, pour faire voir que cette disposition n'est qu'un déplacement."

We have been also informed recently (June, 1887), by Dr. Anton Stecker, that he saw stately trees of catha near kórata on the lake of Tana, Abyssinia. And again, another highly competent authority, Dr. E. Glaser, now (June, 1887) at Prague, tells us that the plant is termed Kat in Southern Arabia, Tsat or Tschat in the Abyssinian idiom of Amhara. In the countries on the lake of Tana, they call it also Kut es Saláhin. In a letter to Professor Euting of Strassburg, Dr. Glaser states that in Abyssinia the area of catha is limited to those districts south of the lake of Tsana. The most northern region where catha is to be met with in Arabia is apparently a place north of Sana; it succeeds best in the valleys of 'Uppas and 'Afis, south of Sana, as well as in the mountains of Yemen at elevations ranging from 2200 to 2400 feet.

In Abyssinia they chew the young leaves of catha, either fresh or dried, or they use their infusion sweetened by means of honey. According to Dr. Stecker, only the Mahometans chew the drug; he is of opinion that the plant was taken to Yemen by the Mahometans of South Abyssinia.

In 1859 James Vaughan, Assistant Surgeon, Civil and Port Surgeon at Aden, mentioned kat among other drugs observed at Aden. He speaks, in the *Pharmaceutical Journal*, vol. xii. (1859, Nov. 1), p. 268, of the strong predilection which the Arabs have for kat; the quantity used in Aden alone averages about 280 camel-loads annually. The exclusive privilege of selling it is farmed by the Government for 1500 rupees per year.

Captain Hunter, in 1877, informed one of us (F.) that in the previous year 1200 camel-loads of kat found their way to Aden, and that 8000 rupees were paid for the privilege of collecting duty on the commodity.

Vaughan gives a good representation of two bundles of kat, viz. "Subbare Kat." about 6 inches (14 centimetres) long, and Muktaree Kat," about half that size, and states that the former is considered of superior quality.

In the interior of the peninsula the use of kat seems not to be known. We are informed, for instance, by Professor Euting, that, in December, 1883, in his journey in Arabia, he was told at Hajel by people belonging to the tribe of the Kahtani that with them, in the Wadi ed Dawasir (about 19° to 22° N. lat. and 45° E. of Greenwich), kat chewing was not practised at all.

Another of the recent explorers of the interior of Arabia, Dr. Glaser, on the other hand, informed Professor Euting, that in the valley just named, as well as in the Nedjran (18° N. lat), kât *i. e.*, chiefly its young leaves, was chewed when Dr. Glaser paid a visit to those regions; he himself chewed the drug, which, however, he never appreciated very much.

From all the foregoing statements,* it appears that catha is much appreciated in Yemen as well as in the interior of north-eastern Africa. In a description of the island of Perim,† in speaking about the Arabs, the author says:—"They also frequently come across the straits in canoes with fresh provisions of all kinds for sale. . . . . They also sometimes bring the leaves of a shrub called *Kát*, a drug much used by the Arabs and Somalis as a pleasurable excitant, the leaves and tender shoots being said, when chewed, to produce hilarity of spirits and an agreeable state of wakefulness."

Another statement‡ is to the effect that the leaves are shipped at Berbera, on the Somali coast, for Yemen, where they find a good market; the people there chewing them say that they have an action similar to that of opium, but milder.

As the tree or shrub is also largely cultivated in the interior of southern Arabia, mostly in gardens along with coffee, bundles of twigs tied together with strips of bark find their way to Aden. The effects of the leaves being the same as those of strong Chinese green tea, a synod of learned Mussulmans issued a decree acknowledging that it was perfectly lawful to use kat, as it neither injured the health nor hindered the proper observance of religious duties. It produces wakefulness and watchfulness, so that a man may fulfil the duties of a sentry all night without a feeling of drowsiness.*

Catha appears to have been introduced some time ago in European temperate houses; in 1867, the plant flowering in the botanical garden of Basel, Dr. Christ availed himself of the opportunity of examining exhaustively the floral organs of catha, which he figured at the same time in the *Archiv. der Pharmacie*, vol. cxli. (1870), p. 67-71. In an additional note, in the same periodical, cciii. (1873), p. 52, Dr. Christ very accurately described the bluntly conical capsule of catha, as ripened in the botanical garden of Lissabon. It is triangular or quadrangular, having three or four dehiscent valves, the whole fruit being 6 or 8-celled. Dr. Christ also pointed out the peculair form of the arillus in the very small seeds of catha.

We may state here that one of us has repeatedly observed the living plant in the beautiful garden of Mr. Thomas Hanbury at La Mortola (Palazzo Orengo), near Mentone. The small stipules, as pointed out by Bentham and Hooker, *l. c.*, which Dr. Christ failed to notice in his specimens, distinctly occur in the shrub as growing at La Mortola. The largest leaves to be seen there are 11 centimetres (4½ inches) in length by 7½ centimetres (3 inches) wide; in some shoots they are opposite, in others alternate. We have branches before us showing both kinds of the arrangement of leaves. The petiole does not exceed 1 centimetre in length, but usually reaches but half a centimetre. The margins of the leaf, on each half, display, in the largest leaves, about forty short blunt teeth, ending with a glandular organ. Perhaps these glands are more developed or more active in the East. In the fresh leaves of La Mortola we failed in perceiving any marked taste or aroma, whereas Botta, as mentioned above, alluded in high terms to the pleasant smell and taste of kat. Forskal, on the other hand, was not at all aware of these virtues of the leaves. In Aden, as Professor Schär, Zürich, was informed by Mr. Escher, a correspondent of his anti-aphrodisiac powers are now attributed to catha.

It would appear that the climate and soil of Mr. Hanbury's estate at La Mortola, on the Mediterranean, are very congenial to catha; it has been most luxuriantly growing and flowering there for nearly twenty years, forming a few slender bushes 6 metres (about 18 feet) high; the largest stem is 21 centimetres in circumference (nearly 3 inches in diameter) at a distance of 10 centimetres from the earth. One of us collected there, in April, some flowering branches. Mr. Hanbury says it is in flower for months in the winter and spring, yet it has never fruited with him. It was introduced in that garden by the late Daniel Hanbury in 1868, as we are kindly informed by his brother, Mr. Thomas Hanbury.

The fine plate, No. 30, of Richard's 'Botantical Atlas' to Lefebvre, Petit et Quartin-Dillon's Voyage en Abyssinie,' gives an excellent figure of catha. The identity of the Mortola plant is, therefore, unquestionable; still we never met there with so narrow

* We omit a few others of very little interest which are mentioned by Friedrich Tiedemann, 'Geschichte des Tabaks und anderer ähnlicher Genussmittel,' Frankfurt, 1854, 429.

† *The Geographical Magazine*, November 1, 1877, p. 291.

‡ *Preussisches Handelsarhive*, 1875, ii., 404.

* *Pharm. Journ.*, xiii. (1883), 840, from *Produce Markets Review*, March 24, 1883. An abstract will also be found in *Just's Botanischer Jahresbericht*, 1883, p. 396. No. 61, as well as in the 'Year-Book of Pharmacy,' 1883, p. 219. The same statements also occur in Captain Hunter's 'Account of British Settlement of Aden in Arabia,' London, 1877, p. 139. All this second-hand historical information is due to the writings of Silvestre de Sacy and d'Herbelot.

leaves (14 millimetres, little more than half an inch). Such a striking difference may explain that, for instance, at Harrar there are no less than four varieties of kat in the market.* The leaves we received from Aden may be said to range between Richard's figure and the Mortola plant as regards their average size, answering to the figure of "Subbare kat" of Vaughan's paper. It is, on the whole, quite natural, that a shrub or tree which is so widely distributed and so extensively cultivated should accordingly display considerable variations.

The leaves of catha are leathery, of a dull shining green on the upper surface, paler beneath, entirely glabrous and traversed by a reddish midrib giving off a system of veins running towards the edges and the apex without exhibiting any remarkable peculiarity. The same applies to the anatomical structure of the leaf. The transverse section shows the usual structural elements as met with in many other leaves, without any peculiar feature. The leaves belong to that class provided with but one layer of "palissade cells" within the epidermis of the upper surface; in catha that layer is built up of a double row of those vertical, elongated "palissade cells."†

There is no evidence of catha having been used in ancient times; no mention of the leaves is met with in the great Cyclopædia of Ibn Baitar, written about A. D. 1240. We are informed by Professor Noldeke, that, according to S. de Sacy's 'Chrestomathie arabe.' 2nd edition, i., 462 Abdalkadir, an author of the sixteenth century, stated that in Yemen they used "Kafta" long before they indulged in coffee. The latter was resorted to in Aden when in the time of Dhabhani, in the fifteenth century, kafta had become a rare article, kafta, says Abdakadir, being the same as kat, a stimulating, not inebriating drink, which is consequently permitted like coffee. Kat would appear to mean the leaves, kafta the drink.

Similar statements will be found in D'Herbelot, 'Bibliothèque orientale,' i. (La Haye, 1777), 461, under the article "Cahnah." ‡

All the above statements concur in attributing eminent powers to kat, which would seem to be possibly due to caffeine.

Attfield failed in discovering caffeine in the leaves of catha (*Pharm Journ.*, vi., 1865, p. 400), and one of us § likewise ascertained that they do not contain that substance. The absence of caffeine was again proved, *Pharm. Journ.*, xvii. (1887), 1009, by Dr. Paul.

Professor C. Schorlemmer, F. R. S., also devoted an interesting note‖ to the leaves of caffea, thea and catha as grown in the temperate house at Kew Gardens. He ascertained the presence of caffeine in the cultivated leaves of *Caffea arabica*, *Caffea laurina* (none in those of *Caffea liberica*), *Thea viridis* and *Thea assamica*, but failed in discovering caffeine, both in the fresh leaves as well as in old ones from the museum, of *Catha edulis*. Professor Schorlemmer only isolated from catha a minute quantity of a kind of sugar, apparently mannite.

Our friend, Professor Semler, Zurich, afforded us the opportunity of examining some bundles of kat twigs of the best quality obtainable at Aden. They were about from 15 to 20 centimetres (4 to 6 inches) in length, each of them provided with about twenty leaves of average size. The leaves alone were powdered, and the powder, 1300 grams (nearly 3 lb.), gently warmed with 5 litres (1-10 gallon) of water containing 10 grams of oxalic acid (nearly one-third of an ounce). After a few hours the whole was packed into a percolator and the liquid drawn off the next day. The washings and the percolate were concentrated to the volume of 2 litres, and mixed with half the amount of quicklime which would have been required for saturating the oxalic acid employed. Then the brownish-green liquid was allowed to stand for some hours; it then became clear, and was evaporated to half its volume. On saturating it with caustic lye in a good excess it turned dark brown. We immediately exhausted it by shaking it repeatedly with light petroleum, boiling point from 30° to 65° C. (86° to 149° F). The petroleum was distilled off for the most part, and the remaining liquid, about 100 c. c., shaken with five consecutive portions of dilute hydrochloric acid. On saturating the clear acid solution with an excess of caustic lye it became milky. By repeatedly shaking the turbid liquid with ether it at last became clear.

The ether, allowed to evaporate in the cold, afforded a trifling quantity, say 0·5 gram, of a thickish oily yellowish matter, which readily dissolved in dilute acetic acid, this solution giving with iodated iodide of potassium or iodohydrargyrate of potassium precipitates which are characteristic for alkaloids.

No trace of crystallization appeared in the residue from the ethereal solution, even after several days' standing at a low temperature. This alkaloid, the small amount of which did not allow of any further purification, readily dissolved in water, and this solution reddened test-paper impregnated with phenolphthalein. The red colour soon disappeared from the paper, probably due to the evaporation of the alkaloid. When the alkaloid, which might be termed *katine*, was treated with dilute acetic acid, a very trifling residue remained undissolved. The clear filtrate, carefully evaporated over concentrated sulphuric acid, yielded a decidedly *crystalline acetate of katine*. Its aqueous solution was not precipitated by tannic or picric acid, nor by chloride of platinum.

We also expressly ascertained that no caffeine was present in our "katine," which, in all probabilty, will prove to be a liquid when perfectly pure.

An epitome of this paper was read by Mr. Naylor.

The President, in proposing a vote of thanks to the authors, said that doubtless these catha leaves were used as coca leaves for the purposes of preventing exhaustion.

The vote of thanks to the authors was carried unanimously.—*Pharmaceutical Journal.*

FRUIT *v.* MALARIA.—Residents in the Western States of America and other regions where intermittents and similar diseases result from malaria state that a regular supply of ripe, home-grown fruit is almost a preventive. Eat the fruit only when fully ripe, and only moderate quantities at a time.—*Indian Gardener.*

THE NEW FERTILISER.—The Thomas-Gilchrist process of steel-making is daily proving an increased source of wealth to the English iron-making districts whose ores are of a phosphoric nature. The employment of the waste slag produced from the basic converters in the course of manufacture in agricultural fertilising is proving very successful. Those chemical elements which, if present in excess, are productive of much loss to the steelmaster are invaluable to the farming community. The Staffordshire Steel and Ingot Iron Company, at their works at Bilston, are experiencing such a good demand for the basic manure that they have made arrangements for doubling their present grinding power. The Company are now manufacturing 100 tons of the finest ground steel manure per week, and if their capacity were doubled they might have orders in hand for 2000 tons ahead.—*Chemist and Druggist.*

* Paulitschke, Petermann's 'Geogr. Mitteilungen,' xxxi. (1885), 165. Hunter, 'Account of the Brit. Settlement of Aden,' p. 111. Also mentions Sabrai kat and Mukh'ra kat, from the districts in which they are produced; the latter bearing the lower price. The two varieties are evidently those figured by Vaughan, *l.c.*

† See Flückiger und Tschirch, 'Grundlagen der Pharmakognosie,' Berlin 1885, pages 102 (fig. 96), 183 (fig. 127), 184 (fig. 128), 185 (fig. 129); or English translation, by Power: New York, William Wood and Co., 1887, pages 186, 210, 211, 212, the figures just alluded to.

‡ Abstracted by the late Daniel Hanbury in his notes to Vaughan's paper, *Pharm. Journ.*, xii. (1852), 270.

§ Flückiger *Archiv. der Pharmacie*, vol. cxl. (1870), 72.

‖ *Chemical News*, vol. xlviii. (Nov. 9 1883) 225.

A NEW VEGETABLE FIBRE, called *Gemoëtie*, hitherto little known in Europe, is now being imported into Rotterdam from Celebes. Various attempts have been made, without success, to apply this substance to the manufacture of cordage. It is principally used at present for stuffing furniture and saddlery.—*Straits Times.* [The fibre of the gomuti palm is by no means a 'new' one.—ED.]

PRITCHARDIA THURSTONI.—This is a new Fan Palm, discovered in the Fiji Islands by the Governor, and illustrated and described by Dr. Drude in the *Gartenflora* for September, in conjunction with Baron Von Mueller. The tall cylindric unarmed stem bears a crown of roundish plicate leaves, from whose axils project long slender stalks like fishing-rods, bearing a thyrse-like inflorescence at the extremity.—*Gardeners' Chronicle.*

CINCHONA BARK USED AS FUEL AT LAST.—We hear that a large mill in Colombo has actually used a lot of twig cinchona bark as fuel for its engines, so that a remark made in our columns some time ago has come literally true. At the present moment twigs cannot be parted with at 1 cent a lb.,and, if planters have any with Colombo agents, it might be well if they advised the latter to put it to the same use as the instance recorded above, provided no account for charges was sent in.—Local "Times." [Can it be true?—ED.]

A GIBBS AND BARRY DRIER ON ELKADUWA ESTATE.—We hear that a Gibbs and Barry's Drier is now in course of erection on Elkaduwa estate, and that Mr. Barry is now on his way out from home, and intends to make a short stay in Ceylon, in order to push the Drier which bears his name. We believe the Gibbs and Barry drier is largely in use in India, and is said to do capital work. The greater the competition amongst patentees the better it will be for planters, and so we welcome this last imported drier into the island.—Local "Times."

RAMIE CULTURE.—The attention of persons intending to engage in the cultivation of ramie is called to the fact that the Hawaiian Legislature, at its session in 1886, voted the sum of $5,000 for the encouragement of ramie culture, to be paid to planters at the rate of $50 per acre, for ramie ready to be cleaned. A further sum of $5,000 was also voted to encourage the manufacture of this article, at the rate of $200 for each ton of cleaned fibre prepared for the market, at the lowest cost to the producer.—*Planters' Monthly.*

"GARDENING IN CEYLON."—Messrs. A. M. and J. Ferguson of Colombo have just brought out a work on Gardening in Ceylon, which has every appearance of proving serviceable to horticulturists in the tropics. It comprises hints on gardening and directions how to manage the kitchen garden and orchard which are full of practical information. The value of the work is enhanced by a list of vegetables, and instructions how to grow roses. The particulars given of the different kinds of vegetables, and the best way not only of cultivating them but also of preparing them for the table, bear the marks of painstaking care to render technical details clear and intelligible. Though Singapore is nearer the equator than Ceylon, many of the hints and directions contained in the work will be found useful to those who take an interest in gardening matters.—*Straits Times.*

THE TEA SUBSCRIPTION.—Mr. Wm. Shakespeare, who not only never drank a cup of tea in his life, but never heard the name uttered in any of its forms, from *Cha* to *Tay*, and so on to *Tea*, never imagined the use which another William would make of his verse in an island of which probably Shakespeare had but the vaguest idea. The general impression is, we believe, that Mr. Rutherford is a wide-awake tea planter, but Mr. Wm. Mackenzie, who evidently sleeps with both eyes open,—one directed towards Glasgow and the other to Melbourne,—modestly takes credit to himself for waking Mr. Rutherford from a prolonged fit of somnolence to a true sense of the duty which Ceylon at this crisis requires of her tea-producing sons. Be this as it may, we trust the planters will be all wide-awake to their own interests in subscribing to the "pushing" fund. For what says Mr. W. Mackenzie's favourite source of inspiration?

There is a tide in the affairs of men,
Which, taken at the flood, leads on to fortune.

OZONE FROM FLOWERS.—It is said that a "professor at Pavia has discovered that ozone is generated in immense quantities by all plants and flowers possessing green leaves and aromatic odours. Hyacinths, Mignonette, Heliotrope, Lemon, Mint, Lavender, Narcissus, Cherry Laurel, and the like all throw off ozone largely on exposure to the sun's rays. So powerful is this great atmospheric purifier, that it is the belief of chemists that whole districts can be redeemed from the deadly malaria which infests them by simply covering them with aromatic vegetation. The bearing of this upon flower culture in our large cities is also very important. Experiments have proved that the air of cities contains less ozone than that of the surrounding country, and the thickly inhabited parts of cities less than the more sparsely built, or than the parks and open squares. Plants and flowers and green trees can alone restore the balance."—*Journal of Horticulture.*

FOSSIL WOOD.—An interesting paper has been communicated to one of the California scientific societies on the fossil wood found throughout the State. This silicified wood is stated to be a variety of quartz; the wood fibre is gradually replaced by quartz, leaving the form of the wood intact so much so that sections cut and placed under a microscope show the characteristic grain of the wood, by which the genera may often be determined, and sometimes the species. In what is known as the petrified forests in Colorado, where are stumps of trees several feet in height and some 12 or 15 feet in diameter, one stump seemed to have been fossilized while in a charred state, and from it fossil charcoal was obtained. Many of the specimens of wood are encrusted with layers of crystallized chalcedony of an opalescent tint, so beautiful that sections have been mounted and worn as jewellery. In Wyoming there have been found sections of trees 20 inches in diameter and several feet in length, like hollow tubes, with the interior surface entirely studded with pure quartz crystals, presenting a most beautiful appearance.—*Indian Agriculturist.*

DOCTOR JOHNSON'S PARTIALITY FOR TEA.—In his review of Hanway's *Tea and its Pernicious Consequences*, Doctor Johnson proclaims himself as "a hardened and shameless tea-drinker, who has for many years diluted his meals with only the infusion of this fascinating plant, whose kettle has scarcely time to cool, who with tea amuses the evening, with tea solaces the midnights, and with tea welcomes the morning." Boswell says that he supposes no one ever enjoyed with more relish the fragrant leaf than Johnson. The quantities he drank of it at all hours were so great that his nerves must have been uncommonly strong not to have been extremely relaxed by such an intemperate use of it. It is related of him, but not by Boswell. that, while on his Scotch tour, the Dowager Lady MacLeod, having repeatedly helped him until she had poured out sixteen cups, then asked him if a small basin would not be more agreeable and save him trouble. "I wonder, madam," he answered roughly, "why all the ladies should ask me such questions? It is to save themselves trouble, madam, and not me." On another occasion he said, "What a delightful beverage must that be that pleases all palates at a time when they can take nothing else at breakfast!" Croker mentions that the doctor's teapot held two quarts.—*Indian Tea Gazette.*

SOME ACCOUNT OF THE ORANGE AND LEMON TRADE OF INDIA,

WITH NOTICES OF THE PRINCIPAL VARIETIES GROWN, CENTRES OF CULTIVATION AND MARKETS,

By Brigade Surgeon E. Bonavia, M.D., Civil Surgeon, Etawah.

(*From Journal of the Agricultural and Horticultural Society of India.*)

Under this heading will be, of course, included, not only the trade in oranges and lemons, but also in limes, citrons and pummelows.

It would appear that on the North-Eastern border of India, there are two or three points at which oranges are grown to some extent for exportation to other places. Nagpore and its surrounding country is another centre of considerable trade in oranges. Delhi is another. Besides the foregoing, there does not appear to be any other centres of orange cultivation, except for local consumption, and for export to the immediate surroundings of the place where they may be grown. Of course, each station has its few orchards of oranges, but these are a mere nothing and their produce is either locally consumed, or finds its way to railway stations in the vicinity; so that in the orange season, a small trade is carried on at almost all large railway stations.

Mr. G. Stevenson, Deputy Commissioner of Sylhet, has very courteously furnished me with the following statistics of the trade in the Sylhet orange, called in Bengal, 'Kamala lemboo,' it is said, from the name of one of the rivers in the vicinity of which this orange is largely grown.*

BOAT TRAFFIC.

	Quantity in Maunds.	Value in Rs.
1880-81	1,20,398	2,40,796
1881-82	1,46,592	not known
1882-83	1,02,631	1,28,288
1883-84	1,11,969	2,27,062
1884-85	1,20,884	2,47,352

This averaged about 1,21,095 maunds of oranges per annum worth from 1¼ to 1½ lacs of Rupees, in favorable years. 1,14,969 maunds of Sylhet oranges are said to be equal to about 8,05,360 oranges.†

These statistics only deal with exports to Bengal, and mostly to Calcutta. No account is kept of oranges consumed locally, and in the immediate surroundings of the orange groves.

Mr. J. D. Anderson, officiating Deputy Commissioner of Sibsagur, Upper Assam, further states that this orange is also called "*Sunthira tenga*," and that the traffic is carried on first by "Barki" boats, of the hill streams, and then by the larger country boats of the "Beparis," who take the oranges to Dhaka and Goalundo. From the latter they are probably railed to Calcutta.

Mr. C. Brownlow, writing in the Journal of the Agri-Horticultural Society of India (part IV, new series, Vol. I, 1869, p. 372) on the orange groves of Shalla, says that in 1869, the trade of this district was in limestone, oranges, potatoes, Indiarubber, and other minor articles. The oranges came from Shalla. The orange mart was at Chattuck, on the south bank of the Soorma river, and directly opposite to the mouth of the Shalla river (a tributary of the Soorma). The custom was to count the oranges in fours, and 750 fours made a "sou" of 3,000. The prices were so much per "sou." Rain is injurious to the fruit when in bulk. It then soon moulds and goes bad. This keeping property is important as far as the Calcutta trade is concerned; so that the finest oranges, with delicate thin skin, are mostly kept for local consumption, as they don't bear transport well. Even of the thicker-skinned ones, which are sent to Calcutta, a certain percentage rots, as they are sent in heaps in boats. No mode of packing was used to prevent the oranges from spoiling on the way.

The oranges at the "Phalli" Bazar were of inferior quality (as far as keeping properties were concerned), being thin and small, but of exquisite sweetness and flavour. They were, therefore, all sold locally and quickly. At the ghât, their price was Rs. 6 per "sou" (3,000), being less than the Shalla oranges, at the groves, and yet, in the case of the "Phalli" oranges, Rs6 included the labor of cultivation, as well as carriage, at the rate of ten men to a "sou." A Khasia reckoned his labor worth 8 annas per diem, and as only half his day must be reckoned, the remaining half being occupied with victuals, it would appear the oranges might be sold at the "Poonjee," at the rate of about 15 for a pice. Mostock is immediately above Shalla, at about 1,000 feet elevation. Mr. Brownlow got very good oranges there, at eight for a pice. From some of these poonjees, as well as from the Mhowmloo valley, oranges are carried to Cherrapoonjee, where, when in season, they sell at five to eight for a pice, and are of a delicious thin-skinned variety. At Cherra, they may be had a month or more after they are out of season. These late oranges, which are much relished by some, sell sometimes at a pice each.

From 1869 to date, I have no other information about the trade in the so-called Sylhet oranges except that kindly sent by Mr. G. Stevenson from Sylhet.

The latter gentleman has also kindly given me the names of the varieties of oranges cultivated in the Khasia Hills; they are the following:—

Bengali names.	*Khasia names.*
1. Kamala ...	... Uso Santra
2. Naringhi ...	... U. Sim
3. Moglai ...	... U. Mongar
4. Satkara ...	... U. Kuhit
5. Kaki ...	... U. Yanpriang
6. Khatajamir	... U. Komphor

Of these, Naringhi, Kaki, and Khatajamir are sour and smaller than the sweet oranges, though of the same family. Satkara is like a citron, and is not eaten ripe, but is cooked green, and used as a kind of sour "Chutni." Kamala and Moglai differ little. The rind of the latter is somewhat thicker, and its color lighter than that of the common orange, the Kamala.

Mr. Anderson of Sibsâgur, Upper Assam, mentions also the following varieties which grow in Assam:—

1. Rabab Tenga.
2. Jora Tenga.
3. Sakla Tenga (bitter lime).
4. Bar Tenga (big lime, not a pummelow), and
5. Naga Tenga, grown in the Naga Hills, 1,500 feet high.

"Buxa Dwar" is another place where fine oranges are grown. I have seen specimens of the Buxa oranges, kindly sent to me by the Surgeon in charge of that Station, at the request of Colonel Rutherford, Commanding the 33rd Regiment, N. I. The Buxa oranges are of the Suntara race, and as good as, though not better, than those of Sylhet. I have no statistics, if there be any, of the trade in Bhootan oranges.

We come now to the borders of Nepal, north of Gorucknpore. Beyond the Raptee, and within the Nepal borders there is a place called Bootwal. In this district a small orange of the Suntara type grows. It is the sweetest, although the smallest of the Suntara race, excepting the "Kumquat." One of the specimens sent from Buxa was not unlike in size the Bootwal orange.

Major Buller, District Superintendent of Police in Gonda, has been good enough to send me the following information regarding this interesting little orange:—

"A Head Constable of mine, says that he had a 'Kohar' once, who had visited Bootwal. This is the name of a large town beyond the Raptee. It gives its name also to a 'Kergh.' The orange is called 'Santolah,' and is not known in Nepal under the name of Bootwal orange. The orange trees are wild, not in the valley but on the hills. However the hills are all parcelled out between different persons and although fruit trees are not in any way cultivated, the produce cannot be plucked and sold by any one, except the owner of that particular plot.

* Or, as the Secretary, A. H. S. I. suggests from Kumilla, the capital of Tipperah.

† This is the number given, but it appears to be small.

NOTE.—Taking 8,05,360 to represent the "Sons" referred to by Mr. Brownlow, the figures would be 2,41,60,800, or about 210 oranges to the maund.—*Eds.*

The oranges are brought down and sold at bazars on market days, in towns adjacent to our territory. They are bought by 'Koonjaras,' 'Kohars,' and other dealers; and by them taken to Goruckpore, Bustee, Fayzabad, Benares," &c.

"Dr. Cameron's Mali in Gonda, says that this orange is called 'Suntowrea,' and that it is grown at 'Bootwal' and there alone."

"I met a Havildar of the 1st Goorkha regiment. He confirms what I told you about the 'Suntolah' orange. It grows wild in *the hills*, and not in the plains of Nepal, the Raptee valley, &c. By cultivation the orange becomes sweeter, bigger, and has a thinner skin; otherwise the wild and cultivated oranges are one."

This small sweet "Suntolah" orange, from Bootwal, was hardly known beyond Goruckpore; some time ago but now, since the railway has been opened north of the Ghagra, this curious little wild and very sweet orange, averaging about 6¾ inches in girth, has found its way to Benares, and no doubt, in time, to other places.

Next to Sylhet and its surroundings, the largest centre of orange trade is Nagpore, and other parts of the Central Provinces.

Mr. J. B. Fuller, C. S., states, that "this orange is the great speciality of the black soil country, in the fruit line." In my opinion, the Nagpore orange is the best flavoured of all the 'Suntara' type of oranges, and the same gentleman thinks it is "decidedly the best of any which he has tasted in India." That from Bootwal is sweeter, but many think it is "too sweet," and that a mixture of sweetness, with sufficient acid to make an agreeable flavour, such as that of the Nagpore orange, is preferred.

The Bombay market is largely supplied with oranges from the Central Provinces; and there is probably little doubt that the black soil of those provinces has a great deal to do with the fine flavour of the Suntara orange grown there.

Mr. J. B. Fuller, Commissioner of Settlement and Agriculture, Central Provinces, has courteously furnished me with some statistics of the orange trade of Nagpur. The paper was drawn up by the Superintendent, Government Garden:—

"Within the last twelve years many new orchards have been planted in Nagpur, Kamptee, and other parts of the district; and orange cultivation is now spreading rapidly in other districts of the Province. There is a great demand for the Nagpur orange in Bombay, and considerable quantities of the fruit are annually exported to this and other places. In the year 1885, 22,609 maunds of orange fruit were exported from the Nagpur station, out of which 21,400 maunds were exported to Bombay alone."

Mr. J. H. Fisher, Collector of Etawah, who had been at one time stationed in the Central Provinces, has kindly given me the following information:—

"It is now ten years since I was in Nagpur and Chattisgurh Divisions of the Central Provinces, and I write from memory. In the Wardha District, as in Nagpur, there were a good number of large orange groves, the produce of which was sent down to Bombay. The tree there, gives two crops: one ripens in the spring, called 'Miragbahar' (the young fruit setting in the rains *); the other ripens in the winter, and is called 'Ambiabahar,' as the young fruit sets at the same time as the young mango fruit sets.

The orange trees thrive prodigiously in the rich, black soil of the country which, being decomposed trap rock, is highly calcareous, so that they get the lime that the whole tribe of citrus so delight in. The orange groves are planted, not only near the railway, but at considerable distances from it. I remember some in the Arvi Tehsil of the Wardha District, and also in the Sanar Tehsil, in the south of the Chindwara District. The groves that I remember were planted out in theopen, without reference to any shelter or protection from large trees.

When I was in camp in 1873, in the S.-E. corner of the Raipur District, in the Zamindari of Khariar, I remember the Raja of Kalabandi, a Feudatory State in the neighbouring district of Sambulpur, coming to see me. He brought with him some huge baskets full of oranges, the produce, he told me, of wild orange trees, which grew in certain places in the forests, on his estate. As they were out of my district, I never had an opportunity of seeing these wild trees, and forming an opinion as to their origin, *i. e.*, whether they were really indigenous, or were the descendants of trees brought from elsewhere. In any case, the oranges, though not so large as the cultivated variety, had the same characteristics as the Nagpur orange and were very sweet.

When at Chindwara in 1876, I imported (with vines, olive grafts, figs, and mulberries) some varieties of oranges from Naples. One or two of the plants I took with me to Jabalpur in 1877, and left them there in 1878. The others remained at Chindwara. Whether any of these trees have survived the changes of District Officers that have since taken place, and established themselves in these districts, I know not.

Delhi and its surroundings is another centre of some orange trade, but it appears to import more than it exports. The 'Sintra' orange of Delhi is sufficiently well known. It is a baggy, loose-skinned orange, usually without much pretension to symmetry of form. I need hardly mention that the 'Sintra orange has *nothing to do* with the Cintra town of Portugal. It is merely a corruption of 'Sûntara,' which word, as I have elsewhere explained, appears to be of Sanskrit origin. In Delhi the Sintra orange is often called Rungtra. The origin of the latter term is rather hazy. Mr. George Smyth, Deputy Commissioner of Delhi, has courteously given me the following statistics regarding the orange trade in that city. The Memo. was drawn up by the Tehsildar of Delhi.

The Rungtra orange of Delhi is exported to Meerut, Jeypore, Bombay, and to some other minor places; about 200 maunds are exported per annum, valued at Rs. 1,600, or Rs. 8 per maund.

Then from Ulwar, Nagpur, Gurgaon, and villages across the river Jumna, about 2,000 maunds are imported into Delhi, valued at about Rs. 24,000 or Rs. 12 per maund.*

The Memo. also states that the Rungtra orange is cultivated to some extent in Lahore, Ulwar, Meerut, and Bulundshuhr.

We have then the Sylhet orange 'Kamalá lemboo,' the Bhootan orange, the Bootwal, or 'Suntolah,' or 'Suntowrea' orange, the Nagpur and the 'Sintra' of Delhi—all *varieties* of the *one* type of the Indian loose-skinned orange—the Suntara of Sanskrit origin.

This type of orange is found in many other parts of India, and also in Ceylon. In Lahore, a pretty pear-shaped variety is grown under the name of 'Karna,' or Sungtara. In Mooltan, another round variety is also called 'Sungtara'; a variety grown in Poona is also called Suntara. In the Shevaroy hills, another curious variety of the same type goes by the name of 'country orange.' I am indebted for specimens of this variety to Dr. John Shortt. In Yarcaud, it is given the native name of 'Kolinge,' and about Madras 'Kitchlee.' I was informed that in Canarese the orange is called 'Kitle hannoo.'

The Western coast of India, south of Goa, is supplied from Coorg with an orange of the Suntara type.

In Ceylon, they have a 'Konda Nârun,' almost an exact copy of the Nagpur orange; and also a larger variety called there 'Jawa† Narun.' In Kandy, the latter is smooth, but in Colombo, there is a large variety, which is subwarty, with a more pronounced pear-shapedness. Somehow, these Suntara oranges of Ceylon have got the name of Mandarin oranges; none of the above, however, is *true Mandarin*, although the latter is *allied* to the Suntara type of orange. Any one having once scented the leaf or the rind of a true Mandarin, can recognise it again, even blind-folded.

Curiously enough, I found that in the Peradeniya Botanic Garden, they *have* the *true Mandarin* orange, with its distinctive scent of leaf and rind, and with a

* This is the 'Dumrez,' or after-crop of other places

* This figure seems somewhat doubtful.

† Jama.—ED.

fine aromatic flavor. Dr. Trimen, the Director, searched among the Garden records, and found that His Highness, Ibrahim Pasha of Egypt, in 1847 had sent a present to the Peradeniya Garden of a collection of various kinds of orange trees, and Dr. Trimen thinks that these true Mandarin orange trees, or their parents, may have formed part of that collection.

The 'Konda Nârun' of Ceylon, which, as I said, is much like that of Nagpur, is eaten in its *green* state. It could be found in the markets of Ceylon during all November. It had not then an unpleasant flavor, but was distinctly unripe, and some said that in its green state, it is better flavored. It is so habitually plucked, sold, and eaten in its green unripe state, that the people there have come to look upon it as a *green* orange, which never turns of an orange color.

As I had never heard of a green orange, and as I did not believe in one, I bought two dozen of these green Konda Nârun, on leaving Kandy, on the 11th December. I wrapped each in a bit of newspaper, and packed them loosely in a covered bamboo basket. They travelled with me from Kandy to Colombo by rail; crossed the Channel to Tuticorin on the 19th, and travelled all the way by the South-India Railway, Madras, G. I. P. and E. I. Railways, to Etawah, where I reached on the 1st January. On opening the basket I found only *one* spoilt. All the others were either turning, or had turned yellow. I kept them still wrapped in paper till the 20th January, when I found that all had turned of a yellow orange color, only one more had spoilt in the meantime. All the rest (22) were sound, and of a nice flavor and juicy. I sent some to Lucknow, to Mr. Ridley, who found them also very nice.* It would appear, therefore, that the Ceylon *green* orange has no *locus standi*. It may very probably be, however, a variety, which is late in taking on color.† The Nagpur orange, I think, colors earlier.

The fact is, in Ceylon, not only the orange is gathered unripe, but all other fruit. I was never more astonished than when I visited the Ceylon markets. All the fruit I found, was unripe. Even pineapples which ought to be the glory of Ceylon, were unripe and inferior in flavor to those of Philibit. The only fruit worth having then, was the plantain, and this is one of the few which can be gathered in an unripe state, and hung up to ripen, without losing much flavor.

It should not be, however, supposed that people in India are innocent of the vice of gathering fruit in its unripe state. They everywhere do so, more or less: 1st, because sometimes it pays them better to do so; 2nd, because the longer they leave it on the tree, the longer they have to watch it; 3rd if they don't watch it, it is likely to be stolen,‡ or, eaten by parrots, monkeys, &c. In the Etawah Jail Garden, the purchaser of the fruit gathered all the Malta oranges in October, in their *green* state. There was a 'mêla' on, and he said he could get a good price for them. The palate of the people of India has been mostly spoilt, because they have rarely had a chance of tasting a delicious fruit, *well ripened on the tree*. The mango and the plantain are perhaps exceptions, as they can be ripened off the tree and retain their flavor, if not plucked *too early*. They often, however, spoil mangoes by endeavouring to bring them too early into the market. If a fruit is plucked *just before* it ripens, then its freshness enables it, off the tree, to continue the change to full ripeness.

Besides oranges of the 'Suntara' type, which are smooth, and of a yellowish orange color, there are those called 'Naringhi,' or 'Keonla.' They are rougher and redder. The latter name appears nothing but a modification of 'Kamalâ.' In other respects they are not very different from the Suntara orange. If anything, they are usually smaller, and more sour unless perfectly ripe, and often they have a flattened mamilla on the distant end. Natives often make a distinction between 'Naringhi' and 'Keonla,' but I could not find any difference. If there be any, it is perhaps, that some 'Naringhi' are sweeter than the 'Keonla.' The latter, in its unripe state, is very sour, and unless thoroughly ripened on the tree, or, as some say, off the tree, it is hardly edible.

By December and Christmas time all the 'Suntaras' are gathered. They are left so long on the trees, because they fetch a good price during Christmas week. They would improve vastly in flavour if left on the tree for another fortnight or three weeks. Some varieties, however, if left too long on the tree, dry up and become juiceless, especially if the trees are not watered. Whether this depends on the soil, the climate, or the nature of the variety, I do not know.

The 'Keonla' orange sweetens later, and is better for being kept on the tree till the end of January. It thus comes in as a late orange. It does not appear, however, in great favor, probably on account of its sourness. It is nevertheless a good cropper. It is found everywhere, but I am not aware that there is anywhere in India any great centre of trade in the 'Keonla' orange, as there is in its more popular sister, the 'Suntara' orange.

Besides the foregoing type of orange, there is another, and a totally distinct one. It is larger and closer skinned, and with a totally different flavor. I mean that of the Malta orange type. Although I have met with many varieties of oranges of this type in many parts, I don't think they are of Indian origin. This variety of orange probably came originally from China, and recently this type has been re-introduced by three or more different persons.

Colonel Clarke, then Deputy Commissioner of Gujranwala in the Punjab, introduced the Malta blood orange there, between 1852 and 1856.

I introduced the blood, egg, and common round oranges of Malta into Lucknow, in November 1863, together with the Mandarin orange and Malta lemon. These were budded on the Séville, and through their stock, I also obtained the Malta *Seville* orange.

Mr. C. Nickels, of the 'Passewa' Factory, Jaunpore, introduced the Malta blood orange from England in 1872. It was budded on the lemon, and through the stock he propagated what may now be called the English lemon also. About the same time, Mr. Nickels introduced by seed what he calls the *Suez orange*. This is the same as the Malta common round orange, and is a very well-flavored variety. It was taken at Suez and issued to the passengers bound to Bombay.

Of course, the Malta orange trees of Lucknow, since 1863, have been distributed almost everywhere. Curiously enough, natives often call this *Sylhet* orange. It has, however, nothing to do with that loose-skinned type of orange, which is in every way different. It is only in Tanjore that I met with a variety of the Malta type, which had a *vernacular* name, although it is found in many parts of India. This would point to its *not* being of indigenous origin.

The Gujranwala blood orange must have also been distributed to some extent in the Punjab since 1852-56.

Irrespective of these recent introductions, before the Mutiny, there was an orange tree, of the Malta type, in one part of the Padshabagh, in Lucknow. I propagated this, and now it is there known by the name of 'Paenbagh' orange.

In Poona I found a variety of this type called 'Mussèmbi.' It is supplied to the Bombay market. In Poona they told me, it keeps in condition for a whole year, *on the tree*, and might therefore, be useful as a late orange.

* In Nov. 1876 we took a dozen of these so-called mandarin oranges to England as an experiment, placing them in the nest in our cabin, and moving them daily. Only one spoilt, and the rest, which were green when we left Ceylon, but become almost completely yellow at the end of the voyage and were in first-rate condition.—ED.

† Our climate is so wet that the oranges are apt to spoil if left to ripen fully on the trees.—ED.

‡ A reason which applies to gathering unripe fruit in Ceylon.—ED.

In the Bombay market I found an egg-orange, also called 'Mussèmbi,' which is imported from Zanzibar. It is a small Malta orange, and is known in Bombay, either by the latter name or that of 'Mussèmbi,' which is evidently a corruption of Mozambique. An officer of one of the coasting steamers, who knows the Zanzibar orange well, told me that it is far better than either the orange of Malta or Spain. On this same steamer, I saw some oranges of the Malta type, which I was told were purchased about a month before at Madras.

In Ceylon I found the Malta orange at Colombo, Kandy, and Hagkala, near Nuwara Eliya. It is known there by the name of 'Arange,' or "Pœni Dodan" (sweet orange.)

At Tanjore I found two varieties of the same type. One of a yellowish color, called 'Spanish orange' by the English. The other a large, fine orange, sweet and very juicy. Curiously enough, the English there call it 'sweet lime.' The natives call it 'Bandir.' It is a variety well worth propagating. It can be cut in halves transversely, and the interior easily eaten with a spoon.

I have left the blood oranges for the last. The specimens of blood oranges sent to me by Mr. Steel, Deputy Commissioner of Gujranwala, in my opinion, are the *best oranges* that I have tasted in India, of any kind. The pulp is of an orange-claret color. Many of the specimens were full-blooded, and smeared externally with a blood tinge. The juice was simply nectar-like. In short, their flavor was, in my opinion, perfect. I thought it equal to that of the blood oranges of Malta, but Mr. Steel thinks it superior to them, and perhaps he is not wrong. Mr. Steel states that the soil on which they grow is a stiff clay, with plenty of 'kunkur' in it. But the real secret, he thinks, is to bud them on the *sweet lime* stock. He says they are larger, but not so fine flavored, when budded on the 'Khatta' or 'Pummelow' stock. This is a hint worth making a note of. If experiments are made with all sweet oranges, budded on the *sweet lime stock*, they might possibly lead to a revolution in the cultivation of the orange in India. It appears that in Gujranwala there is a suitable soil and climate and the best orange in India. There is also skill to turn these materials to account. Here then is a chance of creating an extensive trade in blood oranges, as a speciality of Gujranwala. They are not only exquisite oranges, which, if properly packed, would bear long journeys, but they are *late* oranges, and therefore would not compete with 'Suntara' oranges, which flood the Calcutta and Bombay markets, from Sylhet and Nagpur. The specimens were sent to me in February, but Mr. Steel said they were "barely ripe yet, and would remain on the trees till the middle of March. Last year, some, by careful packing, were kept in good condition till July." What a boon it would be for the people of Calcutta and Bombay, and, in fact, of all stations, to have such fine oranges in the hot weather! And what a chance of developing a fine orange trade between the Punjab and the capitals of India! This fine orange appears to be little known, beyond the neighbourhood of Gujranwala.

The next best blood orange I have come across in India, is that of Mr. C. Nickels, of Jaunpore. He evidently has there a suitable soil, and has managed it well, and if he takes the hint about budding on the *sweet lime* stock, he might with this, and his 'Suez orange,'—another fine flavored variety,—make a speciality with late oranges also, in Jaunpore.

The Lucknow blood orange, and in fact, all the oranges there of the Malta type, have not succeeded well. The former is only *streaked* with blood, and all want flavor. Of course, the former may not have been a full-blooded variety, in the first instance, but probably the soil they are in, is poor. It is almost pure sand, and wants clay, lime, and probably iron also, Mr. Ridley is making experiments in Lucknow, with a view of discovering the wants of the orange trees, and providing a remedy. In Lucknow, in the Charbagh and the Aishbagh, there is much better soil, and this type of orange might do well there.

With regard to the Mandarin orange, it has not succeeded either in Lucknow or in Etawah, although in the latter place, the soil contains a good deal of 'kunkur,' and is stiff. This fine orange tree is a delicate variety, and is almost killed by the hot winds. It hardly recovers before the next hot winds come on. What fruit it produces is at first sour, and when ripening time comes, its pulp dries up and becomes juiceless. It might do well where hot winds do not prevail, as on high land in Bengal, and in Sylhet, and may be other places.

The only place where I have seen good fruit of the Mandarin orange is at Peradeniya, in Ceylon; but there it did not appear to be appreciated, and is hardly *cultivated*. The highlands of Ceylon, all about Kandy, and up to Nanoo-oya, appeared to me suitable to the development of a fine orange trade, and if the cultivation of this choice Mandarin orange were extended and developed, not only the local trade might be supplied, but also the markets of Calcutta, Madras, Bombay, and other places in South India. From Colombo to Bombay the P. and O. Steamer takes four days, and to Calcutta about seven days; so that if the oranges be properly packed the voyage to these capitals would be a mere nothing. I have already mentioned how well the Ceylon 'Suntara'—the nice 'Konda-narun'—bears a journey to long distances.

The Seville orange, which is found in most parts of India and Ceylon, makes a good marmalade, and its decoction is a good febrifuge, but I am not aware that anywhere in India there is any trade in this aromatic orange.

The 'khatta' orange, which is found almost everywhere, is also a good febrifuge, and has a fine acid pulp; but there is no trade in its fruit. Native nurserymen in large stations make a limited trade in young 'khatta' plants to be used as stock for budding the better kinds on; young plants are largely used almost everywhere for this purpose. In Nagpur and Gujranwala, however, the sweet lime stock is mostly used for this purpose, and it would be well if native nurserymen turned their attention to the sweet lime stock, as probably it influences for the better the flavor of the sweet kinds budded on it. The 'khatta' stock could be still largely used for working all kinds of sour oranges and lemons on.

There now remain the pummelows, lemons, limes, and citrons.

The best pummelows I have seen are the thin skinned red pummelows of the Bombay market. They come in about Christmas. They are juicy, and of the color of raw beef internally and of a globose shape. There is no reason why this fine thing should not be extensively grown. All the other varieties of pummelow I have seen in India and Ceylon are not to be compared with this, and are hardly worth propagating to any extent.

The citrons are very little used, except for medicinal purposes. On the Western coast of India, they have many large varieties, and at Mangalore they eat the thick sweet skin, after peeling off the bitter rind. In Lucknow, and in Rampur, Rohilcund, and other places they make a preserve of the thick skin of the citrons, which they call 'Turunj.' All the citrons, both sweet and sour, have a dry pulp.

From the borders of Nepal, I received a citron-like 'khatta' orange, of the size of a small jack-fruit, with a girth of 24 inches, a length of 10 inches, and a diameter of 7½ inches. There it is called 'Kathairee-nimboo,' or 'Ruskunkur,' or 'Beora.' It had no seeds, a pale sour pulp, and a thick sweet skin, which is the only part eaten. These specimens were sent to me by Major Buller. Mr. Hein, of the Lahore Government Garden, sent me a smaller specimen of this same variety which, he said, is there called Gulgul.

The true limes are the most used. They are to be found everywhere, and even where no other citrus is found, some kind of lime is sure to be seen. Nevertheless, it is astonishing that so common a thing, so useful a fruit, and a tree so easily raised from seed, is not to be found in *villages* of the North-Western Provinces. There is probably not a *village* in the whole of India where the 'Kaghzi-nimboo' would not readily grow. A large and profitable trade might be made from the sweet limes. Although they are called limes

I believe them to be an *acidless* variety of one of the *lemons* of India. They are much appreciated by natives, and fetch a good price. They call them 'Sherbetee,' or 'Mitha-nimboo,' and also 'Amrutphal.' The best flavored sorts are grown in dry climates, such as those of Mooltan and Muscat. Bombay is supplied with this 'Mitha-nimboo,' both from Nagpore and from Muscat. From the latter place, two sorts are imported. A round one of the size of the Indian sweet lemon, and a larger pear-shaped one. The only specimen I saw of the latter was shown to me by Mr. Gubboy, of Ezra Street, Calcutta. It had a girth of 13¼ inches and a length of 5½ inches. I was told that in Bombay it was known by the name of "Muscat sweet orange," and was imported about January. These sweet lemons are well worth the attention of any one desirous of growing fruit for profit; natives appear to prefer them to any other kind of citrus, and give a higher price for them. To the European palate, however, the total absence of a sub-acid is a disqualification, though certainly not in the opinion of all. Mr. Moore, the Acting Commissioner of Customs, Bombay, has very courteously furnished me with the following statistics regarding the imports of oranges and sweet lemons from Zanzibar and Muscat :—

	1884-85	1885-86
Zanzibar Oranges ...	Rs. 1,743	Rs. 836
Muscat Sweet Lemons	„ 1,555	„ 1,695

The figures for 1885-86 are from 1st April 1885 to 22nd March 1886.

The sour lemons finally may be divided into 'Bajouras,' a sort of citron lemons with a good deal of sour juice in them, lemons proper, and a group of sour citrus known by the name of 'Gungolee' and 'Behari' lemons.

The former two groups I have not seen in any market except that of Pondicherry. They have there a lemon, which appears like the Malta lemons, but smaller. They call it 'citron' in French, as they do the lemon in France.

I have grown the Malta lemon largely in Etawah, and have tried to bring it to the notice of natives. I have succeeded to a great extent. Before the knew of it they looked upon the Kaghzi nimboo, of which they make a rather nice pickle, as the best sour citrus for domestic purposes. But since I brought before them the Malta lemon, they tell me that for pickle or other domestic purposes, if they could get the lemons, they would not look at the lime. Since I have brought this fine sour citrus to the notice of the public as a medicinal fruit, and also for making lemon jelly, a great demand has arisen for lemon plants. In my opinion the lemon is a sound, the most useful acid fruit. It has a fragrant skin, not too thin so as to be useless for candying. It has a pure and abundant acid juice, it is one of the best for preserves and for medicinal purposes, and it is difficult to find a variety of citrus more easy to cultivate and to propagate. When in full bearing, moreover, it has the habit of producing a 'Dumrez' crop, which comes to maturity very usefully and appropriately in the hot weather. There is no reason why so useful and so easily propagated and cultivated a tree should not in time be as largely grown as the lime, the orange, and other useful kinds of citrus. I sent lemon plants to Sibsagur, in Upper Assam, and to Devikulam, in South India, besides many other places. They travelled well, and are flourishing there.

In the Punjab they have a large sour lemon, about two or three times larger than the Malta lemon. It is there called '[illegible]' It is a very good lemon, where a large quantity of juice is wanted at one time, or for making lemon jelly or bottled lemon juice. They have a similar one in Kumaon, which is there called Kumaon lemon. It is also found in Saharunpore, and I have been told that during the month of April it is largely sold in Mussoorie. All these lemons would keep well if left on the trees, a certain number on each tree, so as not to prevent the spring flowers from setting. Natives are always in too great a hurry to gather and sell their fruit. It left on the trees till the hot weather, especially where there are extensive groves, these sour lemons would vastly increase in value, and be much more appreciated in the hot, than in the cold weather, when they are often a drug in the market.

The 'Gungolee' and the 'Behari' lemons are not very common. They are either oval or pear-shaped—some are purse-shaped, like the large 'Behari' lemon of Lucknow. From Jhansi, I received a very curious citrus, probably belonging to this group. It was thin-skinned, and with a diameter of 1¾ inches, it had a length of 3½ inches. There they appear to call it 'Kaghzi nimboo,' but this might only mean that it is thin-skinned; not having seen the tree I am in doubt whether this variety is a lemon or a true lime.

Considering that many varieties of orange, citron and lemon are indigenous in this country, in my opinion, the citrus trade of India is absurdly small. It would admit of great expansion with profit to the grower and the consumer; and now with the network of Indian railways already made, and annually increasing, there are, I should think, few places to which some variety of citrus could not be carried in a short space of time. There is probably no part of India, from the Himalayas to Ceylon, and from Sylhet and Bhootan, to Sindh and Bombay, where either one variety or another might not be largely and profitably grown.

As I have shown, in the case of the Mandarin and Malta oranges, every soil and every climate will not suit all kinds of oranges, lemons, &c. This is a great advantage, as every soil and climate could then create a speciality of one or more varieties of citrus, which would be *best suited* to that locality. In this way, the varieties would not compete with each other, and thus flood the markets with the same kind at the same time.

From what I have seen of the different varieties of citrus in India, I might here, perhaps, sketch a sort of geographical distribution of the best kinds, which would find favor with the public. Of course, this sketch is very imperfect.

Gujranwála and Jaunpore might grow, with advantage, the late blood and other Malta oranges. Nepal—its sweet little 'Suntolah,' and its fine round sour lemon: * Bhootan and the Eastern hills, the 'Kamla lemboo', Delhi, Nagpore, and Ceylon their own fine special Suntara. That of Ceylon is the so-called 'green' orange. Then the highlands of Bengal might perhaps grow the choice Mandarin orange, where it would be out of the influence of hot winds. Burmah might be found also suitable for this fine orange. Tanjore might grow its fine 'Mandir' and Pondicherry its 'citron,' Aurangabad, Deccan, its fine warty 'Keonla,' the best of its kind I have been seen. Poona might make a speciality of, and improve, its flat 'Laroo,' another kind of 'Keonla,' and also its furrowed 'Mussembi,' of the Malta type. Bombay, or wherever it is grown, would do a service, if it made a speciality of its fine, thin-skinned round, red, and juicy pummelow, and supply half India with it. This unique pummelow would probably also export well to England. From Mooltan and Sindh would come the best flavoured 'Sherbetee nimboo,' or sweet lemon. Although this can be grown in other places, it is not so well flavoured. Lucknow might make a speciality of its fine *large* 'behari nimboo,' and its 'Kaghzi Kalan.' In this locality also grow well the Sylhet variety of 'Suntara' originally raised from seed and the 'Paonbagh' orange. Lahore, then, has its pretty pear-shaped 'Karna.' The large, sour and juicy lemon, called 'Gulgul,' grows well in the Punjab, Kumaon and Saharunpur, and on the borders of Nepal, and would probably grow well in other places, as I saw it growing well in Benares. Finally, the Malta lemon and the different varieties of true limes appear to grow well all over India, and as they are very useful both medicinally and for various domestic purposes, it would be a great advantage to grow them, and

* Called Nepal lime

only in every city and large town, but in every village in every part of India.

By restricting the varieties, to be be grown on a larger scale to those localities to which they are most suited, a race of growers would be trained who would thoroughly understand the wants of that particular variety, and would grow up from their childhood thoroughly conversant with the best mode of dealing with it, not only with regard to cultivating, propagating, and pruning it, but also the best mode of packing, and keeping its fruit for a long time.

Then for carrying the oranges, lemons, &c., from place to place, quick steamers are wanted, good cheap coal in India for the return journey, and refrigerators. Perhaps petroleum may yet be cheap enough to be used extensively as fuel. When that time comes, as Indian wheat competes favourably in the European market, with American wheat, so might, not impossibly, Indian oranges, of a dozen different varieties, compete favorably with Florida, Trinidad, and Brazil oranges.

Excluding Europe, however, from the orange trade, there is looming in the distance an opening for an extensive trade in the oranges and lemons of India. The Russians are hurrying on their railways from the North, and the British from the South-East. These two railway systems are bound to meet sooner or later, because it will probably be the interest of both Empires to make them meet. When that time comes, the orange and lemon trade of India will receive a great impetus. The Russians are great tea drinkers, and their favorite mode of drinking tea is with a slice of lemon, with sugar, and the hot tea poured over them, without the use of milk. This Russian mode of drinking tea is extremely nice. Now, supposing each Russian used only one lemon per day, it can easily be seen what a vast number of lemons Russia would consume. The Central Asians are also great tea drinkers, and they will not be slow in adopting the Russian mode of drinking tea, with a slice of lemon; so that the future prospects of the lemon trade in India are not at all bad.

But again, leaving the foreign trade entirely out of the question as chimerical, there is no reason why the internal trade in oranges and lemons, all over India, should not be largely developed, and there appears no good reason why, with management, the supply of oranges, should not be kept up from December to July, considering the many fine varieties that India possesses. Then there is no reason why some sort of sour lemon, lime, or orange, should not be procurable all the year round. In Italy the time lemons are most used is in summer, for making 'granita' or iced lemonade. And there can be hardly a doubt that India, with its numerous varieties of sour citrus, could supply the internal trade all the year round. To effect this, besides growing the sour citrus largely, in suitable localities, cheap and quick railway transit for fruit would be required. A waggon or two for fruit might perhaps be attached to mail trains, and fruit carried at the cheapest *goods* rates. Thus convenience and advantage to everybody might be the result. There is also no good reason why in each passenger train fruit-sellers should not have a stall in one of the 3rd class compartments, wired in to prevent stealing. In my opinion, enough sensible use is not made of passenger trains.

The following will show to what distance fresh fruit can be carried, provided it is sound and carefully packed. In the *Gardeners' Chronicle* of 6th March 1886, p. 306, under the head "Fruit from the Cape," this occurs:—"Messrs. Webb & Co., of Covent Garden, last week received a small consignment of Pears, 'Louis Bronne' and 'Beurre superfine,' in splendid condition, after a voyage of 8,000 miles. They anticipate in the future, from the same source, a regular supply of various sorts throughout the spring."*

When in Ceylon, I read in one of the papers that a planter had sent to England some Ceylon oranges and they arrived there in good condition.

I have already shown how well the 'Konda-nárun' of Ceylon stands a long railway journey, being kept packed for more than a month.

It would appear that the tough, thin, Indian paper, said to be made from bamboo, is suited to packing oranges and lemons.

Etawah. E. BONAVIA, M.D.

NOTES ON PRODUCE.

(From the *Home and Colonial Mail*, Sept. 23rd.)

Careful preparation and delicate fragrance first brought Japanese teas into favour with Americans and enabled them to supplant to a large extent those of China. Only the fine grades of Japan tea were at first exported, and all were shipped in their natural condition. But, as time went on, growers, in their desire for quicker and greater profits, grew more and more careless in their pickings, and foreign shippers in Japan, in order to hide a steadily decreasing quality of the natural tea, were compelled to have recourse to artificial methods of colouring and preparation. The consequence was that the entire American market was flooded with tea that was both cheap and nasty, and, though the export from Japan steadily grew in quantity up to 1880, there was by no means a proportionate increase in value. The continued fall of the export in 1883 and 1884 at last awakened the Japanese to the bad reputation which their teas were obtaining, and, in the latter year, a Central Tea Industry Association was established under the auspices of the Department of Agriculture and Commerce, the chief object of which was to exercise a supervision over the tea industry which would prevent adulteration and bad manipulation, and secure the sale by the Japanese of the best possible pure leaf. This Association has since been in active operation, and its efforts are gradually bringing about a much-needed improvement in the natural leaf. Some tea missionaries from India and Ceylon are wanted badly in America and Canada.

The Americans and Canadians prefer Japan tea probably, because they are used to it rather than any other reason. The export of tea from Japan during the last seven years has been as follows:—In 1880, 40,436,877 lb.; 1881, 38,483,854 lb.; 1882, 37,734,845 lb.; 1883, 37,146,914 lb.; 1884, 35,766,600 lb.; 1885, 41,244,718 lb.; 1886, 47,595,651 lb. These figures show that the export for 1886 exceeded that of any previous year in the current decade by over 6,000,000 lb., and the average export during the period 1880-85 by over 9,000,000 lb. Practically the whole export of tea from Japan for 1886, was sent to the United States and Canada. In the United States, the rate of consumption of tea is calculated to be about 1½ lb. per head of the population. Taking the same low rate for Canada, the total annual consumption by the two countries amounts to nearly 70,000,000 lb., two-thirds of which may be said to consist of green teas. It is remarkable that up to now the Americans will not

* Since writing the above, we hear that the Colonial Exhibition in London is supplied every week with *fresh* Apples of various kinds from Australia! The following item appeared in the *Journal of Horticulture* for 27th May, and requires no comment:—"Another large shipment of FRUIT FROM SOUTH AUSTRALIA AND NEW SOUTH WALES has reached the market for Colonial produce, held in connection with the Colonial and Indian Exhibition. It was brought over per the Orient Liner "Cuzco" and proved to be in excellent order. The South Australian Consignment consists of selection of Apples, Pears, Oranges, Grapes, Quinces, Almonds, Rasins, Currants, &c. A case of eleven Pears weighed no less than 31½ lb., five of them being 16¾ lb. They were shown in the South Australian Court on the occasion of the recent visit of the Queen to the Exhibition, and were much admired by Her Majesty, the Prince of Wales and Princess Beatrice, to whom a basket of the fruit was presented. The shipment from New South Wales comprises twelve cases of various descriptions of apples and grapes, from the district of Orange, packed on an improved system which has resulted in a complete success. The clusters of grapes were perfect."

drink Indian or even Chinese tea. Surely they might be converted. [The recent high price of coffee has led to increased use of tea, and we hear that Indian and Ceylon tea are finding favour.—ED.]

CEYLON TEA.

The praises of Ceylon tea are sung this week by the *Grocer*, which seems to be gradually deserting its early love, China, and placing its affections elsewhere. The rapid rise of the tea industry in Ceylon is a fitting subject for laudatory comments, and now that the tide has so distinctly set in favour of Indian and Ceylon teas, it is well that retail traders should be informed as to the developement of the industry. Says our contemporary:—"When the cultivation of tea in the island of Ceylon was begun in earnest in the year 1880, the number of 'gardens' where it was grown was only thirteen, producing about 1,300 packages; but in 1882 there was a speedy extension to fifty-six gardens, when 9,500 packages of tea were raised; and in the following year there were as many as 111 gardens, yielding 22,500 packages; which was further augmented in 1884 to 135 gardens, bearing sufficient tea to fill 32,600 packages. Since then, year by year, there has been a great number of gardens planted out, till in 1886 the total, according to Messrs. I. A. Rucker and Bencraft's list, comprised above 900, being equal in acreage to about 120,000 acres under tea.

"At an average of only 500 lb. of tea to the acre, the production in one year would amount to 60,000,000 lb.; or if at the rate of 800 lbs. to 1,000 lb. per acre, as some are inclined to calculate, with the additional gardens formed this season, the entire crop would turn out to be something between 9,600,000 and 120,000,000 lb. now, especially as the plants bear more plentifully than they did at the commencement of the industry. The increase in the imports of tea from Ceylon to London has been equally marvellous, as the subjoined figures clearly show:—1880, 114,850lb; 1881, 311,150lb; 1882, 621,070lbs.; 1883, 1,500,690lb; 1884, 2,285,300lb; 1885, 3,702,950lb; 1886, 6,874,900lb; 1887 (eight months), 7,663,000 lb.

"Progression so remarkable as the above has seldom been witnessed in any new enterprise, still less so during recent years, when trade in nearly all parts of the world has been as bad as it possibly could be, and some persons, whose judgment and experience entitle them to be received as authorities on the subject, are of opinion that there is a fear of the supply shortly overtaking the demand, and of growing so enormous and unwieldy as to entail a serious loss instead of bringing a decent profit to the planters and importers. But there are several reasons for not believing that this will be the case, although the tendency of some moves in commerce and agriculture is to go from one extreme to another. May be the utmost limits of production have not yet been reached, and therefore there is no immediate danger of the market having a glut of supplies; but even supposing arrivals of Ceylon tea were to come forward much more extensively than they have done, the demand, which is likewise an increasing one, promises to continue unimpaired so long as the 'quality' is kept up to its usual standard of excellence; and to ensure this desideratum the planters out there must spare no pains to grow and prepare such teas as they know are particularly appreciated by the British public. For the great body of consumers it has been proved that many grades of China teas, though perfectly pure, are too thin and weak to be taken alone, and often need an admixture of the pungent Assam kinds to make them entirely palatable to those who prefer having their tea strong. Or, to reverse the case, such tea-drinkers as cannot imbibe Indian growths of full strength are glad to reduce their rasping flavour by adding the milder and softer qualities of China tea, which to some palates are simply perfection. Now, it so happens that Ceylon teas naturally combine all the finer attributes of both Indian and China descriptions, and have on that account commanded so much attention from the trade since they were first tried, that at the moment it seems as if the demand would never be permanently satisfied, so strongly does it set in one direction.

"By attending to the main requisite in their supplies, viz., the 'quality' of the teas they produce, the Ceylon planters may rest assured that there will always be a ready market here for all they may send; and so long as uniform strength, flavour, and fragrance can be relied on, new purchases will succeed the old ones, until a demand as great as that for either China or India teas will grow up, and further stimulate the production in our British Colony. While the demand and supply are of nearly equal extent, with the latter, if anything, rather in advance than otherwise, as a safeguard against undue speculation or 'cornering,' prices are likely to remain at such a moderate level as will tend to promote consumption, in spite of the sharp competition prevailing from other sorts; and let Ceylon tea once establish itself as a favourite, nothing but the grossest folly or short-sightedness in studying the wishes of the public will cause it to lose ground afterwards,—so that all the planters have to do is to go on with their enterprise as they have begun it, doubting not that they will achieve success. They should also bear in mind that what consumers want most is a really useful and strong brisk-flavoured tea at not more than about 1s per lb. in bond, as there are more teas sold at and below that figure than any other, and those who import the largest quantities and the best qualities at such reasonable prices may depend upon obtaining the lion's share of what patronage there is to bestow."

TO THE EDITOR OF THE "HOME AND COLONIAL MAIL."

Sir,—I have the pleasure to enclose you copy of a letter received from Mr. J. Berry-White, and should feel greatly obliged if you could give it a place in your next issue of the *Home and Colonial Mail*.—Yours, &c., W. A. GIBBS.

"Monkham's Hall,
"Waltham Abbey, Essex, Sept. 12th, 1887.

"To W. A. Gibbs, Esq.,

"Dear Sir,—I regret that great pressure of business has prevented my replying to your enquiries before.

"There are seven or eight of your Gibbs and Barry tea-drying cylinders in use on the estates in which I am interested, and after some years' experience of their working, I am satisfied that they proved more economical than any other appliance for drying tea that has as yet been introduced.

"I cannot give details as to the savings effected, as it would be only misleading to compare the cost of production on an estate using your cylinder against the cost of production upon another estate using a different drying apparatus without at the same time showing the conditions under which the estates in question are worked; but the broad fact remains, that *tea is produced at a lower cost at those factories using the Gibbs and Barry machines than elsewhere in India.*

"This does not apply alone to my gardens, but to all the neighbouring estates in Upper Assam, and I believe that this statement is equally true as regards Cachar.

"Economy is effected by the smaller consumption of fuel and less labour required to work the cylinder than any other machine turning out a similar large quantity of tea. The simplicity of its mechanism and consequent non-liability to get out of order also tends to this end.

"The fear that the exposure of tea in course of manufacture to the direct influences of the combustion of coke would prejudicially affect its flavour, has been proved to be utterly unfounded, some of the highest priced teas sold during the last four years in Mincing Lane—notably those from the Panitola and Kellyden gardens—were dried in your cylinders.—Yours, &c., J. BERRY-WHITE.

TEA MACHINERY.

TO THE EDITOR OF THE "HOME AND COLONIAL MAIL."

Dear Sir,—About a year ago, when I was in Ceylon, there was a great deal of talk there about the need

sity for new tea machinery, and there were rumours of one or two startling inventions, which were to do all kinds of things and cost very little. I have been on the look out for these wonderful machines but have not seen anything of the kind. The old and tried machinery keeps the field, and, no doubt, deservedly so, but at the same time I think inventors and manufacturers would do well to consider the requirements of planters with a view to economy. Cheap machinery is wanted, and the firm who can give us anything simple and effective at a low cost will have no reason to repent the time spent in thinking it out. I say this without prejudice to the existing machinery and makers, who, clever as they are, do not give attention to the economic side of the question.—Yours truly, COLOMBO.

THE JUBILEE OF INDIAN TEA.

It is estimated that ninety million pounds of the present season's Indian tea will be imported into the United Kingdom. As the total quantity consumed in the year will probably fall short of two hundred million pounds, our Indian empire will thus contribute almost exactly one half of the whole. This is gratifying proof of the development of a trade which was established just fifty years ago, and which, having already conferred great benefits upon our merchants and upon the natives of India, promises to attain proportions that a quarter of a century back were undreamt of.

In 1821 it was discovered that the tea plant was indigenous in India, but some time elapsed before a serious attempt was made to cultivate it, and it was not until 1838 that the first parcel of the product was sent to England, the quantity then exported being five hundred pounds. From that time the industry has advanced so rapidly that in the home market the growers have nearly, if not quite, overtaken the producers in China, and are threatening to beat them out of the field. The rate of progress made in the last decade has, indeed, been remarkable. Ten years ago less than twenty per cent of the tea consumed in the United Kingdom came from India, and now, as we have said, the percentage is about fifty. Where will it stop? This is the question that has been forced upon the attention of the Chinese officials. England is far and away the best customer China has for its tea, and it is obvious that, with the consumption per head remaining almost stationary, as Mr. Giffen has shown, the relative progress of Indian tea must be a serious thing both for the Celestial Empire and for the merchants who trade with it. Even within recent times there was an idea in the popular mind that tea was cultivated in China alone; but the Indian and Colonial Exhibition did much to dispel that illusion, and the public have become so far awakened to the merits of British-grown tea that retailers no longer think it advisable to place it in packets intended to convey the impression that it comes from China. The demand for it is rising by leaps and bounds, and Chinese officials, who were slumbering in misplaced confidence that the virtues which are necessary to the production of tea were peculiar to their own soil, have at length opened their eyes to long-established facts, and made half-hearted endeavours to check the adulteration and improper preparation of their best known article of commerce. Whether they will be successful in re-establishing the reputation which China tea has in some degree lost remains to be seen. It may well be doubted, however, whether that object will be accomplished. At all events, the Indian growers are increasing their output every year, and it is becoming more and more appreciated in England—the great tea market of the world. There can be no doubt as to the advantages which have accrued to India from the development of the tea industry there. Many millions sterling have been invested in it, and it has provided employment for swarms of the natives.

Rapidly, however, as the tea trade of India has advanced, the strides made by that of Ceylon have been still more remarkable. The tea plant was introduced on the island about 1842, but at that time the planters were prospering on the coffee industry; and not until their plantations were destroyed by disease, and ruin was staring them in the face, did they turn their attention to the cultivation of tea. With a courage which was astonishing under the reverses to which they had been subjected they substituted tea for coffee, and they have gone a long way towards obtaining the reward they deserve. In 1873 Ceylon exported twenty-three pounds of tea; today the exportation considerably exceeds ten million pounds, and it is increasing every year. The colonists are looking forward to the time when seventy million pounds shall be annually produced on the island, and, as there is practically no limit to the possibilities of the yield in India, there soon may be enough tea grown in the British Empire to meet all the wants of the home market. Whether it will entirely supersede China tea in England is another question altogether. There are many people who prefer the product of China, partly perhaps because they are even now susceptible to the appeals of the gaily dressed Mandarins, who, in the tinsel-glories of the tea-chest, took a strong hold upon their imagination in childhood. Moreover, China tea appears to be well adapted for blending purposes. It is admitted that the liquor produced from it is thinner and less pungent than that obtained from Indian tea, and a blend of the two varieties of leaf is considered by numerous competent judges to form the best material for infusion. Blending has, in fact, become an important branch of the tea trade, as it has, of the trade in whisky. Many grocers buy their tea separately, and mix it themselves: but a large number, distrustful of their own skill and knowledge, like to get it ready blended, and there are several firms in the City of London who make a special study and practice of the work of blending. Indian tea was formerly the subject of a good deal of unjust suspicion, owing to its superior strength. Accustomed only to the less pungent article from China, consumers used Indian tea too freely, with the result that the liquid was black and strong, and repelled some by its colour, and others through apprehension of prejudicial effects upon the nervous system. The remedy has been found in a more sparing use of the tea or in its blending the China leaf, as, in either case, the strength can be reduced to the required standard. Present appearances point to the probability of China tea being employed in this country in the future very largely for blending purposes, but much depends upon the introduction of reforms in the preparation of the leaf and the spirit in which they are accepted. With the tenderness that they always display for the usages of their ancestors, the Chinese prepare tea for the market in the manner in which it has been done from time immemorial. In India, on the contrary, machinery has been brought into requisition for every operation after the leaves are gathered, and the objectionable Chinese custom of doing all the work by hand is abolished. If the Chinese are well advised, they will adopt the more cleanly and in every way more satisfactory method of treatment, but they have such an incradicable aversion to change that it would be unsafe to speculate on their doing anything of the kind.

The diminution in the price of tea has kept pace with the increase in production. Isaac D'Israeli quotes an old bill, in which the advertiser took credit to himself for selling tea at the low price of fifty shillings per pound. At the present day a fairly good article may be bought for one shilling and sixpence per pound, and when one remembers what reduction has taken place in the price within the last few years, he would not like to predict that the limit of cheapness has yet been reached. While the price has been going down, however, the expenses in the gardens have been brought lower, and the principal Indian companies are consequently able to maintain their dividends at tolerably high figures. The increased production has naturally depressed prices and thus stimulated the demand, and there is no doubt that had it not been for the supplies thrown on the market from India the consumption per head of the population would have been very much smaller than it is. At present the consumption of tea in the United Kingdom is equal to about five pounds per head annually, and it is noticeable that, though tea is sometimes said to bring on nervous disorders, the Anglo-

Saxon race, which is not commonly supposed to be the most effete, takes by far the largest proportion of the fragrant leaf. The only people who consume more tea per head than we do ourselves are our colonists in Australia and New Zealand, and there is no country in Europe that approaches us. We drink, for instance, five hundred times as much tea per head of the population as the Spanish do, but it is true that Spain stands lowest on the list in Europe. Yet, great as the consumption is, it is doubtful whether the ordinary English housewife has acquired the art of distinguishing between tea and tea, and of preparing the liquid in the best possible way for the table. People who would declare that every species of potato requires its own special treatment in cooking regard all teas as alike when they get it into the urn or pot, and do not dream that the character of the water affects the liquor, or that one variety of tea may be longer than another in "drawing." Everybody can make tea in a fashion, but, as a matter of fact, it is a very delicate operation to make it properly, and one that very few housewives strive to master.—*Standard.*

ABOUT TEA AND ITS SUBSTITUTES.

[By G. A. Sala (?).]

There is always something interesting in facts and figures about tea, that useful sister of the proud and ornamental camellia-plant, that luxury of the richest and solace of the poorest. The Commissioners of Customs have just given us a new batch of them showing that, in the long rivalry between tea and coffee, the former is winning the race of popularity and becoming year by year more widely consumed and more financially important to the Chancellor of the Exchequer and to commerce. For some reason, not easy to determine, the fragrant "berry of Mocha" is gradually but evidently declining in favour. The gross amount collected on coffee for the last ten years has been mainly moving in a downward direction. The bulk consumption for the year ending December 31st, 1875, was 32,286,016lb., showing a demand per head of the population of ·961lb. The gross consumption for the year down to December 31st last was 31,608,304lb, showing a sale per head of the population of ·861lb., a decrease per head of ·100lb., or at the rate of 10·4 per cent. While the receipts from coffee, however, prove a substantial diminution, those from chicory fairly keep pace with the increase of population, a sinister piece of statistics which goes to demonstrate that adulteration may have much to do with the apparent decline of coffee. Why, indeed, should the wholesome and aromatic infusion, which, properly made, is so restorative and digestive become less in vogue, if it be not either that the mass of the people fail to get good coffee, or are not supplied with it brewed in the proper manner? Probably both causes are at work against the berry which the Prophet would wisely have blessed and recommended in the Koran if he had lived to taste it. Coffee receives very scant justice from Western cooks. In the East they would be scandalised to think of persons so ignorant as not only to roast but actually to grind it weeks and months before use. The delicious flavour of the bunn in Turkey or Egypt or Syria is due to the simple fact that the aromatic oils of the kernel are brought out by heat at the moment of consumption, and that the cafedji scorns to mingle the vulgar imitation of chicory, or the viler produce of burnt beans, with that cup which the Arab fondly calls "The Brace of the Pipe." The chief virtue of coffee—the way in which it preserves indefinitely the subtle odours and flavours gathered in the tropical sunshine, but once pulverised quickly parts with them—is against its use. The public must have something extremely convenient in respect of its meals, drinks, lighting and everything else. Eggs are so universally employed because they are the very quintessence of food, condensing nourishment in the most portable and available form. Gas, which ought to have been abolished long ago in favour of the electric lamp, holds its own because of its fatally obvious handiness as an illuminant. So tea outdoes coffee in popularity, because it yields its best result with so little trouble or precaution; for, if the leaf is good at first, it is only necessary to keep it well closed from the air to have as good a bowl as the Empress of China could desire. The pale green berry, however, ought to be roasted and broken and ground every time a real cup of coffee is required, which rule is seldom or never observed. The consequence is the administration of poor decoctions which might make Mr. Nathaniel Canopus, the Cretan, who first brewed the true beverage at Balliol College, Oxford, rise from his grave to protest. Strange, indeed, it is to reflect that the West has only known coffee since 1640 A.D.; and the earliest coffee-house in London was opened by Edwards, the Turkey merchant, at George-yard, Lombard-street, in 1652 A.D. Now far and wide, in climates fit for it, grows the beautiful coffee-bush, with its creamy flowers, scarlet "cherries," and glossy dark green leaves; since even here a pound per head of the population implies a considerable cultivation, and, abroad, wherever the narghileh, the hookah, the cigar, cigarette, or pipe "weave their light blue tangles in the sun," there coffee is the indispensable companion of the weed.

Tea, meanwhile, notwithstanding occasional protests from doctors and deans against its alleged nerve-exciting qualities, grows steadfastly in use among us. The Commissioners of Customs inform us that, taking the same years for comparison, in 1875 the bulk consumption amounted to 151,274,852 lb. equal to a demand of 4·52 lb. per head of the population; while in 1886 the bulk consumption amounted to 178,909,881 lb, equal to a sale of 4·87 lb. per head of the population; an increase per head of 0·35 lb.; or at the rate of 7·7 per cent. Here, again, is a most marvellous development of an experiment in commerce, for in 1669 the East India Company quite timidly instructed its agent at Calcutta "to buy for forty shillings the best tay you can gett," and old Pepys records how he drank his first cup of it with all the complacent self-glorification which that primæval gourmet must have exhibited who swallowed the first oyster. Tea is tremendously historical; it separated the United States from England; but, although everybody knows how the tea-tax led to the American Rebellion, few are aware that the tax was voted by the merest accident in the House of Commons. Tea will become more historical still, for it seems destined to reverse the places of India and China, and, with the wheat and jute trade, to pour new rivers of wealth into the Queen's Eastern dominions. Hindostan is rapidly gaining upon China as our source of supply. In 1876 China and Hong Kong supplied 84 per cent. of our total importation of tea, and India and Ceylon 15 per cent., while last year the proportions were 63 and 35 per cent. This is not altogether, say her Majesty's Commissioners, to the advantage of the revenue, as, the teas from India being stronger than those from China a smaller quantity of them goes as far for the same purpose as a larger quantity of teas from the latter country. But who cares a pinch of Bohea for Treasury officials when such things are at stake as the welfare of India, and the brewing of a really good afternoon cup? Indian teas are almost always prepared with scrupulous honesty of manufacture, which is more than can be said of those sent from the Celestial Kingdom, although with the low duty at present existing there is not so much adulteration in this article as once prevailed when "lie-teas" used to come over which scarcely contained a single leaf of the genuine "thea viridis." Rubbish is of course imported even now, which is made to serve its purpose by crafty blending with better samples; but the people at large are good judges of the commodity, and the seller of sloe-leaves and willow-leaves coloured with gypsum and indigo does not find his knavish business prosper. All dealers admit that, excepting the very finest qualities—such as the young Hyson, styled "mandarin-tea," made of the tender bud, and seldom seen in this country—the Chinese leaf profits by ad-

mixture with the Indian. The gardens of India and Ceylon now send to Great Britain, as we see, 35lb out of every 100lb. employed among us, having increased their supply more than twofold in ten years. And when we consider what 180 million pounds signify in the breadth of land occupied by the tea-plants, the number of hands employed in picking, drying, rolling, sorting, packing, and exporting the immense harvest; that "forty shillings' worth of the best tay," hazarded as a speculative consignment by the old Company, wears an aspect more wonderful than the scriptural "grain of mustard-seed." Philologists, too, might find much to discourse upon in the way in which the "cup that cheers" has had its name changed. In China, its original home, it is "tcha"; in India, its adopted home, it is also "chay," and such was its original pronunciation with Englishmen, as is plain from the couplet, "Here thou, great Anna, whom three realms obey, Dost sometimes counsel take, and sometimes tea." Perhaps its was the French "thé" or the Spanish "té," which altered the original appellation. *

An Indian tea-garden is at the proper season a very beautiful sight, especially when cultivation has been clean and careful. They are spreading, and they will greatly spread; but if tea and coffee should never be wholly dethroned from their dietetic pride of place, it is quite possible that new beverages may be invented to rival them. Maté, which the Peruvian sucks hot through a silver pipe; guarana, much richer than the Mocha berry or the Chinese leaf in theine; the kola-nut and the coca plant are all possible competitors. The negro of the Soudan, Mauritius, West Indies and Brazil would not give up the kola-nut for the best of tea or coffee. Then there are millions of people who drink infusions of the leaves of saxifrage, of ledum, of pimento, and partridge berry, and hundreds of unsuspected plants contain the ingredients which the human race seeks for in such beverages. The chief of these are the alkaloid which is present by a proportion of about 3 per cent. in ordinary tea, and the aromatic oil which gives to that and to coffee their special flavour. The Chinese will not drink new tea because it contains too much of the latter ingredient, and is sometimes actually intoxicating. The "theine" diminishes the waste of the body, enabling it to get along with less nourishment, so that it saves food, and is instinctively valued for this by the poor. The Tartars obtain still more sustenance from their brick-tea by powdering it and boiling with salt and mutton fat whereby the caseine or gluten of the plant becomes extracted. Then they can live for weeks on the tea-leaves which the British housewife throws away. On the other hand, it is distinctly bad to let tea stand too long; that brings out tannin, and too much tannin will turn meat taken at the same time into a sort of leather within the stomach. There can be little need however to instruct the matron of these islands in the art of tea-making. From the silver-gilt equipage of the duchess to the brown stone pot in which the washerwoman solemnly prepares her evening dish of tea, the art of making it is essentially feminine, and has been profoundly studied. One hundred and eighty million pounds per annum all passed through teapots—what a river to spring from Pepys' first tentative spoonful and the modest investment of the old East India Company!—*Daily Telegraph*, Sept. 5th.

ADULTERATED TEA AND COFFEE.

The report of the Commissioner of Customs on the examination of teas in bond made by their analyst under the 30th section of the Sale of Food and Drugs Act, 1875, shows that the sale of adulterated tea in this country is now carefully watched, and will, no doubt, ultimately be suppressed. The Commissioners state there were 2,546 samples received, which may be classified as follows :—1,452 faced green; 42 unfaced green; 332 capers; 219 congous; 77 dust; 424 siftings. —Total 2,546.

These samples represent consignments amounting in the aggregate to very many thousands of packages. The teas from which 2,422 of these samples were taken were delivered on the authority of the analyst. Though many were of very low quality, yet as their inferiority was the result of natural causes and not in any way attributable to adulteration or the presence of exhausted leaves, they did not come under the condemnatory clauses of the Act. The remaining 124 samples, representing a total of 8,086 packages were disposed of by order of the Board, under the following circumstances :—802 were capers. These the Board permitted to be entered for home consumption. Though low in attractive matter, due to natural inferiority, they were not artificially exhausted; they contained, however, about seven per cent. of mineral matter. Twenty-nine packages of green tea dust were also permitted to be delivered into the market by order of the Board. These contained five per cent. of mineral matter, but in other respects were unobjectionable. The 7,255 packages remaining came under the prohibitory provisions of the Act, and were consequently either seized or restricted to exportation. 5,113 of these were capers. They were adulterated with exhausted leaves to the extent varying from ten to twenty per cent., besides being loaded with from seven to eleven per cent of sand. 1,693 were Congous, 1,575 of which were China teas from Marseilles,* the remainder from China. These teas were all adulterated with exhausted leaves varying from twenty to thirty per cent. 420 were tea dust from China, containing ten per cent mineral matter; 21 tea dust from Japan, with eighteen per cent of mineral matter; four packages green tea from Singapore, with six per cent mineral matter, and mied with leaves other than tea.

There were also 4 packages which were unfit for human food, and which were seized and destroyed accordingly.

The following table is an abstract of the samples analyses in this department during the last five years:—

	1882.	1883.	1884.	1885.	1886.
Samples analysed	941	852	870	1,430	2,546
Do. delivered by analyst	925	838	850	1,311	2,422
Do. reported to Board	16	14	20	119	124
Do. delivered by Board for home consumption	—	—	1	17	10
Do. delivered by Board for export	2	14	19	98	110
Representing packages ..	88	665	978	9,069	7,251
Seized by the Board.. ..	14	—	—	4	4
Representing packages ..	164	—	—	4	4

Thus it would appear that the practice of importing adulterated teas into this country with the view of their passing into consumption is by no means extinct, and that it would probably increase but for the existence of this office.

COFFEE.—The unavowed mixture of chicory with coffee is still general. As chicory is worth only about 2d, a pound, and as so-called "French coffee" has been found to contain more than 70 per cent. of chicory, the profit of the sale of the mixture at 1s per lb. is considerable. Of seven samples of "coffee" reported by the analyst for Buckinghamshire as adulterated, one consisted entirely of chicory and the others contained respectively 36, 40, 65, 75. 80, and 90 per cent, of that inexpensive root. It ought to be known, however, that in the case of *Liddiard v. Reece* (44 J. P. 233) where, on coffee being asked for, a mixture containing only 60 per cent. of coffee was supplied, the High Court upheld the conviction of the seller (notwithstanding the fact that the parcel was labelled as "a mixture of chicory and coffee") on the ground that the justices had found that the chicory had been used fraudulently to increase the bulk and therefore the seller was not protected by section 8 of the Sale of Food and Drugs Act, 1875.—*H. & C. Mail*, Sept. 23rd.

* Not so: *té* is the Amoy pronunciation of the name of the plant, which in all other parts of the empire is called *cha*.—ED.

* N.B.—ED.

PLANTING ON THE KAREN HILLS, BURMA.

We have to thank Mr. Petley for a copy of his report on planting on the Karen Hills above Tounghoo. The condition of affairs compares favourably with that of the preceding year; and now that the labour question has been settled matters should rapidly improve.

Report of cultivation on the Karen Hills North East of Tounghoo for the year 1886-87.

Tea.—Owing to the casualties as noted in my last year's report, the outturn for 1886 could not be expected to show a full yield; this produce has however given a very fair yield in proportion to the circumstances, as shown in Tea Report to Government dated 29th December 1886 of over 300 lb. to the acre, nearly all best Tea, notwithstanding the drawbacks.

Coffee.—The crop of 1886, (gathered January 1887) resulted in a better outturn than was expected under the circumstances shewn in my former report, and affecting it like the Tea. Looking to the now well known quality and demand for my coffee in the local market, this produce is offering well; through which encouragement I have cleared land, and set out 52,000 young plants, keeping vacancies that occurred among the weaklings filled in, so that at date the said field is complete with healthy, thriving young plants.

I have also large supplies of young plants for public sale; my coffee has been tried and found to thrive well in the plains.

Liberian Coffee,—Continues as before.
Chinchona do do

Fruit Trees.—The apricot and plum noted and remarked upon in last year's Report will, it is seen, with fair chances, grow in the Hill climate, but they have several drawbacks to encounter from two causes. *viz.*, white ants and the moles which attack and destroy the roots. Ten of the 26 trees from last year have been so killed, and the remaining 16 are now in 4 different places to which they have been transplanted in order to save them, and are now putting forth fresh leaves.

Pears.—The trees thrive and increase vigorously. They, like the apricots and plums above noted, gave considerable trouble when young. Fruits of the orange tribe need no comment, being indigenous.

Oracle Tuber.—Has not proved successful here; it continues to exsist only and comes to nothing. The attacks of the Red headed beetle constantly on the leaves, and other insects, is no doubt the main cause of this tuber not thriving.

Cereals.—I have sown some Behar wheat and Sagaing wheat in well prepared ground 10 days ago; and it will be reported on to the Agricultural Dept. hereafter. Portions also of both kinds with American maize have been handed to others in different quarters for trial.

Crops Generally.—From my own observations and inquiries also, the paddy appears to be thriving badly and very poor crops are anticipated in this quarter of the hills There will no doubt be a scarcity and many will not get enough even for future seed. I hear the crops are fair in the Southern fields among the Pakus.

Remarks.—Rains though not much more abundant have been very severe this season, and weeds have flourished exceedingly. Labour has however come in most freely within the last 2 months and counteracted this. Some of the Padoungs and distant villagers, whose friendly interest it is important to maintain, have come into the work again, and will I trust continue as in former years. Altogether the labour question is looking up favorably for the future. —*Rangoon Gazette*, Sept. 23rd.

THE COFFEE LEAF DISEASE is the subject of a paper by M. Lucien Dugand in the Mauritius *Revue Agricole* for August. The writer describes the effects of the *hemileia vastatrix* on the leaves of the coffee and its microscopic appearance and reproduction. He then speaks of the treatment of the disease, detailing the many substances that have been tried and found wanting: and he ends by drawing the following conclusions:—

"1st. That powderings must be made with solutions having a basis of copper.

"2nd.—(Very important point.) That the remedies must be applied *above the leaves and not below them.*

"3rd.—That they must be applied twenty days before the usual appearance of the disease and not as soon as the latter appears.

"4th.—That, besides the preventive treatment, a treatment be tried as soon as the young berries have set.

"5th.—That the doses of sulphate of copper must be very weak."

He adds:—"N.B.—I do not exclude good manuring and weeding. These latter, although certainly not guaranteeing the coffee tree against the disease, can do it nothing but good."

COFFEE IN ROTTERDAM.—In the report of Consul Turing on the trade of Rotterdam for 1886 the following remarks occur:—Coffee during the past year not only steadily and gradually recovered the fall in prices experienced in 1885, but reached rates such as have not been known since 1880. This improvement has made further progress during the current year, and prices now rule from 100 per cent. to 140 per cent. higher than in January, 1886. The rise has been caused by the reduced estimates of the Brazil crops, which, in the beginning of the year under review, were computed to yield from 7,000,000 to 8,000,000 bags, whereas these figures soon proved far to exceed the reality; which circumstance, coupled with diminished supplies from the Dutch East Indies and unfavourable reports of the growing (1887-88) crop in South America, imparted confidence to all interested in the article, and the statistical future was considered so healthy that the attention of outsiders was likewise attracted, and thus through the combined influence of dealers and speculators prices for good ordinary Java advanced during the last six months of the year from 28c. per half-kilo. (47s. 4d. per cwt.) to 41c. (69s. 4d. per cwt.), which rate, as stated above, has during the current year been far exceeded, 96s. 5d. per cwt. having been paid within the last few weeks. The total imports of coffee into Rotterdam during 1886 amounted to 46,456 tons.—*L. & C. Express.*

FORESTRY IN CEYLON.—A correspondent has drawn our attention to what he terms a spiteful attack on Mr. Vincent, on page 382 of our August number, in the extract from the "Indian Agriculturist" regarding Ceylon. We really regarded it, as the greatest praise for Mr. Vincent to be attacked by a Ceylon Tea Planter, and the remarks about the highly coveted blocks of forest land suitable for tea, which had been withdrawn, on Mr. Vincent's report, show the real reason for the grudge against him. Our own opinion on the great value of Mr. Vincent's work in the Ceylon forests, has already been freely given in our pages, and we did not expect that the extract from the "Indian Agriculturist" would take in any one. We may say that Dr. Meyer, when in Dehra, expressed his views about the miserable short-sighted policy which was denuding the forests of Ceylon for tea planting, the roots of which could in places only hold on to the soil for a few years as the rush was so great, when once the forest had been cleared. It may now be confidently expected that Mr. Thompson will speedily bring the wreck of the Ceylon forests into proper control, and he has all our best wishes for his success in the great work before him.

[The above is from the number of the *Indian Forester* which reaches us just as Mr. Thompson has broken down in health and resigned. As for tea planters, they just as naturally resent the reservation of the finest soil for forest, as foresters choose tracts so distinguished; and the editor in repudiating an attack on Mr. Vincent might have spared himself the trouble of quoting an attack on the tea enterprise in Ceylon which is in fact and science equally erroneous. By "rush" we suppose wash was meant, but whatever was meant, the fact is that the tenacity of the hold of the tea plant, with its long and strong tap-root, on the soil is one of the most remarkable circumstances in the cultivation. Who is Dr. Meyer?—ED.]

Correspondence.

To the Editor of the "Ceylon Observer."

INFORMATION RESPECTING CINCHONA.

London, 1st Sept. 1887.

DEAR SIR,—I enclose a letter dated 27th July, which I was under the impression I had forwarded to you then, also some *facts, deductions and proposals*, which I am circulating among my friends in England who are interested in cinchona. I am asking them whether they would be willing to join such an association as I describe.

May I ask you to be good enough to insert the above in the *Ceylon Observer*, also in the *Tropical Agriculturist*.

May I also ask you, as one of the best friends the planters have, to make your own remarks on the paper in the *Observer* and *Agriculturist*.

I may remark that I have sounded some of the London merchants on the subject of an association and that they consider it a question for the producers, more especially the Ceylon planters (not for themselves) to take up.—I am, dear sir, yours faithfully,

W. T. HODY COX.

FACTS.

1. The present low prices are caused by large production.

2. An increase of 1d per unit (from 3d to 4d) in the price would increase the profits 33 per cent, as all proceeds above a certain figure (say 3d per unit which would more than cover the cost of production) would be clear profit.

3. Increase of consumption would increase demand and therefore price.

4. There is an immense field for increase of consumption in malarious countries and especially in China.

5. In such countries the value of quinine is beginning to be understood but the natives are poor and cannot afford to pay for quinine.

6. It is generally allowed that the effects of "quinetum," a preparation of the alkaloids of red bark, are nearly as good as of quinine.

7. The price charged by the manufacturers in England for "quinetum" is 1s 9d per ounce. The manufacture of quinetum is simple and inexpensive, it is understood in India; quinetum can be prepared in the East at less than 6d per ounce.

8. The cinchona plantations in Ceylon and the East Indies consist chiefly of Cinchona Succirubra.

9. The preparation of quinetum in the East would take a certain quantity of bark off the European market, the effect of which would be to raise the price in England.

DEDUCTIONS FROM THE ABOVE FACTS.

1. The laws of supply and demand would not within a reasonable time create consumption among the "millions" as no private individuals or firms would care to distribute gratis.

2. Such distribution must be made by the producers, at first gratis and afterwards on payment which though small would, through the cheapness of manufacture, bring in a handsome profit.

PROPOSALS.

1. That all those interested in the cultivation of cinchona should form an Association to manufacture in the East, say at Colombo, the alkaloids of red bark in the form of "quinetum."

2. That members take shares of say £1 each in the following proportions:—10 shares for every 100,000 cinchona trees or under, which they may have growing. This is a very small proportion but the object is to get as many as possible to join. Any members wishing to take more shares can do so.

3. That the manufactured "quinetum" be distributed: in India through the Government and its officers, China through the missionaries and "Medicine Men," Africa through the missionaries.

This is merely an outline of a scheme. Planters have been such sufferers through the low prices, that I believe they would welcome and accept only too readily any good scheme.

I for one should be happy to take my proportion of shares in such an Association as I have described.

W. T. HODY COX.

August 1887.

CEYLON TEAS IN THE MELBOURNE MARKET.

SIR,—Should these few lines prove of service, I shall be glad in showing, that pure Ceylon tea, if pushed in the Melbourne market, *is* saleable and sought for at very fair prices. It is but little I have been able to send, but that little has been sold to private individuals at very remunerative prices, viz. 2s and 2s 6d per pound, and some few offered to purchase at 3s if they could *always* procure the *pure* article. Mr. Henry's proposal to establish agencies in Melbourne, and to employ canvassers to carry round samples, could not but succeed if thoroughly carried out. But care should be taken that agents in Melbourne only send round the *pure* article. Much harm is done in the sale of Ceylon tea by mixing China trash with it.

There are in Melbourne some few ex-Ceylon planters, who would be thankful for the canvassing work and *who* would take greater interest in pushing Ceylon products in the market there, than they? if only for the sake of "Auld lang syne."

SPES.

COCONUT CULTIVATION: THE MAIN ROOT AND FEEDING ROOTLETS.

Hapitigam Korale, 16th Sept. 1887.

DEAR SIR,—"Try all things and hold fast that which is best" is a maxim formulated by one Paul of Tarsus, an eminently practical man in his day. I commend this to the notice of your Siyane Korale correspondent who has enclosed himself within a stockade of hypothetical stakes. From his fortress he looks out over the open country, where diligent workers have been searching for truth since he began to suck his mother. As no truth regarding coconut cultivation can possibly be discovered outside his ring fence, he holds all such toilers to be silly and contemptable persons, and if any of those outsiders announce a fact that threatens one of his fence stakes, he turns on the aggressor with all the virus of an overteased monkey.

Dismounting from my metaphorical charger to meet your correspondent on level ground, I have to tell him that he must free his mind from many of his hypothetical theories, and become a more accurate observer of facts before he arrives at the status of a good practical coconut planter. The letter in question affords me ample opportunity of pointing out his errors, both in theory and practice. Has he ever submitted to experiment his theory about the sacred character of coconut roots, and the terrible consequences to the trees, of disturbing them? Has he ever visited a field where periodical breaking up of the soil was practised and compared it with others, where no such reckless destruction was allowed? He has evidently done neither of these, else nothing short of obstinate stupidity could have kept him true to his theory. Again he states as a fact, that most of the feeding rootlets are *round the tree*. In one sense this is true, but, as I understand him, he means that the favourite feeding ground of the roots is within perhaps a few feet of the stem, and on this assumption he builds a system of treatment one part of which is to cut a trench round the

tree, in which to deposit husks and leaves. Pretty well this for a strong conserver of roots, cut a trench round the tree and thereby cut a host of leading roots off close to their source! No digging or ploughing could possibly beat this. As regards the chief seat of the feeding roots being near the stem, I advise your correspondent to look again, when he will perhaps find that, for several feet round the stem the main roots are so closely packed, that there is no room for fibrous rootlets. Perhaps the kind of reason he professes to follow may not admit that the vicinity of the stem, being the first portion of the alloted space occupied by roots, is the most exhausted of the elements of fertility and that the true feeders may be nearer the extremities of the mains than close to their source. Your correspondent reports that he manured coconuts in November 1884 and that the increase only began to come in when the third year was well advanced. I cannot say anything about this for want of more facts, such as the state of the trees at the time of manuring, the quantity used and the method of application. My own experience in the use of cattle-shed manure is that one cwt. spread equally over the space occupied by a coconut tree, bearing more or less and dug in, I reaped the first fruits at the end of eighteen months. It strikes me, that, when your correspondent writes about bone dust, he draws on other resources than his own experience when he declares it to be a stimulant akin to alcohol in the case of humanity. My experience is, that given to a young tree before it shows stem, or to an older one that has been dwarfed on bad soil, it produces no perceptible effect. I conclude, therefore, that if phosphate be a necessary element in the growth of the plant, it is grains rather than pounds it needs, but it is an indispensable element in the formation of fruit, but even for that the quantity necessary is very small, I should say from one to one-and-a-half pound per annum or not over two would keep up a yield of 100 nuts on a vigorous tree, but the tree needs to be kept in vigorous growth by other manures. Ground bones is better for the purpose than superphosphate or steamed bones, because the greater part of the phosphate is not soluble and only becomes so by degrees. There is no danger to the trees in the use of bone dust by those who have the requisite knowledge. I have met, in your correspondent's letter, an old acquaintance, a peculiar Ceylonese argument against the use of manure in the growing of coconuts. "You no doubt increase your crops by manure, but when you begin you must go on, else your trees will relapse into even more hopeless barrenness than before." So have said scores of my Ceylonese acquaintance, and I freely admit that the statement is perfectly correct, but I add why should anyone contemplate the clearing of a business that yields a rupee for every twenty-five cents [illegible]? Your correspondent is perfectly right in preferring a field of moderate extent, skilfully cultivated, to a wide tract under the management of Madam Nature, who treats a noxious weed and the most valuable economic plant with equal kindness. Your correspondent has, however, much to learn and still more to unlearn before he gathers three hundred thousand nuts per annum on fifty acres.

W. B. L.

IRRIGATION APPLIED SUCCESSFULLY TO COFFEE CULTURE IN SOUTHERN INDIA.

Ootacamund, 29th Sept. 1887.

SIR,—I had no idea that my note to you on "Coffee and Irrigation" would cause so much interest in your part of the world; and as requested by you, will try and answer your question to the best of my ability:-

1. The estates in question are fairly flat, at least one is, and the other "undulating" land on which I have to be very careful when irrigating. There is no "wash" on this estate, but on account of the lay of land I often have a small "slip" when irrigating, through carelessness on the part of coolie; so I think I can say that taking the land *altogether* it is not what would be called "flat."

2. Climate fairly dry. Rainfall average about 42 inches per year, only 2 months in the year no rain, January-February. I enclose last year's rainfall.

3. By irrigation, water is taken direct from the Pykara river and carried by a built channel for some 200 yards, after which it flows down the face of the hills by an ordinary drain and so is carried on to the estate, distance about 4 miles.

4. The estate is watered "field by field and four coolies are employed taking it down the lines" from one road to another, each cooly taking four lines, and it takes five weeks for the first round, four weeks for the rest; irrigation is started *early* in January and continued until the S.-W. monsoon has fairly set in. The first round of water produces the "spike," second round brings it out and third sets the crop, after which water is kept going until the rain.

4. Yes, a fair amount of manure is available, but as a rule we do not purchase more than 1,000 lb., the rest is from our own cattle—200 head well littered. I can't say whether bone &c. would answer as well. We use *very* little artificial manure, but as a rule get *nearly* all round the estate with cattle manure. I start manuring early in January, and follow up with water which at once decomposes the manure at the roots into a rich mould, which I think is the *secret* of success on these estates.

I must mention that "*no* pruning or handling" is done on these estates. Last year as our crop was small I tried a little thinning out to see if the quality would improve, but of course can't say yet. All I know is that there is a "bumper" on, and on one estate I shall *not* be surprised if we get over one ton per acre! and this at 100s per cwt. *will* pay, I guess!

I fear I can give you no further information, but shall be glad to answer any question either direct or through your valuable paper, and if any gentleman doubt what I say they have only to come over and nothing will give me greater pleasure than to show them 10 CWT. PER ACRE.

Rainfall 1886.—January nil, February nil, March nil, April 2·70 inches, May 8·46, June 6·88, July 13·78, August 8·11, September 5·25, October 3·35, November 2·60, and December nil.—Total 51·13 inches. This year there were four months without rain, but two months is the average.

You are at liberty to mention my name to any planter that may wish to have direct answer.

I would advise no man to try irrigation unless he can back it up with manure. Artificial may do of course, but I have no experience in it.

WE learn that the Government of Jamaica offers a premium of £100 for the production of the best practical elementary text-book of tropical agriculture specially applicable to Jamaica, and embodying the first principles of agriculture. It is stated that the object of the manual is to create in the mind of the young an early and intelligent interest in the soil and its products, and particular attention is to be paid to simplicity, brevity, and freedom, as far as possible, from technical terms. It is stated that the propagation and cultivation of tropical economic plants should have due prominence. Manuscripts are to be forwarded to the Government of Jamaica on or before August 1st, 1888.—*Nature*.

INDIAN EXPERIENCES.

(*Continued from page 297.*)

THE NEILGHERRY HILLS.

It was at the beginning of 1867 that I left the Wynaad district for the first time, having obtained a situation on the Neilgherry Hills to superintend the opening of a large Cinchona plantation at a place called Deva Shola, situated about ten miles to the south of Ootacamund, the chief town of the Hills. Before, however, giving an account of my experiences as a Cinchona planter, I may be allowed to say a few words on the general aspect, climate, and capabilities of the Neilgherry range, which is without doubt one of the most interesting spots to be found in the whole of our vast Indian possessions, more especially on account of its climate, which is so admirably suited to the European constitution, and producing in a high degree of excellence a vast number of trees, plants, and vegetables similar to those cultivated in Europe.

The Neilgherry Hills (or more correctly, Nilgiris, from the Tamil "nil" blue, and "giri," a mountain) are situated between 11° and 12° north latitude, and 76° and 77° east longitude, and range in altitude from 6000 to about 9000 feet, above the sea level. They are some 250 miles from the Coromandel coast on the eastern side and forty miles from the Malabar coast on the western. The area may be roughly taken at 1000 square miles. The Nilgiris were first visited by Europeans in the year 1820. They are believed to have formed part of the territory of the Pandyan kings, whose dominions included Travancore and the Western Ghauts. The average rainfall is 50 inches in the north and east, and increasing to nearly 100 inches towards the south and north-west. The Nilgiri Plateau is subject to the influences of both monsoons; the south-west monsoon in June, July, and August, and the north-east monsoon in October and November. The geological formation is of the primitive igneous order, the mass of the mountains being granitic. There is little or no lime in the composition of the soil, which nevertheless is rich and productive. The natural aspect is undulating, with isolated patches of low, but very beautiful forest, called Sholas, on the slopes, from the majority of which flow perennial streams of the purest water of more or less volume. There are many swampy hollows, the beds of which have a considerable depth of black mould, and there are bogs in several parts of the Hills, the peat from which is extensively used as fuel. The undulating land, or as Sir E. Grant Duff admirably puts it, the "rolling downs," separating the beautiful shola patches, are covered mostly with short grass, with here and there clumps of shrubs, such as Hypericum, Indigofera, &c. Splendid groups of the Rhododendron arboreum are frequently met with, and are very striking when in full flower about the month of December.

The climate of the Nilgiris is invigorating, and has been declared by competent authorities to be one of the most equable in the world. The following is a correct statement of temperature, &c.

Mean annual temperature	..	..	59°
Maximum „	..	..	77°
Minimum „	..	..	38°
Max. power sun's rays	..	..	21° 73′
Average range	..	..	17°

At Ootacamund, the loftiest and most important station on the Hills, according to a series of observations extending over seven years, the mean maximum temperature ranges from 60·06° in December to 68·76° in May. The hottest months of the year are April and May; the coldest December and January. The hottest hours of the day in summer and winter do not vary more than 9° and the extreme variation of temperature throughout the year is only 21·15°. The mean annual temperature of the four principal stations on the Nilgiris as compared with that of London and the three Presidency capitals of India stands something as follows:—London, 50°; Ootacamund, 57°*; Kotagherry, 62°; Wellington 62°; Coonoor, 64°; Calcutta, 78°; Bombay, 81°; and Madras, 85·2. The second, third, fourth, and fifth named places are the most important stations on the Nilgiris, and have an elevation above sea level of 7227, 6427, 5860 and 5927 feet respectively.

Ootacamund is the coldest and Coonoor the warmest station on the Hills, Kotagherry is a medium between the two. The climate of Wellington, where the extensive convalescent barracks for the army of the Presidency are situated, is the same as that of Coonoor. The latter station being near the edge of the Ghaut on the eastern side is subjected to thick fogs from the sudden condensation of the moisture contained in the heated atmosphere rising from below the tableland.

This may perhaps convey to the reader some general idea of the adaptability of the Nilgiris to the European constitution. If further proof were wanted it could be found in the healthy and robust appearance of the permanent English residents on the Hills, as well as in the rosy cheeks and buoyant spirits of the European children.

The products of the Hills include Tea, Coffee, Cinchona, Peaches, Oranges, Loquats, Pears, Apples, Plums, Potatoes of excellent quality, and most of the other English vegetables, which are all produced both by Europeans and natives of exceptionally good quality, and all the year round. Wheat is also grown as well as Barley, Mustard, Poppy seed, Garlic, two kinds of Millet, called in the native language Koralie and Samey (Panicum italicum and P. miaceum). The last two are extensively grown by the native population, but their cultivation is of a very wasteful description. A piece of land is chosen, ploughed, and harrowed, and the seed sown, land is chosen that has not been under cultivation for some years, no manure is applied and when the crop is gathered the land is left to itself for perhaps three or four years before it is ploughed again.

No such thing as flat land exists on the Nilgiris, excepting the swamps. Consequently when the land for the cultivation of grain is ploughed and loosened on the hillsides, large quantities of soil are swept down to the ravines below by the heavy rains. This denudation goes on to such an extent that I have seen whole hillsides rutted and furrowed to such an extent before the roots of the grain could make sufficient progress to hold it, that it seemed wonderful how a crop could be obtained at all. Of course it never enters into the native mind to construct catch drains or anything of that kind; and, worse than all, he has no one to instruct him. This sort of thing has been, no doubt, going on for ages, the strata of soil becoming thinner and thinner and the crops shorter in ear and in straw year by year.

Another plant called Keeray by the natives (Amaranthus campestris) is grown by the hill tribes, the seeds of which when ground into flour is much relished. A large field of this plant when in full flower has a very striking and beautiful appearance. There are two varieties, one having leaves, stems, and flowers of a bright scarlet colour, and the other of a yellow or buff colour, and when mixed have a very beautiful appearance. The leaves are also eaten as a Spinach. Numbers of English flowers flourish with little or no cultivation, including the Dahlia, Fuchsia, Heliotrope, Pelargonium, Verbena, Petunia, and numerous others. Fuchsias and Heliotrope are greatly used in the formation of hedges, and are to be seen in flower all the year round, the latter particularly making a very beautiful hedge if kept well trimmed, the scent from the flowers being very powerful. It is no uncommon thing to see at Coonoor and other places of the same elevation Pears, Apples, Plums, Oranges, Dahlias, Loquats, Geraniums, Coffee, many varieties of Hibiscus, Tea, Petunias, Allamandas, Asters, Poinsettias, Calceolarias, Begonias, Rhododendrons, Lilies, Roses, and scores of others growing side by side and flourishing in one garden. Passiflora edulis and several species of Taxonia also grow and fruit freely at these elevations. At lower elevation on the eastern slopes tropical fruits and spices are grown, such as the Nutmeg, Clove, Cinnamon, Mango, Shaddock, Pomegranate, Lychee, and many others.

* There must be an error, as this is the mean of Nuwara Eliya, 1,000 feet lower, in an island and 5° nearer the equator.—ED.

Deva Shola, or the God's Wood, the place I was appointed to, is situated, as I have already said, about ten miles to the south of Ootacamund with an elevation a little over 600 feet above sea level. The estate consists of 1000 acres, 500 of which is forest land and the remainder grass. This land was obtained fom Government upon certain conditions, one of which was that the proprietors should supply to the Government so many thousand cartloads of firewood (always a scarce commodity on the Nilgiris) within a given period, cut and stacked from the forest then standing. The proprietors, after having obtained the title deeds of the land from Government, thinking the above condition irksome, and that it might probably hamper them in the rapid planting of the forest area of the estate with Chinchona—for the one object with private planters in those early days of Chinchona planting on the Nilgiris was to be first in the market with bark at whatever cost—bethought themselves of a plan which was ultimately adopted, but which proved, as the sequel will show, vastly more disastrous to the proprietors than to the Government. The plan carried out consisted of first felling the whole of the forest area of 500 acres, which was one continuous block, cutting and stacking the stipulated numbers of cartloads of firewood while it was green, and then politely requesting the Government officials to have it removed at their earliest convenience. The Government were at that time engaged on the erection of the large pile of buildings called the Lawrence Asylum at a great cost within a few miles of the estate, and requiring a large amount of firewood for brick-burning purposes, &c., made the above arrangement, thinking the supply would be spread over a number of years, and that they could cart it away according to their requirements. They were therefore greatly inconvenienced by this act on the part of the proprietors, which proved, after all, to be but a very short-sighted stroke of policy.

The forest had been all cut for some time before I took charge, and the aftergrowth had already begun to make its appearance above the felled timber to a considerable extent, which I viewed with no little alarm, well knowing the difficulties that were in store for me. The primary objects in all planting operations in India or where the growth of vegetation is so rapid, is first to prepare a nursery of young plants; secondly, immediately the felled jungle has become dry enough to burn at once, then pit and plant the whole area thus cleared during the first season if possible; and all planters of any experience will invariably put forth their most strenuous efforts to gain this end, for the reasons that the ground can afterwards be kept clear of weeds at a minimum of expenditure, whereas should any land be left unplanted the undergrowth is sure to attain formidable dimensions before another planting season comes round, weeds also springing up and seeding, rendering subsequent cultivation a very serious matter as regards expenditure both of time and money. This will, in some measure, explain the situation in which I was placed in taking over charge of the property. Instead of the ordinary routine of planting operations having been hitherto adopted, the order of things had been exactly reversed, and I found myself face to face with 500 acres of felled forest which had been cut some eighteen months before, with masses of green aftergrowth appearing all over the surface, including thousands of plants of the formidable Solanum ferox, and many other species of tall growing and thorny plants of the same order. With only one small nursery in course of formation, and with a glass house with a limited number of pots of seedling Chinchonas, and no dwelling house save a rough building intended for a stable, I cannot say that I relished the appearances of things at all. However, I was now in a good climate, a charming and interesting locality, with abundance of good labour and plenty of money at command, so I went with a will to the work of simultaneously constructing a house, rearing some 60,000 seedling Chinchona plants under glass, and forming large outdoor nurseries.

At the time of which I write there were no private Chinchona plantations on the Nilgiris, or if any did exist they were yet in a state of embryo. The Government, under the superintendentship of the late Mr. W. G. McIvor, were pressing forward the cultivation and extension of their plantations on different parts of the hills, and, as Mr. McIvor was considered at that time to be the only authority on Chinchona cultivation, his directions were very generally followed by private individuals. Very few of the trees on the Government plantations had seeded till within a year of the time I took charge of Deva Shola; but at that time seeds of the Succirubra species could be had in abundance, and the plan adopted for raising them was as follows:—The seeds were sown in shallow pans containing sand and brick dust only, and were left uncovered and kept continually moist. After germinating, and when the plants were large enough to handle, they were pricked off into other pans filled with the same material. When the plants had attained a height of about 2 inches they were removed to the nurseries. As time went on it was found that richer soil in the pans had the effect of bringing the seedlings on quicker, till eventually the system of raising seedlings under glass was abandoned altogether, Dame Nature having pointed out in the most unmistakeable manner the easiest mode of propagation—viz., sowing in the nurseries thickly in beds without any covering of soil, but simply shading from the hot sun. The hint was taken in the first place by some one finding on one of the Government plantation innumerable seedlings springing up under the shade of the large seeding trees after the heavy rains had ceased. After this tens of thousands of young plants were annually collected from under the trees and transferred to nurseries, and large quantities of plants were raised from seed in the nurseries in the manner described.—PLANTER.
—*Journal of Horticulture.*

VEGETABLE PRODUCTS IN RÉUNION.

Cinchona.—An interesting account of the vegetable products of Réunion has recently been published in a Foreign Office Report, from which we gather the following notes. Referring to Cinchona, we are reminded that for some years past the plantations have absorbed considerable attention, and although they have hitherto assumed no very extensive development, the results obtained are satisfactory. The plantations are made in forests at a height of about 4000 feet. At this height there exist no high trees, but merely brushwood. Parallel alleys from 5 to 6 feet wide are made, and as far as practicable in spots sheltered from the winds. These alleys are separated by a range of brushwood 10 feet thick on each side, which serves to protect the young Cinchona plants against the violent winds so common in Réunion. The holes are made at a distance of 15 feet from each other, and are 1 foot 8 inches in diameter, and of the same depth. The earth removed is mixed with some prepared mould, in which the young Cinchona plant is placed. In soil thus prepared the young plant experiences no difficulty in its growth, but when it has attained a height of 18 inches care must be taken to cut the roots of the adjacent brushwood which may have found their way into the space reserved for the Cinchonas.

At the end of seven or eight years the plants have attained a diameter of 3½ inches, and are ready for harvesting; this takes place in October, when the bark is more easily detached. The plants are cut about 2 inches from the ground, and the bark when removed is placed in the sun to dry. A large number of young shoots soon spring from the old stump, which, when they have in their turn attained a certain size, it is necessary to lop off, leaving only sufficient for the stump to feed conveniently; they grow rapidly and produce a crop of bark in a period of six or eight years. In this way the cultivation of this product, when once planted, can be continued almost indefinitely and at little expense.

It is evident that the means employed in Réunion for the cultivation of the Cinchona are very practical and far more economical than at Java. Although those plantations have been attempted but on a

limited scale, the results are such as will likely be an inducement to their extension. Experiments have hitherto been made only by the local government, on the Crown lands, and by a few wealthy planters.

Vanilla.—The high prices fetched by Vanilla in European markets have been a great temptation to many to convert what little land they possess into Vanilla plantations; but this happy state of things is not destined to have a long life, for Vanilla is an article of consumption for which there is but a restricted demand, and its over-production must necessarily be attended by a great fall in price.

Tobacco.—Persevering experiments, attempted by a small number of planters to cultivate Tobacco are beginning to give most encouraging results, and Réunion at present can produce very well burning Tobacco. Although its aromatic properties are not as satisfactory as they might be, it is hoped that, with time and a little care, this deficiency will be remedied. It is a well known fact that to obtain good Tobacco, several plantations must have been made in the same spot. As this has not yet been done at Réunion, the Tobacco can hardly be said to have had a fair trial.

Fecula and Tapioca.—The manufacture of fecula and tapioca may now be considered as one of the most flourishing industries of the island. In spite of the first mill which was started having begun under very unfavourable circumstances it may, nevertheless, be said to be on its way to prosperity. Its produce, although not so appreciated as the tapioca from Singapore and Rio Janerio, obtains fairly remunerative prices. No further argument can be advanced to prove that there is a brilliant opening for fecula and tapicoa than the fact that other mills are already being constructed for the making of these articles.—*Gardeners' Chronicle.*

SIAM GINGER.

In the *Botanical Magazine* for July of the present year, t. 6944, Sir Joseph Hooker describes a new species of Alpinia under the name of A. zingiberina, the history of which is interesting, as much, or even more, from an economic, as from a botanical point of view. This plant was first noticed in the *Gardeners' Chronicle* for July 31, 1886, p. 150, having been raised from rhizomes exhibited at the Health Exhibition in 1884.

The fine collection of fruits exhibited by the Siamese Commission at the above Exhibition were at its close presented to the Museum of the Royal Gardens, and in the course of preparing the specimens for exhibition in the cases at Kew, I at once saw that a sample of a rhizome labelled "Ginger" was very different from the ordinary commercial ginger, being much thicker, and more cylindrical, longer, and not so much branched. Upon breaking off a piece of the rhizome the odour was more delicately aromatic than common ginger, and the taste not so pungent. As the rhizome still retained life in it, a piece was sent to the propagating-pits, and from it the plant now figured in the *Botanical Magazine* was raised. As Sir Joseph Hooker points out, "We are still in ignorance as to whether it is a wild or cultivated plant; and if the latter, whether it is cultivated (as A. galloclia is in Siam) for its seeds, or, like the true Ginger, for its rhizomes."

From the fleshy nature of the rhizome, as well as from its delicate aromatic taste and smell, the plant would seem to be worth cultivating for the sake of preserving the rhizome in syrup, if not for drying and using as a condiment in the ordinary way. It is well known that the Chinese preserved ginger is of a more agreeable aromatic flavour than that of the West Indies, and is mostly preferred for table use; in consequence of this it has been suspected that some other plant than Zingiber officinale may furnish some, at least, of the Chinese ginger; up to the present time, however, there is no proof of this. Mr. Charles Ford, of the Hong Kong Botanic Garden, referring to this subject in a recent report, says:—"Some doubt has existed as to whether the Chinese have not one or more kinds of plants in use as ginger that are unknown elsewhere. I have taken steps for collecting together and cultivating all the kinds of plants generally included by the Chinese as Ginger, with the hope that when in cultivation they can be studied and observed in such a manner as to secure all possible information in connection with this subject. While at San-Ui I was fortunate in being able to obtain from cultivated plants good flowering specimens. These I dried, and together with specimens of the roots (properly rhizomes) forwarded to the Director of Kew Gardens for a study of them to made there, when they can be compared with other kinds, or with specimens of the same kind from other places. The specimens which I procured were, without doubt, Zingiber officinale, the species commonly in cultivation in other parts of the world.

"It is, however, possible that some other plant, which is not a true Ginger, may be used in making the celebrated Canton preserved ginger, but all the information which I have yet obtained points to the species Zingiber officinale as the only kind which the Chinese use for this purpose. The Ginger cultivated in the Lo-Fan Mountains has a wide reputation amongst the Chinese as being of unusual efficacy in medicine; this superior quality may, however, be derived merely from peculiarity of soil or climate which communicate to the plant exceptional properties.

The specimens here alluded to by Mr. Ford have been examined by Professor Oliver, and prove to be those of Ginger (Zingiber officinale, Rose).—JOHN R. JACKSON, Museum, Kew.—*Gardeners' Chronicle.*

A BIG WALNUT LOG.—The *Glasgow Herald* says that there was recently landed, *ex* "Lord O'Niel" SS. from Baltimore, U. S., one of the largest logs of Black Walnut imported into the Clyde. Its extreme measure is 17 feet long, 42 inches broad, containing over 200 cubic feet, calliper measurement. To those interested in trees it will not only appear a rare, but also a valuable specimen.—*Gardeners' Chronicle.*

A REMEDY FOR WHITE ANTS is thus given in the proceedings of the Horticultural Society of India:—Mr. L. Liotard writes:—"Some of my Rose plants were attacked by White Ants a month or so ago, although *Firminger* says that these pests do not attack live plants. I have read of several specifics against white ants, but tried one of my own which was accessible at the time. I took a supply of leaves from a Neem (*Melia azadirachta*) tree in my garden and buried a few handfuls round each Rose plant, about a couple of inches below the surface, close round the stem; the white ants disappeared as if by magic, and I have since been free of them: I do not know if anybody ever tried *Neem* leaves before, but they are really very efficacious, and, of course, they form a vegetable-mould when they decay."

THE CITRON TRADE IN CORSICA.—According to a recent Government report from Bastia, Corsica, Citron fruits constitute one of the principal articles of export. The climate and soil of Corsica are said to be particularly favourable to the production of this fruit, which maintains its great superiority over that produced in Greece, Sicily, and the North of Africa, and the excellent prices obtained in the principal markets have caused much attention to be given to careful cultivation, and to the preparation of the fruit for the different markets. Most of the selected fruit is sent to England. Owing to the large number of plantations which should come into bearing during the next few years a large increase of production and consequent decline in prices were to be looked for, but the very severe winter caused the entire destruction of the trees of many important districts, and it is expected that the next crop will be a failure. The manufacture of candied Citron for America and Holland has greatly increased. The best quality of Egyptian sugar is now used for this purpose in large quantities, and is imported direct. The returns of exports to foreign countries show that 1692 tons of Citrons in brine and 435 tons of candied Citrons were exported in 1886.—*Gardeners' Chronicle.*

NOTES ON PRODUCE.

A few years since, a reference to Indian tea in a home newspaper was an unheard of and an unseen thing. Times have changed. Tea is now a subject of very frequent comment, and writers usually extol Indian and Ceylon teas at the expense of China, in a manner which cannot fail to impress readers generally who are consumers of tea with correct ideas on the subject. The *Echo*, in an article published on Wednesday, says:—"Until the last few years the world had to rely on China for its tea supply, but India and Ceylon are already formidable rivals. It will surprise many to learn that in May last the imports of tea from India and Ceylon exceeded those from China in the proportion of 51 to 49. That has never happened before, nor has it happened since, but there can be no doubt that before long we shall receive the major portion of our tea from India and Ceylon. The production for export of China teas appears to have reached its climax in 1879, when the previous speculative rise in prices flooded us with an enormous amount of re-dried rubbish, and this materially served to increase the popularity of the Indian growth. China being a producing and consuming country, can use re-dried leaves for export, while in India the home consumption is small, and not being in the producing districts there is no fear of the tea being doctored in this way. Of course, the deterioration of the Chinese teas sent to the English market is not altogether the fault of the Celestial, at any rate, he was encouraged to ship inferior teas by the demand for a cheap article. It was largely a question of price. In England people bought poorer teas because they wanted something that cost little, and the Chinese ministered to the want by sending qualities which a coolie in Canton or Yokohama would reject. The best qualities they reserved for themselves and for the Russians, who are willing to pay a long price for a good article. The cultivation of tea on Chinese methods was first attempted by the Indian Government in 1834. Chinese seed was introduced, but experience has shown that the most profitable plant is a hybrid between the indigenous and the Chinese varieties. In 1839 the Assam Company, which remains the most important of the Indian tea companies, took over the Government garden in Assam, which is still the great home of the industry, though tea planting is also securely established at Darjeeling in Bengal, along the foot of the Himalayas as far west as Simla, at Chittagong on the further side of the Bay of Bengal, and on the Nilgiris, and other hill ranges in the south. The increase in the exports of tea may be gathered from the following Government returns:—

Year.	Quantity.	Value.	Average value per lb.
1873-4 lb.	19,324,235	£1,742,924	1s. 9·00d.
1882-3	57,766,225	3,690,496	1s. 3·36d.

In these ten years the quantity increased by 198 per cent., the value by 113 per cent., the average value per pound having fallen from 1s 9d. to 1s 3d. Competition is certain to reduce the price much lower, and the manager of the tea gardens have been advised that if they are to hold their own they will have to limit the cost of production to 6d per lb."

Referring to Ceylon tea the writer says:—"In Ceylon the progress of tea cultivation has been even more marked than in India. The development of the Ceylon tea trade, unlike that of India, has been rapid. India commenced the cultivation of the shrub with unskilled planters, and inappreciative markets. Ceylon benefited by the experience gained in the Indian gardens, which enabled her planters to avoid the mistakes made in the early days by the Indian managers, who knew little or nothing about tea-planting. Ceylon, too, was fortunate in supplying a high-class article at a time when China was sending inferior tea to the European market. The result is that Ceylon teas have rapidly gained in public favour, until now there is hardly a grocers shop in which 'Ceylon Tea' is not a conspicuous article of sale. It is noteworthy that the Anglo-Saxon is the principal tea-drinking race in the world, and that none drink so much tea as the Australians, who consume 7·6 lb. per head, as compared with 4·90 in England, and 1·30 in the United States."—*H. & C. Mail*, Sept. 30th.

THE PEARL FISHERIES OF AUSTRALIA.

A little while ago we were taken aback by a telegram reporting the disaster which caused so much loss of life in the pearl fisheries on the western coast of Australia, and as we think the subject may interest many of our readers, we reprint from the Bulletin of the U. S. Fish Commission an account of the way in which these fisheries are conducted:—

The pearl-shell fisheries of Torres Strait belong to the colony of Queensland, and are situated 1,500 miles from Brisbane and more than 2,000 miles from Sydney. Torres Strait is about eighty miles in width and separates Queensland from the island of New Guinea. The navigation of the strait, although said to be safe and practicable, is in fact very difficult on account of the innumerable islands, reefs and shoals scattered about. The chief places at which the fisheries are conducted are Wai Weer, Albany Island, Jervis Island, Endeavour Strait, Friday Island, Prince of Wales Islands and Possession Island.

WAGES OF THE MEN.—A good diver can earn from sixty to one hundred and fifty dollars per month. He usually signs shipping articles for a period not exceeding three years at a fixed sum per month, and has an interest in the catch or lay. Mr. Bayne, of Sydney, the owner of an important station at Prince of Wales Islands, who for many years has been engaged in pearl-shell fishing, states that several divers in his employ have earned as much as three hundred dollars per month. The divers and crews are composed of South Sea Islanders, Malays, and a few Chinese and Lascars. The diver is the captain of the boat, and the other men obey his orders. The duties of the tender consist in waiting on the diver, helping him to dress and looking after him while in the water. The pay of the tender is from ten to twelve dollars per month, with a small interest in the catch, generally from one-sixtieth to one-eightieth part of the value of the shells. Each of the vessels generally has one diver and four tenders, who compose the crew. The tenders are engaged on regular shipping articles, and are paid off like any other merchant seamen. Mr. Henry M. Chester, the resident magistrate at Thursday Island, says, in a recent report on the fisheries, that the natives are never overworked, and that they are always well fed and kindly treated. He further says that payment is usually made them in blankets, clothing, knives, hatchets and beads, and that whenever they are dissatisfied with what they receive they seek other employment. Mr. Chester is of opinion that the competition for their services is of such a character as to secure for them fair treatment. All the available adult population of the island are employed as swimming divers under the "Masters and Servants Act," and while their pay is small it is made in the presence of the local authorities, and all the old men, women and children receive food in seasons of scarcity. Mr. Chester admits, however, that the occupation of a diver is dangerous, and not at all conducive to longevity, but adds that the loss of life among the natives from such causes is more than counterbalanced by the abundant supply of wholesome food given them, and by the decrease in infanticide and other savage practices to which they were formerly addicted.

METHODS OF FISHING.—The method pursued in pearl fishing is for a number of vessels to start out together and fish on the same ground. Each vessel carries supplies to last a fortnight. When in about eight fathoms of water, if the tide is slack, the diver will jump overboard. His boots are heavily weighted with lead so as to hasten his descent. Upon reaching the bottom he walks leisurely along until he comes to a patch of shells; then he signals to the boat to cast anchor. He carries with him a sack or bag to hold the shells, and as soon as it is filled it is lifted up, emptied out and sent down to him again, he being able to remain under water several hours at a time. Some divers remain down from nine o'clock in the morning until five in the afternoon. The pearl oysters lie on the ground with the shells partly open, and great care is required in handling them, for if touched in the wrong way they will close upon the hand like a vice. Accidents of this kind not unfrequently happen to inex-

perienced divers, who are obliged to signal those above to lift them up and remove the pearl-oyster from their hands. The monsoons which blow in the strait from May until the end of September are often so severe that boats have to lay up for as much as ten days at a time. The average catch for each boat is from one ton to a ton and a half shells per month. Unlike the fisheries in Ceylon and the Persian Gulf there is little or no difficulty in collecting the shells, for they either lie loose on the ground or are only partially buried in the mud or sand. The fisheries off the coast of West Australia, and especially at Shark Bay, produce the true pearl-oyster *Avicula margaritifera*. For a long time this shell was supposed to be valueless on account of its thin and fragile structure, but now there is a great demand for it both in America and in Europe.* It is especially prized by the French and German artists for fine inlaid cabinet work. The young or chicken shell is the best, and commands the highest price. When the pearl-oyster is five or six years old the shells become blistered and wormy, and it is said the oyster dies about the age of seven years. The divers in fishing make no effort to select any particular shell, but take every one that they can get, even the dead shells, which have the least value of any on account of various blemishes, rottenness, lack of lustre, &c. Pure white silver-edged shells are the best. The oysters in the West Australia fisheries are generally obtained by passing an iron dredge over the banks, but divers are also employed. Pearl-oysters are gregarious in their habits, and whenever one is met with it is almost certain that numbers of others will be found in the immediate neighbourhood. Divers are expert swimmers, and they go down to a depth of four or five fathoms, where it is said some of them can remain two minutes. The occupation is an unwholesome one, and soon produces deafness and diseases of the chest and lungs. Blood not unfrequently flows from the mouth, ears and nostrils after the usual dip of forty or fifty seconds, which is repeated fifty or sixty times a day. The men also run the risk of being eaten by sharks, although death from this cause is not apt to occur except in untried fishing-grounds, as the noise of the divers is almost certain to drive the sharks away.

THE PEARL STATIONS.—All the pearl-fishing stations in Torres Strait bear a close resemblance to one another, and consist of a small but nice-looking residence for the manager and one of less pretension for the men, a warehouse for storing provisions, &c., and several sheds for drying the shells. Before the shells are brought to the station the boats usually run into land, and the men open the oysters, take out the pearls, if any, and throw the soft parts overboard. The shells are then roughly cleaned and stowed under the hatches. At the end of the voyage they are taken to the station, where they are counted and thoroughly cleaned. The shells are then assorted and dried, and after the outer edges are chipped off they are packed in cases, each case weighing from 270 to 300 pounds, and are ready for shipment. No systematic effort has yet been made to collect pearls at Torres Strait, and such as are found become the property of the men, who secrete them in various ways, often by swallowing them. Some very fine specimens of pearls about the size of a hazel-nut, and of remarkable beauty and clearness, have recently found their way to the market from Torres Strait. Other specimens of a much larger size have been found there, but they were imperfect in shape and colour.

FORMATION OF PEARLS.—In oysters aged four years—which are judged by the shells, weight and appearance—the best pearls are found. The shell, like the pearl, is formed by the secretion of the animal, and is composed of animal matter and lime. The iridescent hues on the inside of the shell are occasioned by the edges of the thin, wavy, concentric layers overlapping one another and reflecting the light. The minute furrows containing translucent carbonate of lime, produce a series of more or less brilliant colours, according to the angle at which the light falls upon them. Occasionally some of the finest pearls are found loose in the shell. As many as one hundred pearls have been found in one oyster, but of little or no value. The pearls of the young oyster are yellow, and in the older oyster are of a pinkish hue.

THE USE OF PEARL-SHELLS.—The pearl-shells shipped from Australia to the United States and Europe are used principally for the manufacture of knife-handles, shirt-buttons, &c.* Considerable quantities are also used for papier-maché, and other ornamental work. The pearl buttons, shirt-studs, &c., now made in the United States, are said to be the best and cheapest in the world—a fact due in great measure to the care used in selecting the material and to the improved methods of cutting.—*Field.*

* Some mistake, or the Australian shells must be superior to those of Ceylon, for which there is now no sale.—ED.

PLANTING IN NETHERLANDS INDIA.

(Translated for the *Straits Times*.)

The Government will lose heavily by the short Java coffee crop. The Minister for the Colonies endeavours to make the best of a bad job, by assuring Parliament that it is no great matter for the estimate all at once to shrink from one million to 377,000 piculs. The cultivators who are forced to grow the berry for the State hardly get 14 guilders a picul, but only for the quantity actually delivered into the Government storehouses. The market value at present stands at about 60 guilders a picul. In the present straitened condition of the finances there is hardly any likelihood of the Government giving a higher price to the growers to make up for the short yield. The struggle for life among the Javanese has become so hard that fiscal illiberality of this kind aggravates their miserable condition. The general run of the people live in wretched looking houses made of bamboos. The furniture is mostly the worse for wear and tear. The inmates live from hand to mouth, and bring up their children in ignorance. The parents have for the most part no other clothing than that on their backs. The children wear none when very young, and the minimum for the requirements of decency when further on in years. Cultivators of this class can only get on by falling into debt, which they do their best to pay off by the proceeds of the produce of their land. They eke out their income by working as labourers on sugar estates, and by earning a little money in delivering coffee at the Government store-houses. The burden of taxation comes very hard upon this class of the population, millions in number as they are. The authorities too often in realising revenue demands, show little consideration for them. To meet the claims of the Government, the poor people have to borrow money, sell their produce for what it will fetch no matter how ruinously low prices may be, and stint themselves in the necessaries of life. In the west monsoon a good many villages actually suffer from hunger. Under such circumstances no wonder that parents instead of sending their children to school are driven to turn them to account as wage earners as early as possible. The land tax relentlessly levied in coin helps materially in reducing well to do families to poverty.

The planting community are also hard put to it by the fall in the price of produce. Two monetary institutions in the island, the Dorrepeal Bank and the Samarang Trading Company have had to go into liquidation from inability, any longer, to struggle on. Hopes are entertained that fresh companies on a new basis may take up their business and carry it on with better chances of success, especially in the direction of plantation enterprise.

* The large mother-o'-pearl shells are now meant, but the writer confuses the two species.—ED.

CEYLON UPCOUNTRY PLANTING REPORT.

PUSHING CEYLON TEA: A DISCOURAGING TRIAL—DEMAND FOR TEA SEED—THE CINCHONA PROBLEM: DRASTIC TREATMENT—THE CROTON CATERPILLAR—BUG IN UVA—THE NORTH-EAST MONSOON AND ITS EFFECTS—COOLY LABOR.

24th Oct. 1887.

The efforts that are being made on all hands to push Ceylon teas into the notice of the world is very characteristic of the energy and enterprize of Ceylon men. The reward let us hope will come in the form of a steady demand and at full rates. It would seem, however, that this kind of thing has to be done in a big way to be done cheaply. Just the other day an order for a sample of Ceylon tea came from the antipodes, it was to be forwarded by steamer and its destination was Tasmania. What it might have led to, is difficult to say. The order was certainly like the grain of mustard seed in size, but whether it would have increased in the same proportion was the unknown, and depended upon the quality of the tea and its cheapness. A 20 lb. box was its modest dimension if I am to descend to figures. When enquiries were made as to what it would cost for freight, to deliver the package at the port of Hobart, R16 was the highest asked, and R10 the lowest! If that kind of thing does not choke off small orders, it ought to. It will pay very much better to subscribe to the Exhibition fund.

The demand for tea seed of local growth has somewhat fallen off even where the jât is first-class. As to the coming crop of seed some places have suffered much by the late drought, and orders in hand have had to be delayed in consequence. Others again, I understand, have much more than was first thought of, and have considerable difficulty in placing the increased outturn. Seed is likely to be cheaper than dearer, although those who have bearers of an approved kind are not yet over-anxious to quote at lower rates. Although extensions of tea are still going on all over the country, yet it will not be difficult to supply what is needed for them. It looks as if the seed "boom" was drawing to a close, for, although supplying will have to be kept up and every place have a yearly nursery, many estates will grow their own seed in preference to buying.

The cinchona problem does not seem as if it were to be solved this year yet, judging by the increased deliveries of bark by rail. As to hope in the future, I know of one who applied for guidance to friends at home, who in their turn sought advice from those who ought to know—the London brokers—and the result of the whole was a statement which would have matched in gloominess the prophet's roll, that was written within and without with lamentation and woe. To harvest now was but to make matters worse, while to delay harvesting meant being swamped with Java in the future. There was clearly not much to choose from. But the future is an unknown quantity and it anything it had it.

A man who has cinchona growing among his tea has lately hit upon a novel plan of keeping his cinchona, without retarding the growth of the other more paying product. And he has done this by lopping off all the branches and knocking the heads off the cinchona trees, till the place looks as if it were stuck over with bare poles. That is pretty drastic treatment, and if the cinchona tree stands it, it will be about the meanest spirited thing in creation, and deserving to fall into the contempt which it has done with its unit at 2d and not even steady at that.

The croton caterpillar is about again. One place I heard of had an acre eaten bare in three days, which is pretty good. A change in the weather checked this rapid consumption, which was a comfort.

The reports from Uva regarding the progress of that pest of pests, the bug, are getting worse and worse. You hear of estates black from end to end, and what that means, is known best to those whose properties have come through it. It is a deplorable calamity, and wants a stout heart and a full purse to see any kind of light in such surroundings.

The N.-E. monsoon is on in fine style now, and the rain is very welcome. Everything is coming away under its genial influence, and there is a rush of growth which is doing its best to make up for the enforced rest of the dry weather. Tea is flushing vigorously; coffee is striving to ripen even where the crop is heavy and the trees leafless; cacao is in the beauty of fresh foliage—with lots of blossom for the future; cardamoms are pushing out their racemes that were shrivelled and brown with lack of moisture and excess of heat. Even the weeds show up, and the mould on your boots demonstrates how all nature rejoices in the muggy heat and does its best to respond.

Coolies don't seem just now to be very evenly distributed, some estates having far too many, while others have a difficulty in getting up the needed staff. The hard-up go on advancing more money, and very soon the idea the Tamil man gets of his modest worth is very exaggerated, and the reward to the European planter for being so free with his rupees is lots of worry, and often a loss of money besides. There are impecunious gangs going about recruited from the bazaars whose working capabilities are enough to drive even an easy-going man frantic, and whose indebtedness grows as they roll. They come into an estate floating on a tide of big advances, are an unsatisfactory connection when they are there, and after a time float out again on bigger tide, created by someone whom they have managed to talk over and whose needs are great, it is a happy kind of life they lead, as long as it lasts.

PEPPERCORN.

"HEAVY QUININE."

The bubble of "heavy quinine" has at length been pricked by its propagator, and it must henceforth rank with the mountain in labor. From a report of the meeting of the Societe de Pharmacie on the 8th of July in the *Petit Moniteur de la Pharmacie*. It appears that Dr. de Vrij revoked the statements he had made on the 5th of May, 1886, that pure sulphate of quinine could only be obtained in heavy crystals, and that the ordinary filamentous condition in which this salt is generally known was a certain indication of its impurity and of the presence of cinchonidine sulphate. Last year Dr. de Vrij was travelling with a sample of the "heavy quinine" manufactured by a French firm, and pharmacists as well as medical men were led to believe that to be the only pure salt. Now this is declared to be a total mistake and the situation is entirely reversed. Dr. de Vrij has been obliged to admit that pure quinine sulphate can be obtained in the light filamentous condition that is familiar to everyone, and he is now travelling with a sample of German make to show that this is the case. We think he might easily have obtained evidence of this fact and of his own error in respect to it without travelling either to France or Germany for that purpose. But it is at least satisfactory to find he is converted, and also that there is really no occasion for pharmacists to be in fear that the light quinine sulphate they have been accustomed to use to be distrusted on account of its levity. It is, however, unfortunate to find that a criterion of purity held out so positively and with such appearance of sincerity as to have induced Professor Jungfleisch to recommend that no other than "heavy quinine" should ever be accepted by pharmacists, turns out after

all to be delusive. To say nothing of the inconvenience that may have been caused to makers and others, such an occurrence is a little apt to lessen the respect for "authorities," and to show that Talleyrand's advice not to indulge in too much zeal is not only applicable to young men.—*Pharmaceutical Journal.*

THE CORK TREE IN THE FORESTS OF TUNIS.*

The forests of Tunis, which cover an appreciable part of the surface of the country, were, until the French occupation, subject to no supervision, and suffered from the many causes resulting from the want of that supervision. In 1883, the French, alive to the importance of preserving what remained of these forests, which are the property of the State, placed them under the management of a separate department, which has carefully explored their extent, and conclusively demonstrated that they are an important element of national wealth.

The explorations of the new department have resulted in the division of the forests into two main groups; one consisting of the cork tree and deciduous oak, locally known as "Zen," covering the north-western angle of Tunis where it abuts on the Algerian frontier and the sea, inhabited by the Kroumirs, and separated from the rest of Tunis by the river Mejerdah. These trees grow in a stratum of sandstone, which again reposes on the upper chalk, and they completely disappear where the latter stratum crops to the surface. They cover an area of about 360,000 acres, on 330,000 acres of which flourishes the cork-tree, and on 30,000 the "zen."

It is to the cork-forests that the attention of the new administration has been mainly directed. They are situated in a country with a very sparse population, dwelling in huts formed of the branches of trees. Their number is estimated at 12,000 souls, or only one individual to thirty acres. It was open to the French administration, which wields the authority of the Bey, to adopt one of the three following systems in dealing with the woods and forests, viz., their sale, their concession for fixed periods, or their management by the State. The last was chosen as the system best adapted for their preservation and extension, particularly as it was held to be of paramount importance to favour the increase of rainfall in the country; the quantity of which is supposed to be intimately connected with the extent of the forests. That they were more extensive in the times of the Romans, and that they conduced to augment the annual rainfall, may be inferred from the discovery of numerous aqueducts among hills which are now absolutely denuded of trees and destitute of springs.

Much has been done during recent years in improving the condition of these cork-forests. Roads have been cut through them, and at stated intervals spacious alleys have been frayed to serve as a means for arresting the march of the destructive fires which frequently ravage them. Above all, much progress has been made in barking the cork-trees, and operation which consists in stripping the rough bark of the trunks of the trees, to the height of five or six feet from the ground. This virgin bark is without value, and only for ten years after the trees have been robbed of it, is the inner bark available for commercial purposes, the trees giving a crop of cork every ten years. To meet the expenses incurred in these operations, there were available the sums accruing from the sale of the trees already felled, and of the bark of the "zen" for tanning. The director of woods and forests has drawn up an estimate of the receipts and expenses of his department for three consecutive decennial periods, according to which in twenty years, or at the commencement of the third decennial period, the anticipated expenditure per annum is £27,000, while the expected receipts are £96,000—leaving a profit of £69,000.

The above calculation regards the cork-forests only which grow on the sandstone to the north of the Mejerdah river, in the region lying between the Algerian frontier and Bizerta. Little has been done towards working the less valuable forests to the south of that river. An experiment has been made in planting with trees a small tract of mountain land near Hammam-el-Enf, some ten miles to the east of the town of Tunis. The operation consists in digging holes at short distances, and in dropping in each a few seeds of the pine tree. Several hundred acres have thus being planted with tolerable success, at an expense of £4 10*s.* an acre.

The worst enemies of the forests are goats. Some French colonists have taken steps to exclude these animals from their estates, and the result has been that shrubs which never attained the height of more than two or three feet, have in four or five years assumed the dimensions of trees. This is particularly apparent in the large domain of Enfida, near Susa, belonging to the Franco-African Company, where the thuja, which covers much of that domain—from a dwarf shrub, has now, within the space of six years, attained a height of twenty to twenty-five feet.—*Pharmaceutical Journal.*

* From a report by Mr. Consul Sandwith.

TEFF OR THAF.

(*Eragrostis abyssinica, Link.*)

(From the Bulletin of the Botanical Department, Jamaica.)

Teff is a cereal, a native of Abyssinia, growing at elevations between 4,000 and 7,000 feet. The grain is of a white or brown colour. It is very small but yet prolific, returning from 20 to 40 times the seed. It is made into flour by crushing it in a stone mill, and the husk is separated by sifting. The best kinds of Teff give a very white flour, exceedingly light, and easily digested. To make the finest kind of bread the sifting operation is repeated several times.

Until the end of last year this grain was quite unknown outside the boundaries of Abyssinia, but the Director of Kew Gardens, being of the opinion that it might be introduced with great advantage into mountainous districts of the British Empire, obtained a small supply from its native country. A portion has just been received from Kew, with information which will prove useful to those who wish to make the experiment of growing it.

CULTIVATION.

Olkraur, 27th Sept., 1886.

Thaf (in the Tigrina language) or Thief (in the Olmharigna language) belongs to the family of grasses and resembles the finest lawn grass.

There are two kinds: White Thaf and red Thaf. Both are, moreover, of two different qualities, according to the time of sowing, and are in consequence distinguished by the names of the Seasons: "Thaf-Hagaiz" and "Thaf-Tseddia." The first is called "hagaiz" from the name of the season which, according to Abyssinian reckoning, includes all our winter and the commencement of our spring: it is sown at the end of Megabit, in Myazya and Ghembot (March, April, and May). The second is called "Tseddia" from the name of the commencement of the rainy season, which follows that of Hagaiz and precedes that of Keremt; it is sown in June and the commencement of July.

Thaf-Hagaiz is of slow, and Thaf Tseddia of rapid growth. These conditions produce great difference in quality, Thaf-Hagaiz being considerably superior; the white, especially, is used for the table by the Court and Chiefs. Thaf-Tseddia is of very inferior quality, and the flabbys cake, or the "Tabita" which is produced from it flour, is as disagreeable to chew as if it were mixed with sand.

It is therefore the early sowing and vigorous growth of Thaf-Hagaiz, due to being two months longer in the ground, that render it of superior quality.

I ought, however, to add that "Hagaiz" and "Tseddia" cannot be sown indifferently for one another. The experiments which the natives tell me have been made have not met with much success. The seed of Thaf-Hagaiz must be used for the first sowing, and that of Tseddia for the second. The difference between them, both in the case of the white or red, is quite perceptible to the naked eye, by the want of plumpness

characteristic of the Thaf-Tseddia relatively to the other. These seeds almost equal barley in their growth and the rapidity with which they come up. Sown at the end of March or in April and May, they arrive at maturity at the beginning of September. Sown in June or July the crop may be reaped in October.

They are cultivated in the warm districts of the "Konalla" or lowlands, at an altitude of from 1,300 (4,264 ft.) to 1,800 (5,904 ft.) metres, and especially in the temperate regions of the "Onayne Dega," at an altitude of from about 1,800 to 2,400 m. (5,904 ft. to 7,872 ft.).

The Thaf comes up very vigorously in heavy lands, but its large and high tuft is richer in herbage than in grain. The exuberance of its vegetation in these heavy lands causes it to be laid, and then its ear rots. It prefers light soils and adapts itself even to the most sandy; it then produces slender, wiry stems, and supports better the weight of the ear.

The land requires to be prepared and cleaned by three or four ploughings before sowing; but it is true that the ploughings in Abyssinia are light and not very deep. It is sown thickly on the surface of prepared ground. It is afterwards lightly hoed, if necessary, when it has come up.

It is not necessary to wait until it is quite dry like barley, to cut it, for when too ripe and dried, the grain sheds in the wind and at the least shock. It is cut as soon as the green ear turns to grey, in the early morning, and is placed in heaps with the ears inwards, and covered to preserve it from rain; it is then left to ripen and to undergo a certain amount of fermentation.

Its flour is only advantageously used in making "Tabita," a kind of large fermented pancake. The "Tabita" of Thaf is most easily digestible, and has none of the bitterness of some other kinds of grain.

(Signed) E. COULBEAUX,
Missionaire Apostolique en Abyssinie.

Analysis by Professor A. H. Church, M. A., F. C. S.

	In 100 parts.
Water	15.2
Albuminoids	8.2
Starch, &c.	68.1
Oil	2.8
Cellulose, &c.	2.8
Ash	2.9

The ratio between the albuminoids, or flesh formers and the heat givers, or force producers (calculated as starch), is here 1.9. This ratio is less satisfactory than that of the majority of the millets, but is near that of Panicum miliare.

CINNAMON PLANTING REPORT FROM SIYANE KORALE.

BETTER PROSPECTS FOR THE BARK—A RETROSPECT: HIGH PRICES IN THE SEVENTIES AND STIMULUS TO CULTIVATION—SPURIOUS BARK AND CHIPS—LOW PRICES AND QUARTERLY SALES—THE AGRICULTURAL ASSOCIATION CALLED TO BOOK, &c.

There is a flash of brightness just now in the prospects of another sorely tried industry. Cinnamon has laboured for long in the throes of steadily decreasing prices. As the cause of this is evident and acknowledged on all sides, one would have thought that a combination between the handful of principal growers to apply the remedy for it was easily attainable; but it is not so. Cinnamon not being an article of diet or of daily consumption it was very easy for the supply to exceed the demand. A stimulus to extended cultivation was given in the high prices ruling for the spice in the Seventies. Anything and everything that could pass off for cinnamon was shipped. Quills were manufactured with cinnamon bark only for the outer covering. Spurious bark did duty for the stuffing. It was about this time that Mr J. D. Stevenson of the Mattakkuliya Mills, then a cinnamon planter in the Ekela district, started a new industry by the scraping and export of chips. "Chips," be it noted, is the bark of the coarsest and most inferior cinnamon, and that cannot be quilled. But was the first downward step; a taste for it, and a demand too, were soon developed; for flavouring purposes it answered as well as the best quality of cinnamon. What it lacked in delicate flavour it gained in pungency. When a suitable quality of cinnamon, though not of a very presentable appearance, could be had for a few pence, it was absurd to imagine that buyers would eagerly turn their attention to cinnamon priced at so many shillings per lb., simply for the sake of a decent and more presentable appearance. A taste for coarse and inferior bark has been created, and we are paying the penalty for it in prices that leave but a narrow margin of profit. When once it was pointed out to us that supply was in excess of demand the remedy was easy, the more so as, unlike with other products, the island did not compete with the world, the production of cinnamon is confined to the island and is in the hands of a comparative few. Shortly after the Agricultural Association was started, a resolution was brought forward, binding its members not to scrape or export chips. After full discussion it was passed. Yet so lightly do its members regard their obligations that they continued the pernicious and suicidal policy as if no such resolution was passed and as if they were not in honour bound to carry out its intentions. This persistence in exporting chips is the more be wondered at, as the members of the Association who are interested in the spice are men of intelligence and withal very shrewd in money matters. A little thought ought to satisfy them that by giving up what yields them but a minimum of profit, is manufactured in small quantities, and is bid for by the farthing, will benefit, by lessening the supply, what yields a higher profit, is calculated by the bale of 100 lb. each, and is generally bid for by the pence. The Association finding it was foiled in its object of reducing supply and raising prices, by the unreasonableness of those most interested, tried the expedient of substituting monthly for quarterly sales. This change was very reasonable considering that cinnamon was the only product that was sold privately, other products, including all manner of spice, being brought before the public weekly. As was to be expected this met with bitter opposition from those most interested in preserving the time-honoured practice—the middlemen or large purchasers who were the principal buyers. By monthly sales they would lose their occupation of vending the spice at their own figures in the long intervals between the sales. The opposition in the Lane met with a response here in the timid who were prepared to sacrifice everything to prevent the price of cinnamon going down. The old conservative members too opposed the innovation as an innovation. In the meantime cinnamon, like all the other products, was receding in price. The English brokers, who seem all along to have been playing into the hands of the buyers, and gave no support whatever to the producers, kept constantly dinning into the ears of the grower that the fall in price was mainly owing to the monthly sales, and that no improvement in the market could be expected as long as these were persisted in. What seemed strange to us here was that the buyers persisted in their opposition to the change although it enabled them to buy the spice cheaper than before. A kind of desultory warfare was kept up between grower and buyer, the former insisting and the latter objecting to monthly sales. The brokers sided with the latter. A climax was reached when the buyers in a body refused to bid at a sale unless the brokers gave them a guarantee that the next sale would take place a quarter hence. No business was effected and the brokers referred matters to the growers. The contest had now become unequal. The brokers openly sympathized with the buyers and many in the island secretly. The growers gave in, and quarterly sales were again resorted to. Of course, the market was not affected in the slightest by it. The brokers must need give some reason for it. One was ready at hand. The monthly sales had so disorganized the market, that the Continental firms who were the principal buyers had their orders attended to locally. We here know that Continental orders were executed

locally long before monthly sales were instituted, and that in the natural order of things the business of those engaged in it has expanded. The figures showing the gradual expansion of the export of cinnamon to the Continent is a study. What with wrangling about the interval between sales, and the increased export of cinnamon, planters are passing through a very trying time. I cannot understand the recent rise in prices. Various theories have been advanced in support of it. We must wait for something authentic from England. It seems reasonable that with the rise in price in the old staple coffee, the spice with which our island has been identified should also rise in price.

ROYAL GARDENS, KEW.

(From Bulletin of Miscellaneous Information.)

XVII.—ANNATTO.

(Bixa Orellana, L.)

In *Bulletin* No. 7, for July last, information was given as regards Annatto which appears to have drawn attention to its present position as an article of commerce. Amongst other communications, we have received from Messrs. Fulwood and Bland, Annatto manufacturers, of 31, Bevenden Street, Hoxton, the following notes, which will usefully supplement what has already been published on the subject:—

The great bulk of Flag Annatto comes from Cayenne and Guadaloupe in the form of a paste made into cakes of about 8 or 10 lb., which are wrapped up in banana leaves and packed in casks weighing about 5 cwt. each. The best kind is that from Cayenne, but it varies very much in quality, so much so that its value at the present time ranges from 5*d.* to 1*s.* 8*d.* per lb.; it also fluctuates very much in price according to the seasons. The Guadaloupe Annatto is very inferior, being very sour, but bright in colour in consequence of the acid that the natives put into it; it is, however, of very little value for manufacturing purposes, and therefore never realises such a high price as Cayenne Annatto; moreover, it does not contain anything like the amount of colouring matter present in the Cayenne kind. Annatto seeds principally come from the West Indies and Ceylon. We have never heard of any being imported into this country from Cayenne or Gadaloupe, the best that we have seen have been from Jamaica; they vary very much indeed in quality in consequence of insufficient care in collecting, curing, and drying them before exportation. Large quantities came into the London market last year very much deteriorated in value in consequence of having been packed when damp and getting heated and mouldy, the colouring matter was seriously damaged, and a good deal arrived shriveiled up and broken into small particles (evidently gathered before quite ripe), which is very objectionable for manufacturing purposes. We bought seeds last year in London at 1½d., 2d., 2½*d.*, 3*d.*, 4*d.*, and 6*d.* per lb., and those at 6*d.* were much the cheapest for our purpose, since the labour and expense with bad seed is just the same as with the best quality.

The supply of seeds on the London market always has been very intermittent, so that we cannot rely upon a constant and regular supply every season, and last year we ordered two tons of some Kingston merchants which they could not supply. We are, therefore, decidedly of opinion that good, sound, hard, whole Annatto seed, properly collected and dried, free from mould, would meet with a ready sale in this country at such a price as would pay the growers well. If, however, they would only prepare the Annatto in the same way as they do in Cayenne, by washing the colouring matter off the freshly gathered seeds, and send it over here in cakes or in a semi-fluid form, it would be better. We are quite sure that it would pay them well to do so, as it would fetch a very much higher price than the Guadaloupe kind realises, and we should be securing an industry for our own Colonies that is now entirely in the hands of the French. This is the reason why nearly all the Flag Annatto is sent to France, to encourage their own shipping, and the French merchants make a good profit out of it before it reaches us. If, therefore, it answers the French Colonists' purpose to prepare the Flag Annatto and export it to France, surely it would pay the growers of Jamaica and Ceylon to do likewise and export it direct to us, they would then get a better price for it than the Cayenne growers do, because they would save the intermediate profits of the merchants in Cayenne and France. They ought to be able to prepare the Flag Annatto in Jamaica and Ceylon quite as well and as cheaply as the natives do in Cayenne; but it would not do for us to attempt it in this country from imported seed, because there is first the cost of freightage over here, and labour is too dear to attempt to compete with the natives of Cayenne in washing the colouring matter off the seeds. You will therefore, understand that we can buy the Flag or paste Annatto very much cheaper than it would be possible for us to prepare it ourselves in this country. Annatto seeds of best quality will consequently never fetch more than about 5*d.* or 6*d.* per lb. because of the competition with the Flag Annatto. Lisbon Roll Annatto is another kind that comes from Para, it is in a paste packed in baskets weighing about ¾ cwt. each. It is wrapped up in dried leaves, and is principally used for colouring butter, being of no use whatever for colouring cheese; this also varies very considerably in quality. We bought it last year from 2*d.* to 1*s.* 9*d.* per lb. according to quality.

It has long been evident to us that sufficient care is not taken in washing the colouring matter off the seeds, and in preparing the Flag Annatto for the market we often find that it is very much adulterated with farinaceous and other substances to increase the bulk, which frequently causes a large amount of trouble to the manufacturer. We, in fact, seldom find two casks alike in quality or colour, and it is frequently kept until fermentation and decomposition set in, which of course destroy the colour; some that we had from the Polynesian Islands consisted simply of the colouring matter washed from the seed without admixture of any foreign substance. It was in a semi-fluid state and very pure, but a little dearer than Cayenne Annatto, and we cannot see any reason why the growers in Jamaica and Ceylon should not be able to teach the natives how to prepare it in this way, and we could then take large quantities of this kind of Annatto annually, and probably all that they could make. We would suggest that some of the growers should make the experiment and send us samples, and we would let them know how much we could give for it and the quantity we would take annually.

The consumption of Annatto throughout the world is of course limited. Our business has been established over 100 years, and for the last 50 years our importation of Annatto has not varied very much. Last year our imports of Annatto of the various kinds amounted to over 50,000 lbs., the great bulk of which was Cayenne Flag Annatto. Had we used the seeds only we should have required at least 200,000 lbs. for our busines alone.

Annatto is principally used for colouring cheese and butter, for which purpose it has to be specially prepared so as to be perfectly pure and harmless when it reaches the consumer.

The following are among the many preparations of Annatto manufactured by us, specimens of which have been presented to the Kew Museum:—

Imperial Black Cake Annatto.
Treble Strength „ „
Extra Superfine „ „
Superfine Orange „ „
Fluid Extract of Annatto.
Butter Colouring.
Butter Colouring prepared in oil.
Roll Annatto, Spanish.
Cayenne Flag Annatto.
Lisbon Roll Annatto.

These are used for a variety of purposes, viz., for colouring jellies, hair, soap, candles, scent, spirits, confectionery, leather, pomades, chocolate, and in

making lacquer for brass work, and dyeing calico, silk, wool, skin, rugs, straw-plait, feathers, wood, ivory, bone, &c., and also as an auxiliary in giving a deeper shade to the simple yellows.

Dyers also use the raw Flag Annatto very extensively for a reddish colour. It is not generally known that two colours can be obtained from Annatto, yellow and red.

Notes on Articles Contributed to the Museums of the Royal Gardens Kew, from the Colonial and Indian Exhibition, 1886.

FIJI ISLANDS.

A large and interesting collection of vegetable products were exhibited from these islands, a fine series of which were obtained for the Museum of the Royal gardens, of which the following is a selection:—

COPRA, the dried kernel of the coconut (*Cocos nucifera*).—This is the most generally useful of all the palms, not only on account of its wide distribution, being found in the low-lying coast lands of most tropical countries, as India, Ceylon, Malay Archipelago, Straits Settlements, the Islands of the Pacific, West Indies, &c., but also for the numerous uses to which the fruits, fibre, &c. are put.

A considerable amount of attention has been given within the last 10 years to the cultivation of the coconut palm in the South Sea Islands, and a number of large plantaions have been made.

The following notes are from the "Handbook to Fiji," issued in connexion with the Colonial and Indian Exhibition of last year:—"A coconut has been known to flower in about four years, and others at longer periods, but a fair crop of fruit need not be expected before the tenth or twelfth year, after which the yield increases steadily for five or six years more, when the maximum should be arrived at; it then continues bearing heavy crops for 50 and even 60 years."

Taking the produce of Fiji at 60 nuts per tree * per year, an acre would give, say, 4,200 nuts. This would make about two-thirds of a ton of Copra, the average value of which is about 7*l*. 10*s*., from which deduct the expense of collecting and manufacture, which is about 2*l*. 10*s*., which leaves a profit of 5*l*. per acre. It may be added that Copra is shipped to Europe, where it sells at from 16*l*. to 20*l*. per ton.

As regards the husk fibre, it is stated that the bulk of the fibre prepared in Fiji has hitherto found a market in Australia and New Zealand, but as the production increases it will be sent to other countries. "The husks from 7,000 coconuts produce about one ton of fibre, which is of the value on the estate in Fiji of from 5*l*. to 15*l*. per ton, according to quality. Brush fibre or bristles is worth from 15*l*. to 30*l*. per ton, and yarn from 20*l*. to 30*l* per ton in Fiji. The cost of labour to produce one ton of fibre, exclusive of cost and wear of machinery, may be put down at from 5*l*. to 10*l*."

Besides the three principal articles of commerce obtained from the coconut palm, copra, coconut oil, and coir, the kernel of the nut is eaten in large quantities when young and fresh, and the hard, bony shell is made into drinking vessels, and other useful and ornamental articles. It is estimated in Fiji, where the coconut thrives so luxuriantly, that it will, ere long, compete with sugar, tea, and coffee, as a source of great wealth to the colony.

NATAL.

The specimens obtained from this Colony were of a varied character, and interesting as showing the progress made since the International Exhibition of 1862, especially in the case of tea and maize. Some samples of tea of very good quality were obtained for the Museum; and it is interesting to know that the China tea exhibited by Mr. Bricknell was procured from plants introduced from the Royal Gardens, Kew, 20 years ago.

In connexion with the tea industry in Natal the following extract from the Natal Official Handbook will be found useful:—"Tea is now looked upon as one of the most promising industries of the coast. A few plants were introduced in the early days of the Colony from Kew, and seemed to do well. About 1863 some attention was given to the subject, but from want of skill in management, the samples produced did not find favour, and it was thought that the variety of the plant was one which would not produce a good marketable article. It was not till the apparent failure of the coffee tree showed that something was wanted to take its place on small plantations that efforts were made for the importation of fresh seed. This was obtained through Calcutta in 1877, and the varieties imported were Assam hybrid and Assam indigenous. Since then the tea enterprise has made steady progress, and seems eminently adapted for small and well-managed estates on the coast belt, and may possibly yet be found profitable further upcountry. The experience gained, not without cost and difficulty by the pioneers, is available for the benefit of the Colony. The climate evidently favours the plant. The yield is large, there is plenty of very suitable soil, and labour is not more costly than in many tea countries. Though struggling against local prejudice and custom, which still cling to China teas of intrinsically inferior quality, there are hopes that Natal tea may become an important article of export as well as of local consumption. It possesses fine flavour and strength, and promises to make its way on its own merits in the London market. There are now 12 growers, mostly in the Tugela division of Victoria county, and the total acreage at present under tea is about 400 acres. About 200 additional acres were prepared during the past year. The yield per acre has been very large, amounting in three years to 200 lbs. of dry tea; in four, to 400 lbs.; in five, to 600 lbs.; and in six to 800 lbs. Tea was exported from Natal in 1883 to the value of 1,499*l*.

CEYLON.

The exhibits from Ceylon were very numerous and very varied; specially prominent were the collections of woods and drugs. Neither of these, however, were available for the Museum of the Royal Gardens; nevertheless, a large number of specimens, including foods, drugs, oils, &c., were presented by the commission, of which the following are some of the most important:—

CARDAMOMS, the fruits of *Elettaria Cardamomum*.—A perennial herb, native of Southern India, and growing abundantly in rich humid elevated forests in North Canara, Coorg, and Wynaad. The fruits are gathered and dried, and then form the Cardamoms of commerce, which are valued for their agreeable aromatic character, and their carminative and stimulant properties. Besides being used in medicine, they enter into the composition of curry powder.

CINNAMON (*Cinnamomum zeylanicum*).—Some fine bundles of this important and well known spice were exhibited. These bundles were remarkable for the smallness of the quills of which they were composed, as well as for their pale even colour and delicate flavour. One bundle was obtained for the Museum.

VANILLA.—The pod-like fruits of *Vanilla planifolia*, a climbing Orchidaceous plant, native of Mexico, where also now it is extensively cultivated, as well as in Mauritius, Bourbon, Madagascar, and Java. The pods after gathering are carefully dried by alternate exposure to the sun and air, and wrapping in woollen cloths sometimes steeped in oil. The vanilla of commerce is obtained from Mexico, Bourbon, Mauritius, Java, Honduras, Brazil, &c.

ARECA NUTS (*Areca Catechu* var. *alba*).—These are the seeds of a graceful palm found throughout Peninsular India, Ceylon, South China, the Philippines, and the islands of the Malay Archipelago. The Areca, or Betel Nut as it is mostly called, is usually about the size of a nutmeg, but more spherical and flattened or depressed; they are marbled throughout their substance with a brown rumination; they are astringent, and are largely used in the East as a masticatory. The actual specimens here referred to are of unusual size.

The following samples of Ceylon TEA were obtained for the Museum:—Flowery Pekoe, Pekoe, Broken

* Too high an average by one-third.—ED.

Pekoe, and Pekoe Souchong. The tea industry in Ceylon has marvellously increased during the past 10 years. In 1876 only 282 lb. were exported, while in 1885 the exportation had reached 3,796,684 lb.

CINCHONA BARKS were fully illustrated at the Exhibition, and the Museum of the Royal Gardens became enriched by specimens, each six feet long, of the following species:—*Cinchona succirubra*, renewed quill; *C. Ledgeriana*, original quill; *C. officinalis*, renewed quill.

A collection of 37 specimens of fruits, seeds, and drugs, new to the Museum, were also obtained from the Ceylon Commission.

STRAITS SETTLEMENTS:

BETEL NUT FIBRE (*Areca Catechu*).—This is the fibrous husk of the fruit exhibited as a paper material. As a waste product it is said to be produced in almost unlimited quantities. Considering the very general practice of Betel chewing in the East, and the abundance of fruits produced, the adaptation of this apparently useless material for paper making would seem to be a very probable benefit to the countries where the *Areca Catechu* is common.

BRITISH NORTH BORNEO.

By far the most important of the vegetable products exhibited by this Commission, and which were at the close of the Exhibition presented to the Kew Museum, were the woods. Some very fine planks of the principal timbers attracted a good deal of attention during the period of the Exhibition, and now form a feature in the timber collections at Kew. Many of these woods unfortunately had no scientific names, such, for instance, as the:—

BILLIAN OR BORNEO IRON WOOD.—It is very hard and heavy, exceedingly strong and tough, "proving," Mr. Ransome says in his report, "more than 50 per cent stronger than English oak in resisting a breaking strain. . . . It is proof against the teredo and white ant, and is consequently in great demand for wharf piles and planks in the Straits Settlements and China. This wood should be largely imported into England, as it could be sold at the London Docks with a good profit at 3*s.* 6*d.* a cubic foot and might take the place of green-heart and teak for many of the purposes for which those woods are now employed."

SUMATRA OR BORNEO CAMPHOR WOOD (*Dryobalanops aromatica*).—This wood is remarkable as being the source of the well-known Sumatra Camphor, which is found crystallised, often in large masses, in interstices of the wood. It is not so volatile as ordinary camphor, and is harder and more brittle. The Chinese use it in preference to the camphor of commerce, which is a product of their own country. The wood is of a dark brown colour, hard, and heavy.

MIRABOU (*Afzelia palembanica*).—This is a strong and durable wood, with a dark brownish figure. It somewhat resembles teak in grain, and is well adapted for furniture and cabinet work, as it works well and takes a good polish.

The other woods received at Kew are:—

Penagah, White Borneo Cedar, Greeting, and Russock. All of them are woods of more or less value. Besides these, various samples of Gutta-percha, and some remarkably fine specimens of Dipterocarpeous Resins, were presented to Kew by the British North Borneo Company.

TOMATOES.

Although the climate of Ootacamund is capable of producing, in great excellence most of the English vegetables and a number of English fruits, there are yet some which cannot be brought to maturity at so high an elevation, unless cultivated under the protection of glass. The tomato may be named as one of the fruits requiring such shelter, and as it is proved to be a highly nutritious and wholesome fruit it would well repay any little trouble expended on its proper culture. The tomato has become highly popular of late years in England as may be demonstrated by the huge quantities of splendid fruit that have been put upon the Covent Garden and other markets, all through the present season. The supply seems not yet to be equal to the demand, so that English growers will most probably find the cultivation of the tomato a profitable employment for some time to come. Large quantities of fruit are sent over from Jersey and Guernsey to Covent Garden, very early in the season, and the supply is continued throughout the summer and autumn months. This imported fruit sells at from 3d to 4d per lb. but is much inferior to the English produce. The foreign tomatoes are of a pale red or orange colour, partially shrivelled from the fact of their being gathered whilst in a green state. They are also of greatly inferior size and quality to the English grown fruit. The latter appearing in the markets of large size, highly coloured, of splendid quality and almost bursting their polished skins with plumpness and high condition. Tomatoes at the present moment make a more beautiful show in the London fruiterers shops than almost any other fruit. English grown fruit fetches from 6d to 8d per lb. and are all grown under glass in low span-roofed houses, where the plants are planted out in well prepared borders and trained to stakes till they reach the roof. I see no reason why this fruit should not be grown at Ootacamund under glass as in England, provided the necessary care be taken to preserve as equable a temperature as possible, as recommended for the culture of the cucumber under similar conditions.

Construction of House.—The cheapest and best form of house is a span, of about ten feet in width with a bed or border on each side of the pathway up the centre, which may be 3 feet wide. The sides may be of rough wood or brickwork about 4 ft. 6 inches high, head room being secured by sinking the pathway. No side lights are necessary, but side ventilation is desirable, and which may be secured by wood ventilators in the wall immediately above the wall plate; or in the case of wood sides a board 9 inches wide fixed to the wall plate by hinges and opening outwards will answer. Ventilation of some kind should be provided for at the apex or ridge of the house. An opening about 9 inches will answer. It may be of wood and made to open and shut by any simple process. The sash-bars may be about 3 inches by 1½ inch fixed about 15 inches apart or at such distances as to suit the width of glass available. Many of the growers for market in England, instead of the ordinary and more expensive sash-bars, simply use rough sawn battens about 2½ inches by 1 inch, on which the panes of glass are laid and secured by small nails or tacks, a slip of zinc is then tacked on to cover the joints. This plan does not secure quite a water-tight roof, but the slight leakage is of little account and does no harm, and the system has the advantage of cheapness.

Preparation of Beds.—The beds for the reception of the plants should be at least 18 inches in depth, six inches of which should be drainage, and one foot of prepared soil. This should be composed of good maiden loam mixed with well decayed cow or horse manure. If the top spit from a field without removing the turf be laid up in a heap for about a year, this will make excellent soil for the beds. Care should be taken not to place the compost in the beds, or work it whilst in a wet condition.

Planting.—The plants may be put out when about 6 inches in height, and about 2½ feet apart. Stakes should be driven in, one to each plant, at the time of planting, or before the roots have entered the soil and reaching to the wire trellis of the house, which should be from 6 to 9 inches from the glass. After placing in the soil the plants should have a rough good soaking of water and should never be allowed to get thoroughly dry throughout the whole of their subsequent growth, because if allowed to suffer in this way, the size of the fruit will be diminished and insects will be sure to make their appearance on the leaves.

After Culture.—Little is required with the exception of attention to watering, and ventilating till such time as the plants begin to show fruit, when liquid manure should be applied liberally once or twice a week. This is simply made by soaking fresh horse droppings in a

barrel or tub and using in a clear state after straining. As the plants get more mature and the beds become filled with roots, a good top dressing of well rotted manure will be of very great advantage, and a good syringing with pure soft water over head, night and morning from the time of planting onwards, will help to keep the plants healthy and free from insects.

Pruning.—Allow the plants to run up with one stem till they reach the trellis, pinching out the auxillary growths as they appear, or when they are an inch long, close to the stem. When the plant has reached the trellis it may be allowed to flower and fruit. The main growth should under no circumstances be stopped till it has reached the ridge. The plants may show clusters of flowers before they reach the trellis, in which case they should be allowed to remain and produce fruit. In this way plants may be had with clusters of fruit from close to the ground up to the ridge of the house. It is most important that all auxillary shoots should be removed as the clusters appear for if allowed to remain, the house will be filled with useless foliage and wood intercepting the sunlight and robbing the main stem and clusters of fruit of support. When the leader has reached the ridge of the house it may either be stopped or turned down again, but care must be taken not to fill the house with too much foliage so as to darken it, as the fruit of the tomato requires a great deal of sunlight to bring out its rich colouring.

Ventilation.—The plants will stand a very high temperature without injury, but the object in a climate like that of the Nilgiris, should be to keep it within the house as equable as possible. If a high temperature cannot be maintained at night, then it must not be allowed to get very high during the day. Where no artificial heat is available, some covering material for the glass would be the best thing to use, taking care to shut up the house close early in the afternoon or before the sun has left it. During the time of flowering, free ventilation should be given in order to secure the proper fertilisation of the blossoms.

Raising plants.—These are easily raised from seed, but some prefer cuttings which are, by some, thought to fruit earlier and more freely, but seedlings, are more easily managed. The seed may be sown thickly and the seedlings transplanted when fit to handle. The tomato plant bears transplanting almost at any stage without injury.

A number of growers for market, instead of planting their plants in beds, use pots and roughly made boxes with success. This plan not only economises soil but also manure. When pots or boxes are used artificial manures are usually applied instead of the ordinary liquid manure from horse droppings, and large crops of splendid fruit are frequently obtained in this way. Clay's Fertiliser is a favourite manure and can be had in boxes or packets and in large or small quantities.

Sorts.—Criterion, Large Red, Mikado, Hathaway's Excelsior and Trophy are the best.—HORTUS.—*South of Indian Observer.*

SANDALWOOD CARVING IN MYSORE.

By Col. BOWEN, R. E.

The tendency of indigenous Indian industries to localise themselves within narrow circles is well exemplified in the case of sandalwood carving in Mysore, an art which is almost entirely confined to a few towns in the north western corner of the Province and in the adjoining Taluks of Bombay. Saugor is the headquarters of the few families that practise this art and who have apparently handed it down for generations from father to son; it has never extended beyond this locality. Caste prejudices may have contributed to some extent to the retention of the craft in this particular district, but it is likely that the demand for the articles manufactured was always very limited, and there was no inducement to outsiders to intrude on the domestic of the few who were, so to speak, born and bred to the trade, more especially as the skill and delicacy of touch required could only be acquired by training from early boyhood. Under these circumstances, it is perhaps strange that the art did not die out altogether during the centuries of chronic disturbance under the Pallegar Chiefs; stranger still that it survived the period of Mahammadan supremacy. It is probable that it was kept alive by the bounty and liberality of a few wealthy local magnates, with a taste for the æsthetic, and although the policy of Hyder Ali and Tippu Sultan aimed at the extirpation of Hindu customs and traditions which invariably find expression in Hindu sculpture and carving, Mahammadan influence never extended to the remoter districts of the Province.

It is not known with any certainty when sandalwood carving was first introduced in Mysore, but there is a tradition amongst the Gudigars, as the carvers are called, that their ancestors came from Saptakoti, Narway, and other places in the Goa country, and that their original language was Konkani. They believe themselves to be decendants of Kshartiyas; that to escape the wrath of Parsu Rama in the 6th incarnation of Vishnu, who had vowed to destroy every Kshatriyas in the world, they adopted the profession of carvers and "Rath" or car builders, and that ever since they have been following that avocation. It is a fact worthy of notice here that "Chitragars" or painters, toy-makers, workers in lace and followers of other refined arts which administer to the luxury of man, have a similar tradition that they are Kshatriyas. They may not be decended from the old Aryan Kshatriyas, but as it has been usual for every ruling caste or class to assume the name of Kshatriya, it is not improbable that these artizans once belonged to the dominant class, but were compelled by conquest and subjugation to adopt some profession for their livelihood, and that they took to these fine arts as more in keeping with their previous habits and delicate breeding. This would imply that those Kshatriyas found the trade ready to hand, that they had only to master its technicalities, and that they ousted out in course of time those who originally introduced and pursued it; it gives no hint as to its origin or early development. We must then imagine that the beauty and fragrance of the wood, the ease with which it is wrought and the wide distribution of the insignificant tree from which it is derived, led in the first instance to its use for domestic articles. The ornamentation of these articles and of the beads, amulets, and articles of personal adornment also probably wrought from the wood in the earliest times, followed in natural sequence, just as the primitive rough-hewn temples of the ancient priests developed in course of time with the growth of the natural artistic instincts of the people into the elaborate and profusely decorated temples of a later period.

In India, as elsewhere, the art instinct of the people first found expression in the decoration of its temples, and when the instinct grew into the desire for the decoration of dwellings or of articles in ordinary use, the figures, columns, and carvings of the temples were naturally adapted for purposes altogether outside of religion. So we find that from the beginning the sandalwood carvers followed the models before them on the walls of their shrines. Unfortunately after the architects and sculptors who elaborated the walls of Belgavi and Halebid had disappeared, a period of distinct art-decadence appears to have set in, and has lasted down to the present day; no original artist arose to treat the subjects of the Hindu Pantheon with entire originality, or to effect improvements on the designs of his predecessors, and the wood carvers have slavishly adhered to the same original models with the result of establishing in their work a purely conventional style. In every article that we have seen, unless in the few cases when the copy of a European picture or print has been attempted, there is to be found the same ever-recurring type of Hindu god or demon, of flower and foliage, of [illegible] border. There may be diversity in the [illegible] or juxtaposition of each conventional part, but the art impression conveyed on the mind by one carved article, whatever it be, is exactly that conveyed by any other.

In mediæval Christian art we find that pictorial teachings in painting and sculpture were the means

of propagating a knowledge of Christian facts and doctrines, and of profane and romantic history. A traditional way of treating those subjects was adhered to by artists of all kinds, and the same mode of treatment was maintained for centuries, yet we find that the mediœval artists were not mere slavish copyists, and though they retained the traditional elements of the subjects and the conventional arrangement of them with curious fidelity, the style of art varied from time to time, and the artist told his story in the art vernacular of his own day. He worked very freely in the details of his picture, translating the customs and architecture, and other accessories into the fashions of his own time. In ancient Greece the same course had obtained, and it produced the greatest artists and the greatest works of art.

Between these and Eastern art, as embodied at least in Mysore architecture, sculpture, and carving, a parallel may be drawn as regards the adoption of traditional subjects and modes of treatment, but the parallel stops abruptly when we come to variety in expression and to modifications, or improvements of the original examples. Centuries ago in Mysore a few beautiful types were created, for a time perhaps slight variations on these were introduced, but stagnation soon followed, and artists in stone and wood degenerated rapidly into mere copyists, and copyists pure and simple they have remained to the present day.

When we come to the "technique" of his art, we find that the tools of the sandalwood carver are simple and rude, all locally manufactured; his modes of working primitive in the extreme. He works exactly as his forefathers worked, his method and means are precisely those of centuries ago. Although the number of tools employed is considerable, many sizes being required at the various stages of each operation, they may be classified simply as the chisel, the curved chisel, the graver, the gouge, the mallet, in addition to which the ordinary carpenter's drill, square and lines are employed. The carver having selected a strong-scented and fine grained log which he himself saws into slabs of ½ to ¾ inch thick, cuts and planes it into panels of the sizes required for the article to be manufactured. He next sketches in pencil the outline of the design on the wood itself, when the design is not very elaborate; when intricate carvings are required, the drawing is made on thin paper which is pasted on to the panel. He then proceeds to cut and engrave the pattern into the wood, working out the outlines roughly at first, following up the first rough stage by a finer one with a finer tool, until by degrees the bold relief and deep undercutting are patiently attained, and the finishing touch given with the most delicate of his chisels. It may seem absurd, more especially when we examine closely the best samples of his work, but it is a fact that the net result to the first class carver of all his patience and skill is for a carved slab, at the ruling prices, the equivalent of a wage of 1½ rupees a day. The apprentice, always a member of the family, begins by simply watching continuously and with close attention the various stages in the work of the master, then he is put to practise on pieces of waste wood, after which he is promoted to the actual carving of inferior articles. He never actually assists the master, who never even guides his boyish hand or shows him how to select and handle the tools; he learns simply from patient watching and imitation.

Such is briefly the history and description of this interesting industrial art, in which Mysore claims a distinct pre-eminence. But what is to be done to raise the carver's work hitherto confined to mere copyism, to the true level of an art-manufacture? Selected specimens of their work have recently been exhibited at the Calcutta and Indian and Colonial Exhibitions. These have been much admired and a stimulus to the demand for sandalwood articles may be thereby created. The number of good carvers is however very limited; a few of them have recently migrated to Cashmere to take service under the Maharaja of that Province, and some have obtained permanent employ under the Maharaja of Mysore, who takes an enlightened interest in their work, which it is his desire to foster and encourage. An enhanced demand is more likely to result in a deterioration of workmanship than in any advancement in style and design; we will have quantity, not quality. The present families of carvers being so few and apprenticeship having to commence at a very early age in order that the necessary delicacy of touch and manipulative skill may be acquired, it would seem impossible to expect any extension of the best class of work or the attainment of any originality or variety in style without the direct intervention of the State. What shape State help should take is the problem. There is no Art-School in Mysore, nor can recourse well be had to the Art-Schools of the Presidency towns, for what would be gained as regards designing by youths attending these institutions would be lost to them as regards the essential manual skill acquired by early and constant practice. The distribution amongst the families of carvers, of suitable modern designs and patterns, periodical local exhibitions, and money prizes may do something; but it is doubtful whether anything short of the endowment of a school to be devoted entirely to this purpose, with the best of the carvers selected as masters and with liberal scholarships, will effect the revival of what appears to be a fast-decaying industry.

INDIAN EXPERIENCES.

(*Continued from page* 334.)

The block of forest called Deva Shola, or the God's Wood—from Deva, God, and Shola, a wood—was, before the advent of the Chinchona planter on the Nilgiris, by far the largest and finest piece of forest on the plateau. Large streams of water flowed through it, and an old road ran through its centre fringed with masses of Ferns, such as Adiantum œthiopicum, A. hispidulum, Davallia tenuifolia, Pteris cretica, Lastrea aristata, Cyrtomium caryotideum, and many others, whilst the ravines were filled with handsome specimens of a Tree Fern, Alsophila latebrosa. The Shola being situated so near the large station of Ootacamund, was a great resort of shooting and picnic parties. The wood consisted originally of from 800 to 900 acres of low but very thick forest, with a very dense undergrowth of a species of Strobalanthus with long interlacing stems, forming in many parts an impenetrable thicket, save for the lanes formed in it by the passage of deer and other wild animals. This famous wood was at one time the home of the tiger, bear, sambhur or large deer, leopard, wild boar, and other animals, which yielded magnificent sport to the residents and visitors to the Nilgiris. The wood was in fact a place of great note and quite a feature of the hills, and was also looked upon by the surrounding native population as a peculiarly sacred spot, the place of abode of their Gods, and where they retired to worship. It was therefore with horror and dismay that they received the news that 500 acres of the sacred Shola had by Government been given over to the ruthless hand of the Chinchona planter. Notwithstanding all this, however, when the time came for felling the forest the natives from the neighbouring villages of all castes, with a true oriental love for gain in the shape of wages, came crowding to the work of destroying the Shola, which had been held to be so sacred by their forefathers for so many generations. There can be no doubt that the destruction of this famous wood was a gross blunder. In the first place the Government were to blame in allowing it to pass out of their hands to the extent they did; and secondly, the parties to whom the land was conceded were even more to blame in ruthlessly sweeping the land of its covering of forest before having a single Chinchona plant ready to be put out, and neglecting to leave all the necessary belts of protecting forest as barriers against the annual gales of the south-west monsoon.

In due course I succeeded in raising some 600,000 sturdy young Chinchona plants, all of the succirubra species, in burning, clearing, and pitting sufficient land to receive these plants, and in building a substantial brick house on a grass ridge adjoining the plantation. All went well till what is called in India the "bursting" of the south-west monsoon, which proved to be the herald of a series of disasters. In the first place, on the second or third night of the monsoon the corrugated iron roof of the newly finished house was blown clean off and carried right away into a ravine below, causing me to seek shelter in an out-house. The gale continued for a fortnight with little or no rain, so that no planting operations could be undertaken. About a couple of acres had been planted the year previous to this with plants of succirubra species of Cinchona purchased from Government. These had grown up into nice plants of over a foot in height, but in this gale were nearly all snapped over close to the ground. This was in the month of July, but as no rain fell during that nor the succeeding two months, I had to wait patiently till the month of October, or the setting in of the north-east monsoon, before beginning planting operations. This monsoon set in in due course and proved an excellent one for planting, so that I had no difficulty in putting out of the 600,000 plants before the rains ceased.

After the work had been completed I began to consider whether a plantation of Cinchona could ever be raised over the whole area of the 500 acres that had been cleared of forest, and I came to the conclusion that it could not. The soil was excellent over the whole surface, and all other conditions were most favourable to the forming of a magnificent plantation. But the question of the wind had to be considered, and it was evident that save in the sheltered nooks it would be quite impossible to form a plantation of even stunted growth. The difference of elevation between the foot of the plantation and the top ridges was as much as 700 feet, and the wind striking these ridges where no sheltering belts had been left came down upon the plantation, sweeping everything before it. Had I been wise I would have relinquished charge of the plantation after the first planting had been completed, but I foolishly waited to see the effect of another monsoon on the plants I had just put out, hoping against hope that it might not prove so disastrous as the one I had just passed through. The planting proved a very successful one, and before the following July the plants had attained an average height of 15 inches. The monsoon burst as usual about the end of June, the wind increasing in strength till about the 15th July, when it culminated in the terrific gale of three days, when it suddenly calmed and the sun came out as bright as ever. I had made it a point not to visit the estate during the whole time of the storm, but when it ceased I had a quiet walk round the plantation to view the damage which I knew quite well had been done. I had put the estimate of damage in my own mind at a pretty high figure, but the result of my walk proved I had not put it nearly high enough, as at least 400,000 out of the 600,000 plants put out had been snapped off by the ground and were blown into the ravines below and on the roads, where they lay in wreaths withering in the sun. The stem of the succirubra species of Cinchona is exceedingly brittle when in a young state, so that the plants were not wrung about and thus destroyed, but snapped clean off, and the land stripped and the year's work and expenditure nearly totally lost. I at once communicated with the proprietors of the property, giving it as my opinion that a plantation of Chinchona could not be produced over the whole area of the land till such time as some sort or shelter could be raised for the due protection of the plants, and offering my resignation. In this opinion they did not concur, and induced me to remain at my post, which I was sorry for afterwards.

Young plants were raised in abundance for three years in succession and the land regularly replanted, the plants as regularly meeting the same fate as those of the first planting. Attempts were made to grow belts of Eucalyptus globulus and Acacia melanoxylon to break the wind, but only with very partial success, the severe monsoon storms retarding their growth generally, so that the cultivation of Cinchona was eventually abandoned on the estate except in the sheltered nooks, which formed but a very small area in proportion to the whole land, so that here was a property all but totally ruined by too grasping a policy in the first instance, and by a total want of knowledge or ignoring of the peculiarities of the climate of the district, and as a monument of this false economy was left a few hundreds of acres of thorny scrub in place of the beautiful and picturesque Shola of former days. The exercise of a little forethought would have prevented all this. Had the forest clothing the ridges been simply left as a protection, the lower portions of the land could have been cultivated in perfect shelter, and with every chance of success, but no cultivated plant, be it Tea, Coffee, or Cinchona, will ever thrive if planted in a position fully exposed to the heavy south-west monsoon blasts, which are stronger as the elevation is greater. In large blocks of forest extending for miles, as in the Wynaad, it is very difficult to say where the wind will strike after say 100 acres is felled; and frequently mistakes of a very serious nature are made, even when the greatest precaution is taken beforehand; but as regards smaller isolated patches, such as are found on the Nilgiris, the case is different, and with ordinary precaution no mistakes of this nature need occur. At the time I write of the succirubra species of Chinchona was alone planted on land under 6500 feet; above that elevation the officinalis species with its hybirds were planted. Since those days the latter has so superseded the former in value of bark that estates of succirubra are at the present moment considered of little or no value, from the much smaller quantity of alkaloids* found in the bark and the greater difficulty in their extraction. No one dreams of planting succirubra in these days, and existing estates of this species I believe are in some cases being replanted with Tea.

While living at Deva Shola I had the opportunity of witnessing the flowering of a low shrub, a species of Strobilanthus, but not the same as grew amongst the trees of the forest. It is a low evergreen shrub which covers the hills for miles, and is said to flower only once in seven years. It has a very beautiful flower, blue and when in full bloom the appearance of the hills is beyond description. After flowering and ripening its seed the plant dies, but springs again very readily from seed, so that after the death of the old plants the hills are soon clothed again. It has been said that it is from this flower that the Nilgiris get the name of the Blue Mountains, but this, of course, is only fanciful. Not far from Deva Sola, and at a slightly lower elevation, the wild orange tree is to be found growing on the grass hills on the edges of the Sholas. It is a very beautiful object when covered with ripe fruit and flowers. I was much struck with its great beauty when I accidentally came upon it for the first time. There were many trees in small groups and dotted singly over the grass hills. The trees were rich both in green and ripe fruit of a large size, and the flowers were abundant. The grass was strewn with ripe fruit, and altogether the sight in the wild was a very beautiful and interesting one. On tasting the fruit I found them bitter beyond expression. Another spot in this locality deserves mention—viz., Mailoor, which is a village about three miles from Deva Shola, and possessing a very mild and delightful climate. A few yards from the village may be seen sculptured slabs of stone, which are involved in mystery, no one knowing who put them there, or why, enhancing the interest attached to them. Near by is a temple belonging to one of the hill tribes surrounded by splendid specimens of

* The smaller proportion of quinine is meant, for the total alkaloids in succirubra is generally as large as in officinalis.—ED.

Elæocarpus trees, their widespreading branches affording a deep shade, which gives solemnity to the scene. The temple itself stands in the middle of a circle marked out with a rugged stone wall 3 or 4 feet in height. The temple is dedicated, it is supposed, to the Fire God of this particular tribe, as within the circle there is a small hollow in the ground, which is the scene of one of their religious ceremonies—namely, that of walking through fire. The hollow is filled with burning ashes, through which each devotee walks slowly and majestically; this rite is performed once a year. This locality is extremely rich in Ferns; in addition to Tree Ferns in abundance there are numerous others, including Adiantum caudatum, A. hispidulum, Davallia tenuifolia in huge masses draping the branches, Pteris geranifolia, P. cretica, and many others, whilst the trees are draped with such species as Asplenium furcatum, Elaphoglossum conforme, &c. Lilium neilgherense is also found in abundance in the neighbourhood. It is frequently seen growing out of the fissures of damp cliffs and rocks, and seems to like a good deal of moisture. As a rule it produces only a single flower on each stem, but I have frequently seen from two to three on a stem, and I believe as many as six blooms have been counted on one stem. It is a very beautiful plant in its wild state. It is now, I believe, becoming very scarce owing to the ravages of collectors.

After building the house on the Deva Shola plantation, I laid out a small flower garden in front, planting it mostly with Verbenas and Petunias the first year, which at that time were all the plants I had available. I devoted a bed to each variety, and the result was startling and unexpected. After the north-east rains ceased the plants began to bloom and for a whole year presented such an appearance as I never saw before produced by plants of the same kind. The beds during that time were simply a blaze of the brightest coloured flowers, and were the admiration of all who saw them. On the pillars of the verandah I had Passiflora edulis, which gave me fruit all the year round, Bignonias and Mandevilla suaveolens, which yielded its sweet scented flowers abundantly at all seasons. By the way, I have seen this plant in the Botanical Gardens at Ootacamund which had found its way to the top of a large tree, covering the crown of its supporter with a wealth of its pure white blossoms, which is another proof of the mild nature of the climate. The above-named gardens are extremely interesting and are well managed, but I shall have more to say regarding them perhaps in my next paper.—PLANTER.—*Journal of Horticulture.*

(To be continued.)

COCONUT CULTIVATION IN CEYLON.

COOLIES' IDEAS OF MANURING—THE STRICTURES OF "W. B. L." REPLIED TO—DIGGING THE SOIL ROUND COCONUT TREES—THE EFFECT OF MANURING.

Siyane Korale, 14th October 1887.

In your issue of the 21st ult. "W. A. D. S." draws attention to a marked peculiarity of all natives to heap rubbish or manure at the foot of trees. It is an inclination which they seem not to be able to overcome. I have found it strong in the Tamil coolie as well. Under your personal direction he will spread the manure round the trunk of a tree: once withdraw it or set him to apply manure without detailed and specific instruction and he will revert to his favourite plan. Nothing seems to be able to convince him that the mouths of the tree are not at the trunk. I had recent experience of this. In my manuring operations, which are rather extensive, or in placing weeds and branches at the feet of my coconut trees, I religiously avoid the trunk or the space within two feet of it. Yet during my recent absence from the estate I find that both cattle manure and husks, which I apply together, had been carefully piled round the trunk. The result of heaping rubbish round the trunk is that it sends out roots, which give to the tree an ungainly appearance, but heap rubbish or not, as a tree increases in height dame nature enlarges its foundation or base. I heartily subscribe to the system advocated of cutting a trench about 18 inches or 2 feet from the tree and 6 to 8 inches deep, either as a receptacle for manure or to receive the droppings of cattle. I have practised this all along.

Now for "W. B. L," from whom a letter appears in your issue of the 12th inst. nearly a month old. A cause is not advanced one whit by abuse or loss of temper, which usually betoken a paucity of arguments. Besides, "W. B. L." has been betrayed by these into making an excellent precept of "one Paul of Tarsus" serve as an introduction to a confused metaphor. What in the name of all that is ridiculous is "the virus of an overteased monkey"? This is evidently an attempt at being smart and caustic, with what result let your readers say.

When he dismounts from his "metaphorical charger," which being translated is "high horse," in which his performance is akin to that of a beggar under similar circumstances, *i. e.* on a horse, no matter whether it is high or low, I feel that I meet him on even terms. I shall not fail to benefit by "W. B. L." 's advice for qualification as a practical planter. I suppose his qualifications to be considered as a practical planter rest on a surer foundation than his claim to being observant. We had lately a specimen of his observation. A man who commenced planting when I was "sucking my mother" lately made the positive assertion that "the first event in germination (of the coconut) is the conversion of the water into a light spongy substance." Why, a schoolboy would have qualified himself for a whipping if he asserted anything so ridiculous and displaying such an absence of observation.

"W. B. L." is guilty of dust-throwing, and is evading the question at issue between us, when he represents or rather *mis*-represents me as predicting dire consequences if the roots of the coconut tree are disturbed. I took and take exception to his dogmatic assertion that he "approves of annual ploughing or digging merely because it cannot in general be done oftener. As to disturbing the roots it is a matter of no consequence; no coconut tree ever suffered from a deficiency of roots to take up any plant food in the soil; I want no main roots within nine inches of the surface, as the deeper lying mains send up abundance of feeders into the upper soil." That is *the* point of issue between us, for I say the above is opposed to all rules of agriculture not to say commonsense. If the richest soil is at the surface, and the "deeper lying mains send up abundance of feeders," then, I say, it is injurious to the tree to have these feeders *constantly* disturbed by ploughings, annual or oftener. I have seen a field of coconuts said to be manured and ploughed annually, and it presented a by no means healthy or vigorous appearance, but I have not seen coconuts whose roots have been disturbed oftener, for I do not think a man so foolish as to do it can be found even amongst uneducated natives, who dig round their trees never oftener than once in two years, as far as I know. I assert and assert unhesitatingly that most of the feeding roots of a tree are well within the shelter of the branches. This is supported not only by observation but by authorities, whom if I cite, even your broad-sheet will be filled. I am not represented correctly when spoken of as a "strong conserver of roots." I am more correctly a strong conserver of roots from frequent disturbance. As a coconut tree, unlike other trees, is constantly throwing out main roots from the stem, any temporary check it may receive from having its roots cut in digging a shallow trench round it is more than counterbalanced by the benefit it will receive from the manure or other plant food placed in the trench, I do not indulge in theories but in facts, therefore the advice given me to again examine the space round a tree in order to satisfy myself that it is occupied by main roots and not by root-hairs is unnecessary. I found and find most of the root-hairs round the stem and within shelter of the branches. I draw a distinction between cattle-manure and cattle-shed manure. In the latter category I include manure made by littering the sheds, so that the liquid portion of the manure is absorbed and does not run to waste. "W. B. L." and I are no

agreed as to the meaning of stimulant. What I understand by the term, is anything that produces a temporary and artificial vitality. That bones produce this undesirable result is abundantly proved by "W. B. L." who says that when it is used "the trees needs to be kept in vigorous growth by other manures." Therefore the position I hold is fortified rather than weakened by the experience of even your correspondent "W. B. L." that bones by itself must be used with caution and that it is in its action akin to alcohol in the animal economy. For to counteract its ill effects on man it is necessary to fortify his constitution with solid, strengthening food. The sneer at "the peculiar Ceylonese argument against the use of manure" is quite uncalled for, for the argument is not found in my letter, even in the form of an "old acquaintance," as your correspondent himself notices the use by me of manure. That I have much to learn and unlearn I freely admit. I am a constant and persistent student of my noble profession; but I must say that the proportion of chaff to grains in the attempts to teach by "W. B. L." is overwhelming. After an interminable search you alight on a few grains of knowledge which hardly repay the search. If one follows the teaching of your correspondent it is easy enough to "gather 300,000 nuts per annum or 50 acres," but not to leave a profitable inheritance to his heirs.

BETEL OIL.—Messrs. Gehe & Co.'s semi-annual circular says:—An important consignment of this oil, mention of which was made in the April circular, has now been received. The article excites a good deal of interest and may possibly become a recognised remedy in disorders of the throat. Mr. Schmitz, a pharmacist in Samarang (Java), is the maker of this valuable oil, and pronounces its active principle to be an aldehyde, while Eykman states it to be a phenol, probably carvacrol.—*Chemist and Druggist.*

WYNAAD NOTES, Oct. 10th.—Crop preparations are well on, and crop prospects pretty generally good. The promise of the early showers was not entirely fulfilled, and I fear some will be disappointed in their estimates. Taken as a whole, however, the outlook is very cheerful and there is a most unmistakable revival in planting interests,—a stir amongst the dead bones, a generally pleasant bustle, and energy which, in itself, is very encouraging. The planter intends ere long, to be regarded no more as "a worm"; indeed, to hear some of us talk, you would suppose we were well on to the butterfly stage already. The greatest difficulty with which we have to contend at present is the labour question. I do not remember any year in which coolies have been so scarce; and it is almost impossible to know how our crops are to be harvested unless our defaulting coolies repent at the last moment, and condescend to fulfil their contracts. Most of us are in a state of irritability over the fearful mess of weeds which we have no hands to extirpate; and local labour, a very broken reed to depend on, is being pressed into our service. Even the Charmas, for some unknown reason, are remaining much longer than usual on the Coast. The Canarese, unfortunately for us, have very fine grain crops this year, and, consequently, will not stir to fulfil the contracts for which they have received heavy advances. Our monsoon has been an exceedingly light one; and we really needed the showers which have just fallen, and which doubtless betoken the breaking of the N. E. Monsoon. The coffee, as a rule, looks splendid, though, in cases where it is bearing very heavily, it is already suffering considerably from leaf disease. The cinchona, as if aware of its own low value, flourishes like the proverbial green bay tree; we regard it, however, with patient satisfaction, and an inward conviction that, like the once despised coffee, its time will come!—*Wynaad Times.*

ARTIFICIAL QUININE POPPING UP AGAIN.—We earnestly entreat holders of quinine not to be led into a panic by the following announcement: "We are pleased to be able to inform our readers that the lawsuit respecting Dr. Cresswell-Hewett's discovery of artificial quinine is at an end. The inventor is now ready to commence the work of manufacturing the artificial quinine in Belgium, a country to which he is attached by bonds of affection and sentiment. By this new process of manufacture the price of quinine will be reduced to one-tenth of its actual value. The English journals have long ago recognised the extreme importance of Dr. Cresswell-Hewett's discovery." We translate this paragraph from the editorial columns of *L'Hôtel-de-Ville* of September 11th, and beg to add, for the benefit of all concerned, that the journal in question is a weekly print, published at Brussels, and boasting of the subsidiary title, *Organe des Honnêtes Gens*. It is of course quite proper that *The Town Hall Organ of the Honest People* should have been selected as the vehicle for the publication of the projects of so prominent a member of the honest community as Dr. Cresswell-Hewett. Persons interested in that gentleman's movements will feelingly note that the "bonds" which attach the Doctor to his new home are merely those of affection and sentiment, and there is a widespread opinion that so clever an inventor ought not to have been suffered to withdraw the benefits of his genius from his native land without at least an effort to bind him to it by bonds stronger than those now allying him to the Belgian capital. Spurned by London, Dr. Cresswell-Hewett seem determined to stick to the honest men of Brussels.—*Chemist and Druggist.*

BOTANIC GARDENS IN THE WEST INDIES.—Referring to a paragraph that appeared in your issue of August 6 (p. 170), by G. Layard, I cannot refrain from suspecting that your correspondent is one of those who take for granted what is told them. Had he ascertained by personal observation, he would have found his assertion "that the Demerara garden was the best in the West Indies" scarcely tenable. That it is a fine garden and well conducted goes without saying, but a garden which was only started some eight years ago can hardly lay claim to be the most useful of the West Indian gardens. The Trinidad garden has long since passed its "jubilee," while Castleton (Jamaica) has yet some time to exist before it complates its twenty-fifth year. It is evident also that your correspondent is unaware of the change of management in the Trinidad garden, for I cannot believe him to be so uncharitable as to attack a management which has existed barely six months. As regards the Castleton garden also, it is a great pity that Mr. Layard should have been so led into error as to describe it as a hill garden, for nothing is further from the fact. Castleton is barely 580 feet above the sea level, and has a purely tropical climate; in fact, it was selected on that account, and though by recent decisions of the authorities it is probable that its days are numbered, it is quite possible that some difficulty may be found in finding as suitable a locality for all purposes in any other part of the island of Jamaica. It may also surprise Mr. Layard to hear that there is a nurseryman in the West Indies; aye, and more—there is a nursery company in the West Indies. Such a company now exists in Trinidad, and has been established for the purpose of growing decorative plants for the New York market. So far—and the company has been engaged in operations for three years—the results have been satisfactory indeed, and such as to warrant a further outlay recently for the extension of operations. Mr. Layard should certainly make sure of his facts before attempting to write upon a question which is itself a commendable one, for he thereby throws an obstacle in its path instead of forwarding—as I presume was his object—the formation of stations for the development and spread of horticultural and agricultural knowledge. J. H. H.—*Gardeners' Chronicle.*

RINGING TREES.

TO THE EDITOR OF THE "AUSTRALASIAN."

Sir,—I have successfully rung whitegum, redgum, stringybark, and yellow box trees by simply putting through the bark one down cut, and, before drawing the axe, wrenching out the bark. The plan was suggested to me by a grazier who had rung large paddocks by this means. The time for doing it he suggested as May; but I worked it the succeeding winter months. The *rationale* of the plan appears to me that the cut and wrench form a trough into which the winter rains run, and, soaking through the sap, descend to the roots, effectually killing the whole tree. No suckers grew from trees so killed. The box is upwards of two years dying, the stringybark a less period, and the whitegum dies in six months. Prejudice won't allow old hands to work this way unless obliged. I reckon the saving in labour to be 75 per cent over cutting through sap. We have rung trees 3 ft. and over in diameter.—Yours, &c., SELECTOR.

THE PREPARATION OF COFFEE IN LONDON.

Mr. Thomas Christy writes as follows:—Wherever coffee has been found indigenous, it has been observed that the natives pick it and dry it in the cherry, or outer skin, and it is well known that this improves the quality, and the flavour is better retained, even for years. In many places merchants can command supplies of coffee in the form of "dry cherry," or in the "parchment," and some parcels in the cherry I sold to houses who roasted it with the outside jacket on; but as this required experienced roasting, the proprietors of the coffee warehouses saw the necessity, and ordered sets of the most approved coffee-dressing machinery, and erected them in London, and large quantities of coffee are treated here which command the full market price. During the last two months I have been seeking for some means of turning the large stock of coffee husks to some account, with the professional assistance of Mr. R. H. Harland, F.C.S., and of Messrs. Cross and Bevan; coffee dressers can find no use for these husks. The great advantage of this established enterprise is that the large companies opening up Africa can purchase the dry coffee in small quantities, and have it home in bags, and as soon as it arrives it can be sent at once to the warehouses to be decorticated, and placed on the market. Messrs. Major and Field, of Red Lion Wharf, allow me to state that in 1886 they decorticated 10,000 bags of coffee, and that in one vessel they received over 3,000 bags of coffee in the parchment to be decorticated. They further state that they have 100 tons of the husk which they would be glad to find a use for at a very low price.

In conclusion, I would like to put on record another fact, viz., that kola is being mixed with some of the preparations of coffee which enables the vendors to state that their mixture contains "no chicory," which is of great importance now that it is proved that the addition of chicory conduces to the growth of hæmorrhoids.—*Planters' Gazette.*

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

PARIS, October 5.

The all-absorbing problem for French and perhaps other agriculturists is to make wheat growing remunerative. Prices now have descended to what they were a century ago. In the old world, land is handicapped with an excess of taxation. Against this the cheap wheat centres, as Australia, the United States, Canada and, less so, India, are not so weighted, but they have to meet the expense of transport. On one hand then, Continental farmers must aim to produce more grain per acre, and their rival competitors to secure the cheapest facilities for transport. Perhaps it is well, that on each side there is a limit to the conditions of the commercial struggle.

In France the problem in general terms is this: The total expenses per acre for the production of wheat are, say 160 fr.; the price to be secured is from 10 to 12 fr. per cwt. The yield becomes then the fluctuating factor, and dependent on climate, culture, richness of soil, and not only sound, but climatic-suited seed. It is only now farmers commence to perceive the importance of the latter influence on harvest returns. Assume the bushel of wheat to weigh 60 lbs. and the yield per acre to vary from 5 to 40 bushels—the quarter being eight bushels. If one farmer only raises the minimum as in parts of Australia, and the maximum as in the United States, France, Manitoba and good wheat soils in England, the solution of the problem lies in how to produce the difference, that is, 35 bushels, or 19 cwts. per are. In some cases soil and climate forbid the attempt; in others high farming must be resorted to.

There are natural laws that regulate the cultivation of wheat in temperate zones. In dry climates wheat only is possible where the rainfall is slight. The culture of a plant, both as to soil and climate, is essentially contingent. The natural conditions, where that culture takes place, demand necessarily some modifications in the processes, but above all in the manurings. Sir J. Lawes has pertinently observed that the inducement to enrich the soil for wheat is diminished by the fact that the profit expected will not pay the increased outlay for manure. The disturbing elements in comparative wheat culture and differences of yield will be found to be essentially local, and can only be regulated or equalized by direct experiment. Some essays in this sense have been made at the agronomic station, Mathieu de Dombasle in the east of France on clay, sandy-clay, sandy and calcareous soils with different varieties of English and native wheats. The aim was to show that by judicious selections of native wheats, equally prolific and more reliable and more precocious varieties could be secured than from foreign samples.

Native grain, weighing 64 lb. to the bushel was sown; on the clay soil it stooled 12 stems; on the loam, 14; on the sandy, but 6. Other result: when the soil was well prepared and the seed spaced ten inches, the yield for native *selected* wheat was very superior to ordinary local kinds and culture. About one-seventh of the total corn raised in France is employed as seed, and it is calculated 20 times too much seed is sown. Hence a wilful loss for consumption. Further the best ears of the foreign samples "Nursery" and "Hunter," as compared with the best of the native varieties, were respectively 49 and 44 per cent heavier.

In the assimilation of lime, potash, phosphorus, &c., the roots of plants act the analogous part of the stomach in animals in contact with the food matters absorbed. The more the roots are developed the greater will be the surface in contact with the soil, and consequently the better the plant will be fed and developed. In a rich clay soil the roots of wheat are vigorous, large in diameter, and less numerous than in poor land. In sandy, but above all in clay soils, the roots are more capillary, fine, long, and more abundant. And these differences in the roots are alike uniform with the same wheats raised on such soils. It is by the direct contact of the rootlets, with the solid food materials that nourish the plant, and not by the absorption of these same materials in a state of dissolution in the bosom of the soil as was formerly believed and that a few still maintain. The practical conclusion of this is, that the soil can never be in too good tilth, nor the fertilizing matters too perfectly reduced and regularly distributed.

It is by instinct that the plant develops its roots, and in proportion as the soil is poor or the materials of nutrition irregularly disseminated, that development will be greater somewhat, as animals will have to range over a greater space where food is scanty in order to secure sufficient for the totality of their wants. This will be still more striking from another point of view. When wheat is sown broadcast about 330 grains fall to the square yard; not more than 180 seeds at most germinate, each sending up one, two, but rarely more than three or four stems. The

one-third of the seed is lost by drought, decay, or consumed by birds and vermin. As previously alluded to if the seed be planted at distances of ten inches, there will be some 64,000 stems to the acre; but if broadcast about 750,000, say one plant to each square inch of surface, being ten times more for the same space of ground than when the seed is drilled. The roots of the plants are thus checked in their development by over-crowding; there is the impossibility that ten can develop as well as one; the roots are restrained in their work, the stooling is effected badly, perhaps not at all, and finally, as is well known the yield will be less than the drilled-in corn, while exacting about 18 times more seed.

It has also been demonstrated that were the roots have full play in wide sowings and good soils, the efficacy of manurings has been *nil*. In other words the wheat's roots found the maxima of their nourishment in the preponderating advantages of greater unoccupied space. But if wheat be spaced on a sandy soil, there will not be much difference in the yield. Add, however, organic matters; bring the light up to the level of a loamy soil, and the wide sowing will exhibit the same profitable differences as an unmanured rich clay.

But here is a curious result from the experiments at the Eastern Agronomic Station. On a calcareous soil, extremely poor in plant-food, the spacing of wheat exhibited no superiority in yield over that sown broadcast, but the moment the soil received an application of pulverised dephosphorised scoriæ, the return was tripled, although the fertilizer contained 50 per cent of its weight of lime. This addition of lime to a calcareous soil was proof, that the action of the phosphoric acid of the scoriæ is not affected by the natural excess of lime in the soil. The scoriæ contains from 8 to 24 per cent of phosphoric acid, associated with 40 to 50 per cent of lime in addition to oxides of iron and manganese, plus sulphur. The presence of the metallic oxides even when as high as 10 per cent offer no danger to vegetation. Doses of the clinker dust from 4 to 28 cwts., following the richness of the soil, may be applied per acre with impunity. It cannot be too well remembered the importance of humus in sandy and very calcareous soils. In the famous black soils of Russia, whose fertility is proverbial, the disparity in returns as compared with soils equally and even richer in mineral plant-food is enormous. The difference resides in the humus. If the light soils be enriched by 50, or even 100 per cent of peat, their fertility will be increased. The organic matter through the action of its microbes and by combining with the insoluble mineral matters of the soil aids in the production and perfect distribution of plant-food. And the fertility of the soil will be raised and maintained in proportion to the employment of the peat or humus. The addition of clay will act similarly—both on root and cereal crops. As a counter proof the addition of turf to clay soils produced no marked superiority in fertility.

The important experiments in question revealed an unexpected result. The ordinary proportion of grain to straw is as 23 to 50. But on poor sandy soils the proportion was 35, and on loams, 25. There is no scientific explanation of this fact; but it is conjectured that in poor soils the plant concentrates all its energies on the development of the seed in order to secure the perpetuation of its species. In conclusion the solution of the wheat-growing problem on the Continent, or in France at least is this: Till the soil well; add per acre, if the land be not sufficiently rich, 8 cwts. of powdered scoriæ—cost 35 fr., and in spring top dress with 130 lb. of nitrate of soda—cost 37 fr; select the best seed, sift it well, and drill on ten-inch spaces.

During fifty years the French cavalry have had to depend on foreign importations for horses, and these principally come from Germany. The Central Society of Veterinary Medicine in June last ruled that carefully chosen, trained, cared, and fed, the native French war horse was equal to that of any other country. It was owing to not giving a sufficiently good price, that the French cavalry received a bad name. The same Society stated that the cavalry did care and train the horses sufficiently, and that the artillery neglected theirs. It is a long standing reproach that the worst hay and oats are reserved for the army horses; it is not food the cattle want, but food of superior quality; hence neither cavalry nor artillery horses are capable of yielding the strength, energy, and endurance expected from them. In the German army the horses are no better fed than those of the French; at the opening of the war of 1870-1, the Uhlans had anything but well-fed mounts; but on quitting France, the German horses, owing to liberal feeding, were models of working vigor.

The Agronomical Stations in France following the example of those in Germany now deliver forms of contracts to farmers to have filled up by seedsmen, manure fabricants, and implement makers, binding these furnishers to deliver their goods according to samples previously deposited at the stations.

Sugar is obtained from beet and cane; but how do these form it? M. Girard, after four consecutive years of experiments on soil, manures, and sugar beet in all the stages of its growth and from every part of the plant, demonstrates that the formation of sugar takes place exclusively in the leaves; that this plant-manufacture of sugar proceeds most abundantly in the day, and most largely as the light is most vivid; and that it is at night this diurnally formed sugar becomes stored in the root.

The wheat question is intimately allied to the production of sugar-beet. In Belgium and the North of France, no grain can be raised if beet does not enter into the rotation. To grow beet remuneratively, four chief points must be attended to: Select the best seed, prepare the soil well, secure adequate and appropriate manure, and till with intelligence. It must not be forgotten, that the sugar is made from the field, and that the factory exists only for its extraction. Since sixteen years the production of sugar has doubled in France; but this increase is not on a par with the augmentation in Austria, Russia, and above all Germany. In the latter two countries it has quadrupled. Belgium is in the same position as France. As the beet sugar can be produced more cheaply in Germany, the expense being less, the German is able—independent of the question of bounty—to monopolize the English market. The ideal for all sugar-beet producers ought to be to obtain a root having a saccharine richness of 13½ per cent. In Germany near Cologne beet has been raised having nearly 16 per cent of richness, and Professor Marcker of Halle-sur-Salle has raised in 1886, 25 tons per acre, having a mean richness of 15¾ per cent.

A FRUIT TREE PEST. *

The author has prepared an extended article on this insect in his annual report as United States Entomologist, which will appear in the report of the United States Department of Agriculture for 1886, now being distributed from Washington, and others in the Bulletin 15 of the division of Entomology of the Department, also just being distributed. These documents can be had on application to the Commissioners of Agriculture, by those interested, and Miss E. A. Ormerod has recently published in England a pamphlet on the same insect. The facts of greatest interest may be thus briefly stated:—

The species is the most polyphagous of Coccids (scale insects), living on a great variety of plants, and thriving particularly on Acacia, Lime, Lemon, Orange, Quince, Pomegranate, and Walnut. It is capable of motion at all stages of development after hatching, and can survive without food for a long period. These characteristics have rendered it

* Icerya purchasi, an insect injurious to fruit trees in Australia, New Zealand, South Africa, and California. Abstract of a paper, by Professor C. V. Riley, read before the British Association for the Advancement of Science, Manchester, September 6, 1887.

the most grievous enemy which the fruit grower has to contend with in Australia, New Zealand, South Africa, and California. It is believed to have originated in Australia, and to have been introduced into other parts of the world upon living plants. But in endeavouring to get accurate data for this belief I have been led to question the specific value of Icerya purchasi, Maskell, as compared with Icerya sacchari, Signoret. This last infests Sugar-cane in the islands of Bourbon and Mauritius, and on the hypothesis that purchasi is a synonym of it, the wide distribution of the pest through the sugar trade becomes at once intelligible, as it is a common practice in that part of the world and in the Pacific Islands to insert a piece or pieces of the cane in the hogsheads or other packages for the purpose of facilitating the drainage of syrup that is an accompaniment of the unrefined sugars produced there.

Thus the question of synonymy bears directly on the orginal source of this pest, and this is important to us practically in any study of the natural enemies of the species, with a view to their artificial introduction into those countries which Icerya has invaded without its natural checks.

This Icerya, on account of the protection offered by the fluted, waxy ovisac, and of its other characteristics already mentioned, is one of the most difficult of all insects to control, as few insecticides will reach the eggs.

In the papers already cited will be found details of experiments whereby the difficulty has been surmounted in California by judicious spraying with kerosene emulsions and resin soaps, as well as by a combination of cyanhydric gas evolved from potassic cyanide, and carbonic gas evolved from sodic bicarbonate, used under a portable tent.—*Gardeners' Chronicle.*

Moss.—An interesting discovery has been made in Switzerland of a bright-green moss, growing on calcareous rock, 200 feet below the surface of Lake Leman. No other moss has been known so far under water, and how colorophyl—the green colouring matter—could have been so richly developed in a place so remote from the light is a problem—probably the extraordinary clearness of the water enabling the sun's rays to penetrate to a great depth.—*Burgoyne, Burbidges, Cyriax and Farrie's Monthly Prices Current.*

ERIODICTYON GLUTINOSUM AS A VEHICLE FOR QUININE.—We find it stated in the *American Druggist* that Mr. J. D. A. Hartz has been experimenting with yerba santa, or *Eriodictyon glutinosum* as a vehicle for quinine. This pharmacist states that he finds it the best means hitherto discovered of masking the bitter taste of sulphate of quinine, and that he has succeeded in preparing from the yerba santa a syrup termed "syrupus corrigens" (or *correcting syrup*), 1 fluid drachm of which will so obliterate the taste of 2 grains of sulphate of quinine, that only a slight degree of bitterness is perceptible some time after the medicine has been taken.—*Ibid.*

PROFESSOR CALVERT has recently made the interesting discovery, by practical tests, that the carbonate of potash and soda possess the same property of protecting iron and steel from rust as do those alkalies in a caustic state. Thus it is found that if an iron blade be immersed in a solution of either of the above carbonates, it exercises so protective an action that if it is exposed to a damp atmosphere it will not oxidise, even after so extended a period as two years. Similar results, it appears, have also been obtained with sea water, on adding to it the same the carbonates of potash or soda in suitable proportions.—*Ibid.*

FURNITURE manufacturers have had their attention directed by enthusiasts to the pulp question. It is argued that pulp can be used as a substitute for lumber in the manufacture of furniture and other articles now made exclusively of wood. By mixing the pulp with clays, steatite, asbestos, plumbago and mica, substances of every possible color and compactness may be produced. It is estimated that only about 20 per cent of the timber felled reaches economic uses, while if the sawmill were combined with the pulping and pressing processes, all the material in trunk might be available.—*Iron Trade Review.*

THE CULTIVATION OF ACACIA DECURRENS.—We hear that the tannin-yielding acacia (*A. decurrens*) is being grown successfully on a somewhat extensive scale at Coonoor, in India. It thrives pretty well also at Ootacamund, but does not bear fruit there. This may very probably be due to the wet, gloomy weather coming on just at the time at which this tree begins to flower. On the other hand, it has been seen growing magnificently on the Palni hills, where it both flowers and fruits every season. The wet, gloomy weather at Ootacamund, seems to have proved favourable enough to another plant, namely our own English dandelion, which is beginning to cover the lawns there with its yellow flowers as it does in England, and in the deeply-tilled soil of the cinchona plantations it has roots 18 inches long.—*Burgoyne, Burbidges, Cyriax and Farrie's Monthly Prices Current.*

MILK.—A novel method of preserving milk for family use was lately made known in the *Australasian*. It seems that Mr. F. J. Stephen had left at the office of that paper some six weeks previously a bottle of milk preserved according to the following directions:—"Clean thoroughly a glass bottle, milk from the cow into the bottle until full to overflowing. Cork the bottle, and tie it down securely. Place the bottle in a vessel of water and boil. (To prevent the bottle knocking against the side of the vessel the bottle should be covered with a straw capsule.) After which remove the vessel of water with the bottle, and let the whole become cool. It need not be kept in a cool place to secure its remaining fresh." Last week the bottle was opened (writes the paper referred to), and a gentleman of large experience in dairy-farming tasted the milk, and declared it to be as fresh as if obtained from the cow the day before. The colour was preserved, and there was not the slightest indication that it had been scalded. Mr. Stephen, in his letter, drew attention to the value of the process to persons about to travel, and to others requiring a constant supply of pure milk, and the test has proved that for six weeks at any rate the condition of the milk submitted to the process is so well maintained that it is impossible to distinguish between it and new milk.—*Qneenslander.*

INDUSTRIAL PLANTS IN THE CANARY ISLANDS.—The dress of the people is essentially Spanish, the cloak and white mantilla being common. Most of the dress material is imported, though local industry produces coarse linen and woollen fabrics. Flax is grown in small quantities and the American aloe (*Agave*) affords abundant fibre for ropes and girths. Silkworms are reared in some numbers, and their produce is partly manufactured into ribbons and hosiery, and partly exported raw. Sumach is grown in small quantities for dyeing and tanning. Cacti, especially *Opuntia tuna*, cover a very large area, being grown for the support of the cochineal insect. The dyestuff obtained from this insect has long been one of the chief articles of export, but like madder and the rest of the organic dyewares, it is fading before the competition of the coal-tar colours; the export in 1883-4 was under 2,500,000 lb., value £112,000. Another dyestuff produced very largely on these islands is orchil (*Roccella tinctoria*), the rocky coast offering a fine habitat for the lichen; the product is chiefly exported; the figures for 1883-4 were 272 cwt., value £641. Hats and other plaited fabrics are made from the fibre of the date leaves. The cultivation of the ice plant (*Mesembryanthemum crystallinum*) is still prosecuted for the sake of the alkali contained in its ashes, exported under the name of barilla, and used in glass making; the shipments in 1883-4 were 6,902 cwt., value £1,102, all to Spain. Tobacco is grown successfully, and is improving in quality; the exports recorded in 1883-4 were 2,292 cwt., value £10,373.—*Journal of the Society of Arts.*

IS LARGE FARMING PROFITABLE IN INDIA?

Under this heading a native correspondent of the *Indian Agriculturist* writes:—

The only instance in India of large farming is tea-planting. Excepting this solitary instance (and perhaps, I should add, the tobacco farm at Poosah), I think I am safe in asserting that all attempts in India at large farming have failed. Even in these two instances it is the manufacture of tea and tobacco which has prevented the collapse of large farming. The fact is that cultivators in India, who are capitalists and labourers combined in the same person, live upon their wages, keeping their capital intact. So that any farming on a large scale which calculates the return of interest upon the capital invested will be a failure.

I have had seven years' experience of tea cultivation, and I am sure that in merely turning out leaf, the ordinary ryots would beat tea planters hollow. But the growth of leaf and its manufacture cannot be separated. And it is this inevitable association of cultivation and manufacture which has kept the planters above competition with the ordinary ryots. In the case of cotton, the cultivation and manufacture can be separated, and there is not, I believe, a single instance in which an English capitalist has ventured to compete with ordinary ryots in cotton cultivation. The next question is, can the introduction of machinery so economise labour as to be more profitable than hand labour? I think on all tea gardens hand labour has been superseded by machinery in tea manufacture (rolling, drying, and sorting). But the real truth is, that hand labour on tea gardens is very dear. The planters pay about R4 to a cooly per month; but taking into consideration the cost of importing, housing, and doctoring them, the cost per head cannot be less than R10 per month. It is the costly labour which is the principal cause of the introduction of machinery into tea-gardens. I do not think rolling and drying machines are so common in Chota Nagpore gardens as they are in the Assam gardens. But then on tea gardens, as everywhere else, it is manufacture proper that machinery has touched. It is a regular fashion to charge the Indian ryots with stupidity for not using mould-board ploughs; but in tea gardens you see neither mould-board ploughs nor Indian *langals*. In farming, or cultivation proper, there is not the slightest substitution of hand labor by machinery.

SWEET SCENTED ROSES.

Having ascertained that I had sixteen varieties of scentless roses in my garden, I made out a list of these, and at the same time, another list of the most popular kinds grown which did really possess the fragrance so much sought after in the queen of flowers. This list—in which the first thirty mentioned are those which, in my opinion, are superior in this respect—may be useful for the guidance of persons intending to improve or enlarge their collections. I have said nothing about the Moss, Provence, Gallica, or Tea-scented varieties, which are all more or less highly perfumed. Amongst the Tea-scented kinds, Maréchal Niel is decidedly the sweetest and most powerfully scented of all. My list embraces Hybrid Perpetuals only.

La France	Marie Baumann
Alfred Colomb	Senateur Favre
Monsieur Woolfield	Louise Van Houtte
Bessie Johnson	Souvenir de Julie Gonod
Madame Therese Levet	Baroness Louise Uxkull
Duchess of Edinburgh	Alexander Dickson
Senateur Vaisse	Duke of Edinburgh
Pierre Notting	Maurice Bernardin
Exposition de Brie	Velours Pourpre
Duke of Wellington	Madame Victor Verdier
Le Rhone	Leopold Hausburg
Madame Moreau	Mdlle. Julie Pereard
Jules Margottin	Duc de Rohan
Mdlle. Marie Rady	Princess M. of Cambridge
Miss Laing	Madame Knorr

The above thirty varieties may be depended on as being amongst the most highly perfumed Hybrid Perpetual Roses in cultivation; the following are, however, little inferior:—

Madame de St. Pulgent	Duchesse d' Orleans
Souvenir de Spa	Vicomte Vigier
Prince Humbert	Abbé Girandier
Madame Auguste Verdier	Ferdinand de Lesseps
Fisher Holmes	Annie Wood
Charles Lefebvre	Madame Chas. Wood
Jean Cherpin (Bennett)	Emilie Hausburg
Cheshunt Hybrid	Camille Bernardin
Lord Clyde	Captain Christy
Madame Marie Finger	Madame Derreux Douville
Xavier Olibo	Duchesse de Caylus
Leopold Premier	Dupuy Jamin
Baronne Haussmann	Gabriel de Peyronny
Madame Clotilde Roland	Mdlle. Marguerite Dombrain
Claude Levet	Felix Genero
Anna Alexieff	Alpaide de Rotalier
Marguerite St. Amand	Semiramis
Madame Boll	Prince Camille de Rohan
Madame Rousset	Gloire de Santenay
Madame George Paul	Adolphe Brogniart
Souvenir du General Doual	Eli Morel
Edward Morren	Beauty of Waltham

—*The Garden.*

THE USES OF ARSENIC IN AGRICULTURE AND IN DESTROYING INSECTS.

I see in your first issue that great trouble is experienced on the Mysore Railway by the destruction of the wooden ties by white ants. I believe we have found in this country a remedy for all such ravages. For some years we have been experimenting on the use of arsenic (arsenious acid, As_2O_3) in agriculture, and with the most wonderful results. We cultivate about 20 to 30 pounds of arsenic, mixed in any desirable proportion with a fertilizer, to the acre of land. *In every case*, every species of worm or insect that lives or hatches in the ground was destroyed, and in the hundreds of acres on which we used the arsenic not a sign of injury by worms to any of the crops has been observed, while in adjoining fields the crops were in some cases completely destroyed. No trace of arsenic is found in either roots, vegetables, or grain, nor is it injurious to animals pasturing on the grass of these fields. I have no doubt you will find, by using arsenic in the preparation of the wood, and probably even by putting some of it in the soil around the ties, the white ants will be destroyed. We prefer the crude arsenious acid made at a Canadian mine than the English refined, for it is finer in the grain and is stronger, but English "powdered white"—now quoted at £8-10 per ton at Plymouth—will answer, and it is more efficient and much cheaper than Paris-green. Should some of your readers try this, and lest any should get poisoned, I will here give the following recipe for a prompt and absolutely effectual cure for arsenic poisoning, whether internal or external; for, if arsenic gets into cuts or sores, it is very difficult to remove it, and it remains acting even under an apparently healing surface.

A Certain Cure for Arsenic Poisoning.—Freshly precipitated Hydrated Oxide of Iron, made as follows:—

Take Sulphate of iron ...	...	280 parts.
Sulphuric acid ...	...	100 "
Nitric acid	...	35 "
Water	...	500 "

Dissolve the sulphate of iron in the water and sulphuric acid; add the nitric acid very gradually towards the last of the operation until the liquor shows a clear red color, keeping the solution hot. Use capacious vessels. Then precipitate with ammonia until the iron is all down. Filter, and wash the filtrate thoroughly with water; keep the filtrate in water in a closed bottle. It is much more efficient when fresh. To apply to an external sore, put some of the oxide of iron with water into the sore:

it at once neutralizes the arsenic. For arsenic taken internally, take a tea spoonful of the oxide of iron; it is perfectly harmless, and more or less may be taken as the occasion requires.—*Indian Engineer.*

THE COLLECTING AND CONSERVATION OF RAIN-WATER FOR THE PURPOSE OF IRRIGATION.

Works of this character are not infrequently referred to in the accounts of the earliest historians. Herodotus describes the immense reservoir of Moeris as formed for the storage and control of the river floods of Nile-nourished Egypt; and of another, constructed by Nebuchadnezzar, at Sippara, of 140 miles in circumference. There is no question as to the existence in the East at the present day (and especially in India and Ceylon) of the remains of what may correctly be termed stupendous works; and the date of the construction of which, as regards India, is in many cases pre-historic. In Spain, also, the Moors (whose occupation of the peninsula terminated in the 13th century) have left dams of great magnitude, situated mostly in the south-eastern provinces of Murcia and Alicante, many of which are still serviceable. The reservoir at Tibi, 16 miles north of Alicante, is formed by an embankment of limestone rock built across a gorge or gully, the height being 135 feet, and contains 130,650,000 cubic feet of water, which is sufficient for two irrigations or soakings of soil per annum at the most needful periods. The extent of land thus available being about 9,150 acres devoted to the cultivation of vines, olives, fruit, cereals, and other market produce; which, in that dry part of the year could only be reared by irrigation; and the appearance of the area (over which the water can be conducted) forms a pleasing contrast to the general aridity of the surrounding district. In the *Planter and Farmer* of September, 1882, on page 236, an account is given of a modern irrigation work in Hindostan, called the Ashti Tank, then just completed at Sholapore, near the Great Indian Peninsula Railway. The *Times of India* speaks of the reservoir as an important addition to the means of irrigation, and says that two canals start from outlets in the dam, each being 15 miles in length, and well able to water a total area of 25,270 acres of land. The entire cost being 6¾ lacs of rupees; and the revenue calculated to yield 4 per cent. on the outlay. The earthen bund or bank to confine and act as a fence against the water, is 12,709 feet long, and 58 feet high, and when full the tank will have a surface area of about four square miles, and hold 1500 millions of cubic feet of water, each cubic foot being equal to 6¼ gallons.

In India and Ceylon the greater number of the ancient dams or bunds are now in ruins. There still exist, however, in the Madras Presidency, a not inconsiderable number of ancient bunds, which serve their intended purpose at the present day as well as ever. Mistakes occasionally occurred in their construction, as is proved by the remains of some such works in Ceylon, where the failure was evidently due to an error in taking the levels. Among the most remarkable of these ancient works is the Horra-Bera* Tank, the bund of which is between 3 and 4 miles long, and from 50 to 70 feet in height; and, although now in ruins, would formerly impound a reservoir lake of from eight to ten miles in length, and from three to four miles broad. There is also the Kala-Weva Tank, with a bund of 12 miles in length, which would, if repaired and rendered perfect, create a lake of 40 miles in circumference. Both of these ruined works are situated in Ceylon.† The third embankment of a similar character is that of the Cummum Tank, in the Madras Presidency, and which, although ranking amongst the earliest works of Hindoo history, is still in such a condition as to fulfil its original intention. The area of this reservoir is about 15 square miles, the dam being about 102 feet high, with a breadth at the crest of 76 feet. The bye-wash is cut in the solid rock, altogether clear of the dam; but the outlet culverts are carried under the bank. Earthwork, in some instances combined with masonry, was a form of construction usual in the ancient works of the East already referred to; but it would appear from the experience of recent years that masonry dams are likely to become as common as those of earthwork, in districts where the natural ground is rocky, and good stone easily obtained. The Velmi dam at Bombay, 95 feet in height, has a wall of clay puddle in the middle of it 10 feet wide at the top, with an increased thickness downwards of 1 in 8. The Oued Meurad dam in Algeria, which is also 95 feet high, was constructed with earthwork 23 years ago. And as the bank was carried up, water was admited, and allowed to rise to nearly the temporary crest of it, and as soon as the earthwork had settled the work was proceeded with and the same process repeated. At page 67 in the *Planter and Farmer*, of March, 1882, and on page 120 of that of May in the same year, a description is given of many other Indian reservoirs, and also various particulars as to the use of the water for irrigating the land, &c.—*Spectator.*

* Horaborawewa.—ED.

† And both have been repaired.—ED.

COCAINE.—The demand for cocaine as a local anæsthetic has had an effect on the export of coca leaves from Peru, the quantity sent from Mollindo during the past year being 705 quintals, of the value of 17,625 dols.—*English Mechanic.*

SOUTH AMERICAN CINNAMON.—The *American Druggist* says that at the exhibition of South American products held at Berlin in the early part of this year, some cinnamon bark was exhibited, which Professor Tschirch considered fully equal in aroma and sweet taste to the Ceylon cinnamon. It was in pieces about 2 inches broad and ⅜ inch thick. The essential oil prepared from it by Tschirch could not be distinguished from that of the Ceylon bark, though the yield was inferior. This is due to the fact that the pieces are taken from older branches which have a bark rich in stone-cells and therefore poorer in oil-cells. It is very low in price, and should have a promising future.—*Planters' Gazette.* [If it has, it will to the further depression of the trade in fine Ceylon cinnamon, which even now is scarcely remunerative. —ED.]

RHEA.—Mr. Charles Maries, of the Durbhunga Raj, has sent us a specimen of Rhea fibre manufactured under his newly discovered process. The fibre is soft, silky, and clean, although Mr. Maries says "it is only a bit of refuse, not picked out." He adds further, that he has now got over all difficulties, and can turn out the fibre in a much simpler way than that described by Mr. A. Sansone, Director of the School of Dyeing in the Manchester Technical College, in an article reproduced by us last week from *Bradstreet's*. This is a very important step gained by Mr. Maries, and one which will, we hope, solve the Rhea difficulty in India. We are, of course, not aware what method Mr. Maries adopts in stripping the fibre from the stem—whether by hand or machine, or the cost at which it is done; but we have his assurance that it is of the simplest kind, and very cheap. We would suggest some of our large textile firms putting themselves in communication with Mr. Maries with the object of coming to some arrangement to work up the Rhea on a large scale. Messrs. Ewing & Co. have so far taken the initiative of inviting tenders for the supply of the stems. We have little doubt that Rhea is destined to mark an epoch in the textile industry of this country; and if Mr. Maries' process proves to be all he claims for it, quite a revolution may be expected in the fibre trade at no distant date.—*Indian Agriculturist.* [Yes: "if Mr. Maries' process prove to be all he claims for it," which only a full and public trial can show.—ED.]

INDIAN TEAS IN MINCING LANE.

(From the *Pall Mall Gazette*, Oct. 5th.)

A VISIT TO THE COMMERCIAL SALE ROOMS.

How they vociferate! Strong lungs and a strident voice are apparently as essential to an expert in the tea trade as a delicate palate. For four or five hours per day and for five days of the week, brokers and buyers assemble in the dingy sale-room in Mincing-lane set apart for the disposal of Indian teas, and bid for the parcels put up with a clamour which deafens and confuses a stranger. From the rostrum the auctioneer indicates the purchaser, but how he discovers the first caller is a puzzle to an outsider.

A CONVERSATION WITH AN IMPORTER.

Indian tea has been for a long time in the ascendant, and the Chinese product correspondingly decadent. Great Britain, which is the greatest tea-consuming country in the world, half a century ago drew its whole supply from China, but such strides has the Indian trade taken that this year almost as much of the one as the other will be imported. In India proper—that is, excluding Ceylon—this year's crop will probably amount to 95 or 100 million pounds, or about 25 per cent. more than that of last year, all of which practically will come here, and the total requirements will be little more than double that amount. Up to date the shipments from China show a deficiency as compared with last year of fully 30 million pounds. We asked an Indian tea importer the reason for this revolution in the trade, and his reply was: "Indian tea has greater strength, which is an advantage, and of late years there has been a tremendous deterioration in Chinese tea. A great deal of absolute rubbish has been sent home, and no doubt spent leaves have been refaced in quantities."

THE PLANTER'S EXPERIENCE.

When tea-growing was first attempted in India by the Government, and afterwards by the Assam Company, some fifty years ago the Chinese plant was introduced, but after some time an indigenous plant was found. A number of hybrids were formed, but both these and the Chinese are inferior in strength and quality to the indigenous plant of India. This knowledge, gained by experience, led many of the planters to lay out their gardens solely with the native plant, and they have not found it unprofitable. Although the demand has gone up by leaps and bounds, the Indian tea planters as a class have not found their investments exceptionally remunerative. Some have undoubtedly done so, and a case in point was mentioned by our informant. On a garden of 500 acres a capital of £9,000 was expended. It was laid out in 1877, and although a garden is not remunerative till its fourth year, and frequently not till the fifth, this one has realized on its capital 289 per cent., and last year it paid 61 per cent. This magnificent return was the result of a carefully selected situation, low cost of making the garden, low working expenditure, and high yield per acre. On the other hand, there are plenty of gardens which have never paid a farthing and never will because of bad situation and bad variety of plant. During the past two years the planters have done much better than before owing to the fall in the exchange. The introduction of machinery has also helped to improve results by reducing the cost of labour and enabling them to produce much larger quantities from the same acreage. By means of tramways for conveying the leaf to the manufactory, a range of gardens can now be worked which was impossible in the old days. Nearly every detail in the preparation of the leaf after it has been plucked is done by machinery except sorting, which requires skill. While we get greater quantities it does not follow that we have better tea under the new conditions, as the old hand-rolled is regarded by experts as superior, but it pays to make a large quantity of inferior tea rather than a smaller amount of better tea. With the exception of the manager and one or, if the estate is a large one, two assistants, who are generally Europeans, all the work is done by natives.

HOW IT REACHES THE CONSUMER.

Practically all the Indian tea is grown in the province of Assam, the little that is raised in the hills being of small account. After being packed it is shipped or sent by rail to Calcutta and it is either sold there in public sale or shipped home for sale in London. As a matter of fact, it nearly all, either in the first or second instance, comes under the hammer in Mincing-lane. There are practically no future dealings—or, indeed, speculative dealings of any kind—in tea, every transaction being made by positive sample, and it can never be sold till it arrives in this country. Between the planter and the consumer are the importer or merchant, the selling broker employed by the importer, and the buying broker employed by the wholesale dealer. Then follows the London wholesale dealer himself, who in many cases sells entire parcels to a country wholesale dealer, and one or other of them supplies the retailer. Of course, as the market is a public auction, all grades of the trade can and do buy there, and in theory the consumer may do so should he wish. This would be rather inconvenient, however, for family use, parcels having been sold in one line of hundreds of chests, containing each about 100 lb. of tea. The duties of the selling broker are to inspect the tea on arrival, see that it is properly prepared for sale, print and issue the catalogue, and sell the tea by auction, he being an auctioneer. Both classes of brokers are paid by commission. The buying broker may buy on his own account as well as for the dealer, with a view to placing the tea in the course of the day. The wholesale houses have also buyers of their own, but they generally do their business in the name of a broker. As the sale-rooms both in London and Calcutta are open to the public, anyone may go in and bid and become a purchaser, but in practice the business is done through the brokers. Attempts have been made to dispense with the services of the broker, which are at times confined to the pocketing of his commission, but the power of a privileged body is not easily broken, and these endeavours have proved futile. A story is told of a merchant in Calcutta who made the experiment, and one day bought several lots. Immediate payment was thereupon demanded, and when a cheque was offered it was declined. A request for a few minutes' delay in order that a visit might be paid to an adjoining bank was also refused, and the tea was at once put up again for sale. On a second occasion a roll of notes was forthcoming, and the outsider scored, but in the end he had to throw up the sponge, for he could not stand out against the whole ring bidding against him whenever he wanted to buy. Merchants and buyers obtain samples of all teas brought upon the market, and place their own value upon them; and, as may be imagined, there is often wide divergence of opinion. A tea which one merchant might think worth 2s will sometimes go up to 3s, as others consider it has qualities which make it worth the higher figure. The planter is not always a good judge of quality, and he is often surprised to find certain lots fetched a higher price than he anticipated, while others fell considerably below his estimate. In recent catalogues the prices have

ranged from 2¾d to 4s per lb. Occasionally there are violent fluctuations, but the market is kept pretty steady by the large number of buyers.

CHEAP TEAS AND DEAR WINES.

Our Indian tea importer is very severe upon the prevailing sentiment with respect to tea. "Gentlemen," he said, "who pride themselves upon their wine cellar, and will boast of the high price which they paid for certain vintages, are not ashamed to say that they bought their tea at 2s a pound. Why should they not pride themselves upon offering their guests the finest tea as well as the finest champagne? It is rare that you get tea of a high quality with a fine rich flavour. The great run is upon a two-shilling tea, what the grocer calls his 'two-shilling canister'! No doubt that is very excellent value, for it is a tea free from adulteration, and obtained by a judicious blending of different varieties; but it is not a luxurious tea." The highest price obtained in the wholesale market this year has been 4s, which, with the duty of 6d per pound, would probably be sold retail for 6s. Nearly everything sold over the counter is blended, a small quantity of the dearer teas being mixed with the cheaper.

PLANTING IN DELI.

(Translated for the *Straits Times*.)

Tobacco cultivation which has been the making of Deli, dates from 1864. That article, now threatened with formidable competition by the North Borneo product has ever since been coming into greater favour on account of the leaves brought to market meeting requirements in size, fineness, and colour. They have proved highly suitable for cigar wrappers, and have come into demand for that purpose increasingly in America. From Deli, tobacco planting has now extended to Langkat, Serdang, Assahan, and Siak. So exhausting has the cultivation of tobacco proved that new ground has to be continually brought under tillage for the purpose. Land once under cultivation has to lie fallow for years, before it can recover. No wonder hence that the area of available land is becoming more contracted every year in Deli, intending planters seek fresh fields in the neighbouring States. Manure, natural and artificial, has been taken advantage of to some purpose in restoring the impaired fertility of the soil. So great has been the profit on tobacco that a run for growing it has set in to the exclusion of other products. The planters are fully aware of the risks attending putting all their eggs in one basket, but tobacco has gained such an overpowering ascendancy that they seem loth to try other produce articles. As may be expected under these circumstances the number of tobacco estates shows a steady increse. As was lately stated by us they are mostly in the hands of companies. It is said that 25,000 dollars are the average expenses attending the opening of a plantation. The scarcity and dearness of Chinese coolies, the planter's mainstay, help to swell the preliminary outlay. Yet, in spite of these drawbacks, tobacco planting there has outstripped the same branch of enterprise in Java. In the latter island, tobacco cultivation has evidently seen its best days. In Deli, the prospects are so briliant that the planters turn to with a will, and look forwards to the future with confident hopefulness. The European element is strongly represented and asserts itself despite Asiatic surroundings, which take less effect there than in many other colonies in the Far East. In the capital, civilising and refining influences have more scope than in the interior, where roughness, as may naturally be anticipated, prevails more prominently. The large estates show most evidence of order and methodical routine. Smaller estates do not enjoy a favourable reputation. On those which are managed in a rough and ready fashion, the management frequently leaves much to be desired. The roads are very bad, sometimes dreadfully so from lack of metalling. Labour for repairing them is hard to get owing to the sparseness of the population. The Deli railway has, in consequence, proved a benefit by supplying an acknowledged deficiency. The estate coolies are mostly Chinese who certainly work hard, but give no end of trouble owing to most of them being the refuse of their race. Immorality, opium smoking, and gambling have a firm grip of them, and no wonder. Drinking is rampant among them. They also readily take to fighting and disturbance. Some pity is due them. They enable the planters to enrich themselves, but die off rapidly in consequence. Few of them ever see China again. Most managers look upon them more as beasts of burden than as the noblest object in creation.—Oct. 17th.

THE GREATEST TEA COMPANY IN THE WORLD.

The following interesting account of the Assam Tea Company appears in *The Stock Exchange* under the head of successful companies:—

"The Assam Company is the oldest, as it has been one of the most successful, of the tea companies that have done so much towards making India a great tea-producing country. Established in 1839, by a special Act of Parliament, its initial difficulties were many, and chief among them was the question of labour. The scanty population of the district in which the gardens are situated knew very little about tea cultivation and manufacture, and several hundred labourers were brought at great expense from China, but the experiment was not a success. The Company had, however, taken over a few of the hands employed by the Government on the experimental gardens, and these, with the pick of the Chinese, worked the estate for a year or two.

"In course of time, however, the labour question became a much less serious one. In tropical countries it must always be a source of anxiety to the employer, but the tea companies are no longer dependent upon foreign labour. The gardens of the Assam Company are now worked almost entirely by natives of India, Assamese and Bengalis, and the rate of wage is low. But the Company have to recruit a large number of new coolies every year to replace those who may not care to remain in their service on the termination of their three or five years' agreement, although a bonus is given to them on re-engaging.

"The extent of the gardens of the Assam Company may be gathered from the fact that they have 8,114 acres under cultivation, and each acre requires the services of one labourer. Last year the gardens produced close upon 2½ million lb. of tea, and no less than 10 million lb. had to be picked to get it. For every pound of the manufactured article 4 lb. of green leaf are required, 75 per cent. going in evaporation and manufacture. To obtain first-class tea it is necessary that the leaf should be young when gathered. The amount of the yield is dependent largely upon the rainfall. Thus the yield last year was 249,769 lb. less than in 1885, and the falling-off is mainly accounted for by deficient rainfall during the early part of the year. In a dry season the sap does not flow in the plant, and the leaf grows very slowly. The tea plant wants plenty of rain, and thrives best in a damp, moist atmostphere, with occasional sunshine.

"At the present time the tea-pla ter is much in the position of the sugar-planter four or five years ago. The competition of bounty-paid sugar was then beginning to tell seriously upon his profits, but the current prices still left a handsome profit to the man who worked his estate to the best advantage. The enormous profits of earlier years had disappeared never to return, but the profit was still two or three times as large as that to be got from English land.

"It is much the same with the tea-planter today. The price of tea has been going down ever since 1876, and now it is not more than half as much as it was then. But to some extent this heavy fall has been counterbalanced by reduction in working expenses. Machinery has to a considerable extent taken the place of hand labour. Rolling the leaf, and drying it, and sifting it, all of which used to be done by hand ten years ago, is now done by machinery, with the result that the labour bill has been reduced very consi-

derably, although 8,200 coolies are still employed in the gardens. In 1876 their tea cost the Assam Company 1s. 6d. per lb., and when their managers were told that competition would make it necessary for them to reduce the cost of production, so that it might be laid down in Mincing Lane at 1s. per lb., they insisted that it would be impossible to grow and manufacture it for that price. Yet last year they did it for 10½d.! Now they are told that they must reduce it to 6d. if they are to successfully meet competition.

"The Assam Company can say what can be said by few other companies, namely, that it has returned its capital of £187,160 *five times over*. Altogether it has returned £996,477.

"Its dividends have varied considerably, but they have almost always been high. In 1877 it paid no less than 35 per cent., and in the last ten years it has declared dividends as follows:—

	Per cent.
1878	25
1879	27
1880	10
1881	7
1882	25
1883	10
1884	14
1885	14
1886	20
1887	10

"The shares have been as high as 400 premium, they are now at 100, and, although the reduction of prices must very considerably affect profits, the position of the Company is extremely strong. Its called-up capital, as we have said, is £187,160, and the value of its estates, gardens, buildings, &c., in Assam is estimated at £198,822. If to these we add other assets at the close of the year, such as stock of tea unsold, stock in hand, cash, &c., the total value of the property and assets of the Company is £300,382, which, with the reserve fund of £40,574, makes a total of £340,965. On the other hand, the balance of bills drawn in India previous to 31st December, and open accounts in India and England, amount to £35,418.

"The demand for Indian tea is, increasing very rapidly. In April last, for the first time, the deliveries of Indian and Ceylon tea exceeded the deliveries of China for home consumption, the proportion being 51 to 49. It is largely a question of price, though not entirely so. The data are wanting upon which to base a confident opinion as to whether tea can be profitably produced in India at a lower price than in China. In both countries labour is cheap, but it may be presmued that British skill and enterprise, the use of labour-saving machines, and superior cultivation and business aptitude, will give the advantage to the British companies, and foremost among these stands the Assam Company.

"In accordance with our usual practice we give the names of the directors of this very successful undertaking:—Mr. G. Turnbull, Chairman; Mr. A. B. Fisher, Deputy Chairman, Major-General Beadle, Mr. G. Paton, Mr. J. Graham, Q. C., Mr. A. Robinson and Mr. H. W. Wimshurst (Managing Director and Secretary).

"Mr. Walter Prideaux, who served the Company as Secretary, Director, Deputy Chairman, and Chairman for a period extending over forty-eight years, that is to say, from the establishment of the Company, retired at the beginning of the present year, owing to failing health and impaired sight.—*Pioneer*, Oct. 4th.

PLANTING IN NETHERLANDS INDIA.

(Translated for the Straits Times.)

The *Java Bode* says that, on behalf of cinchona planters in that island, inquiries on the spot have been made into the condition of the same line of plantation enterprise in Ceylon. They have ascertained in consequence that of late the export of root bark from Ceylon has been enormous. Many cinchona trees have been pulled up altogether from their being stricken with disease, or to make room for tea. In other cases, cinchona trees are either peeled, or shorn of their branches for collecting purposes. No fresh plantations are formed owing to the old ones proving unprofitable speculations.

PLANTING IN MANILA.

(Translated for the Straits Times.)

At Madrid, Senor Taviel de Andrade has brought out a Handbook of the Philippines. It gives not only a history of the country, but also a description of the native races, their manners and customs. Within the present century the import and export trade of the islands has risen in value from $10,000,000 in 1810 to $45,000,000 in 1886. A colony which can aggregate such an amount of trade can hardly be termed poor. It is now passing through a crisis in the production of sugar and tobacco, serious enough, but not in the least alarming when its teeming resources are borne in mind. Notwithstanding the depression of trade, the value of the import and export business done last year showed a falling off amounting only to one and a half million of dollars compared with the corresponding figures for 1885. More sugar and hemp might have been exported in that period had not holders preferred to keep their stocks in expectation of better times. Coffee will yet bear a more prominent part in furthering the welfare of the islands when plantations of it are once carefully seen to and extended. Coffee estates in South America, especially in Brazil, are rapidly disappearing from disease. Coffee trees there are attacked by canker at the root. This opens out a splendid future for coffee growing countries free from canker and leaf disease. With coffee cultivation extended and encouraged, the Philippines will count upon an export product to make up for the losses in sugar, provided the diseases so fatal elsewhere do not break out there.

CEYLON TEA IN FRANCE AND RUSSIA.

(From our Special Correspondent)

VICHY, 29th September 1887.

I have already referred to the benefit which might be expected from the establishment of a Ceylon Produce—and especially Tea—Agency in Paris, and how a Ceylon Café or rather Théerie might yield a good return, if under shrewd management, and combined with the sale of Ceylon produce generally in convenient packets and of curios peculiar to the island. Meantime, recurring to our experience here, we cannot find much trace of the fashion which is said to have become common in society in Paris of "five o'clock tea." At none of the hotels, "Grand" or otherwise, is there such a practice and the quantity of tea used altogether at Vichy is very small. The principal grocery establishments—and one is filled with admiration at the varied and admirable display of products and goods from all parts of the world in these places—keep tea in limited quantities almost entirely to meet English and perhaps Russian requirements during the season. At the chief store we found coffee beans of no less than a dozen countries displayed in large sacks ready for sale at prices varying from 2 to 4 francs (2s to 3s 4d) per lb. The retail price had been raised very recently, we were told, by half-a-franc, and another increase might have to take place if the threatened scarcity and dearness were realized. I have no means here, in the centre of France, of learning what the Customs duty on coffee is—the grocers profess themselves ignorant, buying at secondhand and there is no Ceylon Directory or Whittaker within reach; but making the most ample allowance both for the duty, and for the charges of a fashionable shop, we can judge how enormous is the expense of their favourite beverage to the French people and how very natural it is that the peasantry should drink "coffee" made chiefly from a country acorn with a few beans of the Martinique or Java produce

thrown in by way of flavour! This practice is very common we are told by a French lady at our hotel, whose home is on her own vintage property in Eastern France. At the grocer's, we were told that their high priced coffees were only bought in small quantities to flavour the ordinary, cheaper quality. That adulteration is prevalent and attracts a good deal of attention in France may be inferred from the following translation of an article which has first appeared in a Paris morning journal:—

COFFEE ADULTERATION.

Adulteration is carried on more extensively then ever in France, says *Le Petit Journal*.

In Havre considerable quantities of damaged and renewed coffee have changed hands. But we must distinguish between damaged coffee to which its original good appearance has been restored and artificial coffee which has absolutely nothing but the name in common with the genuine article. Damaged coffee, when sold as such, is not an adulterated article and is not, properly seaking, injurious to health; but we must say that though when sold to wholesale dealers, it is known to be damaged, yet when retailed it is seldom thus distinguished even by the shopkeepers who may be the first victims of the deception. When coffee has not been roasted, damaged coffee may be detected by the brown appearance of the bean although the heart of it is yellow and inclined to green; another almost certain sign is the salt taste.

In order to utilize these coffees, people wash them freely so as to get rid of the salt taste but cannot altogether free them from a very disagreeable brackish flavour. Under analysis, a very considerable amount of chlorine is detected, due to sea-water. In order to hide the defective colouring of the bean, they use cinnamon.

The adulterated coffee that has just been seized in Havre was, it seems, treated more vigorously. By the help of chemicals it was first whitened and then brought to the proper colour.

As to artificial coffees, they are prepared in the following way:—Into moulds having exactly the shape of the bean a paste made of acorn flour *(farina de gland)*, roasted corn and coffee grounds, is poured. This agreeable amalgam moulded and hardened gets its brilliant natural colour by the help of a solution of resin, just as white woods are dyed in walnut juice. Therefore it is only by buying coffee unroasted and testing it in water that you can be sure of the genuine article.

Adulteration and a check to consumption are inevitable results of the very high prices to which coffee has now reached; and I am confident that if the French people only came to learn the valuable dietetic properties of really good, well made tea, there ought to be a very considerable market for our Ceylon staple.

To this end, we have done what we could by way of propagating a faith in Ceylon tea during this brief visit to Vichy, and I am bound to say that the appreciation displayed of an "afternoon tea" at the hotel, by visitors from all parts of France, from Belgium, Italy, as well as Russia, was great, and samples of the small quantity we had with us have been taken away with much interest to Nice, Marseilles, Toulouse, Lyons, and Bordeaux, as well as Paris. In Nice especially, from the number of English and Russians who congregate there during the winter and spring, there ought to be a good market for tea, and I learn from residents that very poor quality is sold especially in "Russian" shops, at exorbitant rates. It is very possible that from the samples, information and addresses we have been enabled to send, orders for tea may reach Colombo direct from Nice. In regard to France generally, I can only at present give our experience of Vichy. At the principal store "The Noir" is entered at from 4 to 12 francs per lb. "The Vert" at from 6 to 8 francs. These prices, as Dominie Sampson would say, are prodigious:—3s 3d to 8s for black and 5s to 6s 6d for green tea! But the fact is that the article is treated here more as a medicine than a food product, and as something only asked for by those wealthy English and Russians. To prove this we found at the local pharmacies tea made up in ounce cardboard boxes at 90 centimes (8½d) per ounce, and in livre (pound) packages at 17 francs, or 14s per lb. In this way, it is quite evident the French people can never be got to patronize tea. We took some trouble to show the storekeepers how they could obtain Ceylon tea at a couple of francs per lb. equal to any in their stock, which even with duty and carriage should be retailed at less than their cheapest. We bought a few ounces of the different teas here to try them, and found them far inferior, to our taste, to average Ceylon, the only exception being some China Orange Pekoe sold to be mixed with common qualities. An English lady who passes her time between Nice and Vichy showed us a half-pound tin package of Horniman's tea prepared specially for the Continent which she bought at the rate of 4 or 5 francs (3s 3d to 4s) per lb. This tea was a special mixture of medium quality, but nothing can excel the neatness of the airtight package with its label printed in several languages. Tea has made the fortune of not a few large English dealers like the Hornimans,—who are millionaires I believe—and it is time now that the profits of the trade should be more equally distributed.

Before leaving my experiences of Vichy and Ceylon produce, I may mention the result of enquiries about quinine: the number of apothecaries' shops here is very great, notwithstanding the high repute of the mineral waters as a remedy for all manner of complaints. We found that intelligent dispensers were aware that cinchona bark and quinine were much cheaper; but they considered the fall in price to be merely temporary, and their very lowest retail quotation for Pelletier's sulphate of quinine is *a franc per gramme*—32 grammes to the ounce—while the rate used to be 2 francs per gramme! With quinine thus costing considerably over £1 sterling per ounce, there is little chance of consumption extending in France. It is really time that producers of bark and manufacturers of the sulphate took steps to let the large number of Continental and English pharmaceutical chemists and the public generally understand that quinine is permanently cheap and available therefore for a host of uses, never thought of when the article was really scarce and dear.

Turning now to Ceylon tea in Russia, I think I mentioned in my last the surprise experienced a few days after our arrival here by the appearance at our hotel table of a slim tall young man whom I took for a Frenchman, notwithstanding his fair complexion, or at any rate a "foreigner," but who soon made himself known as an Englishman fresh from Russia, where he had been resident off and on ten years. This long absence from England, as well as the fact that his father was a Swede, though naturalized an Englishman, accounted for Mr. Stevani's rather foreign air. "The world is a small place indeed," I thought, when one of the first questions put by this stranger from Moscow (who, after trying Carlsbad last year, had been specially sent to Vichy this time to cure enlargement and congestion of liver) was: "Do you know Mr. Graeme Elphinstone?" Of course, no better bond of union could be established than through the acquaintance or friendship in this typical Ceylon colonist. Mr. (now Sir Graeme) Elphinstone had, I learned, both in St. Petersburg and Moscow created a most favourable impression personally

and on behalf of Ceylon; but the Russian tea merchants are too strong and conservative I fear, to give in to the advantage of buying Ceylon teas all at once. However, some enquiry is likely ere long to arise, and meantime it is of interest to read our friend's account of his experience which he has kindly put on record at my request as follows:—

Vichy, 27th Sept. 1887.

Dear F— —,—You would like to know my experiences of Ceylon tea in Russia. They are certainly not very encouraging, but I will relate them nevertheless for the benefit of those who are interested in the Ceylon and Indian tea trade.

The first time I became acquainted with this new kind of tea was about two years ago, when I happened to taste it in the office of a London merchant. At the time I was so struck by its superior strength and flavour to anything I had previously come across, that I determined to introduce it into Russia whenever I had an opportunity. This I did about a year later, when I imported a few chests of Indian and Ceylon. I had no intention of becoming a regular tea merchant as I knew it would be impossible to compete with the large tea houses in Moscow, but I did not despair of introducing the finer qualities among the English residents. To my surprize, the tea did not take at all. The general opinion of those who tried it was that it was too strong, and too aromatic. The fact of the matter was that they had become so used to the light "Russian" tea, that they could not appreciate the real thing when they had a chance of getting it.

As the tea found no favour with my countrymen I offered it to the Moscow grocers, but with very small success. The majority of these gentlemen declared that the tea was scented with herbs, whilst one Soliman coolly informed me that it was not tea, but "tea-extract." In a word it did not suit the market. After calling on nearly all the principal grocers in Moscow without finding a purchaser I managed at last to come across an intelligent Russian, a tea taster, who at once recognized the superior qualities of the Ceylon tea for mixing purposes. This enterprizing individual not only bought up all the tea I had left, but after he had sold it at a high profit had the courage like Dickens's boy to ask for more. One must bear in mind that the Ceylon tea was not sold in its pure state, but mixed with cheaper Chinese tea. This mixture gave great satisfaction, and had I been able to carry on the business I could have sold a much larger quantity.

Judging from my experience and what I have heard from the tea taster who bought my tea, I have no hesitation in saying that there should sooner or later be a good market for the finer qualities of your Ceylon tea in Moscow. The Indian, which is much inferior in quality and flavour, is already imported, and if this is the case Ceylon tea ought to follow. But it is necessary to create a demand before it can be imported in large quantities. The taste of the Moscow public is very hard to hit, and it is only by judicious mixing that Ceylon tea can come much into use in the Moscow market.

In my humble opinion the best way for the planters to obtain a firm footing for their tea in the Moscow market is to open a small tea shop, and sell direct to the customers. There would be no difficulty in obtaining a clever Russian who would see that the tea would be properly mixed. In order to attract the public it would be a good plan to have it fitted up in the Sinhalese style, with a Sinhalese attendant to wait on customers. The cost of such a shop among a number of planters would be very small, and there is every reason to believe that such a speculation would leave a good profit.

Before leaving Russia, a Russian merchant with a capital of 10,000 roubles offered to take me into partnership if I would join him in opening an Indian tea shop, but as I did not wish to bind myself down to that country I refused his offer. Although I have had a small loss on your tea through being as it were the pioneer, I do not regret having touched it, as it has been the means of my gaining some valuable information about the trade which I have no doubt will be useful should I decide to continue the business.

I have also had the satisfaction of making the acquaintance of one of your tea planters, Graeme Dalrymple Elphinstone, Esq. Hearing that I had been trying to introduce the tea he came down from Petersburgh and paid me a short visit. I did not unfortunately see much of him, but the little I did convinced me that he was a "man" in the real sense of the word, and I think you are to be congratulated if you have many such on your island. I have since heard that he has attained to a Baronetcy, and I am glad to hear it, for I an convinced from what I saw of him that the "guinea stamp" has for once in a way been stamped on the true metal. In case I can send you any further information, I shall be very glad.—Yours most truly, W. B. S.

That there is ample margin for a profitable trade in Russia was seen by the table furnished some time ago by Mr. Elphinstone of the retail price in Russia and London value of the samples of tea got by him in St. Petersburg and Moscow. The following table has I think already appeared in the *Tropical Agriculturist*, but it will bear repetition here in connection with Mr. Stevani's remarks:—

LIST OF TEAS FROM RUSSIA.

	Seed ,, ...	18s 6d a 19s 6d

TRIAL OF THE GIBBS & BARRY TEA DRIER AT ELKADUWA ESTATE.

(By our Special Reporter.)

As had been announced previously by advertisement, a trial of the above machine took place this (Tuesday) afternoon (Nov. 1st) at Elkaduwa, and if fine weather, a good attendance, and genial hospitality could insure success, then without doubt this drier would have carried the day by storm; for only one shower fell during the drive up. There was a gathering of some thirty-five of the wisest-headed and strongest-bodied planters of canny Ceylon, and Messrs. Barry, Hodgson and Skrine did all in their power to render our visit a pleasant as well as a profitable one. Traps were in attendance at Watagama station to take the party to the estate, and as there is no train to Kandy later than 1-26, they waited to bring us back again the full 17 miles. The scenery, being new to many of us, was much admired, and the steep, precipitous road was very romantic, but, on the present occasion, romance must give way to hard dry —I may say Drier—prose.

After some very acceptable and ample refreshment in one of the stores, the following gentlemen proceeded to the old pulping-house where the drier has been temporarily erected:—Messrs. K. Anstruther, F. G. Ambrose, H. W. Ashley, Barry, W. Booth, N. S. Brown, Neil Campbell, Hastings A. Clarke, E. M. Davidson, T. S. Dobree, J. M. B. Duncan, T. Dickson, A. M. Ferguson, jr., R. S. Fraser, Jos. Fraser, Chas. Gibbon, Jos. Hadden, T. Hodgson (Manager of Elkaduwa), A. M. Hurst, C. A. Kynaston, A. T. Karslake, Geo. Moir, C. S. Morris, Geo. Reid, E. Gordon Reeves, A. C. Smail, W. L. Strachan, D. Skrine, E. Skrine, A. Tait, Arthur Thomas, and A. Melville White.

900 lb. of green leaf had been withered, rolled, and fermented in readiness, and at 2-11 the first handful was thrown in at the end of the cylinder furthest away from the furnace, the temperature being between 450 and 500; at 2-25 the first tea appeared at the other end, and at 2-38 it began to pour out freely. Of course as the trial went on the work got faster, and fermented tea put in at one end came out ⅞ fired tea in an average of about 11 minutes. I think it is always unfair to judge of a machine by one hour's trial or one day's trial, especially where the working is quite new to most present, and so several minor faults presented themselves in the Drier today which most likely will never occur when the machine is in regular use, a month hence say. For instance, some of the tea came out decidedly highly fired instead of only ¾ or ⅞ done, and at the end of 1 hour and 10 minutes when the machine was stopped only 108 lb. was weighed instead of about 200, as the out-turn ought to have been according to the prospectus. No doubt, however, the second and every succeeding hour would have turned out much more, and I can honestly say that the trial on the whole was a great success. The machine is so simple that, as one planter plainly put it, the stupidest idiot of a cooly could understand it. There is absolutely no handling of the tea after it has once entered the Drier; and it empties itself automatically, so that no cooly can burn or over-fire your tea when once the temperature, angle and rate of feeding have been regulated; and two coolies could easily work the whole machine, furnaces, fermented leaf and all. A proper technical description of the Drier is given below from the prospectus, but in simple language I may say that it is a huge cylinder fitted with shelves, exactly like a water-wheel turned inside out, constantly revolving, taking the tea up and letting it drop down again through the blast of hot air which is sent by a fan from end to end from the furnace, and with such an inclination on it that the tea gradually works its own way out at the other end. The disadvantages of the Gibbs & Barry Drier seemed to many of us to be the enormous price (R4,000 I believe); the burning of coke alone; the huge out-turn fitting it only for very large gardens (though Messrs. Skrine have a smaller one, I believe): and the amount of the wheel's or engine's horsepower it absorbs, 1½ to 2 h. p. I was told. The advantages are its extreme simplicity of construction and in work: the automatic feeding out of tea: its great out-turn: and the amount of heat the large surface of the cylinder would give out for withering leaf.

As we, who had come from far, drove back to Kandy in the cool of a delightfully fine evening, we felt that we had been well repaid for all our trouble by what we had seen of the manifestations of the brain and energy that are being put into our tea enterprise in Ceylon.

THE "GIBBS AND BARRY" TEA DRIER.

After an experience of several seasons, the Patentees are able to claim for this invention that it is acknowledged by competent authorities to be the best machine hitherto produced for drying Tea, Grain, Seeds, etc.

It has been widely used in India during the past three years, and gives increasing satisfaction to the users, as evidenced in the accompanying testimonials.

The Machine is simple in construction, can be easily put together, and with care and proper attention should give no trouble. It may be briefly described as a rotating cylinder, in the axis of which is placed a perforated tube for conducting the hot air or gas which is forced into it by a fan. The interior of the cylinder is fitted with shelves, and the apparatus is placed on an incline. The green leaf is fed in at one end of the cylinder, is constantly carried up by the shelves, and allowed to fall through the current of hot air as the cylinder revolves, thus travelling down to the other or lower end, where it is discharged in a nearly dry state. It can be brought out fully dried, but the Patentees recommend it to be never more than "seven-eighths-fired" when it is discharged from the cylinder, and the final firing to be completed in trays over ordinary "choolas." They prefer the tea to be brought out about "three-fourths-dried."

It is not claimed that tea dried in this machine is superior to all other machine-dried teas, but, as the process is automatic, and consequently must if ordinary care be bestowed, ensure absolute uniformity, it is asserted that it produces tea certainly not inferior to that made by any other known apparatus.

The quantity of tea which can be dried by this machine is very large. There are two sizes; one with a cylinder 18 feet long and 3 feet 6 inches in diameter, capable of "*three-fourths-drying*" about ten maunds of *green leaf* per hour, and the other with a cylinder 12 feet long and 2 feet 6 inches in diameter, which will "*three-fourths-dry*" about four maunds of green leaf per hour. In stating this, however, the Patentees do not guarantee any particular results. In some cases these quantities have been exceeded, while in others they have not been reached.

The Patentees can only guarantee that as each one of the respective sizes is made from the same pattern every machine is identical.

For final firing the tea, ("Pucka batty") and pulping, this Dryer has been conspicuously successful. As many as 30 maunds of tea have been passed through it in an hour.

Both in labour and fuel the Patentees claim for their Invention a superiority in economy. The [illegible] feeds in the leaf is absolutely the only [illegible] required by the machine itself. The men who [illegible] the rolled leaf to, and the dry tea away from [illegible] are not counted because they are so employed in every factory. The same may be said of [illegible] required to look after the working parts and the fur-

nace, for wherever there is machinery there must be an engineer and a stoker who can easily attend to this duty. The amount of coke consumed is very small, and the cost of it per maund of tea compares very favourably with the cost of charcoal as used in the old process.

These results, namely, the large quatity of tea it is capable of manufacturing, regularity in quality, convenience and simplicity in working, and economy in labour and fuel, are claimed as advantages peculiar to this machine, and place the "Gibbs and Barry" Tea Dryer in front of all its competitors.

Particular attention and care should be bestowed on the construction of the furnace. If this be done a vast amount of trouble and inconvenience will be avoided afterwards. Time should be allowed for the brickwork to become thoroughly dry before any fire is put inside the furnace.

For constructing the furnace 300 fire bricks, 6,000 common red bricks, and one cask fire clay are needed.

With reference to the supplementary apparatus of trays sent, if required, with each machine, the Patentees consider it is not needed. Users will find it advantageous to build their own.

A number of machines were supplied last year for the current season, and as there was some delay in consequence of the orders having been received late in the year, it is suggested that orders for machines to be made for use in the forthcoming season should be given at an early date.

It having been ascertained that the cylinder will work as satisfactorily with two, as with four, friction rings, some machines are being made on this pattern. The price of them will be £10 less than for the old style.

Prices (which include packing, pyrometer, belting, and everything complete, except firebricks and clay):—

Large size, with 4 friction rings ...	£275
Ditto, with 2 friction rings	265
Small ditto	175
Supplementary finishing apparatus if supplied with dryer	25
Ditto, if supplied alone	35

Delivered F. O. B. London.

For full particulars apply to J. B. BARRY & SON, 110, Cannon Street, London, or to BARRY & Co., 5, Lyons Range, Calcutta.

The above prices refer to the original type. The prices of the new type are £225 net for large size.

PLANTING IN DELI.

(*Translated for the Straits Times.*)

The weather in Deli during the last month took a turn favourable to the planting interest, hitherto the worse for unseasonable rain. Many planters who had given up all hopes of securing even a moderate crop have been marvellously helped up by this change for the better. September usually a wet month has proved a particularly wet one this year. It has rendered crop operations easy and remunerative. Heavy rain only fell on the 29th of the month.

Coffee is grown to some extent in Deli. One hundred piculs of that article lately brought 53 guilder cents per pound at Amesterdam.. Experiments with cultivating the berry there have so far proved unprofitable enough to discourage planters from trying it They stick to tobacco as the safer investment. Nowadays tobacco holds a high place in the market. That from Deli enjoys a high reputation for wrapping purposes. When North Borneo comes fairly in the field, Deli with its restricted area of land will have a hard struggle to avoid being distanced.

A GROWL AT INDIAN TEA.

Mr. R. M. Holborn, tea dealer of Mincing Lane, who nourishes a singular antipathy to Indian tea, writes a letter to the *Grocer* upon the subject of a recent article on the jubilee of Indian tea, which appeared in the *Standard*, and was given in our issue of September 23rd. Mr. Holborn is indignant with everbody who dares to insinuate that China tea is not all his fancy paints it. He says:—

"Your extract from that journal (the *Standard*), is full of 'crams' from end to end. It is not likely that the 1886-87 import of Indian tea will be 90,000,000 lb.; last year I think that it was 79,000,000 lb. in round figures, but I am short of returns here. Mr. Robert Giffen is a charming and accomplished statist but a very hybrid tea-dealer—probably an Indian shareholder. They really must grow hyperbole in the Himalayas between the tea plants. Invention and imagination have always been blends with any statements upon tea coming from Anglo-Indian sources. They cannot, even in the present article, allude to China tea without the slimy, mean introduction of the odious feature of 'adulteration'! The scribe in the penny daily appears not to know such authorities as Messrs. John Reeves and William James Thompson, sen. who fully satisfied the Special Committee of the House of Commons in 1874 upon the question of adulteration in China tea. As the article before me progresses, a distinct position is given to Ceylon tea, showing that it was not included in the estimate of 90,000,000 lb. I believe that the Ceylon output of 1886-87 was about 9,000,000 lb. and not 10,000,000 lb. —as insinuated, but not stated clearly. Blending tea is not an unalloyed advantage; the fine bloom on a well-cured China tea flies off on disturbance, and may be taken up in palmfuls, as a fine soft grey down in the mixing rooms of our larger dealers. You can see the greyness and the bloom on the face of a sample of high-class Shanghai black leaf; and when this is disturbed, and this tender freshness separated, the richest flavour of the brew goes with it. I deny that the Chinese prepare tea in the manner in which it has been done from time immemorial.' I do not admit that 'the liquor produced from China tea is thinner and less pungent than that obtained from India tea.' The two terms are nonsensically paradoxical. Except fine Hyson, no liquor could be thinner than that for which the Liverpool man got fined by Dr. Brown, the quasis analyst, yet it is the most pungent cup which we have, viz., the finest gunpowder. The beauty of fine green tea in its herbal pungency and natural fragrance. The pungency of Indian tea is produced by firing: it tastes of toast; every minute portion of turpentine* is condensed on and in the leaf; it tastes sharp on the tongue, and it is invaluable as an alternative after whisky. I question, upon this, whether the Belfast dealers are not the most cleverly adaptive men among all your subscribers, for they sell the largest proportion of Indian tea in their total supplies to the public. No doubt, to a very sad extent, the general sense has been weaned and warped—(I do not believe that that taste has been yet entirely perverted),—it is led on, first by economy, 'colour in the cup,' next by 79,000,000 lb. weight of Anglo-Indian pedantry, proselytism, but worst of all, by that easily-acted-upon credulity and prejudice. Prejudice, by the fool, sir! The general grocer, the bulk of your readers, ought to know the meaning and application of the term! Why has his coffee trade gone to false French productions imported here? But there—prejudice! When it first came down upon green tea, I told my dear old Nottingham and Derby friends, 'Fine pure green still sold here,—stick it in your windows.' Prejudice is a thing always to face, always to fight, and to sink. Every grocer might feel that he was a victorious man, because he can hold in ridicule Charles Dickens's vicious nonsense that the grocer 'sanded his sugar.' I submit, sir, this to you, as one of your oldest humble servants."
—*H. & C. Mail.*

AVERAGES OF INDIAN AND CEYLON TEA.

Messrs. Walker, Lambe, and Company say:—"The heavy sales which commenced during the last month have caused a downward tendency in the market, and prices have fallen for all grades, teas with exceptional quality alone remaining at former quotations. The chief weakness has been shown in Souchongs under 8d, which are ½d cheaper, and in poor liquor-

* "Turpentine"! Who ever heard of terebinthine elements in tea? Fanatical prejudice gone insane!—ED.

ing Pekoes and Broken Pekoes under 1s 3d, which are 1d to 1½d lower. The value offering is remarkable for this time of the season, and it is doubtless owing to this that dealers have been able to cope with the quantity so well. There have been some useful invoices from Assam, notably the Kondoloe Assam Company, and Upper Assam Company. Dooars and Terai teas have fallen off in quantity, but some better Sylhets have come forward."

The following are some of the averages realised during the month :—

Garden.		Broken Pekoe.	Pekoe.	Souchong and Pekoe Souchong.	Broken Tea.	Average Price.

THE RIPON PLANTING COMPANY, LIMITED.

Mr. Ahmedbhoy Hubibbhoy presided yesterday afternoon at the third ordinary annual general meeting of the shareholders of the Ripon Planting Company, Limited, held at the registered offices, Elphinstone Circle. The notice calling the meeting having been read, the chairman proposed the adoption of the following report, which proposition was unanimously agreed to :—

The board now submit their report for the year ended 30th June last, together with the audited accounts for the same period. The cinchona is reported to be coming on well, the total area under cultivation now being some 50½ acres. There is very little more land suitable for cinchona. The experiments on a small scale with tobacco and tea have not proved such success as to warrant any land being specially set apart for their cultivation. The board have done their best to reduce expenditure on all heads to the lowest possible limit, compatible with the efficient working of the estate. The superintendent has reduced his estimate for the year ending 30th June, 1888, from about R3,000 to about R2,500, principally by accepting a reduction in his own remuneration and by economies in weeding. The secretaries and treasurers have also reduced their remuneration to R75 per month from August last, on the understanding that any arrears due to them for office allowance will be made good to them at some future date when the company's affairs are in a more prosperous condition. It is expected that these economies and the proceeds of sales of bark (as may be available from time to time), will place the Company in sufficient funds to allow the whole of the cinchona to come to full growth. The prospects of the gold mining industry in the Wynaad district have of late somewhat improved, and some hope is now entertained of the industry ultimately proving a success. This is satisfactory, as the Company has retained the mining rights over the property, and has all the machinery in good order and condition on the spot, which will be a valuable consideration to would-be purchasers, seeing that it is very difficult and expensive to transport machinery to the district.

Messrs. Ragoonath Narayen Khote and Pooranchund Panalal, the retiring directors, were re-elected, Mr. Ahmedbhoy Hubibbhoy being again selected to officiate as chairman for the ensuing year. Mr. Heugh S. Symons having been deputed to audit the books of the Company, on a remuneration of R50, the meeting closed with the usual vote of thanks to the chairman.—*Times of India*, Oct. 28th.

TEA IN JAPAN.

From the report of Mr. Vice-Consul Longford on the trade of Japan for 1886 we extract as follows :—

TEA.

The export of tea from Japan during the last seven years has been :—

	lb.		lb.
In 1880...	40,436,877	In 1884...	35,766,600
1881...	38,483,854	1885...	41,244,718
1882...	37,734,845	1886...	47,595,651
1883...	37,146,914		

These figures show that the export for 1886 exceeded that of any previous year in he current decade by over 6,000,000 lb., and the average export during the period 1880-85 by over 9,000,000 lb.

The only market for Japanese teas is found in the United States and Canada, and practically the whole export of 1886 was to those two countries. In the United States, the rate of consumption of tea is calculated to be about 1¼ lb. per head of the population. Taking the same low rate for Canada, the total annual consumption by the two countries amounts to nearly 70,000,000 lb., two-thirds of which may be said to consist of green teas, and large, therefore, as was the export from Japan during 1886, there is no reason why it should not be maintained or even extended in the future, if the Japanese producers are careful to consult the American taste for quality and flavour, not, as has been done in the past, ruthlessly sacrificing both in the expectation of profitably rushing excessive quantities upon the markets. Careful preparation and delicate fragrance first brought Japanese teas into favour with Americans, and enabled them to supplant to a large extent those of China. Only the fine grades of Japan tea were at first exported, and all were shipped in their natural condition. But, as time went on, growers, in their desire for quicker and greater profits, grew more and more careless in their pickings, and foreign shippers in Japan, in order to hide the steadily decreasing quality of the ar-

tural tea, were compelled to have recourse to artificial methods of colouring and preparation. The consequence was that the entire American market was flooded with tea that was both cheap and nasty, and, though the export from Japan steadily grew in quantity up to 1880, there was by no means a proportionate increase in value. The continued fall of the export in 1883 and 1884 at last awakened the Japanese to the bad reputation which their teas were obtaining, and, in the latter year, a Central Tea Industry Association was established under the auspices of the Department of Agriculture and Commerce, the chief object of which was to exercise a supervision over the tea industry which would prevent adulteration and bad manipulation and secure the sale by the Japanese of the best possible pure leaf. This Association has since been in active operation, and its efforts are gradually bringing about a much needed improvement in the natural leaf.

At present, the tea trade of Japan directly interests Great Britain only in so far as it affords employment for British capital and British shipping. An extension of the trade will bring about a proportionate increase in both these cases, and, in another point, it may afford an opening for British trade in supplying machinery that might profitably be used in the operations that are now done by hand.

On this latter point, I have already spoken in a previous report, and through the publication at the close of last year of a report on Ceylon tea by the United States Consul at Colombo, the attention of the Tea Association already mentioned was directed to the subject. In this report it was stated that Ceylon tea only required to be known to be appreciated in America, and that, once a taste were acquired for it here, it would largely displace that now coming from China and Japan; that the prime cause of its unusually delicious aroma lay in the fact that, after plucking, it was handled and cured entirely by delicate machinery; that the former bad manipulation by hand, was now replaced by ingenious mechanical appliances for withering, rolling, and drying the tender unbruised leaf immediately on being plucked; and finally, that manipulation by machinery rendered the production cheaper than formerly.

Could not these results be equally obtained by the employment of machinery in Japan, and is it not worth the trouble for English manufacturers to investigate, and endeavour to provide, what would suit Japanese requirements in this respect? The Japanese are already fully alive to the advantages of employing machinery in many lines in in which they had formerly to trust only to manual labour. In the silk industry, its profit has been fully brought home to them, and I believe they would soon learn the same lesson if an effort were made to teach them in the case of the tea industry also. But, while British manufacturers devote full attention to the making of suitable machinery for this purpose, any steps to introduce into new countries the result of their ingenuity and handiwork, seem to be entirely beyond them. Catalogues of various kinds continue to reach me; and I am also asked in letters to recommend persons who would undertake the introduction into Japan of the articles named in them. In several instances, it has at the same time been brought to my notice that "under no circumstances whatsoever do we ship, except upon orders and London credits," so that what I am practically asked to do is to recommend to manufacturers person who will consent to pick the chestnuts out of the fire for them. Whenever opportunity offers, I pass on the catalogues to Japanese merchants, but I am not aware of a single instance in which, as regards machinery, my doing so has been productive of any material result, and so long as English manufacturers wait for others to take the trouble and risk which should rightly devolve upon themselves, so long will they fail to obtain the market they hope for in Japan. I am far from recommending, be it remembered, speculative shipments of machinery, even of that which has been already successfully tried in other countries. Such a course could, I believe, result in nothing but loss. What I do recommend strongly, and have recommended in previous reports, is that expert machinists should be sent to Japan to study what would suit the conditions of the country and people; and manufacturers who were guided by their recommendations would, I believe, have no reason to ultimately regret the cost of any experiments made by them.

MOULD IN TEA-BINS.—The following, from the *American Cultivator*, may be useful for tea-planters:—"Readers whose books have been or are likely to be attacked by mildew may preserve them to some extent by placing a saucer of quicklime near, in the bookcase or shelf, or where convenient. The lime absorbs the excess of moisture, and must be renewed, as it becomes slaked and loses its strength. It is equally good for putting in linen chests, iron safes, or wherever there is likely to be any mustiness owing to the exclusion of fresh air."

CINCHONA CULTIVATION IN BRAZIL.—Some time ago we announced that efforts were being made to induce the Brazilian Government to take up the cultivation of cinchona. We now hear that the Brazilian Ministry of Agriculture has divided a quantity of calisaya seed among planters in the province of Rio. The municipality of Santa Maria Magdalena, also in the same province, are to receive a special assortment of seed, and will at once turn their attention to cinchona planting.—*Chemist and Druggist*, Oct. 8th.

FISH CULTURE IN INDIA—WHY NOT IN CEYLON?—In quoting the following interesting notice, we would repeat our strong hope that fish breeding for food purposes may become a universal industry in Ceylon. Perhaps the Director of Public Instruction might, from the book referred to and others, together with local information, get a handbook of fish culture prepared in the Sinhalese and Tamil languages:—

We have received a little book *Pisciculture* * by Baboo Nidhiram Mookerjee. The author has made the subject a study for some years, and has been carrying out a series of experiments on his own estate at Belghurria, where he has established a fish-farm, and his work will therefore commend itself to all interested in the subject as the result of practical experience. The book itself is printed in the Bangalee character, and is divided into five chapters. The first deals with the fish supply of Bengal, and points out that except at certain seasons, the supply is not equal to the demand. When there is an abundance, it is due, he says, to the extensive capture of breeding and undeveloped fish. The second treats of the food of fishes, and the third as to the manner of hatching and breeding. The forth discusses the fish-trade. The author has ascertained by experiments on his farm, that the trade is a very lucrative one, requiring but little capital. He quotes a statement made by professor Huxley at the last Fisheries Exhibition, "that once in a year, an acre of good land will produce a ton of corn, or two or three cwts. of meat, or cheese, while an acre of sea-bottom (water) in the best fishing grounds, yields a greater weight of fish every week in the year." The author, therefore, recommends pisciculture to the serious consideration of his countrymen, as a profitable industry, instead of wasting their time and energy in seeking petty Government appointments. The last chapter deals with the scientific description and classification of fishes, with the names of hundreds of varieties, and their Bengalee equivalents. Altogether, the work is a very useful one, while the subject is one of great economic importance, especially in Bengal, where fish enters largely into the dietary of the people. The author deserves every encouragement in his attempt to bring to the notice of his countrymen an industry with large possibilities, and we recommend the book to all interested in the subject. —*Indian Agriculturist.*

CITRUS JAPONICA.

This is a member of the orange family which, in all likelihood, would do well on the lower slopes of the Nilgiris and the Wynaad. In the Northern United States it is frequently grown for ornamental purposes, but in the Southern States, especially in Florida, it is being cultivated commercially. According to an American paper there are two distinct varieties of this fruit, one having oblong, the other a round fruit. They attain the size of a medium-sized plum or apricot respectively. The tree is hardy, bears extremely young, which of course is a matter of great importance, and the fruit hangs on the branches in the greatest profusion. As many as seventy have been counted on plants not more than from 15 to 24 inches high. It does not claim to be a table fruit, though even eaten raw it has a very agreeable flavour; the rind can be eaten with the flesh, being not thicker than a Plum or Cherry. It has a decidedly aromatic orange flavour; the flesh is very juicy with the sub-acid quality of a lime, very cooling and refreshing and containing only two seeds. The main value of this fruit will be for preserving and crystallising. For this purpose it is eminently adapted. It is not necessary to take off the skin on account of its extreme thinness. The aroma of the rind blending with the acid of the flesh will make it one of the most desirable fruits for preserves, jellies, and crystallised fruit. It is a tree that will soon gain favour and stand on its own merits, once it is thoroughly known. It does not, like all Japanese orange trees, attain any considerable height, its growth being very bushy with long divergent branches, 10 to 12 feet being its height.—HORTUS. —*South of India Observer.*

IPOMŒA NOCTIFLORA.

Mr. M. P. Arnold thus refers to the Moon Flower (Ipomœa Noctiflora) in the *Florida Despatch*. "It claims Mexico for its home, but it takes most kindly to Florida, as I can well testify. I planted a single seed, given to me by a friend, under the protecting end of my kitchen. The soil was dry and sandy, although there was some clay mixed with it. The vine made a slow growth at first, but as the rainy season advanced it became more vigorous. The leaves were much like the common Morning Glory, but much larger. The plant finally became rampant, and clambered over the greater part of one side of the house. I had paid but little attention to it for a long time, when suddenly one evening I was astonished at five or six immense saucer-like flowers of pearly whiteness, which swayed and nodded in the evening wind. They exhaled a delicate Jasmine-like odour that was tantalising in its evanescent sweetness. By sunrise the flowers were faded and gone; but on the succeeding evening a new crop of flowers would gradually unfold themselves, and again would steal forth that subtle, fleeting perfume of the famed Evening Glory. I have frequently taken my chair of an evening and placed it before the vine, and, settling on one particular bud about to open, I would watch the gradual unfolding of this giant of the Morning Glory tribe. It became exciting and fascinating to watch the slow expansion of this chaste and lovely flower. At length the final crease would be drawn out, and the flower would present itself to my admiring gaze. On a dark night a dozen or fifteen immense blooms would startle a stranger on coming suddenly around the corner of the north end of the house. The humming birds were extremely partial to the flowers, and would frequent the vine almost every evening, flitting from flower to flower like feathery sprites." —HORTUS.—*South of India Observer.*

REVIEW OF THE DRUG MARKET.

The following particulars are taken from Messrs. Gehe & Co's semi-annual circular.

CAFFEINE has been considerably reduced in price, owing to overstocking of the raw material and cessation of the shipments to America, the principal country of consumption. This article, along with quinine, may be taken as illustrating the depreciation of fine chemical in the last twenty years. At the beginning of the sixties caffeine cost 680m. to 700m. per kilo; from 1870 to 1880, about 200m.; and now only 70m.

COCA LEAVES.—The importation of coca leaves into Hamburg has lost much in importance now that the demand for cocaine is fully covered by the arrivals of crude cocaine of a reliable quality from South America, which has also rendered unremunerative the extraction of cocaine from the leaves in Europe. The stock of leaves is still sufficient for the requirements, although fine green Bolivian leaves are becoming scarce. Peruvian and Truxillo leaves, also (which latter variety can only be used for manufacturing purposes), are in some instances held at high prices. It is said that new arrivals are not likely to take place while prices remain at the present level.

GUARANA has remained rather dear, with small arrivals. The consumption in Brazil is known to be very large, and, apart from the paste which is brought into commerce by the Indians of the Amazon territory, the guarana plant is cultivated to some extent in the districts of Maué, Villa Bella, and Imperatrix only. The plant, like the vine, flourishes best in hilly districts, and requires a rather dry sandy clay soil. The seeds are placed in beds, and the young shoots are transplanted as soon as they have attained the height of a few inches (15 to 20 centimetres). Another method consists in planting the seed in a small basket filled with earth, which is placed in the soil as soon as the plant has grown to a height of 10 centimetres. The guaranas are placed at distances of 6 to 8 metres, and are trained to grow against lattice-work. The cultivation demands much care, and the first crop is not collected until the fourth or fifth year. The plant flowers in July, and fruits in November and December. From that time forward it has to be pruned yearly, and its cultivation closely resembles that of the vine, but cannot be carried on successfully outside the tropics. The plant is said to fruit for over forty years, yielding from three to four kilos. per year.—*Chemist and Druggist.*

WALNUT TREES AT OOTACAMUND.

From the proceedings of the Madras Agri-Horticultural Society we quote as follows:—

Read the following letter from Lieut.-Col. H. W. H. Cox, dated Coimbatore, 18th June, 1887:—

"Blair tells me that at Cluny, Ootacamund, there is a Walnut tree which every year produces fruit from which young plants have been raised. This may or may not be new to you. I write because I have a kind of impression that unsuccessful attempts have been made by the Society to assist a man on the Pulneys to raise the Walnut and the Almond from imported seed.

"Major Donald McLeod is at present occupying Cluny, and you can get from him confirmation of Blair's information."

Read letter from the Honorary Secretary to Major McLeod, dated 23rd July last.

Read the following letter from Major Donald J. S. McLeod, dated Cluny, Ootacamund, 9th August, 1887:—

"I have been trying to get information on which to reply satisfactorily to your 1059, of 23rd July, but fear I have not been very successful.

"I have in my garden a very good Walnut tree which bears fruit annually, but not in large quantities such as trees at home produce. It is said to have been planted by the Scots, this house for a long time having been Mr. Leeot's property, but no one up here can give me any ideas as to the date, nor as to whence the seed nut was obtained. However, there it is, and it has been the parent of many other trees, though as yet, so far as I am aware, none of its progeny have attained sufficient age to produce fruit. In my garden there are three trees raised from nuts of the parent tree. One is over 9 feet high, and quite a handsome and thriving; another is 5 feet high and [illegible] the third being smaller and rather stunted, I think, because placed in a bad situation. These trees were

planted by Rohde, the present owner of the house' but when, I cannot ascertain. G. Oakes, of Oakes and Co., who is the agent for Rohde, tells me he has some seedlings doing well, grown from nuts of the old tree. He plants them in baskets and keeps them in them until they are strong enough to put out into the ground; all the nuts he put in, germinated, but took a very long time to do so—about 3 months.

"I have enquired about other productive trees, but as yet without hearing of any; however, I will continue my enquiries and let you hear results later.

"My Walnuts are just ripening, I will send you some to distribute if you like. This year there are particularly few on the tree—less than there were either in 1885 or 1886."

SERICULTURE AT THE PARIS INTERNATIONAL EXHIBITION OF 1889.

By ALFRED WAILLY,

(*Membre Laureat de la Societe Nationale d' Acclimatation de France*).

For a number of years the deficiency in the production of mulberry silk, has drawn the attention of Sericulturists to the rearing of the Wild Silkworms of India, China, Japan, America, and other parts; and a great many reports have been published on these Wild Silkworms, some of which are already bred in a state of domesticity or semi-domesticity. My own reports on this subject have appeared during a succession of years in the *Journal of the Society of Arts*, London; the *Entomologist*, London; the *Bulletin de la Societe d' Acclimatation de France*, Paris; the *Isis*, Berlin; and other publications.

Many of these Wild Silkworms produced silk of great strength and beauty, and could all be profitably utilised, if bred in their native lands, on a large scale. Up to the present time I have succeeded in obtaining specimen cocoons, and carded and reeled silks of about twenty different species. These have been sent to the "Societe d' Acclimatation," and they will be exhibited in the Paris International Exhibition of 1889 together with specimens of the Moths and prepared larvæ of the various species.

As it is highly important that this Exhibiton should be as complete as possible, I have been requested by the "Societe d' Acclimatation," to send all new specimens I can collect from abroad. I, therefore, make an appeal to sericulturists, entomologists, and all persons wishing to contribute to the formation of this large and interesting collection of the Wild Silkworms of the World, to communicate with me, and I request them to kindly send me, in small or large quantities, specimens of live cocoons, with names of food-plants for each species, whenever possible, and also specimens of the Moths.

Live Cocoons, which are specially required for the rearing of the species, should be sent to Europe, from October till about the end of March, according to distance; when sent later, especially when sent from tropical regions, the moths generally emerge during the voyage and all is lost.

These specimens which I am so anxious to obtain, will all be purchased or they will be exchanged, if preferred.

Small samples (in strong tin or wooden boxes) of live cocoons and specimens of moths, can now very rapidly and safely be sent by Sample or Parcels Post.

I shall also be happy to purchase live pupæ of various species of lepidoptera, and specimens of Butterflies and Moths in good condition, or exchange them for other species, requesting the senders to kindly state their own conditions for the disposal of the insects.

Persons wishing to obtain some information respecting the rearing of Caterpillars, which would help so much in the safe sending of the pupæ (chrysalides) as soon as they are formed, may obtain my Catalogue of the Wild Silkworms, in which are given the names of food-plants for each species, and information on the larvæ, etc.

I shall also be happy to send any other information in my power, and copies of some of my reports to all persons desiring to undertake this most interesting study.

Trusting that my appeal will not be made in vain, I beg to state in concluding, that I shall remain most grateful to all who will hold out to me a helping hand.

ALFRED WAILLY.

Tudor Villa, Norbiton, Surrey, England.

FROM THE DIRECTOR OF GARDENS AND PLANTATIONS.

To the Editor of the Jamaica "Gleaner."

Sir,—Some time ago Dr. Phillippo called attention to a machine patented by the International Fibre Company of New York. On application to the Secretary of the Company for information about it, I received the following reply:—"We have a Decorticator for Ramie which has been thoroughly tested and works very satisfactorily, and we shall be very glad to show the working of the machine here to anyone you may appoint before shipping it to you, but we would not feel inclined to go to any further expense than we have been at in exhibiting.

"We are the only party who proves their faith in the working of the machine by buying all Ramie decorticated through it, so that should you purchase one as a trial, you would open a market for your fibre at the same time.

"We shall be very glad to hear from you as to the formation of a company and shall be glad to deal liberally with you."

The phamplet states that the machine will produce 3,000 to 4,000 pounds of decorticated fibre a day. A machine which accomplishes such an amount has solved the problem of a practical decorticator for Ramie. Great hopes were at one time entertained that the Favier machine, combined with the Fremy-Urbain chemical process, would prove a success, but a London firm to whom I applied for information about it wrote that "In October 1883, the writer went to Paris with Dr. Forbes Watson to investigate this process and we reported, against it as being wasteful, and needlessly elaborate and complicated and such as would not be economically successful." M. Favier himself confesses that his machine's daily production is limited to the number of stalks that can be fed to it singly and by hand. One hundred pounds of cleaned fibre per diem is the limit of its capacity.

"The International Fibre Company in addition to the perfect machinery for decorticating Ramie in large quantities, has purchased of Senator Feray of France (a practical spinner) at great expense the sole right and property in the machine for spinning, bleaching, carding, dyeing, &c. of Ramie for the United States. The company is about to take measures to establish factories in the East and South with the object of manufacturing Ramie into silk goods for dresses, into lace curtains, lambrequins, portieres, hosiery, carpets, belting, &c.

The Company offer for sale the break machine which cuts out the stalk for the sum of $550. The machine for fibreizing for the sum of $850. Both machines are simple in construction and may be worked by the ordinary labourer. The Company cordially invite the planters of the South, to call in person and examine the machines and manufactured Ramie. The plant may be seen in its growing state and in its crude and preserved condition prior to manipulation. Also dress goods (equal in appearance to silk) sealskin Ramie (worth $18 per yard), window curtains, undergarments, carpets, &c., as well as the uncleaned and cleaned fibre, the unbleached and bleached fibre, and the yarn and threads in colour—for Ramie takes dye equal to silk."

The London Firm mentioned above, say "Our own opinion is that Rhea fibre must be laid down in this market in the state in which it can be produced by Death's machine—that is, rather freer from gum than the China grass as usually imported—at about £25 per ton before any large consumption can be expected."

The cost of cultivating Ramie has been placed at £3 per acre after the first year, but this calculation would be too high for Jamaica, for the rates of wages supposed, women to get 1s 6d, and men 2s 6d a day.

Dr. Phillippo in his Lecture at the Jamaica Institute on Ramie, puts down the produce of an acre as over one ton of fibre.

It is a question for business men to consider whether it is worth while to risk the expense of purchasing a machine. No doubt many have correspondents in New York who would be able to give an opinion on the working of the machine. If it really answers the purpose, it would be an immense boon to the Island to introduce one, for Jamaica can produce enormous quantities of Ramie, and if the Fibre can be extracted at a cost which will allow of competition with flax, the demand for it will be practically unlimited.—I am, Sir, Your obedient Servant, W. FAWCETT, Director, Public Gardens and Plantations.

Botanical Department, 2nd Sept. 1887.

IRRIGATION IN VICTORIA.

The leading features of the Irrigation Bill which the Government have just introduced, and which is one of the most important measures that have yet been brought before the Legislature of this colony, were unfolded in the Legislative Assembly on Thursday last, the 24th inst, by the Minister for Water Supply. The first half of Mr. Deakin's speech, which occupied nearly four hours in delivery, consisted of a retrospect of the water legislation of the colony, and it was shown how first Melbourne and the larger centres of population, then the country towns, and finally the residents of rural district were supplied. Under the Water Conservation Act of 1881 the Government had advanced £178,000 to 23 water trusts, and had expended £57,000 in head works. Eleven of those trusts were now paying interest; ten others had either struck rates or were about to do so, and only two had given no indication that they would meet their obligations. For this expenditure of a little more than half a million the farm lands of Victoria had been increased in value to the amount of a million and a half. The principle of our water legislation in the past had been for the State to advance money for works, for local bodies to carry out those works, and for the consumers to rate themselves to pay the interest. That principle is to be continued in the Irrigation Bill. The present measure, Mr. Deakin pointed out, is the outcome of the growth of knowledge as to the capabilities of the colony in regard to irrigation, mainly attributable to the labours of the Water Commission during the past two years. Three years ago it was considered that there were only 700,000 acres of irrigable land in the colony. Now we have the knowledge that north of the Dividing Range, and without reference to the Werribee Valley, to Gipps Land, or to the Western district, we have 3,221,000 acres of irrigable land. The experience from 1875 up to the present date had been that dry cultivation had been a miserable failure, notwithstanding the richness of the soil, and without irrigation the population of the northern plains must be swept away, and the lands go back to sheep farming. The Government proposition is to borrow £1,000,000 of money to carry out 10 schemes, which will deal with the nothern plains, from the mallee to the Upper Murray. A scheme for each district is set out. Local trusts must be formed to execute the works and to rate the land for the payment of the interest on the capital to be advanced by the state. The state is to assist in "joint works;" it is, under special circumstances, to make "free grants" to the trusts; and where there are large works which are "keys of the position," the Government will treat those works as "national," will construct them, and will take control of them afterwards, charging the local bodies, however, for the water supplied from them. It is held that only the state can see fair play between conflicting interests. The state is to find the money, lay down the schemes, construct the headworks, see to the diversion of the water, and leave to the trusts merely the execution of the works and the raising of the revenue. The money which the state borrows at 4 per cent is to be lent at 6 per cent, so that there may be a surplus for expenses and for a sinking fund. For five years there may be no payment of interest. The object of this concession is to provide that until the farmer actually enjoys the use of the water he shall not be rated. The interest payable during the period of construction is to be presented to him as a gift from the State. The amount of money to be voted to each district is to be fixed by Parliament, and each trust will be elected by its respective district. Such are to be the leading features of the bill. The average cost of water to the farmers, taken all the year round, is expected to be something under 11s. per acre per annum, and it is believed that this amount will gladly be paid for the benefits of irrigation. With regard to the vexed question of riparian rights, the principle adopted in the bill is to be that a riparian owner shall have a right to as much water as is necessary for domestic and stock supply, and no more. All the waters of the colony are to be declared to be the property of the state, and shall be held by the state unless specifically parted with. In conclusion, Mr. Deakin referred to the results already achieved upon irrigated land in Victoria, and declared that if the colony had to expend the four millions of money absolutely, the improvement of our northern areas, and attendant benefits to the whole colony, would soon show that the investment had been justifiable. Mr. Deakin was very attentively listened to throughout his exhaustive address, and there is little doubt that, with more or less amendment in various directions, the bill will be carried into law.—Melbourne *Argus*.

GENERAL PLANTING IN BRITISH NORTH BORNEO.

To the Editor of the "British North Borneo Herald."

Sir,—It is no doubt difficult to overestimate the probable importance to the country, as pointed out in your last two issues of the tobacco planting industry; but, whilst drawing attention to tobacco, let us not undervalue other agricultural products. Some people there are, indeed, who say, that, however great the results from tobacco planting may be, general planting will ultimately prove to be a still more important factor in the future prosperity of the country.

Be that as it may, it is a fact that an experienced Ceylon planter, the first one that visited the country, Mr. T. S. Dobree, said that in his opinion the climate and general conditions were so favourable to the successful growth of Liberian Coffee, that he expected to see British North Borneo one of the chief producing countries in the world for it, when once its cultivation was properly started. This opinion was based upon observations made on the Segaliud river.

Coffee has lately seen some violent fluctuations, but the price now has apparently settled down at a very much higher rate than it was formerly, and one which leaves no doubt of its paying well to the planter, provided no untoward events happen to it: and in the case of Liberian Coffee in this country, nothing untoward is likely to happen as even leaf disease, which almost annihilated Coffea Arabica in Ceylon, and is slowly but surely working havoc in Brazil and Java, is thrown off by Liberian Coffee, not only here, but in the Straits, Borneo, and Sumatra also, I believe.

Several estates I have seen that would have been deserted in Ceylon as exhausted by Hemileia Vastatrix have quite recovered, in some cases the trees having been accelerated by the soil at first getting dung as manure, while in others no manure at

all has been used. It has no other enemies, is a strong and handsome shrub, bears heavily, and it has been said, by Indian planters, who saw some thousands of plants of it on the Sebooga Estate about eight miles away at the back of the town; that it is finer with us at eighteen months old, than in India at three years old.

The last quotation for Liberian Coffee according to Lewis and Peat's circular is from 80/ to 85/ per cwt. Stocks, according to the same authority, show a heavy reduction from what they were at the same time last year.

Another plant that bids fair to have a large share in this country's future prosperity, is the Willoughbeia rubber which grows naturally all over the country, but more particularly about Sandakan Bay; growing under natural forest shade it requires no outlay at all upon felling, clearing, holing, and all the other operations which make ordinary planting so expensive; simply put in at the foot of forest trees, it takes care of itself, requiring no weeding to speak of, and when maturity is reached, yields an abundant supply of the valuable "gutta susu" or India-rubber. As to what the yield is, opinions differ, some place the quantity as bigh as 50 catties to each creeper, others limit it to 20 catties, but, in either case the returns are out of all proportion to the money invested in starting a plantation of it.

The difficulty attending its cultivation hitherto has been the want of seeds from which to start nurseries.

It may be safely predicted that the first person who can get a few creepers of it into bearing, from which to supply seeds, will make a handsome profit, irrespective of the sale of the india-rubber itself.

Other plants wnich seem to promise well to the planter in this country, include pepper, which remains at the very remunerative price of 8¼*d.* per lb. and which is not likely to decrease in price, to any marked degree, owing to the still continued struggle in Acheen. When travelling out of the East this spring, I happened to come across a Capitan China from that locality, who informed me that the pepper crops have fallen off, from 75,000 piculs to about 15,000 per year.

Gambier is also high in price at the present time, and is likely to still further advance, as it is coming into use for various new purposes. This plant has never been tried in British North Borneo, but a wild form of it grows freely all over the country in this neighbourhood.

Tapioca, not systematically cultivated here, produces tubers of unusual size in the native gardens. In other countries it yields large profits to the growers.

Manila hemp, sago, kapok, nutmegs, and many other plants, also promise to repay the cultivator here.—I am, Sir, Yours truly, W. B. PRYER.

Sandakan, 15th September, 1887.

THE CINCHONA BARK MARKET.—Nothing can more strongly illustrate the terrible depression of this market than the fact that in a price current, ledgeriana, the very king of the cinchonas, has its bark quoted at from 3d per lb. for chips and shavings to 1s 5d, the very highest for "stem spokeshavings." Poor Mr. Moens! it would surely have broken his heart had he lived to see his monarch thus dethroned. We do not suppose that in the history of any one important article of commerce the collapse has been so sudden and so complete as in the case of cinchona bark.

TEA-HOUSE FLOORS.—The following extract may give a hint to planters who are building tea-houses:—"The German architects recognizing linoleum as a good, durable stuff, continue to find new application for it every day. The practice is now much in vogue in rooms of new buildings intended for stores, offices, workshops, restaurants, etc., first simply to lay a cheap plaster floor (cement or gypsum), and thereupon to put a layer of linoleum, thus entirely dispensing with a wooden floor. Thus, it is stated, a floor is made, which in its massive underground is impermeable to both vermin and moisture. Such a cover of linoleum takes the place and has the advantage of a carpet and can be made at cheaper rates than wooden floors."—*Philadelphia Record.*

THE RUST MITE is common on oranges up-country. A correspondent of the *Florida Dispatch* gives the following cure:—"An infallible remedy if properly used is, sulphur and soap, as recommended by Prof. Hubbard in his treatise on Insect of the Orange. I would advise all growers to procure it, read *and profit* by it. Take ten pounds whale oil soap to a kerosene barrel of water, and five pounds flower of sulphur, and be careful to stir thoroughly each time a bucketful is taken from the barrel, apply with force pump. All mites will be destroyed, but the eggs will not. The soap causes the sulphur to adhere to the fruit and foliage for weeks and even months; as the eggs hatch the young mites come in contact with the sulphur and are destroyed."

AMSTERDAM QUININE WORKS.—On Sept. 6th a meeting of shareholders in the reconstituted quinine manufactory was held at Amsterdam, for the purpose of fixing the statutes of the company. The capital is fixed at 250,000f. (about £21,000), in five hundred shares of 500f. (about £12.) Four hundred shares have been taken up already, and the remainder must be placed before the end of 1892, at a rate not under par. The building and plant of the old quinine works have been taken over by the new company for the sum of 135,000f. (about £11,250.) Mr. W. Sieger has been appointed managing director of the works, and will be assisted by Dr. E. Sapper as technical manager. A board of five directors has also been elected, which includes Dr. J. E. de Vry, the quinologist. Of any profits made by the concern, after deducting 10 per cent for wear and tear of the plant and 5 per cent. for the factory buildings, the shareholders are to receive a dividend up to 5 per cent. per annum on the amount of their shares. Any residue, in so far as it is not affected by the terms of the agreement with Messrs. C. F. Bochringer & Sons, of Mannheim, be divided between the board of directors and the shareholders, in the proportion of 20 per cent to the former and 80 per cent to the latter.—*Chemist and Druggist.*

PETROLEUM AND COAL are thus noticed in the London letter of the *Indian Engineer*:—

A letter has been published in *Engineering*, from Mr. C. B. Dudley, who was appointed last year by the Pennsylvania Railroad Company to investigate the system of burning petroleum as fuel in use on the Gras-Tsaritzin Railway in Southwest Russia, to Mr. Urquhart, the Locomotive Superintendent of that line and inventor of the system. Mr. Dudley's letter is an emphatic testimonial to the success of the apparatus, and states that, after fitting up a locomotive with it and testing it thoroughly on their railroad, his principals are glad to speak to its entire success and "regard it as a great misfortune that the relative price of coal and oil in this country, and our rather limited supply, will not warrant us in adopting your system for all our fuel consumption." As this letter is recent, bearing date July 7th, 1887, it has an important value in the controversy whether petroleum is or is not practically serviceable as a fuel for steaming purposes. The question of relative economy is another matter and will have a different answer at every different locality. It may be mentioned that, as the result of a long experience, Mr. Urquhart finds that 53 tons of petroleum-refuse are equal to 100 tons of coal such as was formerly used on his (Russian) railway.

CONSULAR REPORTS ON CHINA TEA.

Few documents afford more valuable information than do the reports of British Consular Agents abroad. They touch on nearly every topic of interest, and there are few home journals, of a specialist character or otherwise, which do not largely extract from them. Our latest London letter makes reference to some of them which afford us instructive information as to the growing alarm felt in China regarding the rapid supersession of the tea grown in that country by the similar product of India and Ceylon. The writers of the reports do not fail to recognize the importance of this matter. For several years past, it is true, the exports of tea from China have been falling off, but the results of the latest season have shown this to be so pronounced that the hopes which had been entertained of the decrease in export being but of a temporary character appear now to have been wholly given up, and the reports in consequence teem with suggestions as to how the evil day, which shall see China teas almost entirely excluded from European markets, may best be averted.

The most prominent of these suggestions appears to be that the cheaper teas of China shall be blended with a small proportion of Indian or Ceylon tea. The Consuls do not seem to be aware of the large extent to which this has always been done,—with Assam tea, at least. The idea that the finer growths of China tea may still retain their former pre-eminence in the markets of the world would seem now almost to be abandoned. Russia, the country from whence hitherto the demand for very high class teas has mainly come, is, it is stated, no longer disposed to pay the high prices for such descriptions as she has, up almost to the present day, been willing to pay. We have no information as to the causes which may have given rise to this disinclination. It may be either that in common with similar experiences in the rest of the world the large fortunes (accumulated in the Tsar's Empire under the old days of serfdom) have dwindled down so considerably that even the magnates of that country have to paretise a previously unknown economy, or that a taste for Indian teas is being gradually introduced into Russia, and has caused a cessation of the demand for the more costly productions of China. Whatever the cause may be, it seems to be certain from the statements of the British Consuls at the several leading Chinese ports that a free market can no longer be found either in Russia or in other European countries for the finer varieties of China tea. In the opinion of those gentlemen the trade of the future must be in the coarser description which can be sold in London for about six pence the pound. It is held, apparently, that neither India nor Ceylon can possibly compete with China in such descriptions, and consideration being given to the cheapness of land and labour in the Celestial Empire, and to the abundance of its water-carriage, we should hold it to be extremely probable that such a conclusion is correct even after export taxes and Mandarin "squeezes" are taken into account. But at the same time it is fully recognized that, by themselves, such teas have no chance of meeting with ready acceptance by European tea drinkers, and the recommendation to which we have above referred that such growths should be blended with a "few pennyworths" of Indian tea by the home dealers is put forward as a suggestion for overcoming such a disinclination.

How far Ceylon tea may be equally suitable to that of India for the purpose of such admixture, is a question which our planters may do well to consider. If the suggestion made by our Consuls is adopted to any wide extent than at present by the home dealers, it may have a sensible effect upon the amount of sale of Indian tea, and experts seem to think that the delicate flavouring of Ceylon tea does not lend itself so freely for such admixturing as do the more highly tannin charged teas of India. It will be generally admitted, we think, that the super-excellence claimed for Ceylon over Indian teas is based upon the fact that, while yielding a liquor of equal fragrance and strength with the latter, the former are free from the roughness of taste due to the presence of that excessive amount of tannin which the larger proportion of teas grown in India possess. In one sense, of course, this fact has for ourselves a decided advantage; but it must undoubtedly militate against our successful competition with India if the blending of the cheaper teas of China with Indian tea is very largely carried out. Now it is well-known that the higher the elevation at which tea is grown in Ceylon the less the proportion of acridity noticeable in the leaf. Indeed, we know by a letter on the subject which we publish below, that some tea grown on a small garden possessed by Mr. John Ferguson at Nuwara Eliya had been declared by home experts to be of a quality deserving special classification in the London Market, and such classification has only been denied to it because of the exceedingly limited quantity produced. May it not be deduced from this that teas grown on "lowcountry" in Ceylon may be expected to possess the very quality that may fit them to compete with the more highly tannin-charged teas of India for the purposes of the blending recommended? If such could be shown to be the case, it might prove ultimately to be very profitable for the owners of low-lying estates to send home teas specially prepared and branded as adapted for blending purposes. Some course of this kind would appear to be desirable if the full extent of land suitable for tea cultivation in Ceylon is ultimately to be made profitable. It will be to the interest of our planters to try and meet all and every exigency of demand, and we have pointed out this special one as deserving of their attention.

At the same time, we believe, the growing tendency in Britain is more and more towards using Indian and Ceylon Tea pure and simple, letting inferior China kinds severely alone. The tendency has, of course, increased and will increase as first quality. Indian and Ceylon teas are obtained at prices which make them better value than China teas at still lower rates.

TEA GROWN AT HIGH ELEVATIONS IN CEYLON.

(From our Special Correspondent.)

When Mr. Arthur Thompson, of the well-known London Tea-broking Firm of Messrs. W. J. & H. Thompson visited Ceylon, he was struck by the delicate and superior flavour of teas he tasted in the neighbourhood of Nuwara Eliya, the sanatorium of the island. If there were a sufficient quantity grown at this elevation, it could well be classed separately as "Ceylon-Darjiling" and sold at prices equal to, if not above, those got for the fine delicate teas grown around Darjiling station. But, inasmuch as the Nuwara Eliya tea district, or indeed the area of

tea gardens in Ceylon, as yet above 6,000 feet is very limited, the teas from that region which have so far reached the London market have been necessarily classed with other Ceylons, yielding a much stronger liquor (though with less delicate flavour) and have not realized such good prices as such teas bought very much for mixing purposes.

When Ceylon tea was first introduced to English housekeepers, many thought it too strong and preferred mixing it with China, and this objection is still expressed by some to average Ceylon teas, although they are admittedly less strong and harsh than those from India, and although carefully prepared blends are now freely available in the home market. It was interesting, therefore, lately to get the opinion of a number of people both in England and France on samples of tea grown and prepared in Nuwara Elliya at 6,500 feet above sea-level, These teas (unassorted) have met with general acceptance, indeed marked approval, and it is curious to find how the testimony of private consumers—who know nothing of marketable or analytical tests—confirms what experts and chemists report of such tea. For instance an invalid lady wrote after having a pound weight of the tea referred to (from "Naseby" garden, Nuwara Eliya):—"This is the first Indian or Ceylon tea I have ever been able to get that seems to suit a weak digestion; always previously my mucous membrane has been affected, and disagreeable after effects have prevented me using such tea." Not much importance was attached to this opinion, until a sample of Naseby tea sent to Mr. John Hughes of Mark Lane for his personal use, but without any thought of provoking a special test, much less a chemical analysis resulted in the following communications which so exactly bore out and gave the scientific explanation of the invalid lady's experience. Mr. Hughes was good enough to write as follows:—

Analytical Laboratory, 79, Mark Lane,
London, E.C., Sept. 16th, 1887.

Thank you for the tea from Naseby estate which I omitted to refer to when writing from the country. We have tasted it practically at home, the opinion being that "the tea yields a good deep liquor with fine flavour but wanting in strength." Wishing to submit this opinion to a chemical test I find that there is only 6·37 per cent of soluble tannin as against 10·12 and 15 per cent found in some of the teas examined last year from the Colonial Exhibition. The ether extract is only 2·35 per cent, and there does not appear to be any resinous matter present, and in this respect it quite agrees with other teas grown at a high elevation. I hope to have the full results ready next week and will send them on; as so far they quite confirm the opinion that the *strength* of a tea *chiefly* depends upon the proportion of *tannin*. I have another sample of Ceylon tea sent me for a report, so the matter is of additional interest.—Yours faithfully.

JOHN HUGHES.

Analytical Laboratory, 79, Mark Lane,
London, E. C., Sept. 21st, 1887.

Sample of tea marked pure Ceylon Tea from Naseby estate, 6,500 feet elevation, Pekoe Souchong flavour, received from Mr. John Ferguson, Colombo, Ceylon.

Moisture dried at 212° F.	7·30
Chlorophyl and oil	2·25
Soluble tannin	6·37
Other soluble organic matters	29·03
Soluble mineral matters	2·50
Vegetable fibre and insoluble organic matters	49·62
Insoluble mineral matters	2·93
	100·00

The mineral matters contain

Containing Nitrogen	4·40
„ Potash	2·11
„ Lime	·56
„ Phosphoric acid	·65

This tea yields a rich deep brown liquor of fine flavour and is only wanting in strength.

JOHN HUGHES, F. C. S.,
Fellow of the Institute of Chemistry,
Consulting Chemist to the Ceylon Coffee Planters' Association.

The small proportion of tannin fully explains the good opinion entertained of the tea by invalids and others who find very strong teas disagree with them. High-grown teas of this description should be very suitable for use in the Continent of Europe, more especially France, where delicate flavour and mild teas are in great repute. At Vichy the tea which Mr. Hughes analysed above was very greatly approved. It may be well to mention these facts for the benefit and encouragement of tea growers at a high elevation—say from 5,500 to 7,000 feet in Ceylon. They cannot expect quite such heavy crops through abundant flushes of leaf as their neighbours lower down, nor may their teas be so useful to the Mincing Lane buyers for mixing purposes; but it is something to have a growth which can be thoroughly recommended for direct consumption by special classes who enjoy delicate, high-flavoured though mild tea. And very shortly as production increases we may expect to find even in the principal and central market of the world—that best and final test of value, namely in Mincing Lane,—a demand spring up which can be met and sustained for "High-grown Ceylon-Darjeelings."

THEINE IN GREEN TEA LEAF.—Dr. Hassall, in his work, "Food: Its Adulterations and Methods for their Detection," 1876, gives twenty-five determination of theine in genuine teas of which the lowest is 1·08 and the highest 3·04 per cent. Relying upon these figures, which are for both black and green teas, I reported the theine in Torwood estate dried green tea leaf as unusually high, seeing that the average amount yielded by the four samples analysed was 5·39 per cent of anhydrous theine. Yesterday I happened to turn to the article "Theine" in Wynter Blyth's Dictionary of Hygiene, 1876, and found the following:—"Theine (caffeine $C_8H_{10}N_4O_2$, $H_2O = 194 \times 18$) an alkaloid obtained from tea, and identical with caffeine. It is extracted from tea in the same way as from coffee. The best gunpowder tea contains fully 6 per cent of theine." As the above formula represents theine crystallized with one molecule of water, if we substract 8¼ per cent for water of crystallization, it appears that the best gunpowder tea, which of course is a green tea, contains 5·49 per cent of anhydrous theine. This agrees very closely with 5·39 the average percentage found in Torwood estate dried green tea leaf.—M. COCHRAN.

TEA.

Few industries have undergone more changes during recent years than the tea trade. Whether we consider the countries that supply it, the method of its carriage, or its price, the difference between now and, say, even twenty years ago is striking. Before the opening of the Suez Canal, when all shipments had to be made by the Cape, the fastest clipper ships that could be built were employed in the trade. Many a tale is told of the marvellous feats in sailing of the "Taeping," the "Ariel" and their sister ships. They were the greyhounds of the ocean, carrying a press of sail when other vessels were close reefed, often

losing a spar, but never foundering. Guided by consummate seamanship, and manned by picked crews, they did the passage from China in an incredibly short space of time, and the first to arrive won the substantial prize of £500. The tea race with the new season's tea is still an event in Mincing-lane, but the clippers have disappeared. With the opening of the Suez Canal they had to give place to a different type of vessel—to steamers of modern construction, with high speed. The tea trade has brought into requisition what is now known as the modern fast steamer of the "Stirling Castle" type, which performs the journey from Shanghai to London in less than thirty days. Yet another change seems now to be impending. The Canadian-Pacific Railway is experimenting on the carriage of Japanese tea, in order to show that the route across the American Continent is quicker than by the Suez Canal. It remains to be seen whether the railway will be able to divert any appreciable quantity of China tea freight from the Suez Canal. Operators in China are said to prefer to ship by steamers direct to London, because tea transhipped *en route* often reaches this country in a broken condition, but there are ways and means by which that can be prevented.

The spread of Temperance and the fall in the value of tea have greatly increased the consumption. Thirty years ago about 63 million pounds of tea were used in the United Kingdom, the amount consumed being a trifle over 2¼ lb. per head; while the duty was about 1s 9d per lb., and the average price of the imports about 1s 3d per lb. At the present time we are using about 182 million pounds, or 5 lb. per head, the duty being 6d per lb., and the average price of our imports 1s per lb. The tea season commences about the middle of the summer, when the new teas, picked in China in April and May, arrive in the Thames. Indian teas come later, and are in full supply in August and September. As the teas arrive, they are conveyed to a warehouse, where the various consignments have to be classified and catalogued preparatory to being sold. The cataloguing is a tedious, but important, operation. The packages have to be described as well as the tea itself, and all marks have to be specified. Teas of the same character, and about the same quality, are put together, constituting what is known in Mincing-lane as a "break." During the sale, the broker uses his discretion in dividing the "break" into lots. Thus if there are 100 boxes altogether, he may put them up in tens or twenties, but it is important to have large "breaks," and to avoid the division of tea into too many varieties. It is an understood custom of the auctions that the buyer of the first lot in a "break" is entitled to bid for all the rest, and the selling broker usually runs them off to him at the same price as the first lot. But should he drop a lot, then any other buyer is free to bid.

Until the last few years the world had to rely upon China for its tea supply, but India and Ceylon are already formidable rivals. It will surprise many to learn that in May last the imports of tea from India and Ceylon exceeded those from China in the proportion of 51 to 49. That never happened before, nor has it happened since, but there can be no doubt that before long we shall receive the major portion of our tea from India and Ceylon. The Chinese over-reached themselves. Under the impression that foreigners must have their tea, the Chinese merchants supplied an inferior article, but they did not take into account that other countries were beginning to produce tea. The production for export of China teas appears to have reached its climax in 1879, when the previous speculative rise in prices flooded us with an enormous amount of re-dried rubbish, and this materially served to increase the popularity of the Indian growth. China, being a producing and consuming country, can use re-dried leaves for export, while in India the home consumption is small, and not being in the producing districts there is no fear of the tea being doctored in this way. Of course, the deterioration of the Chinese teas sent to the English market is not altogether the fault of the Celestial; at any rate, he was encouraged to ship inferior teas by the demand for a cheap article. It was largely a question of price. In England people bought poorer teas because they wanted something that costs little, and the Chinese ministered to the want by sending qualities which a coolie in Canton or Yokohama would reject. The best qualities they reserved for themselves, and for the Russians, who are willing to pay a long price for a good article.

The cultivation of tea on Chinese methods was first attempted by the Indian Government in 1834. Chinese seed was introduced, but experience has shown that the most profitable plant is a hybrid between the indigenous and the Chinese varieties. In 1839 the Assam Company, which remains the most important of the Indian tea companies, took over the Government garden in Assam, which is still the great home of the industry, though tea-planting is also securely established at Darjeeling, in Bengal, along the foot of the Himalayas as far west as Simla, at Chittagong on the further side of the Bay of Bengal, and on the Nilgiris, and other hill ranges in the south. The increase in the exports of tea may be gathered from the following Government returns:—

Year.	Quantity.	Value.	Average Value per lb.
1883-4	lb. 19,324,235	£1,742,924	1s. 9·00d.
1882-3	57,766,225	3,699,496	1s. 3.36d.

In these ten years the quantity increased by 198 per cent., the value by 113 per cent., the average value per pound having fallen from 1s 9d to 1s 3d. Competition is certain to reduce the price much lower, and the managers of the tea gardens have been advised that if they are to hold their own they will have to limit the cost of production to 6d per lb. In Ceylon the progress of tea cultivation has been even more marked than in India. The development of the Ceylon tea trade, unlike that of India, has been rapid. India commenced the cultivation of the shrub with unskilled planters, and inappreciative markets. Ceylon benefited by the experience gained in the Indian gardens, which enabled her planters to avoid the mistakes made in early days by the Indian managers, who knew little or nothing about tea-planting. Ceylon, too, was fortunate in supplying a high-class article at a time when China was sending inferior tea to the European market. The result is that Ceylon teas have rapidly gained in public favour, until now there is hardly a grocer's shop in which "Ceylon Tea" is not a conspicuous article of sale. The rapid growth in Ceylon exports of tea is shown by the following figures, which we take from Messrs. Baker's excellent "Trade and Finance Annual":—

Year.	Area Planted. Acres.	Total Exports lb.
1867 to 1873	10 to 250	Nil
1883	32,000	1,999,687
1886	140,000	6,750,000

It is noteworthy that the Anglo-Saxon is the principal tea-drinking race in the world, and that none drink so much tea as the Australians, who consume 7·66 lb. per head, as compared with 4·90 in England, and 1·30 in the United States.—*Echo*, Sept. 28th.

THE AGRICULTURAL PESTS OF INDIA AND OF EASTERN AND SOUTHERN ASIA.*

In 1885 Dr. Balfour, the idefatigable author of that marvel of Oriental knowledge, the "Cyclopædia of India," suggested to the India Office authorities the expediency of requiring annual reports, describing "the insects which injure the agricultural, horticultural, and forest produce of India, suggesting means of preventing, and remedies." These reports, the writer thought, should be restricted to the injurious insects, and he referred to the valuable experience acquired by Miss Ormerod (who, as is well known,

* "The Agricultural Pests of India and of Eastern and Southern Asia, Vegetable and Animal, Injurious to Man and his Products." By Surgeon-General Edward Balfour. London: Bernard Quaritch. 1887.

annually reports, as to this country, on the injurious insects prevalent, and the means of checking their ravages) as supplying hints for the procedure to be followed. The advice seems to have been taken; and some valuable suggestions, by the lady entomologist referred to were communicated to the Government of India.

The amount of damage sustained by the Indian cultivator may be in some degree inferred from occurrences which took place a few years back in Ceylon, where the produce of the coffee crop was, in a few seasons, reduced, by insect ravages,* from 4½ cwt. per acre to less than 2¼ cwt., or by more than one half; the total loss being estimated at fifteen millions sterling in ten years. To turn to the cotton crop in India, the value of which is roughly put at seven crores of rupees annually, we are told by the United States Agricultural Commissioner that, in parts of India "one-fourth of the value of the cotton crop is sometimes lost from the ravages of the larvæ of one insect."

Pending fuller inquiry, Dr. Balfour has has deemed it well to collect, for present information, what is already on record respecting Indian Agricultural pests of all kinds, with especial advertence to insects and fungi. Besides adopting the alphabetical form of arrangement—assuredly the best where so many facts have to be marshalled under various heads, as regards the "pests" themselves, the author has enhanced the value of the little work by naming, under the appropriate heading, the principal enemies of each crop. Thus, under "coffee" we find (p. 43) a list of no less than twenty-seven foes against whom watch and ward ought to be kept on behalf of this important, yet delicate and vulnerable object of cultivation. Wheat, at p. 113, poppy and rice (pp. 93 and 99), silk, tea with its table adjunct, sugar, (pp. 101 to 109), are in turn duly dealt with their many foes, while in a growing state being enumerated, and the means of prevention indicated. A chief measure of protection seems to be, in India as here, a frequent change of crops. As the author well reminds us, "Each insect species has its own particular plants, on which alone it lives, and, when deprived of food by a change in cultivation, they die." Certain crops, too, have a direct effect in killing off certain tribes of "pests." But something more than this method of procedure—at best but partially applicable in India—seems to be needed; nor will washings or syringings, such as those suggested as a *pis aller* in the introduction, suffice to combat the enormous fecundity of the insect world. When we read that, even in Europe, five generations proceeding from a single aphis (plant-lice) reach the number of six thousand millions, we may well despair of realising the magnitude of the evil with which we have to cope. Nature has, however, been by no means niggardly in according us help: and Dr. Balfour, in giving the fullest particulars as to the enemies which beset each insect tribe, and which may be taken as being nature's appointed means of combating its ravages, has indicated a weapon which ought not to be allowed to rust. He has succeeded in compressing, within the compass of 120 pages, adequately, full, and wholly trustworthy details respecting insects, reptiles, and mammals injurious to man and his products, and has added yet another to the many obligations under which he has laid all who are interested in the welfare of India, and the prosperity of its agriculture.—*Allen's Indian Mail.*

* As our readers are aware, although black bug and brown and white grub did much harm to coffee, the great enemy of the plant was a fungus.—ED.

SUGAR.

After corn and meat, sugar has become one of the chief foods of the people of the United Kingdom. The consumption per head of population is now not short of 75 lb. a year, including the sugar in articles exported. At an average retail price of 2*l.* the 1 lb., this will be 12*s* 6*d*. In France the consumption per head is about 30 lb. only; but the retail price there is very much higher than in Great Britain. In Paris sugar is twice as dear as in London. In Germany, also, the retail prices of sugar are much higher than with us, and the population can only afford about 20 lb. per head. The Belgians take about the same quantity per head as the French, and the Dutch the same as the Germans. In Austro-Hungary the people can afford only about 14 lb. In Russia the consumption is less than one-ninth per head of what it is in Great Britain. The retail price of sugar in all these countries due to fiscal arrangements and a strong protectionist policy, is far higher than in the United Kingdom; sometimes double the price, and even more in places. It is well known that the people on the Continent of Europe have a liking for sugar and sugared goods, equal to if not greater than the people of these islands; therefore, if sugar could be had in those European countries for about the same prices that prevail in Great Britain, it is at least probable that the consumption per head would be equal to half that of the people of the United Kingdom. The Continent of Europe would, under these conditions, require about six million tons more sugar annually. Were the European people allowed by their Governments to have sugar cheap, they might even consume the same quantity per head as do the inhabitants of these islands. In this case an additional supply equal to three times the present average yearly output of sugar in the world would be wanted beyond present requirements to meet this extra demand. There can be no doubt the people of the Continent would be glad of a considerably larger supply of sugar for domestic purposes were the price such as to bring the article more within their reach.

A considerable rise in the price of sugar in the United Kingdom would cause a falling off in the consumption, but not to the standard seen on the Continent; because the people of these islands have higher wages, and have been accustomed to the greater supply for their tea and other purposes, and would not relinquish it except under much stress. The use of sugar for many purposes of manufacture would also be checked were the price to rise permanently.

When a people have become accustomed to the use of a commodity on a great scale, it has been noticed that should it afterwards become scarce, or the supply be necessarily reduced, due to greater cost, substitutes are usually forthcoming to, as near as possible, take its place and fill the void at the old price. The rise of the beet sugar industry was primarily due to the impossibility of the French getting cane sugar from the West Indies during the Napoleonic wars, and it was afterwards revived and continued owing to the then very high price of this cane sugar. Should the prices of beet and cane sugars be raised materially beyond recent market prices, we should probably see substitutes making their way in the markets of the world. Machinery and applied chemistry are now approaching that advanced stage of perfection that any raw product whatever known to contain saccharine matter, and from which the sugar may be extracted, will be certain to be utilised if it happens to come within that range which admits of a commercial profit being made out of it. It is well known that enormous amounts of raw material exist (such as the Mahwa flower—corollas of *Bassia latifolia,*) which a perceptible rise in the cost of cane and beet sugars would enable manufacturers to utilise.* Even with cane and beet sugar at their present low prices, an (inferior) article to compete with them, has recently been largely made in the United States. The manufacture of glucose from Indian corn (one bushel of corn is said to yield 32 lb. of glucose) employed 20 factories in 1884, capable of turning out 20,000,000 dols. worth annually, the present output being about one-third of this. This sugar (which may be marketed in the States at from 1*d.* to 1½*d.* per lb. retail, if not for less) possesses only about two-thirds the sweetening power of cane sugar.

* The value of the Mahwa flowers was greatly exaggerated. It is simply a poor article of sweet food for the natives.—ED.

It is used for adulterating cane sugar, canning fruits, manufacturing artificial honey, and in the making of American confectionery, of which so much is now seen in Europe.

With regard to beet sugar, it is generally assumed that the success of the industry of its manufacture is mainly owing to the bounty system. The making of beet sugar has, without doubt, been forced into unnatural proportions by bounties on exportation, and the ultimate and inevitable heavy losses to those engaged in it will, for this reason alone, be only a question of time, not very remote. In many instances the losses have already been serious, especially in Austria and Russia. It must not be forgotten, however, that the sugar cane industry has often been, and is even yet at places, forced by artificial methods which were and are not only as economically unsound and hurtful to a community as the beet bounty system, but morally hurtful also. Fifty years ago cane sugar was entirely grown by slave labour, and to this day the growers of this produce—in British Colonies chiefly—maintain that they cannot raise it successfully by really free labour; they say they require a specially imported low-priced labour, under restrictions—conditions entirely incompatible with what Britons deem to be the rights of free labour in a free community.*

A system of bounties for growing beet might have served a purpose at the time of its inception (the beginning of this century), and its continuance would have been less hurtful had the Governments not been led astray by the interested clamours of manufacturers who sought illicit profits. A bounty on the growth of beet for home consumption only was the original intention, and there was something to be said in its favour in those days when colonial trade in sugar was forced by the owners of colonies into certain channels by restrictive laws, and cane sugar was consequently scarce and dear, and held by monopolists. But when beet sugar manufacturers subsequently perceived that a drawback on exportation would leave them a larger profit due to miscalculations—chiefly made purposely—of drawbacks, than they could obtain by the home sale, they eagerly seized the opportunity, and forced the export market to the front; and the struggle since then has been chiefly in this direction. It is inexplicable how the enlightened Governments of France and Germany should have allowed this development to its present huge proportions. The consequences are that the French and German, instead of profiting by the beet industry, are actually enormously heavy losers by it, and it would have been preferable for them now had there never been any such industry. This is not the usual view taken, but it is the true one. The French protect their corn industry, but only on condition, or at least on the assumed condition, that bread be no dearer in Paris than in London. They do not succeed in this, because the duty on corn and flour does enhance the price to the consumer very materially. Had the manufacture of beet sugar been protected as a home industry for home consumption only, like corn growing, it would similarly cost the French people a good deal to keep it up. But now they have not only to pay this cost, which means paying more than double its real market value for all the sugar they use, but they have been paying something like 32,000,000 francs a year to foreigners for taking that portion of their home-manufactured sugar which by right they should have taken themselves.

In the United States the sugar consumption is abou 52 lb. per head a year. The amount of duties levied on sugar and molasses per head of population is about 90 cents. But, of course, the real purchaser will have to pay more than this added duty. Every charge added to the prime cost of an article in the United States enhances its retail cost to the consumer by at least one third more. This will make Americans pay about 1 dol. 20 cents per head for keeping the system on foot. This is equivalent to a tax of a dollars per family. Notwithstanding all hindrances, the consumption of sugar is increasing in the States, and it is estimated that in ten years, with a population of 70 millions wanting the same supplies per head as Britons do now, nearly 45 million hundredweights of sugar will be required each year. This would necessitate an increase of about 70 per cent in the present cane growth of the countries which export cane sugar.

The object for sugar growers everywhere should be to keep steadily in view, and to prepare the way for the future supplies that will be needed in the world, and not to make efforts, which will be futile for any permanent purposes of individual or national wealth, to restrict supplies from any quarter. The markets of the future will be under such conditions of supply and demand that the national losses made by those countries which pursue the bounty system on exports, and which are being more heavily felt year by year, will be too great and too manifestly purposeless to be kept on foot, no matter how powerfully supported they may be by the interests which now profit by them. There is something to be said for Russia, usually not deemed more forward than its neighbours in economic questions, that its Government should have recently abandoned bounties on sugar exports as soon as it became manifest to the understanding of its financial guides that they served no good purpose, while they weighed so heavily on an already over-taxed population.—*Scotsman.*

* The true state of the case is that at the rates of wages demanded by the negroes the sugar industry in the West Indies could not be carried on. Hence imported labour for which employers pay.—ED.

JAMAICA.—We learn from the *Colonial Standard* that the banana cultivation in this island has sustained much damage by heavy rains which fell during the 22nd, 23rd and 24th of last month. On one plantation alone 1,500 trees, nearly all of which were in bearing, were blown down.—A local Fruit Company has recently been started, and it is anticipated that it will be the means of breaking in time the foreign monopoly in the fruit trade which has so effectively kept down the petty cultivators of fruit. *Dominican*, Aug. 25th.

THAT WEST INDIAN SUGAR ESTATES unencumbered can be carried on with profit, even at the present low prices, we have ample proof from the trustee's report in *re* the estate of Messrs. A. Ambard & Son. After allowing for loss by exchange, the working of the "St. Augustin Usine," under the receiver, shows a surplus of 1,400*l.*, besides the profit on the sugar manufactured from purchased canes. Indeed, the bankruptcy assets are likely to benefit to the extent of nearly 4,000*l.* through the cultivation having been carried on by the trustee. Then, with regard to the "Trafalgar" estate, the property of Mr. L. F. Ambard and Mr. G. A. Cadett, the crop, about finished, will be 670 hogsheads of sugar and 400 puncheons of molasses, which, at 8*l.* per hogshead and $9 per puncheon, will net about $29,000. The outlay, therefore, of $2,708·88, which would have been lost to the creditors had the estate not been carried on, will not only be recouped, but there is likely to be a surplus for the creditors of $1,600, which will be further increased by the proceeds of canes from outlying lands sold to St. Augustin Usine. The estates of "Golden Grove" and "Florisante" are also expected fully to cover the expenses, including the extra money spent upon them by the trustee. Under these circumstances, it is not surprising that many of the largest creditors on this side should be anxious that the working of the estates should be continued under the receiver for another year in the hope of further improvement. Already, we believe that Messrs. A. Ruffer & Sons, Mr. James Nourse, Mr. Edward Carpenter, on behalf of the Colonial Bank, and Mr. B. G. Gray, on behalf of the Mercantile Banking Company of London, have signed a document to this effect, and an expression seems to prevail that the majority of the continental and American creditors will adopt this view. We should add that it is not proposed that "The St. Augustin Usine" should be continued to be worked by the trustee.—*Grocer and Italian.*

TROPICAL PRODUCTS.

Die Tropische Agrikultur. Ein Handbuch für Pflanzer und Kaufleute. By H. Semler, in San Francisco. Wismar i/M. (Germany): Hinstorff'sche Hofbuchhandlung. 1886. 15 Marks.

The first and second parts of the first section of this voluminous and interesting work have just been issued. The author is a German-American of globe-trotting proclivities, who has resided in various parts of the tropics, notably in South America and Western Africa, and who has recently attracted considerable attention in Germany by publications on agricultural questions as affected by the American competition in foodstuffs. In the present work Mr. Semler describes the principal useful plants growing in the tropics from a practical point of view. So far not many plants of special interest to the pharmacist have been mentioned; for the majority of these we must await the issue of the second volume. In the book before us we find hints to planters concerning the choice of plants for cultivation, descriptions of the most useful implements; chapters on tea, coffee, cocoa, the various varieties of palms, kola nuts, guarana, coca and yerba maté. From the last four articles we quote some particulars:—

KOLA NUTS.—The botanical name of the tree yielding the kola nut Mr. Semler states as being undefined, and quoted by various authorities as *Sterculia acuminata*, *Sterculia cola*, and *Cola acuminata*. We should have thought that there was no question as to the first being the correct designation. It is also mentioned that slave dealers were in the habit of carrying with them a supply of kola nuts, for administration to their slaves as an antidote to the suicidal mania with which from time to time they were afflicted, and that it was through these slave-dealers that the kola nut was introduced in the West Indies, Mexico, Brazil, and Mauritius. In these countries, however, the white population have never paid the slightest attention to the tree, of whose presence in their midst the vast majority are quite unaware. A regular export trade is even carried on in kola nuts from Lagos and Loanda to Brazil. It is also suggested that a large proportion of the kola nuts imported into England are used in the preparation of low-grade chocolates, with the addition of a little cocoa.

GUARANA.—In a note on guarana the author states that the word is derived from the Guaranis Indians, which tribe are said to have first prepared the paste. Afterwards the tribe of the Mauché Indians usurped the monopoly of the preparation of guarana, but at present the paste is prepared by Indians and whites alike. The use of guarana has greatly increased in Brazil of late years, and it does not speak for the energy of the natives that they have as yet taken no steps to cultivate the guarana tree. The fruits of the tree are gathered in October and November, and opened with a hammer or stone, and the seeds, of which each fruit contains from two to six, of the shape of a horse-shoe, are abstracted. These seeds are dried in the sun or at the fire until the white skin with which they are covered may be rubbed off with the hand. They are then pounded in a mortar, and kneaded into a dough by the addition of a little water or dew. To this dough a certain quantity of coarsely powdered or whole seeds are added, and the mass is then either formed into balls or, and more frequently, into the sausages which are known to European druggists as guarana paste. The sausages or balls are baked in the sun or by artificial heat, and sent to the market in banana leaves or mats. An inferior quality of guarana is prepared by mixing cocoa or cassava with the seed, but this quality may be distinguished from pure guarana by its paler colour and comparative softness. Nearly all the guarana collected in Brazil is taken to Santarem, in the province of Pará, a town of about 6,000 inhabitants, situated on the right bank of the river Tapajos, near its confluence with the Amazon, and which trades chiefly in cocoa and the medicinal products of the country. The average quantity of guarana brought into this town is estimated at 16,000 lb. per annum. On the Santarem market the price of guarana is generally about 9*d.* per lb., but at the original points of collection, which are mostly situated on the Rio Negro, it is much less.

This statement of Mr. Semler's is in singular contrast with that in Messrs. Gehe & Co.'s last report (*vide The Chemist and Druggist of* September 25) that it seems to be the fact that it does not pay the Brazilian shippers to export guarana if the European price is less than 6*s.* per lb.

YERBA MATE.—Writing on yerba maté, Mr. Semler remarks that it used to be a common idea in Europe that this drug was obtained from the *Ilex paraguayensis* only, while as a matter of fact five other varieties of holly yield the leaves, although the *I. paraguayensis* is the most important among them. Neither Hager, nor Stillé and Maisch, however, speak of maté as being derived from any other variety than the *I. paraguayensis*.

The *Ilex paraguayensis* is common in Southern Brazil, in Paraguay, in the Argentine State of Corrientes, and in the territories of Gran-chaco and Missiones, and is generally found in large rows called yerbales.

Among the native Indians the tree is known by the name of caa. The word yerba is Spanish for herb, more particularly medicinal herb. Maté is derived from the ancient Inka language, and originally meant a gourd or a vessel.

Among the South American Indians yerba maté has been in use for centuries, and at present its consumption in South America is still increasing largely. Brazil exported in 1880 over 28,000,000 lb. of maté, of which fully one-third was contributed by the province of Parana. Of this quantity 23,000,000 lb. went to the Argentine Republic. The exports from Paraguay amount to only about 5,000,000 lb. annually. Chili and Peru take about 1,000,000 lb. between them every year. The consumption of maté in the Argentine Republic reaches the excessive figure of 13 lb. per year per head of the population, and this fact explains the large consumption of sugar in that country, which in this respect ranks next to England and the United States. On the South American markets three distinct varieties of maté are known. The best quality is termed caa-cuys; it is prepared from young leaves, still partly hidden in the bud. Full-grown leaves, carefully selected and frequently divested of the central vein form the second quality, or caa-mira. The lowest quality, or caa-guaza, is composed of old and carelessly-cured leaves and of stems. In South America the maté trade centres in two little towns, Villa Real on the Paraguay, north of Assuncion, and San Xavier for the territory between the Uruguay and Parana rivers.

COCA.—Fifteen pages are devoted to coca culture, on which subject a good deal of interesting information is given. According to Mr. Semler, the Bolivian Government derive an annual revenue of some 40,000*l.* from the lease of wild coca shrubs. It is pointed out how much the value of the leaves could be enhanced by a rational system of cultivation and proper care in the packing of the leaves, for instance by shipping the leaves immediately after gathering in tin-lined cases. But no such rational procedure can be expected from the natives of South American republics, and it will probably be left to intelligent planters in the British or Dutch colonies to supply the European market with an article which has preserved as far as possible its original freshness.

The author appears anxious to make it known that the idea of the work under notice was not conceived by him in consequence of the development of German colonising enterprise, but that for fully ten years he has been engaged in compiling notes as the basis of a book which should be looked upon as a standard work among the large number of his compatriots engaged in planting and commerce in the tropics. He enumerates several English and Dutch works which have been written on the same lines, but claims for himself and for his nationality the honour of having produced the first complete work. In how far this claim is well-founded can only be judged after the publication of the whole series.—*Chemist and Druggist.*

ROYAL GARDENS, KEW.

(Bulletin of Miscellaneous Information.)

ONION DISEASE AT BERMUDA.

(Peronospora Schleideniana, De Bary.)

It seems as if pests were sure to attack any product largely grown, from potatoes up to coffee; the latest victim is the onion in Bermuda, regarding which we get information from Kew, as follows:—

The current *Bulletin* is occupied with the results of an inquiry conducted under the auspices of the Royal Gardens, into a disease prevalent at the Bermudas affecting the onion crop, which is a staple industry of these small islands. Owing to climate and geographical position these islands are enabled to raise large quantities of early vegetables, which are shipped and sold at New York at a time when the corresponding American produce has as yet scarcely shown itself above ground. The onion crop, amongst others, raised from seed obtained from Teneriffe, has hitherto proved most productive; but owing to causes which are discussed in the following pages, this crop has latterly proved less remunerative. An inquiry was desired in the interest of cultivators, and this inquiry was undertaken by Mr. Arthur Shipley, B. A., Fellow of Christ's College, Cambridge. Mr. Shipley's reports deal with the circumstances connected with raising and harvesting of onion seed at Teneriffe, and with an exhaustive inquiry carried on at Bermuda, while the usual crop of onions was being raised for the American market. The results of the inquiry are given with great clearness by Mr. Shipley, and remedial and other measures are suggested which deserve the attention which no doubt they will receive from the persons directly interested.

We quote some interesting information on the onion cultivation of the Canary Islands:—

There are two varieties of onion grown in the Canary Islands, the white and the red. These varieties are not permanent, but pass into one another under altered conditions of the soil, &c. The white variety is chiefly grown in the Island of Palma and on the south side of Teneriffe, in the neighbourhood of Santa Cruz. Those grown in Teneriffe gradually lose their character, become reddish in colour, and after three years' cultivation are indistinguishable from the red variety. Those, however, grown in the Island of Palma maintain their character unchanged, hence the seed for export is obtained from the latter island. The red variety is grown on the north side of Teneriffe, chiefly in the neighbourhood of Tejina.

The strain of onions is preserved from deterioration by alternating the onion crop with Indian corn, or more usually with potatoes, or by planting the onions in newly cleared ground. Thus the same field does not bear onions in two successive years.

The shipping prices for the onions themselves this year (1885) were from 3*s.* to 4*s.* 6*d.* a quintal (100 lb). for the white, and 2*s.* 6*d.* to 4*s.* a quintal for the red. The white variety comes into the market rather earlier than the red, and thus commands a rather higher price.

On the disease in Bermuda, Mr. Shipley reported fully, and he writes:—

I had the advantage of the assistance of Professor Marshall Ward of the Indian Civil Engineering College, a well-known authority upon fungoid diseases.

This, of course, is the mycologist who reported on our coffee fungus. Mr. Shipley states:—

The disease amongst the onions in Bermuda is caused by the presence of a microscopic fungus which lives parasitically upon the leaves of the onion plant. This fungus is known to botanists under the name of *Peronospora Schleideniana*, De Bary, (*Botrytis Destructor*, Berkeley,) and amongst the onion farmers of the Old World as the Onion Mildew.

It belongs to the same order of fungi as the well-known potato fungus. Its geographical distribution is not well known, but it occurs in England, Germany, and has, I believe, been found in the United States.

The symptoms are then described, and it is observed that:—

The conditions of the atmosphere which are favourable to the development and growth of the fungus, and hence to the progress of the disease, are heavy dews or rains followed by warm, moist, calm weather, and the absence of direct sunlight and strong winds. Shady and sheltered spots are usually the most liable to be attacked.

The land along the south side of Bermuda usually keeps free from the disease, and this freedom from attack is attributed by the planters to the fact that there the onion plants are exposed to the early morning sun and to the prevalent northerly winds, which rapidly cause the dew to evaporate.

The progress of the disease is sometimes arrested, after it has appeared in a field, by cold windy weather and strong sunshine, but this is rarely the case; as a rule, when it has once appeared it spreads with great rapidity, large fields becoming affected in the course of a single night.

The Structure and Life-History of the Fungus *Peronospora Schleideniana*, is very fully given, but we need not quote the technical details.

The power of reproduction of the fungus like that of the coffee pest is great:—

If we take 20 as the average number of spores upon one stem, and that is rather below than above the average, we find that a single square inch of a diseased onion leaf may have the enormous number of (20 × 7,000) 140,000 spores, each capable of reproducing the fungus, and hence the disease.

Some of our planters were inclined to trace the development of *Hemileia vastatrix* to the application of artificial manures, but no evidence supporting this view was obtained. Mr. Shipley, however, writes:—

There seems to be some connexion between the extensive use of artificial manures and the origin and spread of fungoid diseases. The potato is frequently attacked and large crops destroyed by fungus which is nearly related to that causing the onion disease. The potato was introduced into England 300 years ago, and for about 250 years it flourished without, as far as is known, any disease appearing among the cultivated varieties. But about 50 years ago, the Potato Fungus, *Peronospora infestans* (Phytophthora infestans, De Bary) made its appearance, and has never since disappeared. Its appearance was roughly coincident with the first general use of artificial manures. A similar connexion might be shown to exist between the origin and spread of the onion disease fungus, which did not make its appearance till eight or 10 years ago, and the recent extensive use of artificial manures in the Bermudas.

Remedial measures are then treated of. We quote as follows:—

It is important to emphasise the fact that manures must not be looked upon as a means of curing the disease, but simply as a means of strengthening the crop of onions.

With regard to the kind of manure it is the universal opinion amongst the onion-cultivators of Europe and America that natural manures are preferable to artificial. Of these that from the hog-pen is perhaps the best, and an excellent manure for onion is made by putting seaweed under the hogs. Stable manure is also very valuable, but it cannot be too strongly stated that the liquid parts of the natural manures are the most valuable, hence care must be taken to prevent their draining away. The manure should be well rotted; during the fermentation which then goes on it loses little of its valuable constituents whilst it becomes more concentrated. At the same time some of its constituents are rendered more soluble, and hence are more easily washed into the soil and more readily taken up by the plant. If kept in heaps it should be turned once or twice, as by this mean many of the seeds of weeds are destroyed.

Owing to the impossibility of keeping much stock in Bermuda the demand for farmyard manures greatly exceeds the supply. In this connexion it is worth drawing the attention of farmers to the compressed manure which is now being prepared by the Horse Car Companies of New York and Philadelphia, and sold by them at a moderate price.

Another manure which has been highly recommended for onions is wood ashes, either scattered on the surface at the time of sowing or mixed with swamp-muck in the proportion of one load of ashes to 10 or 12 of muck. This is said to answer well, but the large percentage of potash in the ashes might, in my opinion, be dangerous where the onion disease is prevalent, as it has recently been suggested that potash manures foster the development and growth of fungoid diseases.

Guano is a very good manure when used in conjunction with others, but it should not be relied upon to the exclusion of natural manures. Owing to its very variable composition it should always be purchased on analysis, and samples should be analysed from time to time to see that, what is supplied is up to the standard.

There is the old recommendation with which we are so familiar to burn all infected plants, but this is only likely to be the case if the destruction of the refuse is universally practised. It is little use for one farmer to burn the diseased plants if his neighbour does not. And it must always be borne in mind that a small patch of diseased onions, only a few square yards in area, will produce enough spores to infect every onion plantation in the Islands.

It has been shown that the onion disease is perpetuated from one season to another by means of resting spores which lie in the ground during the summer and autumn, and which germinate when the new crop of onions begins to appear. In northern climates it is probable that many of the resting-spores are killed by the frost; unfortunately we cannot reckon upon the assistance of this agent in Bermuda.

Rotating the crops is advised, but mixing arsenic with the soil is not mentioned. Mr. Shipley writes:—

If there is any reason to suspect that the farmyard manure is a means of infection, through some refuse of a diseased onion crop being mixed with it, or from any other cause, it would be advisable to water the manure with a week solution of iron sulphate (F_2SO_4) before putting it on the land. One-tenth of a gramme in 100 grammes of water, or a solution of one-tenth per cent is sufficiently strong to kill the spores of the fungus. Again, if the seed is considered to convey the infection, they may be soaked in a solution of the same strength. This will effectually kill all the spores of the fungus, and leave the seed entirely uninjured.

We now come to Mr. Morris's cure for coffee fungus, effectual if it could have been universally applied:—

The first of the chemical remedies which may be applied to the diseased plants with considerable prospect of success is a mixture of freshly burnt quicklime and sulphur.

There can be no difficulty in obtaining plenty of quicklime in Bermuda, and for this purpose it must always be used when freshly burnt as quicklime loses its caustic properties and undergoes chemical change when kept any length of time. After burning it should be crushed to a powder and mixed with powdered sulphur in the proportion of two parts of quicklime to one part of sulphur.

This mixture may be sprinkled on the diseased plants by hand or more effectively by means of bellows, such as the Kentish hop-growers use for sulphuring the hops.

The mixture should be applied befor the dew is off the plants or after rain whilst the plant is still wet.

The chemical interaction which is produced by the mixture of sulphur and freshly-burnt quicklime leads to the formation of sulphurous acid and other allied gases. The gases are evolved slowly, and being readily diffusible they soon spread over the plant, and being easily soluble in water they dissolve in any moisture in the leaves, &c. The solution thus formed is strong enough to kill the germinating spores without injuring the plant, and it does not become concentrated to a dangerous degree. The final products are not harmful to the plant or soil, and the chief use of sulphate of lime is a valuable manure, especially in Bermuda, where the amount of sulphur in the soil is very slight.

A second chemical remedy which may be used for the onion disease is iron sulphate (F_2SO_4), and this has the advantage of being readily soluble in water, and hence can be applied in the liquid form. When in a week solution the iron sulphate will kill the fungus without killing the onion plant. The solution should contain one-tenth part F_2SO_4 to 100 parts of water. It may even be made as strong as three-twentieths per cent without injury to the plant, but anything stronger than this is like to prove injurious.

The diseased onions may be watered with this, or, still better, sprayed thoroughly. The ground in the vicinity of the affected plants may also be watered with advantage with this solution; in this way any spores which have fallen off will be destroyed.

In addition to its antiseptic properties iron sulphate forms a very valuable manure. In a paper published in the Journal of the Chemical Society, 1886, Mr. Griffiths has described many experiments which all tend to show the value of this chemical as a manure. I will content myself with quoting from his paper the results of one experiment. Mr. Griffiths sowed three plots of ground the same size with potatoes. The first plot of ground was not manured; from this he gathered three tons of potatoes. The second plot, which was well manured, gave six and a half tons; whilst from a third plot, which was well manured in the same way as the second, but with the addition of iron sulphate, he obtained eight and a half tons of potatoes. This is only one experiment out of many which all tend to show the value of iron sulphate as a manure.

The iron sulphate should be applied as a top-dressing after the plants have been transplanted. About half a hundredweight should be used to the acre: more than this is apt to prove harmful.

It has been found that wheat crops grown in fields manured with iron sulphate do not suffer with the wheat mildew, and it is very probable that if the land be treated in the manner indicated, potatoe and onion crops would also escape the fungus.*

Iron sulphate has the further advantage of being very easily obtainable at a very moderate cost.

There is a second fungus found living upon the onion plant. This is known as *Macrosporium parasiticum*, and it is one of the Pleosporous Ascomycetes.

This fungus is only found upon the onion after it has been attacked by the *Peronospora*, when the leaves are already dead or dying. It does not attack the healthy plant.

Macrosporium belongs to that class of fungi which are known as Saprophytes; these are characterised by living upon dead or decaying organic matter. They are unable to effect a foothold upon the healthy plant. Hence if the *Peronospora* can be exterminated the *Macrosporium* will disappear at the same time.

The fact that the *Macrosporium* is, so to speak, a sequel to the *Peronospora*, and that with the extermination of the former the latter will disappear, renders it unnecessary to describe the very complicated and incompletely known life history of the fungus.

The summary of Mr. Shipley's observation and conclusions is as follows:—

1. The onion disease is caused by a fungus *Peronospora Schleideniana*, which lives parasitically upon the leaf on the onion plant.

2. The atmospheric conditions which favour the progress of the disease are heavy dews or rains followed by warm, moist calm weather, and the ab-

* All the remedies suggested for the onion disease apply with equal force to the potato disease, which is caused by a fungus, *Peronospora infestans*, a species distinct from *Peronospora Schleideniana*, but resembling it in its life-history.

sence of direct sunshine and cold winds. If favourable weather the progress of the disease is very rapid.

3. The fungus lives in the tissues of the leaf, choking up the air passages and absorbing the nutritive fluid formed in the cells. Its stem protrudes through the stomata of the leaf into the air. Its branches bear spores at their tips.

4. The reproduction of the fungus is effected by means of these spores which float about through the air, and also by means of certain special cells formed by the fungus and known as resting-spores. These pass the winter in the earth, and are capable of retaining the power of germination for two or three years. It is by their means that the disease is carried on from one season to another.

5. One method of combating the disease is to make the onion plants as strong as possible, so as to withstand the attacks of the parasite. Hence the site should be carefully selected, the soil well prepared, good manures used, and the land kept clean and free from weeds.

6. To prevent the spreading of the disease all affected plants must be collected and burned. Whilst doing this care must be taken that the collector does not himself spread the disease by carrying the refuse loosely. Rotation of crops, or, when this is impossible, deep trenching, would lessen the chance of the disease appearing.

7. Diseased plants may be treated with a mixture of powdered sulphur and freshly burnt quicklime sprinkled by hand or by bellows; or they may be washed or sprayed with a weak solution of iron sulphate (green vitriol). In both cases the fungus is destroyed without injury to the onion plant. Further both these chemical remedies have the additional advantage of being excellent manures.

8. Another fungus, *Macrosporium parasiticum* sometimes attacks the onions after the *Peronospora* has taken a good hold of the plant and weakened it. As this only occurs as a sequel to the *Peronospora*, the extermination of the latter would involve the disappearance of the former. The *Macrosporium* does not attack the healthy plant.

9. Only two kinds of insects, the onion thrips and the onion fly were met with, and the latter on only one occasion. The thrips were not numerous and appeared to do little harm. They can easily be removed by application of a solution of iron sulphate, such as is recommended in Section IV. iii.

Should the onion fly ever prove a serious pest, it may be dealt with by covering the bulb of the onion with a thin layer of earth. This prevents the fly approaching the bulb to lay its eggs.

INSECT POISONS.

The Bureau of Entomology, Department of Agriculture, Washington, sends out of the following for use as insecticides on or about plants, etc.:—

London Purple.—To 20 pounds flour from one-quarter to one-half pound is added and well mixed. This is applied with a sifter or blower. With 40 gallons of water one-quarter to one-half pound is mixed for spraying.

Paris Green.—With 20 pounds of flour from three-quarters to one pound is mixed and applied by sifting or by a blower. The same amount of the insecticide to 40 gallons of water is used as a spray.

Bisulphide of Carbon.—For use in the ground a quantity is poured or injected among the roots that are being infected. Against insects damaging stored grain of museum material a small quantity is used in an air tight vessel.

Carbolic Acid.—A solution of one part in 100 of water is used against parasites and domestic animals and their barns and sheds; also on surface of plants and among the roots in the ground.

Hellebore.—The powder is sifted on alone or mixed one part to twenty of flour. With one gallon of water one-quarter pound is mixed for spraying.

Kerosene Milk Emulsion.—To one part milk add two parts kerosene, and churn by force-pump or other agitator. The butter-like emulsion is diluted *ad libitum* with water. An easier method is to simply mix one part kerosene with eight of milk.

Soap Emulsion.—In one gallon hot water one-half pound whale-oil soap is dissolved. This, instead of milk, is mixed to an emulsion with kerosene in the same manner and proportion as above.

Pyrethrum.—(Persian insect powder).—Is blown or sifted on dry; also applied in water, one gallon to a tablespoonful of the powder, well stirred and then sprayed.

Tobacco Decoction.—This is made as strong as possible as a wash or spray, to kill insect pests on animals and plants.—*Southern Planter.*

THE NOMENCLATURE OF FRUITS.

A writer in *Nature* has discovered that the names of tropical fruits are frequently misapplied, and tells us so:—

Owing to the loose manner in which tropical fruits are termed, apples, plums, pears, peaches, &c., when they are neither botanically nor intrinsically anything of the sort, there has arisen considerable confusion respecting them. Again many tropical fruits are suitable only for salads or curries, and should not appear at the dessert table at all. Others are better when preserved or cooked, and they are then both wholesome and well adapted to the wants of the country. There is no good pear (Pyrus communis, L.), as known in England, grown in the tropics, yet we have the name applied to the alligator or Avocado pear (Persea gratissima, Gærts), the anchovy pear (Gria cauliflora, L.), the prickly pear (Opuntia ficusindica, Webb) and the wooden pear of Australia (Xylomelum pyriforme, Knight). Again, the English apple, although grown in the hills in the tropics, is practically of little value, but the name is as loosely applied as in the case of the pear, and hence fruits as widely apart as the poles in their botanical classification are grouped together under the general term of apple. To select a few out of many such names, we have the sugar custard apple (Anona reticulata, L.), the Kei apple (Aberia caffra, H. and S.), the Mammee apple (Mammea americana, L.), the star apple (Chrysophyllum Cainito, L.), the rose apple (Eugenia Iambos, L.), and the golden apple (Spondias lutea, L.). In plums there are the caffre plum (Harpephyllum caffrum, Bemh.), the coco plum (Chrysobylanus icaco, L.), the hog plum (Spondias mangefera, Pers.), the Chinese date plum (Diospyros kaki. Linfil.), the blood plum (Hæmatostaphis Barteri, H. K.), and the gray plum of Sierra Leone (Pariuarium excelsum, Sabine); and so with the gooseberry, essentially a cold temperate fruit. English colonists have applied the name to such widely diverging fruits as those of Phpsalis Peruviana, L. (Cape gooseberry), Peirescia aculeata, Mill (Barbadoes gooseberry), and Cicca disticha, L. (Otaheite gooseberry).

The so-called nuts of the tropics are in a worse state of confusion as regards the common names, and hence it by no means follows that what are imported as nuts belong at all to that category of fruits. The most familiar of tropical nuts is the coconut (Cocos nucifera, L.), a true nut; but the Para or Brazil nut (Bertholetia excelsa, H. B.) is simply the seed, not nut, which is inclosed in a large globular fruit, almost as large as a 36-lb. cannonball; exactly the same occurs in the case of the Sapucaia nut (Lecythis Zabucajo, Aubl.), as well as in the best of these so-called tropical nuts, viz., the souari or butternut of British Guiana (Caryocar nuciferum, L.). The cashew nut (Anacardium occidentale, L.) is a fruit borne upon a swollen pear-like peduncle, and presents one of the most remarkable instances of growth met in the tropics. The fruit when roasted is esteemed at dessert, and passes in India under the name of "promotion nut." The Jamaica walnut (Aleurites moluccana, Willd.) is the seed of an Euphorbia; also the cob-nut (Omphalea triandra, L.).—*Agriculturist.*

THE STRANGE DIFFERENCES IN THE ACTION OF INSOLUBLE PHOSPHATES EXPLAINED.

The following extracts are the reports of thoroughly reliable scientific chemists, made by them after long laborious and exhaustive research. And strange to say most of the tests and experiments were for different purposes and to prove entirely different views. And yet when taken together, grouped and classified, they all lead to one conclusion, namely, that phosphoric acid in conjunction with alumina is the most advantageous combination for plant food.

First, in the published reports of the Agricultural Experiment Station of Virginia, published in Richmond in 1885, on page 11 we find the following remarks:—I could name many farmers in Virginia who, having used phosphates both raw and reverted (in natural guano), have found them absolutely without effect. It chances that I have no report of anyone who has used acid phosphate without resulting benefit. In my own experiences, I have had striking results from the use of phosphatic guano and from acid phosphate mixed with kainit, but raw phosphate has done no manner of good on my land as far as I can discern. My land seems to lack the power of dissolving the so-called insoluble phosphate, (or of helping the plants to do so, which is probably nearer the correct theory) contained in the raw Charleston rock. On the contrary, there are many soils on which it is found most beneficial and economical to apply the phosphate in this shape, sometimes with the addition of potash, sometimes without. "Give it time," say the able writers and farmers referred to, "and the insoluble phosphate will be brought into the condition of available."

"Sow it in the spring upon your corn land; it will increase the crop of corn, and by the fall will be in just the condition to benefit the wheat, or to grow a crop of clover to be followed by wheat. Why spend your money for acid phosphate? You are buying and that too at an increased price, an additional 50 per cent of sulphuric acid and water which the land does not want—nay, which many hold to be positively injurious. Reflect that 400 pounds of raw phosphate contains as much phosphoric acid as 600 pounds of dissolved.

The same authority quotes from the *Journal de l' Agriculture*, published in France, a statement made by M. Deherain, professor at the National School of Agriculture of Grignon, concerning experiments in the use of superphosphates continued during four years. He concludes "that superphosphates exercise no beneficial effect upon the soil of Grignon." Why is this? Why do soils apparently very similar give such different results from the application of the same fertilizer?

On page 12 of the same work quoting still Deherain, he says:—"In calculating the effect to be produced by this fertilizer it is not sufficient to determine the total quantity of phosphoric acid contained in the soil; we must go further and see with what basis the phosphoric acid is united.

Again, "But in all probability there are in certain soils peculiarities which hinder the action of fertilizers; or else the absence of some principle necessary to enable the acids of the soil or the peculiar acids of the plant to act upon the fertilizer and render it available.

M. de la Morvonnais says that it has been found in Brittany that phosphates, particularly fossil phosphates, do not act well on soils that have been recently limed. His theory is that lime neutralizes the acids of the soil necessary to dissolve the phosphates and so hinders the action.

Georgia report 1885 page 30 says:—"The use of floats was attended by actual money loss."

It is generally understood that ground apatite, a crystallized phosphate of lime, is no better in the soil than so much sand; and ground Charleston rock (another phosphate of lime), in a very insoluble condition also does but little good.

These known facts demonstrate that insoluble phosphate of lime has little or no effect as plant food.

On the other hand, the Royal Agricultural Society's *Journal, vol.* 22, part 1st, pages 250 and 251, shows that insoluble phosphate of alumina gave better results than dissolved phosphates, ground coprolites, or bone meal.

Dr. Cook, of New Jersey, says in five cases out of eight "the yields of soluble phosphoric acid were surpassed by those from insoluble forms of phosphoric acid used under corresponding conditions." One of the abovementioned forms of insoluble phosphoric acid was phosphoral—an insoluble phosphate of alumina.

Professor Dunkelberg of Bonn University, in his long report to the German ministry, claims that iron and alumina phosphates are more certain in their action, and altogether preferable to the phosphates soluble in water.

Professor Maercker says in his summary of the results of a large number of experiments with different crops, on various soils, using different fertilizers, that in all instances but one the phosphate of alumina made a greater increase than any of the others.

Hoffmeister's paper says phosphate of alumina gave larger increase than any other, and argues that soluble phosphoric acid becomes phosphate of iron and alumina in the soil, because iron and alumina are always present there.

Next, Stillwell & Gladding's experiments show that soluble phosphoric acid becomes immediately insoluble in the soil. Thenard and Deherain claim the same, and this point is now conceded by all agricultural chemists.

Also Hoffmeister's paper, page 813, states that phosphoric acid when applied to the soil in a soluble form always becomes reversed to alumina and iron bases, because iron and alumina are always present in the soil.

And Muldner, in "Chemie der Akerkrume," vol. 1, page 485, claims that the use of alumina in the soil is to retain the phosphoric acid for the use of plants.

Baron Von Liebig proved long ago that plants had the power to dissolve the phosphoric acid from its mineral salts by the aid of the acids contained in their roots.

And again, Drs. Peterson and Voelcker say that it is demonstrated that plants do absorb the phosphoric acid when in conjunction with alumina and iron.

Therefore it follows that the insoluble phosphates of lime must be made into soluble phosphates, so that their phosphoric acid may be made into a condition to revert to the alumina, from which base the plant has the power to absorb it.

There is, however, one class of phosphates of lime that do some good in an insoluble condition, because the phosphoric acid is in loose combinations, so much so that the action of the acids in the soil is sufficient to make it so soluble that it can change its base and revert to the alumina that is always present there. This class is what is called the natural phospatic guanos of the West Indies, such as Mona, Orchilla, Aves, etc.

The phosphates of alumina that have proved successful by experiments on the land are Redonda (tested by the Royal Agricultural Society) and Phosphoral (tested by New Jersey Experimental Station), and lastly the Combination Natural Phosphatic Guano from the Cayman Islands, this is a phosphate of alumina, iron and lime, the phosphoric acid being lightly combined. This has been well tested in Virginia and North Carolina by the Carib Guano Company, of Baltimore, and in Long Island, New York and New Jersey by the Grand Caymans Phosphate Company, of Kingston, Jamaica, where great results have been obtained from the use of their guano when even only partially ground.

In conclusion, therefore, it follows that phosphate of alumina in easy combination is the exact form to make the best plant food, whereas phosphate of lime must be made soluble that the phosphoric acid may revert to the alumina always present in the soil.—CAUSALITY.—*Oil, Paint, and Drug Reporter.*

THE SUGAR INDUSTRY IN QUEENSLAND.

No change of importance has taken place since the date of my last letter in the circumstances and prospects of those engaged in the sugar industry of this colony. The trouble then was the excessive wetness of the spring season, usually the dry period of the year, and this unusual recurrence of heavy rains has continued to the present time. Perhaps this trouble through rain has been more severely felt in the Mackay district than in any other. During the 18 years the industry has been fairly established there such wet weather has never been known during the crushing months, scarcely a week having passed without rain (more or less) since last April. The difficulties and extra expense this involves can only be fully understood by one practically acquainted with the management of a plantation. It will suffice for me to say that the principal fuel used in the mill furnaces is the crushed cane (megass), and that before this can be utilised it must be spread over the yard and dried. The slightest rain neutralises this operation, therefore the furnaces have either to burn wood or coal, or stop work, and the quantity of wood required to keep a first-class mill going is something outrageous. In the field the wet is equally troublesome and expensive; true it keeps the cane growing, but this is just what the planter does not care about, for it ought to be ripening and acquiring juice showing a high density of sugar. The normal density of cane juice in the spring season in the Mackay district is 10 to 11 deg. Beaume; a heavy rain will bring it down to nine, eight, or even seven degrees, which makes a wonderful difference in the quantity of cane to be crushed in order to get one ton of sugar, and the consumption of fuel for evaporating the watery juice is, of course, also greatly increased.* It must be remembered that it is not so much the increased juice in the cane that is the trouble as it is that the sugar has gone; it is not in the cane. The difficulty of carting from the fields when the season is wet is very great. The fields are principally level, and have a great depth of soil, which has been well loosened to a depth of 18 in. After a heavy tropical rain, they necessarily are as boggy as a swamp, and the horses and drays cannot get upon them. Only those have been able to keep the mills supplied who happen to have invested in some one or other of the expensive portable railway systems. The crop everywhere has been a fairly good one. In the dry district of the Burdekin delta it has been an extraordinary good one. In the Mackay district the estimates are that quite one-third of the crop will remain as a "stand over" for next season's operations. Planters there and elsewhere are still continuing crushing, for the weather since the new year has been fine, but, as a rule, this late crushing never pays, and can only be justified when money must be had, for the actual sugar is not in the cane, which now begins to put on its rapid tropical growth; and, what is of equal importance, the labour and horse stock are required to attend to the growing crop for the following year. The output from Mackay last year was 25,000 tons, and this would again have been reached had not the weather proved so unpropitious for manufacturing. As an approximate estimate, 15,000 to 18,000 tons probably will not be far wrong.

In the Herbert River district the rains also have been almost continuous, and work has been greatly impeded, nevertheless good work has been done, principally owing to the fact that the tramway system is extensively adopted; but the density has been low, and the yields not what should have been; labour again has been scarce. A great deal of cane grown by farmers was crushed by the Colonial Sugar Company, and this company has also taken the initiative in exporting a large quantity of sugar direct to China. On the Burdekin the wet spring has been rather advantageous, the growth of the cane there being far and away beyond what it was ever known to be in any year of normal spring weather. The output will probably be the greatest yet from that rather unfortunate district. Some remarkable returns from the Mourilyan Sugar Company were recently published in the Brisbane papers—and, I believe, re-copied into *The Argus*—but I refer to them again because they point to one of the most anomalous facts connected with sugar-growing in Queensland. The returns showed that up to the 19th November the Mourilyan Sugar Company had crushed 399½ acres. This produced 1,313 tons 3 cwt. 3 qrs. of sugar, of which 77 per cent was white sugar of first quality. The yield per acre, therefore, was 65 cwt. 3 qrs. out of the acreage crushed there were 171 acres of "stand over" cane—that is, cane left from last year, and having 16 to 18 months' growth on it—which yielded 4 tons 13 cwt. 1 qr. per acre. These astonishing yields equal those of the Hawaiian Islands. The remarkable point in connection with this is that the Mourilyan Company's estate is at the Johnstone River, which admittedly is the most rainy zone fall in Australia, and in proof of which I will state that 140 inches in depth had fallen from January 1 to November 29, the date of the returns. Your readers may therefore be inclined to ask how it is this company can not only combat with excessive rains, but also get extra returns in consequence? This is a fair question, more especially when taken in connection with the fact that this district was considered by the early sugar planters of the colony to be unsuitable for cane, owing to this abundant rainfall. The explanation lies in the character of the soil; it is an alluvial detritus washed down by these excessive preciptations, and intermingled with superabundant organic matter, the result of the decaying tropical jungle forced into exuberant growth by this essentially tropical climate. The soil is many feet in depth, and all of the same fertile character; it is porous to an excessive degree, so much so that a rainfall of 5 in. will show nothing of itself in a few hours' time. Nevertheless the land is never dry, the capillary attraction inherent in so much burning, causes it always to be sufficiently moist without saturation to sourness. The company have not a plough upon the place, the cane cutting being simply placed in a hole scratched by the hoe. Neither have they any carting, all the cane being conveyed to the mill by a system of portable tramway laid down in the fields; also, they have their furnaces so adapted upon the modern principle that the megass can be burned while still wet from the rollers, a due allowance of wood also being used to commence the fire, and at stated times. Thus it will be seen that, given the most favourable conditions of a really fertile soil of unlimited depth in a tropical climate and modern appliances, then sugar growing can be made profitable at present prices, providing an exorbitant initiatory expenditure for land and improvements has not been foolishly entered into. Also the difficulties of the labour question are to be considered, but on this topic I shall not touch in this letter, for it is a subject in itself.

On the Burnett River (Bundaberg) the season has been a satisfactory one as regards the yield, which is expected to more than equal that of last year. The same remark, too, applies to the Mary River, still further south. The large refineries on these two rivers intend to re-commence work at a very early date. In the Brisbane and Logan districts sugar manufacture bids fair, in a few more years, to be a thing of the past. Nevertheless some few of the mills in the Logan district have this season been worked with vigour, and the owners being able to buy cane from growers at their own figure, will doubtless show a profit.

The Government scheme of central mills, for the carrying out of which the Legislature of 1885 voted £50,000, has developed so far that two associations of farmer cane-growers near Mackay have organised, and applied for the funds required to erect mills, and the Government have agreed to the proposals. Of course the Government hold a lien on the mills and machinery, and also on the private estates of the association. One of the points of this movement is supposed to be that of demonstrating the feasibility of growing cane by European labour, nevertheless it is a fact that most of these farmers who have

* Here is the reason for the failure of sugar in Ceylon,—excessive moisture.—ED.

signed the arrangement already have cane planted and it to cut, and that kanaka labour has been chiefly employed by them in the clearing of their fields the breaking up of the land, and the planting and cultivation of the present crop.

The sugar exported up to December 31, 1886, showed a total for the season (since July 1) of 31,052 tons, which is about 1,000 tons less than were exported during the same period of last year. The gross yield of sugar for the year up to 31st March prox. will probably be about 45,000 tons.—*Australasian.*

SOILS.—According to the *Nilgiri Express*, the following is the simple result of a comparison of a large number of analyses of soils—good and bad—and plants grown on different soils, to determine what was necessary for ordinary field crops. All the fertile soils contain the following:—*First*—Silica or sand. *Second*—Alumina or clay. *Third*—One oxide, either of iron or of magnesia. *Fourth*—One alkaline earth, either lime or magnesia. *Fifth*—One alkali, either potash or soda. *Sixth*—One mineral acid, either muriatic or sulphuric, or phosphoric. *Seventh*—Vegetable acid, or decomposed vegetable matter. And in all fertile soils, the fourth and fifth were in such quantities as to neutralize the sixth and seventh. The poor soils either wanted some of the necessary ingredients, or had an excess of acid, or alkali. And in all such cases there was an excess of acid, except in one soil where there was an excess of soda.—*Indian Agriculturist.*

ACCORDING to a contemporary, an interesting economic fact is brought to light in a consular report for last year on the trade of Frankfort-on-Main, in Germany, and that is, that the town obtains its supply of patchouli oil from the Indian plant, which must apparently be imported from this country in large quantities. Consul-General C. Oppenheimer, writing on the subject, says that the stock of patchouli oil is so reduced, that a further increase of price will be unavoidable if the import from India of plants does not soon cover the deficiency. The principal difficulty, however, he adds, appears to be in the shipping of the same, as the captains of steamers object to taking them on board on account of their penetrating odour. We are, however, doubtful whether the plant said to be imported from India is really the Indian-grown plant. There are, it is true, several species of the plant which yields the Patchouli perfume to be found in India, as for instance, the *Plectranthus Patchouli*, of Assam, and the *Pogostemon Patchouli*, of Bombay; and both plants are also grown in many places in Bengal, but they are not cultivated commercially. A good deal of the Assam product used to find its way to Calcutta in former years, but this almost entirely the Penang and Singapore products which now occupy the Calcutta and other markets, and we fancy that it is the latter which is again exported from here to Germany, and not the true Indian plant.—*Indian Agriculturist.*

LEAVES.—Enquirers into the physiological functions of the leaves of plants in relation to their bearing upon the animal economy have recorded, as the result of their researches that aquatic plants surpass all others in their power of decomposing carbonic acid, and by this function rendering malarious districts more fit for animal existence. That the knowledge of this important fact should not have been extensively utilized in practice, is one of the mysteries of the age, for it was clearly demonstrated years ago by such eminent scientists as Ellis, De Saussure, Daubeny, and others. But a change is at hand, for we learn from the *Planters' Gazette* (London) that a Dr. Brandes, a physician at Hitzackes, Hanover, has written an article in a German medical paper in which he demonstrates the valuable anti-malarial properties of the *Anarcharis alsinastrum*, a water-plant which has hitherto been regarded as an unmitigated plague, choking up rivers, and altogether useless. Dr. Brandes has remarked that in the district where he lives, and where malaria and diarrhœa yearly appeared in a sporadic or epidemic form, these diseases have gradually decreased since the *Anarcharis alsinastrum* began to infest the neighbouring rivers and marshes and since four years, have totally disappeared. The abovenamed water-plant nourishes itself on decayed vegetable matter, and grows with incredible rapidity. It thus destroys the germs which produce malaria and diarrhœa; and besides, its presence obliges the frequent cleansing of standing waters, a measure beneficial to health. Dr. Brandes, therefore, proposes that the experiment should be tried of planting the *Anarcharis alsinastrum* in marshy districts. It is also useful in protecting the young of fish, and affords an excellent dung. The plant came originally from Canada, whence it was brought to England, and thence to Germany about 1840. In North Germany it rapidly spread far and wide, and this year appears in all parts in unusual luxuriance. This knowledge will, we trust, induce the Government of India to take measures to ascertain, by experiment, whether the hundreds of species of aquatic plants that abound in India possess any special anti-malarial properties. Malaria, as we know, is one of the curses of this country, and any measure likely to render the malarious districts of India less injurious to life, ought not to be left untried.—*Indian Agriculturist.*

KOLA.—At a time when the West Indian planters are casting about for new industries to recoup the losses sustained by the enormous decline in the value of sugar, it is of the utmost importance that they should not be misled—that in seeking to improve their position they should not find themselves, at no distant date going from bad to worse. The controversy on the kola nut, therefore, which is taking place between Sir Augustus Adderley, Mr. Thomas Christy, Mr. Lascelles Scott, and Mr. D. Morris, of Kew, is likely to be of real advantage to the Colonies. If what Mr. Lascelles Scott says be true—namely, that the French and German Governments are introducing kola into their military dietaries, and that in this country several large contract orders cannot yet be filled, owing to insufficiency of supply—we are very glad to hear it. An increased demand will doubtless serve to enhance the price, and then we may expect regular imports of the article into this country. The merits of kola nuts have been known for the last 100 years, and it is nonsense to suppose that the West Indian planters would be so blind to their own interests as to positively refuse to supply a profitable market, either on this side or in America. The fact is, not a few of those who have gone in for the cultivation of kola, especially in Jamaica, have bitten their fingers over this product, and it is not surprising that they should refuse to take it up again until it has been conclusively proved that there is a growing and profitable demand for it. Shipments have been made to this country which really left nothing for the grower after paying expenses, and in some instances the prices realised were not sufficient to pay these. Such being the case, Mr. Morris is perfectly justified in stating that the kola nut is purely in the experimental and speculative stage, and it must be frankly admitted that speculative cultivation is not what should be recommended to the West Indies at the present time in order to benefit them. Does Sir Augustus Adderley, we wonder, know that kola trees take from five to seven years to come into bearing, and can he undertake to say what will be the price of kola in 1896? All that Mr. Morris contends for is that, if there is a fair and legitimate demand for kola, it can be supplied from Jamaica and elsewhere from trees *already established.* He admits all and everything as regards the merits of the nut, and it is worthy of remark that, in his annual report on Jamaica for 1882—two years before Mr. Christy took up the chocolate-from-kola idea—the late Director of the Jamaica Botanical Department reported as follows:—"Kola nut.—This tree, which has lately attracted considerable attention, is common in many parts of the island (Jamaica) under the name of Byssi, and seeds can be obtained in quantity if required for commercial purposes. . . . . These nuts are likely to take their place in the market as furnishing a nutritive and stimulant beverage . . . . and there is a probability that a chocolate prepared from them will more readily agree with delicate stomachs."—*Colonies and India.*

THE CHEAPNESS OF QUININE AND THE OPIUM TRAFFIC.

(From our Special Correspondent.)

The following letter which I have addressed to the Secretary of a well-known London Society carries its own explanation. It is on a subject in which I have long been interested, and with a large sale of quinine (50,000 ounces) in the City the other day at 1s 4d the ounce, there is immense need that the virtues as well as the cheapness of this valuable febrifuge and tonic should be made known to the masses, and especially in the quarters I have pointed out :—

Royal Colonial Institute, Northumberland Avenue,
12th October 1887.

The Secretary to the Society for the Suppression of the Opium Trade,
(Rev. F. Storrs Turner, B. A.,)
Queen Anne's Mansions, S. W.

SIR,—I venture to address you on a subject which, though not directly connected with the suppression of the opium trade, has nevertheless in some respects a very considerable bearing on the objects which all members of your Society must have at heart. To make myself clear, I would begin by referring to the relation which exists between the desire for, and consumption of opium among any people and the more or less prevalence of malarial or other fever of a low depressing type.

In many of the low-lying districts of China, I believe, this is especially the case. My own observation has been confined to a visit paid to the neighbourhood of Canton ; but I think sufficient may be gathered from the accounts of travellers and the experience of residents in China to show that the craving for opium in the first instance, in many parts, is due to the prevalence of a low type of fever. The same thing has been realized for some years back in more than one district in England.

It appears to be indisputable that the consumption of opium, in the form of laudanum especially, has been very large in the Fen districts of Cambridge and Lincolnshire and along the banks of the Thames, more particularly about Gravesend. These are just the situations where a malarial or depressing type of fever might be supposed to prevail. In the London *Spectator* of July 5th, 1879, it was stated by the editors : "We have reason to believe that in parts of England, at all events, laudanum is much drunk by women instead of alcohol. . . We are afraid to state the quantity of laudanum which one wholesale chemist informed us he sent annually to his Lincolnshire customers."

This remark elicited a letter to the editors which appeared in their succeeding issue and from which I quote as follows :—

"I am a country chemist, of the lower grade, one of four (of whom I am not the chief) in two contiguous villages, which together have not more than 4,500 inhabitants. I sell, as nearly as I can judge, about two gallons of laudanum per month, solely by retail; besides, say, some 16 or 20 oz. of opium itself. Most of this is sold to women of the poorer class who must pinch themselves seriously in many ways to purchase this luxury. Most of them are evidently ashamed of their habit of opium-eating, or laudanum taking, as the case may be, but some quite otherwise. Many will consume an ounce of opium every week, and some considerably more. One man I know who will take at a dose twenty grains of muriate of morphia,—and this dose, I believe, he has occasionally swallowed twice in one day.

"These are facts. As to the explanation of them, I am hardly prepared to speak of that. The 'crave,' (your word, sir,) I believe to be a natural one, at least in these parts. How first induced, if induced at all, I know not. It is apparently partly of a physical, partly of a moral origin. Women of low vitality, and poor spirit seem mostly subject to it. Opium is their refuge from the 'dumps.' In fact, as you suppose, it supplies to them the place of alcoholic liquors. May I conclude with a question? Is the trade in this drug an immoral one ?—I am, sir, &c., &c.,

A LINCOLNSHIRE DRUGGIST.

Now I think it would be found that as respects the Fen districts of Lincolnshire and Cambridge and the neighbourhood of Gravesend, the craving which has resulted in a large consumption of opium in one form or other, has had its origin in local climatic causes, although the practice may have now grown far beyond the necessities of the case. And the same may probably be said of the low-lying marshy districts of China.

My object in dwelling on these circumstances is to call your attention to the important bearing which a well-known, and now comparatively cheap, drug, namely, *sulphate* of *quinine*, (or even the cheaper and inferior alkaloids extracted from the cinchona bark) should have on the original causes (as I deem them) for this craving for laudanum or opium, and more especially on the influence of quinine in removing the craving for what may become the very injurious and dangerous practice of opium-eating or smoking, or of laudanum drinking.

My attention was first directed to this point by a certain curious experience related by my friend, Mr. Archibald Colquhoun, in his work "Across Chrysê." I have not the book before me as I write, but I think my relation of the facts recorded will be found generally very nearly correct. Mr. Colquhoun found, in passing up the river beyond Canton on his way across Southern China to Burmah, that at several Mandarins' barriers on the river, where a levy on all travellers and especially traders—a regular "squeeze"—was made, that, when offering gifts to the chief official in order to minimize the delay and expense, more store was laid by a few grains of quinine than by his most polished and attractive Birmingham goods. More than once Mr. Colquhoun was asked by the mandarin if he had any cure for the taste of the black smoke poison (opium) and, on his replying in the negative, the second question would at once be "Have you any quinine ?"—showing that the Chinese, even in these remote inland districts, fully realized the efficacy of quinine in superseding the need for opium and possibly in curing the taste and desire for it.

So much is this known that American Missionaries returning from furlough, often bring back packages of quinine pills for the use of their converts and poor people generally in China, knowing well that nothing is more appreciated or more valuable for securing health.

I have said enough, I hope, to show the importance of quinine as a health-giving substitute for, if not remedy and preventative of the taste for opium. Wherever fever prevails, there can be no better prophylactic and tonic than quinine, and where, unfortunately, the taste for deleterious drugs, such as opium and laudanum, prevails, it would appear to be very important to treat patients with quinine, or to make known how much superior sulphate of quinine, or even the inferior alkaloids from cinchona bark are to opium in any form, for alleviating the evil consequences of malaria and fever depression and for restoring tone and health.

You will now begin to understand, sir, wherein I would ask the aid of your Society. Only a few years back, it would have been of little use in this way to recommend quinine or cinchona alkaloids to the attention of poor people, its cost being almost prohibitory for use save in special prescriptions. But the experiment begun in 1861 by Mr. Clements Markham (under the auspices of the Indian Government) in introducing the cultivation of cinchona plants from America on the hills of India and Ceylon, has produced a great revolution in the market, increasing the production of bark, especially from Ceylon which sends to London as much as all the rest of the world, (India, Java and South America), so that the price of Howard's sulphate of quinine in place of being 10s to 15s per ounce and sometimes even 18s per oz. is now down to about 2s 6d per oz.* The rapid rise of the trade from Ceylon may be judged from the fact

* A large quantity of a good brand has just been sold in Mincing Lane for 1s 1d per oz.—J. F.

that whereas in 1872 only 11,547 lb of cinchona bark were exported, now from 13 to 15 millions of lb. are sent to Europe every year. In passing, it may be of interest to your Society to recall the fact that if India and its British governing authorities have been blamed sometimes for encouraging the opium trade with China, to them also in great measure will be due the credit of supplying the world (through the experiment begun in 1861) with an abundant and cheap supply of the very best antidote, in a prophylactic and tonic of the highest value to the Chinese, as to all others living in feverish or malarious districts.

But, although the *wholesale* price of this invaluable drug (quinine) has been so greatly reduced, it is much to be feared that being a drug, its value to the household is little known, while throughout the country generally, there is no knowledge nor experience of the cheapness of quinine in retail purchases. It came out in evidence in an English County Court a few months ago that a provincial town apothecary charged, in prescriptions, at the rate of a penny a grain of sulphate of quinine—the rate from time immemorial in his experience!—or the equivalent of £2 per oz., for what could certainly be bought wholesale at less than 3s.

Again, at Vichy in Central France, the other day, I found Pelletier's sulphate of quinine, a cheaper article than Howard's, retailing for thirty francs the oz. (25 shillings): it had been, a short time before, 45 fr. or 1½ fr. per gramme.

If your Society in the desire of its members to suppress the opium trade—and, I suppose, the undue and dangerous use of the drug in England, as in China—could see its way to make known to the sufferers and to others inclined to copy a bad example, the great value and cheapness of quinine, much good might result. To show that we in Ceylon have been doing what we can, I enclose some extracts of writings in the *Ceylon Observer* and *Tropical Agriculturist*, calling the attention of the great London drug houses to the same subject; but, apart from business altogether, it would seem to be a true work of philanthropy to make as widely known as possible the present cheapness of so invaluable a prophylactic and tonic as quinine, especially in districts and countries where the people are addicted to the use of opium.

Apologizing for the great length at which I have hurriedly brought this matter under your notice,

I am, sir, yours truly, J. FERGUSON,
Of the *Ceylon Observer* and *Tropical Agriculturist*.

NOTES ON PRODUCE.

(From the *Home and Colonial Mail*, October 14th.)

It is high time Indian and Ceylon tea importers turned their attention to Canada. Advices from the Dominion say that a brisk business in tea, at generally advancing prices, is looked forward to in Canada. It appears that the statistical position is strong, the imports of Japan teas this season up to the end of September having amounted to over 6,000,000 lb. against 12,000,000 lb. for the corresponding period last season. Early in the season comparatively few orders were sent to Japan, Canadian firms believing that all they needed would be sent on consignment account. This expectation has been disappointed, and the market is therefore comparatively bare. During the demoralised state of the market some time ago stocks in the hands of retailers also were allowed to fall very low, and hence the wholesale dealers are now feeling the pressure of the demand for the replenishing of retail stocks.

Mr. Holborn, whose ridiculous growl against Indian tea we published last week, is answered in this week's *Grocer* by the Wholesale Blended Tea Company. The writer says he (Mr. Holborn) flatly denies that China tea is thinner or less pungent than Indian tea, and he gives an equally emphatic negative to the statement that the Chinese prepare their teas in the same ways as their ancestors did. But he does nothing more. He does not enlighten an expectant trade as to how the teas are made, and he sings the praises of green tea—an article which is of so little general use as to be unimportant. Its imbibition is so distinctly an acquired taste that not one in ten thousand will take to it who has not previously made its acquaintance in China; and although "herbal pungency and natural fragrance" are beauties which one appreciates highly (on paper), one greatly prefers an article which no education is required to appreciate. But, shrouded in the words of the *Standard* article, Mr. Holborn sees and fears the "stubborn unlaid ghost" of adulteration; and although the "odious feature" is not mentioned, although it is not even suggested, he feels that China tea has lost its prestige primarily on that account, and that the mention of its departed glory entails a reference to "the muddy vesture of its decay." We will not ask Mr. Holborn to go back to 1874—we will ask him only to recall to mind the close of the year 1879, and the opening months of 1880, when there was nigh a famine of common congou, and when it commanded almost any price on the London market; when week after week saw a continual rise, until the news was sent that 10,000,000 lb. of low-priced tea had been shipped from China to meet the demand; and when, on the arrival of the shipments, parcel after parcel was seized and condemned by the Customs authorities, and when, besides that, tens of thousands of pounds were conveyed to the Nore and pitched wholesale overboard into the sea. We will ask him also to recall to mind the position of green tea for months—we had almost said for years—afterwards when it was knocking about from hand to hand, and pillar to post at from 3d to 1s 6d per lb., and when for months it was a complete drug on the market. Let him recall to his memory these facts (for facts they are), and let him place them beside his remarks on the bloom on Shanghai black leafs, and on the natural fragrance of green teas; let him present the two, side by side, to his friends in Derby or Nottingham, or wherever they may be, and then let him say where prejudice comes in, and where prejudice is justified. Let him, if he can, also quote a single instance in which a single package of Indian tea has been condemned by the authorities, and let him then, if he can, find a justification. "Prejudice! by the fool!" indeed; let 'tis only a fool who would refuse to be prejudiced against the dishonest and fraudulent tricks which many of the China tea producers still attempt to carry on.

"CHILDLIKE AND BLAND."

Signed "Haro," a letter appeared in the *Pall Mall Gazette* of Tuesday, which, if not written by an importer of China tea who wants to move off some of his stock upon easy terms, is, we should imagine, the work of a guileless being, too good for contact with the dust of cities. "Haro," filled with emotion on reading an article on Indian tea in the *Pall Mall Gazette*, says:—"I have just read your interesting article on Indian tea, but ugly rumours are springing up about the unwholesomeness of this new beverage when not sufficiently mixed with the innocuous China leaf, and it is said by many tea drinkers to be so full of tannin as to produce severe indigestion and other more serious ailments, so that the use of it is coming under the notice and censure of the faculty, the curious creamy scum which appears on some of these teas when allowed to stand without milk a little time indicating the deleterious tannic properties it contains. The Russians who are looked upon as being the best judges of tea in the world, will have none of it, and quite a scare was raised in Moscow a year or two ago when this loathesome creamy appearance was said to have been noticed in one of their choice teas imported from China, but it was found to be a groundless alarm. The dislike, however, to anything of an Indian flavour or character still remains, and is stronger than ever in that country. The Chinese look upon it as rank and poisonous." How childlike and bland! It almost suggests the feeding bottle. "Rumours are springing up." One had thought that these rumours were very old and rank and

had been hoed up for some years. "So full of tannin" and the "creamy scum." We fancy we've heard this before "Haro."

"The Chinese," says "Haro," "look upon it (Indian tea) as rank and poisonous." This would delight Mr. Holborn. They are not likely to love it much more as time progresses.

The following reply to "Haro" appeared in the *Pall Mall Gazette* of yesterday, and is to the point:—One who has seen tea made in China and India, and who has rolled it with his own hands, writes:—Your correspondent who writes under this heading in your issue of the 10th instant has certainly succeeded in collecting together as many errors as the space occupied by his letter will admit. (1) The rumours he alludes to as now "springing up" are already ancient history. They had vogue for just so long as it took people of limited intelligence to discover that Indian tea being stronger than China tea, less of the former should be used than of the latter for a given number of cups of tea. Hence one of the merits of Indian tea, its economy, had to be made manifest to some people through the fool's course—experience. (2) The "curious creamy scum" does *not* "indicate the deleterious tannic properties it contains;" being counted to it for righteousness by all connoisseurs, and a sure test that the leaves from which is obtained this creamy appearance are genuine Indian tea leaves, unmixed with Chinese rubbish. (3) To make the Russian taste—for tea—a criterion for Englishmen is more than amusing. And apart from the differences of taste, and of preparation of the tea for the Russian market, Indian tea, even if prepared like the Chinese tea, to suit the Russian taste, would still suffer under the same ban in Russia as Manchester and Sheffield wares suffer under, and would excite a similar patriotic horror. (4) That "the Chinese look upon it—Indian tea—as rank and poisonous" is most natural. They look upon *their own* tea, as prepared for the English market, as no less; then how much more likely are they so to look upon a rival commodity which is seriously affecting the sale of their own poison? The tea consumed by the Chinese themselves is quite a different thing to the tea prepared for this market. Allow me next to call your correspondent's attention to the following piece of information, which may edify him. China tea is rolled—*horribile dictu*!—by the dirty moist hands—and sometimes feet—of the Chinese peasantry. Indian tea is now rolled entirely by extremely clean machinery, is "fired" by machinery, and is sorted through brass-wired sieves instead of each leaf being picked over by more or less unclean fingers, as in China. Thus Indian tea is subjected in the process of manufacture to the minimum, and Chinese tea to the maximum, amount of fingering and handling. Those two pictures should, perhaps, end this reply, but I do not like closing without a reference to the old saw that the proof of the pudding lies in the eating. Teas sold in England as "Indian teas" are too frequently not pure Indian teas; but it is an acknowledged fact that the individual English man or woman who has ever consumed a pound of really decent Indian tea (in speaking of Indian tea I, of course, include Ceylon tea), and has ever again bought Chinese tea from choice, is yet to be discovered.

"Tea Taster" writes:—The British public have been so long enamoured of Chinese tea by their constant use of it that they have failed quickly to detect the great superiority of Indian tea. But the fact really lies in a nutshell. Young gardens, virgin soil, as good, and in many districts a better climate, an intelligent administration, with the assistance of the best machinery procurable, making use of indigenous plants from both countries, crossed and recrossed so as to get the best adaptation to the different environments, have produced teas which the older tea trade—namely, China—cannot equal. This for years past has been admitted by all impartial tea-tasters. Hence the fact that the finest Indian teas have fetched from 3s to 5s per lb. in bond, whilst the finest China teas have not exceeded 2s 6d per lb. in bond. The practical adaptation of this fact has been left to the most intelligent distributors, who deal directly with the public. They realised, and the public soon learned from them, that the so-called deleterious tannic properties simply meant they were getting a better and more powerful property. To put it accurately, one spoonful of Indian tea is equal to two spoonfuls of Chinese tea, so we find that Indian tea has become rapidly popular. That some consumers prefer light and old wines to thick and fruity is of no significance as far as the intrinsic merits of either are concerned. But tea being really a daily food of the multitude their significant use of Indian tea wherever given to them by the distributor speaks volumes in its favour. "Haro" states the Russians are the biggest tea drinkers in the world. Is he not mistaken? I from a large personal experience should say the Irish are, and what do the Irish drink?—why, quite three-fourths Indian tea. They were the first to see its great value, and have since given it their enthusiastic support. In Ireland the popular price is 3s per lb. duty paid, while in England, staunchly sticking to the Chinese growths, it is 2s per lb. duty paid. —*H. & C. Mail*, Oct. 14th.

ADIANTUM FERGUSONI, *Moore*.—The *Gardeners' Chronicle* of Oct. 15th has a full-page engraving of this fern, with the following description:—This singular Fern (see fig. 96) was named after the late Mr. Ferguson, of Colombo, Ceylon, who found it as a chance seedling in his conservatory, and who sent it to Kew in 1885. Considerable variety of opinion was the result of the find, but the late Mr. Moore, while declining to adopt any of these, thought the plant showed affinity to Adiantum Capillus-veneris, but whether a hybrid, or the product of evolution, he was not certain. Mr. J. G. Baker thinks it is merely a giant form of Adiantum Capillus-veneris. The plant at Kew, from which our figure was taken, has stiffly erect fronds, 9 inches in length, exclusive of the stipes, and about 7 inches in breadth across the base. It makes a very handsome specimen. The unusual length of the pedicels gives the frond a rather spare and open appearance; and the leafy portion sometimes runs together towards the end of the pinnæ, giving it a crested appearance. For a full description of the plant, see *Gardeners' Chronicle* for Sept. 20th, 1884.

EUCALYPTUS FOR BOILER CLEANING.—Boiler cleaning is an important subject to all users of steam power. The extract from the leaves of the eucalyptus or blue-gum (which has recently been found so efficacious for the abovenamed purpose) is procured by boiling the leaves in a battery of boilers under a pressure of 40 lbs. of steam. Twenty tons of leaves are boiled every day, and the boilers, after constant use of two years, are as sound as when they came from the shop. Extract of eucalyptus globulus, or blue-gum, has been tested by Professor E. W. Hilgard, of the Agricultural Department of the University of California, in respect to its contents of tannin, its taste being highly astringent. It was found that a standardised tannin solution would precipitate ·337 per cent only of tannin; that beyond these limits either tannin or gelatine solution would produce a precipitate of about equal amount. After removing the tannin as far as possible by digestion with animal membrane, the acid reaction shown by the extract was found to be equivalent to only ·127 per cent of sulphuric acid, an amount so small that it is doubtful whether the cleansing action upon boilers can be attributed to acid solution. In most instances scale will be lessened during the first application; but in others, where the scale is hard, it does not begin to move for six weeks or more. The extract does not act suddenly on the scale, but on close observation good results will be immediately seen. The liquid may be put in through the manhole, feed pipe, safety valve, condenser, or hot-well. After it is put in no new scale will form, and the iron will cease to rust.—*Pacific Rural and Coast Percha Journal.*

TWO NEW VEGETABLE PERFUMES are said to have lately become articles of commerce. On of these is a kind of *xylopia* from the province of Chirigui in Costa Rica. The odour closely resembles that of *Canaga odorata*, and the flowers are now used, like those of that plant, in the manufacture of ylang-ylang. The other is named *ouco*, and is the highly odoriferous blossom of a kind of acacia-tree which is found in Central Africa, and which Serpa Pinto was the first to describe. The *ouco* flowers are brought down the Cubadgin river for sale; they cover the trees on which they grow with such profusion that they fill the atmosphere with the overpowering richness of their scent.—*Chemist and Druggist.*

FRONTIER TEA TRADE.—From an official return it appears that the quantity of foreign tea exported across the Punjab frontier to central Asia in the year 1886-87 was very largely in excess of that of Indian tea exported. The respective figures were Indian tea, 11,352 maunds, valued at R4,41,696, and foreign tea 17,401 maunds, valued at R13,70,920. Another fact worthy of notice is that, while the quantity of Indian tea exported in 1885-86 was only 6,070 maunds, its value was R4,73,535, while that of the larger quantity exported last year was only R4,41,696.—*Pioneer*, Oct. 26th. [It is curious that while Indian tea is so rapidly superseding China in the British market China is still largely preferred to British in Central Asia. Habit and acquired taste are not easily changed, especially amongst orientals.—ED.]

CINCHONA PLANTATIONS IN THE NETHERLANDS.—In its last issue the *O., P., & D. Reporter* devotes a note to these remarkable plantations, the existence of which, we venture to say, will be a revelation to persons outside the *O., P., & D.* office. It seems that the plantations belong to the Dutch Government, and are shortly to be put up for sale. The *O. P., & D.* should give some particulars about the spot where the plantations are situated. Are they to be found on the highlands encircling the Zuider Zee, or, perhaps, on the Alpine ranges which frown upon the city of Rotterdam? We always imagined that cinchona would only grow at an altitude of several thousand feet; perhaps the *O., P., & D.* will point out where that elevation is to be found in the Netherlands.—*Chemist and Druggist.* [The Java plantations were of course meant.—ED.]

THE DUTCH COCOA INDUSTRY.—There are about ten chocolate and cocoa manufacturers in Holland, whose yearly requirements of cocoa beans may be estimated at 3,000 tons in round figures, principally of the Guayaquil, Caracas, and Domingo kinds. They mostly manufacture cocoa preparations, known by the name of soluble cocoa, cocoatine, and cocoa powder—viz., the roasted and powdered cocoa beans, deprived of most of their natural fat, and the cocoa butter, which is used as a valuable ingredient by manufacturers of chocolate, cocoa sweetmeats, and also for pharmaceutical purposes. The oldest of the Dutch cocoa works was founded on a small scale more than a century ago, and most of the other works have existed from forty to sixty years, but all of them remained insignificant until the before-named powdered preparations found their way to foreign countries, especially England and Germany, where certain Dutch brands of powdered cocoa have been very well received and enjoy a large sale. There are people who supposed that the superiority of Dutch cocoa powder is to be attributed to a peculiar mode of manufacture different from the methods followed in other countries. The idea to extract the fat from the roasted cocoa beans and to sell the powder is said to have originated in the brain of a Dutch chocolate-maker about 1830.—*Chemist and Druggist.*

THE TRADE OF FORMOSA: EXPORTS.—There are three distinct products exported in native and foreign bottoms under the name of hemp. Besides hemp proper, which grows on the plains, China grass is found in the hilly districts some three or four days' journey from the port; but the preparation of it is too crude to suit foreign markets, to fit it for which the employment on the spot of machinery would seem to be absolutely necessary. Large quantities are exported by junk to the mainland, and it is much used in the making of cordage. The leaves of the pineapple yield a very fine silky fibre, which is known as "pineapple thread," from which a kind of grass cloth is made. The price is heavy, from 18 dols. 24 cents per picul; and the supply is at present small, but capable of increase. The pineapple grows in abundance on the low hills, about eight or ten miles from Takow; and the thread is sent to the mainland for manufacture. A coarse kind of cloth is manufactured in the island from a grass said to resemble rhea. It is not exported. Indigo was largely grown in the island, but for some years the export has been small. As the cultivation of sugar increases that of indigo diminishes, and now barely sufficient for local use is produced. The indigo is so roughly prepared, and so mixed with mud and sand, that it is found useless to send it to foreign countries.—*Overland Mail.*

SYLHET ORANGES GROWN IN CEYLON.—It is a curious coincidence that just as we had taken notes for an article on a paper by Dr. Bonavia on the citron tribe, and the prospectus of an exhaustive illustrated monograph which he is about to publish, we should receive from Dr. Stork a basket of splendid fruit, described as "Sylhet oranges from imported grafts, grown at Comillah estate, Henaratgoda." The *baggy-skinned* Sylhet oranges are well-known in the Calcutta market, where their colour, like that of oranges everywhere except in Ceylon, is orange-yellow and not green as most of ours are. Dr. Bonavia, however, took some of our green oranges to India and kept them for several weeks until they became yellow, when they were pronounced excellent. The truth is that most of our oranges are pulled green to prevent their being stolen, although it is a fact, we believe, that insects sometimes attack oranges allowed to grow yellow on the trees. Some of the beautiful fruits sent by Dr. Stork have the true orange colour, while others are green and green tinged with yellow. The fruit seems to us to be larger and more juicy than those we saw in Calcutta, with the skin more tightly fitting the pulp. In form, internal structure and taste, they closely resemble what we, in Ceylon, call "mandarin" oranges, the *jamanaran* of the Sinhalese; but the skin of the Ceylon-grown Sylhets does not possess the same amount of volatile, aromatic oil as our so-called "mandarin." The fruit looks beautiful, and the taste is delicious, and by this introduction and others Dr. Stork has conferred a benefit on Ceylon which ought to be duly appreciated. The Sylhet orange would, we should think, do well in our mountain regions.

MORE SYLHET ORANGES.—A correspondent writes:—"I read in the *Observer* about some oranges sent to you from Henaratgoda. Will you try the flavour of these oranges and mandarins. They are from trees planted by the late Sir Richard Morgan round the bungalow at Moonemale estate, at Hanwella." The oranges, which are very fine, are precisely similar to those grown by Dr. Stork, and we have very little doubt the history of the Hanwella trees will be found to be that as grafted plants they were sent to Sir Richard Morgan, by Dr. Stork, when the latter served in Bengal.

CEYLON UPCOUNTRY PLANTING REPORT.

7th November 1887.

The weather is all that can be desired either for tea flushing or planting. It is pretty much of a model N.-E.; only it is S.-W. so often that one hardly knows to which monsoon the credit is really due. Everything seems to be growing well, especially cinchona, which at date is simply disgustingly vigorous. Now that the unit of quinine has only got 1¾d to fall, the end cannot be very far off. If the world is to trade in cinchona at all, and if the tendency is still to be downward, bark will require to become a deal more sensitive than it has been. It won't do to have telegrams out telling us that there has been a fall of ½d or ¼d in the unit of quinine: the market will have to be receeding in thirty-seconds, and advancing in sixty-fourths, if the growers are to be kept in any heart of hope at all, and the game to continue. To my mind the most hopeless feature in connection with the future of quinine is the magnanimous action on the part of the Colombo analysts of reducing the cost of analysis to about a half. When it has come to that—well if it does not look like rats walking out of a sinking ship I don't know. I would not like to seem to appear ungrateful for the relief afforded; what distresses me is the utter blankness of the horizon which must have induced to such a step. There has been no preparing of the public mind; we have seen bark recede bit by bit, and quinine follow suit; but a plunge from R20 to R10·50 is simply heroic. When the history of the romance of cinchona culture in Ceylon comes to be written, the action of the Colombo analysts should make a brilliant page.

Cacao is opening up, but the crop to be gathered, while fair in some places, is said to be very short in others. The trees are, however, in good heart and looking very healthy.

What coffee crop there is in the lower districts is not going to close quite so soon as seemed at first. Even with the favourable weather we have been enjoying there is a good deal of hanging back. There have been neither rush nor push, nothing in fact to disturb in any way the dignified leisure and easy style of working, which is so much enjoyed by the Tamil labourer and so well suits him. Husk coffee, which at the opening of the season was keenly competed for by the enterprising Moorman, is now allowed to languish somewhat, and the extraordinary tales of money dropped in early sales circulate and grow, and choke off the timid.

PEPPERCORN.

PADDY CULTIVATION.

ACCORDING TO IMPROVED METHODS—TRANSPLANTATION—MANURING—PADDY CULTIVATION IN THE NORTH-WESTERN PROVINCE—THE SUPREME COURT ON PADDY CULTIVATION—AN AGREEMENT TO CULTIVATE PADDY LANDS ON ANDA SHOULD BE NOTARIALLY EXECUTED.

The subject of paddy cultivation is one that may appropriately be said to have been well threshed out. It will be admitted that it is as risky an industry as the culture of any other product which is exposed to the ravages of pest and other direful influences. The cultivation being mainly dependent on the supply of water, in districts where there are no tanks or rivers to afford means of irrigation, the cultivation must necessarily depend on the rainfall, and the hardships productive of a drought cannot be overestimated. Supposing the conditions are favourable and there is a sufficient water supply to raise a crop, there is another difficulty—one as insurmountable as the other—to contend against, namely, the failure of crop from the attack of flies. This overcome, the fortunate cultivator may safely expect to reap the result of his industry and toil. Of course where from want of water, the cultivator contents himself with what is known as the dry process of cultivation, and amongst the natives as kekulan, the risk he runs is perhaps greater, for if there is an utter absence of rain, the crop will be damaged by drought, or if the monsoonish rain sets in, it will be destroyed by the superabundance of water. The position of the goiya is certainly very trying. Under these circumstances however much one may deprecate the conservatism of the ordinary native cultivator for not improving his ways in conformity with modern instances, the difficulties which attend the cultivation of his staple food are such as to make the most enthusiastic supporter of the improved methods chary of undertaking to cultivate his paddy land in accordance therewith.

The transplanting of the paddy plant from a nursery into a field is not a novel practice. It dates back to a remote period: but it is novel to the extent that while in the past transplanting was resorted to only in case of supplying vacancies in the growing crop of a field, after the weeds were rooted out, the new method, presumably unattempted before, recommends the transplantation of a whole field from a nursery prepared for the purpose, which not only saves the hitherto unwarrantable wastage of seed paddy, but increases the yield to a surprisingly large extent.

The experiments initiated by Mr. Green with improved appliances and according to the new method have been attended with the success they are deserving of that is in a limited area, but whether they can be tried with equal success on a larger scale without in the majority of cases with serious loss to the experimentalist is a question which admits of much discussion. So far as the new ploughs are concerned the objection raised by the native cultivator to use them is on the score of expense which their purchase would entail, and that their cattle cannot draw them. This is an objection which might be got over after the lapse of time, but, the recommendation of transplanting paddy land from a prepared nursery is one that will take a longer time to commend itself to the native *goiya*.

With reference to the statement by a Galle correspondent in one of your impressions, that cattle manure is used in the North-Western Province in the cultivation of paddy, it is necessary to say that it is not correct. Cattle or any manure has never been used, and the cultivator urges as his reason for this abstention that if once they introduce manure into their fields, it will have to be continued, and in the course of time it will form an indispensable ingredient, not to speak of the expense its use would entail.

According to the practice which obtains in the North-Western Province, and which is to a great extent in accordance with that which prevails in other parts of the island, a landowner gives out his field to be cultivated on *anda*, that is by an implied agreement for a share. If the owner takes no part or contributes in no way towards the cultivation, he gets as his share a one-fourth (*karu anda*) of the crop, the remaining three-fourths going to the cultivator. In case the proprietor supplies the seed paddy for sowing, or otherwise helps in the cultivation either by taking a personal part in the operations, or by supplying the cattle for ploughing, he is entitled to a half share of the produce or *hari anda*. This co-operative system —which has existed beyond the recollection of man—has worked harmoniously and well and has tended to the encouragement and advancement of the cultivation of paddy as well as other grain on chena lands and the pecuniary payment for labour, which is beyond the means of the majority of the landowners, has been obviated.

However, though this system has been in existence for ever so many centuries and is as old as the industry of paddy cultivation itself, the collective wisdom of the Hon'ble the Judges of the Supreme Court has discovered a legal flaw in the implied agreement that is entered into between the landowner and his *goiya* by which the latter undertakes to cultivate the field of the former for a share. Up to this time the highest judicial tribunal in the land recognised the long established custom prevalent among the native population that such an agreement need

not be in writing, as under the Ordinance No. 7 of 1840, it was not "a bargain, contract or agreement... for establishing any... interest affecting land" which requires the execution of a notarial deed. (*Vide* C. R. Balapitiya No. 31,086, 7 S. C. C. 71.) This decision was delivered by the full Court consisting of Fleming C. J., and Dias and Lawrie, J.J., and went upon the lines laid down in a former judgment by Sir Edward Creasy in which it was held that an agreement affecting *fructus industriales* did not fall within the Ordinance above quoted. But by a judgment of the Collective Court, present Burnside, C. J., and Clarence and Dias J. J., this decision has been set aside and the privilege which the cultivator as well as the landowner enjoyed for over the prescriptive period—a privilege based on custom which had immemorial usage for its authority, had been taken away from him. The Chief Justice expressly states that the Court should not concern themselves in "interpreting the law, whether their decisions would encourage or discourage agriculture, or impose hardships" and Clarence J., holds:—"That an agreement to let land for cultivation in *anda* on the terms of the landowner receiving a specific share of the crop is merely an agreement for a lease with the rent to be paid in kind and the term exceeds one month. There is nothing more to be said. No custom can do away with the plain and express effect of a statute." While the "concurring hero" though of a different opinion on a former occasion discloses the courage of his convictions by assenting to the theory laid down by the majority of "my lords." Although Clarence J. is unable to discern the hardship that this iniquitous decree will create, unless, as he says, there be hardship arising out of the scale on which stamp duties are now fixed, those who are conversant with the habits and wants of native cultivators will not fail to appreciate and realize the incalculable harm the ruling in question will do to the cause of native agriculture—more especially the cultivation of paddy and fine grain. As pointed out before, the majority of the owners of paddy land are actually unable and cannot afford to pay for labour, and sheer necessity gave birth and brought into existence one of the most beneficial systems known to grain cultivation, namely the co-operative or bee system. By it the man who is blessed with extensive acres of ancestral paddy and chena land derives the benefit of having them cultivated at scarcely any expense, while his less favoured brother, who has hardly any inheritance to boast of and depends on cultivation for his livelihood, gathers a rich harvest by the sweat of his brow. Thus it will be seen that system in its operations—"blesseth him that gives and him that takes." In addition to the Government by tythes and other legal imposts levied on grain cultivation which are sufficiently oppressive, it is anything but just and fair to emburden an already overtaxed population by the imposition of additional duties. The legal requirement that an agreement by a person to cultivate a neighbour's land for a share is certainly a death blow to *anda* cultivation and a discouragement to agriculture as time alone will doubtless show and in this aspect of affairs it is devoutly hoped that the Legislature will before long come to the rescue of the unfortunate native agriculturists who are affected thereby and restore to them the boon they have hitherto enjoyed by amending the law.

CHEAP AND NASTY.

At a recent meeting of the City Commission of Sewers, at the Guildhall, E. C., on Tuesday, an important question arose with reference to the sale of upwards of a thousand packages of salvage tea at the Mart, Mincing Lane, and in regard to the powers of the public analyst.

Mr. J. Voce Moore (Messrs. Moore, Brothers and Co.) said:—While we are assembled in this court there are being sold in Mincing Lane no less than 1,090 packages of tea said to be so damaged as to be wholly unfit for human food. It may be asked, "How can this be, seeing that a Government inspector was appointed a few years ago?" I am informed by one of the officers of the Custom House that this tea was sound at the time of passing the Customs, but as salvage from fire it is in its present improper condition. I hope the indignation of respectable members of the trade will be such that they will absolutely refuse to pay for such stuff. I ask whether the attention of the medical officer of health has been called to the fact.

Mr. Cloudesley: The tea has been sold this morning, I think for a halfpenny a pound, duty paid. This tea has been salved from the fire in Westbourne Grove. I do not think it is likely to go into consumption. It is merely to find out whether there is any market value attaching to it.

Mr. Moore: The fact of the sale does not affect the seriousness of the subject. There is nothing to prevent this foul stuff being circulated amongst the small dealers throughout the country.

The medical officer (Dr. Sedgwick Saunders) said: On Friday last the secretary of the London Wholesale Tea Dealers' Association called at my rooms and brought me a sample of tea, which he said had been submerged at Plymouth. He wished me to stop the sale of this commodity at the Mart today. I got a sample of the tea and analysed it immediately. I found the tea indicated a quality which it has after being submerged. Instead of being the range of healthy tea—between 28 and 48 per cent.—this came out 19·3 per cent. The ash was 7 per cent. instead of six per cent., but the extra percentage might be fairly due to a little carelessness in packing. I consulted Mr. Blake, the clerk and Mr. Baylis, the solicitor, to ascertain what the power of a medical officer of health was. I found that, unless I could go before a magistrate and swear that the tea was unfit for food, it was impossible for me to interfere with it. I had no legal right to the sample at all, and I could not in any way swear that what I had was a sample of the tea offered at the saleroom. This seems to be a different matter from that referred to by Mr. Moore. I think it was in the process of re-drying the tea that the deterioration took place. Amongst the tea were minute particles of carbonaceous matter. It might have been a wilful foreign admixture, or simple carelessness in drying the tea. It is an interesting question to know how far the medical officer might interfere in future. Unless the tea is absolutely sold to the detriment of the person buying it, there seems to be no legal remedy.—*H. & C. Mail*, Oct. 21st.

CHINA AND JAPAN TEA EXPORTS 1887-8.

It will be observed from the figures we give below, that no important change has taken place in this season's exports from China to Great Britain: the decrease is still about 30 millions of pounds and not likely to be diminished. The Hankow shipping season is now closed with a stock of about two million pounds, which will probably be absorbed by the demand for the north of China. The stock of black tea at Shanghai is about six million pounds, being 3½ millions in excess of that of last year. The shipment of this will be spread over the next three or four months, and we suppose a large portion of it may be shipped to England. The Foochow shipping season will be practically over a month hence, as the receipts are dwindling down to insignificant quantities, the fortnight's arrivals being only equal to 7,500 chests against 22,000 chests the same time last year. The stock at Foochow is equal to 113,549 chests or ten million pounds, against 134,935 chests or 12 million pounds last year. If the whole of the Shanghai and Foochow stocks are shipped to Great Britain during November and December, which is scarcely probable, the export will be 106 millions of pounds, against 140 millions last season. Comparing last year's receipts at Foochow with present year's, there is little probability of November and December's receipts being over 25,000 chests. The decrease of 30 millions

of pounds in the London stock of China tea has apparently had no other effect on the London tea market, but to enhance the value of Indian and Ceylon teas, especially the lower grades. This is of great importance to Ceylon planters, as indicating how easily the public taste has adapted itself to the use of the better qualities of British made tea. That the decrease in the supply of China tea has had so little effect on the prices of this description is, no doubt, chiefly owing to this and to the fact that the supply of Indian tea, until the beginning of next year, will be large enough to meet all the demands made upon it without seriously diminishing the stock. In the beginning of next year, when the usual pause in the London importations takes place, and the consumption until the end of June is, with the exception of the Ceylon supply, out of stock, we shall probably see some further improvement in prices of all teas, especially the lower grades of British made. The important question for Ceylon planters is, whether the decrease in the supply of China tea is permanent or temporary? At present judging from the fact that fluctuations in prices have not during recent years affected the export to Great Britain, we are inclined to the belief that the decrease is only temporary, caused, as the Chinese maintain it was, by unfavourable weather during cropping time. This point cannot be settled however until next June and July. Whoever attempts to forecast the future course of the tea market on this year's experience would make a great mistake if he omitted from his calculation the effect on consumption which the increased use of British made tea would cause—two pounds of this probably goes as far as three pounds of China tea: he may, therefore, see a decrease in the deliveries, which will in some degree counteract the effect of the diminished supply from China.—We will postpone the further consideration of this view of the subject until we write again upon it. It will be noticed that the export to America is 10 million pounds deficient. This is important in so far as a supply of Indian and Ceylon tea may be required to make it good. The decrease can, however, be partly met out of the stock of Formosa tea held at Amoy for an improvement in the American demand. The Chinese have, in expectation of its taking place, held to their stock with great pertinacity. The stock of this description at Amoy is just double what it was at the same time last year. England does not take more than a million pounds annually from Amoy—out of a total of 18 millions of pounds.

PETROLEUM BORING IN JAVA.—A company with a share capital of £12,500 has been formed at Dordrecht (Holland) for the working of petroleum springs in Java. The shares were not offered to the public, but have all been taken up by a few private capitalists, among whom is Mr. B. W. Blydenstein, of the wellknown London banking firm. Mr. A. Stoop, jun., who is now in treaty with the Dutch Indian Government for the concession of petroleum springs in Java, will be the managing director of the concern in the Dutch Indies.—*Chemist and Druggist.*

DRY FLOORS.—The *Java Bode* is assured by a correspondent that the most effective way to keep the ground floors of dwellings and storehouses dry is, when building, to spread over the spot a layer of fine coal dust stamped compactly. A layer of sand of equal thickness is then laid over it, and upon that the floor. When so constructed, the floor will, it is said, always remain dry from the coal dust absorbing the moisture of the soil. The sand layer and hence the floor are secured from dampness and continue dry. To keep away white ants, the laying of a layer of coal dust under ground floors, has proved highly serviceable owing to the inability of these destructive insects to make their way through it.—*Straits Times.*

COCONUT OIL IN THE SEYCHELLES.—The manufacture of coconut oil is carried on in the Seychelle Islands on a very extensive scale. A large portion of the oil sold in England as "Mauritius" comes from Seychelles. Nearly all the mills in the colony are of the most primitive description—a hollow tree trunk, a spar, an ox, and a boy with a stick, and the apparatus is complete. One or two improved mills were introduced some years ago, but they failed for two reasons—they easily got out of order, and "they did their work too well." In these parts the poonac is nearly as valuable as the oil itself; but if all the latter is extracted, the residue becomes almost valueless for feeding cattle, pigs, &c., and it was in this respect that the improved machinery utterly failed. Seychelles is the only place where the double coconut, specimens of which were shown at the Colonial and Indian Exhibition, is to be met with, and even here there is only one island, that of Peaslin, where it grows in profusion. The nut when cut in two and properly polished makes a first-rate and very ornamental bread-dish or flowerstand.—*Chemist and Druggist.*

MANUFACTURE OF CHOCOLATE IN GERMANY.—The chocolate manufactures of Germany have in a comparatively short time attained a position of great importance in foreign markets. It is not long since foreign chocolate—especially Italian, French, and Swiss—was exclusively consumed in Germany, and no slight exertion and sacrifice was required before German chocolate manufacturers secured recognition in their own country. Today a high degree of perfection has been reached in the manufacture of chocolate, this being due to the fixed determination that only a pure article should be sent into the market. As to the method of manufacture it is instructive to observe the various treatments which the cocoa bean has to undergo. Cocoa beans on shipment are as a rule shot into the vessels without packing of any kind, and are only put in sacks on arrival at European ports. In order to prepare the beans for use they are first roasted over the fire in tin drums like coffee, the hull cracking, and an oil having a burnt taste being formed as with coffee, which has the peculiar smell of the bean. The bean is now crisp and of light brown colour. The sharp taste is removed and a mild and bitter taste takes its place. After cooling, the beans are passed into an apparatus where the hull is separated and the kernels broken into large pieces, the root germs having been broken off. The whole mass falls through a sieve, the husks being blown away by a winnowing machine. The cocoa is now crushed by rollers and made liquid by means of warmth (the fat of the beans melts at 30 degrees), and in this condition it is ground as fine as possible by means of a series of rollers, being finally cast in moulds, when it is allowed to harden. This is the cocoa which is used for the making of chocolate.—*Kuhlow's German Trade Review.*

ASPHALT PAVEMENTS.

To the Editor "Oil, Paint and Drug Reporter."

Sir,—What are the best compounds for making asphalt pavements—something which has been tested with good results? R. C.

[The wearing surface is composed of four parts, viz: 1. Refined asphaltum. 2. Heavy petroleum oil or the residuum of the same. 3. Fine sand. 4. Fine powder of carbonate of lime. Asphaltum is refined and brought to a uniform standard of purity and gravity. The heavy petroleum oil, which may be the residuum by distillation of petroleum, must be free from water, light oils and other objectionable impurities, of specific gravity 18 to 20 deg. Beaumé, and must bear a heat test of 250 deg. F. By melting and mixing these two hydrocarbons, heavy petroleum oil and asphaltum the matrix of the pavement, called "asphaltic cement,', is obtained, which cement has a fire test of 250 deg. F., and at a temperature of 60 deg. F. has specific gravity of about 1·25. They are mixed in the following proportions by weight:

Refined asphaltum	100 parts
Heavy petroleum oil	20 parts

The pavement mixture is formed of the following materials, and in the proportions stated:

Asphaltic cement from	12 to 16
Sand from	73 to 67
Pulverized carbonate of lime from	15 to 17
Total	100 100

These proportions are varied according to circumstances, as may be necessary to secure the best practical results. The carbonate of lime may be reduced or omited entirely when suitable sand can be obtained. In order to make the pavement uniform the proportion of asphalt cement must be varied according to the quality and character of the sand.—ED.]

THE COCONUT.

Since it has become known that our fair state of Florida is capable of great things in the growing of coconuts, considerable interest is taken in the subject. This delicious nut as a fruit but a short time since was brought to our shores from the tropics in irregular ways, much as a luxurious delicacy. Now the nuts are so extensively used in various ways, that they have become quite an important article of trade, and are destined to become greater still.

There is no vegetable growth in the great economy of nature bearing so important a part in satisfying the many wants and desires of man as the coconut tree and its products. It is a palatable and highly nutritious food and most delicious drink. It provides him shelter from the inclemencies of the weather, suitable raiment for his person, and its uses for necessary conveniences and fancy are so many as to be scarcely creditable.

Considering the great usefulness of this tree it is not surprising that where grown they are so highly prized. They are familiarly and quite generally known as 'our friend.' Where the coconut is planted and grown for profit the income derived is very great, most sure and reliable, while the labor or expense of cultivation is nothing.* Once a favourable spot is selected in which to plant and the seed nut set in the ground, nature does all else; indeed, until the tree matures into bearing it must be left entirely and absolutely to itself. Then for generations it is almost a constant harvest. Some of the peculiarities of these trees are strange. The tree, for instance, is larger in diameter at eight years of age than at forty, or ever after. When young the tree just above the ground swells out to great proportion, sometimes over three feet in diameter, from which the trunk continues smaller to its feather like top. As it grows older the bulb is gradually absorbed and gradually disappears. The tree never grows perpendicular, but leaning. When ripe its fruit drops to the ground in the night time only.* It requires quantities of salt water to nourish it, which it industriously pumps up in gallons through its queer looking and pipelike roots into the growing coconut, where, by some process and formula of nature, it is as by magic changed to a most exquisite and sparkling drink, hence proximity to the ocean is a necessity to this wonderful tree.

It is unfortunate that this grand plant can be grown only in the tropics, where the people are so indolent and human blood is so tired, for it has never received proper attention and its nature and characteristics no study, for sloven southerners are content to do things in the most primitive way, just as their ancestors did it ages ago, and today they peel or strip off the fibrous husk in which the nut is encased by aid of a sharpened stick, precisely as it was done in the good old days of Confucius. Time, although measured by the liberal scale of centuries, is of small consequence to them in making preceptible progress and material development. The native is ignorant of the best conditions and habits of this to them inestimable product as are the thoughtless monkeys and unreflecting parrots which inhabit the adjacent tree tops. He has ever been content to pluck and eat, never planting, but with sweet san souci puts his whole reliance on his kind old friend, nature, who never fails him, and who does his sowing by aid of the tornado and the hurricane, tearing up and scattering both tree and seed nut over the land. The friendly whirlwind comes often enough for his planting purposes, why should he fret his laggard brain therefore, with tiresome questions of seed time, for the harvest is ever with him in lavishness. He lives in perpetual plenty, and the bountiful supplies of nature surround him. In favourable weather the coconut tree has a succession of crops each six weeks to gladden his heart, tickle his palate, and satisfy the demands of his stomach.

After many centuries of neglect and haphazard growing the coconut tree has finally met in Mr. Ezra Osborn, of Middletown, N. J., one who is developing and making this plant the subject of careful study and investigation. Mr. Osborn is a gentleman of rare mental attainments, an enthusiastic worker, full of energy, and possessed of a large fortune, has reduced the desultory fragments of knowledge pertaining to the subject he could gather into system, and today he is the most thoroughly posted man on it in the world. He has learned what he could in communicating with tropical countries in his researches, planted the nut, and raised the tree in various conditions, observed and studied their development, and learned their habits and peculiarities.

The popular belief has even been that there were several varieties of the nut. Mr. Osborn finds but one, and says that what appears to be differences in variety are but the result of influence, such as climate, soil, location, nourishment, &c., that so susceptible are they to outward things as to quickly assume an apparently decided individuality peculiar to itself. No matter where the seed nut hails from the tree grown from it will adapt itself to the locality where it stands and takes an apparent change of feature.

Mr. Osborn found that parts of Florida below the 27th parallel were peculiarly adapted to growing coconuts, especially on the southeast coast and on the adjacent keyes. He finds that locality, because of the quality of soil and the underlying substrata of lime, then together with the rare climate, is the best and most productive coconut growing region known. He found the fruit on the few bearing trees there to be of large size and of superior quality. Mr. Osborn saw wonderful possibilities of the locality, and at once purchased all the land he could secure there suited to the purpose,a nd started groves of coconut trees, until now he has growing over 300,000 young trees, which is by far the most extensive scale on which they were ever cultivated before. His lands extend along the ocean for over sixty miles, thirty-five miles of which are young coconut trees. They are all planted in the best manner for large yields, and all stand near the restless breakers, where their long reaching roots can get to the salt water, and their

* Neither statement is correct: cultivation costs something and the trees respond to attention; while the nuts, if not plucked, will certainly fall at all hours.—ED.

great leaves receive a continual and abundant supply of ocean spray, carried into their ever thirsting heads by the busy trade winds constantly blowing over the tireless ocean there. In order to plant this vast forest it has required three seasons and the united labor of a large company of trained men. Seed nuts for the purpose were got in schooners from South America, from Trinidad and the Spanish main. The labor, care, trouble, and expense attending it has been great, but handsome returns can be expected. The country thereabouts is wild and unsettled, and those who go there are mostly sojourners in winter from the inclement northern states. There they spend the cold months living in tents. Winter life in tropical part of Florida is full of romance and pleasure. Cold is unknown and all the winter lovely flowers and luscious fruit are abundant. Game and fish are quite common. Oysters, crabs and other delicacies are plentiful. Gigantic vegetation gives grateful shade, and the sweet songs of tuneful birds are a continual serenade, while on the seashore rare and curious shells are found at every step. Out door life is most charming; fresh pure air fills the lungs at every breath. It is not surprising that invalids here gain rapidly in health and strength, for this reason northern people seek this locality and here pass the winter in dreamy blissfulness.

Every part of the coconut tree and its products is of value. The flowers or blossoms and roots are an astringent, and are extensively used as such in debilitating diseases.*

The wood of the tree when young has a fibrous consistency, and resembles a huge rope, used then for spiles; in building docks and bridges it is the best possible material for the purpose, as it never rots, and it is well nigh indestructible. When older the wood becomes solid, very hard, and will take a high polish, and is then known as porcupine wood.

The sap is by a simple process converted into a strong alcoholic liquor. Sugar is also made of it in profitable quantities, but it injures the tree and diminishes its bearing.

The milk is made into cocoa wine. The stem of the great-leaf makes good arrows, excellent spear handles, and elegant canes which when broken, presents sharp needle like points, which can be used as deadly weapons in thrusting. Carrying these canes is prohibited by law in Cuba, where they are designated in the act as dangerous weapons. The husk which covers the nut is composed of fibre, which cut transversely makes useful cleaning brush for the housekeeper. This same fibre is manufactured for the trade into matting, cloth, brushes, parchment, paper, &c. The shell of the nut is made into cups, and carved into various forms and things, but is more largely used to adulterate spices being ground up for the purpose.

The young leaves are used for food, being cooked they somewhat resemble cabbages. The thin fibrous and delicate case within which the leaflet appears is made into fish lines, fine cloth, and is fine, soft, exceedingly strong and tenacious. Ropes made of this are superior to hemp or any other known substance, being durable and strong, floats in the water, and never rots. For use about ships they prove themselves to be of the greatest value.

The oil obtained from the nut is well known, and is used for a variety of purposes where a superior kind is desired. Down south where oiling the body is a grateful process, it is used for that purpose. The poorest of it is used as an ingredient in making the finest soaps and of cocoa butter used in medicine as a basis for salves. Desiccated coconut is now an important element in pastry, sweets, meats, and confectionery. The sale for these purposes is very great and increasing yearly. The demand for these uses alone will ever be so great as to tax the capacity of all the coconut producing land in the world available for the purpose. The base of the leaf makes an excellent paddle for the canoe or dug-out, the natives fans are also made of the leaf. The qualities of this tree would indeed fill a book. Unfortunately the land suited to the successful growth of the coconut is exceedingly small, therefore over-production need never be feared. The demand will continue to be great and more than the supply.

The profits attending the raising of coconuts is sometimes marvellous; for example, each bearing tree will produce nuts yearly to the value of $4 and upward, estimated very low, above all expenses. Each acre of land accommodates a little more than 100 trees, hence on ten acres a clear yearly profit of $4,000 and more is made. All this, with little or no care or labor but the harvest, which consists of the picking the nuts from the ground, one hundred acres of land in coconuts will produce an income not to be despised. The Florida coconut is a large nut of superior quality, and will no doubt occupy a front place in the market.

The vast groves of Mr. Osborn were planted during the past three years and will begin to bear in from five to six years, hence in seven years or so they be producing millions of delicious coconuts.*

Besides the groves of Mr. Osborn others have made extensive plantations in the vicinity, and are devoting to their growth much of their time, and in a few years, when the thousands of nuts now being planted are bearing trees, the coconut industry will be the most extensive and important of Southern or tropical Florida. —*Monmouth Inquirer.*

* Entirely new to us.—ED.

INDIAN EXPERIENCES.

(Continued from page 348.)

The history of the introduction and subsequent establishment of the Chinchona plant on the hill tracts of India has been often written, but a rapid retrospect may not be out of place in these papers. In introducing the plant into British India the primary object of the Government was ostensibly providing the natives of the fever-stricken districts with a cheap febrifuge. Before its introduction quinine and other forms of Chinchona bark extract were only obtainable by the wealthy, the prices to the masses of the natives being prohibitory. It was not intended, in the first instance I believe, that the State, for any length of time at least, should keep itself in the position of a private producer and trader, and regularly place large consignments of bark on the London market in competition with private individuals. This practice, however, has been kept up ever since its adoption in the year 1872, when the trees planted at the commencement were twelve years old. In consequence of this there have been loud and general complaints by private planters against the successive Governments of the day.

It was in the year 1859 that Her Majesty's Government engaged the services of Mr. Clements R. Markham for the special duty of introducing the Chinchona plant into India. He started on an expedition to South America in the early part of 1860, and arrived in India at the end of the same year with the first instalment of Chinchona plants. Mr. Markham was ably assisted in the arduous and dangerous work of collecting, establishing in cases, and subsequent transmission to India of the different species of Chinchona plants by Mr. Spruce and Mr. Cross, both, I believe, practical gardeners and botanists. The plants were taken to the Nilgiri Hills and placed under the care of the late Mr. W. G. McIvor, at that time Superintendent of the Government Botanical Gardens at Ootacamund, and who was subsequently appointed Superintendent of the Government Chinchona Plantations on the Neilgherries. Under his able management the plants thus used from South America were rapidly propagated, and the magnificent permanent plantations of the present day established. The Government, beyond all question, were fortunate in having at hand a gentleman of

* If the whole 200,000 trees were in full bearing and yielded 40 nuts each, the result would be 12 millions. But a proportion of the trees will die and full bearing does not come at twice seven years.—ED

Mr. McIvor's great abilities to at once undertake the work, otherwise the great success of the experiment might not have been so rapidly achieved. Honours were in due season bestowed on the collectors and introducers of the plants, and no one grudged them these, but in the opinion of many these honours ought to have been divided. With the introduction of the plants the undertaking was only, as it were, begun, and all success in this direction might easily have been rendered abortive by subsequent mismanagement, but, as a fact, the whole of Mr. McIvor's labours from the first introduction of the plants to the complete establishment of the enormous plantation proved to be a brilliant success, but so far from his being equally rewarded with Mr. Markham and his coadjutors, we actually find Mr. McIvor in the year 1876, shortly before his death, making the following complaint to the Government of Madras:—"It also becomes instructive to note the effects of this undertaking on the position of the parties employed in its development. Mr. Clements Markham, Mr. Cross, and Mr. Spruce were the prominent agents employed in the introduction of the plants and seeds. The duty on which these gentlemen were employed was of a preliminary nature and of short duration, and the fruits of their labours depended on the judgment with which the plants and seeds were managed in this country. The great success I attained in the propagation and cultivation of these plants secured for these gentlemen a graceful and well merited reward. Mr. Markham received a bonus of £2000, and was created a Companion of the Bath; to Mr. Spruce a pension was granted, and Mr. Cross received a bonus. How different has been the effect on myself. Instead of being rewarded I have been degraded from that independent position I originally occupied. Even the ordinary increments of salary accruing from length of service in every position under the Government has been denied me, and for upwards of ten years I have laboured in this department without receiving an increase of emoluments. I do not make this statement in the form of complaint, because I am not entirely without my reward: I stemmed the torrent of error which would have swept away all benefit from a great national undertaking, and my judgment and courage in doing this has met with the approbation of the civilised world. Still it is important that the illiberal treatment of myself and my department should be understood. It has retarded the development of the undertaking. It has caused all my experienced assistants to leave and seek employment elsewhere."

What made Mr. McIvor's complaint, the more bitter was that he had been recently, and most unjustifiably degraded from an independent position with regard to the Chinchona experiment to a subordinate one under the Commissioner of the Nilgiris consequent upon his indomitable pluck in support of views of cultivation and treatment of the plantations, which he knew to be right, against those of others of no experience, although holding high offical positions. I may be pardoned for thus expanding my remarks on the late Mr. McIvor, when it is known that at the time it was too much the custom amongst the Civil Service officials of India to look askance at successful endeavours on the part of anyone outside the pale of their own favoured community, and the very name of planter, or worse still, gardener, was with them a byword or term of reproach.

In Mr. McIvor the successive Governments of Madras had a man of intelligence and ability, indomitable energy, and great resource, which they were not always willing to acknowledge or act upon. Mr. McIvor was appointed by the honorable East Indian Company Superintendent of the Botanical Gardens in the year 1848 in the uncovenated Civil Service, and this appointment, in conjunction with the Superintendence of the Chinchona experiment he held with honour to himself till the time of his death, in 1876. He was essentially a gardener, and was never ashamed of being called by that name. He lost no opportunity of upholding the honourable character of his calling, or of holding out encouragement to young men in the same profession throughout a long and useful career in India.

About the year 1864, or at an early stage in the Chinchona experiment, Mr. McIvor made the discovery of what is still called the "mossing system," and which subsequently proved to be a very important and valuable one. Whether this discovery was made accidentally or otherwise is, I believe, not known. It consisted in applying to the stems of the trees a thick covering of moss, which was allowed to remain for a year, it was then removed and the bark taken from the tree by alternate strips of about 1 to 2 inches wide—that is, a strip was taken, and one left all round the stem of the tree. It was found that this process of excluding the light and air from the stem had the strange effect of increasing to a very considerable extent the alkaloids in the bark. After the removal of the first strips of bark the stems of the trees were again mossed and allowed to remain for another year before the remaining strips were removed. By this time it was found that the decorticated portion of the stem had renewed its bark all over, and presented a light coloured granulated appearance. This renewed bark in its turn was harvested, and found to contain even a greater amount of alkaloids than the original bark under the mossing process. Mr. McIvor made no secret of this discovery, but, on the contrary, strongly recommended its adoption on the Government plantations. This recommendation was met by a storm of opposition from various quarters. But chiefly from the Government Medical Department, and from the Government Quinologist, who was appointed on a large salary by the Home Government in 1867 to investigate on the spot various questions connected with the elaboration of alkaloids, the harvesting of the bark, the most economical and efficacious mode of preparing the febrifuge, &c. One instance of the kind of opposition offered may be recorded. Dr. Bidie of the Madras Medical Establishment, in a report submitted to Government, bearing date 1874, says:—"As various facts appear to me to point to the conclusion that mossing does not increase the alkaloids by exercising a fostering influence on the process by which they are eliminated from the crude sap, but that the increase is possibly obtained at the expense of the original bark." Dr. Bidie did not state in his report what these "various facts" were, and the groundlessness of this theory was soon after demonstrated by the experiments of the late Mr. Howard on the barks produced under the several varying conditions. The Quinologist himself recommended the coppicing system of taking bark to that of mossing, but Mr. McIvor had already put this system to the test and found it wanting, and so the battle went on, without any very satisfactory results even up to the date of Mr. McIvor's death. The fact, however, that ever since that date renewed barks of all the species of Chinchona under the mossing process have obtained in all the markets of the world much higher prices than those unsubmitted to such treatment abundantly establishes the great value of the discovery. Mr. McIvor made an attempt to protect his discovery by applying for a patent for the process, which was perhaps, very properly refused. At the same time it is the general opinion in India that he ought to have been in some way amply rewarded by a Government that was not slow to take advantage of the discovery.

Private enterprise in Chinchona planting on the Nilgiris has made gigantic strides since Mr. McIvor's time notwithstanding the steady opposition and petty annoyances offered to planters who are willing to invest their capital in the land; in fact, the development of the industry has been so great, resulting in such an enormous production of bark and a consequent reduction in prices, that planters are almost beginning to despair of realising the handsome returns they once hoped for. In addition to the Government still continuing in the position of private producers and sellers of bark on a large scale, they also continue to hamper the private planter in many ways, and

their unwillingness to facilitate the efforts of private enterprise is thus complained of in a recent issue of a Nilgiri journal:—"Thousands of acres of virgin forest in the southern and other parts of India, admirably adapted, not only for the cultivation of Coffee, Tea, and Chinchona, but of numerous other products, are lying idle and unproductive, because the Government choose, without assigning any reason, to put a veto on their assumption by men who would transform them from a desert into a garden, and in doing so find employment for and ameliorate the condition of thousands of natives. The old cry that India is unsuitable for the employment of Europeans is too stale to meet with further credence, and is contradicted by the prosperity of the Tea planters of Assam, Cachar, Chittagong, and the Nilgiris. The real source of this antagonism on the part of the Government will, we think, be found in the old Civil Service jealousy of Europeans unconnected with the Government obtaining any social position, wealth, or influence in the Mofussil. The members of the governing faction naturally recent the influx of a body of men who share with them the respect of the natives, and who, if allowed to become sufficiently numerous, might ultimately be called upon to assume a portion of these magisterial duties which are now reserved for their own particular service, and who in time might render that service almost unnecessary." With regard to the waste land laws the following is the state of matters at present existing on the Nilgiris:—Under the old rules rupees two per acre per annum is charged on all forest lands in addition to the original purchase money, but in no case is any sholah—*i. e.*, forest of more than a quarter of an acre in extent given, and if there should be a spring or passing stream even these small bits are reserved. Under the same rules eight annas or one shilling per acre per annum is charged for grass lands, with the first five years free of rent. This grass land is not rich, and great care and expense have to be incurred before Chinchona plants can be induced to make a start on it, and of course growth is slow and the planter has to wait a long time for any returns.—PLANTER.—*Journal of Horticulture.*

(*To be continued.*)

NOTES ON ESSENTIAL OILS AND ALLIED PRODUCTS.*

The October Report of Messrs. Schimmel & Co., besides dealing with market questions, contains a large amount of other interesting information respecting essential oils and allied products, from which the following statements are selected:—

Anise Oil.—The production of anise in Russia has now attained such enormous dimensions as practically to render all other sources only of nominal importance. Under the name of anisol an article is sent out which is said to be separated from the elæoptin by a cold process, the injurious influence upon the aroma of the oil resulting from the heat necessarily employed in the ordinary rectification processes being thus avoided. It is claimed that anisol represents the anise aroma in the purest and most perfect form, and that it is free from a disagreeable bye-flavour met with in all oils of anise.

Camphor Oil.—The low-boiling portion of Japanese camphor oil (sp. gr. 0·900, b. p. 175° C.) is being largely and increasingly used in various industries, its low flashing-point, 11° C. less than that of turpentine oil, contributing to bring it into favour. It also has the advantage over turpentine oil of dissolving appreciably more readily all resins, paraffin, stearin, etc., and mostly without the application of heat. According to a quotation from Simmler's 'Die tropische Agricultur,' camphor oil was formerly looked upon in Japan as nearly useless, and was only occasionally used for the dilution of lac or by the poorer people as a lamp oil. In a purified condition it is however now used most advantageously in the lac manufacture. A favourite lac in Japan is prepared from 10 parts of camphor oil, 3·3 parts of turpentine oil, and 8 parts of copal resin. Paper treated with a lac prepared from colophony and camphor oil becomes very transparent. By adding camphor oil to melted asphalt a lac is obtained which gives to metal plates as fine and clear a coating as the celebrated Japanese "uruschi"; the best proportions are camphor oil 22 parts and asphalt 5 parts. Paper can be made waterproof with a mixture of camphor oil and linseed oil.

Cananga Oil, Indian.—Under this name a relatively low-priced oil is imported from Java. It is said to come without doubt from the *Cananga odorata*, the same plant as the ylang-ylang oil of the Philippines is derived from, and to which, as pointed out by Flückiger (*Pharm. Journ.*, [3], xi., 934), the name *Unona odoratissima* has been incorrectly given. The odour of the Java cananga oil cannot, however, be compared with that of the finer distillate from Manilla, though whether this is due to the Java flowers being inferior in odour, or to a defective method of preparing the oil, is not yet known.

Cardamom Oil.—The last cardamom harvest in Ceylon is said to have yielded particularly heavy and full-seeded fruit, correspondingly rich in oil.

Cedar-wood Oil.—For the economical production of this oil, which is largely used in Germany as a basis for soap perfume, the waste from the lead pencil industry is said to yield an ample supply of material. Speaking of fractionated cedar-wood oil, prepared for optical purposes, reference is made to a demand for an oil of syrupy consistence, which should be at the same time free from colour. Without affirming that such an oil could not be produced, an opinion is expressed that its preparation in small quantity would be excessively troublesome and tedious.

Citronelle Oil.—Assam appears likely to become a competitor with Ceylon in the production of this oil.

Eucalyptus Oil and Eucalyptol.—Algeria and California are now powerful competitors with Australia in the production of eucalyptus oil. It is affirmed that Algeria alone is now in the position to supply the whole world with *Eucalyptus Globulus* oil, and that a large quantity is available from California, where it is produced as a bye-product in the manufacture of an anti-calcaire preparation for boilers. The production of eucalyptus oil appears, moreover, to be increasing in Australia, where it has spread from Victoria to South Australia, whilst in Tasmania, also, a company has been formed for the distillation of different species of *Eucalyptus*. A statement made in a previous report that the Australian oil from *Eucalyptus amygdalina* contains no eucalyptol, and is inferior in this respect to *Eucalyptus Globulus* oil from Algeria and California, was subsequently challenged and stigmatized as "distinctly erroneous." Messrs. Schimmel, however, now reaffirm that statement, and say that the fraction of the amygdalina oil separable at a temperature of 176°-177° C. has a specific gravity of 0·886 at 15° C. (eucalyptol has a specific gravity of 3·930), and is probably a mixture of a terpin (eucalypten, $C_{10}H_{16}$) and a small quantity of cymol.

Geranium Oil, Turkish, or more correctly *Andropogon Oil.*—It is stated that the more expensive sorts of Turkish geranium or palmarosa oil, coming from Constantinople, are submitted to a special treatment which makes them especially suitable for the adulteration of rose oil; it consists in bleaching the oil in the sun and rectifying it several times over roses.

Hop Oil.—The oil distilled from Bavarian hops has now displaced that prepared from lupulin, which it excels in the presence of a fine fragrant hop odour, and the absence of the smell resembling that of butyric or valerianic acid that accompanies the lupulin oil. Hop oil is said not to possess a narcotic action, but to correspond in this respect with similar volatile oils.

Ginger Oil.—It is pointed out that this oil possesses only the odour of the ginger root and not its agreeable pungency, and that therefore it cannot take the place of

* Abstracted from the October Report of Messrs. Schimmel & Co., of Leipzic.

ginger essence in the preparation of stomachic liqueurs.

Marjoram Oil.—A Spanish distillate of *Origanum Marjorana*, which has recently been introduced into commerce, is said to be unsuitable to replace the oil distilled from German marjoram, since it possesses quite different characters. The Spanish oil may be distinguished by its freedom from colour.

Patchouli.—The insufficient supply from India and Singapore of the patchouli herb has occasioned an attempt to acclimatize the plant in Peru.

Pepper Oil.—The price of pepper oil is said to stand in no relation to the cost of the raw material, it being now yielded as a bye-product in the preparation of piperonal (heliotropin). The oil is reported to be used exclusively in the "improvement" of spices.

Pimento Oil.—It is suggested whether this oil might not to some extent replace the dearer clove oil in perfumery, since it consists chiefly of eugenol, and and the two oils are not distinguishable chemically from one another.

Tansy Oil.—Severe symptoms of poisoning are said to follow taking a teaspoonful of tansy oil, whilst death may be caused by a teaspoonful and a half.

Rose Oil.—Some further information is given as to the progress of the experiment in rose cultivation near Leipzic for the purposes of distillation. The weather during the past year was extremely favourable to the growth and harvesting of the flowers, and the yield has amounted to nearly two kilos of pure rose oil, and about 3000 kilos of rose water, prepared in the proportion of equal weights of roses and water. It is estimated that at present there are about six hectares of land under culture with roses in the neighbourhood of Leipzic, and this quantity will probably considerably increase. The German rose oil is claimed to have an uncommonly fine perfume, and to be the best now met with in commerce, and it is said that a comparison of it with the Turkish article will raise in the mind of any expert suspicions as to the latter. The Turkish oil contains a smaller quantity of the solid constituent than the German, which solidifies at about +20° C.; it would therefore be interesting to decide whether this is a result of sophistication, or whether, as has been stated, the oil from roses grown in high elevations contains less stearoptene than that from roses grown on the plains.

Rosewood Oil.—The wood from which this oil is distilled *(Convolvulus scoparius)* is superficially quite odourless, the rose-like perfume becoming perceptible in proportion with the disintegration of the wood. This would appear to indicate that the oil glands are contained in the substance of the wood, but unfortunately they are so sparingly distributed that the distillation of the oil is hardly remunerative. Moreover, the oil appears too weak in odour to be of practical importance as a perfume. It is said, however, that mixed with twenty times its weight of copaiba oil it is used as a bait for wild rabbits and rats, who are attracted by its perfume.

Sandal Wood Oil.—The wood as imported from India shows great variations in the amount of oil it contains. The best qualities come from Bombay and Tellicherry, and fetch a relatively high price, the supply of root pieces being limited. A small distillate similar to the East Indian oil is yielded by the so-called Macassar sandal wood, which is brought from Timor and Sumba, the "Sandal Wood Islands," off the North-west coast of Australia, to the market in Macassar, and is thence consigned to Holland. The West Australian sandal wood, from Swan River, for which Singapore is the principal market, is said to yield an oil insufficient in quality to meet the most moderate requirements. The so-called "West Indian sandal wood oil," distilled from the wood of an undetermined Venezuelan tree, is disappearing from commerce, though it used to be imported largely into the United States. In respect to odour it is described as not having the slightest similarity to the East Indian oil, and quite useless for perfumery purposes.

The following are described as novelties:—

Betel Leaves Oil, distilled from the leaves of *Piper Betel.*—The essential oil is brown in colour and has an agreeable tea-like odour and burning taste. Specific gravity 1·020 at 15° C. It boils at 250°-260° C., and it consists of a phenol, corresponding completely in properties and reactions with eugenol, and an indifferent hydrocarbon. The betel leaves operated upon, which came from Siam, yielded about one-half per cent. of essential oil; but as according to a statement by the consignor, the leaves had been improperly dried, it may be that they had lost a portion of their oil. If, as there is little reason to doubt, the essential oil is the active principle of the leaves, it would probably be worthy of an experimental investigation. According to the Pharmacopœia of India the leaves are useful in catarrhal and pulmonary affections generally, and especially those of children. The dose is not given, but it seems probable, judging from its composition, that the oil would be harmless, which would also appear from the long and general use of a mixture of the leaves with lime and arecanut as a masticatory in the East.

Masterwort Oil.—The essential oil from the root of *Imperatoria Ostruthium.* It has a strong aromatic odour, recalling that of angelica oil, and a pungent aromatic taste, and consists of a hydrocarbon. It boils between 170° and 190° C. Specific gravity 0·877 at 15° C. One hundred kilos of root submitted to distillation gave 800 grams of essential oil.

Musk Seed Oil.—Distillate from the seeds of *Abelmoschus moschatus.* It does not appear from published reports that this oil has been prepared or is known; nevertheless it is considered by Messrs. Schimmel of great interest, and of value in perfumery, on account of its intense and persistent odour of musk and civet. Specific gravity 0·900 at 25° C. It solidifies at a temperature below +10° C., and contains a free fatty acid which partially separates even at the ordinary temperature. This acid is not myristic, but probably palmitic acid. In the distillation the oil partially decomposes; the distillate is strongly acid and contains free acetic and fatty acid. The oil after being freed from the fatty acid remains liquid at 0° C.

Ledum Oil.—The ethereal oil of *Ledum palustre* from the herb, specific gravity 0·932 at 15° C. Boiling point 180°-250° C. It was prepared to obtain Ledum camphor, but neither the normal oi nor the separate fractions yielded the camphor when placed in a cooling mixture. Neither was the statement confirmed that camphor is formed in the oil when it is exposed to the air. This oil was shown at the Philadelphia Exhibition, and it is said to be very active against moths; but its present high price would hardly allow it to be used for that purpose.

Celtic Nard Oil.—A distillate from *Valeriana celtica*, which grows in the Styrian Alps. This oil, which has a specific gravity of 0·967, and boils at 200°-300° C., is said to resemble in odour rather Roman chamomile oil and patchouli oil than valerian oil. Its perfume is very powerful. The root of *Valeriana celtica* was formerly an important article of Eastern trade; at present it is only obtained with difficulty, and is usually mixed with about 80 per cent of earth adherent to its fine fibres. The root differs in external appearance from the official valerian root as much as the two oils differ from one another.

Michelia Nilagirica.—A very aromatic essential oil has been obtained from the bark of *Michelia Nilagirica*,* a tree said to be distributed over all northern India. The bark was received through London in large flat pieces of reddish colour, apparently derived from large trees. A decoction of the bark is reported to be used by the natives as a remedy for fevers. The oil is said to be well suited for perfumery if a suitable supply of the bark could be obtained.

Lemon Oil, Artificial.—Referring to statements that have been published to the effect that a colourless oil, having the odour and properties of lemon oil, can be prepared by acting on terpin hydrate with hydrochloric acid gas, and treating the hydrochlorate formed with potassium, Messrs. Schimmel say that they have failed to obtain such an oil by the process. But even if it were otherwise they consider the process would have no practical importance, since the oil produced by it would be five times more costly than the natural oil.

* Common in our loftier Ceylon forests.—ED.

Coumarin.—Some surprise is expressed that coumarin does not more rapidly supersede the tonka bean, 15 grains of coumarin being represented as equal to a kilogram of the beans.

Heliotropin or Piperonal.—Respecting this synthetical substance, which is said to be increasingly used in perfumery, and which has been recommended as an antiseptic and antipyretic, a caution is given that in summer it should be kept in a cool place. The preparation melts at about 37° C., and in the melted condition is quite worthless.

Thymol.—It is pointed out that in the event of any insufficiency in the supply of Indian ajowan seeds, the material from which thymol is ordinarily prepared, there would be a good substitute available in the American horse-mint or monarda oil, the distillate of the herb *Monarda punctata*. Thymol is said to be establishing a firm place in dental preparations, and a mouth wash, made by adding ten drops of a 1 in 10 spirituous solution to a glass of warm water is spoken of very highly. In the United States thymol is said to be in use for the disinfection of closets. The thymol is allowed to stand in contact a short time with the water used for flushing, and although it is very difficultly soluble in water (1 in 1000) enough is taken up to impart to the flushing water a slight thymol odour.—*Pharmaceutical Journal.*

(*To be continued.*)

MANURING THE PEACH.

The value of muriate of potash and fine ground bone as a preventive against the yellows has come to be generally recognized by peach growers since the results of such treatment at the Massachusetts Agricultural College were made public by Profs. Goessmann and Maynard. The report of the New Jersey experiment station for the past year contains an account of an investigation of the peach orchards of that State that bear out the results above referred to. There is ample proof that those who cultivate the most thoroughly and fertilize the most judiciously realize the greatest profits in peach growing. The healthiest and longest-lived orchards in New Jersey are those which have been fertilized with potash and phosphoric acid in some form, and those who have used these fertilizers are generally intending to use them again, while those who have only used yard manure or nothing are looking for something better. In setting an orchard care is taken to throw out any tree that looks diseased; and if the yellows appear in a few trees they are at once rooted out and burned. One orchard that had received bone and potash for four years was seeded to clover for one year, and then plowed under after a top dressing of lime, with a satisfactory renewal of thrift on the part of the old trees.

Many cultivators do not rightly discriminate between the yellows and the effect of the borer, attributing the effects of the one to the other. Some of the sure indications of yellows are the dying of the twigs, a rough, prickly bark along the limbs, and premature ripening of the fruit, which usually has a red flesh and a bitter taste. The borers' work is usually shown by a gummy substance or castings at the base of the tree at the surface of the ground, and by yellow leaves when their work is carried to any extent. The remedy for borers is to dig them out with a sharp knife in June and August.—*Rural Californian.*

MANURING FRUIT TREES.

It is singular how long some fallacies retain their hold, even after they have been disproved by facts, and of these, one of the most mischievous is the belief that fruit trees and bushes are liable to injury rather than benefit from the application of manure. All sorts of diseases, such as canker and other ailments to which fruit trees are liable, are set down as the result of applying manure to the roots; whereas, in nine cases out of ten, it arises from poverty of the soil, causing the roots to run down into the bad subsoil. I am continually hearing complaints from owners of fruit trees as to their unsatisfactory condition, and on examination have invariably found scarcely any surface roots or fibres of any kind; nothing but large, thorn-like roots, that run right down into the subsoil. On inquiry I have usually found that manuring or top-dressing had not been practised for many years, their owners having come to the conclusion that such practices were dangerous. I do not say that manure will prove to be a cure for fruit tree ailments of all kinds, but I will briefly detail a few facts that have come under my observation at various times, to prove that starvation of the roots is a more prolific source of injury than abundant feeding of the surface roots, both with solid and liquid manures, and growers must form their own conclusions as to the best course to pursue. The fruitful or unfruitful state of the orchard trees in nine cases out of ten is entirely dependent on the attention which they receive as regards manuring. In the fruit-growing parts of Kent, where large orchards of standard trees planted on grass land is the rule, it is a well established fact that if the grass is cut for hay and carried away, the trees soon become unfruitful and die out; while, on the contrary, if the grass is fed off, so that the nutriment is returned to the roots in the shape of manure, the trees keep fruitful and healthy. I have seen some of the most moss-grown, miserable specimens of starved orchard trees restored to a fruitful condition by making the ground beneath them the winter quarters of sheep and pigs, feeding them the same as if they were in the farmyard, with roots and corn. The finest old specimens of apple and pear trees are generally those in an orchard next to the home-stead that is used as a run for calves, sheep, pigs, and poultry the whole year round. In these orchards the turf is short, and, being full of nutriment, the trees keep healthy and prolific for an indefinite period. Ashes, garden refuse, or any kind of road scrapings, or even scavengers' rubbish may be utilized for increasing the supply of orchard fruits.

They should be spread roughly on the surface in winter, and in the spring harrowed and rolled down firmly. The result will soon be a marked improvement in the size and quality of the crop. Difference of opinion prevails as to pruning or non-pruning trees, some adopting one system and some another; but, be that as it may, I never knew fruit trees continue to yield good crops any length of time unless the roots were supplied with manure in some form or another.—*Correspondent, London Garden.*

BOMBAY MANGOES AND OTHERS.

To the Editor of the "Times of India."

Sir,—Under the above heading you reproduce in your issue of the 12th instant an article contributed to the *Pioneer* by Dr. E. Bonavia, in which he makes some observations on the quality of the Bombay mangoes; suggests the cultivation of mango trees from good mango stones, and recommends the exportation of the fruit to Europe. As the subject of the mango and its cultivation is of great importance, and as it happens to be one to which I have devoted some attention, I shall be glad if you will allow me to make some observations upon the article by Dr. Bonavia.

First, Dr. Bonavia was evidently offered a very bad specimen of Bombay Mango if he found it stringy and inferior in flavour to scores of varieties in Upper India. Our best varieties—the Alphonso, the Pairee, and the Fernandina are on all hands admitted to be, when they are of the real quality, free from strings and very delicate in flavour. It is evident therefore that Dr. Bonavia must have come across a Bombay mango which did not belong to one of these varieties. Connoisseurs who have had occasion of comparing the qualities of mangoes of other presidencies with those of Bombay, still admit, as they did in the days of Clive, the superiority of the Bombays to those of any other. I for my part cannot imagine how one of our really good Alphonso can be improved upon, and I am certain it would stand comparison with any other fruit of its kind either in India or elsewhere.

Secondly, after referring to an extract from Alphonso de Candolles' *Origin of cultivated plants* that *the stones* of mangoes *produce better fruit than that of the original stock.* Dr. Bonavia says that he has preached for many years that it is a grave mistake to throw away the thousands of stones of superb mangoes that are consumed every year. I don't know if Dr. Bonavia can produce any facts to show that the stone of a good mango will give say at least in 5 per cent of cases a better fruit than its parent. Theoretical considerations are out of the question when we have to deal with facts. I have devoted, as I have said, some attention to this subject, and I can positively state that I have never met with a single mango tree raised from a good stone which has ever produced fruit at least equal to much less better than that of the original seed. Of course I must admit that such a thing is possible, and that it has occurred at some time, but in extremely rare cases. I have observed thousands of trees, some of them positively reared from good seed, but I have never met myself with such an instance. Under these conditions, I do not see what *advantage* there is in raising plants from good seed. In every instance in which a plant has been raised from good seed, the fruit, although having a certain resemblance with its parent, has always been stringy and of less delicate flavour—in fact, not fit to be eaten. We know at once by the shape, colour, flavour, and taste that a mango has been raised from the seed of one of the grafted varieties. It is a sheer waste of time and money than to attempt to raise a tree yielding good fruit from the seed of a good mango. It cannot be *ordinarily* done. The arboriculturists, at least of this part of India, are not so ignorant as not to know their own interests. They would not spend time, labour, and money if they could raise good trees without grafting. They even know the difference between the ready grafted plants sold in the Victoria Gardens and elsewhere, and the mango plants which are grafted in their own gardens, after raising the parent stock to a certain height. The former yield produce in about five or six years, but they never grow to any great height, and die early, while the latter, although there is always some uncertainty as to their taking the "graft," always live long and yield comparatively a larger produce. Some trees of this kind have been known to yield annually a produce of from R200 to R600. There is a common belief here of which I have not yet been able to test the accuracy. It is this, that you cannot raise a tree yielding really good fruit if you graft upon plants which originally belonged to the same or similar variety, and that it is necessary that your seed should belong to the inferior kind if you wish to get good graft. It would be interesting if any of your readers would bring forward facts to support or to disprove this belief.

Thirdly, Dr. Bonavia, if he see this letter, may be glad to know that already several very successful experiments have been made in this part of India in preserving mangoes in their fresh condition, just in the same way as we get preserved peaches and pears from Europe. I hear that the necessary machinery has already been ordered from Europe, and that in the next season we may see a large stock of preserved mangoes ready for exportation. Dr. Bonavia is quite right in supposing that we can export mangoes to Europe in their fresh condition. I have myself kept thick skinned mangoes, such as Fernandinas for full 30 days after they were plucked, and we know that we can send them to London within 21 or 22 days. Of course it will be necessary to take some special measure to protect them from exposure to high heat, especially in the Red Sea. I think there is a great future for this kind of trade, and also for preserved mangoes in tins.

Fourthly, Dr. Bonavia is not well informed if he thinks that good mangoes are sold in the Bombay market at the rate of R16 per dozen. This price is only paid at the commencement of the season, when the fruit is rare, but when we are in the height of the season we can get good mangoes at the rate of R8 or 9 per hundred.

Fifthly and finally, I think we in Bombay could give a great stimulus to the cultivation of good varieties of mangoes if we could hold every year in the last week of May or the first week in June a mango show, and give prizes to those cultivators who would exhibit the best variety of mangoes. We know the improvement that has and is taking place in Poona in the cultivation of flowers and vegetables among the natives owing to the annual show there, and I do not see why a similar show should not have a similar effect in the improvement of our king of fruits. Let the show be open to the whole of India, and then we could easily compare our varieties of mangoes with those of Upper India:—Yours, &c.,

D. G. DALDAGO, M. D.

Savantvadi.

[On which we have to remark that while it seems a general rule that to obtain superior fruits, such as apples, peaches, mangoes, and oranges, we must graft with superior kinds, yet very fair fruit is grown here in Ceylon from stones of mangoes, and orange pippins, if only the fruits are allowed to ripen on the trees. Not one mango tree in a thousand in Ceylon is grafted, and the proportion of orange trees grafted is still less, and yet visitors from India have pronounced our Colombo mangoes very good, while in the dry climate and on the lime soil of Jaffna fine fruits with red cheeks which might pass for Bombay mangoes are produced. Oranges left to ripen on the trees, especially the "mandarin" kind, are also greatly appreciated by visitors. What is done without grafting or pruning proves what could be done with proper cultivation.—ED. *T.A.*].

RAB.

The Government of Bombay has published a most interesting report by the Director of Agriculture on experiments with *rab*, which is, both literally and metaphorically, the burning question of the day in the agricultural districts on and near the Ghats. *Rab*, as all the world now knows, is a term applied to the several systems in vogue in this presidency for preparing, and usually also burning manure. It is a term also applied to the finished product, Mr. Ozanne distinguishes three kinds, namely, (1) cowdung, (2) *ain*, and (3) *fangal*. The first consists of layers of cowdung, straw, grass, earth, and pit-manure; the second of freshly-cut *ain*-loppings, coarse grass, straw, earth, and pit-manure (*ain* being the vernacular name of a common jungle-tree—*Terminalia tomentosa*); *fangal* is a shrub (*Pogostemum purpuricaulis*); and the third kind of *rab* consists of layers of freshly-cut *fangal*, grass, straw, earth, and pit-manure; this last ingredient consisting of the contents of the dust-bin with some cowdung added. Small plots of land were manured with these three kinds of *rab* at Lanauli, Khadkala, Igatpuri, Karjat and Alibag. At each of these places the results were largely in favour of cowdung-*rab* as regards the yield of cereals; then came *ain*; and last of all *fangal*.

Mr. Ozanne is inclined to value *rab* more for its efficiency in killing weeds and noxious insects than for its manurial properties, but, in our opinion, his experiments tend if anything to show that the mineral constituents of the loppings are the most potent factors in the success of the crop: only in this manner can we explain the superiority of freshly-cut to dry jungle-*rab*, which is apparently due to the fact that, as soon as the green parts of a tree begin to fade, the most important mineral constituents, with which the leaves are, so to speak, saturated during the period of vegetative activity, flow back in large quantities to the stem, there to remain stored up until the next season. It is, however, very difficult to make comparisons or draw safe conclusions from these experiments, as they vary greatly in regard to the quantities and kinds of material used as well as the conditions under which they were made: besides this, it is not always quite clear what description of material was used, and the areas experimented on were too small to admit of reliable inferences. Nobody is more alive to the deficiencies of these first trials than Mr. Ozanne himself, who

warns his readers repeatedly that it is impossible to draw any final conclusions from them; but, subject to this proviso, he considers that, until the contrary is proved, we may conclude that:—

"(1) The manner in which the ryot utilizes the materials at his disposal is the most economical and the most remunerative. Hence, all attempts to teach him to use manure, or leaves and grass, or the like, in a way different to that in which he uses them, are extremely hazardous and require the utmost caution.

"(2.) Rice can be grown without *rab*. The ingenuity of the ryot has discovered substitutes. But I think it is proved that all substitutes are either more costly or more risky than the approved methods.

"(3.) Though rice can be grown without *rab*, yet *rab* greatly increases the yield, and, therefore, the food supply of the country. The yield now suffices to support a largely increased population with, I believe, a considerable margin for export. If, however, diminished by prohibitions against, or scarcity of *rab*, it is a question whether this margin would not more than disappear.

"(4.) If the full value of the materials used for *rab* is charged in the cost of cultivation, rice cannot be grown with profit. Even without this charge the margin of profit in a good year, such as that during which the experiments were carried on, is not large. It has to cover the charges on account of true rent, from which must come the assessment both on rice-land and whatever area is appended to rice-land for the growth of *rab* material."

These generalizations, as already observed, are admitted to be hastily arrived at, and should be accepted with caution. There can be no doubt that the first conclusion is wrong: it is going too far to assert that the ryot's disposal of the materials at his command is the most economical, when, as a matter of fact, it is well known to be the most wasteful, as we shall be able to prove further on. Again, we can find nothing in the report which proves that *all* substitutes for wood-*rab* are either more costly or more risky than the approved methods.

To show how far from closed Mr. Ozanne himself considers his *rab*-question: how anxious he is not to mislead; and with what serious misgiving he regards the future of the ryot dependent on *rab*, it will suffice to quote the concluding paragraph of his report:—

"I trust that these deductions" (those just quoted) "are sound. They are at any rate made from the unbiassed opinion formed after most careful study of the subject. But I am very far from thinking that I have mastered the subject. I have already begun arrangements for continued experiment. My conviction is that the only way to decide how far in the interests of forests, and in those of the people themselves more especially, the drain on the lands which produce the *rab*-materials, whether in or out of the forest, can be prevented from causing exhaustion—a point which has been nearly reached in Igatpuri, Khadkala and Lanauli—is to go on with the experiments now begun, to show precisely the position of the ryot and what it is tending to become, and thus to make it possible for Government to restrain him from improvidence when it is clear such restraint is necessary."

As in most other matters concerning forest-economy in this country, we may profitably turn to the experience gained in countries more advanced in scientific methods than India, which have gone through, or are still experiencing a phase of agricultural development similar to that which we are now witnessing out here. It does not seem to be generally known, but it is, nevertheless, a fact full of interest to the Indian farmer and his master, that *rab* and *kumri*—the two great evils which threaten to utterly exterminate the hill-forests of this presidency—have been extensively practised in Germany, and that *rab* still is rampant in some States, although everywhere steps are being taken to stop it on Government land, because it has been found to be incompatible with the maintenance of the forests. No wonder, then, that with numerous state-supported laboratories, kept solely for the promotion of forest and agricultural research, German experimental physiologists should have worked out, and be able to explain, scientifically, the effect of *rab* both on the forest, from which it has been taken, and the cereal to which it supplies nutriment.

It is not possible in the short space of an article to go fully into this wide subject, but we may at all events give briefly some important facts which have been established by numerous carefully-conducted experiments.

All trees consist mainly of certain volatile substances—oxygen, hydrogen, nitrogen, and carbon—which are called their organic constituents, in contradistinction to the so-called inorganic elements, which are not volatile. It is with the latter that we are chiefly concerned in this enquiry, because, although all trees consist of over nine-tenths of organic elements, they are dissipated in the *rab* process by burning, and it is only the residue, or ash, that is available for direct use as a fertilizing material. Of these constituents about 45 per cent are carbon, which is assimilated only by the leaves in the form of carbonic acid, which is always contained in small quantities in the atmosphere, and about 48 per cent consists of oxygen and hydrogen, which are taken up by the roots of plants in the form of water and in other ways. The loss of these three elements in burning *rab* is consequently of minor importance, but nitrogen, which is taken up solely by the roots, is irretrievably lost in the air and more difficult to replace.

The essential inorganic or mineral constituents, amounting to about five per cent of the whole tree, consist of potash, soda, lime, magnesia, ferric oxide (iron), manganic peroxide, phosphoric acid, sulphuric acid, silica, and chlorine, which are here given in the combinations with organic elements in which they are usually found in the plant. All these substances are taken up exclusively by the roots, and are absolutely necessary for plant-growth. They are very unevenly distributed in the tree, and wander about, according to the season, in the direction in which they are most required by the plant. Consequently, green parts, notably the leaves when green, which alone elaborate the sap that builds up the tissues of plants, contain a large quantity, the bark and young shoots less, and the stem least of all. During the period of active vegetation (in these latitudes, therefore, chiefly during the monsoon) the quantity of organic and inorganic nutriment in the leaves and young shoots reaches its maximum, the former consisting chiefly of starch and sugar, and the latter of phosphoric acid and potash. But when the leaves begin to fade, the quantity of these substances diminishes, and the fallen, or dying leaf does not contain nearly as much of the most useful nutriment as the healthy green, leaf, nor does a dead or dying branch contain as much as a healthy one. Schröder found, for example, that the ash of healthy leaves of Scots pine contained forty per cent of potash and 19 per cent of phosphoric acid; while the ash of dead leaves of the same tree contained 9·5 per cent of potash and 4 per cent of phosphoric acid. These two substances are quite the most important mineral constituents necessary for vegetable life, and it is certainly a wonderful provision of nature that they should return to the stem just before the fall of the leaf, there to remain stored up for future use. Viewed by the light of Schröder's experiments, which have been verified by others, it is easy to understand why Rambux insists on cutting his *rab*-fuel when vegetative functions are in full swing. It matters nothing to him that he thereby arrests the growth and threatens the very existence of the goose that lays the golden eggs, he thinks the forest will last his time at all events, and regards the man who ventures to suggest the propriety of providing for future generations as hopelessly idiotic.

One of the most important questions which the Forest Commission now sitting at Poona will have to decide, in spite of Rambux's supineness, is

whether the forests can stand the drain to which they are now subjected or not, and Mr. Ozanne has rightly drawn our attention to this part of the subject which is of such vital importance to the *rab*-cultivator. If, as at present constituted, they cannot stand the drain, and if further provision cannot be made to extend the loppings over a larger area, so as to make the effect less disastrous, the situation will be a very awkward one. In that case, if things are allowed to slide in the present happy-go-lucky manner, the final collapse may be postponed indefinitely, but it must surely come, and the last condition of the farmer will be at least as bad as if steps had been taken to grapple with the evil now. On the other hand, if Government decide that *rab* must be stopped or curtailed in Government land, there will be a general howl of indignation from cultivators—who possibly may, with justice, claim a right to *rab*—egged on by a crowd of professional agitators and others not interested in the maintenance of the forests. What hope, then, is there that Government may escape this dilemma? If we turn to the facts elicited by German experimentalists, the prospects of the farmer dependent on *rab* are not encouraging, no matter whether the practice be put an end to by Government interference or not. As everybody knows, the soil of an unrabed forest is yearly enriched by debris of branches and leaves which, in decaying, supply a quantity of organic and inorganic nutriment to the forest. If this litter be removed from a hectare (2½ acres) fully stocked with beech-trees the soil loses annually, on an average, according to Ebermayer's experiments, 3,147 kilogrammes of organic and 185 kilos of inorganic fertilizing matter (a kilogramme being equivalent to 2·2 lb. avoirdupois). In forests which are rabed when green, the loss is greater, because green foliage contains more useful mineral nutriment than dead litter; nothing, of course, is done to replace this large quantity of natural manure.

Setting aside deterioration from physical causes, which is very great in forests whose soil is deprived of its natural covering of dead leaves and twigs, we might almost conclude from Ebermayer's experiments that the exhaustion of soils under *rab* could only be a question of time. All farmers know well enough that even the best soils are soon exhausted when they are steadily deprived of large quantities of nutriment, and no manure is substituted to repair the loss; but, if this is the case with agricultural soils, it must, *a fortiori*, be the same with forest-soils, which are generally much poorer than cultivated land. Stöckhardt has submitted the matter to a thoroughly practical test by examining two plots of ground, side by side, both stocked with Scots pine fifty years old, of which one had for some time been deprived periodically of its dead litter, and the other had not been interfered with in any way. The ground was examined to a depth of twenty inches, and the results were as follows:—

The untouched area contained 19,950 kilos per hectare of mineral nutriment soluble in muriatic acid, and 4,720 kilos of mineral nutriment soluble in water. The rabed area contained 14,950 kilos of mineral nutriment soluble in the acid, and 2,865 soluble in water. A very decided deterioration had, thererore, taken place in the supply of mineral nourishment, but the loss of organic nutriment was naturally still more marked. The protected area was found to contain 139,670 kilos of organic matter to the hectare, and, of this quantity, the nitrogen weighed 8,354 kilos. In the rabed plot, the organic matter amounted to 60,438 kilos to the hectare, the nitrogen weighing 4,759 kilos. The difference in favour of the unrabed plot was, therefore, 79,232 kilos of organic matter. The reader can easily draw his own conclusions from these experiments in regard to the fate which is in store for rabed forests which are not of vast extent relatively to the area they manure.

Customary usage in Government forests, which, in spite of all legal maxims to the contrary, may easily amount to a prescriptive right in the eye of the practical legislator, may necessitate the continuance of abuses, but an abuse which involves the ruin of a valuable state-property may perhaps be tolerated, but certainly should not be allowed to spread: the immediate interests of a few must give way to the lasting interests of the many, and, if the evil cannot be eradicated, its growth may at least be arrested. Systematic experiments would in time show whether the area available for *rab* is sufficient to admit of the practice being perpetuated, or if it must sooner or later come to an end: in the meantime, having no actual facts to go upon, excepting those obtained in foreign countries, we have no means of forming a decisive opinion.

Apart from considerations of rights of usage, it appears doubtful if the game is really worth the candle. Even to the farmer, supposing him willing and able to employ his labour in other ways, the advantages are perhaps less than one may easily be led to suppose. Mr. Ozanne, who certainly takes a most unbiassed view of things, but who, as Director of Agriculture, cannot fail to be more interested in the welfare of the ryot than in that of the forests, frankly confesses that, on the evidence collected by himself, *rab* does not pay. It is only by ignoring the wages of the farmer and his family, and the sale value of the *rab*, that a profit is made out. Surely there must be something radically wrong in a system of Agriculture, which cannot be made to pay its own way. The amount of labour which the farmer must bring to bear on the *rab* system must be very great in proportion to the effect. Wolff, for instance, calculates that 330 hundredweights of dry spray and leaves of oak | or beech would yield one hundredweight of potash and phosphoric acid, but that the collection and carting to destination of this quantity of *rab* would alone cost more than the value of the same quantity of artificial manure; of course, this statement is probably not applicable to Indian conditions, but it shows that enquiry in this direction would not be without interest.

To show to what extent forest trees are able to supply the mineral nutriment requisite for agricultural plants, we may quote the results of some experiments. The most important mineral compounds of plants are potash, lime, phosphoric acid, and silica. According to Ebermayer, a hectare, cropped with the following species, requires these substances in the following average quantities per annum for each species:—

1. *Potash.*		2. *Lime.*	
Potatoes	120 kilos.	Potatoes	37
Clover	102 „	Clover	112
Fodder-grass ...	78 „	Fodder-grass ...	49
Peas	48 „	Peas	47
Wheat	29 „	Wheat	9
Beech	15 „	Beech	96
Spruce	9 „	Spruce	70
Pine	7 „	Pine	29
3. *Phosphoric Acid.*		4. *Silica.*	
Potatoes	36	Potatoes	8
Clover	31	Clover	8
Fodder-grass ...	24	Fodder-grass ...	80
Peas	21	Peas	9
Wheat	21	Wheat	97
Beech	13	Beech	63
Spruce	8	Spruce	58
Pine	5	Pine	7

According to this statement, it would require about three acres of well-stocked beech forest at its best (*i. e.*, before deterioration by *rab* had set in) to provide sufficient mineral nutriment for one acre of wheat; beech, be it noted, being a tree which yields relatively to most other species, a large quantity of nutriment, and only grows in comparatively good soils.

It would require comparative experiments on Indian forests and cereals, similar to those we have referred to, to enable us to say roughly what quantity of forest of any given description is, on an average, capable of fertilizing an acre of land under costlier conditions, and to what extent *rab* affects the growth of forests. It is hopeless to expect to arrive at any satisfactory conclusion until these data are worked out, for, although the results obtained in German

may be considered sufficiently clear and conclusive for that country, it is not likely that people out here will admit that what has been found true for a far off land must necessarily be true for India.

Another matter, to which, no doubt, the Agricultural Department will direct its attention, is a means of more economically exploiting the rabed areas. We have seen what an enormous loss of organic nutriment is occasioned by burning the produce; possibly some method might be devised, by which only a small portion should be burnt and the rest utilized in the natural way.—*Times of India.*

HALF-A-CENTURY OF IRRIGATION WORK IN THE MADRAS PRESIDENCY.

Southern India is famous for its possession of remains, more or less perfect or in ruins, of irrigation works of great magnitude, formed by the genius of a race of ancient tank-makers, who, it is next to certain, stamped the impress of their skill not only on their own country, but on the tank region of Ceylon also. Not less famous is the Southern Indian Presidency in the annals of modern irrigation for works which are amongst the grandest and most successful which the world can show, the result of the genius of Sir Arthur Cotton and officers like-minded with that great man. Like many other great men, Cotton had a hobby in favour of water transit which he was inclined to ride to death in tilting against the far speedier and more effective carriage by railway. Our own Governor's recent notice of the canal to Chilaw shows that, apart from the great expense of cutting canals, the expenditure necessitated in keeping them open for traffic, by the repair of eroded banks and by the removal of silt, renders them in many cases inferior to railways as transit agencies, even on the score of cheapness, which is the great argument,—and a very true and forcible argument in some cases—in favour of water carriage. In India there are some strikingly successful examples of extensive canalization, where the two objects of land irrigation and cheap water carriage are combined (as was supposed to be the case with our Ceylon "Sea of Prakrama"), and others in which water carriage alone is served, as in our own system by which sections of canal connect the salt pans of Puttalam, *via* backwaters and rivers, with Ratnapura and intervening stations, including Colombo. In Madras, in modern days, the greatest successes seem to have been achieved with works such as are now in progress in Ceylon, to restore and add to the irrigation and fertility of the delta of the Walawe river, near Hambantota,—by the formation of anicuts or weirs across rivers so as to divert portions of their waters into irrigation channels ramifying through alluvial lands and bringing out their latent fertility by the application of the necessary moisture—a tropic sun doing its vivifying part. These remarks have been suggested by the perusal in Sir Charles Lawson's Madras Jubilee Volume, of a concise summary of irrigation work accomplished in the Madras Presidency during the half-century terminating with the Queen's Jubilee. A similar account of operations in Ceylon,—although the half-century was long spent before the British Government was fully aroused to the duty of furthering the irrigation of the soil so practically appreciated by many of the ancient monarchs, would be useful and interesting. The cases of Madras and Ceylon differ, essentially, however. With us works of magnitude consist in efforts, more or less successful to restore ancient tanks and channels, such as Horaborawewa, Kantalay, and what is likely to be, and we trust will be a great success, Kalawewa and the connected Yodaela, the latter destined to supply irrigation and drinking water along its route of fifty-four miles to the ancient city of Anuradhapura, the tanks in and around which it will fill and keep full. The distinctly new works here have not involved designs of any magnitude. In the Madras Presidency the process has been exactly reversed: the ancient irrigation works are in the Jubilee year of the Queen's reign very much what they were when the reign commenced in 1837; while the modern engineers have compelled the deltaic waters of the Coleroon, the Kistna, the Godavery and other great rivers, instead of sending the whole volume of their waters uselessly to the sea, to yield portions of them for the use of man, in the irrigation of the soil and in aiding inland navigation. The one exception is the delta system of the Cauvery, which is virtually of native origin, the deltaic branches of the river forming natural irrigation channels. The engineering works of this great and beneficial system have, however, been very largely improved in modern times by English engineers.

We quote the interesting article to which we have been referring, and which our readers will find well worthy of perusal.

(*From the Madras Jubilee Volume.*)

The net result during the last fifty years of the work of the Public Works Department in the matter of ordinary irrigation works, that is, old native works, such as tanks and channels, may be summarised as follows. A great number of works have been kept in good repair, and others greatly improved; but the condition of the bulk of them is in the year 1887 much what it was in 1837. On the other hand, much valuable information has been collected at the cost of much time and trouble, and is recorded in a convenient shape, and matters have generally been put in train for the steady and continuous repair and up-keep of this important class of works on scientific principles. It may reasonably be hoped therefore that the reviewer of fifty years hence will be able to record great and uniform progress. If, in the matter of ordinary irrigation works, the progress may not be considered altogether satisfactory, in the conception and execution of works that are great in an Engineering point of view, and successful beyond measure as pecuniary investments, and as a source of wealth and prosperity to the country, the fifty years since the Accession of Her Majesty have been most fruitful.

Among the most successful and important may be mentioned the Coleroon, Godavery, and Kistna Anicuts, which, constructed across the rivers of the same names, ensure the irrigation of the three great deltas of the presidency; the Nellore, Streevaikuntham, Palar, and Peldendorai Anicuts, built respectively across the Pennair in Nellore district, the Tambraparni in Tinnevelly, and the Palar and Vellaur in the North and South Arcot districts. The channels taking off from these latter anicuts feed series of tanks, all old native works, the supply to which, now fairly certain and sufficient, was in days previous to the anicuts most precarious and variable. These works therefore may be considered productive, that is they give in some cases a very large, and in every case some percentage of return on the outlay incurred. Among later works the Sangam and Barur Projects may be mentioned. Neither of these is yet fully completed. The former consists of an anicut across the Pennair river in Nellore district, below the existing Nellore anicut, and is intended to render certain the irrigation under existing tanks, and also to greatly extend it; while the latter is a scheme for the improvement of the supply of water to a number of existing tanks by constructing an anicut across the Pennair river, in Salem district. The Sangam Project, which should be completed in 1889-90, is calculated to give a return of 5 per cent. on the total capital outlay: while the Barur, which is now nearly complete, will, it is expected, pay 6 per cent.

Of the works mentioned, the most famous are the great delta works of Tanjore, Godavery and Kistna, and some description of these may not be out of place. The Cauvery delta system is virtually of native origin. The delta differs in one most important and essential particular from the deltas of the Godavery and Kistna. While in the two latter the irrigation and drainage channels have to a great extent to be artificially constructed, in the Cauvery delta, on the contrary, the numerous deltaic branches of the river form in themselves the natural sources of irrigation and drainage. This essential difference may explain why even under the native *régime* the delta of the Cauvery was a thriving district, while the districts of the Godavery and Kistna were miserably poor.

Tanjore came into the possession of the English about the year 1800, and at that time the irrigation was carried on by cuts in the banks of the various rivers of the delta. This system, defective in itself, was rendered still more so by the precarious nature of the supply available. The fall of the Coleroon, which branches from the Cauvery, is far greater than that of the latter river, and consequently there was always a tendency for the Coleroon to draw off too much water, and for the Cauvery to silt up at its head. The prevention of this was a source of constant trouble and anxiety to the officers of the district. It was not till 1836, when, at the instigation of Captain (now Sir Arthur) Cotton, the Upper Coleroon Anicut was built, that all fears on this head were set at rest. Since that time improvements in the shape of regulating works, sluices, and embankments have been steadily carried out; and quite lately the construction of the Cauvery and Vennar regulators may be said to have practically ensured the safety of the delta against future floods. These regulators built across the Cauvery, and its main branch the Vennar, in connection with the Grand Anicut,—an old native surplus work, which has been much improved,—allow of the supply during floods, being so distributed between the Coleroon, the Cauvery, and its several branches, that the delta need never receive more water than it can with safety dispose of, a danger to which it had always been exposed since the construction of the anicut which while it effectually prevented the possibility of a too scanty supply created the opposite evil of a too excessive one. Some idea of the success of the Cauvery delta as a financial investment may be gathered from the returns of 1885-86, which give the total outlay on new works and improvements as R16,59,254, the area irrigated as 905,284 acres, and the percentage of net revenue on outlay as 38·98.*

Next in order of age came the Godavery Delta Works which were commenced early in 1847. The desirability of throwing an anicut across the river had first been brought to the notice of Government towards the close of the last century by Mr. Topping, a Civil Engineer, but no steps were taken in the matter till 1844, when the rapidly decreasing revenue of the district, and the poverty of the ryots, led to the project being again taken up. In this year Sir Arthur Cotton submitted a general report, followed in 1845 by a more complete one together with detailed estimates for the anicut, and approximate estimates for the system of channels in connection with it. The project received the approval of the Court of Directors, and the construction of the work was commenced early in 1847. The total outlay incurred to the end of 1885-86 was R1,21,67,097, the area irrigated 555,908 acres, and the percentage of net revenue on outlay was 10·29; the project will it is expected, be fully completed in 1889-90 at a cost of R1,30,32,653 when the area under irrigation will be 612,000 acres, and the percentage of net revenue on outlay 12·7.

The Kistna Delta Works, which come next in order to the Godavery, were commenced in 1852, when the construction of the anicut was put in hand. The outlay incurred to the end of 1885-86 was R75,55,996, the area irrigated 330,159 acres, and the percentage of net revenue on outlay 11·01. On the completion of this project, which it is hoped will take place in 1901-2, the figures are expected to stand as follows: total expenditure R1,49,00,944, area irrigated 475,000 acres, and percentage of net revenue 8·22. The decrease in this last figure is due to the fact that a considerable expenditure has to be incurred in increasing the efficiency of existing works without extending irrgation, and on this expenditure there will be no return.

How greatly these works have benefited the country may be gathered from the fact that in the famine of 1877-78, when every unirrigated district was importing grain in enormous quantities, the grain exported from the Godavery was valued at £1,740,000; and yet, in the year 1844, the district was described as being in a poverty-stricken state, with a steadily declining revenue. Similarly with the Kistna. This district, now one of the richest and most thriving, was previous to the construction of the anicut, one of the very poorest in the Presidency, and suffered very severely in the famine of 1833-34. A noticeable feature of the works described is their construction solely at the cost of Government. This system, with its concomitant evils of grants varying in accordance with the state of the Exchequer, explains why many of the works were so long in hand, and why the actual outlay in many cases was much in excess of the original estimated cost. It appears to justify the view that a more liberal policy on the part of Government in encouraging their execution by private enterprize would have given better results. The Kurnool Canal, however, the one solitary example in this Presidency of a large irrigation work carried out by a Company under Government guarantee, by no means supports this idea. The Company, known as the Madras Irrigation and Canal Company, for the execution of the Tungabudra Project, as the scheme was then called, was incorporated in 1858 and the regular contract deed was signed in 1863. In 1866 the Company was already involved in monetary troubles, and from that period to 1882, the year of the transfer of the Canal to the Secretary of State for India, its history was one long record of financial difficulties ending in eventual failure. Since its transfer, the work has been a losing speculation to the Government, and when the large capital already sunk is considered it is to be doubted whether the works can ever be remunerative.

The works above alluded to may be generally classed as productive; that is, works the outlay on which was in the first instance justified by the more or less large percentage of returns expected. The occurrence of the famine of 1876-78 first compelled the acceptance of the necessity of protective works, that is, works which, though not sufficiently remunerative to justify their being classed as productive, are still calculated to be a preventive of famine, and to guard against a future heavy expenditure in relief to the people. Of this class of work, only one, the Rushkkulya Project in the Ganjam district, has as yet been commenced. Sanctioned in 1883, the preliminaries for commencing work were undertaken towards the end of 1883-84, and it is expected that the year 1894-95 will see it completed. The scheme is to utilize the waters of the Mahanuddy and Rushkkulya rivers for the purposes of irrigation and navigation. The net revenue anticipated on the completion of the works is 5 per cent. on the total capital outlay. Among the schemes not yet put in hand may be instanced the Peryar Project, which has received the sanction of the Secretary of State; it is a scheme for diverting, by the construction of a dam across the Peryar, the waters of that river into the Madura district, a district which at present receives but a scanty supply from either monsoon, and in the last famine was among the localities which suffered most severely. The Project* is to take six years to complete, and on completion is calculated to pay 7·8 per cent. net revenue on total outlay. It may therefore be fairly classed as productive; but in addition to this, its importance as a protective work cannot be over-estimated, as its successful

* In round numbers 40 per cent on outlay, a result, we suppose, utterly without precedent or approach?—ED.

* A gigantic one: diverting the waters of a large river from one district to another, by engineering works of a most interesting character.—RD.

execution would convert the barren district of Madura into a veritable garden. The Tungabudra Project is a scheme for giving the cantonment of Bellary a good supply of water, and at the same time extending irrigation in the district. The Maraudahully Project is designed to improve the supply to certain tanks in the Salem district. The last two Projects, though fully worked out as regards investigation, have not yet been sanctioned. Other important Projects have been suggested and investigated, but the want of funds has indefinitely postponed their execution.

Turning from irrigation works proper, some mention should be made of the lines of water communication in the Presidency. In the two northern deltas the main lines of Canal are utilised both for navigation and irrigation, but until the last few years, these deltas, though connected with each other, had no connection with the south of the Presidency, and it was not till the Famine of 1876-78 that the importance of water communication between the north and south was fully realised, and that an attempt was made to improve and extend the East Coast Canal, to meet the fresh-water high-level Canals of the Kistna Delta. The East Coast Canal, or, as it is now called, the Buckingham Canal, in honour of the Duke of Buckingham and Chandos, Governor of Madras, 1875 to 1880, is a salt-water Canal, and to some extent tidal. It was begun so long ago as 1801, but up to the years 1876-78, the total expenditure upon it was only about 5½ lakhs of rupees. In the years mentioned, the Canal was taken up at the instance of the Duke as a famine relief work, and an expenditure of 29 lakhs was incurred. Since that date improvements have been carried out steadily and continuously, and at the present time there is very fair through communication between Madras and Pedda Ganjam in the Kistna district. At this point the Buckingham Canal meets the Kistna high-level fresh-water Canals, and is, through them, connected with the Godavery system, thus opening up traffic with the sea-port of Coconada. The completion estimates lately sanctioned amount to nearly 100 lakhs, and it is expected that the works will be completed in 1893-94. Until this is the case, and the Canal has been fully protected from river-floods, it cannot be considered an altogether safe means of communication. Its value, as a cheap means of transport, is already recognised; its prospects in the future are very favourable; and by connecting the City of Madras, or the head-quarters of the trade and railway system of the Presidency, with the deltas of the Godavery, Kistna, and Nellore, it will be simply invaluable in times of famine.

On the West Coast also the subject of water communication is receiving much attention. The benefits to be derived from expenditure on a large scale are, however, not so obvious as in the case of the Buckingham Canal; for already Cochin has very good water communication with Trichoor, a town situated twenty miles from the Madras Railway station of Shoranoor. From Tirur, another station on the same line, there is also a continuous line of canal to Cochin. Portions, however, are not excavated to full depth, and in consequence the traffic is diverted to Trichoor. Estimates for improving this latter line have been prepared, and the work will no doubt be put in hand when funds can be spared. From the above brief sketch, it will readily be admitted that whatever may be the shortcomings in regard to ordinary irrigation works, the fifty years since Her Majesty's accession have been marked by progress that has materially improved the condition of a very large number of Her Majesty's subjects in Madras.

PUSHING CEYLON TEA: CLAIMS OF MESSRS. SHAND AND McCOMBIE MURRAY TO HELP.

We insert (on page 400) a letter to Mr. Rutherford from Mr. Shand in which he shows not only what he has done but what he has suffered for Ceylon. There are also letters addressed to us from Mr. McCombie Murray, which are of a similar tenor: he has done much to push Ceylon tea in America, has expended his capital, lost money by exhibiting at a fair, and he must retire from the fight in favour of Ceylon tea discomfitted, unless help goes to him from Ceylon in the shape of consignments of tea to give away, so as to spread a knowledge of and a taste for the article. It will be seen that an influential firm, Messrs. Finley Acker & Co., have promised to aid the crusade, if only we in Ceylon do our part. While measures are being taken to do justice to Ceylon tea at Glasgow and Melbourne, Mr. Rutherford and other leading planters will feel the duty of recognizing the claims of those who, at the sacrifice of effort, time and money, have fought our battles for us at Liverpool and in Philadelphia. The case of Mr. McCombie Murray is specially urgent and ought to receive immediate attention, because, while our tea has already secured large triumphs in Britain and tardy recognition in Australia, it has to conquer acquired taste, strong prejudice and powerful vested interests in America. In at once acting in aid of Mr. McCombie Murray, so as to prevent the collapse of the most determined effort yet made to give Ceylon tea a footing in America, we feel certain Mr. Rutherford will be sustained by the planters. Government might well be asked for a grant of money in this exceptional case, as well as in that of Mr. Shand. The packet of miscellanies which has reached us shows how indefatigable Mr. McCombie Murray has been in advertising our pure tea. It was sold hot and iced at the Exhibition to which he refers, and delicate muslin handkerchiefs were distributed on which the merits were described in print of the product which the head of the firm had come a distance of 13,000 miles to introduce. The photograph referred to includes three figures,—Mr. J. McCombie Murray; Sinhalese Ayah; Lady Assistant. The ayah comes out exceedingly well, and looks quite effective with a tea tray before her. Prominent are the inscriptions:—"CEYLON TEA AND COFFEE EXHIBIT;" "TRY CEYLON TEA," &c.; and it is explained that a glass globe which is conspicuous "contains the result in liquor" from one ounce of Ceylon tea. Frame top of show case is the President's letter, flat case on counter, samples of Ceylon Tea and Coffee. The charge of 5$ for tea was made to keep off a class of 'how-much-can-I-get-for-nothing' people, who do nothing but obstruct business. Those who showed any interest, nice people, or purchasers, were not charged. Length of Exhibit 15 feet by 10 feet deep. About 10,000 circulars given out during the fair."

It will thus be seen that Mr. McCombie Murray has worked hard in a cause which is largely that of the Ceylon tea planters, who would benefit immensely were our cousins in the United States to acquire a taste for and widely use our teas, instead of confining themselves chiefly to the highly fired article from Japan with some China, chiefly the produce of Formosa. We feel sure the claims of Messrs. Shand and McCombie Murray will receive recognition from both Government and the planting community, and that from the planters' meeting in December, if not earlier, will go a cablegram to the latter announcing "Tea coming for distribution."

It is with much regret that we have perused the letter of the Government of India in which they state their inability, owing to financial pressure, to recommend for sanction to the Secretary of State the scheme lately sent up by the Bengal Government for the establishment of a Veterinary College for that presidency. The Government of India recognise the great importance of making provision throughout India for veterinary instruction, with a view to checking the enormous amount of preventible mortality among cattle, and it is with "great regret" that the Governor-General has decided to postpone this scheme. This postponement has a precedent in the Bombay Veterinary College, which has now, however, been established. We trust the same may be the case with the Bengal institution.—*India: Agriculturist.*

Correspondence.

To the Editor of the "Ceylon Observer."

MR. McCOMBIE MURRAY'S EFFORTS TO PUSH CEYLON TEA IN AMERICA: HELP NEEDED.

Office of the Ceylon Pure Tea & Coffee Company,
9 North 13th St., Philadelphia, 6th Oct. 1887.

DEAR SIR,—We have had a long personal interview with Mr. Finley Acker of this city, and may say, in a few words, that he is willing to place his channels at our service provided we are backed up by the planting community of Ceylon with a consignment of tea to be given away as free samples in the city and suburbs.

We can say no more now as mail closes, but will give you full particulars by next mail.

We *do* trust that the planters will seize this, the *best possible* opportunity to assist us, in placing their teas on the market. Messrs. Finley Acker & Co. are the most powerful and enterprizing firm in Philadelphia, and if we have your assistance they will, in Mr. Acker's words, work it for all it is worth. We have been trying to get Mr. Acker over to this for some time back. Now that we *have* been successful in our purpose, we look to Ceylon to bring about the completion of our arrangements by a liberal contribution of tea with which to "boom" the city.—Yours very truly,

J. M. MURRAY & CO.

Philadelphia, 8th Oct. 1887.

DEAR SIR,—We have now pleasure in enclosing a letter from Messrs. Finley Acker & Co. which shows that we have at length been fortunate enough in securing the interest of one first-class firm to take up Ceylon tea in earnest if the planters will show a little interest in our undertaking and assist us. We only regret that winter is so near at hand. People are already coming back for the season. The tea ought *now* to be on the way. Nevertheless, if a consignment were sent off straightaway, we are here to see Ceylon tea "boom'd" in this city in such a way as to force it upon public attention. As a powerful, enterprizing, and influential firm, Messrs. Finley Acker & Co. stand *alone* in this city. If there is a *real* desire among the planters to establish their teas in one great city in the United States, let them seize their opportunity now.

We are glad to see substantial assistance given to Messrs. Shand, Haldane & Co., London. They, no doubt, require it at the hands of their late fellow planters. We can sympathize with them as they with us.

If, in a country where the people take so kindly to Ceylon tea, those gentlemen find it hard to make a business, what, do you suppose, have we to contend with where we have to introduce the same tea to a people quite unprepared for such a total change in flavour?

The writer would that he could stand in the midst of his brother planters once more as they assemble themselves together within the Library walls at Kandy. One hour there would be better than volumes of letter writing. It is *hard, discouraging* work here. We wish you to know it. We could make money by selling blended teas and leaving pure Ceylon out of the question, but we *don't*. Nor can we afford to *wait* for the assistance we ask. While we work we have to live, and to live we must be doing business. We have taken bold steps that Ceylon tea may be brought prominently before the public and that at the risk of our own livelihood. If we do not make enough headway during winter to keep us afloat, the "Kootee" Brand must die in its infancy for want of support from the mother country, the nurse in this country having no more milk to nourish it. The machinery for working Ceylon tea into this market is in motion and must not be allowed to stop for want of driving power. What say you?

Now words won't keep the thing going. What is done at all must be done at once and we will do all *we* can to help. If anyone with authority will cable us to go on, we will to save time put out samples from our own stock provided our stock is replenished by the planters as soon as possible. Everything depends on prompt action during the month of December when people feel disposed to spend money and feed fat on the best of everything. As a representative tea we will put out a blend of a tea which cost 1s 3d and a tea which cost 2s 3d per lb. in London. This will be some guide to the planters as to the tea we consider most suitable for this market. We have now said our say—we are prepared to continue the fight if provided with powder.

We send you a weekly publication received this morning. A reporter interviewed us last week about Ceylon tea at the request of their representative at Pittsburgh where an interest in our teas has apparently been awakened. The notes under the heading of Protection are scarcely in keeping with information given by the writer—who merely stated that it would not pay a Ceylon planter to send in adulterated teas or rubbish into the London market, as the result would, in all probability, be a change in the superintendent, and possibly severe criticism at the hands of the local press who jealously guard the name of their produce and very properly reprimand any defaulter who might send teas to London which would tend to damage the name of Ceylon as a tea-growing country.

We have sent off two photos of our exhibits at the fair. On account of a strong light behind the exhibit, these photographs do little more than show that there was something there representing Ceylon. Unassuming as was our show, these photos in no way do us justice. There were other tea and coffee exhibits, but ours got the only diploma in the line. The President of the Agricultural Society congratulated us on our endeavours, and wished us every success in our undertaking. This exhibit, although it proved an excellent advertizing medium, cost us about $100 more than we realized on sales of tea and coffee. Few came to the fair with the intention of buying, and giving away was so common that we had some difficulty in persuading that our packets were for sale, and that our cups, saucers and spoons were for the practical purpose of enabling those interested to taste our tea, and not, as many supposed, for free distribution as mementos or as samples of china-ware.—More anon.—Yours faithfully,

J. M. MURRAY & Co.

Mr. J. McCombie Murray, Philadelphia.

Dear Sir,—We are in receipt of your recent favour in relation to pushing the sale of Ceylon tea in Philadelphia and America. In reply we would say that we have carefully tested the sample of tea which you kindly sent us and think that it has sufficient merit to warrant considerable effort, on the part of those who are directly interested, to push it. We think the most effectual way to do this is by the free distribution of samples, accompanied by appropriate advertizing matter. Should your tea friends in Ceylon see fit to send a good sized quantity of tea for the purpose of sampling, we will be glad to co-operate with you in getting them into the best places. We will also permit you to have the native, to whom you referred, appear in costume and give out cups of Ceylon tea in our establishment. In addition we are willing to make

frequent allusions to Ceylon tea in *Table Talk*,* of which we send you specimen copy.

It will be well, however, to realize that success can be achieved only by whole-souled effort. A half-hearted interest by yourself or the planters will not eventuate in a permanent business in America. If anything is done it should be done at once, and done thoroughly.

Wishing you success we are, very truly yours,

FINLEY ACKER & Co.

APPLICATION OF A GRAIN DRIER TO THE ROASTING OF TEA?

Deeside, Maskeliya, 16th Oct. 1887.

Would not the grain-drying machine invented by Mr. James Black, Dumfries, of which the following is a description, be a cheap and suitable *tea drier*?

"The machine, although a small one, will dry at the rate of 40 bushels an hour.

"It consists of an iron case, in the interior of which are four wire cylinders extending its whole length, about 14 feet. The heated air from a furnace below rises through this case, and gradually dries the grain, which is supplied at the top and is carried from cylinder to cylinder in turn, and eventually discharged perfectly dry. An exhaust of air expels the steam as it rises from the grain.

"It is said that the drying is more equal than when effected in a kiln, and that the heating can be done at a less cost. The machine has another advantage in being portable, for it can be shifted from place to place."—Yours, &c.

WM. MITCHELL.

[The machine costs £200. It resembles in principle the Gibbs & Barry tea drier.—ED.

EFFECT OF THE LATE DROUGHT ON CINCHONAS.

22nd October 1887.

DEAR SIR,—In a recent issue of your paper you commented on the large amount of cinchona which had been carried by rail, as contrasted with a previous period.

If the experience of other cinchona planters be like mine, the recent excess harvested is easily accounted for. The work has not been voluntary but compulsory, the trees having been so seriously affected by the recent drought as to compel their removal, otherwise they would have died, and the bark, if not taken off at once, would have been lost to the proprietor.

In my case I have had to harvest over 20,000 lb. of dry bark, *against my will*, and I have no doubt others have had to do likewise. This will show most thinking men that the quantity of cinchona bark recently carried by rail is not likely to be repeated, except with disastrous results to the proprietors.—Yours faithfully,

X.

PADDY CULTIVATION.

31st October 1887.

DEAR SIR,—I was lately told authoritatively that in the Southern Province three crops of paddy are often raised in one year by sowing the fields with paddy of a few months' growth. I am very sceptical of this, for I know from experience that it takes about two months to properly prepare a field for sowing. I shall be much obliged if Mr. Elliott will support or refute this statement and give us the result of his observation. As far as I know three crops in two years are about as much as one can reasonably expect, for if a field be sown for the *maha* season which lasts from June to August, the crop is harvested between the end of November and January according to the kind of paddy sown. This will permit of the land being prepared for the *yala*, the sowing months of which season are April-May. The crop will be harvested in September-October, when there will be no time to prepare the field for the *maha* season which will already be passed, and the fields will be fallow till the next *yala*. Under the circumstances I fail to see how it can be possible to get three crops in one year even if paddy of a few months' growth be sown.—Truly yours,

B.

PATCHOULI OR POGOSTEMON HEYNEANUS.

Minuwangoda, 13th Nov. 1887.

DEAR SIR,—Can you or any of your readers let me know whether the Patchouli leaves sold in London are those of the plant Pogostemon Heyneanus, or commonly called *Kollankola*? I have seen it growing in several villages in large quantities. If it is the genuine commercial kind, I would like to know how the leaves are prepared for market and from whence is the present supply derived.—Yours truly,

W. A. D. S.

[The Patchouli of commerce is derived from the leaves of *Pogostemon Patchouly*, which is supposed to be a cultivated variety of the *P. Heyneanus*. The scent is distilled from the leaves and young tops.—ED.]

IMPROVEMENTS IN AGRICULTURE.

Kalutara, Nov. 9th, 1887.

SIR,—A short time ago, I had occasion to drive from Piliandera to Kalutara *via* Bandaragama, and as I passed the ninth mile-post at Gammanpila, my attention was attracted by a field, on the culture of which much care and skill had evidently been bestowed. I was led to make inquiries in the neighbourhood, and found that it bore the name of "Wewedeniye," a piece of Government land, and was cultivated by Mr. Rodrigo, the Government Agriculturist of the district. After seeing this field I was not at all surprized that he should court competition in point whereon he was so very likely to bear away the palm. This field has not been in his possession more than six months I heard, yet in spite of its original poverty he has made it very productive by a judicious course of the application of manure and the use of other means. Indeed, it is very attractive, for he has planted the paddy in regular lines, which I have not seen done anywhere else in that quarter. This year Mr. Rodrigo's paddy will surpass in excellence and the crop, I am sure, will be most abundant. Mr. Rodrigo as a cultivator of the soil is worthy of being taken as an example by his brother cultivators of the district. Hoping, sir, that the heads of departments will pay more attention than they have hitherto done for the improvements of agriculture and the retoration of tanks and canals, and above all thanking you for the attention which you as an editor of a valuable agricultural journal pay to the true interests of agriculture, I am, sir, your obedient servant,

AGRICOLA.

A WORK on "The Cultivated Oranges and Lemons, &c., of India and Ceylon," by Brigade-Surgeon E Bonavia, M. D., of the Indian Medical Department is about to be issued. The writer's object is mainly practical and economical, but he deals also with some questions of purely scientific interest. His researches have brought him into contact with every variety of Citrus in India and Ceylon, and he claims that he has been able to dispose of, or at any rate to throw new light on, certain disputed points, both botanical and historical, in connection with this genus. The book will be accompanied by an atlas in folio of large size, consisting of 259 plates of outline drawings of all the varieties of Citrus to be found in India and Ceylon.—*Nature*.

* An interesting magazine of general literature and information for the household.—ED

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

PARIS, October 29.

The dairy industry is more and more extending on the Continent. It is divided into two distinct branches: the preparation of butter and the manufacturing of cheese. Both are conducted on more or less extensive commercial bases. It is chiefly to the application of machinery in the working up of the milk, that dairy industry owes to-day its vast progress and the ameliorations have not yet reached their final limit. Indirectly, the soil has been improved also as despite the most ingenious and labor-saving apparatuses, milk-farming to be remunerative must rest on selected breeds of cattle, and choice dairy stock demands suitable aliments, and hence good soils to produce such.

In Denmark there are co-operative societies for butter farming; in Holland for butter and cheese; and in Switzerland for cheese alone. These societies vary, due principally to local necessities. In Denmark an association or a large butter manufacturer contracts to purchase the milk from farmers, representing collectively 500 to 1,000 cows. In both cases the aim is the same; skim the milk with the most perfect creamers in the shortest time and in the most economical manner. There are Belgian centrifugal creamers that will separate instantly 9 gallons of milk in less than 30 minutes. The key to the Danish co-operation system lies in leaving to each farmer to deliver his milk himself at the central establishment and to take away his proportionate quantity of the skimmed milk which is usually employed for hog-fatting, or making inferior cheese. In the case of an association all expenses for machinery &c. are borne by the members *pro-rata* to their deliveries of milk. A council composed of 6 or 7 members is elected to superintend the receipts and expenditure, while a paid manager devotes his time exclusively to the out-put of butter. Every week a balance sheet is submitted, and the associates paid their respective net amounts for milk delivered.

As all deliveries are not of the same quality, the price of the milk is determined by weighing the cream removed from the daily deliveries, and next testing the richness of the milk furnished by the Fjord apparatus. No one establishment could keep a sufficient number of pigs to consume the skimmed milk, so each client takes his share back to utilize as observed on his own farm. This allows the central dairy to devote its undivided attention to turning out a sole product—butter. It has been found that the larger the quantity of milk worked up, in other words the more numerous the associates the greater the returns and the less machinery expenses. One matter that should never be lost sight of in preparing butter, whether for home or foreign market have a distinct quality, a factory mark as it were by which the article can be ever recognised. This is the secret of the French butter trade. As yet co-operative dairies are in their infancy in France. The peasants bring their butter in rolls to the market; the wholesale dealer purchases following quality. But when the butters arrive in his warerooms, they are classed with the most punctilious care, then each class-mass is separately mixed and prepared to form a distinct grade or mark specal to the fabricant. It is similar as with French brandies and wines. The merchants purchase right and left, then blend or grade, and therein lies the secret of their business and the success of their firm. Scandinavia patronizes the Burmeister and Wain Creamer; in Belgium, France, and Switzerland the vertical Laval creamer is preferred; it is simple, so does not get out of order; it separates the cream almost as completely as the horizontal machines, and is less laborious to work. It is besides cheap and adapted to a daily milk-yield of 33 to 60 gallons, while exacting no technical cares.

Switzerland affords the best types of co-operative cheese-farms. They are not the most ancient since France claims to have *Fruitières*, or associated dairies in the Jura since 1650. It is only at the commencement of the present century that Switzerland entered into the manufacture of its celebrated type-cheese, *gruyère*, of which that from Emmenthal and Simmenthal have a world-wide renown. Three centuries ago the price of gruyère in Switzerland was a fraction less than four sous a pound; it has recently fetched as much as 17 sous per pound. The statistics for the total dairy products of Switzerland are not complete; however, the little republic, with an area of 16,000 square miles and a population of three millions exported in 1885 a total of these products representing a value of 56 million francs. One-half of the milk yielded is worked up for exportation, and strange fact, Switzerland, the first milk-producing country on the Continent has to import, and mostly from France nearly her whole supply of butter She purchases annually 3,000 tons of butter and as many of lard.

In Switzerland then cheese is a natural product, and each region claims to have its special brand; just as in France each vineyard has its characterized *cru*. At the recent agricultural show held at Neuchâtel, the section devoted to dairy industries attracted not only the curious but business thousands. Every modern utensil or machinery connected with dairy industry was exhibited, and what was better still tested. A steam engine set in motion an army of churns and creamers—Danish, Sweedish, Laval, &c. The latter creamed at the rate of 172 gallons of milk per hour. Laval's *délaiteuse* or milk-expeller which completely removes the milk from the butter and so secures its perfect conservation was much admired.

The dairy section also served as a capital school replete with object lessons; a specialist lectured on some improved utensil, some ameliorated process of butter or cheese making, the lecture being accompanied by practical demonstrations of cheese and butter preparation in their several stages.

Cheese farming has ameliorated Swiss agriculture from every point of view. The peasant possessing only a few cows has by the principle of co-operation been enabled to share in profits, that isolatedly he could never dream of realizing. The French Government is studying the encouraging of cheese farming in the mountainous districts of the Alps and Pyrenees as a means of leading to the treeing and grassing of hill slopes, and by such means controlling in a sense the watershed or climatic conditions of these regions. Taking one of these cheeseries that of Eschholzmatt, which has been in operation since 1849, 34 associated farmers supply annually 770,000 gallons of milk. This realised a sum of 14,000 fr. less 400 fr. expenses. Over a series of years from 1854 to 1883 the milk has realized, that is, paid at the rate of 7 to 13 sous per gallon when converted into cheese. It is a singular fact that the number of members has always remained the same and belong to the same families who orignally founded the association, while the quantity of milk furnished by them has doubled and the receipts have trebled. Their holdings have not been augmented, but their fields have been ameliorated and their stock improved.

The Canton of Bern has 639 cheeseries, Zurich 282, Lucerne 358, and the other Cantons in proportion. The preparation of condensed milk has so extended, that in 1885 Switzerland exported 16,000 tons of that commodity which sells at 9 sous per lb. Another speciality is milk sugar, of which 114 tons are annually exported and selling at 21 sous per lb. Milk sugar was discovered by Bartoletti in 1619; one gallon of milk contains about 7¼ ounces of sugar. The latter is prepared from the whey in cheese making. After subjecting the whey to evaporation, it deposits on cooling, irregular sand-like grains, which next undergo refining. Marbach is the head centre of this industry since the early part of the present century and where 8 out of the total of 11 sugar refineries exist. Previous to the extraction of its sugars, the whey was given to hogs—the least profitable mode of utilizing it. About 9,000 gallons of milk will yield one ton of sugar and the expense

are 480 fr. per ton; the mean average wholesale price of the latter is 1,200 fr., and 112 lb. of brut give 65 of refined sugar. This sugar was till recently largely employed in the silvering of glass and the making of artificial pearls. At present the apothecaries are the best customers for milk sugar though higher priced than that from cane and beet, it can be pulverised easily and resists humidity. It enters to the extent of 99 per cent in the manufacture of homeopathic pills and globules. What quantities of the latter can be prepared with the Swiss output of 114 tons of milk sugar annually.

Switzerland has 660,000 milch cows, all of native breed, and divided into two sharply defined races—the brown and the spotted. The former color varies from deep-faun to mouse-grey, this latter shade being held in most esteem. The brown race is short horned and considered as the original type. It corresponds to the remains found on the sites of the Roman cities of the third century of our era. The skulls of this race furthermore are identical with those found in the Swiss lake-dwellings. The spotted race peculiar to Bern and Fribourg is believed to be of Scandinavian origin. From the milking point of view, there is not very much difference between either race. The average daily yield is about two gallons or 12 gallons per 112 lb. of live weight. The percentage of butter to the milk varies from 2¾ to 4¾ per cent.

In Germany, much attention is given to stolen or intercalary crops; these succeed rye and barley, generally sickled in the middle of July when maize is sown to be either soiled or siloed. White mustard, however, is becoming more the favourite and yields good cuttings during October and November. But with this green forage it is best to give a cow of 10 cwt. 84 lb. of the soiling with 8 lb. of straw and 2 lb. of crushed oats daily. White mustard is most nutritive, a little before and pending the flowering; mown later it becomes fibrous and difficult of digestion. It is best to sow the mustard not at once, but at intervals of 8 or 12 days so as to have bands maturing consecutively.

Calabar beans *Physostigma venenosum* are the fruit of a climbing plant of the order *Leguminosæ* peculiar to West Africa near the sources of the Niger. A special alkaloid called *Eserine* or *Physostigme* is prepared from the beans and which is a violent poison. Professor Dieckerlioff of Berlin recommends it as remedy for colic in horses when such is due to excessive accumulation of food in the stomach or of matters in the intestines. Following Professor Zürn, it is employed only in the form of sulphate of eserin in the proportion of 0·10 grammes dissolved in distilled water and injected by means of an appropriate syringe under the skin into the sub-cutaneous cellular tissue either in the front of the horses' chest, or on the left side of the neck. The remedy is cheap, easy to execute and convenient. No secondary disagreeable action is to be feared. It is also rapid in its effects and acts directly on the ganglions of the stomachic and intestinal nerves. The remedy is not efficacious against colic produced by mechanical obstructions, as calcareous intestinal deposits or lesions in the coats of the stomach, intestines, &c.

In Switzerland farmers will not purchase seeds, unless the merchants bind themselves to have the purity of their wares controlled and guaranteed by an agronomical station. No more purchasing with closed eyes, hence no room for adulterations. The agronomic station at Turich issues for a modest sum, albums containing dried specimens of the bad meadow grasses, also of the best one adopted either for temporary or permanent pastures.

Another instructive plan is exhibiting maps of meadow land where only bad natural grasses existed, and the same soil after being fully prepared and judiciously sown. At an altitude of 6000 above the level of the sea, there are maps of grass land such as it appeared in 1882, next to sterile, and maps of that same land in 1887 producing the remarkable total yield of over four tons of hay per acre.

AMONG THE GUMS AND TURPENTINES.

During a recent excursion of one of our artists along that portion of the Northern railway route lying between Gosford and Lake Macquarie, New South Wales, he was astonished at the wealth of timber that will become marketable when the railway is open. At Gillaby Gillaby, forests of gum trees or eucalypti may be seen towering as high as 200 feet, and of as much as 15 feet diameter, without a branch for 50 or 60 feet. The turpentine trees are equally remarkable in appearance, as it would be difficult to find a crooked trunk within hundreds of yards of any point. The latter trees have not yet been sufficiently appreciated, though several years ago the late Captain Shoobert announced the fact that it is the only indigenous timber New South Wales has possessing the merit of being impervious to the attacks of the Teredo navalis. This he proved most conclusively, and latterly almost every new wharf constructed in and about Sydney stands upon turpentine piles.

When means of transportation by rail become available, those who are fortunate enough to have land timbered with this invaluable tree will have reason to congratulate themselves on their good fortune. The white gum, found growing in the southeast part of this province, also at Echunga in the Valley of the Onkaparinga, and in other parts of the colony, is probably the tallest tree we possess. Its height varies from 70 to 140 feet. In West Australia the Jarrah reaches 200 feet in height.—*Pictorial Australian.*

NAGPUR EXPERIMENTAL FARM.

The official review of the report on the operations of the Nagpur Experimental farm during the year ending March 31st, 1886, states that

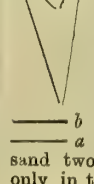
"So far as the *Khariff* crops were concerned, the season was a favourable one, especially in the case of the cotton and til crops which yielded a larger outturn than has been obtained during the late years. The prospects of the *rabi* crops were somewhat damaged by the failure of rain in September, but this was to a great extent compensated for by a fall in October, and the crops in the early part of the season promised well. But the continuance of cloudy weather during December and January induced an attack of rust of exceptional severity, which very greatly reduced the out-turn of the wheat and totally destroyed a large portion of the linseed. That the decrease in out-turn has resulted from the seasons and not from any loss in fertility on the part of the Farm land is established by the fact that the out-turns follow tolerably closely the 'anna' out-turn estimates which have been framed each year for the Nagpur district. The rust attacked with most severity the crops which were on the richest soils, and hence the results which have been obtained in comparative experiments with manures are nearly valueless. The out-turn of straw was but little affected by the rust, and hence there is the anomalous result that in the season under report the weight of straw is a better indication than the weight of grain of the effect of each manure. The most practical of all the manure experiments is that conducted by ploughing hemp in green—a process which has yielded excellent results on the Cawnpore Farm. But this experiment suffered this year a special disadvantage. Owing to the failure of the September rain, the hemp did not decompose as it should before the sowing season, whilst the deep ploughing which was necessary in order to turn it into the soil occasioned a loss of moisture which could not be spared. The results of the past season throw but little light on the real utility of this process. The Upland Georgian variety of cotton has now proved its value. The out-turn was not very large in quantity as the crop was grown on comparatively poor land, but it was quite as large as would have been gathered from cotton of the ordinary kind on this land. The quality of the produce was very favourably reported on by the Manager of the Hinganghat Mills. An endeavour

is being made to induce a large number of cultivators in the Wardha district to grow this cotton during the coming season. An experiment of some practical importance is that which is being tried to determine the utility of embanking land as opposed to open field cultivation. Black soil is extensively embanked in the neighbouring district of Balaghat, and over a tract of country stretching northward from Balaghat which includes a large portion of the Seoni, Mandla, Jabalpur, Damoh, and Saugor districts. The field banks in these districts represent a very large outlay of capital. In the black soil of Nagpur, Wardha, and the Narbada Valley the open field cultivation is the rule, and it would be interesting to discover by experiment whether this is the result of circumstances which render field embanking less profitable than in the eastern districts. The experiments of the past season go to show that embankments would yield a fair profit on the farm land. But the experiments were only initiated during the year under report and their results must be checked by those of two or three seasons.

An ensilage experiment with Guinea grass succeeded very well, and the experience of the year under report bears out that of previous years in showing that green fodder may be successfully stored in pits against the hot weather. I may mention here that during the year under report grass was very successfully ensilaged by the Superintendent of the Maharaj Bagh in the same manner as that adopted on the Farm. The trial was an interesting one, as the grass was cut while in flower before the end of the monsoon, when it was at its prime for cattle feeding purposes, instead of waiting till the rains were over. The quantity stored was 70 maunds, and the expenditure was as follows:—Digging pit R1-3-2; cutting, filling, and ramming R3-14-10. Total R5-2-0. About one-fifth of the grass was spoilt by mildew and, making a deduction on this account, the cost per maund (of 80 lb.) was R0-1-6. The cost of cutting grass when dry, at the close of the rains, and stacking it is about R0-1-4 per maund. Deducting for the weight of the excess moisture in silage, its cost compared with that of dry grass is about R0-3-0 per maund. Very careful experiments would be required to show precisely the fodder value of silage as compared with dry grass. But it seems hardly possible that to obtain green fodder in the hot weather would not be worth an extra outlay of R0-1-8 per maund. Nothing new was done in the way of experimenting with improved implements. The implements which were recommended in last year's report (viz. the Swedish plough, the Bihia Sugar Mill, the Cook's Evaporator, and the Winnower) continued to give satisfactory results, and what now is wanted is not so much an extension of experiment as some practical measure to bring about the sale of these implements. The only one of them which has as yet obtained a market is the Bihia Sugar Mill, 96 of which have been sold in the Betul district, owing to their having been pushed by private agency. It is only by enlisting private enterprize that the Government can expect to gain a sale in this country for implements which are new to the people, and endeavours are now being made to induce private agency to take up the sale of such implements as have been proved beyond doubt to be useful. The Farm Superintendent, Mr. Krishna Iyer, has, on the whole, done very well. He takes great interest in his work, and has shown considerable energy in carrying it out."—*Madras Mail.*

DESIRABLE FOREST PRODUCTS TO INTRODUCE INTO SOUTH INDIA.

We are not aware that the extraction of the black Burmese varnish has ever been fully described, and as some planters on the Nilgiris intend introducing the plant on their estates, and there is little doubt that in the near future it will be as largely cultivated as Cinchona, it is of the first importance that all practical details relating to the industry should be carefully studied in order to carry the enterprise to a successful issue. We likewise invite the attention of the planting community and Forest Department to equally valuable products which would undoubtedly thrive in Southern India, particularly in the Nilgiri District. The varnish tree, *Melanorrhœa usitata*, belongs to the order of *Anacardiaceæ*, which comprises the Mango, the Piár or Chirongi, (*Buchanania latifolia*) the Bhiláwa (*Semecarpus Anacardium*) and the varnish tree of Japan (*Rhusvernicifera*). It is found almost everywhere in the Eng Forest of Pegu and Tenasserim; and in the Tharawaddi district: it is particularly common in the lower part of the Eng belt, where the soil is said to be better than further east near the foot of the Gomah. The tree does not attain the same size as the Eng, Engyin or Theya, and at this time of the year (August) it may be known at once by its darker foliage. The leaves resemble those of the *Semecarpus* (*Chayben*), they are ovate-lanceolate, pointed at both ends, and covered with soft short pubescence; they are narrowed into a short petiole, while the leaves of Eng (*Dipterocarpus tuberculatus*) are glabrous, much larger, and have a broad cordate base. Those of Engyin (*Pentacme Siamensis*) which have about the same size, and of Theya (*Storea obtusa*) are also glabrous, of an oblong shape with rounded ends. While these trees are in leaf it is easy to distinguish them. A large proportion of the Thitsee trees—from which varnish is likewise extracted—is generally found with the varnish tree in Eng forest, and also a number of trees found in South India, though they are wanting in North and Central India. Of cultivated trees, the Mango, Plantain, Custard-Apple, and Jack fruit are common. The trees which have been tapped are at once known by triangular scars about nine inches long and five inches broad, the apex pointing downwards. On some trees from forty to fifty of these scars may be counted, and many incisions are made at a height of thirty feet. To work the higher scars a most ingenious ladder is used which is permanently attached to the tree. It consists of a long upright bamboo with holes cut through at intervals of from two to three feet. Through each hole are passed two flat bamboo sticks driven with their pointed ends into the bark. These form the spokes of the ladder and are about twelve inches long. The scars or notches to extract the varnish are made with a peculiarly shaped chisel about fifteen inches long; the handle is of iron, of one piece with the chisel and about nine inches long, the lower end thicker, hollow, and closed with a bamboo plung. The chisel is wedge-shaped, about six inches long (the edge half an inch broad) and forms an obtuse angle with the handle. With this instrument, two slanting slits, meeting at an acute angle, are made upwards through the bark, and the triangular piece of bark between the two slits is thus slightly lifted up, but not removed. A short bamboo tube, about six inches long, with a slanting mouth and a sharpened edge, is then horizontally driven into the bark below the point where the two slits meet, and the black varnish, which exudes from the inner bark near its contact with the wood, runs down into the bamboo tube, which is emptied at the end of ten days, when it ceases to flow. A second cut is then made so as to shorten the triangular piece of bark which had been separated from the wood when the first cuts were made. A shorter triangular piece of bark remains, ending in an angle less acute than before, and the appearance of the scar is then as below. The bamboo tube, which before was at *a*, is moved a little higher (to *b*) and the edges of the original cut (*c b* and *d b*) are cut afresh. The varnish then runs out for another ten days, after which the scar is abandoned. The trees vary in yield exceedingly. A crooked tree with very scanty foliage, which Mr. Douglas examined, was said to yield a good outturn, while some of the largest trees were said to yield very little. Mr. Douglas saw trees tapped which had a diameter only nine inches. One man is employed to cut two hundred and look after one thousand two hundred scars per diem. Work is carried on only in those parts of the forest where the trees are



fit to tap, are abundant, and stand close together. The tree yields nothing while it is leafless in the hot season, and the best season for working is from July to October. One man collects from forty to fifty viss (one hundred and forty six to one hundred and eighty two pounds) in one season, and the viss sells at Rangoon for one rupee. In the slack season these men are employed in making torches of the Eng tree woodoil, and we add particulars of the method pursued in the collection of this valuable article. Unlike the varnish, the wood-oil exudes not from the bark, but from the outer layers of wood. It will, however, be remembered, that among conifers, which all belong to one natural order, some, such as the Larch and *Pinus Pinaster*, exude resin from the wood, while others, like the Spruce, produce it in the bark. Deep, semicircular niches are cut into the wood: the first cut is from four to six inches deep, and from twelve to eighteen inches wide; the bottom of the niche being slightly hollowed out, to receive the oil. It oozes out and collects at the bottom of the niche about three days after the cut has been made. The surface is then charred with fire, after which the oil runs for three days; this process is repeated four times, and at the end of fifteen days, the surface of the niche is cut afresh, the old charred wood being cut away and the niche enlarged. After the oil has run for three days, the surface is again charred, and the original process repeated. The Eng tree yields oil throughout the year, and one tree often yields oil from several niches at the same time. Mr. Douglas saw a tree with six niches, two of which were yielding oil at the time. One man can make from two thousand to three thousand torches in a year, and one hundred torches require about ten viss (thirty-six pounds) of oil which is mixed with touch wood and neatly wrapped up in the leaves of palms or of the Tsathoaben, a species of Pandanus, so as to form cylinders about twenty inches long and two inches in diameter. They are tied with thin strips of bamboo, generally of the *Schizostachyum pergracile*; leaves of the *Licuala pittita* are likewise used for this purpose. A man can collect from seven hundred to one thousand pounds of wood-oil in a year. The wood-oil of the Kanyin tree is collected precisely in the same manner. One man can manage from thirty to forty oil-yielding Kanyin trees; he goes around with a number of hollow bamboos or other vessels, and one collection gives him from three to four viss. The torches sell at the rate of fifty per rupee and the Eng torches at rupees five per one hundred. The Eng and Kanyin trees so valuable for their wood-oil; the Bambouay, (*Careyea arborea*) Thanat, (*Cordir grandis*) Mhayah (also a species of *Cordia*) *Maranta dichotoma*, of which the beautiful soft Thimbu mats are made the getechu and varnish trees, and several species of *Sterculia* for rope and an immense variety of other useful and necessary articles, would all thrive in the Nilgiri District and Wynaad, and would amply repay the planter for the cost and labour of cultivation. We commend these congenial branches of industry to planters who are seeking other investments for their capital than the played-out and overdone Coffee and Cinchona industries.—*Nilgiri Express.*

NOTES ON TREES SUITABLE FOR PLANTING IN AND ABOUT TOWNS IN THE WEST INDIES.

(From *Jamaica Botanic Gardens Bulletin.*)

A very large number of seedling trees can be supplied from the Gardens at the nominal price of 1d. to 3d. each. Carriage is not undertaken by the Department, but can be arranged for at the rate of about 2 dozen plants for 1s.

The trees should not be planted closer together than 20 or 30 feet, according to the length of the branches. If it is found possible to plant them at regular intervals, it is preferable to have all the trees in one street of the same kind; if, on the other hand they stand at irregular intervals, it is better to have a variety.

In forming new streets, the rule to be adopted for the position of the trees on the road is that they should be 4 feet from the foot path, and clear of the water-table. They should never be planted on the foot-path where they would hinder foot-passengers, and raise the pathway by the growth of their roots.

In a road or street, the holes should be dug larger than in ordinary ground about 5 feet wide at the top, and 5 feet deep. The earth taken out from holes in streets should be replaced with good soil well mixed with well rotted manure.

If an iron grating is placed on the surface round the stem, the soil remains soft, and allows water and air to penetrate to the roots. Probably the best plan in this climate would be to have a kind of gridiron arrangement with the bars attached by nuts, so that as the stem expands, the innermost bars could be removed. The grating should be at least 3 feet square.

It is also necessary to protect the young plants by means of upright guards, which should be 4 or 5 feet high; and stakes are necessary until the plants are well established. Pruning is constantly necessary to keep the trees within bounds, and to give them a good shape. The trees, especially while young, require constant watering.

The following are a few of the trees suitable for planting:—

The Eucalyptus or Gum trees are natives chiefly of Australia where they form forests, but they are also found in the Malay Archipelago. They are the largest trees in the world, some which were measured proved to be more than 400 feet high. The leaves hang vertically, thus giving a remarkable character to the scenery. Several species of Eucalyptus grow more quickly than any other tree; the timber is at first soft, and is easily felled, split, and sawn, but when thoroughly dry, it becomes as hard as oak.

Eucalyptus trees have acquired a reputation for planting in malarial swampy ground, and that for two reasons, first because they absorb an immense amount of moisture from the soil, practically draining it, and secondly, because there is a large quantity of aromatic essential oil contained in their leaves, which becomes oxidized by the action of the air, and produces an active disinfectant,—peroxide of hydrogen.

The "Red Gum Tree" (*Eucalyptus rostrata*) of Southern Australia thrives in wettish soil with a clayey sub-soil, even when the water is slightly brackish. It is recommended as an antiseptic tree for cemeteries in tropical countries. It is of rapid growth, often attaining a height of 65 feet in 6 years, eventually reaching to a height of 200 feet. The timber is thought highly of, lasting well above or below ground, or in water. The government of Victoria, whenever practicable, use no other timber for bridges and railways; as railway sleepers it lasts 12 years.

The Yate Tree (*Eucalyptus cornuta*) of South-west Australia, is reported to have reached a height of 8 or 10 feet in the first year in plantations at Lucknow. It prefers a wettish soil. The wood is equal to the best ash.

The Iron-bark Tree (*Eucalyptus Leucoxylon*) supplies a valuable timber, worth 2s. 6d. a cubic foot in Melbourne. The wood bears twice the strain of American oak or ash. The tree grows to a height of 100 feet; it is generally found on slaty formations, but accommodates itself to any soil.

The Swamp Mahogany (*Eucalyptus robusta*) is said to thrive best in low, sour, swampy ground near the sea-coast. It grows 100 feet high with a grand mass of foliage, and resists cyclones better than most other Eucalyptus.

Other desirable Eucalypti are the Manna Gum Tree (*E. [illegible]*), the flooded Gum Tree (*E. [illegible]*), the Tallow Wood (*E. microcorys*), the Red Gum Tree (*E. [illegible]*), and the Stringy Bark Tree (*E. obliqua*). A mass of information is contained in Baron von Mueller's Work.

The Tamarind [illegible] though of slow growth, is suitable for planting in towns, as it is large and ornamental, affording pleasant shade with handsome, fragrant flowers. The fruit is useful,

and the timber is beautifully grained and valuable for building.

Bauhinia variegata, a native of India and China, is a beautiful shrubby-looking tree of 20 to 30 feet in height, suitable for open spaces. The flowers are handsome of a rosy-white colour. The dark wood is sometimes called Ebony, but is of little use The astringent bark has been used as a tonic in medicine, and also for dying and tanning. *Bauhinia megalandra*, a native of some of the West Indian Islands, may also be planted in the same way.

Cassia siamea (also known as *Cassia florida*)* grows to a height of 80 feet at Castleton. It has large, showy, yellow flowers. It is a native of India and Malaya. *Cassia Fistula*, the India Laburnum, has flowers of the same kind, it is a middle sized erect tree, reaching a height of 40 to 50 feet. The pulp round the seeds is a mild laxative

Lagerstroemia Flos-Reginæ (Queen's Flower) when in blossom, is one of the most showy trees of the Indian forests. A moist, damp climate is most suitable for its growth and for the full development of its rose-coloured blossoms. It reaches a height of 50 to 60 feet. The timber is blood-red, and as it lasts well in water, it is used for boat-building. In Burmah, it is employed more than any other timber except teak, for a variety of purposes, but it soon decays under ground. The astringent roots have been used as a remedy for thrush; the bark and leaves are purgative.

Spathodea campanulata grows to a height of 80 feet at Castleton. The branches do not spread, but the mass of rich orange-coloured flowers gives it a most attractive appearance.

Caryocar nuciferum produces the Souari or Butter Nuts, the kernels of which have a pleasant nutty taste, and from which an oil may be extracted by pressure. The nuts have a very hard shell, and are enclosed, 2, 3, or 4, together in a fruit about the size of a child's head. The flowers are very large, and of a deep purplish brown colour. The tree is a native of Guiana, where it often grows to a height of 100 feet. The timber is very durable, and is used for ship-building.

Sterculia carthaginensis, called "Chica" by the Brazilians and "Panama" by the inhabitants of the Isthmus, is a fine tree, 40 to 50 feet high. It has become naturalized in the West Indies, and does well in the plains. The flowers are yellow, spotted inside with purple. The seeds are about the size of pigeons' eggs; they have an almond-like taste, and are sometimes eaten.

The Candlenut, sometimes called Walnut (*Aleurites triloba*) grows to a height of 30 to 40 feet. The seeds yield oil, which is a good drying oil for paint. In the Sandwich Isles 10,000 gallons are annually produced, and used there as a mordant for their vegetable dyes. The cakes, left after the oil has been expressed, is used as food for cattle and also manure. It thrives along roads.

The Mountain Mahoe (*Hibiscus elatus*), a native of Jamaica and Cuba reaches a height of 50 to 60 feet. The timber is valuable, especially to cabinet-makers; it has the appearance of dark-green variegated marble. The fibres of the bark make good ropes. The lace-like inner bark was at one time known as Cuba bark, from its being used as the material for tying round bundles of Havanah cigars.

Three species of Ficus are growing well in the Parade Garden:—(1) *Ficus indica* is one of the Banyans, the roots which drop from its branches becoming new stems with spreading branches and fresh branch roots, so that of some of these trees it is said, "at the age of 100 years one individual tree will shade and occupy about one and-a-half acres, and rest on 150 stems or more, the main stems often with a circumference of 50 feet, the secondary stems with a diameter of several feet." (Mueller.) (2) *Ficus lucida*, another native of Indica, affords dens shade (3) *Ficus Benjamina*, a native of North Australia has handsome, drooping, willow-like branches. It forms part of the avenue at King's House. All these trees form very shady avenues.

The Ginep (*Melicocca bijuga*) is a native of Guiana and New Grenada. It is a good shade tree, and there are very fine examples at King's House. The timber is hard and heavy, and the fruit has an agreeable flavour, but the stringy portion which is usually swallowed by children, is most injurious, and according to good medical authority has frequently caused death by coating the lining of the stomach.

The Flamboyante (*Poinciana regia*) is a native of Madagascar. It is a tree with very showy flowers, and is suitable for planting in open spaces, or in broad mixed avenues.

The Red Bead Tree (*Adenanthera Pavonina*) is a native of the East Indies and China, growing up to an elevation of 4,000 feet in Sikkim. The common name is derived from the bead-like seeds, which are of a bright scarlet colour, and of a uniform weight (4 grains) so that they are used by jewellers in the East as weights. By rubbing the wood against a wet stone, a red dye is obtained, which is made use of by Brahmins for marking their foreheads after religious ceremonies of bathing. The tree affords hard, durable timber called "Coral Wood," or "Red Sandal Wood." There are trees in the Parade Garden and in Orange Street. They are well suited for avenues.

The Kananga (*Cananga odorata*) of India is largely cultivated there for its ornamental appearance. It is soft-wooded, quick growing, ultimately reaching a height of 150 to 200 feet. The specimen at Castleton is at present about 40 feet.

The Guango or Rain Tree (*Pithecolobium Saman*) is a native of Brazil and Venezuela. It is fast-growing and ornamental, and very suitable for open spaces. It is so much desired in India that in 1880 the Jamaica Botanical Department sent 130 lb. weight of seed. Dr. King, the Government Botanist in Calcutta, says of it:—"This wonderful tree grows faster than any hitherto introduced into Bengal with the single exception of Casuarina. It gives a beautiful shade and yields a pod with a sweet pulp which is greedily eaten by cattle. For avenues, cantonments, squares, and situations where dense shade is wanted, no tree is more suitable than this."

The Casuarinas are mainly Australian, but are also found in the East Indies and Polynesia. They grow quickly but are not good shade trees, for the leaves are represented by scales. The general appearance is something like the larch. The timber called "beefwood" in Australia is hard; it makes excellent firewood, and as the ashes retain heat for a long time, it is much used for ovens and steam engines. *Casuarina equisetifolia*, the Swamp-Oak, is found in the East Indies and Polynesia. The hard wood is known as "Iron-wood"; it is durable under water, forms good posts, and bears a considerable strain. This is an excellent tree for planting in sandy districts along the sea-coast. *Casuarina stricta*, the Hurricane Tree, is found in the islands of the Pacific. At Castleton, it has grown to 80 feet. *Casuarina muricata*, from India, has a showy wood of great weight. Grown close, it forms pretty avenues in narrow roads.

The Betel-nut Palm (*Areca Catechu*) of Tropical Asia is a very graceful palm of remarkably perpendicular growth, with a trunk seldom more than 6 or 8 inches in diameter, it grows to a good height,—at Castleton, it has reached 60 feet. The flowers are very fragrant. There is an immense trade in the nuts in the East, for the Malays and other natives use them for chewing, rolling a small piece up with some lime in leaves of the Betel Pepper.

The Talipot or Umbrella Palm (*Corypha umbraculifera*) of India and Ceylon is a very fine Palm, 60 to 70 feet high, with fan-shaped leaves, 12 feet in diameter.

One of the Royal Palmettos (*Sabal umbraculifera*), a native Palm, is well worth planting.

The Oil Palm (*Elaeis guineensis*) has become quite naturalized, growing wild in some parts of Jamaica. The Coconut (*Cocoa nucifera*) is also suitable for planting.

* The *Wa* of the Sinhalese, used largely as firewood on the railway.—ED.

DISEASE IN ORANGE TREES.

Last May the following prescription was given to be used for Orange trees which had begun to die off. The bark was decaying at the collar, and from the original starting point the decay was spreading and in some cases had completely encircled the stem. The leaves had begun to turn yellow, and there is no doubt that the whole plantation was doomed, unless the remedy proved effectual:—

Apply to the wounds in the bark a mixture composed as follows:—2 lb. stiff clay, 2 lb. flowers of sulphur, ¼ lb. soft soap, 1 tablespoonful kerosene oil, mix with water to consistency of paint and apply with a brush. The oil should be added last, and the mixture should be allowed to stand 12 hours before being used.

It is satisfactory to have received the following statement, dated 2nd September:—

"After having applied on two different occasions—at an interval of 10 days—the preparation you were good enough to prescribe for my Orange trees—the disease—whether fungoid or animal which attacked them at the end of the stem just where it touches the earth—completely disappeared. The trees whose peel had been eaten away all round the stem have died, but wherever there remained a strip of peel to connect with the peel on the roots the tree has recovered after lingering more or less according to the injury it had sustained prior to the application of your prescription.

There is no appearance of the disease at present on any of the trees, and the peel newly formed is covering over that part of the stem which the disease had eaten away.

It seems to be rather singular that all the trees of a plantation numbering over 200 were attacked simultaneously by this disease, and that they were mostly young trees, though a few old trees in the immediate neighbourhood suffered equally.

(Signed) OSCAR MARESCAUX."

CINCHONA.

Some Cinchona trees have lately been dying off. On investigation, it was found that the bark at the junction of stem and root had been injured, and that in consequence the mycelium of a fungus had penetrated between the bark and wood. The bark had become loosened on the roots, and decayed away. It is probable that the injury was caused by the wind during the last hurricane. It would be difficult to detect such injury at first, but probably an early application of the remedy prescribed above for the Orange trees would have saved the trees. Trees which are too far gone to save, should be taken up by the roots, and barked. The bark may be stored, after thorough drying, for mildew does not affect the quantity or quality of the alkaloids, when once the bark is cured.

COFFEE CULTURE IN RIO JANEIRO.

Reporting on the general state of the province of Rio Janeiro, the British Consul thus speaks of the coffee:—

In the districts of Cantagallo, S. Fidelis, and other parts, for some years past, the coffee trees have been subject to a disease manifested firstly in the yellowness of the upper leaves, and afterwards in the shoots, the trees soon drying up. In this way about one-tenth part of the trees in the above-named districts have perished. This disease is supposed to be propagated by an insect which lives in and feeds on the roots. It deposits its eggs in the knots of the roots causing the fibres of the same to rot. On this the eggs are seen, having the shape of mushrooms. This generally takes place in the heaps of weeds or grass which rot at the foot of the trees, forming a fine soil for the new root fibres. As a remedy against this evil it is recommended by Dr. Glacion that the weeds and grass should never be heaped up to rot near the roots, but should be left to be dried by the sun and afterwards burnt on the ground and burned. The Orange trees are also said to be attacked by the same pergue. Dr. Glacion is convinced that this evil can be attributed to that in two years time the coffee estates will return to what they were formerly.—*Gardeners' Chronicle.*

NOTES ON SOME PLANTS LATELY RECEIVED.

Seeds of *Ceropegia pusilla* have been received from Kew with the following note from Mr. Morris:—"Besides the flowers which may be interesting in a West Indian Garden, the tubers of this plant are, according to Mr. Jamieson of Ootacamund, eaten both raw and boiled by the natives in the Nilgiris."

The Superintendent of the Forest Department, Singapore, has kindly sent seeds of a rare Palm, the Malawarin or Red-stemmed Palm of the Malayan Peninsula (*Cyrtostachys Rendah*). He speaks of it as follows:—"The plant is doubtless the most conspicuous and beautiful object the rich forests here possess. When planted on a lawn in suitable soil, it readily throws up a succession of stems from the bottom of the parent stem, and thus grows into a pyramid covered with leaf spathes of a dazzling bright red: these, when suddenly come upon in the forest standing out against a back ground of deep green, present an object not soon erased from the memory of the beholder."

DOES CINCHONA-GROWING STILL PAY.

It has been frequently stated of late, and sometimes with a certain show of authority, that the value of cinchona has now depreciated to such an extent that Ceylon Planters cannot possibly find it profitable to grow it any longer. At present we have no thoroughly reliable statement respecting the minimum price at which cultivators in our own colonies can still have a margin of profit left, but recent discussions among planters and others interested in the Java cinchona industry have shed some light upon the position of the industry in that island, and, indirectly, in other countries also. At a meeting of planters held some months ago at Bandoeng, in Java, a gentleman connected with the Government plantations asserted that even at a sale price of 5 cents per unit per half kilo, or about 9-10th d per lb the bark could still be made to yield a profit to the planters, provided the trees were not cut down until the sixth or seventh year. Mr. van Romunde, the director of the Government cinchona plantations in Java, gave a qualified support to this assertion estimating the lowest sale price at which a well-managed plantation would be profitable at 7 cents, or about 1 3-15th d. But another view of the case is presented by another Java planter, Mr. von Winning, who, in the *Indische Mercuur*, protests against the above-mentioned assertions, which he stigmatises as totally erroneous. In a very interesting letter Mr. Winning points out that the official report of the Government cinchona plantations in Java for 1885, the last year for which a complete statement has been published, proves that the average cost of price of Government bark in 1885 was 37½ cents per half kilo, or about 6¾d. per lb., while the average proportion of quinine sulphate amounted to 3·15 per cent., costing 2 1-10th d. per unit. Now, it should be taken into consideration that a private planter has to defray several expenses from which the Government plantations are free, such as taxes, insurance, interest on capital, &c. Taking these into account, the cost of production of similar cinchona bark on a private plantation is estimated at 50 cents per half kilo, or 9d per lb., and the unit cost at 2 9-10th d. Mr. von Winning estimates the total charges on cinchona bark produced in Java and sent to Holland for sale at 2 7-10th d. per lb. Formerly they averaged as much as 4 7-10th d. per lb., but the expenses have been gradually reduced, mainly by more careful management of the plantations. These charges include everything, from the stripping of the bark on the plantation until the proceeds in cash are received by the planter. They show that with the unit at 9-10th d. it would be quite useless if not absolutely ruinous, to collect bark of less than 3 per cent. quinine value, or of less than 2·2 per cent. if the unit does not exceed 1 3-15th d. the [illegible] which Mr. van Romunde thinks it still possible for the planter to reap a profit. At present the average proportion of quinine in Java bark happily [illegible] per cent although it is to be noted that this proportion will gradually increase, and Mr. von Winning points out that if the unit should fall to 1 1-10th d. the greater part of the Java plantations will have to be [illegible]

At the same time he declines to commit himself to a definite opinion as to the lowest price at which cinchona growing can pay. The cultivation in Java, he asserts, is still too young an industry, and its future much too uncertain to admit of any close calculation. No one can say, for instance, whether the soil after a period of twenty years or more will still be suitable for cinchona culture. Nor has the vexed question of shaving the trees yet been solved, for while in certain plantations shaving has yielded the most favourable results, in others it has been a complete failure. The future average proportion of alkaloids also is entirely undeterminable, so much so that the bark of young cinchonas raised on the same soil from the seed of the same mother tree yielded bark varying in alkaloidal richness from ½ to 10 per cent. Moreover, statistics kept on carefully managed plantations show that a period of even twelve years is far too short to admit of an average calculation of the yield. Mr. von Winning's contribution to the controversy, although it does not definitely settle the question, is valuable in showing that, even taking his own estimate as correct, the unit obtained at the public auctions in Amsterdam until quite recently has been high enough to leave a small margin to growers. His figures of course bear only indirectly upon other cinchonas, but they go far to show that in all probability the Ceylon growers have not yet lost much money on the bark sold here, unless on parcels averaging a very small proportion of quinine, and this hypothesis points to a continuance of the heavy bark shipments, and, in sympathy with the latter, of low quinine prices.—*Chemist and Druggist.*

SUGAR BOUNTIES.

It will be seen by our telegrams that M. Sans Leroy, who was appointed by the French Government to inquire into the operation of the sugar bounties, has reported strongly against them. In every country of Europe they are falling into disfavour, and in the Legislatures they have been condemned even by protectionists in unmeasured terms. Nor is the reason of this change of opinion on the part of the financial authorities of the Continent far to seek. When the bounties were first imposed the production of beet-root sugar was small, being little more than a tenth of what it now is. As cultivation increased, and as machinery which extracted a greater amount of sugar from the beet-root was invented, the unnatural stimulus produced a glut, which was followed by disaster, bankruptcies, and distress. Owing to the keen competition of Germany, and to the difficulties of the producers, both France and Belgium have been obliged to revise their tariff. Germany and Austria have passed through a severe crisis, which has brought with it many failures among the capitalists, and widespread distress among the workmen. According to a member of the German Parliament, the subsidy on sugar has amounted to eight or ten per cent. on the capital invested; or, to take another calculation, it has nearly paid the wages of the workmen employed in the business. Yet, in spite of this subsidy, there have been many failures, and heavy losses, both to the Treasury and the community, on unrealisable property.

The question, therefore, has arisen whether any real prosperity is represented by the figures which record the rapid growth of the beet-root industry. Any other department of human labour would have shown an equal advance, if it had been supported by a similar subsidy. The difficulties which beset the manufacture of sugar, when it is kept up by direct state aid, may be taken as sufficient to condemn the whole bounty system. But the losses that have been caused by over-production followed by stagnation, are not the only losses that can be traced to the bounties. It is said that the German manufacturers of sweetmeats are undersold everywhere by their English rivals. Owing to the cheap rates at which the latter have been able to buy their sugar they have succeeded apparently in laying hold of the German market. By way of returning the kindness done to them by the bounty system, they send across the manufactured products at a price with which the local makers find it difficult to compete. Nor does even this exhaust the complaint which is now made against the bounties; for sugar costs at least twice as much to the German or French as it does to the English consumer. While in England it is universally used, the consumption in these other countries remains almost at the same level. In other words, the people of the Continent are heavily taxed to produce a cheap luxury for the English people which they cannot afford for themselves, and at the same time the industry has never been as profitable as it was expected to be.

The artificial stimulus, however, to the production of beet-root has most injuriously affected the sugar plantations of the colonies, and to a considerable extent the refineries of the mother country. But the latter suffer solely from the recent importations of refined, and not from the production of raw sugars. It is not the cultivation of beet-root but the competition of refining establishments elsewhere that has deprived the fifty thousand men who recently marched through the streets of London of their employment. Some three years ago, when the heavy fall in the price of sugar told severely on the owners of plantations, the refiners were importing huge quantities of the beet-root product at a low rate. It is probable, indeed, that the importation of these low-priced sugars gave an unhealthy impetus to the trade, and led to an unwarranted extension of business. But in spite of foreign competition, not more than one-fifth of the sugar imported into England is refined. Four-fifths of the imports consist of raw sugars, and while there may be considerable depression, there is certainly not the ruinous condition which is described by those who would fain impose a sugar-tax. It may be doubted whether anything tending to add to the cost of the raw material would be to the ultimate advantage of the refiner, since the competition would still remain, and the demand would probably be lessened. The people who have most plainly suffered by the bounties, and who will be most directly benefited by their repeal, are the cane-growers. The production of cane sugar, indeed, has not diminished. On the contrary, it has kept pace with the growing consumption, and in some of the West Indian islands the production is much larger than before. But the low prices have necessarily inflicted great damage in places like Queensland and Fiji, where the expenses of beginning the industry have to be incurred; and in Mauritius, where the soil has been long worked. The demand for cane sugar has been little interfered with by the cultivation of beet-root, for the simple reason that the cheapness of the article has enhanced the consumption. But while the reduced prices have told against all planters, they have been ruinous for local reasons to many. It is to be hoped that the difficulty will be ended, not by any artificial help to the plantations, but by the abolition of the bounties, and that the people of the Continent staggering under a heavy burden will have sense enough to throw it off. The planters will then meet fair competition and receive a fair price, and the reduction of cost which would follow on the Continent would probably elad to a better demand.—*M. Argus*, Oct. 14th.

Correspondence.

To the Editor of the "Ceylon Observer."

CINCHONA.

London, 26th Oct. 1887.

DEAR SIR,—As anything bearing on cinchona is always interesting to Ceylon growers, I have been endeavouring to get some particulars which may be of use to those who like myself are interested in the article.

Our New York friends, Messrs Castleton and Moffat, under date of 15th October write us as follows:—

"*Quinine and Bark.*—We find that the stock of bark in United States on 1st September was 1,984 packages, of which more than ¾ was almost worthless, being rejections of former years. This is outside of manufacturers hands.

Stock of quinine in United States is variously estimated at from half a million to one million ounces, probably 600,000 to 700,000 is a fair estimate of stock held by speculators; or in excess of dealers' usual supply.

The consumption of quinine in 1886 was 3,100,000 oz. The consumption has increased 70 per cent in this country, during the past 5 years. [*N. B.*—ED.]

The value on this market keeps almost on a par with London and Germany.

The present stock of bark in Europe and America contains 3,740,000 oz. of quinine, which gives us as visible supply

	oz.
Stock of Quinine in America	700 000
Estimated stock of Quinine in Europe	1,000 000
Do do Bark	3,740,000
Total visible supply	5,440,000

or say 10 or 11 months' supply.

The estimate of European stock of quinine is mere guess work, as we have no figures to base it upon, but believe it is a full estimate.

We enclose statistics of supply and consumption running back to 1874, which are instructive, the present price being far below anything in the previous history of the article.

Can you give us any information as to prospective supplies of bark from Ceylon? This is the point on which the whole question rests. If Ceylon is going to be short this coming year, *or its supplies could be held back for a time to give the Trade a breathing spell*, a marked change in the situation would be seen.

The world's consumption of quinine in 1886 was a little over 6,000,000 oz., and it increases year by year about 10 per cent."

From the above you will see that the position of bark is good; and a great deal more depends on growers in Ceylon as to the future price of the article; if they wish the price to go up they *must stop* harvesting, and even if the unit price was to jump to 100 per cent, they must still keep back supplies; it's the only way we are ever likely to get the price here to a paying point. Yesterday's auction went flat at 1½d to 1¾d per unit, a price that will not cover the charges on low class bark.

Those planters that are *compelled* to ship, let them do so by sailing vessels via the Cape; they thus have 3 months' storage room free, at only an extra cost of about ¾ per cent for insurance f. p. a. or 1 per cent if insured with average and a possibility of a cheaper rate of freight.

Stock of bark in London on 26th October was 60,190 packages against 60,370 same date last year, it is impossible, as no records are kept, to find out how much of this is good bark, but a fair average would be 1½ per cent of quinine per lb.

Manufacturers here do not hold much stock, preferring to supply their wants at each auction.

If Ceylon growers would now only combine to keep back their stocks, and let the trade have time to work off imports; we would soon see an appreciable rise. The markets on this side are governed by Ceylon, and I wish Ceylon men to bear this in mind. Trusting, foregoing may be of some interest to your readers, I remain, yours truly,

E. T. DELMEGE.

COCONUT CULTIVATION.

Hapitigam Korale, 11th Nov. 1887.

DEAR SIR,—During the forty years that I have been an occasional contributor to the columns of the Old Rag, I have had many disgusting experiences of the transformations made by your P.D.; the last not being the least. In a recent communication I ventured to use an expressive fragment of my mother tongue, signifying impulsive briskness, which, to my horror, came out of your shop as *virus*. If writing a book be a grand opportunity for the enemy of the author, a printer's error will sometimes serve equally well.*

After one of the fierce political debates that habitually took place between Aristides and Themistocles, the former turned to the people and told them that the affairs of Athens would never prosper till they seized the pair, himself and his opponent, and threw them into the Barathrum. In the case of your Siyane Korale correspondent and myself, I do not advise any measure so radical, but I think you might close your columns to both of us until we learned to discuss personal matters in a philosophical spirit, seeking truth rather than victory. For any departure from this spirit, in my own case, I repent in dust and ashes, in cow-dung and rattan [illegible]

Planters compelled to ship are compelled to realize rapidly.—ED.

* What was the broad Scotch word [illegible] answered to "real money" made good use of, though rather emphatic.—ED.

in bone dust, sulphate of ammonia, nitrate of soda, and all the abominations arising from organic decomposition.*

This reminds me of Dan O'Truff, a coconut planter of former days, who had an unshrinking appreciation of stinking things. On one occasion he put some tons of poonac into a pit to ferment, and there it lay till the passengers along the public road held the snout, and mended the pace. When the mass was at its nastiest, Dan had it stirred up for inspection, and snuffing up the fumes with enthusiastic relish, cried in ecstatic approval, "Ah! That 's the stuff!"

Henceforth, I will be ready to discuss coconut cultivation in a candid spirit with all comers, and, as new light appears, I will not shut my eyes to it, shine from whence it may, but to cavilling critics who set up in the trade on scanty capital, and that mostly borrowed, I will be dumb.

Coconut cultivation is essentially a matter of experiment, and the bolder the experimenter the better chance of success, whereas he who brings rules and analogies and untested theories from outside only fetters his own hands, and contracts his own field of action, tying him down to a narrow routine or sending him off in a wrong direction misled by preaccepted theories, or early imbibed prejudices. It is the business of the coconut planter to obtain the greatest possible amount of produce at the lowest possible expenditure of capital. It will be well for the planter to know the leading principles of vegetable physiology and agricultural chemistry, but the habits and wants of his cultivated plant should be his stock study, pursued early and late and under every circumstance that appears wherever he goes. If he brings a free mind and a free hand to his task, he will accept no theory old or new without bringing it to the test of experiment, and he will reject nothing without the same test. Though coconut planting as an investment is now above half a century old, so small is the intelligence that has been brought to bear on it, that both scientifically and practically it is still in its infancy; still planters perform the most injurious operations not knowing what they do, and were it not that the coconut tree survives under more bad treatment than any other plant, tens of thousands would have perished. For instance, it will hardly be denied that the coconut sends its roots out far and wide, in search of its specific pabulum. I have measured a primary root washed out on the shore that was forty-six feet and may have been much more, as it was broken off; and I have seen some that have wound their way through six feet of cabook. I suppose it will not be denied, that the principal feeding ground of the plant is well within one foot of the surface. With those facts so legibly written that those who run may read, the common way of applying manure is in a circular trench round the stem, varying in diameter and depth, according to the individual idiosyncracy of the operator, some going as close to the stem as three feet and going two feet deep, others take a wider circle and less depth, but however modified the system, it severs from the tree the whole army of roots, with their myriads of sucking mouths, just as deep as the trench is carried. The wise wight of the Siyane Korale owns to a depth of eight inches, yet with strange inconsistency falls foul of me, for periodically breaking up and aerating the whole surface to the depth of only six or seven inches, because, forsooth, I must cut roots in the operation. Saul slays thousands, but David slays tens of thousands. The writing of this guide and friend of the coconut planter bristle with errors in fact which are less excusable than errors of theory, as impeaching the accuracy of his eyes. As I am for this time at the end of my tether, I can only promise him some facts of my own, and some theories on first-rate scientific authority, on another occasion, that will rather astonish him. W. B. L.

* Aristides was sentenced not to penance but to death. —ED.

COUNTRIES IN WHICH TO PUSH CEYLON TEA: WHY NOT CHINA?

November 12th, 1887.

DEAR SIR,—There has lately been some little discussion in your paper as to the best methods and places of pushing "Ceylon Tea," in the doing of which I think we all agree that a long, strong push and a push altogether is the best way possible. I have tried, as no doubt many of us have done, to create an interest in the fragrant leaf as prepared in Ceylon, and I have found it much appreciated in Malta, Crete, and the Midland Counties. I am glad to see our tea is to be represented at Glasgow and Melbourne, as it is sure to do a great good, if only people inquire for Ceylon tea there as I saw them doing at the Colinderies. It was there I was somewhat surprized to see a gentleman, evidently by his pigtail and general appearance, an inhabitant of the Celestial Empire, thoroughly enjoying a cup of Ceylon tea in the Ceylon Tea House. Now, if he enjoyed it, why should not his *millions* of compatriots have a chance of so doing by our supplying it to them (as I see by a recent paper "they will not drink the poor class of tea they export")? I feel sure that if after conquering Glasgow and Melbourne the P. A. had a few rupees to spare from the tea fund they would be well spent in introducing our lower grades of tea into Chinese teapots, or in Singapore where there is a large tea-drinking population.—Yours faithfully, HENRY H. KIRBY.

MR. J. L. SHAND ON THE PUSHING OF CEYLON TEA, AND WHAT HE HAS DONE AT SERIOUS PERSONAL LOSS.

Nuwara Eliya, 12th Nov. 1887.

DEAR SIR,—Mr. Shand sends me enclosed saying as much or as little as I like may be published. Please publish those parts you think should be known to the public.—Yours, &c., H. K. RUTHERFORD.

My dear Rutherford,—I read your trumpet call in the train yesterday on my way, and I hope it may arouse the apathetic, and that your practical suggestion of a "voluntary tax" may be carried out.

You are within the mark (and any broker or dealer of repute would tell you so) in saying that South Kensington and Liverpool Exhibitions have put a penny per pound on to Ceylon teas, but you are wrong in thinking when Glasgow Exhibition is over, the United Kingdom will have been conquered. There is to be an exhibition in Birmingham next year, and there, or wherever men do congregate, no opportunity should be lost of pushing our enterprize. Let the Ceylon grower know that if we in any way relax in our efforts to maintain that superior publicity which we have acquired, we must be contented to take a back seat and prices will at once fall to Indian levels. I was beginning to get somewhat lukewarm about Glasgow until last mail came. My experience here (though I consider I have fully achieved the object I came for) has been personally a bitter one. Admitting that we must advertize if we want to retain our position, and that the recan be no such advertizing medium as an exhibition if it is properly done, and admitting further what all Ceylon men who have been here I think do admit that it has been well done by me here, I think I have met with but scant support. I have already explained to you the circumstances under which I felt obliged to suddenly take up the Liverpool Exhibition. I, of course, never expected to come out a loser, for justice

to those dependent upon me would have prevented my taking up a thing which I thought would be accompanied by a loss, but I weighed the possibility of a loss. I concluded that the Ceylon Government, the public bodies, and private enterprize would see me through, but what is the position? Government graciously lent me some exhibits which cost me a large sum to pack, insure, and transport. The Chamber of Commerce thanked me, the Agricultural Association did not answer my letter, the P. A. lent me their cases &c., which also cost me a large sum to purchase glass for, pack and move, and were it not for the liberality of some of my friends in Ceylon, and some who are not known to me (a liberality for which I am truly grateful), I should not have received an atom of assistance.

Of course, those who are in the same line of business as I am are not unnaturally jealous, and may think I am building up a connection to their detriment, but it is not so. My connection derived from South Kensington was not worth a ten-pound note to me, and any dealer in Ceylon ea can, if he likes, derive just as much benefit from the way it has been pushed at Liverpool as I do, and when the Exhibition closes next week, I shall feel that I have put tens of thousands in the pockets of Ceylon tea growers (while not one estate in six has contributed a farthing to help me); thousands in the Ceylon treasury, while I have lost six months of my time, been put to a heavy personal expenditure, and apart from this, lost a considerable sum in connection with the Ceylon Court here. Government should do something towards these things. The dominion of Canada and Ceylon are the only two dependencies which will derive any benefit from the Liverpool Exhibition, but the Dominion has spent a good deal and has a well paid official in charge, while the cost of Ceylon has all fallen upon an individual. We have been able to do a good deal for coffee here and proportionately more for Ceylon cocoa than for tea, so if you hear of anyone whose barns and bank accounts are swollen with heavy crops and good prices you can tell them a small conscientious contribution will be thankfully received. I saw D. Reid for five minutes yesterday just as I was leaving town for Liverpool and we meet in Glasgow on Monday. If we have a credit for £1,000 we can put Ceylon forward thoroughly, and the money will come back forty-fold, but Government should do something and at all events the official status of Ceylon Commissioner should be conferred on someone.—Yours truly, J. L. SHAND.

THE MARKET FOR BARK AND QUININE.—We print above a very valuable letter from Mr. E. T. Delmege, in which the important information is given that, in five years, consumption in the United States has increased 70 per cent. Mr. Delmege, like everyone else, recognizes the fact that the future of the bark market depends on Ceylon, and he urges the cessation of shipments, advice which large numbers of planters are now following because shipments do not pay. A private letter which accompanied the one for publication is so little of a private nature that we do not hesitate to quote it here:—

"I hope my letter on cinchona will be of some service to my fellow workers in the article. I have read it to some influential men in Mincing Lane, who wished very much to have copy of the figures. I declined to give it till the mail had left, so that you should have first details for the East. I have tried to get correct details of the quantity of the bark in stock here: while some are willing to give full particulars, others decline to give any. I think the article has now touched bottom, and if you could use your powerful pen to induce planters and others to keep back supplies, we must ere long see an upward movement in the price. Present prices do not pay the charges, so what is the use of shipping? and thus incur a certain loss. I know a good many men have been obliged to ship to raise funds for planting tea; but those who now can hold will find cinchona in a year or two will pay them better. Whittall, Arbuthnots and ourselves decline to sell at anything like present prices.

"You have, no doubt, seen the sales on 6th October of 53,000 oz. Italian manufactured 1883 and 1884 quinine at 1s 4d to 1s 4½d, and on 20th October of 10,000 oz. German 1886 manufactured at 1s 1 per oz. These sales took place from *second* hands, and holders had to take what they could get, being pressed for money. When the market is cleared of these *speculators*, the manufacturers will be able to get better prices, which will give a healthier tone to the bark auctions. You will see the enormous increase in consumption of quinine in America,—70 per cent in five years, and this will go on increasing as the country gets opened up.

"Is it impossible to get *reliable* figures as to prospective supplies of bark from Ceylon? This is the point on which the whole question rests." We only wish we could obtain reliable figures as to Ceylon probable shipments; but we feel confident there will now be a material decrease.

ADIANTUM FERGUSONI.—The following information concerning the origin and character of this remarkable Fern (see fig. 96 p. 469) is extracted from the late Mr. Ferguson's correspondence with Mr. Dyer. In April 1885, Mr Ferguson wrote:—"The following facts may interest Mr. Baker, Mr. Moore, and yourself. On my return from Puttalam, about 85 miles north of Colombo, in November, 1881, I stopped a night at Negombo, about 21 miles north of this, and visited F. J. de Livera, Esq., District Judge. I found this Fern (A. Fergusoni) for the first time in a small pot between plants of A. tenerum and A. Farleyense. I remarked that I thought it was A. Farleyense, which had taken a great bound and gone back to be a fruitful form. Mrs. de Livera got the plant from a family close by, who professed to have obtained it at a sale of plants at Colombo. With me it is a tall Fern about 2 feet in height and 1 feet in expansion. It has seeded freely here, and has come up in the crevices of the walls round my house. It has no barren fronds at all, and the seedlings show no difference from the parent. It is surely too robust a plant to be squeezed into any form of A. Capillus-veneris, and the nearest to it that I can suggest is A. concinnum. I feel very grateful to Mr. Moore for the honour he has done me in naming this rare Fern after me." In May of the same year we received at Kew living plants of this Adiantum, and there is now a fine example of it in our collection, quite as fine as that described by Mr. Ferguson. Its spores vegetate in all sorts of places, and we have already distributed a considerable number of plants thus raised among nurserymen and others. A frond measured by me today is 30 inches high, the lowest branch being 18 inches from the top, and the width of the frond at the base 12 inches. It is one of the handsomest of Adiantums, and is certain to become a popular garden Fern. With regard to its position as a species, it appears to me that it must take rank with the numerous and exceedingly varied forms of A. Capillus-veneris. Whether it is a sport from the latter, or a hybrid between it and one of the forms of A. tenerum, cannot be determined; but certainly it is not more extreme in the circle of A. Capillus-veneris than such as, for instance, the variety known as daphnites. I am responsible for the statement in the note that accompanied the figure of A. Fergusoni, to the effect that Mr. Baker had decided it to be a form of A. Capillus-veneris; this is not exactly correct, Mr. Baker believing that Mr. Moore's view was the true one, namely, that A. Fergusoni is related to A. Capillus-veneris, but whether a hybrid or a sport is not certain.—W. WATSON, Kew.—*Gardeners' Chronicle*, Oct. 22nd.

CEYLON TEA ON THE CONTINENT OF EUROPE AND IN THE UNITED KINGDOM

(From Our Special Correspondent.)

COFFEE IN MINCING LANE : A DEAR, SCARCE ARTICLE—CINCHONA BARK AND QUININE AT ITS CHEAPEST.

"Were I a young man and anxious to make money," said Mr. MacAll to me, "I should certainly endeavour to start a popular restaurant for the supply of tea in Paris." I may have already alluded to this remark in connection with the field which Paris seems to present for the multiplication of cafés or rather "thé-eries," not only in view of the need of supplying a good, wholesome, refreshing beverage to a people who are essentially temperance-living, but as a check on the liquor and beer shops which of late years have sprung up mushroom-like on every side in the French capital. I have alluded to the legislative attention recently given to alcohol laws as an evidence of the change coming over Paris, and in corroboration of this statement, as also of that respecting "five o'clock teas," the following amusing extracts may be worth giving :—

"The Alcohol Committee was formed today at the Finance Ministry. It is divided into three sub-committees. The one named to report on the proposed Governmental monopoly for the sale of alcohols is headed by M. Léon Say, and includes M. Wilson. The second, which is to report on the hygienic bearings of the scheme, has for its chairman M. Sadi Carnot ; and the third, which will report on small distilleries and private stills, is headed by M. Tirard. As the scheme stands it is proposed to let every one who pleases distil alcohol, but to allow nobody to sell it unless to Government, which will be then the great retail dealer, as of tobacco and matches. If the alcohol is of the same inflammatory strength as the matches it will be quite inoffensive.

We have become, says *Le Petit Moniteur*, the prey of the English, the German, the Yankee, the Spaniard, the Italian, and *tutti quanti*. Most of all, however, it appears that the British yoke is pressing French society. To wit : "A brutal shake-hand (!) has replaced our former elegant way of kissing a lady's rosy fingers. The quadrille, so convenient for the exchange of spirited talk, is replaced by boorish Boston, a sort of dance more suitable for kangaroos than for our graceful Parisian ladies. If we look at our dress and at our language we find the same state of things. Before long our great boulevards will be nothing but atrocious caricatures of Regent-street or of Fifth-avenue. Look at these young men. Are they Frenchmen, or are they not rather stable-lads in their Sunday garments ? And where are they going ? to the five o'clock tea of a society lady. The five o'clock tea has existed at all times, only formerly it was called *le goûter*, and pretty women used to fly at it with fruits or light pastry. Now England has quickly put her heavy paw on the graceful custom, and at these orgies of English tea, ham, sandwiches, muffins (!), pudding, gengember-pie (!), &c., are swallowed down, and our bordeaux has given way to chemical compositions known as cok (!) tail and sherry gobler (!). We have no longer any cafés; they have become taverns, bars, and musik (!) halls."

That a good deal of tea is drunk through the fashionable five o'clock custom is evidenced by the sales made from the one well-known depôt in Paris, the "Hotel de Lille et d'Albion," Rue St. Honoré. There is a want of attractiveness about the place, the service and the supply of good things usually associated with the drinking of tea here, so that the proprietor chiefly depends for a business and profits on the sale of tea in the bulk. But that progress has been made at all, in view of the non-attractiveness referred to, is evidence that with due enterprise and knack, the promoters of "thé-eries" could speedily get Parisians and Frenchmen to overcome their objection to tea (as a drug) and to understand that the same refreshing, sustaining property equally belongs to tea as to their favourite but now scarce and expensive beverage, coffee. The linenweavers of Belfast and Ulster generally long ago showed that tea (the strongest and dearest to be got) and potatoes sustained them at work in a way other food products could not with so much acceptance; and a French Commission on one occasion reported that coffee and potatoes constituted at once the most economical and suitable food coalminers in the South of France could work on. "The most logical people in the world," as the educated French consider themselves to be, would speedily appreciate such facts as these, together with chemical analyses, testimonials from hygienic and food authorities, if such were freely distributed to back up the claims of tea in the householder and the habitué of cafés and restaurants. I have said the "educated French;" but with free, compulsory education, the rising generation will be all ready to read and appreciate what can be said for tea or any other good article placed before them. Never at the most crowded London station in the busiest season did I witness such a scene of pressure and enormous passenger traffic as at the commodious station of the P. L. M. (Paris, Lyons and Mediterreanan) railway at the beginning of this month. The explanation was found in the return from the holidays of the immense multitude of students from all parts of France who make Paris their resort for the benefit of some of the ablest lectures and thoroughly worked classes known in Europe—the charges being either *nil*, or at extremely moderate rates. So much by the way.

Since my return to London I have learned that some of our Ceylon Tea Agencies have begun to do a fair business with Paris, and I have heard of several tea-sellers throughout France who are anxious to touch this product. I have also learned that a public-spirited Ceylon official (soon to be with you again) has, during recent residence in Germany and Switzerland, done much to make Ceylon tea known, several orders for chests recently reaching London being traced to his making its virtues known. His opinion, I believe is, that tea can never be expected to be largely consumed in the Southern, cheap-wine-drinking countries of Europe; but that in the Middle and Northern States there ought soon to be a considerable and increasing demand. As regards Germany, this is borne out by the opinion of an Anglicized German House in Great Tower Street, long established as coffee buyers for the Continent, who tell me that a change in the direction of tea—a really good article—must inevitably set in, in view of the scarcity and dearness of coffee. Already small parcels are being sent on trial sales in new directions.

As regards Russia I have had the benefit of several chats with Sir Graeme Elphinstone, who tells me he was much pleased with the prospects opened out through his visits to St. Petersburg and Moscow, and that nothing but the family afflictions which occurred soon after prevented him from following the matter up then. True, repeated samples forwarded have failed to reach some of his agents, being confiscated in the Customs; but through private channels he has been able to make our teas known and thoroughly appreciated, and he means very shortly to push the matter to a practical issue. This good opinion of Ceylon tea in Russia is confirmed by letters I have seen from the family of Prince Gargaim and the ex-Minister of Public Institution, both of whom much appreciate Nawara Eliya tea and want to know how they can be regularly supplied. In Mincing Lane, yesterday, again I learned of one broking firm at least who were endeavouring to push a

trade in Ceylon tea with Russia. This same house —one of the best known in produce trade—is very hopeful of the prospects of good teas such as Indian and Ceylon in America.

But is it not almost premature to be anxious about pushing Ceylon teas in other countries when it is well-known that even now twice if not three times the quantity of tea produced by Ceylon during the past season has been consumed as "Ceylon tea" within the United Kingdom! Such is acknowledged to be the case by all the Lane brokers, and I have it from the leading men in the trade—among whom I have been going up and down this week—that the very *name* of "Ceylon," apart from intrinsic quality, is worth "twopence" a pound to a tea in the present universal demand for "Ceylon." At last sales, our island teas freely sold 2d to 3d per lb. above values as compared with Indian, in consequence of the widespread popularity of our produce and name. Of course, there is an immense quantity mixed and distributed by middlemen and grocers, under the name of "Ceylon," which never grew in the colony, and a great deal still of inferior, adulterated stuff of which the sellers may well be ashamed. Samples of the latter under new brands have been given to me by Sir Graeme Elphinstone, to whom the colony and our tea planters are indebted for untiring efforts both in England and Scotland to make a demand for the product in circles where its goodness was likely to be appreciated. Perhaps the first credit for making a market for Ceylon teas at a time when few or no ordinary buyers would look at them is due to Mr. Figg of Messrs. W. J. & H. Thompson, who in the early days spared no effort in placing the limited quantities that reached the London market. Altogether, the planters have good friends in the Brokers of the Lane, and much good advice has come from the latter in respect of preparation which has borne fruit. "Keep up quality," is the one universal bit of counsel tendered to Ceylon men now. The ball is at their feet, so long as they do justice to their leaf in manufacture, and so the name having been thoroughly established, when 20, 30, or even 40 millions of "Ceylons" come forward, whatever may be the fate of "China" or "India," there would be a good market for all our produce. There is not much fear of consumers who have become accustomed to a really good tea, going back to common stuff; and as regards the sellers of adulterated or false "Ceylons," it is quite expected that under the new Act prompt steps can be taken for the punishment of offenders. To Mr. Pasteur (from members of whose firm, Messrs. Patry & Pasteur, I have got much useful information) I am indebted for a copy of the following circular issued by one of the large Co-operative Stores to show the penalties incurred now-a-days by making up or selling any food article which is not in reality what it professes to be:—

THE MERCHANDISE MARKS ACT 1887.—By this Act, which only received the Royal Assent on the 23rd August, 1887, after the greater part of the September Price List and Stores Circular was in print, penalties are imposed upon all persons who apply "any false trade description" to the goods sold by them, and a "trade description" includes any direct or indirect statement as to the place or country where the goods are made, or the materials of which they are composed. In addition to this, the seller is deemed to warrant that the description is not "false" within the meaning of the Act, unless the contrary is expressed in some writing signed by, or on behalf of the seller and delivered at the time of sale to, and accepted by, the purchaser. Moreover, even if a trade description is now lawfully and generally applied to any goods, to indicate the class or method of manufacture, the Act applies where it includes the name of a place or country, and is calculated to mislead as to the place or country where they were made or produced, unless they bear an equally conspicuous notice of the place or country where they were made or produced.

As many articles sold by the Society are known by the name of some place or country (*e. g.*, Windsor Soap, Vienna Baking Powder, Bengal Chutnee, Turkish Towels), and it is impossible to predict in what cases this description would be held "calculated to mislead customers as to the place or country where the goods are made or produced," members ordering any such articles from this list are hereby informed that the Society does not give any warranty that they are made or produced in the place or country after which they are named.

By Order,
Secretary and Assistant Manager.

1st September. 1887.

Mr. Pasteur thinks it is much more important now to check tea than coffee adulteration—although he has not abandoned the latter, but thinks that in the present state of the market, with high prices and general scarcity, there would be some risk of throwing out coffee altogether from consumption! As it is, the old experience holds true, that, even for the sake of a few shillings, buyers are eager after the very commonest qualities of coffee, rather than the pure qualities. This is always the case when prices are high; while alone low rates prevail, common qualities are scarcely looked at. The colouring of Central and some South American coffees to imitate that bloom peculiar to Blue Mountain Jamaica or highgrown Ceylon has now become quite an art, and I was astonished to find that finelooking Guatemala, which I admired alongside of Gonomatava and others of our Ceylon coffees, was all artificially coloured. The practice is now so well-known as to be appreciated at its proper value, which is very little. Mexico is becoming quite an important coffee country, now, no doubt near the borders of the Central American States. What a difference the falling-off in our Ceylon crops and the diversion of trade following in the opening of the Suez Canal has made to Mincing Lane! In 1869-70, Ceylon coffee in the one per cent commission alone was worth £40,0 0 to the Lane brokers: now, £5,000 would probably cover the commission. As a consequence and in view of the rise of tea, some of the old coffee firms are adding a tea department to their broking. Through their connection with India and Java as well as Ceylon, Messrs. Gow, Wilson & Stanton pay as much attention as any others, perhaps, to tea of the three countries, and *Observer* readers will shortly have the special benefit, I hope, of information provided through this firm, so well-known in Ceylon through Mr. Gow's interest in our industry. This gentleman, I am glad to learn, returns almost immediately to take up the management of his Kelebokka property for at least some years, so that we may count on Mrs. Gow and himself becoming comparatively permanent residents.

To turn to "coffee" again, it was instructive to note the depressed tone of buyers whom I remember very buoyant a few years ago. "Thank goodness," says my Continental buying friend, "I have but very few barrels in my hands; but look at that group over the way; among them are very large holders of your fragrant berry, and they have but a poor prospect of realizing profit at present rates. Let us ask what is the latest news.——"Hallo what's in from New York?" (making a dash into the centre of a dozen or so holders and buying men discussing the situation). "Twenty cents down" is the reply, which is at once accepted as evidence of the unsound, speculative situation

at present existing. But with bad news of crops from nearly all producing countries, it is difficult to understand how even now the prices can be said to be too high. Coffee is surely for a long time to be a scarce and dear article.

I have been with Mr. Morris at Kew, and corresponding with Dr. Günther—to whom Mr. Gow has been sending specimens of green bug—but I must reserve details and information for another time.

To revert to tea, it is quite evident, as Messrs. Geo. White & Co. were reminding me, that China cannot do much to retrieve the position it has lost unless some of the heavy levies made on tea in that country are relaxed and modified. Even as it is, the low price at which decent Congous can be sold is wonderful: one sample passed at 4¾d per lb. surprized me.

But what is this to the position and price of our other planting staple—CINCHONA BARK? With 50,000 ounces of quinine selling at 1s 4d or so per ounce, and with 250,000 ounces besides, said to be in middle hands, there are some authorities on the bark market who say they would not be surprized at a regular crisis, through manufacturers refusing for a certain interval to buy any more bark, until the stuff in middle hands and their own stocks are more freely passed into consumption. I have had the privilege of discussing the question with several Ceylon merchants or agents, and with Messrs. W. H. Cole & Co., Mr. John Hamilton, Mr. J. H. Roberts, and others. In the office of the first-named, I saw a circular issued by an American firm, in the drug trade I fancy, trying to bear the market by prophesying that quinine would be a shilling an ounce, and even then that the planters of 'ledgeriana' could make 100 to 200 per cent profit on their capital! By the way, I was clearly shown the absurdity of the notion freely held in Ceylon and lately propounded by Mr. Hody Cox (whom I have yet to see) that the very large quantity of common twig &c. bark has much to do with the keeping down of prices. Quantity also (especially of inferior bark) has not much leverage on a market where buyers are guided solely by analyses and percentages. Everything is analysed, and therefore 500,000 lb. of one per cent bark has not as much influence on prices or the market as 100,000 lb. of 4 to 5 per cent quality. Of course, the point where the twig bark ceases to be profitable of harvesting is a very practical and important one to consider; and certainly to get all unprofitable stuff kept back is very desirable. With prices at less than 2d per unit, no doubt Ceylon planters will be very chary of harvesting common stuff. But they have scarcely had such an experience as a recent sale of cuprea bark at little more than one penny per lb. presents! The dock charges alone are in excess of the sale-proceeds, apart from freight agency, carriage, cutting. No wonder, though all imports of South American forest-cut barks should be disappearing; but cultivated Bolivian kinds are coming in their place, and the quality is well spoken of, while I am told that owners of plantations there make out that 8d or 8½d per lb. in London will pay them, just as 6d used to be the limit fixed for the cost of average bark from India and Ceylon. By the way, the higher percentage of Ceylon bark for last season, as a whole, has attracted attention; and also the fact, that, as soon as the past season closed, with a less export than in 1885-6, there was a rush during the opening week of 1887-8 and a big comparative increase established! London brokers and buyers doubt whereto this may tend—and I am, of course, besieged with enquiries as to the probable export for the current season. To such I can only give very tentative cautious answers. I do point out that reserves have been largely trenched on, that much has died or been cut out, that with a wider area bearing tea the labour force will not be available for cinchona harvesting, and the planter not so necessitous about "raising the wind" from bark only. On the other hand, there is the chance of cinchona which interferes with tea being cut out more freely than ever nowadays, so adding to the exports temporarily, and there is also the prospect of increased returns from Java and India, if not from Bolivia and Jamaica. It is an order to buy bark that may be looked for from America nowadays, but as I say to my friends (the speaker, a man of experience in the bark market) they had better send over here to buy quinine in the alkaloids by the ton! All have been much interested in my letter to the "Opium Suppression Society," which has been acknowledged as exceedingly interesting by the Hon. Secretary, and which is to have a large circulation. I have yet to see some of the big houses about making the cheapness of quinine better known. There is a strong feeling in the City that an organization to promote the free distribution by sale in small packets of the invaluable tonic and febrifuge should be established. America seems to be the only country—that is the Southern States—where the cheapness of the article has been so realized as to lead to a special increase in consumption. It was expected that the demand from Southern Europe would expand freely, but this is not the case; nor have the brewers, German or otherwise, done much with cinchona, finding a cheaper bitter (or substitution of hops when scarce or dear) in quassia, calumba root, &c. All this is disappointing. But there is undoubtedly much room for the legitimate use of quinine in a very extensive way in England, and in India and China.

TEA.

It is an ungrateful task, year after year, the prediction of low if not lower prices for China teas, and the perpetual preachment of caution in their purchase; but the event unfortunately seems always to justify the forecast, and there is little reason to anticipate a variation in the future. China teas pay, of course, when they are judiciously bought, and when circumstances are favourable. Sometimes—as last year—it is the commoner sort which "come out;" sometimes, as this, it is the better kinds which thrive; that is a question of luck and discretion; so much indeed, it would often appear, of luck alone, as almost to justify Mr. Ryrie's recent classification of shares and produce in the same category. It would be a dull trade, however, which had no fluctuation, and it may be this very speculative element, which stimulates the perennial supply of credits. Still it is none the less true that the course of the market, year after year, is downward—precisely as might be anticipated from the careless manufacture to which Sir Robert Hart called attention, and from the increasing competition of India and Ceylon. It was not to be expected that tea would escape the depreciation which monometallism is bringing about in all values at the present moment. It shares on the other hand, with Indian wheat, the counter-balancing advantage of low exchange, in that the taels of silver with which it is bought cost fewer pounds sterling. But the causes we have named are more depressing than currency fluctuations which thus roughly regulate themselves; and never perhaps has their effect been more marked than in the current year, when, in spite of a short export of nearly 30,000,000 pounds, "dull and declining" is the current quotation for China tea.

Yet the season opened luckily for buyers. The prospect of the largest first crop ever known, coupled with a failing demand in England, caused extreme caution. Indiscretions were committed; men standing too near the edge showed symptoms of slipping into the water, but recovered themselves after a slight splash; and buyers showed on the whole unwonted wisdom. So low indeed were the prices offered, and so slack was the demand at Hankow, that the Chinese held over a large stock; nor was it till half the first crop had been settled that the report of a serious deficiency in the second crop gave life to the market and cause for congratulation to those who had bought early and bought well. And, as a result, a good deal of good first crop tea, judiciously bought in China and judiciously sold in this market, has paid. We say "judiciously sold," advisedly, for indiscretions there were, at this as well as at the other end; teas were forced off by auction at a loss which might have returned a profit if more firmly held. On the whole, however, the earlier purchases came out fairly well, and lucky plungers have made small fortunes which they will no doubt proceed to lose with equal recklessness, in following seasons.

Years ago, this combination of statistics and results would have caused a boom in China. It did produce the effect of hardening the market, but again has proof been afforded that the lesson is partly learnt. Most men seem to have realised that, even if well-bought teas were coming out, the market here would not support higher prices in face of Indian competition. Shanghai advices of Sept. 10th show that a drop of £1 per ton in freight to London had been too much for the equanimity of some buyers, who had forthwith made a present of the opportunity to Chinese dealers by taking off their hands a quantity of tea which had been practically unsaleable under previous conditions; but the spurt was, we believe, temporary and partial, and was quickly checked by news from this end of the wire. The latest advices from London can, in fact, scarcely have encouraged a continuance of operations, as—while "dealers in Indian teas are (we are told) doing a large business, and their heavy auctions have passed off with better spirit"—China teas have continued dull; and "buyers are apathetic and disinclined to operate, partly on account of the cheapness and abundance of the lower descriptions of Indian tea, and also from the fear of heavier shipments of inferior and common Congou later on."

Cheapness and abundance of Indian tea, and apprehension as to the action of buyers in China! those seem to be the keynotes of the situation; and it must be admitted that the temporary rush which followed the fall in freight justifies a measure of apprehension. A deficiency of some 30,000,000 lb. in the China export—20,000,000 lb. in the North and 10,000,000 lb. in the South—must have a tempting sound in the ears of local buyers. At the same time they have learned by wire, long ere this, the fallacy of any expectation that the London market would spring under these conditions. "Common and medium leaf Congous (runs a contemporary circular) have suffered a sharp decline in the public saleroom; nor does the demand appear in any way stimulated by this lower range of prices." When we hear, indeed, of new season "whole leaf" selling at 4d. and 4½d. per lb., we may well wonder what temptation there can be to repeat purchases of such stuff, or what possible profit can be imagined in face of such prices. For even fourpenny tea has to be gathered, dried, packed, conveyed to market, shipped, insured, handled, and to pay duty, as well as high priced leaf.

From whatever point of view, in fact, we regard the position, we are brought inevitably back to those two crucial tests, prevailing inferiority of China tea, and increasing severity of Indian competition. Statistics fortnight ago showed a decline of 10,000,000 lb. in arrivals of Congou tea as compared with 1886, but a falling off in deliveries also of 7,000,000 lb., in face of a reduction of 17,000,000 lb. in stock while the import of Indian teas had risen 1,000,000 lb., and the deliveries 1,600,000 lb., with an increase of nearly 6,000,000 lb. in stock. The moral is obvious that, unless Chinese growers take to heart the warning uttered by the Inspector-General of Customs, they must be prepared to see a great source of income falling steadily away. A stagnant market, in face of a reduced export of 30,000,000 lb. is a condition of things that conveys its own lesson. There is an ample demand, still, for good China tea. There is about it a delicacy of flavour which people who have been accustomed to it seek in vain in the stronger Indian leaf; there is, of course, a demand too for inferior kinds, to mix with Indian sorts to make up the average tea of commerce; but it is abundantly evident that greater care will have to be exercised in preparation, and greater care in buying, to enable China dealers to hold their own against the growing competition. The trade will otherwise resolve itself into the pure gamble which Mr. Ryrie described, and one in which the lucky hits will be fewer and ever farther between where partially good seasons like 1887 will poorly compensate for wholly bad ones like 1886; and where the process known as "survival of the fittest" will become more and more marked in its operation among both merchants and credit-givers. *L. & C. Express.*

THE DETERIORATION OF CHINA TEA.

The following letters have been published at Shanghai:—

THE COMMISSIONER OF CUSTOMS TO THE CHAMBER OF COMMERCE.

Custom House,
Shanghai, 21st October, 1887.

Sir,—The Inspector General of Customs having been in communication with the Tsung-li Yamen on the subject of the decreased consumption of China tea in the English market in particular, owing as is alleged to deterioration in the quality of the leaf, excessive admixture of dust, etc., etc., has called on me to furnish him with a report setting forth what faults are found with teas placed on the Shanghai market, and what remedies can be adopted for their removal, in order that through the instrumentality of the Yamen, detailed instructions may be framed for the general guidance of producers in the interior. I should add that the Yamen being fully impressed with the importance of the interests at stake is anxious to obtain the fullest information possible

I shall be obliged therefore if your Chamber will give this matter its early and best consideration, and furnish me with any suggestions which it may think worthy of being submitted to Peking. To any members of the native tea guild, or to any individual local dealers which the Chamber may care to introduce, I shall be happy to explain personally as to the object of the information now sought for.—I have the honour to be, sir, your obedient servant,

A. ELGAR HOBSON,
Commissioner of Customs.

The Chairman, Shanghai General Chamber of Commerce.

THE CHAMBER OF COMMERCE TO THE COMMISSIONER OF CUSTOMS.

Shanghai General Chamber of Commerce,
Shanghai, 24th October, 1887.

Sir,—I have the honour to acknowledge your letter No. 78 of the 21st instant asking for the Chamber's co-operation in making a report asked for by the Inspector-General of H. I. M. Customs on the alleged deterioration of teas placed on the Shanghai market and suggestions as to the best method for their improvement, which has the immediate attention of the Committee, who propose in the first instance to publish the correspondence with the view of obtaining the information desired from all those interested in the subject, foreign as well as native, the results of which will be communicated to you in due course.

I have the honour to be, sir,
your obedient servant,
J. J. KESWICK,
Vice-Chairman.

To A. E. Hobson, Esq., Commissioner of Customs, Shanghai.

—*North China Daily News.*

THE ART OF MANURING.

In the year 1852, Mr., now Sir J. B. Lawes, a manufacturer of artificial manures in England sowed some barley in a field, which was divided into several plots. Some of these plots received no manure of any kind; one received farmyard manure at the rate of 14 tons per acre; another received superphosphate of lime at the rate of 3½ cwt. per acre; another received a mixed manure at the rate of per acre of 3½ cwt. of superphosphate of lime and 200 lb. of ammoniacal salts; and several others received dressings of various manures, artificial or otherwise. And for twenty years continuously barley was grown on all these plots, each of which for all these twenty years received substantially the same treatment in regard to manuring as it had received in the first year. The following statement shows the average annual yield of dressed grain per acre grown on four of those plots during the five years, 1852-56 the next five years, 1857-61; the third five years 1862-66; and the last five years, 1867-71:—

	1852-56	1857-61	1862-66	1867-71
	Bushels.	Bushels.	Bushels.	Bushels.
Without manure	27½	20⅛	20¼	15⅞
With 14 tons farmyard manure	41½	48½	55⅜	49⅞
With 3½ cwt. superphosphate	31½	24½	25⅞	20½
With 3½ cwt. superphosphate and 200 lb. ammonical salts	43¼	48·1-7	53½	43¼

Or, taking the whole twenty years, the average annual yield without manure was 21 bushels per acre of dressed corn; with 14 tons of farm-yard manure, 48¼ bushels; with 3½ cwt. of superphosphate of lime, 25½ bushels; and with the same quantity of superphosphate, together with 200 lb. of ammonia salts, 47 bushels. These figures are so striking in themselves that comment upon them seems almost superfluous. They illustrate in a very forcible way what can be done by proper manuring. In every agricultural country attention must, sooner or later, be turned in all seriousness to the subject of manuring, by which we mean scientific manuring, or manuring by method. The first settlers in a new country can grow their 50 and 60 bushels to the acre year after year without troubling themselves about how crops grew, or from whence the fertile soil obtains its virtue. And it is well, no doubt, for the first settlers that this should be so. Their difficulties in selecting land and opening up new country are very great; and the ready fertility of the virgin soil may be looked upon as in some sort a compensation for the labours of first settlement. But this ready fertility does not continue long. In five or six years the crops begin to show signs of decreasing, and in two or three decades the 50 or 60 bushels of the first years have come down to 15 or 20.

This has been the case in Victoria, as in every other newly opened up country. Even the rich volcanic soils of this colony, so noted in the early days for their productiveness, now yield only half of what they used to do. In America we hear of how formerly famous crops were grown on the newly cleared lands with no more attention than just scratching the surface and putting in the seed, but as the lands first opened up became exhausted, settlers had to move further and further inwards, until at last their distance from the seaboard became a set-off against the fertility of their land, and since then they have had to study the art of systematic manuring. The same thing has been seen more recently in the coffee plantations of India, Ceylon, and Brazil; and coffee growing in the two former countries may now be regarded as almost a defunct industry.

The necessity of adding liberally to the soil the materials which are taken out of it in the form of crops, is of course widely recognised in Victoria, and it is well illustrated in the figures above given. The soil which in 1852-56 gave, counting good and bad seasons, an average annual crop of 27½ bushels of barley to the acre, twenty years later gave an average biyld of very little more than half that amount, namely, 15⅞ bushels. It is a very common custom in Victoria, when a soil shows itself exhausted, to apply bone dust; but the uselessness of bone dust when used alone cannot be better shown than by a reference to the above figures. Sir J. B. Lawes used the bone dust in the form of superphosphate of lime, in which form it acts more quickly and gives an earlier return for the money expended in purchasing it, than does the unmodified bone dust. Of this superphosphate he used 3½ cwt. to the acre—certainly a liberal enough supply. But what was the result? An increased yield on the average of only 4½ bushels to the acre; not sufficient indeed, to pay the cost of the manure if reckoned at Victorian rates. The 3½ cwt. of superphosphate used by Sir J. B. Lawes may be reckoned as equal to 3 cwt. of the superphosphate supplied in Victoria. Now 3 cwt. of superphosphate, at 7s per cwt., would involve an expenditure of 21s, and the total cost of this manure when applied to the ground may be put down as 24s. The return for this 24s worth of manure was 4½ bushels of barley, which, reckoned, at 3s 6d per bushel, would give a money return of 15s 9d. There would, of course, be a small extra quantity of straw and chaff, as well as refuse corn; but still there would be a loss of 6s or 7s, and by referring to the above figures it will be seen that the land was being exhausted with the use of superphosphate alone just as rapidly as without any manure.

Here, then, we have a striking comment upon the action of those Victorian farmers who use bone dust, and bone dust alone. There is no wonder that their land deteriorates, that their grain crops are poor, that their grass is thin and patchy. The bone dust supplies phosphates, but it is no use supplying phosphates unless other soil constituents, which may be deficient, are also supplied. Tons of phosphates might be supplied, and yet no greater crops obtained. The two constituents in which soils become soonest exhausted are phosphates and ammonia. Sometimes, also, they become exhausted in potash and lime, and more rarely in magnesia and in silica. The soil in which the above experiments were made was evidently in want of ammonia, as well as of phosphate; and when 200 lb. of ammoniacal salts were mixed with the superphosphate of lime, the effect was simply wonderful. With just this 5 cwt. of mixed chemical manures, the crops were more than double what were obtained from the unmanured land, and nearly double of what were obtained by the use of superphosphate alone. They were, in fact, very nearly equal to what were produced by the regular use of 14 tons of farmyard manure.

The use of the superphosphate alone we saw resulted in a loss. Now, let us see what were the financial results of the experiment with the mixed superphosphate and ammonical salts. The cost of the superphosphate, as before, would be 21s; and the cost of 200 lb. of sulphate of ammonia, at 16s per cwt., the price at which it can be obtained in Melbourne, would be 28s 6d; making a total cost of £2 9s 6d, or reckoning the cost of carriage, and other expenses, say £2 15s, put down on the land. The average increased yield through twenty years due to this expenditure was 26 bushels of barley, which, reckoned at 3s 6d per bushel, would mean an increased revenue of £4 11s, leaving the handsome profit of £1 16s per acre, or 66 per cent on the cost of the manure, without taking into account the increased yield of straw, chaff, and refuse grain; and, moreover, it is to be observed that whereas the unmanured land and that manured with superphosphate alone were becoming rapidly exhausted at the end of the twenty years, as shown by the yields in 1867-71, the plots treated with the mixed phosphate and ammoniacal manure gave as good a yield at the end of the twenty years as it did at first.

The practical lesson of all this is that the use of one kind of manure alone can be of no use where the soil requires two or more kinds. Therefore, let those farmers who have used bone dust or superphosphate alone with disappointing results mix it with sulphate of ammonia, and, if that is not enough, with potash salt also. The results, providing the seasons

are favourable, will most certainly not be disappointing. We say, providing the seasons are favourable, and we would venture to remark that the time has now arrived when the effect of the Victorian climate and seasons upon the action of artificial manures should, in the interests of the agriculture of this colony, be authoritatively tested. Scientific manuring was originally worked out in the European climate. It is not to be supposed that the results here will be the same as in the damp soils of England. Hitherto, failures resulting from the use of these manures in Victoria have been put down either to the bad quality of the manure or to their improper application. There may, however, have been more in the influence of the Victorian climate than has yet been admitted. We commend the matter to the attention of the Minister of Agriculture.—*M. Leader.*

PROCEEDINGS OF THE AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.

FOR OCTOBER, 1887.

Brazil Nut. (Bertholletia Excelsa.)—Mr. C. Nickels, of Jaunpore, presented a specimen of this plant to the Society, which, however, very unfortunately was destroyed in transit, having apparently been attacked by rats. On Mr. Nickels being informed of the circumstance, he at once sent a second plant, his only remaining specimen. This plant fortunately arrived safely and is doing well. The best thanks of the Society are due to Mr. Nickels for his liberality in making this presentation to the Society. The tree would be a valuable introduction could it be acclimatized in Bengal. Some years ago many unsuccessful attempts were made by the Society to raise plants from fresh imported seeds, and since then little has been heard of this fine tree. Probably Mr. Nickels' plant is the only one in this Presidency. Mr. Nickels in forwarding the plant writes:—"The Brazil Nut suffers very much from the cold. I kept it last year in my Chick-House (Fernery); the pot was placed on the ground, and a big glass cover put over it, and on very cold nights a mat used to be thrown over the glass. Even then the cold seemed to effect it. I would therefore suggest its being kept through the winter in your conservatory, and about the beginning of February it should be planted out. I should say it would do better if it had the protection of other trees round about."

THE BETEL VINE.

(*Straits Times*, November 8th.)

In Europe attention has been called, of late, to the valuable medical properties of an article which, hitherto, has occupied rather a subordinate place in the trade products known under the generic name of Straits produce. The article we refer to is the *sirih* or betel vine, the leaves of which are in great request for chewing purposes among certain sections of our native population, especially the Malays, who set no small store by the practice in question. The healing powers of the betel vine leaf have not escaped observation. Its curative properties are pretty well known in the tropical districts, where the vine in question has a local habitation and a name. The natives have not failed to take note of the fact, and to profit by it in their own peculiar way. So strong is their liking for betel that, in the early days of the Settlement, it formed a source of revenue in the shape of an Excise Farm. In the infancy of Singapore, with heavy expenditure to meet, such small game as a sirih farm was not deemed beneath notice by the Treasury, which now-a-days can afford to dispense with its aid in extending the area of taxation. With the classes of natives in question, chewing [illegible] is not only serviceable to pass the time, but has certainly proved conducive to health. In this part of the world, these facts have been known for centuries, but no advantage, till recently, has been taken of its healing virtues, in the interest of Western medical science. In Europe, they have set [illegible] notice that hardly anything relating to the betel leaf is met with in pharmaceutical text books. There is every prospect of material improvement shortly in this respect. At Surabaya, experiments and trials have resulted in the discovery of a method to separate from the betel leaf the volatile oil to which the plant owes its healing qualities. It seems that the reasons why, in Europe, hitherto, no use has been made of betel leaves for curative purposes reside chiefly in the fact that the leaves are soon liable to become damaged, and in drying, altogether lose their aromatic, spicy, and stimulating odour. In this part of the world, so far as observation goes, betel leaf is used medically for sundry ends. It has been outwardly and inwardly applied with some measure of success in different disorders. In headache, cough, and affections of the throat, sores, and wounds, it has been found highly efficacious. In Europe, the same remedy may be turned to account by making use of the betel oil now available. Already in Germany, highly satisfactory results have been achieved by prescribing it against these diseases. It has been found beneficial even against consumption. This out-come certainly affords gratification, from its increasing the resources of civilisation in the medical line, and alleviating the suffering arising from the diseases it cures. In these hard times, when profitable investment of capital looks so difficult, the cultivation of the betel vine might be worth a trial. It is worth while noting that the word betel is, properly speaking, applicable to the *sirih* vine only. It is sometimes applied to the arecanut palm, better known here by the name of *penang*.

[That the betel leaf is a narcotic stimulant is well-known. We should like to have assurance of the other virtues ascribed to it. It might be interesting to treat some of the leaves like tea, and test the infusion.—ED.]

PEPPER GROWING.

In hard times like these, when planters' lines are far from being cast in pleasant places, and cultivating enterprise has to cope with so many difficulties and hindrances, it is worth their while to pay attention to a branch of cultivation too much overlooked by European produce-growers, and great deal too long left in the hands of natives and Chinese, heedless and reckless whether they exhaust the soil or not. The cultivation here meant is that of the pepper vine. Of all the kinds of produce grown within the tropics, hardly one can be pointed out which, as regards cheap upkeep and planting, quick growth and early and abundant yield, can be compared with pepper. It has in consequence, from time out of mind, been held in high repute throughout Sumatra, for instance, as a paying produce article. The Chinese, too, both here and in the neighbourhood, have readily turned to and taken every advantage of this branch of planting industry. Even with their primitive and unskilful way of working, pepper growing has proved highly remunerative. Undoubtedly it would turn out still more payable and more susceptible of heavier yields were Europeans to take up the cultivation and bring to bear upon it the greater scientific knowledge at their command. One indispensable condition for the success of pepper growing is good choice of ground, especially as regards the lie of the land. Flats or gently sloping land of sedimentary and plutonic formation have invariably been found most suitable for the purpose and to meet every requirement. Of any short supply of lands answering the demands of planters there need be no fear. In the neighbouring Native States, far reaching and fertile plains are available in any quantity. The consumption of pepper, not only in Europe and America, but also in China has, of late, proved so steady and rapidly increasing, that the supply has utterly failed to overtake the demand. Last year, in particular, this has been markedly the case to a very great extent, owing [illegible] Acheen, in former times the chief source of supply, [illegible] not producing any quantities worth mentioning in market reports. As [illegible] will pass away before that country regains its former high reputation as a pepper producer. These [illegible] justify the conclusion that while many other branches

of plantation enterprise show signs of falling off more or less, pepper growing on the contrary has before it an encouraging and bright future. The outlook is the more promising from there being no prospect of any fall for the present in the value of the article.

The only example within our knowledge of a European having set about starting a pepper plantation in this quarter, is that of Mr. Stevenson who some time ago took up land for that purpose in Klang. Planting operations there, though on a small scale, have turned out well, the outcome being encouraging enough to justify hopes of his enterprise prospering still more in years to come. Considering this satisfactory result it is surprising that other Europeans do not follow the path he has trod successfully so far. With pepper quotations steadily rising and no chance of a heavy fall for many a year, it would be indeed a pity were John Chinaman allowed to pocket most of the profit the article is sure to bring to both producers and sellers.—*Straits Times.*

LALLANG.

The tale of Straits produce bids fair to be increased by an article which, though of indigenous growth and, hence, highly suitable to both the soil and climate of the Settlement, has hitherto been persistently looked down upon and deemed an unwelcome visitor wherever it put in an appearance. This addition to the muster roll of the few local productions calling for notice is nothing more or less than lallang grass, hitherto despised and neglected, notwithstanding its advantages in being cultivable indeed without requiring any forethought and care in the least. How prominently it is coming to the fore may be judged of from the circumstance that, according to the Samarang *Locomotief* of the 23rd July, a planter at Buitenzorg in Java has received permission from Government to set up on his estate, works driven by steam or water—whichever may be found suitable—for making paper from *lallang*, grass, paddy-straw, &c. Should the scheme be effectively carried through, there is every prospect of its yielding high profits. At present, thousands upon thousands of guilders worth of paper are imported yearly into Java, though, on the spot, cheap and abundant paper-making materials are handy, of which lallang is the most readily obtainable and cheapest. A few years ago, a French trade journal drew attention to the advantages of grass in making paper, when cut and reduced to pulp, from its yielding very flexible, silky, long and strong fibres, admitting of manufacture into paper considerably finer and more transparent than the linen article used for drawing purposes. All kinds of grass may be turned to account in this way, provided they be secured before flowering and ere the blades become withered, besides from rags, of which those from linen are better than cotton ones, paper is made from straw, bamboo, mulberry and rameh leaves, bark, and even wood. No wonder hence that enterprising people availing themselves of the aids science places at their disposal, bethought themselves of making paper out of grass, an idea already crowned with success as regards esparto and New Zealand flax. These encouraging results justify the hope that not only in Java, but also in suitable localities elsewhere serviceable paper can be made out of lallang, the fibres of which are certainly as flexible and silky as those of the grasses found in France and England, and are undoubtedly longer and stronger than they. In this part of the world, where, owing to the natives wearing their clothes until they can hold together no longer, and to the latter being mostly made of cotton, rags are not readily available, lallang and other grasses present the advantages of being cleaner, easy and cheap to get, and yielding fibres more resembling linen than cotton ones. The only easily grown Straits product likely to stand comparison with lallang seems to be the pine apple which, since several foreign European residents began to tin it for sale in Europe, has become an important export article. This branch of fruit preserving, judging from appearances, has developed itself so quickly and remuneratively that sometimes five hundred cases each containing two dozen tins each, are forwarded by a single steamer. The preserving process is said to be very simple. The result has been to push on the planting of pine apples here from their thriving on poor soil. Wide stretches of land are reported to be under cultivation with this article, chiefly on steep hills where hitherto nothing more profitable could be raised. However great may be the headway made by the pine apple, now that a steady demand has set in for it, lallang may be fairly expected to distance it from greater adaptation to poor soils and more abundant yield. Anyhow success attending the paper-making venture in Java betokens a bright future for a product hitherto looked upon as an eyesore and a nuisance.—*Straits Times.*

[We need scarcely repeat that *alang alang* or *lallang* as it is here termed is identical with the Ceylon *iluk*.—ED.]

THE GEOLOGICAL FORMATION OF COAL.

Prof. Henry Hirsching, Pres. Polytechnic Institute, Salt Lake City, Utah, is not satisfied that coal beds are the result merely of changed vegetation. He regards the plants in coal merely as fossils, preserved by gases and oils, resulting from carboniferous rocks subjected to volcanic action. Here is the substance of this new and startling theory:—

The chemical changes of carbondioxide under different degrees of pressure vary according to the presence or absence of an opening towards the surface; thus we have to subdivide the process into two parts in order to cover all the possibilities.

1. When an opening toward the surface is formed.
2. When no opening is formed, what becomes of the carbondioxide (CO_2)?

When an escape of the gas is possible, a volcano becomes active, the escaping gases change the chemical character of all the rocks they come in contact with, and build up resources for another era, in fact, the district begins to develop as a new field for further useful rocks. In the next following revolution, some part of the escaping carbon gases came in contact with sulphur, hydrogen, oxygen, nitrogen, and deposit in the branch channels, light and heavy carburetted hydrogen compounds, which flow over, and on account of the chemical affinity of kindred elements immense quantities of oils are produced, which saturate the silicious rocks and by continuous changes and pressure, slate, graphite and similar deposits in all parts of other rocks were formed. Their stratification is due to the successive saturation of siliceous rocks with oils which soften the rock. The subsequent pressure creates a stratum, and the body of such deposits depends upon the quantity of the produced oil, in this new formed oil reservoir. This saturated stratum is hermetically sealed, therefore just suitable for holding liquids or gases of all kinds. During this process, hot springs swell up, superheated steam in enormous quantities is produced, which at last becomes condensed. This water is in a very pure state, and has consequently a high solvent power: therefore as soon as it is collected on this hermetically sealed bottom, disintegration of the rocks above begins. In various places cracks are formed and the spring discharges in these channels towards the surface. During the passage through the channels cooling takes place, and crystallization of the dissolving ingredients follows, thus forming rocks like granite, etc; but more on this subject another time. By this process large reservoirs are formed which are subsequently filled by oil or carbo-hydrogen compounds; they are the true vaults for all gas and oil wells. Gradually the light carburetted oils escape through cracks, and the oil condenses rapidly and at last becomes solidified, forming the first deposits of carboniferous or bituminous coal banks without animal or plant life. When destroyed animal or plant bodies come in contact with this oil or liquid they become saturated, and of course their decay is impossible, as the carbon and other compounds prevent decompos-

ition, so the entire body of plants or animals can be found in these deposits.

In the jurassic age, or epoch, the process of fossilization was similar, only the saturating liquid was a warm spring water containing lime, etc.

The second division is again subdivided:—First we know that carbondioxide (CO_2) becomes liquid by pressure and in this state it flows through the cracks formed in the earth and by its presence the rocks are cooled; at last it comes in contact with already reduced elements which absorb oxygen readily and carbon is set free again. This process will cool down the metal bath and subterranean water flow into the cooler chambers and float the carbon off into pockets or vaults already formed by previously described changes. These subterranean basins (pockets) have been by another revolution filled with a forest, and now these trees and plants are immediately saturated with oils and carbon, and so decay is checked, the spaces between them are filled with carbon; by means of pressure the carbon becomes successively compact; marsh gases are produced which escape and form again mineral oils. During the passage through the channels at last the oils become solidified, their quality depending upon the region and materials through which they flow. These deposits by certain ages and influences become dry, so that the whole process resembles a fractionate distillation. All sorts of coal and asphaltum are liable to be formed, depending entirely on the character of the stoppage or condensation to which they are subjected. Also gilsente, so-called which is nothing else than a dry specimen or small deposit of albertite on the surface, which will change as soon as depth is gained. I could easily refer to coal beds in this country, where the truth of this theory can be seen, but I am not willing to occupy so much space in writing out examples. I only wish that this article may bring forward scientists to a closer and a more impartial investigation of this subject.

Furthermore, I will state that all other formations depend upon this process, but they are due to springs and volcanic actions of which I will speak another time.—*Chicago Mining Review.*

FISH CULTURE.

The subjects of fish culture and fish acclimatisation have, during the last quarter of a century, received extraordinary and well-deserved attention from nearly every nation in Europe. The Americans, with their usual energy and go-aheadism, took up the matter, and were soon in advance of those who had had a long start of them. In the United States fish culture is regarded as a national business, and is carried out on a scale of great magnitude. While other nations are hatching out ova by tens of thousands and hundreds of thousands, the Americans are dealing with hundreds of thousands and millions, for they have rightly judged that in order to do the business thoroughly it must be carried out on a large scale. Congress votes large sums annually, and many of the States, as well as private individuals, contribute liberally. A large number of intelligent and enterprising men have devoted themselves to the work with singular wholeheartedness. The results have been eminently successful, rivers and lakes that had become depleted, or nearly so, now teem with fish of the best kinds; shad, which the Americans appear to regard as the most important of their fishes, salmon, trout, alewife, white fish, pickerel, and other choice kinds, now abound in waters in which they were, not very long ago, scarce or entirely absent. No trouble or expense is considered too great to introduce new fish, or to distribute wellknown and approved sorts. The *Salmo Ischia*, Danube salmon, is imported from Germany, and the *Salmo quinnat* is brought by rail all the way from California, and with success. Aquarium cars are frequently attached to trains, and I have been informed by travellers that on the journey between the Eastern States and San Francisco it is no rare occurrence for a train to stop near a lake, river, or rivulet, and an attendant to hurry down to the water with a tin can or two of fish which he liberates and immediately returns. In this way vast numbers of fish are distributed in the most expeditious manner over an extensive area and at comparatively little cost. On one occasion a river became in a curious manner stocked with fish. A train in passing over a bridge met with an accident, several carriages, including an aquarium car containing a large quantity and variety of fish were precipated into the stream, which thus received far more than its intended quantum, and was soon afterwards found swarming with fish. The American fish culturists are now directing their attention to the artificial propagation of sea fish—which exhibit signs of exhaustion—with satisfactory results.

In England fish-culture is making steady progress. It does not appear that the business is aided pecuniarily by the Government, probably because private enterprise is found sufficient. By far the most important fish-cultural establishment in Great Britain is that of Sir James Maitland, at Howietown, in Stirlingshire, on which over £12,000 has been expended. Exhaustive experiments have here been carried out, and the long-vexed question whether the Parr is a salmon or not has been decided in the affirmative. The curious fact of the reproduction of hybrids has been established. It has also been found, as in the vegetable world, that individual fish improve with culture; not only are the fish themselves finer but their ova is larger than with fish in their wild state. At Howietown large numbers of salmon and trout ova are yearly hatched and distributed. The establishment is conducted on commercial principles, and has been managed with sufficient judgment and skill to prove a financial success.

The oldest fish-cultural establishment in Europe is at Commachio, in Italy, on the Adriatic. The lagoons, which were at one time dreary wastes, run parallel with the sea; they are about 130 miles in circumference, and are divided into 140 basins, surrounded with dykes, and are all in communication with the sea. Eels abound there to such an extent that the inhabitants sell them throughout all Italy. During the months of February, March, and April the gates are left open and all the passages free; the young eels enter of their own accord, and the more abundantly as the weather is stormy. Once in the basins, the fishes find nourishment so abundant, and so well suited to their wants, that they do not attempt to leave until full-grown—that is, about five or six years, when they return to the sea to spawn. The lagoons yield about 1000 tons of eels annually, and a net revenue of nearly £20,000. In some parts of Ireland the eels fisheries are second in importance only to the salmon. In London the eel ranks with salmon, turbot, sole, and a few others which are termed "prime," and realise about 1s. per lb. It is a fish that could, I think, be successfully, and with little difficulty, introduced into our waters. There are some twenty-five species of eels; the one recommended, and which we should be careful in procuring, as it is by far the best, is commonly known as the silver eel.

France, Germany, Belgium, Russia, Sweden, Norway, Switzerland, and other countries in Europe have achieved great results of late years in fish culture. To one establishment alone is there space for a brief reference—namely, to the celebrated fish farm at Hüningue, founded by the French, but now in the possession of the Germans, who carry it on with surprising energy. The success of this establishment was at first mainly due to the exertions of the distinguished M. Coste, a man of high scientific attainments as well as of singular practical ability; under his direction it soon became the leading fish cultural establishment in the world. Many of the exhausted rivers of France were speedily stocked with fish, the fishing industry revived, and the revenue derived from the river fisheries became greatly augmented. With commendable liberality the French Government extended the benefits of Hüningue to other nations, young fish and ova being sent thence to various parts of Europe.

In no country has fish culture been practised so extensively as in China, where it has been carried on from time immemorial, with the patience and skill characteristic of the Chinese, but they have never known the art of artificial fecundation. This important discovery, or possibly rediscovery, was made in Westphalia about 130 years ago, by J. L. Jacobi, a lieutenant of militia. The English Government thought so highly of this discovery that it conferred a pension on him.

And now a few words as to what has been done by our Australian colonies and New Zealand. Tasmania has achieved the distinction of standing at the head of the list. She fortunately possessed patriotic and far-seeing men who took the matter in hand with praiseworthy enthusiasm, and carried it out with untiring energy; nor did she begrudge a liberal outlay of money. We all know the brilliant results accomplished. Salmon, salmon trout, river trout, perch, carp, and tench have all been acclimatised. The Tasmanian authorities have in the most generous manner distributed young fish or ova to New Zealand, Victoria, New South Wales, South Australia, and Western Australia, in each of which colonies a desire has arisen to acclimatise most of the fishes enumerated.

Victoria and New Zealand have made direct importations of salmon and trout ova from Europe and America. Considerable success attended some of the New Zealand shipments; many of her rivers abound in trout, which grow much more rapidly than they do in England. More than a year ago trout from New Zealand were on sale at a fishmonger's shop in the Strand, London.

Queensland has hitherto attempted little or nothing in fish culture or acclimatisation. She has certainly not taxed the generosity of the Tasmanians to any great extent. The Hon. W. H. Walsh several years ago brought some small perch from Hobart Town, thirteen of which, I am informed, survived and were placed in the Enoggera reservoir, where they may be at the present time, no one knowing aught to the contrary, though none have been seen. The second trial was made by the Hon. A. J. Thynne, who on a visit to Tasmania a few months ago had the courage to make an attempt in defiance of the hot weather prevailing. Perch and trout were the fishes selected, about sixty in all; the trout died before Sydney was passed, and of the perch one alone reached Brisbane alive. Some years ago a few gouramie were brought to Brisbane and placed in a pond in the Acclimatisation Society's gardens—they soon died. About eighteen months ago six gouramie were sent to our Governor, Sir Anthony Musgrave, by Mr. Neild, the British Consul at Batavia; five died before reaching Brisbane; the sixth on the arrival of the "Quetta" at the wharf was found lying on its side at the surface of the water, apparently *in extremis*, but on removal to a vessel of Enoggera water it at once recovered and throve wonderfully, disporting itself in the aquarium at the museum for several months, when it also died, being killed by the cold.

The fifth and last experiment was made recently with English fish from Lake Wendouree, Ballarat. So far as I am aware these few efforts at fish acclimatisation form the sum total of what has been done in the past. It is truly a poor record, and one of which Queensland has reason to be ashamed, but may we not easily and speedily atone for our apathy by at once taking up the subject with the spirit and energy we observe elsewhere, and that we ourselves have practised in other matters?—D. O'C.—*Queenslander.*

NOTES ON ESSENTIAL OILS AND ALLIED PRODUCTS.*

(Concluded from page 393.)

YIELD OF ESSENTIAL OIL BY DRUGS AND PLANTS.

In the following list the figures given represent the quantity in parts by weight of essential oil, which in the experience of Messrs. Schimmel is yielded by 100 parts of the raw material mentioned. The botanical names used by Messrs. Schimmel have been retained, although in some cases they differ from those now applied to the respective plants in this country.

Ajowan Seed (*Ptychotis Ajowan*).—3 per cent.
Almonds, Bitter (*Amygdalus amara*).—4 to 7 per cent.
Angelica Seeds (*Archangelica officinalis*.—1·15 per ct.
Angelica Root, Thuringian (*Ditto*).—0·75 per cent.
" " Saxon (*Ditto*).—1 per cent.
Anise Seed, Russian (*Pimpinella Anisum*).—2·8 per ct.
" " Thuringian (*Ditto*).—2·4 per cent.
" " Moravian (*Ditto*).—2·6 per cent.
" " Chili (*Ditto*.—2·4 per cent.

BRIEF NOTES FOR POULTRY KEEPERS.

Chickens should have all the soft feed they can eat, but should not be fed so much that any will be left to sour.

Mix ground cayenne pepper with the morning food for chicks twice a week, one teaspoonful of pepper for every fifty chicks.

In the poultry districts of France the usual food fed to chickens consists of milk, butter-milk, barley, oatmeal, and a little rice refuse.

When a cock has passed his prime his progeny are more liable to leg weakness, roup, gapes, &c., and the progeny will be ailing and very poor layers.

Wheat screenings and damaged wheat make a good feed for fowls.

Hens two or three years old will not lay so great a number of eggs as will pullets in the first twelve-month after they commence to lay. In quantity, therefore, yearling will excel, but not in quality for hatching purposes.

Charcoal is sometimes eaten by fowls with great avidity. It should always be kept by them, pounded to the size of kernels of grain, for the varying need of animals directs their appetite, and therefore what they crave will be good for them.

The hen-houses should be fumigated and cleaned this month, if this has not already been done. The old laying and sitting nests are alive with small vermin now in many places. Clear out the filthy straw and burn it up. Wash the nests with kerosine oil in a thorough manner. Keep down the lice, and your fowl stock will be comparatively comfortable during these warm days and nights.

It is proper to say hens *sit*, not *set*. Eggs for *setting*, or better, for *hatching*, not for *sitting*. A *set* of eggs, not *sitting* or *setting* of eggs. Eggs have been *laid*, not *lain*. A hen offers to *sit* of her own accord; we *set* her when we prepare the nest, furnish the nest, &c. However, *set* has been used so often and so long, in the place of *sit*, that some persons have insisted that such use is sanctioned by custom.

There is no more fruitful source of cholera and other poultry diseases than water that has become stagnant or heated. Endeavour to have some kind of a trough or earthen vessel in a shady place, and fill it with fresh water twice, or even three times a day. The drinking cups of hens with broods of chickens will need special attention, as, being shallow, they are quickly emptied.—*Poultry World*.

IRRIGATION IN INDIA.

Irrigation is frequently necessary, and there are various kinds of apparatus for this purpose. Basket irrigation is done by means of a basket of bamboo, in shape something like a dustpan, from holes made near a tank or stream. Four ropes are tied to the basket, one to each corner, and two men, standing on opposite sides of the hole, each holding two of the ropes, dip the basket in the hole, and, swinging it with some force, throw the water on to the adjacent land. Another mode of irrigation is accomplished by means of a long canoe, usually made of the trunk of the Palmyra palm. This canoe is balanced in the middle, and is first dipped into the water at one end and filled, after which the balance is reversed and the water is emptied into channels carrying it to various parts of the land. These processes apply only to cases where the water is near the surface of the land. In wells where the water is from 12 to 20 feet below that level the water is raised in buckets by hand, with the help of a beam and counter balancing weight. In Southern India a man raises the water by running from one end of the beam to the other. In the Punjab and other parts the Persian wheel (whose operation is similar to that of our rope dredger) is employed. When the water is more than 20 feet from the surface another plan becomes necessary, and a slope from the well is constructed, spiralling in rough fashion between the mouth of the well and the water level. A leathern bucket, holding about 100 gallons, is attached to a rope passing

over a pulley above the mouth of the well, and connected with the gear of a pair of bullocks, which are driven down the slope and thus raise the bucket. A man standing at the mouth of the well empties it into the proper channel, and the bullocks are then driven back and thus lower the bucket for a fresh supply. Several chain pumps have been introduced, but they are very little used, and a cheap and effective implement for raising water from wells 60 or 80 feet in depth is a great want throughout India, and one to which manufacturers may direct their attention with advantage.—*Mark-lane Express.*

METHOD OF PRESERVING TIMBER IN JAPAN.

Now that we are getting tea boxes from Japan, the following extract from the *Journal of Forestry* will be interesting. Be it noted, then, that the Japanese use only wood previously preserved as follows:—

PRESERVATION PROCESS APPLIED TO TIMBER.

At a distance of 20 or 30 chos (1 cho=about 120 yards) from the sea, and near the mouth of a stream, a large pond is dug, so that the sea may have free access to it. This is called Kakoitori (or storing pond). Its size is not fixed, but generally it contains an area of 14,000 or 15,000 tenbos (1 tenbo=about 36 square feet), and its owner keeps his office near by, so that he may transact his business on the spot. The circumfrence of the pond is built of stone or wooden walls, and a canal is dug on one side to communicate with the river, and thence with the sea; the flow of the tide being regulated by means of a sluice. The pond should not be deeper than 5ft. in the central parts at full tide, and not shallower than 2ft. in the margin at ebb tide. The right proportion of salt and fresh water for the pond is six parts of the former to four of the latter, for if the salt water exceeds this proportion timber becomes blackish in colour, and is liable to be much eaten by worms; if, on the other hand, the proportion of salt water becomes less, it is much sooner decayed than otherwise. The velocity of the flow of tide should also be very carefully regulated, for if the current is either too rapid or too slow, timber is again very liable to be much injured by worms. Hence in those places where there are two or three ponds near one another, their owner generally amalgamates them, on agreement, by means of small canals, which arrangement regulates the flow of tide very considerably. Timber for storing is usually piled in five layers according to its quality; the lowest layer consisting of middle-class timber, the next layer of first-class timber, the next layer above again of middle-class timber; the next layer of third-class timber; whilst the uppermost layer, which is usually exposed above the surface of the water, consists very low quality, and by its weight the lower four layers are kept sunk under water. Those five layers are piled one upon another alternately at right angles, so that the whole arrangement presents the appearance of a toothed cube. Sometimes, however, the pile consists of only two or three layers; in that case they are tied to a big log (about 12ft. or 15ft. in length, and 7in. or 8in. in diameter) standing near by, and are thus prevented from floating about freely; sometimes also one or two separate pieces of different kinds of timber are kept in the pond for specimens. The durability of timber depends greatly on the amount of care bestowed on it, and to this end the washing is the most important. Twice in a year, generally in June or November, the cubical mass of timber above described is disengaged, and each piece is well washed by means of a straw brush. The different pieces are then reconstructed in a cube, but with the following alteration in the arrangement:—The middle-class timber which before constituted the third layer now forms the lowest layer, and the middle-class timber which in the former case was at the very bottom now occupies the third layer. If washing cannot be done twice a year, it must be performed once a year at least. In the following table are shown (in the first column) the names of different kinds of timber, in the second column the number of years for which they may be preserved in the timber store, and in the third column the period at which they are best adapted for use:—

I.	II.	III.
Hinokai (Thuia obtusa)	for 8	after 3
Matsou or Momi (Abies firma) ..	„ 4	„ 1·5
Sugi (Cryptomeria japonica) ..	„ 5	„ 2
Tsuga (Tsuga Sieboldii)	„ 6	„ 2
Hiba (Thuia dolabrata)	„ 8	„ 3
Tawara (Thuia pisifera)	„ 8	„ 3
Reyaki (Zelkowa Keyaki	„ 8	„ 3
Kashi („ „)	„ 10	„ 4

(The number of years is calculated from the day of felling and the time which is spent before timber comes to the store is reckoned to be one year.

A pond of 15,000 tembo in area can on the average store up about 10,000 pieces of timber. They are of various lengths, as the following figures show:—

Length of timber (in kens) .. 2, 3, 2·5, 4, 3·5, 4·5, 6.

Percentage number .. 50, 20, 1·0, 5, 1·0 5, per cent.

Thus one-half of the whole timber in the pond is of 2 kens in length, one-fifth is of 3 kens in length, &c. (1 ken=2 yards).

At ordinary times only three or four men are employed, whose daily wage is 35 to 45 kus (?), but at the washing season 15 men are employed daily for a period of about half a month.—*Australasian.*

JUBBULPORE MINERALS AND INDUSTRIES.—Under the above heading there is a paper by Mr. C. W. McMinn, C. S. in the *Indian Agriculturist*, which, if correct, shows that the reduction of iron ore in India must be a very different process to what it is in Ceylon. Iron and steel and articles made from them in Jubbulpore, are said to compete successfully with home iron and steel manufactures from them. The article concludes thus:—"Surely there is hope for Jubbulpore steel and iron when at present under every disadvantage, we make and sell a sound razor for three pence half penny, a pair of stirrups for eight pence, a bit for two pence, and a pair of scissors for three half pence."

CINCHONA IN BOLIVIA.—An interesting paper on the cultivation of cinchona in Bolivia, read by Dr. Rusby before the American Association for the Advancement of Science, appears in the *Pharmaceutical Record* (Oct 1, p. 305). The author admits the great tendency of the plants to hybridize, and the difficulty of referring the various forms to their proper position, and seems to rely on the venation of the leaves as affording the best distinctive character for the different species. He points out that every species, variety and hybrid, is represented in the native classification, with one exception, by three forms, *morada*, *verde*, and *verde morada*, that is, red, green, and red-green, according to the colour of the leaves. On every tree there are two very distinct forms of leaves, viz., those growing on the lower or flowering branches, and those on the young, upper and flowerless branches of the present year's growth. The latter are usually broader and more abruptly acuminate at the base, sometimes appearing even decurrent on the petiole. They are more membranous, and the pubescence when present is more pronounced. The old tabla, or flat bark, is now almost unknown, the bark being collected either in shavings, or in quills two feet long. The latter are collected from March to June, at the close of the raining season, when the bark strips more easily. The shavings are taken from the top and branches, after the tree has been cut down, and are much adulterated, since admixture is less easily detected. The natives prefer decoctions or infusions of the bark to the extracted alkaloid, alleging that a fever cured by the former stays away longer than when treated by the latter. The gelatinous young terminal buds are crushed and applied to fresh wounds, and are said to produce excellent stimulant and antiseptic results.—*Pharmaceutical Journal.*

PEARLS OF JASMINUM SAMBAC.

Dr. Riedel tells us in *Nature* of September 15 (p. 461), that he possesses in his collection two melati pearls of *Jasminum Sambac*. I beg to say that, as in the case of tabasheer (see *Nature*, vol. xxxvi. p. 30), and in that of coco-nut pearls (*ibid.* p. 158), Rumphius, in the almost inexhaustible treasure of his "Herbarium Amboinense," has already mentioned the pearls found also *in the flowers* of *Jasminum Sambac*. He gives in his fifth volume, in the 30th table, a good picture of that plant, and says in the description that a "dendrites" found in its flower in 1672 was sent to him two years after. It had the shape of a bud of the same vegetable, and was white-coloured and hard like silica or alabaster; moreover, it must have been without doubt a carbonate of calcium or some other alkaline earth, for Rumphius remarks that when the pearl was imprudently moistened with citric acid part of it was consumed by the acid. He also tells us that the common name given to all stone-concretions in fruits, wood, and animals by the Malayan people is "mestica," which corresponds well with Dr. Riedel's name of "mustica." ["In Celebe, ac præsertim in Macassara in *cunctis* sæpe fructibus dendrites quædam reperiuntur, ubi inter alia in hoc quoque frutice (Jasminum Sambac) talis detecta fuit, quæloco floris inventa fuit anno 1672 in horto quodam Germani ibi habitantis, quæque mihi biennium post transmissa fuit. Formam habebat capituli, seu instar veri floris Bonga Manoor, nondum aperti, eratque alba et dura instar silicis seu alabastri; inventa autem fuit in tubo veri floris atque petiolum habebat ex ligno et lapide sensim compositum; quique hanc invenerat, imprudenter in mensa deposuerat, limonum succo commaculata, qui subito eius portionem consumserat."] Frankfurt a. LETTERS FROM JAMAICA:—NO. XX.

WEATHER AND CROP—REMEDIES FOR BUG AND LEAF DISEASE—PROPOSED RAILWAY IN JAMAICA.

Blue Mountain District, 4th Sept. 1887.

When I last wrote you, I stated that fine weather was needed to make the coffee trees on the higher Blue Mountain estates produce fine blossoms and good crops. I regret to state that our hopes have not been fulfilled, for August has proved an unusually wet month. Thank God we have so far escaped floods and hurricanes, but there have been but few days without some rain more or less. This far more conduces to the making of leaf than of flower, yet the trees are in excellent heart, and if we but have some favourable weather during September without much wind, we may yet have good crops in the upper fields in 1887-88. As to prices, on 22nd July at Liverpool the tip-top figure of 146s per cwt. was realized for a parcel of "Newton" coffee, and 136s for some from "Cold Spring" estate. The pity is that crops have been so small, and that coffee planters should never seem to have everything *couleur de rose* for the crops turned out even shorter than was expected; estates which gave 20 to 30 tierces last year only yielded 4 to 5 tierces, and another only gave 16 as against 50 the previous crop. This forcibly proves how disastrous were those awful cyclonic storms of June and August 1886, followed by a terrible *Norther* in January last. It does seem as if we had really entered upon a cycle of wet years, as compared to those of from 1880 to 1885 which were unprecedentedly dry and drouthy, yet at home in England the year 1887 has been unusually dry, and water at famine prices at many of the seaside watering places. The native settlers have however no reason to complain, for these constant showers are most beneficial for low-lying places, and they are likely to reap another good harvest, as prices are likely to hold up at least till the end of the year, when some authentic news may be ascertained as to the probable outturn of the Brazil 1888 crop, and the prospects for 1889. I was sorry to learn from the Ceylon papers that though the "leaf disease" was less virulent, the attacks of "green bug" had in no way abated. I was reading about cures in the *Tropical Agriculturist*, and see that a mixture named "phenyle" had been successfully (so far) applied to a tree by young Mr. Green of Eton, in that while it was free of disease, all the others round it were as bad as ever; this mixture being an extract of coal tar will, I believe, prove a success. I note that mana grass was said to be a failure. I am surprised at this, for I well remember having two acres of very bad bug at the top of East Delta where it bounds with Whyddon. There was a field of mana grass close at hand. I caused it to be cut, and thatched the soil of the two acres therewith *very thickly*. Not only did the bug disappear, but the field subsequently yielded two very heavy crops. So with coal tar. There was a piece at Blue Fields, also very badly black-bugged; to this a small quantity of coal tar was applied to the roots well mixed with earth: certainly it cured the bug, and I should not be surprised that if applied in the same way for *green* bug it would be efficacious, as it seems to be somewhat akin in species to black bug, and if coal tar can be more cheaply and expeditiously applied to the trees in the form of "phenyle" the sooner coffee planters set about it the better, as present high prices and good prospects of a paying market in the future fully justify them in making the experiment on a large scale, and undertaking the necessary expense.

As to Jamaica news proper, things have been very dull since the occasion of the Jubilee. The heat in Kingston has been very oppressive, and all who could get away have sought refuge in the hills. It is strange how little rain Kingston seems to get. At the foot of the adjacent hills, within 3 or 4 miles as the crow flies, there is generally abundance; and this is what would make Kingston such a suitable place for the preparation of coffee for shipment.

As regards the railway, the two proposed extensions are being surveyed, and, besides, two gentlemen of experience have been selected by the Governor to travel into the districts through which the new line will pass, and take evidence as to probable traffic and other items it would be useful to know before finally committing the colony to the work: not but that in my belief a railway in Jamaica must, as in other countries, bring success along with it; indeed Jamaica is now sadly suffering from want of means to bring produce cheaply and expeditiously to market.

P. S.—Sept. 13th, 1887.—Since writing the above we have had a week of fine weather. On some days the heat was very oppressive. We are still looking for a good blossom from the top fields. W. S.

SIYANE KORALE.

AGRICULTURE IN EUROPE AND PADDY CULTIVATION IN CEYLON—SOIL AND MANURING.

11th November 1887.

The letter on Continental Agriculture in your issue of the 9th inst. has an intimate and interesting bearing on a subject that exercised the public mind not very long ago. I refer to the Topper experiment in rice cultivation by the means of plants, and the eminently satisfactory results it yielded. People's heads were completely turned by the return of 108-fold which followed the use of the new plough

and transplanting, and bright visions of golden harvests were opened to owners of rice fields who determined to follow the example set by Mr. Green's Agricultural Instructor, with a certainty that like results must inevitably follow. How apt we are to indulge in hasty generalizations! Because a certain system of cultivation yielded certain results, therefore the universal adoption of that system will yield similar results. No account is taken of the difference of soil prevailing in fields even in one district and a host of other circumstances. Experiments with wheat in France showed that "on the clay soil it started 12 stems, on the loam 14, on the sandy but 6." It therefore follows that the percentage of yield depends to a very great extent on the soil. During the discussion that the results of the Toppur experiment evoked, the waste of seed that resulted from thick broadcast sowing was prominently brought to notice, and we were led to believe that this waste was a peculiarity of oriental agriculture, and that more enlightened methods prevailed in Europe; but we are told that "one-seventh of the total corn raised in France is employed as seed, and it is calculated that 20 times too much seed is sown." This, it is shrewdly said, is "a wilful loss for consumption." About 330 grains of wheat to the square yard fall it appears if sown broadcast and of those only 180 grow, the rest falling a prey to drought, birds, &c. Of those that grow each seed sends up between one and four stems. If the plants be put down 10 inches apart there will be about 64,000 stems to an acre, as against 750,000 if seed be sown broadcast, or one plant to every square inch of surface. The growth of the plants is thus checked by overcrowding and while 18 times more seed is used the yield will be less. If the above figures be trustworthy, and there is no reason to doubt that they are not, a large quantity of seed is absolutely wasted by broadcast sowing in France than locally. Competent authorities asserted lately that from 4 to 5 times more seed is necessary for broadcast sowing than for transplanting, but of course paddy plants are not planted 10 inches apart, seldom over 6 inches; even making allowance for this, 18 times more seed for broadcast sowing wheat does seem extraordinary.

As pertinent to your inquiry when noticing the Toppur experiment, whether manure helped the extraordinary yield, we are told that "it has been demonstrated that where the roots have full play in wide sowings and good soils, the efficacy of manurings has been *nil*." This seems hard to believe. I cannot quite understand how it is that however good the soil may be, manure had no effect whatever on the vegetation it supported, unless indeed the soil had a plethora of all the mineral constituents contained in the manure used. If this be the explanation, then the soil must have been an extraordinary one. But with whatever reservations we may be inclined to accept the assertion that when plants are well spaced out on a rich soil, manure does not benefit them in the least, it is important to bear in mind that with full scope for roots on "good" soils, which includes, I suppose a good mechanical condition, the effect on the growing plants is so great as to induce the belief that manure can exercise no further beneficial effect on them. It is important to bear this in mind not only in the cultivation of cereals, but also in the cultivation of perennials where overcrowding is practised. "If wheat be spaced on sandy soils, there will be not much difference in the yield" is true also as regards paddy. We have been told before now that to improve a sandy soil it is necessary to add to it clay or humus. In paddy cultivation generally the improvement of sandy soils is slow and is effected by ploughing in the weeds. I am much afflicted by the presence of sand in some portions of the field I cultivate, where the unsatisfactory growth of the paddy plants is a perfect eyesore. I attempted once to improve it by green manuring, *i. e.* by scattering leaves over those portions; but the continued unsatisfactory growth of paddy on these spots makes it only too apparent that the quantity I used was insufficient. The collection of leaves where no jungle growth exists hard by is an expensive job, as all the leaves must be obtained by lopping off the branches of trees, and where these are not numerous, the cost is great. However great the cost, the improvement of these sandy portions is to be taken on hand before long. When travelling by train once I met a portly and not very hirsute Gansabhawa President. The conversation turned not unnaturally on paddy cultivation, when he declared that he had found a means to render a sandy soil muddy. It did not require any pressing for him to divulge his secret. He had used cattle-manure, and he declared with the utmost blandness "I don't know what became of the sand after that. It all disappeared." We, that is another low-country planter and I, pressed closer to him to get further details of this most important discovery. "How much manure did you use?" was asked him. "Nine cartloads for one bed" was the response, after which we found no difficulty to account for the mysterious disappearance of the sand, a new soil had been made on the top of it.

When recently noticing Mr. Jansz's intended experiments with different kinds of manure, it was said that a theoretical as well as a practical knowledge of agriculture was necessary to carry out the experiments. Otherwise mistakes would be made in applying leaf-forming manures on rich soils and *vice versa*. It is well known that in a rich humus the leaf forming tendency has to be repressed by cutting down the paddy stalks, in order to induce them to form ears. In poor sandy soils the plants grow badly but only too readily form ears. In France "the important experiments in question revealed an unexpected result. The ordinary proportion of grain to straw is as 23 to 50. But on poor sandy soils the proportion was 35." I see nothing unexpected in the result, for the difference in growth between paddy stalks in rich and poor soils affords a ready solution of the disparity, at least as far as paddy is concerned. It is said that "there is no scientific explanation of this fact" and in its absence the conjecture is made that poor soils help plants to concentrate their energies in the formation of seed as a means of perpetuating the species. What *does* the following mean? Either the writer of the letter has stated the opposite of what he means or science and reason have gone mad:—"It is by the direct contact of the rootlets with the solid food materials that nourish the plant, and not by the absorption of these same materials in a state of dissolution in the bosom of the soil as was formerly believed and that a few still maintain!" Won't starving mankind have reason to be thankful if they are nourished by simply coming in contact with food without tasting it? Here is something equally startling but which has an air of plausibility in it:—"It is by instinct that the plant develops its roots, and in proportion as the soil is poor or the materials of nutrition irregularly disseminated, that development will be greater somewhat, as animals will have to range over a greater space when food is scanty in order to secure sufficient for the totality of their wants." The development of root surface is supposed to be simultaneously followed by an increase of leaf surface, if the above be true then a poor soil will favour the growth of leaves, but this is contradicted by the writer himself when he says "that in poor soils the plant concentrates all its energies in the development of seed." Many parts of this instructive letter are amusing as well, from its peculiar idiom.

GRAFTING MANGOS.—The Superintendent of the Public Gardens, Allahabad, reports that Mangos grafted on young seedling stocks are as fruitful as those grafted on older stocks, but they are later coming into fruit. The trees so produced are much larger than seedlings of the same age, so that what is lost in time is gained in produce. Mr. Maries suggests that late-fruiting varieties should be grown on seedling plants of late-fruiting varieties and *vice versâ* instead of promiscuously, as is done now.—*Gardeners' Chronicle.*

CEYLON UPCOUNTRY PLANTING REPORT:

AGRICULTURAL WEALTH OF CEYLON—TEA PROSPECTS—TEA FUND SCHEME—WEATHER—CACAO CROPS.

21st November 1887.

The estates which go in for a variety of products are kept pretty busy just at present. The weather is so favourable to growth of all kinds, and especially to the ripening of fruit, that if one were to name the whole circle which constitutes the agricultural wealth of Ceylon, a very large proportion would now be found to be in full blast.

Regarding tea, everybody has a better account than another as to the flushing capabilities of their trees, and some have sorrowfully to confess that even doing their best they can't keep up. Estimates which a few months ago looked as if they were altogether unrealizable are now secured, or all but, and with six weeks of the year to run those that are still behind are far from despondent, if the present style of things should just continue. The talk is of new rollers and driers, enlarged stores and increased labour force; indeed with the rush of flush at this end and the good prices, and fair prospects at the other there is considerable exuberance of spirit and "high falutin." The falling-off in the deliveries of China tea, and the marked advance of the public taste for the superior article produced in Ceylon, is taken as a matter of course. That "heathen Chinee" whose competition we all so much dreaded, and of whom we were well told that he would take a good deal to beat him, is now looked upon as a bankrupt Mongolian, who has gone down, before we were fairly girded for the tussle. As to the Tea Fund, and what it won't do, its possibilities loom very much larger than the number of estates who have agreed to support it. We have the Continent of Australia, the ancient Kingdom of Scotland and the European nations to be educated—to appreciate and thirst for our new product, and when Mr. McCombie Murray has distributed his R2,000 worth of gratis samples it will want a goodly number of American "drummers" to book the orders that will flow in from the great Republic of the West. That interesting fact that the name of Ceylon was worth 2d a lb. on tea, which your Special kindly forwarded the other day, has made us all feel as if in the tea line we were the favourites of Providence. It 's a long time since that feeling has crept over us; we have had a good deal of rubbing against the hair from time to time, have come to look upon that style of things as our heritage, and now that the order changeth, and a more excellent way obtains akin to the golden past, it 's the poet's longing realized—the touch of the vanished hand.

We have been a long time in travail in the valley, and are perhaps a little affected by the rarefied air as we toil upward, but a change is always good, and we will do and are doing our best to get one.

The cacao crop is on, and the pods are ripening up. It is not a pleasant thing to learn that the Sinhalese are cultivating a taste for cacao curry. Yet this seems as if it were so. The young pods are found to be toothsome, and in some parts are now stolen by the peasantry, and used as an article of daily food. Squirrels that prey upon the cacao can be kept down by the gun. Porcupines move off to the martial music of the tom-tom, but the thievish native, who is stealthy in approach and fleet of foot, is not quite so easily settled with. He having so little to steal too, now that coffee is all but extinguished, is an added horror, for although the Sinhalese has no great persistency of purpose, yet when he does apply his mind to raiding into cacao having so little else to occupy it, he certainly manages to make his presence felt.

PEPPERCORN.

THE DETERIORATION OF CHINA TEA.

(From the *N.-C. Herald*, Oct. 27th.)

The step which the Tsung-li Yamen has taken in directing Sir Robert Hart to ask foreigners what faults are found with the teas now brought to market in China, and what remedies can be adopted for their removal, is one of the most important, as regards the foreign trade of China, that has ever been taken. The Chinese mind is nothing if not practical; a falling-off in the export of China tea this year, amounting already to some thirty million pounds, is an unanswerable argument. As long as foreigners went on buying all the tea that was produced, the Yamen could afford to neglect the remonstrances that have been made for some years past against the continuous deterioration of its quality, and the warnings that India and Ceylon were rapidly supplanting China. As long as the revenue from tea kept up, the disasters which foreign buyers had to suffer were unheeded by the Yamen, but such a falling-off in revenue as the returns shew this year has at last opened its eyes. Chambers of Commerce and private merchants have been imploring Sir Robert Hart to take some steps to improve the trade, and however good his will has been, as we know it has, he has not been able to secure the attention of the Yamen; but the deficiency in the revenue has made the Yamen listen, and, "being fully impressed with the importance of the interests at stake," it "is anxious to obtain the fullest information possible;" and, putting its pride in its pocket, the Yamen asks the foreign merchant to assist it with its advice, so that "detailed instructions may be framed for the general guidance of producers in the interior." It is probably the first time in the history of the foreign trade of China, that the high authorities at Peking have acknowledged that the Chinese and the foreign merchants have common interests, and that the former may get from the latter information which will be of mutual benefit. The interests involved are so important to the foreign buyer as well as the Chinese producer, and the new departure taken by the Yamen is so satisfactory in itself, that the latter may rely on getting all possible information with the greatest readiness from the foreigners concerned. A roving commission, which would have visited the various tea-ports and taken evidence, sifted it, and combined it into a report, would probably have commended itself to a European Government; the plan adopted, of addressing the various Chambers of Commerce, is rather more cumbrous, but will no doubt produce as valuable results.

In a discussion which took place at a meeting of our Chamber of Commerce last year, one plan suggested for rehabilitating the China tea trade was the abolition of the export duty and the transit duties, with which the product is now loaded. There are no such duties in India and Ceylon, and those countries thus start with an advantage over China of about two-pence a pound, at the outside. With these duties abolished, tea could be laid down cheaper to this extent in Europe; but in the first place we may be sure that the Yamen would not entertain the abolition of the export duty, it being the loss of revenue this year that has moved it to act in the matter; and in the second place, it is not the cheapening of the product of China that is required, but the improvement of the quality. Really good tea can be made in India by the large plantations to sell in London at an average price of 7½d a pound, and in Ceylon at 9d, and in the face of these facts, the cheapening of the China product two-pence a pound all round, will not restore it to its old position. The advantage which India has over China is the advantage that the manufacturer has over the handicraftsman. The small plantations cannot compete with the large ones in

India, and are being rapidly absorbed or amalgamated. It is these large plantations with ample capital, improved machinery, and the most expert supervision, that are controlling the London market; and the little farmer with his two or three *mow* of ground on a hillside in Hupeh, cannot hope to compete with them. In India the leaf is fired the day it is picked, and all its strength and aroma are preserved.* In China the packer of the tea sets himself up in the country village, and the small farmers come in from all round each with his picûl or two of leaf, and as soon as the teaman has collected enough for a chop, he fires and packs it, days having probably elapsed since it was picked, while the farmer was haggling over the price. The teamen would scorn to use the machinery for firing and sorting which have been found so useful in India; they stand on the ancient ways, only anxious to get their teas as quickly as possible to market, the time of arrival being a more potent factor than the quality in extracting a profit from the foreigner. The most effective remedy for the present condition of the trade would be to allow foreigners to go freely into the interior, and introduce the modern methods of preparing the leaf for market. But the jealousy of the people and officials is too great to allow us to expect this concession at present. It is not to be supposed that the plant itself has deteriorated in China. The leaf no doubt is as good as it ever was, though it might still be improved by more scientific cultivation; but this we cannot know until expert foreigners are encouraged to go up to the tea districts, and learn for themselves how the leaf is grown and picked now, and are invested with authority to point out to the growers what improvements in the cultivation they should introduce. Failing this concession, it would be worth the Goverment's while to send a deputation of intelligent Chinese to India to inspect the methods in use there. The Indian Government would, without doubt, give them every facility to learn what are the arts by which they are being beaten, and they might on their return induce their countrymen to co-operate in the introduction of some system equivalent to the Indian plantation system. The Chinese, though conservative by nature, are quick and apt to learn when their pockets are involved, and even the farmers in the country must begin to see that some reform is necesary. Minor improvements, such as more care in firing and packing, and less hurry in bringing the teas to market, should be made concurrently, but more drastic measures are required to re-establish the trade on its old basis, and these the Yamen will soon learn from the answers it will receive to its application, through the Inspector-General, to the Chambers of Commerce.

TEA: A WOOD-CONSUMING STOVE FOR THE GIBBS AND BARRY TEA-DRIER.

A few days ago we had the privilege of inspecting the working of a model of a stove designed by Mr. Gibbs for the employment of wood as fuel for drying tea in the Gibbs and Barry Drier. This stove was constructed some years ago, but was set aside in deference to prejudices then existing, in favour of the stove for coke now in use. When we were told, preparatory to viewing the stove at work, that we should see fuel, composed of one part of coke to eight parts of wood, burned in such a manner that the products of combustion thereof would be sufficiently innocuous and free from smell to permit of the drying of tea by direct application of these products of combustion, we confess to having found the demand upon our credulity rather a "big contract." The great economy of this fuel as compared with "all coke" was of course manifest, and an enticing prospect truly; nevertheless we confess that it required all our faith, even in Mr. Gibbs, to meet the aforesaid demand. To our readers we can but give our own experience as derived at the trial of this working model, and if the result staggers them, it shall be from no exaggeration on our part. A description of the stove it is unnecessary to give, as the stoves now in use can be converted at a trifling cost of a few pounds to act upon the principle of this model. It is merely necessary to mention that a feeding-hopper and flue have to be added to the coke stoves in such a manner that the charge of coke can be dropped in from above, and the wood then dropped upon the coke; one charge of coke sufficing for eight consecutive charges of wood afterwards. To be strictly accurate, this proportion commences after the first four charges of wood have been consumed, as after the top half of the *first* charge of coke has been consumed another whole charge of coke is required (owing to details connected with levels, after which eight charges of wood follow; then one charge of coke, then eight more charges of wood, and so on. In the case of the model, we saw the charges all weighed, and the result justified what we had been led to antcipate by Mr. Gibbs. The wood destroyed was three-parts last year's wood and one-fourth green, cut from the tree the same morning, and full of sap. From the trial we should judge that the proportion above mentioned will only be maintained when fairly dry wood is used; still, the saving in the differnce between wood and coke is so considerable that, even though the above proportion were greatly reduced, the economy would still be very serious.

Having weighed the charges of wood and coke, we saw Mr. Gibbs drop the charge of coke down the hopper or flue. "But how about the lighting?" we naturally asked, as the coke disappeared from view. "Wait a bit, and you shall see," was the reply. Having dropped the coke into the cold stove, he next dropped in a charge of wood. Still no light! Next, however, he pushed down some paper, and the reason for this "laying the fire upside-down" at once became apparent; as he applied a match to the paper, and ordered the fan—placed as usual—to be turned on. The only ingress for air was down that hopper, through the interstices between the bits of wood and bits of coke. The suction produced by the fan drew down—up, we were going to say—a roaring fire, igniting first all the wood and then all the coke within about six minutes. Until the coke was fairly ignited, a very little smoke passed out of the air-duct just at first, followed for a few moments by a perception of sulphur and pyroligneous acid when one applied one's nose, mouth and eyes to the full force of the blast; but when the coke was thoroughly ignited there was no trace—marvellous to say!—of either sulphur or pyroligneous acid perceptible to either smell, taste, or even by any smarting of the eyes. Charge after charge of wood was added and consumed in turn, and not even when the charge of freshly-cut sappy wood was added was there any trace of pyroligneous acid by the above tests! The hot air was exceedingly "dry," and the temperature of the blast just at the point of leaving the fan was kept between 430° and 450° throughout. The green wood, when added, produced a momentary decline to the 430°, above which, however, the temperature soon rose again as the green wood ignited. The "purity," so far as smell and taste could test it, of the hot air was indeed surprising. Chemical hypothesis for this purity we will not venture upon. Whether the water in the sap becoming decomposed, liberates sufficient oxygen to decompose the sulphurous and pyroligneous acids, or whether the ammonia plays a prominent part in their neutralization, we will not pretend to say. This much is certain, that coke and wood burned separately give off products which are decomposed or neutralized when the two are burned together under the conditions described above. If these conditions produce the same results when the experiment is tried on a working scale, with the working air draught, then this discovery is indeed a valuable one. At present no full-sized stove with regulation-sized fan has been tested; till then there is, of course, an opening for doubt. Meantime the working results of this model stove justify the fullest measure of hope.

* Scarcely: the withering process alone occupies from 24 to 48 hours, after which some hours are occupied in the rolling and fermenting processes, before firing is commenced.—ED.

[Since writing the above we have received a letter from Mr. Gibbs, in which he says:—"By still more recent changes I have been able to keep the heat up with *all* green wood to 550°, and by a simple further addition to the stove I have burned the smoke from coal also, so as to render the resultant air as pure as that from wood, *i. e.*, pure enough to be inhaled without any disagreeable effect. In about a fortnight I should have pleasure in showing these results to any of your readers."—ED. *H. and C. M.*]—*H. & C. Mail.*

PLANTING IN NETHERLANDS INDIA.

(*Translated for the Straits Times.*)

In West Borneo, so says the Surabaya *Courant*, the Netherlands Resident and his subordinates, contrary to the policy pursued by their fellow officials in the outlying possessions in the Dutch East Indies, do offer encouragment to private enterprise in the cultivation line. This became manifest recently in the quest for the Tebu Keong, a variety of Borneo cane noted for enormous yields of juice. Parties from Java coming over to West Borneo to seek for this cane of promise met with every facility from the Resident. The Government and most of the officials in high position show such indifference to the well-being of the outlying settlements in Netherlands India, that the exceptional attitude of the above mentioned Resident comes as a kind of pleasant surprise. The great misfortune besetting Netherlands Borneo arises from the fact that Dutch commercial associations are quite ignorant of its teeming productive resources, all from lack of an enterprising spirit. This is mainly ascribed to the objectionable mode of Government which is based on doing as little as possible for the outlying possessions for the sake of economy. Now that Java planters and mercantile men have begun to take an interest in West Borneo, it is expected on good grounds that the resources of the country will no longer escape their notice. The riches of the country lie so readily within reach that it only requires an enlightened policy on the part of Government to encourage people to seek for them. At present the products of West Borneo find their way almost exclusively to Singapore. In that territory there are found, for instance, gold and diamonds, valuable vegetable tallows, gutta percha, copra, dammar, and pepper, besides many other highly prized articles of trade, not to mention the vast tracts of fertile land and extensive forests awaiting the stimulus of business enterprise.

PLANTING IN DELI.

(*Translated for the Straits Times.*)

The law in Deli seems to be systematically evaded by sundry planters as regards the treatment of their labourers, and the payment of wages in due time. They are illtreated and their wages kept back on certain estates, without the planters concerned being brought to book for it, owing to the local officials being ignorant of what was going on, and taking no pains to remove this ignorance. It seems to be rare for a Controller to visit the estates in his district. Controllers indeed have but little time to spare for the purpose, owing to the heavy pressure of duties which keep them closely tied to the desk. Other officials seldom think it worth while to make themselves acquainted with estate affairs, to the advantage naturally, of the law-breaking planters. The latter are only brought to book when their misdeeds become too flagrant to be overlooked.

In Deli, competition with British North Borneo is looked forwards to with some apprehension. The local *Courant* urges the planters to look less to Government to render the struggle for existence easier, than to their own energy and perseverance. Tobacco curing is still susceptible of improvement. The improvement of the tobacco brought to market in quality, needs to be kept in view more than ever. At present, the question of quality, that is how many piculs of the article can be produced stands too much in the foreground. The times have come to such a pass that planters must face the need for taking particular care to turn out marketable tobacco. Complaints now are too frequent regarding brandy, bad sorting, cheating in trade marks, &c. They have become so general as to be beyond suspicion of being lightly made. The planters have besides too strong a tendency to put all their eggs in one basket, by exclusively trusting to tobacco. Trials with new produce articles have never been earnestly pursued. Tobacco at any time may fail them. With only one article to fall back upon, adversity will come upon them unprepared, with but ruinous consequences in its wake.

THE IVORY TRADE OF THE EAST COAST OF AFRICA.

A correspondent of *Das Handels-Museum* of Vienna says that for centuries Zanzibar was the chief mart of ivory, which was formerly brought partly from the coast, partly from the interior. But with the increased consumption and value of that article elephants are being exterminated and have to be sought far away in the interior to the west of Tanganayika and north-west of Victoria Nyanza. The chief trading centre in the interior is Tabara, in Myamwesi, where various caravan routes meet. The practice at present is for Indian traders to equip a caravan in Zanzibar and place it in charge of an experienced and trustworthy Arab, who takes it from Bagamoyo, opposite Zanzibar to Tabara. If he finds enough ivory there he exchanges goods which he has brought for the purpose, and starts on the return journey; but as a rule, the caravan and to go further, and by the information he receives from returning caravans the conductor judges where he can go with most chance of speedy success. Large quantities of ivory are usually in the hands of native chiefs, with whom it is a kind of treasure, and sometimes, it is said, the Arab conductors, who are usually accompanied by well-armed escorts, will make war on a chief, seize his ivory, and sell his people into slavery. If force cannot be used, the trader must patiently purchase small quantities from time to time as occasion arises, and sometimes he is forced to wait for years in the interior before he can part with all his merchandise and obtain his loads of ivory. The greater part of the ivory arrives in Zanzibar in July and August; the Indian merchants go to Bagamoyo to meet their conductors, and then a settlement takes place. The cost of the caravan with 15 per cent per annum is charged to the Arab, the Indian takes the ivory, sells it on account of the Arab, and pays the latter the balance. Arrived in Zanzibar, the ivory is either sent by the Indian merchants direct to Bombay or to London, or it is sold to Hamburg or American merchants on the spot. The trade, therefore, is wholly in the hands of Indian merchants; but the advantage of having agents of the European merchants in Tabara to purchase ivory systematically and forward it to the coast has been discussed in Zanzibar, and one Hamburg firm there decided to try it. A caravan under two Germans was despatched to Tabara, where one was to remain to establish a branch, while the other pushed on to Uganda, so as to be able to purchase at first hand. One died soon afterwards, and the other fell ill and was forced to return. The close connexion between the ivory and the slave trade in the interior must always act as a hindrance to Europeans trading at first hand in ivory. The Arabs usually transport the ivory to the coast by means of natives whom they have enslaved or purchased at very low prices, and then can sell the latter on the coast at a profit of $10 a head. European traders, on the other hand, must pay the bearers $5 a month and a yard's length of cotton stuff per day. No statistics exist respecting the annual export from Zanzibar.

but the writer is convinced that for ten years past it has been pretty regular. In the past 35 years the price has trebled. About 1840 ivory cost $1 a pound; now it costs $3. Large tusks, weighing 150 lb. to 190 lb., are much rarer than they were ten years since, and the number of smaller tusks has greatly increased. Zanzibar ivory stands higher in the market than that from Abyssinia, Egypt, or the West Coast. The export from Mozambique and the north and south Somali coasts is comparatively small. The best ivory is used for the manufacture of billiard balls; the inferior sorts are converted into knife-handles, ornaments, &c. —London *Times*.

TEA IN NATAL.

To Mr. H. K. Rutherford we are indebted for the following notice of tea in Natal:—

TEA IN NATAL.

The following extract from a letter received by Mr. Rutherford from Mr. J. L. Hulett of Kearsney tea estate, Natal, will no doubt prove interesting to Ceylon tea growers.

"TEA SEED.—The jât which we are growing is exceedingly good and was obtained from Assam in 1878. Several Indian planters have stated that we could not have got a better class of Assam Hybrid than we did. I have an abundant supply of seed and am disposing of my surplus, and am careful in selection. The tea plant is remarkably well adapted to this climate, and from information obtained from Indian and Ceylon people, we should do well. No estates in Ceylon are yielding better than this. I have an area of nearly 200 acres planted and a plucking area of 100 acres, but only partial on a portion; after 5 years old no difficulty in obtaining 1,000 lb. of manufactured tea per acre. We are still in infancy and the manufacture is still imperfect, though my teas have realized as high as 2s 2d in London but we are not shipping, the colony at present taking all. I have an Excelsior Rolling Mill and Davidson's Sirocco, and have just put up a new dryer by Gibbs & Barry. I had a dryer XL. ALL., Greig, Edinburgh. This troubled us but we have altered it and just got it to work with great advantage; but the alteration has made a new thing of it, having doubled its size and introduced new principles. I cannot say I like the Sirocco or any *Tray* machine. The rotating nature of Gibbs & Barry and Greig's certainly gives improved appearance to leaf. If Natal people go into tea planting the colony will be well able to compete with any other country and it possesses a finer climate than any other tea producing country. Mr. A. H. Bisset, formerly in coffee in Ceylon, is going in largely for tea. He is situated about 70 or 80 miles below Durban; I am 50 miles above Durban on North Coast. I am looking forward to a visit to Ceylon ere very long to pick up information as to manufacture. As to cultivation I am better able to work according to knowledge of the climate than to receive information from others whose experience is from a different climate. I am an old coffee planter here and the coffee failing, have gone into tea."

Mr. Hulett's notice of the failure of coffee in Natal reminds us of the curious fact that of the two tropical products to cultivate which Indian labour was introduced into that colony, namely, sugar and coffee, nature seems at once to have placed her ban on the latter. Here, in Ceylon, the plant flourished and for the best part of half a century the results were generally profitable, until blight overtook the plant and the enterprise in the shape of a blood-sucking fungus, green bug following so as to be in at the death, apparently. Sugar planting has been more of a success, although scarcity and dearness of labour render competition with the neighbouring colony of Mauritius an uphill task. The Kaffirs do not take kindly to steady work, and a very elaborate report by Mr. Justice Wragg, formerly of the Ceylon Civil Service, which has reached us as well as comments in the Natal journals ,show that immigration from India has been anything but satisfactory in its results. So we suspect must Indian immigration as well as Chinese always be, where the climate is sufficiently temperate to permit of labour by Europeans, or men of European origin, in the open air. Such is the case in Natal, and we were much interested, about a couple of years ago, with a statement by Mr. Hulett, which we copied into and commented on in the *Observer*, that Mr. Hulett and his sons performed the whole work of the tea estate! The property was of course young and still is. As it advances, and especially if the sanguine (over-sanguine, surely) estimate of 1,000 lb. of made tea per acre is fulfilled, a considerable force of hired labour will be absolutely necessary. What the result will be to Mr. Hulett and the pioneers of the Natal tea enterprise remains to be seen, but we believe the cost of labour will place limits to the extension of tea culture in Natal, such as will prevent that colony becoming a formidable factor in the supply of the world and in competition with India and Ceylon. We shall be the better able to speak with confidence on this topic when we have had time to study the report referred to. Meantime it is interesting to hear the result of a trial of Greig's XL (Excel) All Tea Machine, as well as of the Gibbs & Barry Drier.

COFFEE NOTES.

(*Rio News*, Oct. 5th.)

The local papers state that the coffee bloom in the district of Amparo, S. Paulo, is such as has never before been seen.

Dandelion coffee essence is endorsed by the *Lancet* and *British Medical Journal*. A shilling bottle makes 25 cups of coffee. With green Rio worth about 9d per lb. the essence seems cheap.

Experiments are about to be make at coffee-growing in the province of Rio Grande do Sul, the municipalities of S. Antonia de da Patrulha, Conceiçao do Arroio and Torres being considered suitable.

From Baturité, Ceará, a correspondent writes to a journal in the capital of the province that the coffee crop has been very good, and if it can be sold at 10$ per arroba, the product will reach 6,000,000$ or the crop will produce about 150,000 bags.

THE FERTILIZATION OF THE COFFEE PLANT.

I send you the following notes on the fertilization of the coffee plant (*C. arabica*) which I made some time ago, and which may be interesting to those who study the subject.

Your readers are doubtless aware that coffee was cultivated some twelve years ago to a very large extent in Ceylon and South India, but owing to the attacks of leaf disease, the area has been rapidly reduced, except, I believe, in some parts of Coorg and Mysore, where the climate is drier, and the leaves suffer less from the fungus. It has now been largely replaced by tea.

The jasmine-like flowers of the coffee are borne in clusters in the axils of the leaves, and appear simultaneously all over the estates. After a prolonged drought of one or two months, or even more, at the beginning of the year, there is generally a heavy fall of rain, sometimes lasting only an hour or two, sometimes continuing for two or three days: the amount that falls must be enough to saturate the ground, and should not be less than one inch.

In from six to eight days from the time of the first shower, the flowers burst into full blossom, last for a day, and then drop off. On the evening before the blossom is fully out, if the flowers are examined it will be found that they are partially open, the stigma being protruded and receptive. During the night the hum of insects can be distinctly heard, and I am of opinion that the flowers are largely fertilized by

night-flying insects which carry pollen from those flowers which happen to be open rather before the others, as some are delayed. On the following morning all the flowers will be found open, and the field of coffee presents a sheet of white. These flowers are frequented by immense numbers of bees, of two kinds one about three-quarters of an inch long and black, the other smaller and with white bands round its abdomen. The stigmas now are covered with pollen, and the anthers bursting, and the larger of these bees may be seen buzzing from flower to flower sweeping up the grains of pollen between its front legs, and rolling them into balls. Long before evening all the anthers are exhausted of pollen, and the insects have departed. Besides bees some butterflies visit coffee, such as *Hypolimnas bolina*, *Papilio Polymnestia*, and two or three *Danaidæ*.

The coffee plant by being proterogynous is intended by Nature to be cross-fertilized, but owing to all the plants in one clearing being usually grown from seed of a single estate, there must be a great deal of interbreeding, more especially as all the coffee of Ceylon and most of South India is supposed to be descended from a single plant introduced into Batavia about two centuries ago. This may have something to do with the manifest deterioration in stamina of the younger coffee.

While on this subject I may mention the curious alteration in the position of the organs of *Clerodendron infortunatum* when flowering. This plant is proterandrous: at first the style hangs down, while the stamens are erect: as soon as the pollen is shed the stamens drop, while the style rises, and the stigma becomes receptive. The chief carriers of pollen in this plant are small ants. T. F. BOURDILLON.

Quilon, S. Travancore, India, Sept. 13th.
—*Nature*, Oct. 20th.

THE DECADENCE OF THE CHINA TEA TRADE.

This subject is now being discussed in the principal China newspapers.

It appears that the loss of revenue arising from the decrease this year in the exports has induced the Chinese Government to inquire into the causes which have led to the British public refusing any longer to drink the rubbish which has hitherto been foisted on them by the Chinese under the designation of common congou, because it can now obtain from Ceylon and Java good and unadulterated teas at prices relatively as cheap as the China stuff.

The Government has invited the Shanghai Chamber of Commerce to give its opinion as to the causes of the alleged falling-off in the quality of a great portion of what has recently been exported and to point out how the deterioration is to be remedied. The Chamber will, no doubt, furnish the Chinese Government with the same advice which the Mincing Lane brokers give to Ceylon planters, namely, to improve their manufacture and make nothing but fine and first-class tea, as if self-interest is not as inherent in the soul of the Chinese cultivator as it is in that of the Ceylon planter, who makes the best tea his ability and circumstances permit him to make, and the Chamber will probably further recommend the Chinese to consume their own rubbish and send to England nothing but their best descriptions.

The Chinese Government will thereupon issue directions to the Governors of provinces to impress upon the cultivator the necessity of improving his method of converting his green leaf into better tea than he has lately been doing, if not for his own interest for that of his paternal Government.

As explained by the *North-China Herald* it is impossible for him to do this, unless the conditions upon which the green-leaf is grown and manufactured are revolutionized.

The Ceylon planter is now supposed to be initiated into the mysteries of good tea making. He knows that if he wishes to make the finest qualities he must pluck fine, and if he thinks a larger yield of medium quantity pays him better than fine plucking he plucks accordingly, but in both cases to ensure the manufacture of the best of each description, the most careful and delicate methods of withering, rolling, oxidizing and firing the green-leaf is necessary, and as shown by the *North-China Herald* in the following article, the Chinese cultivator cannot manufacture his leaf under the conditions necessary to insure the manufacture of good tea:—

"The advantage which India has over China is the advantage that the manufacturer has over the handicraftsman. The small plantations cannot compete with the large ones in India, and are being rapidly absorbed or amalgamated. It is these large plantations with ample capital, improved machinery, and the most expert supervision, that are controlling the London market; and the little farmer with his two or three *mow* of ground on a hillside in Hupeh, cannot hope to compete with them. In India the leaf is fired the day it is picked, and all its strength and aroma are preserved. In China, the packer of the tea sets himself up in the country village, and the small farmers come in from all round, each with his picul or two of leaf, and as soon as the teaman has collected enough for a chop, he fires and packs it, days having probably elapsed since it was picked, while the farmer was haggling over the price. The teamen would scorn to use the machinery for firing and sorting which have been found so useful in India; they stand on the ancient ways, only anxious to get their teas as quickly as possible to market, the time of arrival being a more potent factor than the quality in extracting a profit from the foreigner." Moreover the area of competition is extending. Ceylon is now a large producer, and South Africa and Fiji have both commenced, with some success, the business of tea planting. The monopoly once enjoyed by China can therefore never be regained. While this fact has to be faced, there is no reason why she should not continue to keep a large share of the trade if only proper attention be directed to the cultivation and firing of the leaf. The stock is said to need renewing in some districts, and the methods of firing can be improved in all. The admixture of dust and rubbish in the shape of used and spurious leaf can easily be remedied. This is a question of common honesty. Tricks in trade never pay in the long run; attempts to palm off inferior articles always recoil, sooner or later, on the dishonest dealer. We do not know whether the Foochow Chamber of Commerce has also been invited to give their co-operation in the work of discovering a remedy for the decline in the tea trade, but its assistance should certainly have been asked, as it is in a position to throw a good deal of light on the question.

A considerable portion of the tea shipped from China to England is now selling at 4½d to 5d per pound. Well! we are sufficiently acquainted with the circumstances under which the China tea is manipulated to know that at such prices neither the cultivator nor middleman can obtain any profit out of the export of tea, the Chinese Government is the sole benefitor by the trade. Therefore, as far as the cultivator is concerned, the importance of the export trade is, as we have previously said, overrated. The Chinese Government obtains a revenue of about a million sterling per annum from the export duty, and it is the prospect of losing a large portion of this which is now exercising the mind of the Chinese Government. The only way of remedying the inferiority complained of is by the construction of central factories, where the cultivator can take his few piculs of green-leaf, before it has become unfit for making good tea.

This, of course, cannot be done, nor can the Government increase the remuneration of the grower

on the present system by taking off the Lekin or Octori duty. The Chinese Government can no more exist without revenue than more modern governments can. The removal of the export duty would only benefit the middlemen and the merchant by making it possible to continue shipments of rubbish at very low prices.

THE SHUMSHERNUGGER TEA COMPANY, LIMITED.—Under the above title a company was registered on the 14th Oct., with a capital of £25,000, in £10 shares, to take over from a company of the same title incorporated in India, the Shumshernugger tea estate, district of Sylhet, British India, for £21,000 in fully-paid shares. The subscribers who take 1 share each, are:—Col. A. J. Filgate, R.E., United Service Club; Major-General E. C. Williams, R.E., 73, Lexham Gardens; M. Fox, 2, Catherine Place, Bath, railway contractor; C. A. Goodricke, Dashwood House, tea merchant; J. Sanderson, 46, Queen Victoria Street, solicitor; Major-General J. Bird, West Monkton, Taunton; G. Seton, 34, Old Broad Street, Indian estate agent. The number of directors is not to be less than two, nor more than five; the first three subscribers, and Mr. John Steel will be directors, qualification, 50 shares.—*H. & C. Mail.*

COFFEE AND CINCHONA IN JAVA.—According to the latest advices the Government's coffee crop on Java is again 5,000 piculs less— the quantity will be thus 285,000 piculs. The Netherlands India Agricultural Company held its annual meeting yesterday. From the report it appears that the coffee undertaking, "Soember Wangie," yielded a crop of 1,944 piculs, against an estimation of 1,500 piculs, and realised fl.47 per picul. The claim of the company on the firm of Lens and Bergsma necessitated a further writing off, the total loss amounting thus to fl.34,000. The amount of stocks is decreased by fl.73,000, required for working capital, and amounts at present to fl.227,000. Drafts accepted reached the amount of fl.58,000 on March 31st. The agricultural undertaking, Siti Ardja, situated at Tjitjalengka, near Bandong (Java), is to be converted into a limited company, with a capital of fl.500,000. The undertaking was started in 1874, is cultivated with 1,000,000 coffee trees and 100,000 cinchona trees, of which 75,000 are Ledgeriana. The largest crop of coffee of this undertaking has been about 7,000 piculs.—*L. & C. Express*, Oct. 28th.

ENSILAGE.—Mr. David Burril, of Little Falls, New York, states that by the aid of ensilage he is now keeping one hundred and forty cows on the same land where he formerly kept only forty. There is no increase of capital for land, only a small outlay for the silo and the growing of Southern sweet corn for ensilage purposes. Hiram Smith has a similar experience. Right here lies the secret of reducing the cost of milk and increasing the profit. Two things only are necessary: 1st produce more fodder on the same land at less cost per ton; 2nd, as soon as possible, procure a class of cows that will give an increased amount of product for the amount of food consumed. When one cow will produce as much butter as two ordinary cows, and one acre will furnish as much food as six acres ordinarily do, the dairy farmer may be certain that he is on the right track. We want to see more productive acres and more productive methods of tilling them; also fewer cows and better ones. The great reason that the poor farmer can make nothing at farming is because what he produces costs twice as much as it does the good farmer. There is room right here for good, long, strong thinking.—*Hoard's Dairyman.*

COOKING AND FOOD.—The question as to whether cooked food possesses any advantage over raw food for stock, has been settled to a certain extent by the New York Agricultural Experimental Station, which reports the results of an investigation into the matter. It appears that cooking food for stock lessens the nutritive value, over the same food in a raw state. The chemical evidence shows there is a loss of albuminoid in the process of cooking, and also an apparent loss in the fat. By cooking the loss in albuminoids hundred pounds of the food showed in the case of clover hay ·188 of a pound, in the fresh ground meal 1·09, and in the case of old meal ·543 of a pound. Cooking proved disadvantageous, both in the loss which occurred of actual albuminoid, and in the depreciation in the digestive value of the albuminoid that remains.—*Indian Agriculturist.* [This is a result so unexpected and so contrary to previous impressions that we should think it must be received with considerable qualification, at least this, that the easier mastication and digestion of the cooked food enables the animals probably to assimilate more of the nutritive matter than that could do in the case of uncooked food.—ED.]

CINCHONA CULTIVATION IN JAVA.—Mr. Van Romunde's report on the Government cinchona enterprise in Java for the the third quarter of 1887 is as follows:—

The weather continued pretty dry during July and the first half of August; in the second half of the month and also during September a relatively large quantity of rain fell. The moist weather was favourable for the growth of the young and old plants, and did much good to the extensive nurseries. While in consequence of the mild east monsoon of 1886, the harvest of cinchona seed was so small, that during the fourth quarter of the year at the most only a single sale of ledgeriana seed can be held, the rainy east monsoon of this year leads us to expect, that the blossoming of ledgeriana and the consequent crop of seed of next year will be meagre in the extreme. The harvest of 1887 consists of about 450,000 pounds bark, of which by the end of the quarter 382,587 pounds had been dispatched to Batavia. The crop would have been already considerably larger had not the excessive rain during the last few months hindered the operations connected with the gathering and drying of the bark. The produce was obtained chiefly by the thinning out of closely planted ledgeriana and succirubra plantations and to a certain extent by the uprooting of single trees of *C. josephiana.* On June 2nd and July 14th sales of Government cinchona bark of the harvest of 1886 were held in Amsterdam. The average prices obtained at these sales were 57·77 and and 56·79 cents per half kilogram. The experiments with the grafting *C. ledgeriana* on *C. succirubra* in the open air have, in the initial stages, yielded no good results, but if persisted in and carried out with greater precautions they promise to give better results.

SALE OF CEYLON INDIARUBBER.—The following has been sent to us for publication:—

24th Sept. 1887.

Messrs. Forbes & Walker, Colombo.

Dear Sirs,—We have now to send you report on Indiarubber, and to advise sale of it at 1s 4d all round. 14 days less 2½ per cent and payment on re-weights. It is a very saleable article in large quantity; and price is very low at present of all kinds. It resembles slightly Mozambique kinds and in some respects the kinds that come from the West Coast of Africa and South America. You will observe what is said about this lot being rather heated. Can this be avoided? Is it an original product of your island?—Yours truly, LESLIE & ANDERSON.

29, Mincing Lane, London, E.C., 23rd Sept. 1887.

Messrs. Leslie & Anderson,

We beg to hand you report and valuation of your Indiarubber per "Goorkha" from Colombo.

Mark.	Val. abt. per lb.	Sold at per lb.
HMP 1.—1 case about 21 lb. mostly liver but part scrappy Ball, rather heated and sticky.	1s to 1s 3d	1s 4s
2.—1 bag found in case; about 22 lb. scrappy ball; part heated.	1s 4d to 1s 6d	

In quantity we think this rubber, if not heated, would bring 3d to 4d per lb. more.—Yours faithfully, DALTON & YOUNG.

TEA IN JAPAN.—From the British consular trade eport for Kanagawa for 1886 we extract as follows:—Tea occupies the second place amongst the staple products of Japan; the value of the export last year being £830,000, exactly one-fourth the value of the silk export. The aggregate export was about twenty-eight million pounds in 1886 as against twenty-four million pounds the preceding year. This is all taken by the North American continent, in the proportion of rather more than one-fourth by Canada and less than three-fourths by the United States. San Francisco, as the centre of distribution for the Pacific coast, takes about one-sixth, not of the aggregate export, but of the quantity consumed in the States; and the remaining five-sixths go, in nearly equal portions, to New York for distribution amongst the Eastern cities of the Atlantic states, and to Chicago for distribution amongst the towns and hamlets of the great agricultural West. Although England does not take any Japan tea, the export business in it is largely in the hands of British firms.

A PHOSPHATE ISLAND.—Large amounts of phosphate rock are being landed at this port from the Island of Redonda, British West Indies, consigned to the new phosphate works at South Camden, N. J. The soil of the island, which was recently purchased by English parties, was supposed to be worthless, but upon an analysis being made it was discovered to possess fabulous wealth. The fact that this rock is brought into competition with the Southern phosphate rock has been the means of starting others to look in the same direction. The Island of Redonda lies eight miles from Montserrat and thirty five miles from St. Kitt's, and rises 1500 feet, showing a bare white rock. This whiteness is said to be due to the number of sea birds which frequent the island to lay their eggs and rear their young. The rock is procured from the almost perpendicular cliffs with great difficulty, and is discharged into lighters, and subsequently into the vessels awaiting loading. Laborers are procured from the adjacent islands, and they procure sufficient meat for their sustenance from the game which abounds on the island. The British bark "Mary" has landed several thousand tons of phosphate here and is now bound out for another cargo.—*Philadelphia Record.*

TEAK IN SIAM.—Consul Gould, writing from Bangkok, says, with regard to Teak, that there has been an increased export as regards quantity, but the profits realised have been by no means satisfactory owing to the remarkable drop in the value of this wood in Europe. There is, however, no likelihood, at present, of this trade diminishing, but the small margin of profit will direct, more and more, the attention of the merchants and saw-mill owners to forest operations, by which they can secure timber at more favourable rates, and with greater regularity than by purchase in the open market. The export trade in this article is now almost solely in the hands of British merchants. The forest operations have hitherto been chiefly carried on by British Burmese, but the British merchants have begun to invest capital upcountry also in this trade, and in future this practice will probably be forced more and more upon them, to the benefit of the country and ultimately also probably to themselves, though the want of experience in this peculiar branch of industry may cause some preliminary disappointment.—*Gardeners' Chronicle.*

ABYSSINIAN ECONOMIC PLANTS.—Among the vegetable articles of diet of the Abyssinians, the first place is taken by *t[illegible] (Poa [illegible])*, a herbaceous plant, whose grains are as small as a pin's head; the meal from this forms the bread in general use. A much inferior black bread used by the poor is made from a kind of millet called *[illegible] ([illegible])*, frequenting the low grounds. Another admired vegetable is the flower stalk of the local plantain, called *[illegible] (Musa Ensete)*, the fruit of which is dry and unfit for eating. The stem is cooked with milk and butter. It is cut off just above the rootlets, and about two feet high; if old, the green outer coat is peeled off till the white interior shows. It is as tender as a well cooked turnip, with a flavour like the best new bread somewhat underdone. It is an excellent dish, nourishing, wholesome, and digestible. From meal cakes a fermented drink called *bousa* is made. The coffee grown in Abyssinia is principally sent to Djedda and Upper Egypt; though not of first rate quality, it possesses a special aroma, and is sold at the rate of 16 dollars per *cantaro* of 113 *rottoli* (say 37s. per cwt). The women of Gurage makes mats of the leaves of the *ensete.* The *ecra* of the Abyssinians, a species of asclepiad, produces a tough fibre, used in making cordage and tissues on the Red Sea littoral. The bark of *Calotropis gigantea* affords excellent fibre used for various purposes. The tender leaves newly pulled from the stipa of the *doum* palm are woven into all kinds of matting and basketware. The powdered seed of a large tree called *berebera* (*Milettia ferruginea*) is thrown into the water to stupefy fish and facilitate their capture. The native dress consists of a large folding mantle and close-fitting drawers. The houses are rude conical structures covered with thatch. Among the local products figuring in the exports are:—Calves' hides, salted and sun dried; beeswax, chiefly from Gedaref, tamarinds, ostrich feathers, gutta-percha, from Kassala; gum arabic, mother-of-pearl leopard skins, about 1,000 annually to India; musk, contained in bulls' horns, to the number of 200 to 300 a year; honey and tobacco, chiefly from Sanaaid.—*Planters' Gazette.*

HOME AND FOREIGN SOURCES OF MEAT.—An interesting conference on home, foreign and colonial sources of meat supply took place at the Colonial and Indian Exhibition, South Kensington, last week Sir James Caird, presiding, when Major Craigie read an instructive paper of the above subject. The following is a summary of the opening address:—Major Craigie said:—In discussing the nature and sources of our meat supplies on this occasion, the immediate object is no doubt, to realise the part played by our colonies as caterers, for the mother country, and the prospects of increase or diminution. Although the 36,000,000 people of the United Kingdom have not for many years raised all the meat they consumed, home produce still forms by far the largest section of the whole supply. On the basis of the estimates commonly employed, it is supposed that 25 per cent of our cattle, 40 per cent of our sheep and 116 per cent of the enumerated pigs of each year go annually to the butcher. If so, the home produce of 1885 may be put at 1,361,000 tons of meat. The imported supplies were of two sorts, live animals and dead meat, the former representing 129,000 tons, and the latter 335,000 tons of meat. The entire consumption of the country was thus 1,825,000 tons or 112 lb. to each inhabitant. —*Indian Agriculturist.*

RICE SOILS AND RICE MANURES.

The following contribution to tropical agriculture written for us by Mr. John Hughes, F. C. S., is well worthy of attention, especially by the Director and his Department of Instruction :—

Rice is certainly one of the most generally diffused and useful of the grain crops, and probably supports the largest number of the human race. Not only is it produced in large quantities in India, China and the east generally, but we find it extensively cultivated under the most favourable conditions as regards irrigation in the southern portions of Italy, Spain and Portugal, as also in parts of the West Indies, Central America and the United States. It would therefore appear that provided there is a sufficient supply of water, rice can be produced on all kinds of soils and under various conditions of climate. Doubtles if inquiry were made, this would be found to be practically the case ; at least so far as the writer's own experience, gained after visiting certain rice districts in the south of Spain and Portugal, and subsequently making a careful analysis of the soils. The most essential thing in the soil itself is that it should be in a minute state of division so as to supply an abundant source of soluble silica which is so necessary in the formation and successful growth of the straw, and without which it would be quite useless to expect to obtain a good crop.

In other words it is very much the same as we know is fully recognized in regard to wheat, namely, that the best crops are produced on naturally stiff clay soils which contain plenty of available silica and potash. Indeed all good rice soils must be stiff ones, so much so that frequently portions of the soil become when pressed and dried as hard as bricks, and this fact leads us to understand how necessary a sufficient supply of water must be, not only in the preparation of the land for the seed, but during the early period of growth, during which, unless the soil was kept in a *soft pliable state*, it would be impossible for the delicate roots to permeate it in search of plant food. In 1873, certain doubts having been frequently expressed as to the value of, or necessity for, irrigation in the growth of rice, a great number of interesting experiments were carried out in the Midnapore district by Mr. Apjohn, the general results being that the crops irrigated from the beginning of the season exceeded in value the altogether unirrigated ones by R16 per acre, the value being calculated from the selling price of the paddy and straw on the ground.

In making this comparison it is only fair, however, to remember that the year 1873, being one of deficient rainfall, was decidedly favourable to the crops irrigated by means of canals, and unfavourable to the crops grown without the aid of additional water artificially supplied. It may, however, be safely inferred that in bad seasons the canal-irrigated crop will be four or five times better than the unirrigated one, and that in ordinary years the former will still compare favourably with the latter and yield a return equal to one-fifth or one-sixth more, an increase which perhaps may be considered small when merely one acre is considered, but which becomes immense and of vital importance when the area of cultivation is reckoned in hundreds of thousands of acres. These are the views put forward by Simmonds in his excellent work on *Tropical Agriculture*, and they are worthy of serious consideration when we look into the question of the annual food supply of the natives of India and the recurrence of famine as the result of long continued drought.

In the extension of canals for irrigation purposes, and in the introduction of improved machinery for preparing the rice for market, European aid under Government supervision can be most profitably employed. In the actual tillage of the ground probably the natives are as skilful, and certainly more likely to raise crops with profit, than the majority of English residents fresh from home who frequently have had no previous practical agricultural knowledge.

We should always bear in mind that the local customs for treating land and raising crops like rice have grown out of the accumulated knowledge of many past generations, and we should treat them with that deference and respect which well directed age should always command.

Leaving then the extension of canals and the construction of suitable tanks for the storage of water to the careful consideration of the responsible Government authorities, and the introduction of improved appliances for threshing the paddy (rice in husk) and preparing the rice for market to the inventive genius of our agricultural implement makers, let me proceed to place on record a contribution to the examination of the chemical composition of rice soils with a few remarks respecting the kind of manure which has been found after some years of trial most suitable for application, and to yield the most remunerative results.

As already stated, rice is doubtless grown on a great variety of soils, and the two following analyses are only introduced as examples of the difference that obtains in their chemical composition. Many others could be produced if the soils were available for examination :—

ANALYSES OF RICE SOILS IN PARTIALLY DRIED STATE.

	No. 1. From Valencia in south of Spain.	No. 2. From near Lisbon in Portugal.
Water ..	7·11	7·34
* Organic and volatile matters	6·55	8·34
Oxide of iron ..	3·91	4·30
Alumina ..	3·61	5·26
Lime ..	21·04	trace.
Magnesia ..	2·21	·34
Potash ..	·65	·49
Soda ..	·03	·41
Phosphoric acid ..	·17	·09
Sulphuric acid ..	·17	·17
Carbonic acid ..	15·79	·53
Chlorine ..	not made	·08
Insoluble siliceous matters (in a very fine state) ..	38·76	72·65
	100·00	100·00
* Containing Nitrogen ..	·180	·233

Now both these samples were in a very fine mechanical condition, and the soil to the touch was soft and free from coarse sand. The silicates were in a form readily assimilated by the roots of the crop.

But while one soil (2) showed only a trace of lime, and in this respect probably resembles most of the Ceylon paddy soil ; the other contained 21 per cent of lime, equal to about 37 per cent of carbonate of lime as existing in the soil.

Both specimens are specially rich in potash as we should expect from their clayey nature ; the Spanish soil containing the most, namely ·65, as against ·49 in that from Portugal. In the matter of nitrogen, however, there is a reverse, the Lisbon one being somewhat richer, though both soils are deficient in this important constituent of plant food, and, as we shall presently see, receive artificial supplies in the form of manure in order to produce good crops.

In phosphoric acid the Spanish soil is again the richest, ·17 as against ·09, but phosphate have to be supplied like nitrogen by yearly applications of some phosphatic manure.

Rice like all cereals naturally requires a generous supply of nitrogen in some form, but being grown (up to the flowering season) in ground through which water is passing it is most important that the manure used should not be of too soluble a character, also that proper control of the water should always be observed, as otherwise there would arise a great waste of fertilizing material. Of course the water, when properly held in check, furnishes an excellent medium for equally distributing the valuable ingredients of the manure, but great care must be exercised, and not too much water allowed in the fields and no overflowing of the banks or walls.

The manures that have been found to yield the most economical and remunerative results in the south of Spain rice fields are mixtures consisting of

Superphosphate
Fine bone dust or fish guano
Dried blood finely ground
Sulphate of ammonia
Sulphate of potash

The materials are carefully mixed and so compounded that the nitrogen, phosphates and potash shall be supplied in different conditions of solubility to meet the requirements of the crop in its various stages of growth.

For some years there has been carried on a steady and increasing trade in these rice manures, some hundreds of tons being to my own personal knowledge shipped from London alone—the weekly steamers from Liverpool also taking consignments from the manufacturers of the north.

With ample supplies of castor poonac, finely ground dried fish and steamed bone meal of the very best description already available in Colombo, it is certainly a great pity, as well as a distinct local loss, that no well-organized system for applying manure to the paddy fields should have been carried out in Ceylon.

At the present time Indian bone-dust is coming into the London market at the same time as Indian wheat and Calcutta rice. It is too hard on the land to be constantly draining away its stores of accumulated wealth, and the soil must indeed be rich that can long stand such a drain. Unless some manure is returned, the yield fails and the quality becomes impaired and if it pays to manure in the south of Europe and the States it must surely pay in India and Ceylon where labour is so cheap and railway transit rapidly extending.

Analytical Laboratory, 79, Mark Lane,
London, E. C., Nov. 4th.

A NEW USE FOR RUSHES.—In olden times the so-called pith of Rushes was made use of universally in the manufacture of candles. This state of things has, however, passed away, and but little use is now made of Rushes, except for the seats of chairs, coarse mats, and similar purposes. Our French neighbours have devised another means of utilising this material, and which we bring to the notice of those engaged in church decoration and other similar purposes. Strolling through the quaint old market-place at Calais lately, we observed wreaths and bouquets of Box, intermingled with which were small tufts and loops made of the "pith" of the Rush. For any purpose where formality of arrangement is not objectionable, this contrast of the deep colour of the evergreens with the white of the Rush is very effective.—*Gardeners' Chronicle.*

A FRUITLESS SEARCH.—Planters in our East Indian possessions take great interest in all new febrifuges, and anything new which is likely to replac cinchona and its products is generally hailed with something like alarm. Of course they have a stake in the cinchona industry, and it was natural when the reports of the salutary influences of the eucalyptus in removing malaria reached them that they should keep their eye upon it. Now an Indian contemporary informs us that "after all we have read of the *Eucalyptus Globulus*, and the wonders we have been led to expect would result on its introduction into and cultivation in this country, it is sad to find on reading the opinion of an expert that our hopes have been founded on sand. The bark and leaves of the tree have now been examined, and neither quinine, quinidine, cinchonidine, nor cinchonine is contained in the plant in any proportion. And this when we were previously led to believe that the tree was almost, if not quite, as good as cinchona in furnishing the world with a febrifuge." This is disappointing, for, according to the *Lancet*, two learned professors obtained an alkaloid from the bark which crystallised, like quinine, as a sulphate, and which yielded the ordinary reaction of quinine with chlorine water and ammonia. Taking everything into consideration we should have inferred that the *Lancet* was wrong. Our Indian contemporary also finds that, instead of producing rainfall, the eucalyptus takes up more than its fair share of water. But the investigations were not carried sufficiently far to lead to the discovery that the water-imbibing propensity is the reason why the eucalyptus has found new homes in the malarial districts of Italy, California, and other previously unhealthy parts of the globe.—*Chemist and Druggist.*

PLANTING FRUIT TREES.—In performing this operation care must be taken that the trees are not planted too deeply—in fact, they are best left a little raised above the level of the surface, so as to allow of the trees sinking somewhat afterwards; neither should trees planted against walls have their stems placed close to the wall; they are much better for being kept 6 inches away from it. Assuming that the sites intended for the new trees are fully prepared, the planting is thereby much expedited as soon as they come to hand. In planting, take care that the small fibrous roots are evenly spread out, and at slightly different levels, and that all strong roots and others that have become injured on removal be cut back with a sharp knife. In carrying out the work some of the finest of the new soil should be inserted amongst the roots, making all firm by treading as the work proceeds, and by giving the trees a good watering before finally filling in the soil. After planting it will be necessary to fasten the trees loosely to the wall, to prevent the branches from being blown about by the wind, the proper nailing of the wall trees being deferred till spring. Pyramid and standard trees will require staking, to prevent rocking, placing some soft material round their stems, so that the bark is not injured; and in the case of orchard tree, they will also require the stems to be protected from injury by game; it is not safe to leave them even for one night without taking some precautions against this kind of injury, as any fresh occupants of the orchards are readily found out by hares and rabbits. To give the kitchen garden a pleasing appearance, a narrow border should be formed round the vegetable quarters, which should be planted with pyramid trees of Apples, Plums, and Pears, planted form 6 to 8 feet apart, so that eventually the trees will occupy the whole of the space; and in the meantime small bushes of Gooseberries can be planted between to fill up space, but on no account should the ground near their base be cropped by vegetables under any consideration, but the ground should be kept clean by the use of the hoe, or, better still, kept well mulched with well rotted manure.—E. WARD, Howell, Bromsgrove.—*Gardeners' Chronicle.*

TEA—COCOA—KAPOK—DRUGS—DYES—RUBBER—WOOD FOR PAPER—QUININE.

LONDON, 28th Oct. 1887.

As to new PRODUCTS, CEYLON TEA never stood in higher favour than at present: if only quality can be kept up as at present (say experts from one end of the City to the other) Ceylon tea must be the tea of the future. One explanation of the high values lately given for our teas is that the large number of distributors and dealers in packets have got alarmed about being called to account—fear of each other!—under the new Act for selling blends as pure Ceylon tea; and that they must have the real article to meet customers' demands. I hear most satisfactory accounts of high-grown teas:—Glencairn, Errol, Calsay, Abbotsford, Mooloya, and of course Loolecondura. A friend who casually met a tea expert travelling in a Midland town was amused at the enthusiastic way he spoke of Ceylon teas:—"He said it would be the tea of the future if a sufficient quantity was produced and if the quality were maintained, by manuring, &c. He added there was one brand which generally fetched up the prices when on sale, Abbotsford"!—and this without the slightest idea of its reaching those interested.*

By the way, I find this question of *manuring* tea to keep up quality in Ceylon seriously discussed in several City quarters, though in others carefulness in manufacture is considered of most importance.

In the office of Messrs. Wilson, Smithett & Co., I hear that some doubts are begining to be thrown on Ceylon 'Cocoas,' some samples recently not being up to the usual mark; but this may be a passing incident. This same firm have been introducing Ceylon 'kapok' to the notice of manufacturers (who mix it with silk) with success, and I should fancy a good demand must set in.

In "Lane" offices, as well as from the editors of the *India Rubber* and *Chemist and Druggist* journals, I learn there is a good prospect before 'rubber.' The ways in which it is utilized are increasing every day, and raw material at 2s 6d to 3s should pay the Ceylon owners of trees by-and-by when a good yield of milk can be looked for.

Dyes and Drugs and Coca leaves are subjects of inquiry, and Mr. Thomas Christy, whose store and offices have been enlarged since I was last over (his store being a regular museum), is busy in introducing new drugs to the trade. His patent "incubator" has also been now perfected he thinks after many years of experiment, and he has also a very promising invention in hand in connection with the distilling of water which is likely to save much expense in many directions.

At the great "paper" house of Messrs. Spicer & Sons, Upper Thames Street, I was much interested in learning from one of the partners how largely their manufactories had come to depend on "wood" for raw material. Pinewood from Norway and Swedon, straight, smooth and free from knot or excrescence, worked to mucilage by an abundant supply of varied chemicals, gives the paper from which nearly all the London newspapers are supplied!

A visit to the manufactory of various machines connected with tea-mixers or blenders, cutters, &c. in company with an experienced China tea merchant, whose guest I was some years ago in Canton, but who is now a Lane broker eager after Ceylon tea, was interesting, and here I saw an ordinary but useful article which, I think, should be in request in Ceylon tea stores:—steel scoops, flat and half-round, very strongly made. Specimens are to be sent out to Ceylon. I was glad to see Mr. T. J. Lawrance (growing portly enough to qualify as Alderman and Lord Mayor one day) at the headquarters of the Ceylon Produce Company so largely interested in cacao and tea plantations (Peradeniya, Kawdapellella, &c.). This new Company alone has been the means of introducing £100,000 of fresh capital into Ceylon, and than Mr. Alexander Ross, they could not have a better representative in the island.

Messrs. Gow, Wilson & Stanton have made a new departure in selling valuable tea seed in the Lane—see their catalogue for "Manipuri Indigenous Tea Seed."

See also the interesting Produce tables of Joseph Travers & Sons I send, and Cooper, Cooper & Co. on Teas.

* In reality Abbotsford tea sells, at public sales, at only a respectable average. The flavour is delicate, but the tea does not seem to be strong enough for the purpose of those who practise blending. Used alone its delicate mountain flavour tells.—ED.

QUININE AND OPIUM: THE CINCHONA BARK TRADE.

To turn to another topic, that of the abundance and cheapness of quinine and the need of extending consumption, my letter to the "Society for the Suppression of the Opium Traffic" has brought the following acknowledgement:—

Society for the Suppression of the Opium Trade,
Offices:—Broadway Chambers, Westminster, S. W.
J. Ferguson, Esq.

October 19th, 1887.

Dear Sir,—I beg to acknowledge the receipt of your interesting letter of the 14th Oct. Unfortunately our periodical *The Friend of China* is only published quarterly, the last number having appeared on Oct. 1st, but we shall have your letter set up in type, and before it is published, endeavour to obtain some influential medical opinions in support of your valuable suggestion.—Yours faithfully, F. W. CHESSON, Hon. Secy.

The subject has been a good deal talked of in many circles, not only Medical and China Missionary, but among press and City men. Geo. Augustus Sala may have something to say about it, and already the editor of the *Christian World*—one of the most widely circulated of London weeklies—has taken up the matter in the following leaderette:—

Mr. John Ferguson, of *The Ceylon Observer*, has written to the Society for the Suppression of the Opium Traffic, calling attention to the value of quinine as a specific against the taste for opium, and to the present cheapness of the article. His contention is that the appetite for opium, as is evident from what is seen in the malarial regions of China and of the Fens in England, is due to a type of low fever, and that the appetite thus acquired is then passed on by generation until it has become a habit apart from the original cause. The counteractant of this appetite is quinine, and it is so recognised even in the remote parts of China. Quoting from "Across Chryse," it is shown that quinine is more highly esteemed in China than the brightest Birmingham goods. Mr. Colquhoun, the author of that work, was asked more than once by Mandarins if he had any cure for the "black smoke poison" (opium), and on his replying in the negative, "Then have you any quinine?" would be asked. The American missionaries, too, recognise this fact, and are introducing quinine pills largely at their mission stations in China. On the second point, the present cheapness of quinine, Mr. Ferguson urges on the Society the policy of recommending the use of quinine. A few years ago it would have been idle to make such a recommendation to poor people; but the success of the Government experiments in India and Ceylon in the cultivation of the Cinchona plant has produced a revolution in the market, so that the price of Howard's Sulphate of Quinine, in place of being 10s to 15s per ounce, is now down to 2s 6d. If the British Government has sinned in encouraging the consumption of Indian opium in China, they are now making some amends.

and it is hoped that the present considerable exports of the antidote will be vastly increased by the action of the Society to whom Mr. Ferguson has addressed himself.

Probably the doctors may dispute the value attributed to quinine in the case of opium victims; but there can be no question of its importance in reference to the general condition of the people in China, India and the Fen and other marshy districts in England, where malaria prevails and where the popular belief continues to be that quinine is a tonic far too expensive to be thought of in connection with ordinary everyday requirements. This belief, country dispensers do little or nothing to dispel, but rather encourage it by the high rate—usually 1d a grain, or 40s an ounce—charged for quinine. Far more intelligence of course is displayed in London in regard to the bearing the very low price ought to have on the distribution and use of the article. One wellknown doctor has been heard to say:—"No one in England ought to have a cold this season with quinine so cheap as it is." This points to the need of a wide distribution, say by the sale of 6d and even 3d packets, of the tonic by grocers, or at bookstalls. This was suggested some time ago in your columns by Mr. Thomas Wright (whom, by the way, I was glad to meet in the City the other day looking exceedingly well). The idea of doing something to promote a wide popular sale in this way has been seriously discussed in leading City offices connected with the cinchona bark trade, and no wonder when one hears of the ruinous losses holders of the manufactured article are bound to make if a better demand do not spring up. One gentleman invested in 10,000 ounces at 3*s*. some time ago, thinking the very lowest point had been touched; and now a Philadelphia firm, interested in lowering prices, speak coolly of quinine coming to a shilling an ounce as an established rate, which, they say, will leave from 100 to 200 per cent profit to planters of Ledgeriana! In the City this week I got some interesting information from the head of a house largely concerned in the bark trade, Messrs. C. E. Meier & Co. This firm, I believe, acted for the Syndicate which held a very large quantity of bark at the time that Ceylon was thought to have reached its maximum export with 8 to 10 million lb. But the unexpected development of our Colony's trade in this article—unexpected as much in Colombo as in London—played "ducks and drakes" with the position of the Syndicate, profits being substituted by heavy losses I fear—and all through the extraordinary operations of "the Sinhalese planters," as some Londoners speak of our bark cultivators and exporters. In 1881, Mr. Meier and his colleagues contracted with the German Government for the supply of £220,000 worth of bark (I think at 11d the unit of quinine—now the price is 1½d to 2d) and £90,000 worth of quinine! No such heavy transaction in the trade has taken place since. In fact the whole value of the annual trade in London, in consequence of the fall in price, is now scarcely worth so much as this one contract—at any rate the sales of this year do not aggregate as much. Mr. Meier recommended a friend who holds quinine for over 3s, to sell at 2s lately, but no, the other—a man of capital—is determined to see his investment through for some time yet, whatever the result may be.*

I was, however, assured in this office that, on the whole, the consumption of quinine—especially in the Southern States of America—had very largely increased of late years. The total rise has been from 40,000 kilos (88,000 lb.) to 200,000 (or 440,000 lb.),—that is for the world's consumption at present; nor are the stocks considered unduly high in view of this demand, although the manufacturers have a great deal on hand. Still, the latter cannot afford to keep their staff idle, and bark will be bought, at least all bark of 2 per cent and upwards. Mr. Meier tells me that there is sometimes as much as 1 per cent difference in the London analyses of the same bark, through the great difficulty attending the drawing of fair samples, and this accounts for the very different values by different brokers of the same stuff at times. It is not thought that low prices affect the leading manufacturers too much: they generally calculate on 6d an ounce, and two chief houses at least—Howard's and Pelletier's—manage to keep up their price, though many people do not consider their quinine (at 2s 4d) much more valuable intrinsically than that sold in "the Lane" lately for 1s 4d.

The question asked now is "Has the limit of profitable harvesting and export been reached for Ceylon bark, with the price at from 1½d to the unit of quinine?" In the case of South America, London authorities are very decided that nothing can be done in respect of forest bark, and even in Bolivia and on the cultivated plantations, the cost of land carriage is a very serious item, nearly as much as first cost of the bark. The quantity of cuprea bark available was accurately estimated in London soon after it came into use, through what was known of the forests; but no one feared such an influx of stuff from Ceylon. The average, too, of bark this year has been much better than last, and it would seem that year by year our barks on the whole are improving, although we cannot equal the Java barks rising to 10 per cent, which have been already seen and more of which are expected in the market.

It is, however, quite a mistake to suppose, as Mr. Hody Cox and others do, that if the commoner qualities—the kinds of bark below 2 per cent—were not exported from Ceylon, the prices would rise in proportion to the quantity less exported. The big buyers in London study the *percentages* quite as much as the *quantity* exported. A million lb. twigs kept back might not have so much effect on the market as one-fourth that weight of root or renewed bark. Of course, it is not expected that it will now pay Ceylon planters to harvest, pack and ship the very common qualities. But the information got by a well-known planter as to the quantity of bark received by the Ceylon railway from the older and northern districts shows in a very interesting way how apt we are to be deceived as to the quantity and location of the bark left in Ceylon.

* A Ceylon holder of bark in London is said to have entered in his will in case of accidents that his stock is not to be sold until the market has risen!

TEA CULTIVATION: SPECIAL PAPER.

By MR. C. S. ARMSTRONG.

PRUNING—PLUCKING—YIELD—AND HOW TO OBTAIN IT.

(Written at the request of the Dimbula Planters' Association.)

Mr. Chairman and gentlemen,—I regret that a short notice and many pressing engagements prevent my dilating as fully as I could wish on the subjects you have asked me to express my opinion on today. I trust, however, I have touched sufficiently on each, to show those who require it the way to obtain 400 lb. an acre, and more, if this will not content them. It is necessary to say my remarks apply to tea at 3,500 feet elevation up, and as in duty bound to your district, Dimbula, especially. Before entering on my subject you will excuse I am sure my giving you a few words of advice. Think well before sacrificing good coffee to tea, lu

by all means have both. When, after due consideration, you decide upon what fields of coffee to plant with tea, lop your primaries, leaving only 2 sets on. Line carefully, *take only one crop off your coffee, and uproot it.* A wavering policy here is fatal to both coffee and tea. Make up your mind which you are going to have and stick to it. Our experience, and certainly mine, for some years, now, has shown me this advice cannot be too often repeated. Tea to pay must have the ground to itself, coffee the same.

TIPPING, TOPPING, AND PRUNING.—Before telling you what to do, it is best I should tell you what not to do. Do not let your young bush grow away unnoticed, and think you are acting kindly by it in allowing it to "form root." How often do we not hear this expression made use of. Watch it carefully, and when you find the majority have reached 30 in. "tip" back everything that will make tea, at above 24 in., using a measuring stick with a cross piece at 24 in. as a guide. After this pluck away in the usual manner, always above your first level, 24 in. up, until your bush gets a little topheavy, or at four to six months from "tipping;" "top" with the knife at 15 in. to 18 in. according to jât and elevation, cutting straight across your bush with a level surface, and touching nothing below this. Your bushes will now carry you on with regular rounds of plucking for 12 to 15 months, NOT LONGER, when they are ready for their first *pruning*. Pruning is a most important work, although most simple —and here again it is best I should tell you how not to do it. Our good friend Ramasamy is a capital coffee pruner, and he thinks tea should be pruned in the same way, and some of us agree with him. Do we not see every day a most elaborately pruned tea bush, centres all well cleared out, laterals stretching their long (too long) lean arms all round the bush as if we were trying to grow fishing rods, and do we not for a short season feel proud of our neat pruning and great stretch of bush? "That is the way to get a cover, my boy!" and so it is, but not leaf. It will be found but too soon these long lean primaries give us a bunch of shoots that don't hurry themselves to be plucked in the least degree. The deluded pruner blames the weather: too much rain, too much sun, those cold nights, that dry wind, anything but his system, and this system, too much thinning out, and too much stretch, it is difficult to break Ramasamy of, who approves of it, and who, when he thinks he is right, is obstinate, our difficulty with our pruner is then to get him to leave on the wood and not to cut it off.

HOW TO PRUNE.—Give your pruner a measuring stick at 3 in. to 3½ in. long. Let him place this in the centre of the bush at the shoulder of the shoot starting from last year's cut, and cut straight across his bush at this level,—3 in. higher than last cut, which was say at 18 in.—our surface is now level at 21 in., tip back with the knife all laterals below this surface, into the same style of wood if possible as is at the surface, reducing proportionately the girth of our bush from our surface level to the lowest lateral, endeavouring to cover it with the same strength of wood as far as is possible; in any case always cut to one eye below *green* wood. Having cut our surface to a given level,—from the centre outwards, moving round the bush as we cut,—and tipped or cut back all the side branches, we next proceed to "*handle out*" from off the OLD primaries all their weedy growth that has not developed into laterals sufficiently strong to be cut back. Do not allow the bush to be overstripped, if in doubt, allow the weedy shoot to remain, another season will prove its value beyond doubt. Do not strip off any leaves below the pruned surface, and do not aim at making the bush too thin. Cut below a "crow's foot" always, but with careful plucking these will not be found at our pruning level. This is all. Proceed thus, rising 3 in. to 3½ in. for at 4 to 5 prunings.—I say advisedly prunings, not years, as an annual pruning is not necessary—which will have brought up our bush to at 30 in. to 33 in. Our pruning after this is a *cutting down* again to at 18 in. to 24 in. according to jât and style of growth on the bush. It is impossible to give a fixed height as much depends on the bush that is operated on. Suffice it to say it should not be lower than 18 in. nor higher than 24 in. Here again curtail your bush proportionately all over from the surface to the lowest lateral, leaving on here also the same style of wood all over, this time all old hard wood, and gradually bring up our bush at each *pruning* as before, till 33 in. is reached, only let the first pruning be at 4 in. above the "cutting down" level, as the eyes, with shoots given by such hard wood as we will have pruned into, will be further apart than is the case with the first flush from younger wood, and we should aim at having two to three eyes to give out shoots.

THE BEST SEASON TO PRUNE.—So far as my knowledge of your climate goes, and I have had considerable experience of tea in Dimbula, your pruning should be done between the months of June to September. Your *best* plucking months are October, November and sometimes December and March to May, sometimes June, always dependent upon the weather, a month earlier or later according to the severity of the S.-W. rains, and the temperature during the N.-E., December to February. In taking pruning in hand the one object to keep in view is to bring our bush into the best flushing condition for the best months, and sacrifice yield (as we must, when we get it all the year round) during the worst. After the first pruning after topping, a twelve-monthly pruning is not necessary, and here comes the difficulty, how to run our bushes with the least loss? We must sacrifice a little in order to gain much. Let me give you an example, always open to exception dependent on condition of wood which again is dependent on the weather. Say planting in the S.-W., "tipping" takes place the following S.-W., topping had best be done in February following, towards the end. March and April will develop our bush well, which is all we seek for at this period; our first pruning would take place in May year, say the 15th month from topping, thus getting the full benefit of March to middle of May. Our second pruning would take place during August year, thus running our bushes about another 15 months, October bringing forward our bearing wood for us. The third pruning might be done September-October, equal thirteen to fourteen months. The fourth pruning, July-August, equal ten to eleven months. Our fifth pruning in the same months, equal twelve months, if the bushes do not require cutting down, which will at this stage be found necessary sometimes. If they do, then begin this in June, when with a good hybrid jât and *with careful plucking* it will be found they will run two full years. We thus run our bushes from the first pruning for five years and seven months before cutting down, and again for six years and seven months to the next cutting down, and on thus. Above example is not to be considered a rule. No rule can be laid down except when *not to prune* in Dimbula, so much depends on jât, soil, aspect and *plucking*. However, with a good medium hybrid and careful plucking, above example

may be worked on safely. It is a much easier task to tell you when not to prune as at 4,500 ft. elevation up. Do not prune as between the middle of November to February, more especially during December, January and February. It is too cold, with frost sometimes, as last year, to develop good running wood in time to get the full benefit of your best months, which then merely serve to form the bush for your worst. I would, however, rather prune in December or January than defer it to March or April, as it is better to form wood before than in your best months, and the greater the state of perfection you can bring your wood into for the best months the better. To sum up then, try and avoid pruning during the months of December, January, February, March, April and until after the burst of the S.-W. in May. Choosing in preference to all months July, or as it is impossible to complete the pruning in one month and keep the labour going, let it be done for choice during July, August and September. And to sum up again: after first topping, your bushes may as a rule run with most advantage 15 months up to 16 months, and under exceptional circumstances up to 18 months, thus for two prunings, say two to three more at 12 months, when cut down and run for 24 months, always dependent upon careful plucking, as I said before, and a good hybrid to back you.

PRUNING, a most important factor with regard to yield, requires much more space than we have time today to give it. I trust, however, I have touched sufficiently upon it to be of some assistance to those of you gentlemen who require it, and always bear these two rules in mind: *Never cut away a good lateral and tip back everything.*

PLUCKING.—As a general rule *here* is where fault has to be found, and here it is that yield is lost. You make a great fuss about your surface, your topping, your gentle treatment afterwards. You start your coolies at plucking and hug yourselves with the belief that all must now go well in the field, and those of you who have factories stick at them all day, thinking your own individual presence is here absolutely necessary in order to make good tea, kicking up an occasional row with your pluckers, because their average is short, you take every opportunity of talking about manufacture and of picking up all the wrinkles you can on this subject. Quite right in its way, but you do not begin at the fountain-head of all good tea—the plucking of the leaf—so long as you get good looking leaf and a fair average you are content. You never made a greater mistake. Time goes on, your "liquor," with all your personal care and attention, is not quite as good as you hoped, or as you deserve, after all the care you have given to the manufacture of the leaf, carrying out to the letter every rule you know or can hear of, and then, whilst suffering from a rather more violent attack of dyspepsia than usual, brought on by "strict attention to business" and your tea drier, your kangany in reply to a pertinent question as to the reason why the leaf is falling off in quantity, tells you there is not enough rain, or there is too much. The appearance of your bush does not please you, and you call in the aid of "one of those tea chaps" who tells you you have over-plucked, and there is nothing for it but to cut down and lose two of your best months. This is not an overdrawn picture, gentlemen, and much as supervision is necessary in the factory it is equally as necessary with the pluckers, and walking over the tea fields to judge how to continue your round and when to "lift" your pluckers—owing to various causes which it is unnecessary here to enter upon, it is sometimes necessary to "lift" your pluckers over a field and give it a few days longer law—again you may find you are getting too rapidly over the ground, which would result in too severe treatment with the last portion plucked, throwing the flush back and making each succeeding round harder on the bush, till it "shuts up." Afford yourselves then a "tea maker," train him well, when an occasional "look up" will keep all going as it should be in the factory, and give all the time possible to your pluckers, with an occasional walk round the totum to see how the various fields are coming on. Without good healthy leaf you cannot make good tea, and without constant attention to your pluckers you will lose yield, and in losing yield, good leaf—*i.e.*, good liquor. I will now give you safe rules to go by to insure good leaf and good yield, and pray understand me, these rules apply to high-grown tea only. We are supposed to be working on a good jât hybrid "topped" at 18 in. (not pruned, remember), age say 18 months to 2 years. Pluck your first round at 24 in. and above, using, for one round only, a measuring stick with a cross piece at 24 in; with this stick in the centre of your bush, the cross-piece aids the plucker in plucking at a level surface, take everything that will make tea above 24 in. at one "pluck," *i.e.*, with as many leaves and the bud on each shoot plucked, as will make tea, leaving full leaves below the level; tip off bangy at sides but pluck no running growth below 24 in. So soon as the bush has thrown out another primary growth which shows above the last level plucked, pluck it at the level; with secondary growth pluck, allowing one developed leaf and the "fish" leaf to remain on the shoot, tip "bangy" as before, and as some of the laterals or side shoots, especially low down on the bush will now show signs of a stoppage of growth, pluck these, removing at one operation a bud and a leaf, and if a thin straggling shoot, a bud and two leaves. From now on, tip all side branches that will not run up to the level, and pluck surface and sides at one full leaf above last plucking, and thus till the time comes to prune. After pruning pluck primary growth at the surface at above two to three leaves according to the strength of the shoots and the jât; at the sides, at above three to four leaves. Pluck secondary growth at above two or one leaf, as the case may be, at the surface; and at above two to three at the sides, pluck tertiary growth, at the surface, at above one leaf; at the sides, at above one or two as the case may be. Pluck all succeeding rounds at above one leaf, and on thus. Another mode, necessary with a lower class hybrid, is to pluck to a shoulder thus: primary growth after pruning pluck at above three leaves then take half the top leaf allowing two leaves and a half (a shoulder) to remain. Secondary growth pluck at above two leaves and take half the top leaf equal one-and-a-half leaf remains, the sides the same way, beginning at one leaf higher, getting to the one-and-a-half leaf stage at the tertiary instead of at the secondary growth. At about six months the bush will begin to show rather thin flushing wood. When this is apparent, discard the shoulder plucking and pluck down to at above one whole leaf, when the shoots will thicken out again. Light, thin, semi-bangy flush it is that gives poor liquor, avoid getting this style of growth on your bush. Growth of flush is more rapid from a shoulder than from a full leaf, but thinner; and therefore although at the beginning of the season the yield from a shoulder plucking will be heavier, it falls off as the season advances. The exact opposite is the case with the full leaf plucking. Be patient, and pluck strictly according to rule, although you may be leaving that which will make tea on your

bush. Always bear in mind your bush has to carry you through a whole season and well into the next, by worrying your bush you get more out of it, but for a short time only, and as the season advances you lose all you have gained and more, finding yourself with a worn-out bush throwing out thin weedy flush with nothing in it. By starting with careful plucking you not only produce healthy flushing wood, but you are also bringing your bush into its fullest development with power to give you its full yield. To quote from my former paper: —"One simple rule is to avoid having a bare shoot without a leaf to help your next flush on, and give it a healthy, strong growth. I myself used to be an advocate for shoulder plucking, but I find plucking with a full leaf runs your bush longer without pruning, is less strain on it, gives well-formed flush, and, taking two seasons together, better results in yield, although under some conditions and with some jats shoulder plucking is still the best. Pruning on the same principle I advocated when the Dikoya Association honoured me by asking for my views four years ago. I now "tip" with the finger where I then topped with the knife, thus beginning to form my bush by bringing up the lower laterals, and I cut my bush lower at the first pruning. I find whilst developing my bush quite as well I get a very much larger yield at two years to five years, and this without any injury to the bush whatever, and without reducing its growth laterally. I may as well explain what I mean by primary, secondary, &c. growth, in plucking. Primary is the first growth from the pruned branch, secondary the shoot from a plucked primary, tertiary a growth from a plucked secondary. A rule for plucking cannot be laid down for first round, second round &c., as it will be found our second, third and sometimes fourth round, is of leaf plucked from a primary growth. It may at first sight appear a difficult matter to get our pluckers to follow out the rules I have here laid down: plucking at above three, at above two leaves and so on; I have not found it so in practice. You should, of course, put on a gang of your best coolies only to start your plucking after pruning, and when you get to the one leaf stage, it is impossible for the pluckers to go wrong.

YIELD.—Your tea in Dimbula has been, and still is in many cases, much handicapped by coffee, and loss of yield the consequence. This should not disappoint you. I think also you are a little impatient. Take my own experience at Rookwood, where my old tea runs at from 5,000 to 5,600 feet elevation. My yield per acre at 2½ to 3½ years was only 165 lb. made tea per acre, at 3½ to 4½ 292 lb., at 4½ to 5½ 262 lb.—the falling-off in yield this year was due to a heavy pruning—at 5½ to 6½ 450 lb., and for the four succeeding seasons ending the 30th September last, I can show an average yield at 650 lb. per acre, which I may now look upon as my average from this tea for ever. I say advisedly for ever, as tea where it does grow seems to be everlasting. Now, gentlemen, what do these figures prove? 1, that high-grown tea does not come into full bearing till its seventh year, although giving remunerative crops at from 2½ years up; 2, that when you once get a yield you can maintain it. It may be argued, four full seasons is not long enough to prove this. Old Loolecondura can give us three times this, or twelve seasons, which will prove the same thing, an even average yield throughout. Let us come nearer home for yield. Look at Abbotsford, and what our good friend of the *Observer* has shown us it can do. I am told last year this estate averaged 500 lb. per acre for young and old tea, 2 years to 10 years old, of which the greater portion is young. You have the soil, none better in Ceylon. You have a leaf-making climate, as witness your coffee. And your tea is not planted upon that mythical "washed out coffee estate." With the land given up to tea, and with proper treatment to this tea, 400 lb. an acre and more in such a district as yours is indeed easy of attainment, with your bush matured. Four years ago I publicly stated that our Tea at six years old and up, in good soil, might be safely estimated to give an average yield of 400 lb. per acre, and with increased experience I can today repeat this. I trust the few remarks I have made today may put you on the right road to obtain this. And let us now prepare for the future, and one and all pull together, to push our teas and make new markets for them, and with this object in view I would entreat those of you who have not yet promised your support to Mr. Rutherford's scheme to do so now without delay.

C. SPEARMAN ARMSTRONG.

GROUND COFFEE digested in cod-liver oil quite over comes the fishy taste of the latter.—*Chemist and Druggist.*

HOME AND COLONIAL TOBACCO CULTURE.—The following letter has been received by the Secretary of the Ceylon Chamber of Commerce:—"Botolph House, Eastcheap, London, E.C., 13th Oct. 1887. Dear Sir, —I beg to remind you of the circular I had the pleasure of sending you in March last with reference to the two prizes of £50 each, offered by this Chamber's Tobacco Trade Section, for the best samples of home and colonial grown tobacco. In transmitting the circular, I requested your assistance in making the offer known in your district by such means as you thought desirable, and I shall now be glad if you will kindly circulate through the same channels a further notification of the sixth condition of the competition, viz., that 'the tobacco grown in the United Kingdom shall be sent for inspection on or before the 1st of March 1888, and that of other places on or before the 1st of December of the same year.' My tobacco section also desire to be informed of the names of competitors as early as possible, in order that proper storage room may be provided; and would call attention to the removal of the London Chamber from King William Street to Botolph House, Eastcheap, London, E. C., to which address all communications should be sent.—Yours faithfully, KENRICK B. MURRAY, Secretary."

COOWAREE SEEDS.—At the last drug sales, 15 bags of pale coffee-coloured seeds, cylinder shaped, and about ⅛ in. in length, the ends being somewhat oblique, were offered for sale. No one appeared to have the slightest idea of their use, and the lot, altogether about 22 cwt., was withdrawn. The parcel was imported here from Bombay, and we understand that the seeds have been identified by Mr. Holmes as the seeds of *Cassia tora*, Linn., or oval-leafed cassia, called *Kulkul* by the Arabs and *Peti tora* by the natives of Ceylon. The shrub which attains a height of about 5 feet, grows in most parts of British India, and is extensively cultivated by the natives for the sake of its leaves, which play an important part in Hindu pharmacy. It also grows in Japan, and has been found in Central America by Houstoun. In Cochin China, also, it is very common, but in the latter country, it does not seem to rank among the medicinal plants. The *Cassia tora* seeds, ground with sour buttermilk, are occasionally used as a cure of itchy irruptions; but the leaves, which are strongly mucilaginous and of a highly disagreeable odour, are a household remedy among the Hindus. In the form of a decoction they are given to children during teething, fried in castor oil they are used as a cure for foul ulcers, and finally, rubbed up with lime juice, they form a popular remedy for ringworm. For the latter purpose, and in a similar manner, the root is also used. In Western India a blue dye is also made from the seeds in combination with *Nerium tinctorium*, Roxb. The seeds have been imported into this country before now, but it does not seem that there is any demand for them.—*Chemist and Druggist.*

THE SAFFRON CROP.

The Spanish saffron crop which has now been gathered has, according to all accounts, been an exceptionally good one, rain having fallen throughout Eastern Spain in time not only to save the crop but to benefit it materially. In the ordinary course of things a considerable decline in the price of the drug may therefore be expected, but as the article is a comparatively small one, and liable to be kept artificially at high values by speculation, it is doubtful whether after all the quotations will fall to the extent which the circumstances would warrant. In 1885 and 1886 the Sanpish saffron crop, which governs the market of the article, remained much below the average, and the price has therefore risen to an abnormal figure, as much as 56*s*. per lb. having recently been quoted for best Valencia saffron. It must, moreover, be borne in mind that the stock left over from last season is a very small one. An average crop in Spain is estimated to produce about 110,000 lb.; but we have heard it stated on good authority that the cultivation of the plant is extending, a statement which appears strange in the face of the fact that the field for the employment of the article is certainly not increasing. Dumesnil has calculated that it takes about 7,300 flowers to yield one English pound of fresh saffron, which by drying is again reduced to about one-fifth of its original weight. To a person of an arithmetical turn of mind it will therefore be evident that the total yearly saffron production of Spain should represent something like four thousand millions of flowers; but much of, if not nearly all, the saffron brought into commerce is more or less adulterated, most frequently by the addition of calcium carbonate and similar ponderous substances; and this calculation is therefore probably rather above the mark. But it is clear, at any rate, that the collection of the drug is a most laborious occupation, and it is scarcely a matter of surprise that the mere cost of gathering the saffron, even in a country where labour is so cheap as in Spain, should be said to be over 15*s*. per lb. The bulk of the Spanish saffron is brought into commerce by way of the port of Valencia, to which market it is carried from the growing districts in the provinces of Aragon, Valencia, Murcia, and Andalusia. The saffron business forms a considerable branch of trade in the city of Valencia, but the market is dominated by a few large houses. From Valencia the saffron is distributed to different quarters of the globe, Marseilles receiving the heaviest consignments. Alicante is also a centre of the Spanish saffron trade, but it has lost much of its former importance in consequence of the barefaced manner in which "loading" with mineral substances is carried on there. Alicante saffron, for this reason, is generally quoted from 30 to 40 per cent lower than the Valencia variety. Of late years Marseilles has gained considerably in importance as a saffron market. In 1886, 51,280 lb. saffron were imported there, while the exports amounted to as much as 59,342 lb., two-thirds of which went to British India. The Marseilles market has also obtained an unenviable notoriety for systematic saffron-doctoring, and it is there that the article is especially manipulated to suit the requirements of the different markets. British India absorbs the commoner qualities of saffron; that country is the largest consumer of the drug, it being a highly-prized ingredient in Hindu cookery, as well as a valuable colouring agent in the manufacture of those textile fabrics for which India is famous. In Europe the use of saffron as a dyeing material in textile industries is now almost obsolete; but it is still largely used as a colouring matter for confectionery and other foodstuffs, as well as in the manufacture of liqueurs and gold-lacquer. Bird-fanciers also use it to some extent, believing it assists the birds in moulting. It enters into seven B.P. preparations, the principal of which are tincture of rhubarb, compound decoction of aloes, and Huxham's tincture. The colouring power of saffron is said to be so great that one single grain of the drug, rubbed up with sugar, is capable of giving a yellow tint to ten gallons of water.

A fine variety of saffron is produced in the French district of Gatinais, near Orleans, but in all porbability only a very small part of the saffron sold under that name is really of French growth. The total yield of Gatinais saffron is said to average about 7,000 lb. per annum, yet French official statistics show that in 1886 alone no less than 70,634 lb. of saffron declared to be of *French growth* were exported from the country, the greater part to Germany. In Austria some saffron was formerly cultivated, but the industry has apparently been abandoned, as it had become unremunerative to the farmers. It is, in fact, the principal obstacle to saffron-growing that the cultivation of the plant requires such immense care, and the growing crop is so easily damaged, while on the other hand the yield is so comparatively small that the cost of production must always remain too high to admit of any large extension in the use of the article. In Italy saffron-growing is said to be reviving, and about a year ago we had occasion to inspect some very fine specimens of saffron raised in that country. Beautiful saffron grown in Ceylon was also exhibited at the Colonial and Indian Exhibition, and it seems strange that more attention should not be paid to the cultivation of the drug in that island, as well as in other parts of our British Indian possessions (where it is known to succeed well), considering its extensive employment in India in the arts and for domestic purposes. A bulky treatise might be written on the various modes of adulteration practised on saffron and the tests recommended for the detection of these sophistications; but the best *Prima-facie* evidence of the genuineness of a sample is certainly that the three stigmas of the crocus, which form the saffron proper, should be found united at the base, as in nature. In the middle-ages the adulteration of saffron was a capital crime, and in the middle of the fifteenth century several people in Germany found guilty of that offence were buried alive or burnt at the stake *pour encourager les autres.—Chemist and Druggist.*

SHORT MANUAL FOR THE CULTIVATION OF JUTE:

By the Resident J. A. B. Wiselius.

(*From "De Indische Mercuur."*)

There exist two principal species of jute (goni): 1st, the Corchorus capsularis, and 2nd, the C. oliturius, which both are important for the fibre formation. The fibre of the last named species is used by preference in the jute-weaving business. They are mostly cultivated in the lowlands and on watery grounds, while the C. capsularis thrives better on the higher grounds (tegallans). Both species of jute nevertheless may be grown successfully on tegal as well as sawah and rawa-grounds. That planted on tegal-grounds has a short but fine fibre. More general is the cultivation of jute on grounds which are covered from time to time by shallow water, or which are often inundated, or on which a layer of slime has been left behind; on sawah-grounds and on those composed of clay and sand as on the banks of rivers, etc. The best sort is thought that which is grown on garden grounds (pekarangans). Soil, which is never totally inundated, whether situated in low or high lands, but is never dry and always moist, is said to satisfy the best for this culture. The jute grows luxuriously in a warm and moist atmosphere.

When the plant has reached a height of 2 feet, heavy rains cannot hurt it any more. In general, the plant is more damaged by too much dryness than by too much rain.

When jute is grown on grounds, which are dependent on rain, it is best to begin tilling the soil before the falling in of the rains. When the ground is of a porous nature there, twice ploughing suffices, but the clods must be well crushed.

For sowing, must be taken the seed of those plants which have not yet arrived at blossoming. The seed cases are dried in the sun for 4 or 5 days, and in very moist districts to even during 10 days. Then they are dressed, and the forthcoming seed is preserved in baskets: per bouw (acre) may be obtained †4½ picul of seed. About 6 catti of seed will de needed

for sowing 1 bouw. The sowing is done with a broad throw, and rather on a clear day. A thin layer of earth is strewn over the sown seed. If the time allowed is sufficient, the plant profits better by sowing the jute seed first on a nursery ground, and replanting it afterwards (as padi). The time for sowing is not everywhere the same. It is preferable doing it when a first shower of rain as forerunner of the rain monsoon has moistened the soil. Germination of the seed takes place in moist regions in 3 days, and in a dry climate after 7 days. Once or twice thinning and weeding is to be recommended. The little plants ought not to be nearer one from another than 8 or 10 centimeter.

The ripening of the plant takes place 4 months after sowing, and after one month more, the crop is gathered. With manuring and sufficient irrigation, one harvest of padi and one of jute can be reaped in a year.

The cutting of the plant takes place just above the root.

When reaped too soon the fibre is weak, and when the plant is already running to seed, the fibre is duly strong, but not glossy and too stubborn for proper spinning.

After the harvest, the plants are bound in gerbs, or they are let lying in little heaps on the field to expose them to dew and sun till the leaves have fallen off. Then the plants are bound together in bundles, so as to form the freight of one man, and are laid in water for softening. Both standing and streaming water have their advantages on this view, which cannot now be further explained.

By the process of softening or maceration, care must be taken that the whole bundle remains submerged. The time during which the bundles must remain submerged, depends much on the nature of the water, and may be from 3 to 30 days. But when the softening lasts too long, the fibre loses force and colour. Precepts in this matter are difficult to give; however, care must be taken, that no black spots are shown on the fibre, for these diminish its value. When the maceration has proceeded so far that the fibre loosens itself, then the bundles are unbound, the stalks are taken in the hand and struck or shaken some time in the water, that the slimy parts may be severed. By this process, the fibre loosens itself naturally, first at the tenderest part, but by continued striking the rest follows easily. The cooly, performing this labour, stands to the waist in the water; he takes so many stalks in hand as he can hold and strikes these with the butt-end on the water, holding the thin ends in his hand. To hasten the loosening of the fibre, an incision can be made at some distance of the root and at the top. Another method is to bruise the top of the stalk a little with a wooden hammer, after which the fibre can be stripped off from the stalk with the hand. By this last method it is not needed to let the stalk soften during so long a period, and the fibre will be stronger. One man can prepare by peeling a hundred or more of plants in a day and deliver at least ¾ picul of fibre. After stripping and peeling, the fibres must be well washed and wrung out afterwards. The more washing is done and the purer the washing water is, the whiter the product. The value of the product declines considerably when the jute is not totally dry before being bound in skeins or bundles for exportation, and it is by carelessness in this respect, or because moisture has been expressly let in to make the produce heavier, that so much inferior species are brought to the market.

The preceding shows, that for the native with own labour, the costs of producing jute are small; if, however, as by the culture of rice one should wish to achieve every factor arising in the cultivation by hired labour, and this labour should be paid, then the cultivation of jute can be not, or little remunerating.

For fear of exhausting the soil, it is well not to sow jute more than twice in succession on the same field. It is best to grow padi and jute alternately on the same grounds, if, namely, sufficient water can be obtained.

Moreover jute has the peculiar quality of destroying the germs of weeds which grow between padi. Besides the fibre, the plant yields still other advantages; the leaves and the tops of the plant are a savoury vegetable, the stalks serve as firewood; the roots are sought as material for paper-mills, and the seeds can be used for the fabrication of oilcakes for animal food.

In Bengal where much jute is grown, it is said that rice and jute are the principal elements of the native agriculture in those districts where both grow well. A bouw (acre) may produce from 15 to 45 piculs of jute, and on good sawah-grounds with living water and careful management, still more.

Some years ago, at Calcutta R2½ were still paid per basket (=3/5 picul) of rough jute. Perhaps the product has become cheaper now, but the great demand at that place for good rough jute also renders the price of the product stationary.

VARIETIES OF BREAD—FRUIT.

From the proceedings of the Madras Agri-Horticultural Society, we quote as follows:—

Read the following letter from B. Lovery, Esq., dated Palmlands, Kelpauk, 17th September, 1887:—

"When I was in Bangalore last year, my attention was drawn to the Seed Bread-fruit tree growing in the Lal Baugh, and which the people there regarded as the only variety of the *Artocarpus incisa*. The gardener showed me a quantity of seeds resembling those of the Jack, or *Artocarpus integrifolia*, collected from the trees in the garden, and told me that they are not edible, but that the tree was cultivated on account of its handsome foliage. Evidently the seed variety was mistaken for the seedless. To correct this erroneous notion, I addressed the accompanying letter to one of the local papers and put myself in communication with Mr. Ricketts, the Conservator of Forests, Mysore, to whom I sent a few of the seedless fruits from my garden in Madras. He tasted one after having cooked it in the mode I had explained in my letter, and sent one to H. H. the Maharajah and one to the Dewan, all of whom, Mr. Ricketts afterwards told me, pronounced it a very palatable fruit. I also sent him a sucker from my tree, but it died in a few weeks. I mean to present the Lal Baugh with another sucker, the only one I have at present, as soon as the cold weather sets in, for I wish to see this valuable food-producing tree propagated as widely as possible in this part of India.

"In continuation of the observations contained in the paper I am forwarding for the Society's information, for I know you are interested in the cultivation of this edible fruit, I have to state that the modes I have tried for obtaining plants from the parent tree, *viz.*, inarching on seedlings of the common kind, putting down root cuttings in pots of sand, digging a trench around the tree and laying bare the roots here and there, have all failed. But I am inclined to think that the failure of the two last modes was owing to mismanagement on the part of my gardener, for Sir Madava Row put down some of the root cuttings in his garden at the Luz, and has succeeded in obtaining 2 or 3 shoots, which are now in a thriving condition. I mean to repeat the experiment this cold season; and shall be happy to forward some roots to the Society's garden for a similar trial by the Superintendent. The plants which I gave to some of my friends in Madras in February, 1886, are growing up vigorously and promise to become fine trees in course of time.

"The young tree in my garden, now about 7 years old, to which I refer in my paper, and which is a sucker from the old tree, is now bearing for the third time, though not as plentifully as the parent tree; but the fruit is lighter, larger, and has a better flavor. I send you a couple by the bearer.

"I learnt from some works on Botany, kindly lent to me by Mr. Ricketts, that besides the use of the fruit, the economical purposes to which the other

parts of the tree are applied are various. The wood is used for building boats and houses; the leaves, which you are aware are divided into lobes, for wrapping up food and wiping the hands instead of towels; the juice, which is milky and gummy, for making bird-lime and a cement for filling up cracks in vessels for holding water; and the flower when dried serves for tinder, and the inner bark beaten together makes a species of the South-Sea cloth.

"The edible quality of the fruit appears to be owing to the presence of a large quantity of starch in its succulent head. The milkiness of the sap is in itself evidence of the presence of caoutchouc.

"If the plant I sent you last year has died, and if you care to have another, I shall be glad to give you the sucker I have reserved for the Lal Baugh, and send that Garden the next plant I may succeed in getting from my old tree."

Read also the following paper referred to in the above letter:—

"*The real Bread-fruit tree.*—There are two varieties of the fruit, one containing seeds, and the other none. The former is much inferior to the latter, though in cases of need it is roasted and eaten by the natives of the South Sea Islands, where the Bread-fruit forms the chief support of the people. It is the seed variety that is found growing in the Lal Baugh and in some gardens of Madras, and is, I fear, mistaken for the other more useful variety. The seedless fruit, when roasted or boiled and the rind pared away, is fit for food; the pulp, which is farinaceous, has a consistency like that of wheaten bread, and is pleasant to the taste and highly nutritious. The other fruit, when cut open, is found to contain a number of hard seeds resembling those of the Roseapple, imbedded in a pulpy substance as in the Jack-fruit, another species of the Bread-fruit. I am not aware if the seeds are eaten by the natives of this country. Perhaps the Superintendent of the Lal Baugh will be able to tell us.

"The tree referred to by Captain Cook and other navigators was evidently the seedless variety, of which I have two in my garden, the only two in Madras. One is more than 30 years old, the plant having been brought by a former owner of the house from the Western coast, where it grows plentifully; and the other about four or five years, a sucker of the old tree. It bears twice a year, in January and February, and in June and July, and in each instance there are not fewer than four or five hundred fruits on the tree; hence confirming the statement that in the Pacific Islands one or two trees will suffice for a man's yearly supply, and that a tree is considered a a fortune for a small family.

"The young tree began to bear in the third or fourth year of its growth. The first crop was very scanty, consisting of two or three fruits only, but the second, during the current month, is very plentiful, and the fruit is considerably larger in size than that of the parent tree. I have tried several modes of propagating this tree, but have failed in all but one, but the success even in this single instance was so partial that I am inclined to doubt the general efficacy of this mode.

"I had a few roots dug up, of the thickness of the forefinger, cut up into pieces of six or eight inches in length, and buried horizontally in pots. After the lapse of many months a shoot appeared only on one of the roots, which I reared with care and forwarded to the Agri-Horticultural Society in Madras in February last. Why the other roots have not put forth any shoots, I am unable to say. But Dr. Shortt told me that this is the usual mode of propagation adopted by the natives of the Laccadives, which Islands he visited some years ago. Another mode that has been suggested to me is to dig a trench around the tree, expose the creeping roots here and there, and have the trench well watered. I am trying this, and hope to be rewarded with success.

"The only way then of obtaining plants from the tree is to wait till the roots send up suckers, which, in the case of my tree, has occurred only about three or four times during the past 20 years. When the suckers attain a height of a foot or a foot and a half, detach them carefully from the parent stock by severing the connecting root; allow them to remain in the ground for a month or two, and then, if found to be healthy, transfer them to a pot, whence they may be transplanted any time to a suitable part of the garden, taking care to have the pit four or five feet deep, and four wide, filled with stable manure.

"In February last, I had about six or seven suckers from the old tree, which I distributed among some of my friends in Madras and sent one to the Lal Baugh. I have heard that they are all thriving, except the one in the last named garden.

"There are various ways of cooking the seedless fruit. It may be roasted or boiled entire, the rind pared away and the pulp cut into slices and eaten as a potato. Or remove the rind, cut it up as slices of potato and fry or cook it as a curry. The two latter modes of preparation are preferred by my Hindu friends to whom I have sent some fruits. I prefer it boiled or made into a pudding.

"The bread-fruit, as the food of man, at one time excited so much attention that the poet Byron referred to it in the following lines*:—

'The bread-tree, which, without the ploughshare, yields,
The unreaped harvest of unfurrowed fields,
And bakes its unadulterated loaves.
Without a furnace in unpurchased groves,
And flings off famine from its fertile breast,
A priceless market for the gathering guest.'"

Recorded with thanks and resolved that efforts be made to obtain suckers from the Western Coast, where the tree is reported to be not uncommon.

CHINA TEA.—Mr. Consul Alabaster, in his report on the trade of Canton for 1886 says:—The export of tea was less than it has been in any of the preceding ten years; but although this should have made the business more profitable to those concerned, it is not said to have been a good year. Those who were concerned in the earlier shipments in most cases lost heavily, and those who got the advantage of the better realisation of later parcels, in their own words, were just scraped out. India and Ceylon teas' cultivation has increased so enormously that the market is over-stocked, and for some years at least those engaged in the trade, as with those of late years interested in sugar, are likely to have hard times of it.—*L. & C. Express.*

A CURE FOR COFFEE LEAF-DISEASE.—From the *Straits Times* of Nov. 21st we quote as follows:—

The *Java Bode* of the 8th November announces on good authority the important fact that Dr. Burck, the manager of the Government Botanical gardens at Buitenzorg has hit upon a remedy for the dreaded coffee leaf-disease. His method of cure so far has only been experimented with on a small scale. But the results have been successful enough to warrant sanguine expectations of its effectiveness. In a Java planting periodical attention is drawn to a method of counteracting leaf-disease which seems singularly enough to have escaped the notice of the parties interested. The method suggested offers for all that reasonable chances of success to planters willing to give it a trial. The idea put forward comes to rearing a variety of coffee sure to be proof against the disease. Progress in this line may take different directions. In estates under leaf-disease among the coffee trees, individuals have been met with which have either escaped altogether the fate of their fellows, or have been only partially stricken. All experienced planters know this. They have often noticed the strange phonomenon. The causes of the total or partial unsusceptibility have not yet been made out. Without troubling themselves about the why and wherefore, planters would do well to take advantage of this unsusceptibility by rearing plants sprung from these exceptional trees. By carefully cultivating the variety, they will likely be gainers in the long run.

* The Island, can to the second, xi, line 23.

THE INGA DULCIS.

By Dr. E. Bonavia.

Some time about the year 1864, I obtained some seeds of this tree from Madras and introduced it into the Horticultural Garden of Lucknow. I was told it made good hedges. I found, however, that it made not only good hedges, but good trees, which produced a screw-fashioned pod containing a sweet pulp greedily devoured by natives. I also found that some varieties had a white pulp, and others a red pulp, and that the pulp of some was sweeter than that of others.

This interesting tree appears to have been finally located by botanists under the genus *Pithecolobium*, and called *P. dulce*. Its synonyms are *Mimosa dulcis*, and *Inga dulcis*: the last is short and sweet. The tree has minute spines, and leaves, with two pairs of leaflets. The seeds are black, and are embedded in a spongy sweet substance, either white or red, botanically called *arillus*. Sir J. Hooker, in his *Flora of British India* says, it is "cultivated throughout India, but not indigenous: a native of Tropical America."

I soon discovered that this tree was a valuable introduction for many purposes. If planted thickly and kept closely cut it makes a very good hedge. The tree, singly grown, would make a good road tree. A row of *Inga* trees makes an admirable screen against the hot wind for orchards, gardens, &c. Another good quality of this tree is that, if cut down or blown down by the wind, it does not mind it, but sets to work again and pushes forth new branches and soon makes a new tree. Its best feature, however, is that it produces abundantly a very useful sweet pod, much liked by poor natives. To prevent any misconception I should be clear. Its sweet and spongy pulp is not suited to the palates spoilt by Covent Garden peaches, and apricots, and hot-house grapes, but quite suited to that of the poor natives of India, and therefore very useful as a famine tree. When I was at Peradeniya, Dr. Trimen told me that, when he first took charge of the Ceylon Botanical Garden, he contemplated making a catalogue of the Ceylon plants which natives used for food. He said he soon discovered that natives ate *everything* but what was actually *poison*, and therefore, as he was making a catalogue of the plants of Ceylon, he did not see the necessity of getting up a *separate* catalogue of food plants. There is no need of any fear that natives would refuse any but first class fruit. The difficulty was always to keep natives, and boys especially, from eating the *Inga* pods before the seed was ripe. When ripe, the pod splits up and the seed is scattered. It all germinates with the first showers.

Why this tree—admirable as a screen, admirable as a hedge, admirable as a subordinate food producer for poor natives, and useful for firewood—is not found in every public garden, in every jail and tehsil garden, and in every village it is difficult to say. When in Lucknow I wrote of it in my reports, and distributed maunds of its seed, and since I left, I believe this dissemination of *Inga dulcis* seed has continued. Nevertheless, although Sir J. Hooker says it is "cultivated throughout India, from Umballa to Tuticorin, and from Culcutta to Bombay," out of *Madras* and *Lucknow*, I don't remember having come across a single tree of this interesting and useful *Inga dulcis*. Is it the apathy of natives, or that of officials or that devourer of everything green—the goat—which prevents this food tree from making its way? It would make a good tree for canal plantations, for village jungles, for firewood, &c. Probably one of the reasons why it has not made sufficient progress is because it was distributed in large packets. Then the receiver may have looked upon it as the seed of some useless "*Kikar*" weed. I think it would be better to distribute it in small packets of a dozen seeds. Then they might be cared for as something rare; and I am sure if only *one* seed succeeded in establishing itself in a garden, it could not fail eventually to force itself on the notice of natives.

Mr. Ridley writes of this tree that "it is a really good thing for the people generally, and grows so easily. It is not half enough known, and it deserves to be widely disseminated." In Lucknow, natives have given it the name of "Hinga" or "Bilati Imli." Colonel Pitcher further writes as follows about these useful trees:—"I hope in your zeal for date palms, &c. you have not forgotton your old flame the *Inga dulcis*. I noticed this year that, both at Lucknow and Cawnpore the pods were more abundant and fuller than I had ever seen them, and that parrots were having a high time over them, in company with all the vagabond children who could get near enough."

Meer Mohamed Hossein kindly undertook an experiment with *Inga dulcis* in feeding sheep. A comparative experiment was at the same time made with *Babul* pods, after the manner of certain dwellers in Baiswara. Ten sheep in each batch, of equal ages and condition, were experimented upon. One batch got 5 seers of *Inga dulcis* pods per head per day, and a similar number got 5 seers of *Babul* pods, and both batches were turned out for three or four hours a day, for air and exercise, and such grass as they might pick up in May. No other food was given. The period of experiment was 24 days: limited by the supply procurable.

Result.

Inga dulcis. Ten sheep, weighed 5 maunds and 2 seers at commencement, and 5 maunds 20 seers at conclusion: gain 18 seers.

Babul. Ten sheep, weighed 6 maunds and 4 seers at commencement, and 6 maunds 15 seers at conclusion: gain 11 seers.

We may therefore add to the merits of this tree that its sweet pods are a good food for cattle, &c.

As the wild mango by selection has been turned into the many fine and unique fruits of the cultivated mango; and as out of the wild date have come the hundreds of cultivated varieties of dates, some of which are so full of syrup that it literally drops on the ground, so may this first step in the history of the *Inga dulcis* lead to many useful cultivated varieties. If the seeds of the sweetest and largest pods are always selected for special attention and cultivation, there is every reason to believe that Nature will not fail to respond to human efforts.

In the meantime it would perhaps serve some purpose if a catalogue could be made out of the places where this useful *Inga dulcis* has or has not *established* itself, in order to ascertain whether even the millionth part of the seed distributed has come to any good.

To commence with Etawah, I read in some old Report that a quantity of *Inga dulcis* seed was sent to Etawah, result: not a single tree is to be seen anywhere! Lately, Mr. Ridley sent me some young seedling date trees. The pots had evidently been kept under a Hinga tree, as two seeds of the latter had germinated. I saved them and they are now flourishing. I hope by means of these two seedlings to establish at last this tree here.—*Pioneer*.

[We believe it is not more than a generation ago since this plant was introduced to Ceylon from Madras, and it is fully established as standard tree and hedge-plant. There is a magnificent avenue of the trees forming a long gothic arch along Skinner's Road, Colombo. The value of the pods for forage does not seem to be appreciated.—Ed.]

BALATA &c. FROM BRITISH GUIANA.

In the volume of Reports recently published by the authorities of the Colonial and Indian Exhibition, the Report on Gums, Resins, and Analogous Substances is the work of the well-known rubber expert, Thomas Bolas, Esq., F.C.S. With reference to the Balata of British Guiana, a product which has already received considerable attention in our columns, Mr. Bolas writes as follows:—

First, then, with regard to the balata, a quality of gutta-percha, the excellence of which is not fully recognised by consumers. The bullet-tree (*Mimusops balata* or *Sapota Mulleri*) is a forest tree which reaches

a height of 120 feet and a diameter at base of 4 to 5 feet. Although to a great extent characteristic of British Guiana, it is found over an area extending from Jamaica to Venezuela and French Guiana; but it is still an open question whether two species are not included under the term bullet (or bully) tree. Mr. G. S. Jenman, the Government Botanist of the Colony, says in a report, dated 1885:—"The vernacular name appears to be applied to two species or sub-species, which are united by Griseback in his Flora of the British West Indies. Young plants of *Mimusops globosa* of Jamaica and Trinidad growing in their gardens, seem to be distinct from the Guiana type."

Jenman in his report* (Demerara *Royal Gazette* Office, 1885) gives interesting and valuable particulars regarding the bullet forests and the collection of the material. In speaking of the extensive bullet-tree district, that extends from the Canje to the Corentine River, he says:—"Since the days of the first colonisation of Berbice, it has been occupied by woodcutters; and though so much timber has been got out during the last century, I found the bullet-tree more plentiful there than perhaps anywhere else on my journey." The population seem to be living in a condition approximating to one of peaceful anarchism, Jenman saying:—"The centre of the district is about 70 to 80 miles from New Amsterdam, so that the inhabitants have very little outside intercourse. They live almost entirely to themselves; there being no magistrate or doctor or other official on the River. . . . At Baraccara there is a Presbyterian Mission Station, with a resident schoolmaster; this is visited three or four times a year by a minister. The children assemble on Monday at school, and remain in the neighbourhood with friends till Friday, when they return to their homes. The schoolmaster having been a dispenser formerly, prescribes for the ailments of the children; the older people depending chiefly on their 'bush' remedies."

There seems to be much misunderstanding about the relative values of the gutta from the bullet-tree and that from other sources, and it is very desirable that certain injurious misunderstandings regarding the matter should be cleared up. That, as a general thing, the crude gutta-percha from British Guiana possesses a greater use-value than the average crude gutta from other sources, I regard as certain and established, and I am inclined to attribute this largely to the higher moral character of the people who collect it; this higher moral character bringing about a corresponding care to deal intelligently and honestly with the material, and an obviation of those adulterations which give the manufacturer so much trouble, and which often seriously injure his machinery. It is because I take this view, that I quote what Jenman has written about the social condition of the people of the Baraccara district.

Admitting the use-value of the product to be above the average of crude gutta, the question arises how it is that, excepting when sold to the actual customor, it has often, and perhaps generally, realised a far lower price than it should do on its merits.

The reason is, as far as I can gather, that a notion exists that balata is a distinct material, that it is not gutta-percha, but a material having qualities between gutta-percha and India-rubber, a notion for which Dr. Hugo Müller is principally responsible. In my Lectures on the "India-rubber and Gutta-Percha Industries," published in 1880 by the Society of Arts, I merely alluded to balata by saying, "The South American bully-tree has, of late years, afforded a considerable supply of an excellent quality of gutta-percha which passes under the name of 'balata.'" Previously to writing this I had quite satisfied myself of the real identity of the so-called balata with the ordinary gutta-percha of commerce, and I thought it quite sufficient to merely allude to balata as "an excellent quality of gutta-percha." But so great is the vitality of the old, and as I distinctly contend, erroneous notion, that Jenman commences his report on the nature of balata by this statement: "Balata is intermediate in character between the India-rubber and gutta-percha. It combines the qualities of both, and is said to be as good as the best combination of these materials that can be made." Jenman, however, is probably not to blame, as he takes his cue from a chemist of such high repute as Dr. Hugo Müller, who, in a report on balata from British Guiana, made at the suggestion of Sir Joseph Hooker, and presented to Government, says, "It seems that balata is treated by manufacturers simply as a superior kind of gutta-percha, and therefore its name disappears when manufactured. Nevertheless, balata is distinctly different from gutta-percha, and this is especially manifest in some of its physical properties; for instance, it is somewhat softer at ordinary temperatures, and not so rigid in the cold. In one respect, balata shows a very marked and important difference from gutta-percha, and that is in its behaviour under the influence of the atmosphere; whilst gutta-percha, when exposed to light and air, soon becomes altered on the surface, and changed into a brittle resinous substance, into which the whole of the mass is converted in the course of time. Balata, on the other hand, is but slowly acted upon under these circumstances. I enclose a piece of balata tissue which has now been in my possession quite six years, and it is still supple and coherent. A similar piece of gutta-percha tissue would have long before now become entirely converted into a brittle resin."

To begin with, Dr. Hugo Müller is quite mistaken when he says that "Balata is somewhat softer than gutta-percha at ordinary temperatures, and not so rigid in the cold." In so far as any given sample of gutta-percha has been carefully collected and well preserved from the air, will it contain more of the plastic principle which has a composition corresponding to the formula $C_{10}H_{16}$, and also more of a volatile, oily, and odorous principle which appears to be metameric with the plastic principle, and these are the circumstances which influence the hardness or softness, not whether the sample has been taken from a tree of the order *Sapotaceæ* in British Guiana, or from a tree of the same order in an island of the Malayan Archipelago. Gutta-percha, as imported from the Malay islands, often contains 20 to 25 per cent of a nearly useless oxidised product ($C_{10}H_{16}$) $2O$ removable by very patient treatment with hot alcohol; and such a gutta will certainly be much harder and less supple than a carefully collected sample; but at the same time it will be correspondingly far on the road to that destruction by oxidation which all gutta tends towards.

With regard to Dr. Müller's contention that balata resists oxidation better than gutta-percha, and his illustration of this from the fact that a sample of balata tissue remained sound for six years, while gutta-percha would long before have become entirely converted into a brittle resin, I may say that this seems to show that Dr. Müller is hardly aware of the fact that although the nature of the decay of gutta by oxidation is well understood, the exact conditions under which it oxidises are not by any means clear at present. A sample of gutta-percha may decay to the dusty stage ($C_{10}H_{16}O_x$) in one year, or the tissue may remain sound for twelve years or more. To illustrate this point, I may quote from my lectures, published in 1880:—

"When submerged in water, or in any way protected from the action of air and light, gutta-percha has little or no tendency to change; while, on the other hand, constant exposure to light, together with alternating conditions of dryness and dampness, is most unfavourable to its well-being. The products formed by its oxidation are of a resinous nature, as in the case of caoutchouc; one of the most notable of these being a body resembling Spiller's caoutchouc resin, and containing 27·9 per cent of oxygen. It occasionally happens that samples of gutta are met with which resist decay in an extraordinary manner Here, for example, is a sample of thread which Mr. Walter Hancock has had in his possession for over twenty years, and you will note that it is tough

* See *India-Rubber Journal*, June and July 1886.

and strong like new gutta. Other samples, kept under similar conditions, fell into dust as soon as they were touched; and Mr. Hancock tells me that he cannot account for the difference between them.

It may be mentioned as probable that the rapid decay of thin-sheet gutta is often due to the action of ozone, as this reagent attacks gutta (and rubber, too, for the matter of that) with intense energy; a thin leaf of gutta falling to dust almost immediately in strongly ozonised oxygen.

Coming on the market as a material essentially differing from ordinary gutta, and under another name, the product of the bullet-tree is considerably handicapped in the market; and this more especially as the supplies have arrived at irregular intervals. The speculating commercialist has frequently availed himself of these circumstances to purchase bullet-tree gutta at a simply nominal price—sometimes only 6 cents a pound—but the manufacturer seldom gets hold of it under the market price for best gutta.

The capabilities of supply in British Guiana seems to be enormous, and if the misleading term *Balata* were dropped, and relations opened directly with manufacturers, an enormous trade could probably be done in this article.

Even though more carefully collected and less adulterated than other guttas, there is still room for improvement as regards the collection, and if some system of coagulation could be systematically employed, the quality of the product would be enormously advanced, or rather, one should say, the deterioration of the hydrocarbon by oxidation would be minimised. The difficulty is to find a coagulating material which shall be sufficiently cheap, and which, if some of it remains in the product, shall not work mischief.

I may point out that it is desirable to mould the gutta-percha rather in compact masses than thin sheets, as other things being equal, the oxidation is directly proportionate to the surface exposed to the air and light.*

Very much more might be said as to the condition and possibilities of the gutta-percha industry in British Guiana; but space does not admit of it.

India-rubber was shown in the British Guiana department, and it appears in irregular balls of from 2 to 4 inches in diameter. This rubber appeared (with the exception of a few balls which seemed to have been damaged by contact with grease) to be sound and of good quality, although not very clean. There seems to be no certain information as to the origin of this rubber; but there is but little doubt that a good deal of it is obtained from the touckpong-tree already alluded to in a foot-note. The tuckpong grows very rapidly, is abundant on the Canje, and a variety growing near the coast has been identified by Professor Oliver, of Kew, as one of the seventeen varieties of the *Sapium biglandulosum* (Arg). The touckpong is said to be one of the Euphorbiaceous order, and the Pomeroon variety appears to be regarded by Oliver as one not hitherto recognised.

The partly-dried juice is boiled in water and made into balls; in former times it has been too much the custom to mix the milk of the touckpong with that of the bullet-tree; but one cannot too strongly insist on the necessity of keeping the two products separate.

A tree called *Barta-balli* yields a very inferior rubber, and from what I can gather, the only thing to be observed with regard to this tree is to suggest to the authorities to keep its product separate from that of the touckpong, if, indeed, it is considered worth gathering. The admixture of barta-balli milk with the gutta-percha milk is likely to be very injurious.

* Jenman, in the report quoted, refers to the balata milk—for which the collectors receive so much per gallon—having occasionally been mixed with the milk of the tree called by the people touckpong. Now the touckpong yields a true rubber; and it may be that some of the samples of balata which were pronounced to be intermediate in properties between gutta and rubber were prepared from the mixed milks. The collectors should be instructed to carefully avoid any admixture of this kind.

It seems probable that the touckpong is the tree generally known as the *Hevea Guianensis*; but as regards this matter there seems to be no very certain information at present.—*Indiarubber and Guttapercha Journal.*

INSECTS INJURIOUS TO FRUIT CROPS.

The report on insects injurious to fruit crops prepared for the Agricultural Department by Mr. C. Whitehead, F.L.S., F.G.S., was issued on Tuesday. The introduction states that the report relates entirely to insects injurious to fruit crops, and to those among them which cause the most serious losses to fruit cultivators. There are others whose injurious effects are comparatively inconsiderable, so that it has not been deemed necessary to describe them here. For the most part the insects which have been described are formidable enemies, and in many cases more formidable because their work of mischief either is attributed to other cause, or is not discovered until it is too late to adopt means of prevention, or to apply remedies. Some of these insects cause the failure of an entire crop, as, for example, the *Hyponomeuta padella*, or ermine moth, by whose action the apple crop has in some seasons been destroyed throughout large areas of orchard land; while others, like the *Carpocapsa pomonella*, or codlin moth, materially damage the appearance and quality of the fruits. Fruit growing is a most important branch of agricultural industry, and, taking the average of seasons and of the various fruit-producing districts, has proved profitable when other crops have not answered. The acreage of fruit land in England, according to the statistics given in the "Agricultural Returns," was 197,539 acres in 1885, and probably at this present time amounts to over 200,000 acres, as there has been a gradual increase in the acreage during the last ten years at the rate of about 3,500 acres per annum. Besides this acreage, properly termed "arable or grass lands used for fruit trees of any kind" in the "Agricultural Returns," which *bonâ fide* farm fruit land, there is a large aggregate acreage of garden ground appertaining to all houses in the country from the nobleman's mansion to the labourer's cottage, upon which much fruit is produced, and whose full yield is most important to the owners and to the consumers of fruit, which in its natural state, or preserved, forms an important and most wholesome part of the diet of the people. Information as to the history and habits of the chief insect spoilers of the fruit crop may, it is hoped, tend to their discomfiture, and to the larger production of the fruit lands of this country.

The following insects are mentioned in the report:—The raspberry beetle (*Byturus tomentosus*), the green chafer (*Cetonia aurata*), the strawberry weevil (*Otiorynchus sulcatus*), the red-legged garden weevil (*Otiorynchus tenebricosus,*) the raspberry weevil (*Otiorynchus picipes*), the apple blossom weevil (*Anthonomus pomorum*), the nut weevil (*Balaninus nucum*), the pear saw-fly (*Selandria cerasi*), the gooseberry and currant saw-fly (*Nematus grossulariæ*), the currant clearwing (*Trochilium tipuliformis*), the goat moth (*Cossus ligniperda*), the wood leopard moth (*Zeuzera æsculi*), the Lackey moth (*Clisiocampa Neustria*), the common vapourer moth (*Orgyia antiqua*), the magpie moth (*Abraxas grossulariata*), the winter moth (*Cheimatobia brumata*), the coddin moth (*Carpocapsa pomonella*), the small ermine moth (*Hyponomeuta padella*), the strawberry moth (*Pempelia comitella*), the currant borer (*Lampronia capitella*), the raspberry shoot borer (*Lampronia rubiella*), the cherry aphis (*Myzus cerasi*), the apple aphis (*Aphis mali*), the plum aphis (*Aphis prunicola*), the currant aphis (*Siphonophora ribis*), the woolly aphis (*Schizoneura lanigera*), the mussel scale (*Mytilaspis pomorum*), the red spider (*Tetranychus telarius*), the black currant mite (*Phytoptus ribis*), and the natural enemies of injurious insects.

Two reports by Mr. C. Whitehead, F.L.S., F.G.S., were issued on Wednesday by the Agricultural Department. The first of these treats of "Insects Injurious to Hop Plants," on which subject Mr. Whitehead writes.—There is an increased and increasing

risk of loss and destruction from injurius insects to many of the cultivated crops of this country. Thus, corn of all kinds, fruit trees, hop plants, clover, turnips, and mangel-wurzel are continually attacked by insects, both of kinds well known and long known, as well as of kinds that are new, or whose ravages have only been recently noted, and which in certain cases, as the mangel-wurzel fly, *Anthomyia Betæ*, seem to have been imported with the plant. The mischief caused by this fly has become greatly intensified even within the last five years. Curtis, writing of it in 1859, thought that its injuries would not be of much consequence. Again, the "turnip fly" or "flea," *Phyllotreta nemorum*, has enormously multiplied with the extension of turnip culture, and in some seasons has caused very heavy losses to farmers. Originally feeding upon charlock and other cruciferous plants, it leaves these now for more grateful food, and breeds rapidly in these favourable circumstances. Naturally this increase of insects follows *pari passu* the extension of culture and the distribution of the plants which are the special subjects of their attacks. But it is found that in the case of wheat and clover and other crops which have been cultivated in due rotation in the same fields new injuries from insects have been noticed. It must be remembered, however, that the number of observers among agriculturists has increased of late, and the manner of observation has been changed and improved. It is, of course, quite possible that the supposed new insects may have been working unnoticed for generations. Admitting to an extent the advance of intelligent observation and the spread of entomological knowledge, it is quite clear that not only is the destruction occasioned by insects larger than ever it was, but that there are insects at work in the fields which were not there in the times of our forefathers. One reason for the progressive increase of insects is that a larger supply of food encourages the proportional propagation of insects fond of and living upon it. Another undoubtedly is that the systems of land treatment have completely changed, and become more artificial, by which the balances of nature, "the aggregate action and product of many natural laws," as Darwin has it, have been disturbed. Insectivorous insects, for example, may have been diminished by changed methods of management. High and altered farming may have made certain crops more delicate and liable to insect attack. The slaughter of insectivorous birds and animals is most wholesale and indiscriminate. The hand of every one, to take an instance, is against moles, and yet farmers wonder that wireworms become more abundant each succeeding season. With regard to new insects, there are continuous opportunities for their introduction into England in all kinds of agricultural produce from all kinds of climates and soils. Insects are probably imported into as they are exported out of England. Fortunately the climate of this country does not suit the habits of most foreign insects. The dreaded potato bug, *Doryphora decemlineata* would have, without any doubt, gained a settlement here if the conditions had been suitable. But on the other hand, it is tolerably certain that the hop aphis was taken to America in hop roots or sets sent from England. Until 25 years ago, Professor Lintner states, this insect was unknown in the American hop plantations, and now it is becoming a serious trouble. Several other insects destructive to corn, hop, and fruit crops have been brought into America from Europe with seeds, plants, and fruits, and are threatening to become more troublesome in this "home of insects," as America has been called by entomologists, than they ever were in their native land. America has retaliated by exporting the phylloxera into the French vineyards, to the utter confusion and indescribable loss of the wine producers. Within the last few years scale insects have appeared in the Californian orange groves from Australia, and orange, citron, and lemon growers in other parts of the world have lately been exercised in their minds by the appearance of pests of this species. Seeing, then, these dangers from the spread of indigenous insects, and the fear of the introduction of new species from foreign countries it is most desirable to diffuse entomological information as to the habits and life history of injurious insects, in a simple and intelligible form, for the use of farmers, fruit-growers, market gardeners, and all who cultivate the land, and at the same time to give practical modes of prevention and remedies against their attacks. The hop plant in particular has many insect enemies. Some of these are most dangerous and destructive, and if not prevented or checked will soon ruin the crop. It appears as if the liability of hop plants to be attacked by insects has considerably increased during the past 30 years, and it is believed by hop planters that some of the insects which now vex them were not known in the hop plantations until recently. As the planters are anxious to learn what has been ascertained regarding the insects affecting hop plants, it is considered desirable to publish this record of ten species of insects more or less injurious to them, giving descriptions of each insect, together with its life history, its modes of attack, and the results of its injuries, also an account in some detail of methods of prevention, and of measures which have been found efficacious in stopping or alleviating injuries.

The following insects are mentioned in Mr. Whitehead's report:—The hop fly, *Aphis humili*; the hop cone fly, *Dilophus vulgaris*; the hop wireworm, *Elater lineatus*; the hop jumper, *Euacanthus inturruptus*; the hop flea, *Haltica concinna*; the otter moth, *Hepialus humuli*; the thousand legs, *Julus Guttatus*; the hop bug, *Lygus umbellatarum*; the red spider, *Tetranychus*, *Telarius*; the strig miner, *Psylliodes attenuatus*, or *Agromyza fontalis*(?).

The second report relates to insects injurious to corn, grass, pea, been, and clover crops; as to which Mr. Whitehead writes:—"It will be seen by the above title of this second instalment of the series of reports upon insects injurious to agricultural crops that its scope has been somewhat extended. Originally it was intended to confine this second report to insects injurious to corn crops, but as the work progressed it was found desirable to include those destructive to grass crops, as some of these insects are common to both. Again, it seemed well while dealing with cereals to treat also of pulse—peas and beans—and to describe the principal insects that affect them, especially as some of these crops are liable to be attacked by the same insects. Besides, there would hardly have been enough materials for a separate report upon insects injurious to pulse alone, and it is important that their history should be given. A description also of a genus of insects injurious to various kinds of clover is added as being the most important enemies of this order of plants. There are other insects more or less injurious to clover crops, and many others which at times are troublesome to cereal and pulse crops. It would be impossible to include these in a work of this kind, which is intended merely to give a short account of insects that most frequently attack cultivated crops. Some explanation is necessary as to the arrangement of the monographs in this report. It would have been difficult to arrange them alphabetically, or according to the recognized scientific classification of insects, and it has been thought better to group them under the respective headings of corn and grass, peas, beans, and clover, and to take the insects in each group as far as possible in the order of their injurious effects. It may be objected that as the *Julidæ* and the *Vibrio*, or *Tylenchus tritici* are not insects in the scientific acceptation of the term they should not have been included in the series. But these reports are written to convey useful and practical instruction to the cultivators of land, and are not intended to be solely for scientific readers. And it is only following in the footsteps of the great agricultural entomologists, John Curtis and Dr. E. L. Taschenberg, to describe these creatures destructive to crops in company with true insects. There are other insects which are destructive to the various crops dealt with in this report. It is, however, deemed desirable to treat only of their chief pests and those which give most trouble and occasion most loss to cultivators. With regard to these it has been

endeavoured to collect all the information that is known about them, and to bring this down to the latest date. It is believed that each monograph is a *résumé* of all that is known of its subject, of its life history, and the means of prevention and remedies against it. It is admitted that in several instances the information is still imperfect, and in compiling this series of reports I have been more than over impressed with the necessity of enlisting skilled workers in this cause, as well as of urging and encouraging habits of observation among those who superintend the cultivation of the land and those who work upon it."

In this volume an account is given of the corn aphis, *Siphonophora granaria*; the wheat midge, *Cecidomyia* (*Tipula*) *tritici*; the barley midge, *Cecidomyia cerealis*; the ribbon-footed corn fly, *Chlorops tæniopus*; the lined corn fly, *Chlorops lineatus*; the corn saw fly, *Cephus pygmæus*; the frit fly, *Oscinis vastator*; the crane fly, *Tipula oleracea*; the wireworm, *Elater lineatus*; the cockchafer, *Melolontha vulgaris*; the small chafer, *Anisoplia* (*Phyllopertha*) *horticola*; the mole cricket, *Gryllotalpa vulgaris*; the thousand-legs, *Polydesmus complanatus*; the antler moth, *Charæas graminis*; the corn thrips, *Thrips cerealium*; the ear cockle (or purples) worm, *Vibrio* (*Tylenchus*) *tritici*; the corn weevil, *Calandra granaria*; the corn beetle, *Trogosita mauritanica*; the corn wolf moth, *Tinea granella*; the pea and bean beetles, *Bruchus pisi*, *Bruchus granarius*; the pea and bean weevils, *Sitona lineata*, *Sitona crinita*; the pea moth, *Grapholitha pisana*; the bean aphis, *Aphis fabæ* (*Aphis-fumicis*); the pea aphis, *Aphis pisi*; the clover weevil, *Apion apricans*; the Dutch clover weevil, *Apion flavipes*.—London *Times*, *August* 1886.

THE HESSIAN FLY.

To the Editor of "The London Times."

Sir,—It may interest your readers to learn that this most destructive insect, the Hessian Fly, *cecidomyia destructor*, has not been known before to attack corn crops in England. There was a great fear at the beginning of this century that it had appeared in this country, but it was soon decisively settled by authorities that the injuries attributed to it were caused by another insect, the *chlorops pumilionis*.

Its ravages in America were first noticed in 1776, and as it was supposed that it was introduced from Germany in straw with the Hessian troops during the American war, it was called the "Hessian Fly" and was affirmed "to be more formidable to us than an army of 20,000 Hessians."

This insect is of the same genus as the wheat midge, *cecidomyia tritici*, though it is essentially different in its mode of attack. The Hessian Fly confines its injury to the joints of the straw, causing a disorder analogous to that of root-fall and "gout" in the stems; while the wheat midge, as most farmers know to their cost, produces the red maggots which so seriously damage the ripening ears of corn.

The Hessian Fly is of a dark-brown colour, and in shape and appearance is rather like a tiny gnat. It is about the tenth of an inch long, having a wing expanse of from the eighth to the ninth of an inch. The female places its light red-coloured eggs not much larger than pins' points and of a cylindrical form, in groups of from three or four to 30, by the side of the ribs or divisions of the upper surface of the leaves of the corn plants. According to Packard and other American entomologists, there are two broods, the first laying eggs in April and May, and the second in September and October.

In the course of from four to ten days, according to the weather influences, larvæ come from the eggs. These are maggots without feet the fifteenth of an inch, or a little more, in length, nearly translucent, but after a time showing green stripes under their skins. Directly after they are hatched they attach themselves, Packard says, head downward, to the stems of the corn plant, close to the second joints above the roots, and suck the sap from them, causing general weakness and disorder, as well as setting up a local irritation occasioning disease in the joints.

These larvæ work mischief in this way for five or six weeks and then change to incomplete pupæ of a chestnut colour, rather longer than the larvæ, resembling small and rather elongated flax seeds. On this account they are called "flax seeds" in America. This is exactly the description of the pupæ which Miss Ormerod discovered in the wheat and barley plants near Hertford, and it is for these that farmers should now closely examine corn crops showing any symptoms of disorder.

As these pupæ—as they may be termed for practical purposes, though they do not put on the perfect chrysalis form until a short time before transformation—rest in the lower parts of the straw, it is obviously most desirable that they should not be carried with the crop into stacks and barns, and that measures should be taken at once to prevent them from changing to flies which might, in favourable conditions, affect wheat plants this autumn, or from hibernating in pupal, or semi-pupal, form and attacking wheat and barley plants in the coming spring.

To effect this, corn crops that are in the least degree affected should be cut high above the second joint from the root. The stubble should either be collected with scrupulous care and burnt, or it should be deeply ploughed in and every particle carefully covered over directly after harvest. All manure brought from London, or other towns, or warves, in which there is any long straw should be immediately mixed and subjected to heat.

It is supposed that the insects which have done so much mischief to crops near Hertford were brought upon the farm with the straw in the manure obtained from London, and that the infected straw may have been brought from America, or Canada in packing or cases.

It is possible that they may be disseminated with seed corn. In the Hertford case, however, the seed corn was home grown, so that the attack could not have originated in this way. Still it is most important that seed corn should be minutely inspected before it is sown; also that the corn grown in fields infected with these insects should, on no account, be sown or sold for seed.

These are simple means of prevention involving but little trouble and expense, and it is hoped that they may be adopted in all cases where these "flax seeds" are found, and that every effort will be made by farmers to stamp out this insidious and destroying enemy.

May I add that I have just received information of an attack of this insect on corn crops near Romford. —I am, Sir, your obedient servant, CHARLES WHITEHEAD, Barming-house, Maidstone.

TEA DRINKERS' DISEASE.—Says Dr. J. E. Taylor in his "Notes on Popular Science" in the *Australasian*: —Attention has recently been drawn to the appearance and spread of what is called the "tea-drinkers' disease." There can be no doubt whatever that immoderate tea-drinking proves as bad as immoderate alcoholic imbibition, and, as regards its cumulative effects on the race, perhaps even worse. The new disease has been called by the singularly inappropriate name of theism, from the French name for tea. It exists in three stages. In the first, the symptoms are congestion of the aphalic vessels, cerebral excitement, and animation of the face. These are succeeded by a reaction of mental and bodily depression. Nervous irritability, cardiac troubles, &c., are added to the list. Nutrition is disturbed, nightmares are engendered, nervous tremblings follow. It is a fearful list of complaints from what we have considered a harmless habit. [It might have been added that the cases are so rare as to be scarcely seen by one physician out of ten thousand.—ED. *T. A.*]

Correspondence.

To the Editor of the "Ceylon Observer."

CINCHONA BARK AND THE EXTRACTION OF QUINETUM NEAR THE SOURCE OF PRODUCTION.

14, Victoria Grove, Kensington,
London W., 20th October 1887.

DEAR SIR,—In reference to the "facts, deductions and proposals" and proposal, for an Association of all those who are interested in the cultivation of cinchona with the object of increasing the consumption of the cinchona alkaloids, I had better mention that I am working in the matter now in combination with influential men, that we have decided that it would not be advisable to prepare "quinetum" in the East for several reasons, one reason being that the cost of exporting the chemicals for the manufacture would cost as much as to convey the poor bark to England.

I hope soon to be able to send you something definite with regard to the scheme for the Association.—Yours faithfully, W. T. HODY COX.

CEYLON TEA AT THE EXHIBITIONS.

England, Nov. 5th.

DEAR SIR,—Your remarks and the letters in your Overland issue of Oct. 8th, respecting the representation of Ceylon tea at the Exhibitions to be held in Glasgow and Melbourne, induce me to offer a few suggestions on that subject.

It is evident that the vastly increasing production of Ceylon teas is bound to depress their value most seriously in the immediate future unless it is possible to make the demand keep pace with the supply.

Their great adversary—Indian tea—will be certain to fight them in price most keenly during the next few years, and the similarity in the two growths is so great as to enable the retailers here to use whichever is the cheaper, unless it is possible to *so educate* the public taste, as to induce purchasers to insist on having Ceylon teas. This end is materially assisted by the new Trade Marks Protection Act, which makes it penal to wrongly describe any article of commerce, so that it will now be very risky for persons to call any tea Ceylon tea, if it is not so. This fraud has been practiced already. Up to the present a sufficient demand has been created to secure for Ceylon teas exceptionally high prices, but this state of things cannot continue without an effort is at once made to widen the demand immensely.

The Ceylon teahouse at the Colonial Exhibition produced an incalculable effect in popularizing the tea in London and England, and it is certain that a similar result would follow a like effort in other places.

If nothing is done the demand falls off and so does the price. A drop of one penny per lb. on your estimated crop for next year (24,000,000 lb.) means, £100,000 loss to the planters, and the fall would not be measured by one penny per lb. It is not expected that India will cease producing increasingly, and many think that China will make up presently and flood the market; then if Ceylon teas are not able to monopolize a considerable share of public favour, they will have to be sold at prices not at present contemplated, for it must be borne in mind that the consumption of tea in Great Britain does not increase to any extent now, and that therefore Ceylon teas have to supplant those other growths at present in use. This it can do, if rightly handled.

Mr. Rutherford's estimate of cost for the two teahouses in Glasgow and Melbourne is not too much to pay for the advantage that will be gained, but a great work might be done for a considerably greater sum; and why not do the thing thoroughly? Spend a few thousands of pounds on each Exhibition and it will produce a return such as could not be obtained by a lucky gold digger.—Yours faithfully,

P. S. V., AN ENGLISH TEA AGENT.

AN ENEMY OF TEA.

Kelburne, Haputale, 9th Nov. 1887.

DEAR SIR,—By today's tappal I send you a poochie found in the stem of a tea plant (standing about 8 inches high) in the nursery. It looks to me to be a species of borer, and I should like to know whether any of your numerous correspondents have discovered this pest in any of their nurseries.—Yours truly, ARCH. C. CHAMBERLIN.

[We regret that this letter has been overlooked. The enclosure unfortunately escaped en route: a borer should not have been sent in a match-box.—ED.]

ORANGE CULTIVATION IN MALTA AND ITALY: INTRODUCTION AND CULTIVATION OF THE FINER KINDS IN CEYLON.

Udapussellawa, 11th Nov. 1887.

DEAR SIR,—Five years ago, whilst visiting the San Antonio gardens, near Valletta, I asked the superintendent to make up a wardian case of orange grafts which I sent on to Ceylon. On my return I had some difficulty in tracing the trees, but I have still three, two sweet oranges and an egg, which are now bearing heavily. The blood variety I have lost. The fruit has no pips and a distinct flavour of its own. The blood is by far the most luscious type of the orange tribe and should be introduced into Ceylon. It is a common idea accepted by intelligent people that the claret colour of the pulp and juice is produced by grafting on a pomegranate stock. I recollect mentioning this to my friend Dr. Stillon, the popular medico savant of Valletta, who was much amused at the notion.* Under his auspices I saw a good deal of the careful and laborious cultivation which goes on, under cover of those high limestone walls, which render the neighbourhood so dreary—large tanks are dug out of the solid limestone underground for the storage of the rain water. The excavated stone is used in building the surrounding walls (and each enclosure is not more than 40 ft. square) which are necessary to shelter the trees from the cold winds which blow from the north-east as well as from the Sirocco which occasionally sweeps across from the African Continent. A very limited number of trees are grown in each square, which are watered daily, until the fruit is within a month of maturity. In a dry climate like Malta (24 inches per annum) water is the first necessity, every drop which falls from the clouds is conserved—and sometimes the tanks are replenished from the aqueduct (nine miles long) which supplies the city and garrison with the best of water brought from the springs of Citta Vecchia. Payment is made at so much per hour for a 3 inch pipe run of water, but cannot always be procured at any price. The careful cultivation, the soil which answers all the conditions required by the culture, the concentrated heat from the walls and its radiation at night assimilate to hothouse glass culture and all combine to produce a fruit which is simply superb. The oranges exhibited for sale in the market are chiefly Tangier. The choice bloods are mostly sent to London and Paris, where they command extreme prices, "Does it pay?" I asked a Maltese gentleman. "That I cannot say," was the prompt

* We should think so, the trees having no affinity. Dr. Bonavia's article, which we have given in the *Tropical Agriculturist*, shows that the "blood orange" has been successfully introduced into India.—ED.

reply, "but my orange groves are my delight in my retirement." The Maltese lemon and citron did not appear to me to compare with those produced along the coast of Sicily from Syracuse to Messina, where a most careful husbandry is carried on in a splendid soil, by means of irrigation from wells. Most of the vegetables and fruit for the supply of the garrison at Malta and the crews of the Mediterranean fleet are here grown. The supplies are put on board native crafts at sundown, and are delivered at Valletta harbour at dawn on the following morning. At Messina I saw a large steamer being loaded up with country wine for Bordeaux —also large barrels lined the quay which were being filled with sliced lemon peel. The peasantry brought down large baskets of peel, which were weighed and paid for on the spot. It was thrown into the barrel and then drenched with a syrup —after each layer had been packed. The cask was covered in when nearly full with crystallized sugar and then headed up and shipped. On arrival at Bordeaux, I fancy this became the candied peel of commerce.

The finest lemons I have seen are grown in the Western Riviera in the neighbourhood of Mentone and Bordighera. They are quite smooth in the skin and look, when ripe on the trees, like a gigantic magnum bonum plum. Swift schooners take most of the crop to New York and St. Petersburg. It must be a profitble trade, for the Mentonese are all engaged it in and during the season talk and think of nothing else than the golden harvest they are gathering. The lemon trees are all grafted on bitter orange stock.

The fruit trade is an expanding one, and I see no reason why this island should not secure a share of it. We want the introduction of best varieties and we want instruction in their cultivation. The trees must be produced from grafts grown on hardier stocks before we can secure the best quality. It is a field of usefulness which Dr. Trimen and Mr. Nock might take up with great advantage to the country.

There is a tradition amongst the Sinhalese that long ago there existed extensive groves of superior oranges round Palugama, which were devasted and destroyed during a raid made on this part of Uva by their hereditary enemies from Saffragam.

There is no doubt that at the base of these limestone rocks, all the conditions favourable to orange and lemon cultivation exist, if only shelter could be provided from the terrible south-west winds.

Dr. Bonavia's article on this cultivation in the *Tropical Agriculturist* opens up a world of possibilities. Discussion may result in more attention being drawn to this cultivation and another product added to the cultivation of the island—Yours truly, G. A. D.

CEYLON TEA IN THE UNITED STATES.

Hoolankande, Madulkele, 18th Nov. 1887.

DEAR SIR,—While fully alive to the necessity of pushing Ceylon teas, there remains a little doubt in my mind as to whether the course proposed (that of scattering large quantities of tea broadcast and *santosam*) is the course likely to be productive of the most paying results.

It goes without saying that our Yankee friends will be very glad to receive a present of a lb. or two of pekoe; but would they not be likely to bestow a little more thought and consideration on the tea, if they had to pay something for it? I throw out this suggestion, backed by the fact that I have received an order from my agent in Virginia for 500 lb. of tea, all of which is to be pekoe, at the London delivery rate of 1s 10d per lb. in bulk.—I am, yours faithfully, E. GORDON REEVES.

[The fact mentioned is gratifying, and we trust further and larger orders will follow. Nevertheless, the prejudice generally is so strong that the scheme of distributing *ounce* packets is good.—ED.]

COCONUT PLANTING AND PLANTERS.

Kandy, 20th Nov. 1887.

DEAR SIR,—I have read a series of letters in your journal from your Hapitigam and Siyane Korale correspondents on coconut cultivation. Your Hapitigam Korale correspondent "W. B. L." is no doubt an old and experienced planter. An opinion given by him could safely be relied on, as he is a thoroughly practical and scientific man, well read on all subjects referring to agriculture. He could count over 30 or 40 years' experience as a planter. I remember the time when he had charge of several coconut and cinnamon estates in the Kadarana, Ekelle and Ratmalana districts. He was one of the leading planters of the day, and was in charge of the famous Celambalam estate in Kadarana, where monuments of his work could be seen up to this day. As a curer of copra and manufacturer of oil and cinnamon there was none to surpass him. Poor Johnny Koch, Raoul Piachaud and Minto, his assistant, and afterwards in charge of Yalla in Ekelle, were rivals of "W. B. L." who could never compete with him. His oil, copra and cinnamon fetched the highest in the English and local markets, and he carried all the prizes at the exhibitions in the English as well as the local market. I believe he was the first man in Ceylon to work his chekoos with horse, and the work done was enormous. I would advise my old friend "W. B. L." not to discuss coconut planting and manuring with your Siyane Korale correspondent. From his writings I am able to judge that he has no personal experience, but that he picks up scraps from books and gathers information from his coolies and villagers. From what I could gather from his writings on coconut cultivation, his trees must be in a jaded condition. In his opinion he fancies everybody is wrong and that he is right. I would advise him to take lessons on coconut and general cultivation from "W. B. L.," F. Schrader and William Jardine and J. F. Drieberg, such thoroughly practical men. If he does not wish to go to their feet who are not his countrymen, I would advise him to go to Mr. J. F. Drieberg, his countryman. I mention Mr. Drieberg as I had occasion to see Professor Wallace and he spoke of him on highest terms as a practical planter. Well done young Ceylon. I wonder if Mr. Drieberg is brother of the late Mr. A. Drieberg whom I used to meet very often at Bedford Square in 1857.—Yours truly,

S. T.

CULTIVATION OF BARLEY.

Farmer's Cottage, Bandaragama, Nov. 21st, 1887.

SIR,—There is a good deal of land well adapted to the cultivation of barley here in the Rayigam Korale, but nobody that I have met with knows how to cultivate it. If this should meet the eye of anyone acquainted with this subject, I for one would be much obliged by full information.

Your insertion of this at your earliest convenience will greatly oblige, your obedient servant,

J. A. JNO. RODRIGO.

[Barley is not likely to flourish in our lowcountry climate.—ED.]

CULTIVATION OF CUBEBS.

Matale, Nov. 21st.

SIR,—It is curious that even among planters who are specially well informed regarding all sorts of "new products," comparatively little seems to be known about the cultivation of cubebs. Glancing through the *Chemist and Druggist* the other day, I find notice repeatedly called to the growing scarcity of this drug, and I note in a recent issue of the *Observer* that the price now obtainable is from 23 to 25 shillings a hundredweight. Peppers of all kinds have been notably successful here, particularly in low-lying ground, the vines twining over cocoa or jak trees most luxuriantly and covered with clustering fruit. As I am certain the raising

of the cubeb or Java pepper could be developed into a most remunerative industry here both for Europeans and natives. Some authentic information as to the cultivation and harvesting would much oblige OLD MATALEAN.

[We have applied to correspondents in Java for some information.—ED.]

MODE OF INCREASING THE GROWTH OF ARROWROOT.

Farmer's Cottage, Bandaragama, Nov. 22nd, 1887.

SIR,—I hope the following observation of my arrowroot plantation may interest, if not be useful, to your numerous readers, as I have seen the tubers grown here in this district are very small. The flowers being cut off as they appeared on the plants, the number of tubers produced was much greater than where the blossoms remained untouched. When they are about six months old the stem and the leaves of the plants which had not borne flowers were strong and green, the other yellow and in a state of decay, The plants which had been stripped of flowers produced (on the same space of ground) about three times the weight of large tubers, very few small ones being found. Those on which flowers had been left produced but a small number of middling sized tubers with a great number of small ones.—Your obedient servant, J. A. JNO. RODRIGO,

Agricultural Instructor.

METHODS OF DESTROYING ANTS.

Bandaragama, 24th Nov. 1887.

SIR,—I recommend to your numerous readers the following methods which I quote from an agricultural magazine) of destroying ants:—"Oatmeal 1 lb., coarse sugar ½ lb., to be well mixed together; to this add 2 oz. of finely ground pepper. Lay the mixture upon white earthenware where the ants resort, and cover it over to be kept dry."

Another Method.—Toast the inner side of the skin of a piece of bacon till it becomes crisp. Lay it on the ground in such a manner taking care to prevent its getting wet), that the ants may "step in," which they will do, and fasten themselves to it; lift it up quickly and immerse it in water.—Yours faithfully

J. A. JNO. RODRIGO, A. I.

CINCHONA IN JAVA.—In Java the area planted with Cinchona on private account is estimated at 21,000 acres, and the number of trees at 3,000,000, of which about 1,400,000 are of *C. succirubra*. The estimated crop of the year is about 1,433,250 lb. The average proportion of sulphate extracted from the bark is estimated at about 3 per cent.—*Indian Agriculturist.*

CLEANSING OF CHAMOIS LEATHER.—Chamois leather, so much used in the laboratory and experimental rooms, may be cleaned by rubbing into it plenty of soft soap, and then laying it for two hours in a weak solution of soda and warm water. At the end of this time rub it until it is quite clean, rinsing it in clean warm water, in which soda and yellow soap have been dissolved. It should then be wrung dry in a rough towel, pulled, and brushed. This process makes the leather soft and pliable.—*Indiarubber and Guttapercha Journal.*

TEA CULTURE AND MANUFACTURE constitute, as Mr. Armstrong has shown in his latest and not least valuable contribution to the literature of the subject, an art that demands large scientific knowledge. Even the pruning of the tea bush, so as to secure the largest possible quantity of leaf in the best possible condition, requires an amount of experience and observation, reflection and watchful personal attention, such as go far beyond the requirements of the fruit-yielding coffee bush. The amount and the variety of machinery required for the manufacture of tea and the delicacy of the process of withering, fermenting and roasting, the latter by fire heat properly regulated, demand that the superintendent of a tea estate should combine the training of the engineer with the knowledge of the chemist. And, as in our island, so close to the equator and so distinguished for warm moisture, the tea bush flushes practically all the year round, unremitting labour and attention are necessary, instead of the alternations of hard work and comparative leisure which coffee planters were accustomed to and the long winter holiday which tea planters in India enjoy. On all estates of any size, of course, more than one European is employed in addition to trained natives, so that division of labour, field and factory, is possible, and one of the superintendents at a time may occasionally be able to be absent so as to visit other estates or even Colombo. But clearly the position of a tea estate superintendent is one which requires good natural abilities, acquired knowledge and experience, and a physical constitution able to endure hard and constant work, exposed to the elements in the field or to the heated atmosphere of the factory. A good constitution, physically and mentally, come, as Dogberry said reading and writing came, by nature. But to gentlemen of intellect, reflection and large experience like Mr. Armstrong, young tea planters and indeed all connected with the enterprize are deeply indebted for the statement of results and principles such as are contained in the able paper we print on page 436.

TEA IN JAPAN.—From the British Consular Trade Report for Hyogo and Osaka for 1886 we extract the following:—

In the export of tea the returns again show that a considerable increase has taken place over that of the previous year. In 1886 the export reached 18,020,060 lb., as against 16,538,858 lb., in 1885. The declared value of the year's export is $2,649,072 (£441,512), as against $2,510,869 (£432,402) in 1885. Prices at the opening of the season, in May, were about $2 per picul higher than the rates paid at the commencement of the previous season. A gradual decline took place until early in August, when prices receded some $3 per picul from their highest point. During the last five months of the year, prices for common grades gradually advanced, there having been a steady demand for this class of teas, to the comparative exclusion of the finer kinds. The average price paid for tea here last year, according to an estimate with which I have been favoured, was $19¼ per picul. The estimate of settlements of different priced teas, from which the above average price is deduced, is as follows:—

	Picul. (of 133⅓ lb.)
$ 5 to $11·50	10,915
$12 to $16·50	37,933
$17 to $21·50	46,251
$22 to $25·50	24,529
$26 to $29·50	15,631
$30 to $39·50	4,137
$40 upwards	46

It will be seen from this that the tendency to lower-priced teas, remarked in previous years, still continues. About two-thirds of the quantity exported was invoiced to the United States and the other third to Canada. Some portion of the latter, however, was disposed of in the United States. The export to the United Kingdom and the British Colonies, apart from Canada, is estimated at no more than 50,000 lb. A new and interesting feature in the carriage of tea last year from this port to the North American Continent was the shipment of this article by sailing vessels to Port Moody, for transport thence to the Eastern cities of Canada and the United States, by Canadian Pacific Railway. Three such vessels took in part cargoes here and proceeded to Yokohama to fill up; for four other such vessels shipments were made by coasting steamers here, to be transhipped in Yokohama. The total quantity of tea thus sent from this port which went to Port Moody by sailing vessel, is, according to a revised estimtae which I have obtained, put down at 3,352,122 lb.

ON PULVERIZING SOILS, AS A MEANS OF IMPROVING THEM.

Farmer's Cottage, Bandaragama, October 7th, 1887.

The fertility of adhesive or sticky soils becomes greatly increased by exposing them to the action of the atmospheric agents, by which means they become so much pulverized as to encourage the growth of the fibres of plants. The atmospheric agents promote the decomposition of any sour and acrid matter present in the soil, changing it into good wholesome plant food, rendering some of the dormant matter into an active form and making the soil loose and free for the growth of seed. One cause of the unproductiveness of the adhesive soils is, that air cannot penetrate to the seeds of plants; preventing the germination of the former, and the future well being of the other. In such cases the roots of plants can receive no advantage from the carbonaceous matter which exists in the atmosphere from the decomposition of animal and vegetable substances on the earth's surface. Another cause of unproductiveness is that such soils cannot retain moisture, but are saturated upon the surface at one time and burnt as hard as a brick at another. In the former case the fibres of plants are generally rotted, whilst in the latter they are torn in pieces by the cracks in the ground. The moisture will neither sink freely nor rise freely, when the sun has evaporated the moisture on the surface. Again in such soils the full advantage of manure cannot be realized as it must be within the reach of the atmosphere, before those changes can be effected, by which alone it can become the nourishment of plants. Hence the importance of ploughing, ridging, and frequent digging, by which a larger portion of the soil is exposed to the atmosphere and rendered more friable and open in its texture. The more complete the division of the soil, *the more* easily will the roots penetrate throughout the land, and thereby the increased supplies of food are more easily made use of by the growing crop. The depth will depend upon the nature of the soil and subsoil: strong soils can scarcely be dug or ploughed too deep; nor, indeed, can any soil, unless the subsoil contains something noxious to vegetation. The more soil is stirred among crops of any description, the more fibres will plants produce, and this increase of strength to the plants will more than pay the labour. Believing pulverization to be of great importance for loosening the texture of strong soils, enabling the fibres of plants to run in all directions in search of food, imbibing and imparting a sufficiency of moisture, without receiving it too much or retaining it too long, and also as tending to eradicate deleterious properties in the soil, I should wish to see it more generally adopted, and extended to the cultivation of many of our field crops.—J. A. GNO. RODRIGO, A. I.

TOBACCO CULTIVATION IN SOUTHERN INDIA.

The following letter from Mr. H. Caine, Tobacco Curer, to the Commissioner of Revenue Settlement, Land Records and Agriculture, dated Madras, 14th September 1887, has been published by the Madras Government:—

I have the honour to submit the following report on the prospects of tobacco in the Kurnool, Trichinopoly, Dindigul, Madura, and Coimbatore districts, visited by Mr. Benson and myself.

I arrived at Dhone in the Kurnool district according to appointment, where I met Mr. Benson, Assistant Commissioner of Agriculture. From Dhone we travelled to Kurnool, inspecting the tobacco villages on our way.

From information received from the tobacco cultivators in one of the villages named Rimallakot, it appears that the tobacco seed is sown down in flat beds about the end of June, fourteen days after the first rain, the land having been ploughed four to five times beforehand.

Manure.—Twenty cart-loads of cattle manure are then carted on the land and left for the rain to moisten; when well rotted it is ploughed in. Sheep and goats are also penned on the land for two or three days on every 50 feet square of land throughout the year. The manure is previously collected in pits during the year, and when the rains commence it is thrown on the land. When the soil has been well ploughed over, it is got ready for transplanting by having a sort of harrow with teeth placed conveniently apart drawn over the land to mark out the furrows where the seedlings have to be planted. The land is then left alone till the seedlings are big enough to bear transplanting.

Seed-beds.—The seed-beds are prepared by being ploughed up and levelled; the soil for these beds is not raised as in Upper India, but made flat; the seed is sown broadcast in proportion to half sand to half seed, at the rate of 28 tolas of seed per acre. The beds are then watered by hand-sprinkling from chatties both morning and evening daily. The seed germinates in seven days and the seedlings are large enough to transplant in thirty to forty-five days.

Transplanting.—Transplanting is done throughout the day when cloudy, the evening preferred; the largest sized seedlings are preferable to the small ones, although both may be able to bear transplanting; seedlings which have leaves 3 to 4 inches long are selected. When transplanted the plants are left pretty much to themselves; if after a fall of rain the surface cakes and hardens, a guntaka is run between the rows to break the top soil. About three weeks after transplanting, the soil is worked round the plants with an iron instrument. The plants are planted $2\frac{1}{2}' \times 2\frac{1}{2}'$ apart and are topped (*i.e.*, flower-bud pulled off) when the plant is 2 feet high.

Outturn.—The outturn per acre is said to be 600 to 750 lb.—leaves large, 2 feet long by 5 inches broad. The tobacco is said to be ripe when brown spots appear on the leaf, and also when portions of the leaf crack when doubled up between the finger and thumb. Grass-hoppers and caterpillars do not appear to cause much damage. The most destructive pest seems to be a kind of worm which works up inside the stalk of the young plants (presumably the wire-worm).

Curing.—When the tobacco plant is ripe, the stem is cut off close to the ground, gathered together in rows, and left exposed for three days; after this period the plants are heaped up two plants high one on the top of the other. The most favourable weather for curing is said to be heavy dews at night with a hot sun during the day. The plants remain five days thus heaped up, when they are turned over and remain another five days. The plants are then removed under shelter, the stalks being still green, but the midribs dry. The size of the bulks (heaps) depends on the quantity of tobacco available; about 10 feet high by 5 feet broad seems to be the usual size. The heaps are covered round the sides and top with rice straw and palmyra leaves, the top being weighted down as much as possible so as to press the tobacco. After four days the heaps are opened and the plants shaken and cooled, then heaped up again, and so on whenever the heaps get hot; this continues for fifteen days. The tobacco is supposed to be properly fermented when the leaves turn red, which color appears the most desired. After fifteen days the leaves are stripped from the stalk and tied up with anything available, plantain leaves, &c. About ten leaves go to make one bundle. The leaves are then heaped up for one month, opening when hot and cooling till disposed of. The cultivators informed me that tobacco was grown once in four or five years on the same land, grain crops being grown in the meantime.

Soil.—The soil in this village is of a black clayed tenacious character, difficult to work properly, much too retentive of moisture to grow tobacco of a light quality.

I was shown some tobacco of the former year's crop which had been cured as above stated, but it was poor stuff, uneven in color, and no texture, torn, mouldy, and streaky, only suitable for the native market. I also saw some leaf which had been shade-

cured by a Native; there was no difference in the color and appearance of the leaf; the latter had been valued at a higher rate than the former.

In another village in the same district I inspected a field where no manure had been used. This soil was of a light red color; this might have grown good tobacco if proper care had been bestowed on the preparation of the land, but the work had been carelessly done, the land being full of weeds and unbroken lumps of soil.

Seed-beds.—The seed-beds at this place had been sown down in the middle of July, the seed having been previously soaked for five days; this seed germinated in three days after sowing. The outturn estimated to be about 500 lb. to the acre. The curing in this village visited differs, but little from the process already explained, except that the plants are kept a few days longer exposed in the field after cutting.

Transplanting.—Some tobacco was being transplanted at the time of my visit; this was done by making a hole in the ground with the finger and pressing the root of the seedling (which should be put in straight) down with the thumb, thus damaging the tap-root; in this way so many plants die that transplanting has to be done two or three times over.

In another village visited the land was prepared in the same way, the soil being of the same black tenacious character, the amount of manure used being about 4 tons to the acre. The manuring depends on the amount available. I think 10 tons per acre of old manure is about the maximum used.

Curing.—The curing of the tobacco plant throughout the Kurnool district is much the same, the object being to obtain a red and dark brown color.

Some samples of the former year's crop were shown me here, but the leaf would be of little value for the European market owing to defective curing, the leaves being coarse, ribs thick, uneven in color, little gum and not fermented enough. I left written instructions at this village about curing in the shade.

In another village named Gani in the same district, some of the soil was of a lighter character and more suitable for tobacco than any of the others which I had seen. Some of the black-cotton lands in this village had also been taken up for tobacco. The lands here are ploughed up during the mango showers in April and harrowed over, the collected manure being placed in heaps about the field. As soon as the soil is in a condition to work, a small plough is used to work in the manure; sheep and goats are also penned on the land. The growing crop is treated in the same way as in Rámallakót, the flower-bud being pinched off when the plant is 2 feet high to ensure large heavy leaves. There is a slight difference in the method of curing pursued here.

Curing.—The ripe plants when cut are left one night on the ground; the next day they are hung up on poles with rope till the midrib is dry; the rest of the process is the same. The outturn per acre is said to be 600 to 750 lb., seven to ten leaves being left on each plant; ten plants average 1 lb. in weight. I saw some samples of the former year's crop; the leaves were much the same as the others which I had seen; the texture was good, leaves large and well grown, fairly gummy, color uneven, pale red, burnt badly.

The conclusion, which I have been able to come to (considering that I was unable to see any tobacco growing or curing) in the Kurnool district, is that I do not think cigar tobacco of quality can be grown in the way the leaf is treated by the Natives. Only cow manure should be used; sheep and goat droppings form a manure too strong for tobacco and would probably injure the flavor. The plants are also topped (*i. e.*, flower-bud nipped off) when too small, a much finer leaf and smaller ribs would be obtained if the plants were permitted to attain 3 feet in height before topping, leaving twelve to fourteen leaves on each plant. The outturn per acre would be lessened in weight, but the finer smaller leaves produced would more than compensate for this decrease by commanding a higher value as a cigar tobacco.

A leaf thus grown and properly shade-cured would turn out a much better and finer cigar-wrapper of country tobacco than that which is at present used. The object of the cultivators in topping so low down is to grow heavy-leafed tobacco, which suits the Native market and brings them in a heavier outturn per acre. The distance the plants are grown apart would much depend on the richness of the soil; in rich lands the plants might be grown 2 feet × 2 feet apart; in ordinary land 2½ × 3 feet would probably be the most suitable.

Curing.—The Native method of sun-curing, as far as I could judge from the samples received, is defective in many ways. The curing by sun is much too rapid to obtain the clear brown color required for cigar-wrappers; there is also too much manipulation of the leaves when in a half-cured state; the leaves get doubled and become bruised and streaky and remain thus discolored; a good deal of dust accumulates on the leaves. A pale reddish color is the result, which color becomes darker through fermentation. The Native method of fermenting the leaves when in bulk can also be much improved; some of the leaves get more fermented than others owing to want of care showed in cooling and bulking; the leaves are rebulked into another heap indiscriminately without paying attention to the outside plants of the first bulk, which should form the inside of the second bulk, and *vice versâ*.

We left the Kurnool district on the 2nd September and arrived at Madras on the 3rd; left Madras on the 5th and arrived at Trichinopoly on the 6th, where Mr. Benson and I visited several Native cigar-makers.

The method pursued by these different makers is identical as regards the making up of the cigar. In one or two places the Sumatra leaf (erroneously called Java) was used as an outside wrapper on account of the fineness of its leaf, color, and covering qualities. One of the largest makers used no Sumatra at all, the cigars being made up with country tobacco steeped the night before in jaggery water. The cigars are all hand-made, but mostly too tightly made.

All the Indian (country) leaf which I saw in the godowns of these makers was of a very large-leafed tobacco, very like "American seed-leaf" formerly used in Europe for cigar-wrappers. The ribs, however, are so thick and large that the wrappers here are sometimes cut from between the ribs; two pieces of leaf thus cut are joined together and rolled round one cigar; the join is, however, easily detected.

The tobacco used in the manufacture of these cigars is too new and rank; the idea appears to be to make up cigars of one-year-old tobacco, and then keep them, instead of keeping the leaf tobacco two years or so and then manufacturing cigars. What is really wanted is a medium-sized leaf of finer texture and of a better color, and this can be obtained in the way I have suggested by letting the plants grow higher and by properly conducted shade-curing and judicious fermentation.

I have to remark that there is also a great deal of waste amongst the Native cigar-makers in the way the cigars are made up. The cigars being hand-made, nothing but long strips of leaf can be used up, the smaller pieces—an inch long or so, quite capable of being made into cigars—are thrown aside with odds and ends of Sumatra and sold locally for a mere nothing. In the use of wooden cigar moulds all these bits could be used without deteriorating the value of a cigar. The cigars in several cases were badly made, burning too rapidly inside, while the outside wrapper would not burn at all, owing, in most cases, to two wrappers being used for the cigar instead of only one. A specially made knife would be of great advantage in cutting wrappers, instead of using scissors, which go clipping round a leaf instead of making one clean straight cut. In some cases scissors may be used, in a large thick-ribbed leaf for instance, when only the finer outer edge is used for a wrapper; but these coarse leaves should not be used for wrappers. With the Sumatra leaf a knife should certainly be used.

One man is supposed to roll 300 cigars medium-sized daily. With the aid of moulds a European

workman can roll 400 to 500 medium-sized cigars daily. Sumatra leaf costs the makers from 3 rupees to 4 rupees per lb. landed here. A pound of this leaf covers 500 cigars. A pound of country sorted wrapper will cover 400 cigars of same size. The tobacco used in the manufacture of cigars in Trichinopoly comes from the Dindigul and Coimbatore districts.

Leaving Trichinopoly on the 9th instant, we arrived at Dindigul on the same day.

Irrigation system.—Received following information from tobacco cultivators: The land is ploughed in August after the first rains have set in; ploughed seven times during the month. The lands are manured with cowdung 10 tons to the acre; sheep and goats are penned on the land: 1,000 sheep an acre for two or three days. The seed-beds are made flat, small bunds on all sides to retain the water; soil properly prepared, the seed is sown broadcast; transplanted when seedlings 6 inches high. In rainy weather, transplant all through the day. Seedlings are planted out 2½ feet × 2½ feet. Irrigated every other day for two months. The flower-bud appears in sixty to seventy days and watered for fifteen days afterwards. The plants ripen in seventy-five days from time of planting. The curing is on the same plan as that pursued in Gani village in the Kurnool district. Brackish water preferred for irrigation owing to the salt in it. Land appears to grow good crops of tobacco, the outturn being 750 lb. per acre. The soil I saw was of an ash color; the best land I was told was of a red color. There was some of this 15 miles from Dindigul, which, owing to time being limited, I was unable to see.

I went over Mr. Heimpel's cigar factory; same manner of making up cigars as pursued by the Trichinopoly makers, although everything much cleaner. Mr. Heimpel also used Sumatra wrappers on his superior cheroots.

We arrived at Madura on 10th instant and visited the farm there, the soil of which is, however, too sandy and light for tobacco. Some samples seen there showed a nice medium-sized leaf of good texture, quality and burning capability very inferior. Left the Superintendent some seed and written instructions as to curing.

From Madura we went to the Coimbatore district; the soil, from the little I could see, would suit fine quality tobacco very well; soil red in color and easily worked up. Sample of tobacco seen at Uttakúli was very poor; of little value, round leafed, thick ribbed and not much gum.

Some samples of tobacco received from Kistna are the best I have seen here: leaf medium size, veins and ribs fine, texture very good; with proper shade-curing should turn out a first-class tobacco for cigar-wrappers.

Mr. Benson and I arrived in Madras on 14th instant.

I should suggest that some arrangement may be made before I come down in August 1888, so that some suitable place may be selected for teaching the Natives shade-curing, which I am perfectly certain would greatly improve the country tobacco.

THE CULTIVATION OF COCA.—A merchant inquires:—"Can you tell me where we can put our hand on an account of any experiments tried in Ceylon with the cultivation of coca. We have looked through the *Tropical Agriculturist*, but have not come across what we want—namely its cultivation in Ceylon." [In the annual reports of the Director of the Peradeniya Gardens embodied in the *Tropical Agriculturist*, reference will be found to coca, but we are not aware that outside of Peradeniya any experiment in coca cultivation has taken place, of any extent. We shall be glad to learn if there has.—ED. *T. A.*]

BURMESE FOREST PRODUCTS.—The most interesting of these products, which came before the Chemical Examiner in Burma last year, was the wood of *Artocarpus integrifolia* which yields a fast yellow dye much used by the natives. It may be extracted by boiling the wood with water, but more conveniently with alcohol. As thus prepared it is a resin resembling the colouring matter of turmeric. The leaf of the teak tree when crushed yields a red dye which dissolves in alkalies, forming a blue or violet solution. It is a mixture of two or more substances. The colour is principally due to a crimson body which may be separated from the others by ether, which dissolves it. It forms insoluble compounds with lead and baryta. The *nim* tree, used as a febrifuge in India, yields a resin which appears to be the active principle. The examination of it is not finished.—*M. Mail.*

PADDY BLIGHT IN JAFFNA.—I am informed that the paddy plants in most of the villages of Jaffna are this year also, as in last year, affected by a disease called in Tamil the "kurukutti," literally meaning the destroyer of tender shoots. This is, of course, a destruction caused by certain insects in a certain stage of the plant, when there is not a sufficient supply of water. If there is water enough, the insect cannot approach the plants. Last year when I was in Jaffna, I had examined a paddy plant so affected, and found some insects living at the bottom as in a white-washed house. These metamorphic insects lay eggs, and in their larval state seem to feed on the tender shoots, and in their normal state become flies. They leave a limy secretion which binds up the stalks together, giving the stalk the appearance of a white-washed stick. The best remedy for this would be to allow a sufficient quantity of water into the field, so as to cover the plants to three-fourths of their height, so that these depradators may be washed away and drowned and fresh shoots come up. But what is poor Jaffna to do which is dependent solely on heaven's refreshing showers?—A. SWAMYNATHAPILLY, *Agriculturist.*

SUGAR AND MANURES.—An interesting contribution to the discussion of agricultural topics was recently laid before the Barbados Legislature in the second annual report of the results obtained on the experimental field at Dodd's Reformatory, by Mr. J. B. Harrison, the Barbados Professor of Chemistry, and Mr. J. Bovill, the Superintendent of the Reformatory. The object of these experiments was to ascertain: 1. The effect of the various manurial constituents when applied to the ordinary Bourbon variety of the sugar cane upon the soil and under the climatic conditions existing during the year at Dodds. 2. To ascertain the value of the new varieties of sugar cane, selected by, and forwarded under the directions of Mr. Morris from Jamaica, and to compare them with the varieties at present cultivated in Barbados; and 3. To continue the investigation into the composition of the rainfall which was commenced in 1885. The excellent work which is being carried out on the experimental farm is very apparent from the series of careful analyses and the various suggestions which are to be found in the pages of the report. The report commences with an analysis of the rainfall for the period under investigation—December, 1885, to April, 1887—which amounted to 87·88 inches. The highest rainfall occurred on August 16, 1886, and amounted to 9·14 inches; the lowest in April, and was ·05 inch. It is somewhat interesting to note that careful experiment has led Messrs. Harrison and Bovill to the conclusion that the Bourbon variety of the cane now generally cultivated is the one best suited to the condition of the soil and climate, and that "with the exception of the Mauritius cane, the varieties selected by Mr. Morris do not exhibit, under present conditions of cultivation, any well-marked characteristics to recommend them to the planter." The experimentists find it difficult to reconcile the results obtained by them and those obtained by Mr. Morris. They can only suggest that the discrepancy may arise either from the unfavourable climatic conditions existing during 1885 and the early part of 1886, or to the change in soil, climate, and culture, or that the varieties are unsuited for the climate and soil of Dodds,—[illegible]

THE BEST TEA,—THE FINEST THE WORLD PRODUCES,

forms the subject of a Circular by Cooper, Cooper & Co. of London, from which we quote as follows :—

It is a natural and laudable aim of every housekeeper to get the best of everything for her money—the nicest dresses and the prettiest bonnets—but for the male portion of her household the "Edible and Potable" are of primarily daily importance. The juiciest joint from the butcher—the milk most heavily laden with cream from the dairy—the ripest fruit from the stall, and the newest laid eggs from the farm—these are, one and all, desired to sustain the inner man and fit him for his duties, but of not less importance is the cup that aids his digestion and clears his mind from the fatigues of the day and recruits exhausted and worn out nature at eventide.

Now, though tea is perhaps of more general consumption in every household than any other one article, it is a singular fact that it is bought with greater carelessness and want of thought than any other thing which we consume.

A Poet remarks of one of his unregardful characters that

> "A primrose by a river's brim,
> A yellow primrose is to him."

Simply that and nothing more. So it would seem to many that a cup of tea is simply a cup of tea, simply that and nothing more. Unfortunately a cup of tea is frequently a great deal less, and often something more. A great deal less in that it is largely composed of withered and spent leaves that no more represent tea than a sucked orange represents the fruit of the orange tree, and something more, in that much common tea is largely made up with filth and dirt "that never budded into vernal bloom"—to add to its weight. Now Cooper Cooper & Co. have devoted their lives and energies to put it in the power and reach of every householder in the United Kingdom to procure both good and genuine tea of the highest character—and at prices showing only a bare commission on the prices paid in India, Ceylon and China for the tea they sell.

How many of us turn with loathing from the tea presented to us in many places of public entertainment, and even at hotels of respectability, and sometimes, alas! even at the table of our friend or neighbour we are compelled to mutter "Faugh, it is *abominable*."

How different when asked to partake of a dish of REAL TEA made from choice Indian, Ceylon or China leaves, redolent with rich bouquet and spring freshness!

It is a well-known saying of epicures "The best is good enough for me." Now the best growths of tea from India, Ceylon and China are only just good enough for Cooper Cooper & Co. to sell. The best grown and sent from these countries Cooper Cooper & Co. do sell at 3s a pound.

Cooper Cooper & Co. also sell choice teas at 2s 6d and at 2s a pound, and these teas are economically cheaper than any teas sold at lower prices. They are cheaper because they have got more in them, more real tea extract from a given quantity than can be got out of lower priced teas.

In the Indian gold mines we hear that certain ores give so many ounces of pure gold to the ton—some, two or three ounces: some, especially rich, eight to ten ounces to the ton; but no one would contend that the richer ores are dearer because they would fetch twice the price per ton, for it is the gold that is of value, the refuse is valueless. So with tea. One pound of the fine tea sold by Cooper Cooper & Co. will yield more real tea extract than twice the quantity of inferior tea, and not only twice the quantity but twice the quality—*refined gold not mixed metal.*

Try it for yourselves! Become your own analyst: put it into the crucible, viz., the teapot, and you will find the proof of the tea is in the drinking.

Nevertheless, Cooper Cooper & Co. are simply the servants of the public. They have been asked thousands and thousands of times to supply tea at a lower price than they have formerly done—in fact, they have received a *Mandate*—not from a small constituency, but from the people of England, Ireland, Scotland, and "gallant little Wales," to supply tea at a lower quotation and to supply it genuine and honest, not mixed with rubbish or attenuated by previous infusion, and this Cooper Cooper & Co. have now done, and have added to their list, black teas at 1s 8d and 1s 6d and 1s 4d a pound. These are all perfectly genuine teas, pure and fit to drink, analyzed by Cooper Cooper & Co., and selected from the robust productions of India, Ceylon and China, and there is no tea sold in the United Kingdom of equal value.

An additional slip states :—

There is no tea of equal value offered for sale in this Kingdom, as the robust and intermingled Indian, Ceylon and China teas, now selling by Cooper Cooper & Co., at 1s 4d, 1s 6d and 1s 8d a lb. They are as strong as a cart-horse.

The teas at 2s, 2s 6d and 3s a lb. are economically cheaper—they have more stamina in them.

From a pamphlet by the firm we quote as follows :—

CEYLON TEAS.

The increased production of Ceylon Teas, and the excellence of a great portion of the Teas grown in that Island, have induced Cooper Cooper & Co. to offer selections of the best specimens, which they are now selling at the following prices :—

17 Ceylon Pekoe Souchong at 2s a lb.
18 Ceylon Pekoe ... at 2s 6d a lb.
19 Ceylon Orange Pekoe at 3s a lb.

Cooper Cooper & Co. being simply dealers, and under no obligation to further the interests of any particular gardens, give their customers the benefit of their technical knowledge of the article. Being specialists in Tea, they select only the choicest sorts.

Tea growing in Ceylon is quite a new industry, but this Island seems well adapted to the development of the Tea plant, and Cooper Cooper & Co. look forward to a considerable increase in the production.

HOW TO BREW TEA.

Cooper Cooper & Co. wish to state that, to brew Tea properly the water should be poured on the moment it boils, or it becomes *hard*, and fails to draw out either the colour or the strength and entirely destroys that fine aroma or bouquet which is so characteristic of choice and rare Teas; at the same time it is most important that it should boil thoroughly (simmering won't do), or it quite spoils the Tea.

Tea should be brewed either in China, earthenware, or silver pots, in no case in metal, pewter, or *German silver* ones as these impart a metallic flavour which detracts pence a pound from the quality even should they have been in use for years. Carbonate of soda spoils Tea—it destroys the briskness and pungency in which (in a great measure) consist the value and quality. Tea should be brewed ten minutes, and all the water poured on at once.

HOW TO KEEP TEA.

It is most important that Tea should be kept in a dry place, well covered up, and not stored near coffee, spices, oranges, or any kind of fruit. Fine Tea so readily absorbs any flavour with which it may come in contact, that the necessity of keeping it apart from other articles of consumption will be at once apparent.

THE MERCHANDISE MARKETS ACT, 1887.

The *Produce Markets' Review*, after quoting the main provisions of this stringent Act, remarks :—

The above extracts will show traders how important the new Act is in extending the scope of the old law dealing with adulteration, to the offence of misrepresentation of goods, which now, as it will be seen, subjects the perpetrator to most severe punishment. So drastic a law cannot fail to have widespread consequences, and, as it apparently is within the

power of any one to put it into motion, there will probably be ample use made of it. The analysts also, by combining prosecutions under the new Act with the prosecutions hitherto brought for adulteration, could probably bring a good many, who have hitherto escaped within the limits of the law.

It certainly behoves traders carefully to look through their stocks and quotations, and to guard themselves from consciously offending. To accurately define and describe the thousand and one articles sold by a modern storekeeper would pass the wit of man, but still direct misrepresentation is another matter. In the Grocery trade one of the subjects that will attract the attention of wholesale Dealers is the so-called "French Coffee." In a case when this substance had nothing to do with France, and consisted mainly of chicory roasted in England, and flavoured with a little Coffee, is it likely that the Coffee Planters' Association would allow such an abuse to continue with such a stringent law at their back? And who would they be likely to attack—the small Grocer or the wholesale packer? Of course, all so-called "French Coffee" is not like the extreme case imagined; but, though it is often good and cheap enough, it is certainly not "French," because it is not imported from France. That extent of misdescription seems to constitute a crime in the eye of the new law. Nor, again can a substance be Coffee if it contains more than half its weight of Chicory and other substances. The packers of Cocoa, Mustard, and the like, will also have to carefully look through their labels and descriptions in the light of the new Act, and drapers may, perhaps, do well to measure a few reels of their cotton. It is satisfactory that this new enactment should go to the fountain-head, and, if an attack is to be made or packed goods retailed in the state in which they are supplied, that the wholesale manufacturer will be liable as well as the retailer. This, however, would not so entirely apply to goods sold in bulk, and the retailers will have to protect themselves in cases such as those in which pepper husks, or qualities of pepper containing an undue proportion of husks, are sold to them as pepper. Possibly, however, the description of such goods as "pepper" on the invoice would enable the retailer to proceed against the wholesale dealer, and there certainly appears to be an opening for actions of the sort if ground "pepper" is openly offered for sale at 1d, 1½d or even 2d per lb. below the cost of the whole corns. In the same way, the sale of arrowroot under the name of Bermuda, when mixed with the much cheaper Natal and other kinds; and similar misdescriptions with other goods, would have to be guarded against. In respect to this Act a protest was made and seconded at Wednesday's Spice sales against further parcels of so-called Penang White Pepper, which are known to be admixed with stones or clay pellets made to imitate pepper, being catalogued and offered in public sale as "Penang White Pepper." In this case the so-called pepper was offered "with all faults," but the trade held that this did not meet the case, and that the commodity should be described as "pepper mixed with clay pellets." Turning to another trade, the port wine shippers may if they please interfere with Tarragona being sold as "Port"; and many similar observations might be made about wines and spirits. The object of these remarks, however, is only to draw general attention to this matter, for the Act is one that is really drawn in the interest of traders, and will be very beneficial to them in the long run.

This new law suggests another point, and that is that it would be very advantageous if such laws were enforced by people acting with full knowledge, and at the same time with proper consideration for those who, from ignorance or other circumstances, may be unacquainted with the requirements laid upon them. For instance, the Grocer's Company might revive the dormant powers which should never have been allowed to lapse—in return for which it enjoys its revenues, and become a living body again like the Fishmongers' Company has done, by preventing the debasement of the trade from which it springs. The "endowment of research," which it offers, may be an excellent thing, but the Grocers' Company was chartered for the prevention of adulteration and of similar offences, and if its long-disused powers are insufficient, the Legislature would readily strengthen the hands of a trade guild which desired to exercise its functions, especially if it again came into touch with the branch of commerce it is supposed to represent.

PLANTING IN DELI.

(Translated for the *Straits Times*.)

In the Netherlands India budget for the next financial year, there is not a single vote regarding the despatch of a mission to India to devise measures for furthering coolie emigration from thence to Deli. Nothing is known as to whether the idea has been lost sight of, or has been dropped owing to its becoming inexpedient to bring the matter forwards for the present.

The state of the coolies in Deli still falls short of the mark. The Netherlands India Government are so alive to this that they have instructed the local authorities to make enquiries on the subject, and report on what amendments may be made in the coolie ordinance. The Government seem also to wish to fix a minimum coolie wage a month. The *Courant* objects to a minimum monthly rate of wages being fixed by law, on the ground that it would encourage idleness among the coolies. On almost all estates there, the minimum monthly rate of pay amounting to $7, is looked upon as high enough for fellows who do not care to increase their income by task work. On behalf of Government, raising this minimum to 16 guilders has been suggested with scant chance of its meeting with general acceptance with the planting community. The planters do not want any more tinkering at the present ordinance. It has shortcomings like other pieces of human workmanship, but it meets all reasonable requirements on the part of employers and labourers. The only complaint against the ordinance is that it is not strictly put in force. The ordinance does seem however to require some revision in the direction of furthering the interests of the coolies. They in fact stand in need of better provision for medical attendance and fairer treatment generally as regards housing, rationing, and accommodation.

The accepted economic dogma that supply and demand regulate prices, does not hold good in Deli. There the system of tendering for tobacco takes effect in the direction of fixing the value of that article, without much regard for that elementary principle of political economy. The most influence too on this head is exercised by excessive purchasing competition on the part of Dutch and foreign firms, who have large capital at their command. The consequence is that wholesale dealers do not find their profits at all commensurate with the risks run. Instances even are known of prices paid which can only be the outcome of determination to cut out competitors at all costs. The planters meanwhile take advantage of this keen competition to realise enormous profits. So sure were they of remunerative returns that slovenly packing became common. With such a spur to exertion, no wonder that tobacco 'growing spreads apace. The resulting crop aggregated 110,000 bales in 1886, being 15,000 more than in the previous year. The increasing area put under the leaf, will beyond doubt tend to render the supply greater than the demand. At the close of last year, for example, second hand dealers had larger quantities of it in stock than ever before. The outlook is the gloomier from the prospect of British North Borneo soon entering the field with a heavy yield of tobacco, now that the pioneer consignment of leaf from that quarter to Amsterdam has proved to be of highly superior quality. Should this forecast hold good, overproduction will become an important factor in the market. To cigar makers the vital point lies not so much in quantity as in quality. The average tobacco in the market from Deli and Lankat of late seems, so says a German trade journal, to show a steady falling off. In these two districts the exhaustion and wasting of the soil have begun to tell in the direction of the deterioration of the product unless manure be more freely resorted to.

COFFEE, SUGAR, CINCHONA, IN MANILA.

(Translated for the Straits Times.)

The *Comercio* calls attention to the steady fall in the imports into Manila, compared with last year as evidenced by the unfailing test of the customs returns. They point unmistakably to the unpleasant fact that from January to September last, the decrease aggregated no less an amount than $387,000. It is only one phase of the crisis which the Philippines are passing through. Any change for the better depends upon the speedy discovery of a remedy.

Another matter of great moment to the Philippine mercantile community is the critical state of the sugar trade. The sugar produced in the islands turns out to be of such superior quality, that it is believed locally to be the only one that can withstand competition with the beet root article. In spite of this advantage, the low price ruling is proving ruinous to the unfortunate growers. Their main difficulty lies in the impossibility of materially curtailing the cost of production.

Another produce article, coffee, shows no sign of falling off in value. On the 24th October, the price at Manila reached $40 per picul. The coming crop promises to be so much more abundant than that for the present year, that contracts for delivery in January next have been concluded at the rate of $25 to 30 per picul. This hopeful prospect brings prominently into notice a piece of official folly. Some years ago the then Governor General proved wiser than the ordinary run of individuals there, who happen to be clothed with a little brief authority in that high position. He ordered the provincial authorities wherever circumstances favoured to direct the natives under their control to set to work planting coffee. This was done far and wide. But the Governor-General's departure proved fatal to the success of the scheme. When his eye was no longer upon the provincial authorities, the newly laid out coffee plantations were neglected. Their wreck and ruin soon followed. The far seeing policy which started them has only now received adequate recognition. Had these plantations been now in existence, they would be in bearing by this time, and would have become a productive source of revenue.

Though the mountain ranges offer facilities for the cultivation of cinchona, that branch of planting enterprise is ignored in the Philippines. It is indeed surprising that considering the increasing consumption of quinine throughout the world, its cultivation in those islands has never been taken in hand. The main difficulty in the way of plantation enterprise lies in the obstructiveness of the land regulations. The Home Government shows signs of amending them, but its good intentions have so far borne no fruit.

TROPICAL PRODUCE TRADE REPORT.

42 Cannon Street, E. C., Nov. 3rd.

ANNATTO.—Twenty-four baskets good bright fresh Parà roll are offering at 1s 6d per lb. Half-cwt bright powder from *Java* was bought in today at 1s 6d per lb nominally. Nine bags fairly bright *Ceylon* seed sold at 3d per lb. The article shows no alteration.

CROTON SEED.—Our market is burdened with a stock far above its assimilating power, and at today's auctions the already very low rates experienced a further heavy decline, 12s per cwt. being accepted for fair pale seed, and 9s for dull mixed. Dark seed is held at 8s per cwt., but found no buyer even at that figure.

CUBEBS.—At Amsterdam a parcel of 17 bales bold berries of mixed colour was offered for sale by tender last week. Six bales sold at a price which has not been made public, but is stated to have been under 25*l* per cwt. On our market the article remains extremely scarce. Two bags grey and brown mixed berries, rather stalky, were bought in at 25*l* per cwt.

KOLA NUTS fetched good prices, 8½d per lb for good new *Jamaica*, 8½d to 9½d. per lb for small bright *Grenada*.

OILS (ESSENTIAL).—*Cinnamon* oil has been shipped from Ceylon during the season 1886-7 to the extent of 62,668 oz, the smallest shipments since 1880. Last season the exports were 139,094 oz and in 1884-5 117,023 oz. Good oil may be had at 1s 6d per oz *Cinnamon leaf* dull at 1½d per oz. The total exports of *citronella* oil from Ceylon during the season which closed on October 1st have been 8,371,426 oz, against 6,461,278 oz in 1885-6, 5,721,112 oz in 1884-5, and only 1,760,677 oz in 1880-1. The article remains neglected at ¾d to 15-16 for native brands. *Cloves* 6s 3d to 6s 6d per lb. For oil of *cubebs* higher prices rule, owing to the increased value of the drug. *Lemongrass* quiet, at; 1¾d to 2d per oz. Oil of *limes* sold at 2s 3d per lb; more is obtainable at that price. Fisher's *Patchouly* oil bought in at 3s 3d per oz nominally,

PATCHOULY LEAVES.—A shipment of 58 bales has just been received, and was offered at the auctions today. Although the article is so scarce no bids were made, and the whole was bought in; good-flavoured brown leaves, sifted and without stalk, at 1s to 1s 1d per lb; stalky, partly damaged, at 9d per lb; one case dull brown leaves, rather damp, sold at 9½d per lb.

WAX (Bees') steady and in fair demand. *Jamaica*: Good orange, 5*l* 12s 6d; red, 5*l* 7s 6d; chocolate and brown, 5*l* 2s 6d to 5*l* 5s; dark 5*l*; *Ceylon*: Dull grey, 82s 6d.—*Chemist & Druggist.*

SUCCESSFUL SILAGE EXPERIMENTS.—A paper received from the Madras Government records the result of a trial of ensilage by W. Dumergue, Esq, Acting Sub-Collector of Salem.

For the purposes of the experiment a spot was selected in an open elevated place in a Government tope near Hosúr and a pit measuring 30′ × 12′ × 6′ was excavated in the end of August. The sides of the pit were made perpendicular and no lining of mortar or any of the substance was applied to them or to the bottom of the pit, nor was the pit dried artificially. Filling commenced as soon as the pit was ready and was carried on for twenty-one days until the grass stood about 5 feet above the level of the top of the pit. It was then left for three days to allow of sinkage, and next, in order to ensure equality of pressure, split bamboos with stones placed on them were laid along and athwart the grass. Half the amount of earth excavated from the pit was then thrown on, and the silo was finally closed the next day with the remainder of the earth. Some days were allowed for the subsidence of the mass, and lastly the mound of earth, which were about 2 feet above the level of the ground, was made slopely and extended a foot beyond the margin of the pit on all four sides. Thus the time occupied in filling the silo extended to twenty-three days. The cost of digging the pit amounted to R5 and that of cutting grass, filling and cleaning the pit to R35, making a total of R40. I regret that I had no means of weighing the grass, as it was put into the pit; but, as will be seen below, an account has been kept of the number of pounds af silage taken out. The silo was opened on 23rd March bnd emitted a strong smell not unlike that of a tannery, out this smell evaporated with a few hours' exposure to the sun and the silage then had a faint odour of hay. Details of the quantities of silage issued will be found in the accompanying form B, from which it will be seen that 14,350 lb. have been used. There still remain about 650 lb. with which I am feeding castrated ponies. It may at once be stated that the results of the experiment have been most satisfactory, and I had from ryots more applications for silage than I could comply with. One ryot (No. 1 in the list) after feeding a pair of bullocks on it for thirty-one days came and asked me if he might sell them as they had come into such good condition that he would get a good price for them. Another (No. 2) worked his pair of bullocks from morning to night for twenty-eight days without intermission, and when I saw them at the end of the time one was certainly in much better condition than at the beginning. The other showed no difference, but, considering its extreme age, the fact that it was living and working was surprising. I myself fed two milch cows on silage and their yield of milk certainly diminished when silage was discontinued.

CHINA AND JAPAN TEA EXPORTS 1887-8.

THE PROSPECTS OF A DECLINE IN THE CHINA TEA TRADE.

As the arrivals of tea at Foochow for the current season are all but over, we are in a position to estimate what the entire season's shipments to Great Britain are likely to be, since, henceforth, they must be altogether out of the stocks at Shanghai and Foochow.

The stock of black tea at the former place is estimated to be about 100,000 half-chests of 50 lb. each or about five million pounds. Add to this 5 million lb. green tea, which however is chiefly for local consumption, only a small portion being likely to be shipped to America. At Foochow the stock may be computed to be 95,000 chests of 90 lb. each or about 8½ million pounds. Another million pounds may be put done for Canton, making a total of 14½ or say 15 million pounds.

The export from all China so far has been according to the subjoined figures :—

Exports from China and Japan to		lb.
United Kingdom	...1887-8	98,704,453
" " " "	...1886-7	127,513,072
" " " "	...1885-6	130,433,560
" " " America	...1887-8	46,459,001
" " " "	...1886-7	52,995,564
" " " "	...1885-6	49,760,091
" " " Australian Colonies	...1887-8	20,841,569
" " " "	...1886-7	19,007,742
" " " "	...1885-6	20,817,817
" " " Continent of Europe	...1887-8	13,199,579
" " " "	...1886-7	8,317,410
" " " "	...1885-6	8,618,678

The total export for the season at the end of April will therefore probably be 114 million pounds against 150 million pounds at the same time last year, or a decrease of 36 million pounds.

The statistics issued by the London Tea Brokers' Association and by the India Tea Association to the end of October are interesting and instructive. By the former we learn that the imports from all quarters are 17¾ million pounds short of the previous year, owing to the decrease from China of 28 millions, which was partly compensated for by an increase of about 8 millions from India and 2 millions from Ceylon. The deliveries of all descriptions were 5¼ million pounds below those of last year, but, as the home consumption was a million pounds in excess, the decrease in the deliveries was owing chiefly to a falling-off in the export of 5 million pounds. That there should be this falling-off in the export is strange in the face of the export from China and Japan to America being so short, but this is partly counterbalanced by the increase to the Continent of Europe. We can scarcely think that consumption has fallen off in America and the Continent so largely, and, if it has not, the present decrease is in favour of a larger export later on.

By the India Tea Association's returns, we learn that not only had the whole season's increased supply been shipped in the first six months, but two millions pounds more. The total increase this season from India is estimated at seven million pounds, whereas an increase of nine millions has been shipped, namely 50 millions against 41 millions. As the total shipments to England to the end of April next are estimated at 81 million pounds, there are just 31 millions to be shipped during the six months ending the 31st March. The probability is, this quantity will be shipped during November, December and January. The increase from India has fortunately been disposed of, but there is little room for doubt that the large quantity of Indian tea placed on the London market during the dull season of the year accounts for the depression recently telegraphed in the face of more favourable statistics than we may ever see again in the history of the tea trade unless the Continental and American peoples go in specially for tea. The increase from Ceylon for the last six months of the current year is about three million pounds, and that of the first six months of next year will be about six millions, or an increase of nine millions for the year: this with the seven millons increase from India reaches sixteen millions, against the decrease from China and Japan.

Since writing the above we find in the China papers the following long deliverance on the causes of the decline in the China Tea Trade and the remedy therefor. The information given respecting the adulteration of China teas, and especially as to the mode of cultivation in former times, is rather amusing. We cannot believe that tea shrubs pruned annually, cultivated and manured regularly, and only plucked three times a year, were found to be used up in eight years and accordingly taken out of the ground and burnt. Impossible! We have heard of tea bushes in China, properly treated, bearing crops for a hundred years.

THE DECLINE OF THE CHINA TEA TRADE.

THE OPINIONS OF THE FOOCHOW MERCHANTS.

Sir Robert Hart having requested, through the Commissioners of Customs at the various ports, the opinions of the merchants as to the faults found with Chinese tea and the remedies suggested to improve its quality, a valuable report has been drawn up in reply to the request by the Foochow Chamber of Commerce, and has been printed together with some correspondence on the same subject. A separate report having been asked for in regard to any steps thought desirable and practicable to be taken with a view of placing the teas on the London market at cheaper rates, the Chairman of the Chamber writes as follows :—

Foochow, 3rd Nov., 1887.

Sir,—In connection with my other letter of this date, I have the honor to wait upon you with a separate Report, as requested, having reference, solely, to the excessive taxation with which the China Tea Trade is burdened, as compared with the Free Trade of India and Ceylon in the same produce.

The Export Duty amounts to Tls 2.5 Haikwan Sycee per picul, that is Tls 2.75 currency, which together with Lekin and other small Taxes (say Tls 1.75) gives a Total Taxation of Tls 4.50 per picul, or about 2d per lb in London.

Taking the average cost of Congou at this port during the past season at Tls 14 per picul, duties alone thus amount to no less than 32 per cent, an exorbitant tax, which the article cannot reasonably be expected to bear. It is a significant fact that in the matter of Dust and Siftings, Indian teas of this grade can actually be laid down in London at the equivalent cost of the Duty levied in China.

It is obvious that this question of Duty is the vital point, and it rests with the Chinese Authorities themselves to determine whether they are prepared to go with the times, and the altered conditions of the trade, by relieving it of these taxes, or allow it to pass into the hands of their free trade competitors.

In conclusion, I would point out, it is estimated that in the year 1890 the entire crop of Indian tea will be laid down in London at a cost of 6d per lb. or under, while the average value of the crop of Foochow Congou this year was Tls 14 or the equivalent of 9d per lb. laid down in London for teas immeasurably inferior to those of Indian growth—I

have the honour to be, Sir, your obedient servant.

(Signed) R. W. H. WOOD,
Chairman of the Foochow Chamber of Commerce.

To Charles Hannen, Esq., Commissioner of Customs, Foochow.

On the same date the following letter was addressed to all the Foreign Consuls at Foochow:—

Foochow, 3rd November, 1887.

Sir,—I have the honor to enclose copies of the correspondence that has taken place between this Chamber and the Commissioner of Customs at this port, with reference to the abuses complained of by the merchants, regarding the serious decline in the tea trade of this and other ports in China, and I would ask your special reference to a paper read by Mr. Berry White before the Indian Section of the Society of Arts which is given in the Appendix F.

From the Report you will observe that the real difficulty arises from the fact that the teas from China have to submit to a very heavy burden of taxation before they leave this country, while the teas from India and Ceylon are exported free of all duties.

The export duty was originally fixed by the Treaty of Nankin, August 29th, 1842, (Article 10), and by the Treaty of Tientsin, 26th June, 1858, (Article 26) at Tls. 2½ per picul, which was to represent the rate of 5 per cent "ad valorem."

As the average price of tea in China has never reached so high a figure as Tls. 50 per picul, it is difficult to understand how such a rate as Tls. 2½ per picul, (as representing only 5 per cent on the average value of the article) could ever have been agreed upon, and that such an extraordinary mistake should have been allowed to pass unnoticed at the time.

In addition to this export duty the Chinese officials have imposed an inland duty called Lekin or War Tax, together with other minor Barrier exactions, making a total impost of about Tls. 4½ per picul, before the teas are shipped, so that estimating the average value of the crop of Congou at about Tls. 14 per picul these duties on exporting the article represent 32 per cent, or about six times the originally intended Tax. It would seem, therefore, to become merely a matter of right for merchants at the treaty ports to demand a revision, and readjustment of this quite unwarrantable tax, which, based upon the present value of the article should certainly not exceed Tl. 1 per picul, viz., 5 per cent ad valorem, as originally contemplated by the Treaties of 1842 and 1858.

It should be borne in mind that Article 27 of the Treaty of Tientsin of the 26th June, 1858, stipulates that either of the high contracting parties to the Treaty may demand a further revision of tariff at the end of each successive ten years; under these circumstances no time should be lost as any alteration must take effect from the 26th June next, or better perhaps from the commencement of the Tea Season in May, 1888.

I would beg, Sir, therefore, to urge that you will communicate the purport of this despatch to your Minister at Peking, and as the subject is of such vital importance to Foreigners and Natives alike, I trust the grievance complained of will be at once brought to the notice of the Tsungli Yamen, and receive the immediate and earnest attention which the matter undoubtedly necessitates.—I have the honour to be, sir, your obedient servant.

(Signed) R. W. H. WOOD.
Chairman of the Foochow Chamber of Commerce.
Addressed to all the Foreign Consuls at Foochow.

The following is the report "on the decline of the China tea trade with suggested remedies":—

It cannot be doubted that the falling-off in the quality of the China staple is the cause of its rapid decline in favour in the great consuming centres, and we will now give, as concisely as possible, the opinion of this Chamber as to the causes which have produced this deterioration in the quality of teas produced in this province.

A very full report was presented to the Authorities of Foochow in the year 1876 from this Chamber in which most of the grievances were pointed out. Eleven years have since elapsed, during which period no attention whatever has been paid to it, while the predictions therein expressed have been fully borne out. On the other hand, our competitors in India and Ceylon have received every encouragement from their Governments, who do not levy any duties whatever, and assist them by the construction of roads and railways to the more distant plantations, and in fact have done everything in their power from its infancy, to foster a trade which has in consequence already reached such gigantic proportions.

A table is appended giving the total deliveries of tea in London during the past seven years, also the deliveries of China Congou and of Indian and Ceylon teas during the same period, these figures showing the marked increase in the latter and very serious decline in the former, cannot fail to strike even the most casual observer. There will also be found added thereto the figures for the first four months of the present season (1st June to 30th September) received by telegram, and which, compared with those for the same period last year, are even more alarming to those interested in the trade of China.

It is an acknowledged fact that the quality of Foochow teas was at its zenith during the period 1864 to 1866, gradually declining to its present low level, and it may be useful to compare the prices ruling on this market then and now, and to show what should be the present value of similar quality owing to the decline in the rate of Exchange on London, the average rate in the years 1864 to 1866 being 4s 8d per dollar, and for this purpose a Table marked Appendix B is given, and to which is added a Table giving the present value of Indian Tea on the London market and its equivalent in Taels on this market.

On the most reliable authority obtainable it is found that when fine Tea was produced in this province, it was the custom on the plantations, after the picking of each crop to thoroughly trench the ground giving a liberal supply of manure in the form of fresh grass cut in the immediate neighbourhood to each plant, to prune the plants at least once every year, and when they became eight years old they were destroyed as worn out, new shrubs being planted in their place. And another most important matter, only three crops or pickings were taken in each year.

Now what is done? Simply nothing, no trenching, no manuring, no pruning, no replanting. While in most districts five crops or pickings are taken each year from the old worn out plants, and the 4th and 5th crops are torn off the trees with shears or a bill hook.

Foreigners who have lately visited the once famous Pak Lin districts state that the tea plantations are utterly neglected, overrun by weeds, and the shrubs full of dead wood and covered with blight, while between each row sweet potatoes are grown.

To this Chamber the remedy seems very simple.

New plantations on new ground must be laid out, and well fostered as of old. This, however, is of necessity a work of years, but the following may be suggested as a temporary and immediate remedy.

The plantations should be thoroughly cleansed and trenched, the plants *well pruned*, a very liberal supply of manure given, and when practicable new shrubs be introduced. And it is most important that only three crops or pickings should be taken each year.

The natives state that the increased cost of labour prevents this being done, but the Tables given in Appendix B show that improved quality gives improved prices, while if nothing be done, the tea trade of Foochow will become a thing of the past.

If, as stated before, the finest teas were produced with only the application of grass as a fertilizer, then it would seem unnecessary to go into the question of other manures, more especially as for some unknown reason the Chinese have a strong objection to their use, but we would draw attention to the extract from Colonel Money's well known work on tea cultivation in India, Appendix C., which shows that chemical manures

have been used there with great advantage. And in the interest of this most important trade we would venture to suggest that the Chinese Government should cause experiments to be made with the various well known manures, say grass, bean cake, animal guano, and chemical, and we would further suggest that the said experiments should be made on the Pak Lin plantations, under the immediate supervision of a foreign expert. Further: instead of reproduction being carried on in the old way from cuttings from the shrubs, new plants should be raised from seed which might be obtained from India and Ceylon, and might also be interchanged with the varieties from the other districts in China. From the close proximity of Pak Lin to Foochow these plantations could be visited from time to time by the Native and Foreign merchants interested.

Another question of great importance is that of firing and curing the Teas. In the early days Teas were well and strongly fired, and it is a well known fact that their quality was as good at the end of a year as on the day they were shipped; now, presumably on account of want of sap in the leaf, it is so lightly fired that the tea commences to deteriorate within three or four months from the date of packing.

We would now call attention to other grievances, perhaps of less importance than the improvement in the quality of the tea, but which in themselves greatly militate against the trade of the port, and first on the list is: *excessive proportion of Dust and Stalks.*

The tables given show (Appendix D) the percentage of Dust as found this season, as well as what is considered should be a fair proportion.

This is a very important question, more especially as regards the trade with the Continent of Europe. Australia, the United States and Canada, where, until late years, Foochow teas were exclusively taken, but now owing to this excessive proportion of Dust, merchants are being compelled to draw their supplies from other sources, and on the Continent of Europe Ceylon teas are finding much favour to the great detriment of Foochow tea.

The evil is one of long standing as shown by the protest made by this Chamber so far back as 1876, Appendix E., but unfortunately it has continued to increase, and in this year's crop the percentage of Dust is probably the largest yet known.

In the above-mentioned protest attention was drawn to the poor condition of the packages and thinness of the lead; instead of any improvement however, in this respect, complaints have become more frequent of late years. There has also been much irregularity in the packing of the teas; in some instances a discrepancy occurring of 4 or 5 lb. in packages of a parcel or chop, which is a constant cause of disputes in striking the average weight.

A further and much to be regretted abuse in the trade is the constantly recurring attempt at fraud on the part of some teamen, in the endeavour to sell their produce by false samples and muster packages. This is specially the case with Souchongs.

Three distinct attempts have been proved during this season against a Tea Hong and its branch firms to defraud the foreign buyers by means of these false samples, which, had the matter passed undetected, must have led to very serious loss; the difference in value between the muster package and the bulk being from Taels 4 to 5 per picul.

It appears that many teamen are in the habit of packing, separately, a small quantity of superior quality leaf to the rest of a chop, which is sent out as a sample fairly representing the bulk, trusting that if detected a cut in price will be arranged, which would not even then sufficiently compensate the buyer.

Such fraudulent and dishonest practices can but tend to the injury of the Tea Trade and to the loss of that confidence and cordiality which should certainly exist between buyer and seller.

A case of detected imposition by the Hong above alluded to has lately been brought to the notice of H. B. M. Consul, through whose representations to the Native Authorities a fine of Five hundred Dollars has been imposed.

There is another matter which calls for suppression, viz., the admixture of Lie Tea, or leaf other than Tea Leaf, and the employment of cangee or rice water, tea dust, soot, and such like deleterious substances in the manufacture of locally packed Teas. The natives affirm, with truth, that the demand "for price" has led to these malpractices, as with the sizing of cheap shirtings in Manchester, "to meet a demand." Be this as it may, there can be, nevertheless, no necessity for the introduction of lie leaf into the finer grades of Scented Tea, which even experts have difficulty in discovering. The honest trader is thus seriously handicapped, as he can only obtain "market price" for the legitimate article, costing taels per picul more than the Teas of this unscrupulous rivals.

The only remedy that occurs to this Chamber is for the Board of Trade Commissioners to offer an ample reward for the discovery of any Hong having Lie Tea in its possession, and that a severe example be made of the delinquent.

Some time ago a quantity of Lie Tea was publicly burnt, but the operation was carried through in a half hearted way, and it is said the soldiers who superintended the matter secreted and resold a considerable quantity.

In conclusion we can only add that it is the opinion of the Chamber that if the Tsung-li Yamen approach this important question in the manner it deserves, and causes the various remedies to be carried out, then the Tea Trade of Foochow may be revived; but if not, its very existence will cease in a few years.

Sub-Committee { JOHN ODELL, H. P. TENNANT, WM. L. HUNTER, FRANZ SCHONFELD, T. PIM.

A letter signed by all the foreign merchants at Foochow has been addressed to the Commissioner of Customs signifying their entire approval of the correspondence and the report.

CEYLON UPCOUNTRY PLANTING REPORT.

PIONEERS IN TEA—"KNOWING TEA CHAPS" AND PRACTICAL TEA MAKING—ELABORATE PLUCKING.

5th December 1887.

To our pioneers in tea we all owe much: and when one of them comes forward with a paper on our rising product, as Mr. Armstrong did the other day at the request of the Dimbula Planters' Association, *we* look for instruction, and *he* has the certainty of at least a patient hearing.

There is a considerable amount of honour attached to being one of these knowing "tea chaps," not to refer to more material rewards. When he speaks, his audience is a wide one, including in fact the tea-growing brotherhood of Ceylon and elsewhere; and when he condescends to put his mature ideas into black and white—"copy" for the press in fact—it savours somewhat of temerity and more besides, to do aught else than bow down and adore. I would be reverential if I could, and see in Mr. Armstrong's latest deliverance, an inspired message to our new dispensation; but I am bound to confess—humbling as the admission may be—that I can't do this, for I came out of the perusal of Mr. Armstrong's paper in a hopelessly muddled and be-fogged condition, and with feelings the reverse of devotional—a chapter of the stiffest metaphysics was nothing to it. "When treating of plucking," then the "agony" was especially piled, and when I thought of the mental capacity of our labourers, the amount of supervision it was possible to afford, the elaborateness of the instructions laid down, and that horrible nemesis in the shape of "a poor liquid" which would follow the neglect thereof—bitterness filled my heart, and I heartily wished that our local oracle had been a dumb one, or that fate had never made me a tea planter. Much more reading of that

kind would send a lot of us out of our minds, and fill the Home for Incurables. I got my first ray of comfort, through cherishing a wickedly heretical opinion. This unholy suggestion presented itself to my be-fogged mind in the daring question: Is it possible that one of these "tea chaps" could put on "side"? After this effort the mental atmosphere cleared somewhat, and I was enabled to see that tea is not half so particular as a tea authority, and that however scientific and elaborate his style of culture may be, the tea plant does not necessarily retaliate the neglect thereof. I could remember what I had seen in one of our famed gardens when I went one day to have a look at their pluckers, having heard from the manager before what their system was. It was a very simple system, but I did not find it quite carried out. A great deal more was taken than was allowed, and yet I suppose every effort had been made to keep things right, only with the scores of pluckers at work, Tamils and Sinhalese, how little could be done. Yet spite of this seeming laxity and want of rule, the results financially have been a splendid success.

Systems of elaborate plucking break down in the field and are bound to. Fancy poor Ramasamy with the following in his mind, rendered more limpid even than the original when translated into durai's Tamil:—"Pluck to a shoulder: primary growth after pruning pluck at about three leaves, then take half the top leaf allowing two leaves and a half (a shoulder) to remain. Secondary growth pluck at about two leaves and take half the top leaf equal, one-and-a-half leaf remains; the sides the same way, beginning at one leaf higher, getting to the one-and-a-half leaf stage at the tertiary instead of the secondary growth!"

And all this wealth of loving care Mr. Armstrong assures us is necessary with "a lower class hybrid"! When planters read such detailed instructions, bearing the imprimatur of authority, it affects them in several ways. The men who are in the thick of the work, and have some experience, "smoil a smoil," put the thing aside, and go on pretty much as before. The others, who have not yet got their tea in bearing and are filled with that reverential respect for authority so becoming to inexperience, finding the depths so very deep, dismiss the subject from their minds in the meantime—no need to worry themselves yet. In time they too get an increase of knowledge of a practical kind, and laugh in their turn.

If a proprietor wanted to quarrel with his manager or S. D., I fancy he could not get up a 'row' readier than by handing him Mr. Armstrong's remarks on Plucking, with the request to carry them out. He would very soon have an opportunity to "let into him." Without doubt there is much valuable matter in this paper of Mr. Armstrong's, but it is just a little hard to get at. It wants the services of the Grand Squeezer to make it available for the vulgar mob. The story of that official's rise is as follows:—"Long ago the library of the Indian Kings was composed of so many volumes that a thousand camels were necessary to remove it. But once on a time a Prince who loved reading much and other pleasures more called a Brahmin to him and said: 'Books are good, O Brahmin, even as women are good, yet surely of both these goods a Prince may have too many; and then, O Brahmin, which of these two vexations is sorest to princely flesh it were hard to say: but as to the books, O Brahmin, squeeze 'em'! The Brahmin understanding well what the order to 'squeeze 'em' meant (for he was a bookman himself, and knew that as there goes much water and little flavour to the making of a very big pumpkin, so there goes much words and very little thoughts to the making of a very big book), set to work—aided by many scribes—striking out all the idle words from every book in the library; and when the essence of them had been extracted it was found that the camels could carry that library without ruffling a hair. And therefore the Brahmin was appointed 'Grand Squeezer' of the realm. Ages after, another Prince who loved reading much, and other pleasures a good deal more, called the Grand Squeezer of his time and said: 'Thy duties are neglected, O Grand Squeezer! Thy life depends upon the measure of thy squeezing!' Thereupon the Grand Squeezer in fear and trembling set to work and squeezed, and squeezed, till the whole library became at last a load that a foal would have laughed at, for it consisted of but one book, a tiny volume, containing four maxims. Yet the wisdom in the last library was the wisdom in the first." When the Grand Squeezer of today applies himself to the paper under notice what will be the result? Doubtless there would be some aphorisms left, which would entitle Mr. Armstrong both to our gratitude and honour.

PEPPERCORN.

NUTMEGS AND COFFEE IN NETHERLANDS INDIA.

(*Translated for the Straits Times.*)

By last advices from Banda, the news of a rise in the price of nutmegs and mace at Singapore and in Europe, has forced up the value of these articles respectively there to 115 and 157 guilders per picul. It seems however that growers in that quarter have no prospect of profiting long by this turn in their favour. As appearances go, not much of a crop can be expected from the nutmegs from August to November. The yield during that period is hardly expected to cover working expenses. They do not anticipate a change for the better till early in the following year. The crop then is looked forward to with eager expectation in the hope that it would improve matters. Even this depends upon the absence of scorching winds and heavy rains to cause the nuts to drop off unripe. In that case their position will be an unenviable one.

This year's coffee crop in Java looks promising enough. The weather has proved as favourable for the purpose as can be desired. The heat and rain are both moderate enough to suit the planter's requirements. Leaf disease turns out to be decreasing. In short, appearances point to a remunerative year for coffee growers.

In these hard times, planting enterprise has proved so unprofitable that large areas of land taken up for estate operations have been left on the hands of the Java Government, from inability on the part of the lessees to cultivate them with any prospect of success.

BRAZIL AND THE COFFEE MARKET.

Reliable information respecting the prospects of agriculture in Brazil would be of great value to coffee planters in Southern India and elsewhere. There is, however, very little available, and even that is often misleading. Those who believe in the likelihood of high prices continuing point to the facts that the stocks of coffee are 6,000 tons less than they were two years ago; that the last Brazilian crop was small; that it is rumoured that the plantations there are being attacked by disease; and that the planters are having difficulties with their slaves. On the other hand the market has been lately depressed—which means, in other words, that large holders have been frightened into selling at a loss—by the reports of the blossom this year being very fine, and of extensive openings for the cultivation in various provinces of Brazilian Empire. That any one should be influenced by the first of these statements speaks badly for his intelligence. About the time that the blossom comes out the planters are endeavouring to raise money for the following season's working, and are not inclined to spoil their chance of getting it. The

device is a stale one, and has regularly lowered the London quotation for plantation coffee for many years past during November and December; it meets, however, with unvarying success. The fact that Indian and Ceylon planters who are able to sell their crops locally, usually do so about now, may be a mere coincidence. As to cultivation being extended, no doubt those planters who have the means at hand have enlarged their borders; labour is, however, very scarce, and at the best the new estates cannot come into bearing for some years.

An article contributed by Mr. Wells, lately a resident in Brazil, to the *Chamber of Commerce Journal* is valuable in connection with the subject of coffee. He points out that the difficulty of obtaining an idea of how things are going on arises from the vast size of Brazil. Merchants in different seaports form their opinions according to their individual local experience, and from their good or bad fortune in their own business; hence a traveller who had not been over the whole Empire is unable to give a trustworthy account of it. This is true of India as well as of Brazil. The emancipation of the slaves is proceeding rapidly. Less than a million slaves are now in bondage, as against three millions a few years ago. The general opinion amongst English residents is, that the extinction of slavery "will be the death-blow to the profitable cultivation of coffee, an article that at present constitutes the main strength and wealth of the country." Mr. Wells does not believe this. The collapse that overtook the industry in Jamaica, was, he thinks, owing to the sudden manner in which emancipation was carried out, the planters there having had no time to substitute other labourers. The movement in Brazil has been very gradual, and time has been given to prepare for its completion, and to enable owners to make other arrangements; possibly they have done so, but to outsiders it seems as if the only steps taken had been to throw obstacles in the way of the slaves obtaining their freedom, and to wring the last ounce of work from them. The writer has moreover a very high opinion of the character of the free negro in Brazil. In the interior he found all the best work as navvies or muleteers was done by this class. But it must be remembered that however good workmen the negroes may become when freed, it is improbable that they will work for the low rate of wages that planters pay them during bondage. We are not told what is usually given for work of this kind; but from what happened in the West Indies when the cutting of the Panama Canal was commenced we can gather that planters there cannot compete for labour in the open market. In some cases planters in Brazil are doing all in their power to make their slaves comfortable on their estates, paying them for overtimes, and putting them up comfortable houses, in the hope that they will remain on after they are freed. Mr. Wells, however, admits that it is only adopted in a few instances, and owners are generally unwilling, or unable, to undertake the risk. In the northern parts of Brazil, where the emancipation has made greatest progress, the sugar planters have managed to dispense with slaves; the sugar industry is however not flourishing just now, and the number of properties thrown out of cultivation has no doubt enabled owners who have gone on working to make better terms for themselves. With coffee it would be different, and planters would be forced to go on raising rates till the competition became ruinous.

While, then, Mr. Wells "does not endorse the pessimist's view of the disastrous consequences to Brazil of the extinction of slavery" he is obliged to admit that the future prosperity of the country depends very much upon European immigration, and—for he is an engineer and there is nothing like leather—upon the opening up of the interior by railways. That being so, two questions arise. Is the Brazilian climate suitable for the European labourer, and are the Government and inhabitants ready to welcome him when he arrives? The best question our informant answers by saying that the climate is a much maligned one, and that the degeneration and failure of immigrants hitherto is due to the ill-effects of slavery in destroying "the dignity of manual labour." How far the improvement has proceeded may be gathered from the fact that Mr. Wells' assistants cut him for showing some bricklayers how he wanted their work done, and that he considers it a hopeful sign that a gentleman will now sometimes venture to carry a parcel in the streets of Rio. Be this as it may, there is no doubt that in other countries between the equator and the twenty-fifth degree of latitude, white men have seldom found hard work in the open air dignified enough for them. Northern Queensland is a case in point, though slavery does not exist there. As to the second question, immigration is certainly encouraged in a sort of way. The Government has spent several millions in establishing colonies in the interior; the colonists were pushed up through trackless wilds, presented with a piece of land, and left to shift for themselves. Being without means to keep alive till their crops grew, and without a road to remove them when harvested, they found that they might appreciate the dignity of labour till a Carlyle would have burst with envy, and yet starve—which they did. The lands near the coast, or connected with it by rail, are in the hands of great proprietors; they are very glad to employ all the labour they can get, and even in some cases to admit the co-operative principle into their contracts; this is, however, not the sort of work to attract Europeans. A new feature in the colonisation of Brazil is the purchase by an English Company of a vast tract in Parana from one of these landowners. Mr. Wells is very hopeful of the success of this enterprise, which is to introduce capital and colonists where both are badly wanted. In latent wealth of gold, silver, and diamonds Brazil is perhaps second to no country in the world, and British capital may be profitably employed in bringing these to the surface. But can agriculture with imported white labour be made to pay in the tropics? It could not do so in Natal, which is hardly in them, nor in Queensland, nor in the Upper Transvaal. The "unaided European" has seldom or never succeeded in the attempt.—*Madras Mail*, Dec. 2nd.

SUNFLOWER CULTURE.

You favoured me in August of last year with some valuable information about the cultivation of Sunflowers. My project for the reclamation of Aboukir (30,000 acres) is in course of execution and will be completed next year, when it is my intention to cultivate Sunflowers largely. The flower is cultivated here as a garden ornament, and reaches dimensions exceeding a foot in diameter. But the Egyptian gardener has water on the brain, and, believing one cannot have too much of a good thing, he deluges the soil with water. The result is, that, in our rich soil and hot sun, the plant reaches maturity in two to three and a half months; and being thus prematurely developed most of the seeds are barren, although externally they present all the appearance of being full. In order to study the cultivation of the oil-yielding flower on the spot, I lately made a tour in Little Russia up to the frontier of Bessarabia, where it is an important local industry. There are two kinds, the edible and oil-yielding seed. The former, of which I enclose a small sample, is, as you see, somewhat elongated; and at Odessa and neighbouring provinces, wherever a few peasants are sitting together, the ground is strewn with the husks of the seeds, which are eaten the same as ground nuts, or Brazil nuts are eaten elsewhere. This description contains a small proportion of oil. The latter, which is grown at Orel, Saratow, and all the way up to the neighbourhood of Moscow, is shorter and thicker than the edible seed, and I expect presently to get a bag of this year's crop, which was reported everywhere to be fine. I enclose a copy of an article on the cultivation of Sunflowers that was translated for me at Odessa. It may be of some interest to you. I have received from Sutton & Sons a small supply of their Giant Sunflower, with which, as well as with oil-yielding seed from Russia, I intend to carry out exhaustive experiments on my land this coming sea-

son: That is, I intend to begin my first experiment in November or December, when the soil retains the moisture of the inundation, which will be sufficient to stimulate the earlier stages of growth, and from that period till March or April there will be sufficient rain and moisture from dew to bring the plant to maturity. A second crop will be sown in June; but artificial irrigation will be required till the Nile comes down in flood in July, August, and September. In Russia I was told the plant requires very little rain, and the only objection to the cultivation was the exhaustion of the soil, which scarcely applies here.—WM. GRANT.

Translation.

"There are two kinds of Sunflower seeds—those for eating and for oil extraction—Polish and Saratov. Saratov Sunflower seed is superior to Polish as it contains more substance, but the latter has a better form. Saratov seed is heavier than Polish, and from it more oil can be extracted than from Polish 4½ to 5 poods (36 lb. English equal 1 pood) of good Saratov Sunflower seed being required to extract 1 pood of oil, whereas to get the same quantity of oil from Polish Sunflower seed 6½ to 7 poods are required. The Sunflower requires strong and well prepared soil; for this reason the soil must be prepared as carefully as possible in autumn. It is generally sown broadcast and covered with seed-covering plough and harrow. In sowing about 26 lb. on the desiatina (desiatina equal 27 acres) are used. The seeds of the Sunflower must be changed very often, as they soon degenerate. As soon as the sprouts of the Sunflower are grown a little it is necessary to remove weeds and extra plants. The moulding and cleaning of the soil is done with a hoe, which at the same time moulds up and turns the soil well over. (This hoe is more like a small heart-shaped shovel set on a shaft like a hoe. ED.) On good farms they look well to the removing of the extra plants, as they should stand for three-quarters to 1 arshin (21 to 28 inches) apart. The Sunflower plant cannot endure the presence of any other plants in its neighbourhood, and as soon as such appear they should be removed. Two cleanings of the soil are usually necessary, but the land is sometimes hoed a third time. It occurs very often that some seeds grow up later; these when hoeing a second time should be destroyed. If it be desired to obtain an extra good crop of Sunflower seed the land must be hoed three times and ridging be well attended to. The following is an account of the crop of the Sunflower seed for oil extracting during the following years:—1879, 70 poods, 1880, 40 poods; 1881, 80 poods; 1882, 45 poods; 1883, 65 poods; 1884, 97 poods; therefore the average of the Sunflower seed is 66 1/6 poods=2387 lb. per desiatina."—*Gardeners' Chronicle.*

A TEA PLANTATION IN THE SUMMER.

Assam "swelters" for half the year. During that period the sun does not rise. He leaps at a white heat up from the nether world over its eastern rim, beginning his day's work in fire and haste, without preface, prelude, or preamble. The clouds melt and vanish into space. The wild animals rush away panting into the dark cool recesses of the woods. And the birds, who, poor things, must improve the shining hours or starve, open their beaks and gasp for breath. He lays his fiery hands upon your bungalow, and in five minutes it is an oven. He glides on along your tea house's iron roof, and it flashes, shimmers and glows until life is a burden beneath it. And unwary crows get their poor feet blistered when they alight upon it. He beats into your coolie lines, pours his shafts down the straight rows of the tea beyond, fires the stately forest crests, and flashes at last into the soft haze that hides the tranquil grandeur of the distant everlasting hills. All this is done in a trice, in the twinkling of an eye, at a glance, any second between five and six o'clock a. m., during these six months aforesaid. It is a wonderful phenomenon, and all your coolies see it every morn. For two hours before it happens all the cocks begin to crow, while their throats are cool, and set everyone astir. For if one man stirs all must stir, because all coolies are made alike, think the same thoughts, do the same things, eat the same food in the same unsociable way, wear the same fashioned clothes, tell the same lies, and get drunk on the same kind of liquor on the same day.

There is a beautiful uniformity about everything concerning them which would delight the Socialist and all other men of equally-balanced minds. Every hut is turned out of the same mould, with two pumpkins sleeping on its roof of thatch. A little garden behind it, so many feet from north to south, so many feet from east to west, climbing beans trailing over poles, plantain trees with ragged stems and tattered leaves, and lowly pot herbs of wondrous form and taste. And in each hut are a man and his wife, and two children, brass pots, and fowls, and a goat or two, and nastiness they call medicine, and hoes, and leaf baskets, and money buried in the same place under the floor. Thus the dream of the Socialist comes to be realised at last. First comes out to catch the sun the oldest of the coolies, because his blood is thin and his joints are stiff, things he was not told to expect at the banquet of life. A century or so of similar habits has thickly corrugated his ancient knees; his hair is mostly grey, his skin is tight, and in colour like unto a duck's leg. He is a most admirable and useful being. At his withered feet the new arrival picks gleefully up all the tricks, dodges, deceptions, frauds, wiles, and impostures whereby the virtuous cooly sweetens his daily toil, and baffles his natural enemy the sahib. He has sold his daughters in marriage to two or three different suitors in turn, and farmed out his sons until they were old enough to know better. And he is now living in much comfort on the proceeds of their cash transactions, and on the approval of spotless conscience. He will squat there at his door, pensively scratching his shrunken hams, until he gets warm and feels young and lusty again. Then he will go inside and thrash his only remaining daughter for overboiling his rice the day before.

Meantime men and women have come out, and keen-eyed boys, and bright-eyed litte maids and brown babies, naked as cannon balls, tumble about among the goats and fowls. The full-fed shopman who lives apart has roused himself from dreams of pice, and rolls yawning to his door. Therein he frames his convex bulk, the programme of the goor and ghee he sells, and the envy of all clever men who have not shops. And the sun glares, and the babies cry, and the girls and boys chatter, and the dogs finish the barking the leopards would not let them do at night, and the women quarrel and scream at one another many matters. *Histoires de femme*, my masters, matters of bangles, of betel nut, of umbrellas, of witchcraft, of drawing water, of a thousand things one comprehendeth not. The men get ready their hoes for the daily task, and the two or three who want to go a fishing, get ready a lie for the native doctor, who will now be going round. But these score not, and the lines chaukidar will subsequently shake them out from the inside of their huts, and drive them off, hoe, on shoulder, in sorrow but not in shame, scornfully likening them to the village pigs of their native country. But they will tell the same lie again tomorrow, and the next day, and until they get their fishing because they cannot help it, and because hope is eternal. The gong at the factory booms out its summons, and then sirdars shoot forth vociferating. "Come out! all ye men and women, come along!" And the men and women say to one another many times "Come along, brother." But no one moves, and each looks at the other as though he had just dropped from a distant planet, and lost his way. At last the men remember that they must go and hoe, and the women remember that they have to go plucking leaf. So all doors are shut that casuals may not fall into temptation, and all depart to work. Then the cattle are driven out to pasture, the dogs coil themselves down in the shade, the goats wander

out to browse, and the ancient coolie woman comes forth. She is gifted with the evil eye and dared not show before, not to mention possible difficulties anent certain potions, drugs, philtres, charms, and spells, she is always taking liberties with, in her enthusiasm for the propagation of sin and devilment. She is a most estimable creature, she hath lean lips and a sharp look, and her eyes are red and hungry, a very Sycorax and she never die.

The tea cooly is obliged by law to get drunk once a week. Of course the law does not put this plainly, that would foolishly defeat one of the objects of law, and reduce all judges, barristers, vakils, and others concerned to become planters, a most appalling thing to contemplate. But the law says that for one of every seven days the cooly shall do nothing. The only use the cooly is intended to put this superfluity to is to drain the joyous cup, bang the resounding tom-tom, and make love to his neighbour's wife. The right of women to get drunk upon the occasions is fully recognised, but they prefer to keep sober, and to keep the feline eye upon the men, whose cheerfulness sometimes impels them to the amiable pursuit of strange goddesses, and other diversions. And all that night they dance and sing. There is only one dance and one song, and these are ten thousand years old and never vary, and will be joys for ever. The women enlace each other round the waist, and dance in line, five steps to the right, then five steps to the left, and they also "skirl." The music is of drums, beaten by men who also dance facing the women, and who "skirl" likewise, but louder. The score of this opera has six notes only, and is all chorus, and can be heard at the distance of twenty miles in a bee line. Ever and anon the first drum makes a bound in the air, as though kicked behind by a steam hammer, and cuts a demi-volt, and gives a smack to his tom-tom that makes every child in the lines jump in its skin. And the audience cry 'Wah!' and everyone is very pleased, but why or what about I know not, and no man knoweth. Thus is night made terrible to the wicked; until in an interval a solo is heard in notes of anger hatred, defiance, hysterics and drink. For Mooga, who is dancing, has been caught smiling the smiles that never should be smole, and winking the winks that never should be wunk at the first drum; and Sooga, who has a life interest in that personage, is resenting it. This she does by depicting the habits and character of Mooga in a series of copious and unlady like allegories which would make a monkey blush. And Mooga retorts in kind, and matters are beginning to get very blue, when an order comes down from the Lord Manager to annihilate every one without distinction of age ar sex. And in the morning every one has hot coppers and hammers beating on the back of his head, and decants into himself gallons of cold water and curses the joyous cup. And Mooga and Sooga polish their faces with oil and streak their foreheads with red ochre and clothe themselves with modesty, and complain before the Lord Manager. And that potentate admonishes them and bids them keep the peace. But the admonition goes in at one ear and out at the other, and they go away, and do not keep the peace. Again booms the gong, and all to work. And below everything is quivering in the heat, and above the vultures circle wing-wide upon the glowing air, and—"tomorrow and tomorrow and tomorrow."—*Englishman.*

INDIAN EXPERIMENTS.

(*Concluded from page 391.*)

The Government botanical garden of the Nilgiris is situated on the slopes of the Dodabetta Mountain at Ootacamund, and, as previously stated, was first laid out by the late Mr. W. G. McIvor in 1848. Since that date it has undergone considerable change and improvement, and is now under the direction of Mr A. M. Lawson, late professor of botany at Oxford, who was appointed some few years ago director of Government Cinchona plantations, parks, and gardens, with Mr. Jamieson, the former superintendent, as curator. The gardens, since the time of its first formation, has gradually developed into one of the most beautiful, and, on account of the climate, one of the most enjoyable spots on the face of the globe. Beautiful trees, shrubs, plants, and flowers, collected from many lands, may be seen and studied in their fullest development in the open air all the year round. Originally the site of the gardens was a thickly wooded ravine with a range of altitude of from 200 to 250 feet. Mr. McIvor, with great skill and taste, contrived, by preserving portions of the natural forest and large individual trees, to lay out, by paths, terraces, parterres, and pieces of water, a garden at once beautiful and picturesque, a veritable queen of pleasure grounds. Above and around the garden the slopes of the Dodabetta Mountain are clad with splendid specimens of Australian and Tasmanian trees, including many examples of the Blue Gum and other species of Eucalyptus, as well as numerous species of Acacia, all of which take extremely kindly to the climate of the South Indian hill tracts.

At the entrance gate is a large conservatory, in which is grown tender plants, such as Begonias, Bougainvilleas, Orchids, &c., but no artificial heat is ever used. The director's and curator's houses are situated near the centre of the garden, and there are other glass structures which were built for propagating purposes during the early stages of the Chinchona experiment. The garden is entirely worked by coolies from the Mysore and sometimes Chinamen, with East Indian overseers. The only portion of ground in the garden that may be called flat is situated near the entrance, and this is occupied with lawns, ponds, and flower beds, together with many fine specimens of coniferous and other ornamental trees and shrubs. This is the only portion of the grounds that suffers from frosts during the winter months. Hoar-frosts may frequently be seen here in the early morning, while the upland slopes escape altogether. Many of the pieces of water contain miniature islands planted with grand specimens of Pampas Grass and Arundo conspicua, both of which yield at Ootacamund larger and finer spikes of flower than any I have ever seen in England. Around the edges of these ponds may be seen, with their roots reaching far into the water, luxuriant plants of the Lilly of the Nile (Richardia æthiopica) with their perennial display of white blossoms. Fish, consisting of rudd, lake trout, tench, carp, gold and silver fish, &c., were introduced into these ornamental ponds about the year 1869. Since that date quantities of these fish have found their way from the garden ponds to the Ootacamund lake and to many streams on the Nilgiris. To the late Mr. McIvor and to Dr. Day must be accorded the credit of having introduced European fish to the waters of the Nilgiris.

The first terrace is laid out in flower beds in the Italian style, with a very ornamental band stand in the centre. This portion of the grounds is a favourite promenade for the public. Rising from this in successive terraces and winding paths the top of the garden is reached, from which a magnificent view of the whole station of Ootacamund is obtained, with its beautiful lake in the centre, and picturesque houses on every hill. Throughout the whole station the Australian Eucalyptus and Acacia are planted in abundance, giving a somewhat sombre and churchyard appearance, but this is somewhat compensated for during the months of July and August by the glorious display of the yellow blossoms of the Wattle Tree (Acacia dealbata). During these months the appearance of these trees is truly magnificent.

The paths and walks of the garden are mostly hedged with such plants as Fuchsias, Heliotrope, Roses, &c., and all yielding an abundance of blossoms all the year round, such plants as Roses and Heliotrope being wonderfully fragrant. Large and magnificent plants of Bougainvillea sanguinea and spectabilis are continually met with on the steep grassy slopes, clad in their huge pendant blooms, which at nightfall throw off their peculiarly agreeable fragrance. Branches of these plants roughly lopped off and stuck into the ground, will as quickly form plants in this

climate as Willows do in England. Grassy banks covered with Hydrangeas covered with bloom may also be seen, which are perfectly wonderful to behold. The flowers are usually of a very deep blue tinge, 'tis said from the presence of iron in the soil. French spotted and large-flowered Pelargoniums bloom admirably when planted out permanently on the sloping banks, and required no other treatment save a yearly pruning. I have seen banks of these plants covered with immense trusses of bloom and lasting for many months in the rarest beauty. In one particular recess towards the top of the garden there used to grow and bloom freely a clump of Camellias of various colours, and climbing up, and growing in the surrounding trees and borders, and flowering luxuriantly withal, such plants as Clianthus Dampieri, Habrothamnus, Tacsonia, Mandevilla suaveolens, Kennedya, Chorozema, Begonia fuchsioides, Azaleas, Aloysia citriodora (huge trees), Aralias, and scores of others.

A very beautiful fernery exists near the top of the garden, which is very tastefully arranged and planted with numerous Ferns indigenous to the hills as well as from other countries. Although the Ootacamund botanical garden contained a most extensive and very rich and interesting collection of plants brought together from all parts of the world, no attempt—at least up to the year 1877—was ever made at scientific arrangement, which was always a matter of deep regret. No better locality on the face of the globe could be found than Ootacamund for a garden of instruction in the true sense of the word, and where expensive glass structures are not necessary for the bulk of the plants grown. Matters have no doubt improved since the advent of the present Botanical Director, Mr. Lawson, who, no doubt in time—should he be allowed the necessary means—will make the gardens at Ootacamund worthy to be classed with the best botanical institutions of the world.

In closing these articles I have only a few words more to say with regard to the general appearance and climate of these beautiful hills. The first visit of those who have been for some time located on the hot and arid plains of Madras is delightful and exhilarating to the last degree. The visitor as he begins the ascent of either of the Ghauts leading from the plains, is not prepared for the wonders that are gradually revealed to his gaze as he ascends mile after mile of the winding mountain road. Leaving the steamy and hot village at the foot of the Coonoor Ghaut, with its acres of graceful Cocoanut and Areca Palms, the traveller gradually mounts into a region where the rich tropical vegetation gives place to a more stunted form of growth. From the splendid forms of the Palms at the foot to the region of Cinnamon, Cloves, Guava, Loquat, Mangosteen, Nutmeg, Papaw, Theobroma, and Vanilla, and higher still into the region of Coffee, Tea, and Chinchona, till at last the plateau is reached where is produced the Orange, Pear, Apple, Plum, Wheat, Barley, and innumberable other plants and fruits from the temperate climates of the world. And if this view of the cultivated products of this wonderful region be deeply interesting to the visitor, still more so is the natural scenery of the mountain gorge through which he has passed for a distance of some eight or nine miles, and rising in that distance to an elevation of 6000 feet. At an elevation of 3000 feet the scenery becomes bold, increasing in grandeur till huge walls of rock rise on each side of the road, every rift and cranny of which sends out its living mantle of everlasting green, while on one side of the path is a deep ravine choked up with a mass of forest verdure, on which you look down with awe and hear, but cannot see, the rushing and tumbling of a stream far in the depths below. Streams of water dashed into the whitest spray fall at intervals from the heights above down the face of the rocks, giving infinite beauty and grandeur to the scene. Ferns and Lycopods innumerable clothe the roadside banks, including species of Adiantum, Microlepia, Davallia, Pteris, Angiopteris, Asplenium, &c., while the graceful tops of the Tree Ferns (Alsophila) may be seen in every ravine pushing through the mass of other foliage.

On the plateau itself may be found wild in abundance the Dog Rose, Honeysuckle, Cotoneaster, Hypericum, Passiflora, Rhododendron arboreum, Indigofera, and numerous other flowers and shrubs. Many plants, such as the common Groundsel, Œnothera, French Marigold, and others, which have originated no doubt from seeds imported from England, have become acclimatised and now grow as weeds on cultivated grounds. I have seen the Neidewattum Chinchona plantation belonging to the Government literally covered with the French Marigold, the product of self-sown seed. The roads of this plantation are all hedged with Box, which is allowed to grow from 2 to 3 feet in height, and which looks very trim and beautiful. In addition to the numerous plants met with on these hills, both introduced and indigenous, the song of the thrush and blackbird is continually heard in the glens and woods.

The plateau is not rich in showy Orchids, but there are some at the higher elevations which are to be found in large quantities, and are very pretty. Coelogyne corrugata and C. oloratissima are both found growing on sheet rocks, sometimes in large masses of ten or a dozen yards square, which are very lovely when in flower. These two plants, I believe, are supposed to be difficult to flower in this country, and this, I imagine, is from the want of proper treatment. I recently saw a large plant of C. corrugata at Kew in a house amongst other cool house Orchids; the pseudo-bulbs were very large, but the foliage was at least 3 or 4 inches longer than I have ever seen it in its wild state on the Nilgiris. The pot was at that time placed in a position at least 10 feet from the glass, and I was told that the same plant had been in the gardens for three or four years, but had never flowered. It ought to be remembered that these plants come from a climate where the maximum temperature is only 77°, and where the mercury frequently falls to 38°. They also grow on sheet rocks on the grassy slopes entirely unprotected from the bright sunshine and monsoon rains. They have also to undergo the annual privation of from four to five months of total drought without one single drop of rain to moisten their leaves or roots. I would humbly suggest to growers of the two Orchids named above that they never be subjected to any great heat, and be kept during the period of their growth in an open frame fully exposed to both sun and rain at least during the height of the English summer. On the slopes of the hills leading to the plains numerous Orchids are found including Dendrobium album, D. Pierardi, D. barbatulum, Vanda Roxburghi, Saccolabium (several species), Aerides crispum, and numerous others.

In closing these articles I would give a word of warning to young gardeners about to go to India to engage in planting. In India with care there is little or no danger to be apprehended from the climate, and there is always the chance for a steady man to do well and save money. On the other hand, if extravagance be not avoided, disappointment and ruin will be the inevitable result.—PLANTER.—*Journal of Horticulture.*

TEA IN FRANCE.—Messrs. Somerville & Co. report on samples of tea from Vichy and Paris :—We have tasted the samples and don't think much of them. The "pekoe" at 12 francs per lb. must be very *good business* for the retailers! At the same time the leaf is *very good* and nothing but "*tips*" with a pale straw colour liquor, scented, and of pleasant flavour, but no strength. The little parcel of Horniman's 2s pure black is regular *packet tea* and of fair strength in cup, but *common* and must pay them well. There is no trace of *Ceylon* in any of them and hardly any "Indian." China simply walks in at present.

PLANTING REPORTS FROM THE HILL-COUNTRY OF CEYLON.

TEA FLOURISHING—ABSENCE OF INSECT AND FUNGAL ENEMIES—THE DEADLY SYMPLOCOS.

UPPER DIMBULA, 5th December.

A long walk through tea, which, in many parts, is plentifully interspersed with rows of cinchona officinalis, has left on my mind the impression that never previously have I seen either plant looking so fresh and flourishing, so clean and free from all signs of disease, whether of insect or fungus origin. Grub, so formidable an enemy of coffee,—only second in mischievous effect to *Hemileia vastatrix*, need not even be mentioned amongst the enemies of tea. Here there is no sign of grubs or of the parent beetles, the cockchafers, flights of which some six to eight years ago consisted of tens of thousands, and, to use a Yankee expression, "filled the whole afternoon full" of humming. Of brown bug and the black fungus which ever accompanies it there is not a trace, while the green coccus has not, so far as I know, ever been seen on tea. Red spider, which is pretty plentiful on the neighbouring jungle plants and which has been seen on plants cultivated in the garden, has not, as yet, at least attacked tea here, while the small white moth which lays its eggs in young leaves, so leading to their curling and dying, our chief tea pest of the slightest consequence, has for a long period now entirely disappeared. So with green fly, and as for helopeltis, the one specimen which was recognized under the microscope remains unique,

"None but itself its parallel."

The usual flight of butterflies was seen a few days ago, and a few curious butterfly moths have been found in limited localities, but not on the tea, which, as I have said, is absolutely free from aerial or above-ground enemies. I might write that no trace of anything inimical to tea exists here, but for the fact that, now at very distant intervals, we have proof in the "dying off" of several fine tea bushes in particular localities, that our most formidable subterranean enemies, the poisonous or deadly-fungus-producing symplocos-roots are still in the ground, and still the cause, in their decay, of the death of healthy living tissues. As tea estates advance in age, we hear more and more of the mischief arising from leaving in the ground the yam-like roots of this baneful, large-leaved jungle tree. The percentage of bushes so destroyed on an estate may not be absolutely large, but the gaps created amongst tea, often of mature age and in most luxuriant condition, are ugly and sources of great annoyance.

THE SUCCESS OF TEA IN AMBAGAMUWA AND THE KOTAGALOYA VALLEY—GOOD PRICES FOR TEA ESTATES—COFFEE AND RATS—TEA ESTIMATES SHORT—RAINFALL.

UPPER DIMBULA, Dec. 7th.

Nothing strikes the traveller hitherwards more than the wonderful success of tea in Ambagamuwa, and especially in the Kotagaloya Valley, in which district and sub-district coffee proved in so many cases a failure, tea flourishes in conditions of soil and climate—ferruginous clay, in the one case and heavy rainfall in the other—which were adverse, if not to the growth of coffee, yet to its producing crops of fruit. Old Ambagamuwa is rapidly passing from a scene of abandoned coffee estates to one of luxuriant tea fields, the green of which vies with that of the lovely English-like sward of so many of its vales and hills and mountain sides. One feels a melancholy sensation still to see plantations where once the coffee smiled now expanses of weeds and low bush; but there are views from the train in passing through Ambagamuwa, especially when gaps reveal the opening up of the Kelani Valley and other "low country," such as can scarcely be surpassed for beauty. It is the views *from* the Kotagaloya Valley of "the Duke's Nose," of Talankanda, of the grand Great Western, the St. Clair Falls, the Kotmale Gap and the Peacock, which impart interest to the valley that links Dikoya to Dimbula, apart from the fine tea which has so rapidly taken the place of coffee of varying quality, but generally poor. In passing along the valley our attention was attracted to a fine little tea estate of 160 acres, for which £7,000, or at the rate of £43 15s per acre, had been offered, but for which £8,000, or £50 per acre, had been demanded. Subsequently we learned that for tea land taken for public purposes in Maskeliya over R800 per acre had been granted. There is this to be remembered, when a whole estate of mature tea is in question, that the amount of capital invested in it in the shape of stores and especially machinery is much higher than was ordinarily the case with coffee property. For coffee a pulper sufficed in the shape of machinery, the final processes of cleaning from parchment skin and packing being conducted in Colombo. But tea must be packed on the estate ready for shipment, and the leaf must be rolled after withering, roasted after fermenting, sifted, sorted, the larger leaves cut, finally fired, and packed in lead-lined boxes. An estate of any size cannot calculate on less than £1,000 for store and withering lofts and £1,000 more for rollers, driers, sifters cutters and power to drive them. For a tea estate in full bearing and fully equipped therefore, R500 an acre or even £50 sterling is a price by no means above adequacy.

I have already spoken of tea and cinchona as looking almost perfect. Since writing I have gone over the remains of what was once an expanse of about 350 acres of fine-looking coffee. On most of the trees still in the ground (the tea plants not being old enough to suffer injury from them) a sucker has been allowed to run up, so as to double the orthodox height of 3/ 6/ for a properly topped and pruned tree. I know well from the experience of several inroads in former years, what mischief the coffee or jungle rats can effect, by cutting off primaries with their incisors as cleanly and completely as if a pruning knife had been employed, but until I had ocular demonstration yesterday, I had no idea of the climbing powers of the rodents. Up to their tops, at 7 feet from the ground, the suckers had been deprived of their succulent primaries, or large portions of them. The greater proportion of the suckers, however, and in some cases the original bushes as well, had a fair amount of crop on them in all stages of green, yellow, pink and dark red, while blossom promising a moderate spring crop showed its snow-white contrasted with the emerald and ruby tints of the berries, or beans, or cherries. In planter parlance the word "bean" is used only for the separate seeds enclosed in "parchment" skin, and it was pleasing to see the clean, white beans on the barbecue and on the store loft, and to hear that the size of the bean and its quality were specially good. About 500 bushels have been already gathered, and more than that quantity is still on the trees. The rains, therefore, are welcome for filling out the coffee beans as well as drawing out the flush of the tea buds. This, which will probably be our last appreciable gathering of coffee, is specially welcome this year, when our large supplies of cinchona bark have to be returned for a better market and in face of the certainty that owing to months of unfavourable weather during the early in the year and the necessity of planting much larger areas of tea than was anticipated, we shall be short of our estimated out-turn of leaf

by fully 20 per cent. The experience is very general, and we, like others, look to "next year" for more than compensating results. All looks promising. The cause of the irruption of destructive coffee rats was the old story of the flowering and dying down of the *nilu* undergrowth in the forests,—forests which are now carpeted with seedlings of the *strobilanthus*. It may be a serious question whether at the next dying down of the *nilu* bushes the famished rats may not attack our tea. At present the rodents resemble the cardinal who "made a distinction,"—between soup and hot water. As yet rats have shown as little predilection for tea, as have grubs and other pests. Some patches of coffee seen yesterday were badly affected with leaf disease, and green bug could be found if looked for. The debility superinduced in the trees by repeated attacks of leaf disease became obvious in cases where a sucker was covered with fruit, while the bush whence it arose was leafless and white-branched. The temptation to give plants of the old staple another year is strong, and where the tea has been only just planted the uprooting process may be safely delayed. Next year, however, will be the last year of the life of the proportion of coffee of which this year it will not be said "Why cumbereth it the ground?" Yesterday morning only 5 cents of an inch of rain were measured, there being a natural reaction from the great fall of close on 2 inches in the previous 24 hours. This morning's measurement, however, gave 66 cents, the rain having fallen very freely from about noon to between 2 and 3 p. m. yesterday. The effect of one limb of a magnificent rainbow lying along the range which separates us from Nuwara Eliya was exquisitely beautiful. The forest trees are all out in full flush, and the members of the large *Eugenia* family called *dambas* are rapidly putting on those robes of red, which in less than two months will clothe the mountain forests with tints such as autumn gives to the woods of Europe. This morning rose clear as crystal after the rain, but moisture was still in the atmosphere, as was proved by the strata of deep blue which alternated with bars of white cloud over Haputale. The sun shone hot, and as the day advanced the sky became filled with masses of fleecy clouds. We knew what all this and the warm temperature betokened, and as I write at 20 minutes to 2 p.m., the rain is pouring down. Now as previously there is scarcely sufficient movement of the air to stir a leaf. As we have still a new clearing to plant, as well as "supplies" to put out, we are rejoicing in the rain on that account and on the brightness of heat of the sun for the withering as well as the flushing of the tea. The nights are as yet as warm almost as the days, so that we suspect the settled fine weather will not set in for a week at least and probably not for a fortnight yet. Let us hope that on this occasion Nuwara Eliya and its neighbourhood may be spared the cold winds and the frosts, which have unfavourably distinguished the two previous seasons.

8th December 1887.

Rainfall yesterday 61 cents, and a cloud-laden sky promises more. Temperature remains mild.

JACKSON'S NEW TEA DRIERS.

Mr. Jackson has been working hard, and has devoted much time during the past summer, at the works of Messrs. Marshall, Sons and Co., Limited, at Gainsborough, towards perfecting his new Tea Driers. We are pleased to learn that he has been rewarded for his pains. He has not only succeeded in instituting several very marked improvements, but he has, moreover, received the most pleasant of all proofs that his labours are appreciated, in a thoroughly satisfactory demand for his driers. It is unnecessary to illustrate the most recent improvements in this column, as illustrations are given elsewhere in our advertisement pages, to which the reader can turn. These illustrations show the material and important nature of the changes effected in the construction of the driers, particularly in the heating stoves, which are now quite accessible from the tea house floor. The air-heating pipes are so arranged that any one of them can be withdrawn and replaced in a few minutes, even when the fire is burning, and without one having to touch the driers at all. It is evident at a glance that the new form of construction effects a considerable saving in brick-work and fuel.

The Venetian Driers have acquired another great advantage: they are now self-delivering. When the bottom drying surface is opened the tea is at once discharged outside the machine, on to the tea house floor itself. Here again the absence of a pit is a manifest convenience, and a saving of time. It will be allowed that the above alterations form a very creditable outcome of a summer's work.—*H. & C. Mail*, Nov. 18th.

MESSRS. MAIN AND DICK'S NEW TEA WHITHERER.

We are informed by Messrs. A. J. Main and Co. that success continues to attend the trials of Messrs. Main and Dick's new wet-leaf drying and withering machinery. Mr. Dick, who is still in India, has telegraphed home to the effect that he has had a most successful public trial in wet-leaf drying and withering, which has given general satisfaction to those who witnessed it. We understand that these processes of drying wet-leaf and then withering it was accomplished in an hour, which, it will be allowed, is a marvellously short time if the leaf remained uninjured, as was apparently the case, since the telegram leads it to be understood that the result was thoroughly satisfactory. Such an achievement can only be regarded as of the utmost importance to tea growers, as it not only minimizes the amount of roofed space, time and labour required, but prevents deterioration of the quality of the tea in wet weather, and prevents that congestion of accumulated leaf which has so often been the despair of the tea-maker in prolonged wet weather. By drying wet leaf it should be understood that we do not refer to drying *tea* as this machine, as at present constructed, is not intended for that purpose.—*H. & C. Mail*, Nov. 18th.

AUSTRALIAN FRUIT IN INDIA.

Mr. Jas. Inglis, who had for some time charge of the Indian Court at the Melbourne Exhibition of 1880-81, and who is now Minister of Public Instruction in New South Wales, has sent us papers referring to a consignment of New South Wales oranges and lemons sent by him to Calcutta. The fruit was simply packed in ordinary boxes which were stowed as ordinary cargo, there being no refrigerator in the horse steamer in which they were despatched. The voyage was protracted, and about 30 per cent of the oranges were spoiled. The remainder, though not of superior quality, sold readily at one shilling per dozen, no Sylhet oranges being in the market. If sent in the proper months, therefore, and in fast steamers provided with cold rooms, Australian oranges would probably sell well in Calcutta. But for lemons there seems to be no demand, the people preferring the flavour of their own limes. It is possible that consignments of Ceylon oranges may yet be sent to India, yielding profitable results.

AVERAGE PRICES FOR CEYLON TEA IN THE LONDON MARKET.

The superintendent of an estate, the whole crop of which, from finest broken pekoe down to pekoe souchong, broken leaf and dust, is practically sent to the London market for sale, the average realized being calculated on the several quantities and prices of the several kinds, points out the disadvantage at which this and other estates so acting are placed by the practice of quite a number of estate owners and agents who sell all their inferior teas and dust locally, and so get the credit of high averages in London. In a recent case an "*average*" of 1s 6½d was placed opposite an estate, that being simply the price of the only sort of tea sold, viz., broken pekoe. In another case, the average was deduced from the prices of broken pekoe and pekoe. The averages so obtained were, of course, higher than the 1s 3d of the estate which sent not only its broken pekoe and pekoe but its souchong, broken leaf and dust for sale; but the so-called averages in the cases where no low quality tea was included were not, it is contended, fair and honest "*averages.*" The process adopted is shown, our correspondent points out, in several cases of estates, whose inferior teas and those only were submitted at the latest local sale. One well-known estate was represented neither by broken pekoe nor pekoe, which will, of course, show a high average in London, in consequence of the sale locally of

Pekoe souchong	2,000 lb.
Dust	770 ,,
Red leaf	300 ,,

In the case of another estate, the local sale consisted of

Pekoe souchong	1,350 lb.
Dust	1,400 ,,

Our correspondent submits that a "respectable average" of 1s 2d or 1s 3d is better and more honest where all kinds are sold, than 1s 6½d or even more where only broken pekoe, or that and pekoe, are sold in London.—The right of parties to dispose of their teas as they deem best is not disputed, but it is proper that practices which vitiate averages and give certain estates undue reputation should be known and taken into account.

THE ALKALOIDAL VALUE OF IPECACUANHA CULTIVATED IN INDIA.*

BY FRANCIS RANSOM.

The success that has attended the introduction of the cinchona into India and Ceylon has naturally suggested the possibility of the profitable cultivation of other South American plants. Ipecacuanha, being a drug for which there is a large and steady demand, has received considerable attention for this purpose. It appears to have been first introduced into India in 1866, but for several years no encouraging results are recorded. During 1877 plants were distributed throughout the central and southern parts of the Peninsula, and the cultivation was also attempted in Burmah, Singapore, and Ceylon.

In the same year Dr. King, the Superintendent of the Botanic Gardens, Calcutta, reports that the profitable cultivation of ipecacuanha as a crop at the cinchona plantations seems hopeless, owing to the cold of the winter season, even in the warmest valleys, being too great for a species so thoroughly tropical.

In spite of discouragement, continued attempts have been made, and an important fact relative to the cultivation was communicated by the Director of the Kew Gardens to *Nature* in the beginning of the present year. From a report on experiments carried out at the Government Cinchona Plantation at Darjeeling, it appears that two varieties of ipecacuanha, sent respectively from the Botanic Gardens at Kew and Edinburgh, have been introduced into India. Whilst those from Edinburgh have entirely disappeared, the plants from Kew, cultivated under exactly similar conditions, continue to live.

The latest information on the subject appears in the *Pharmaceutical Record* (Oct. 1, 1887), where it is stated that the experimeats have proved that the plant flourishes best at Nilambur.

The value of the cultivated root compared with that obtained from the wild plants of Brazilian growth is a subject of interest and importance. Dr. King reported in 1877 that the Indian cultivated ipecacuanha had been used in the Medical College Hospital in Calcutta, and had been found to be quite as efficient as the best South American drug.

Mr. Holmes has recently placed in my hands a sample of the Indian root, which I have examined with the object of ascertaining its alkaloidal value. In appearance it closely resembles the drug imported from Brazil.

The method adopted for the assay was that proposed by myself at the recent meeting of the British Pharmaceutical Conference at Manchester (*Pharm. Journ.*, Sept. 17, 1887). It consists in percolating the finely powdered root with chloroform previously rendered alkaline by agitation with strong solution of ammonia, completing the exhaustion in an extraction apparatus with boiling chloroform, extracting the alkaloid from the percolate with very dilute sulphuric acid, and estimating the acid solution volumetrically with Mayer's reagent.

By this method I found 1·7 per cent of emetine present in the root.

In my previous examination of the Brazilian drug I found that ten samples varied in value from 1·3 to 2·3 per cent of alkaloid, the average strength being 1·66 per cent. As these were all, in appearance, fair commercial specimens, we may conclude that the Indian cultivated ipecacuanha is quite equal to the average Brazilian root.

It is to be hoped that before long it may become a frequent article in the London market, and that well-merited success may reward the enterprise and perseverance of those who have bestowed so much care upon its cultivation.

DISCUSSION.

Professor Thiselton Dyer said this communication, although very brief, was one of the most interesting which had been made in connection with pharmaceutical research for some time. The story of the attempts made to introduce the ipecacuanha plant into India was a very long one, the first effort, as was stated in the paper being in 1866, when Dr. King, then Assistant Surgeon in the Bengal army, successfully conveyed to India by the overland route the first plant of this invaluable species. That plant came from Kew, and as far as he could make out, for he had not been able to investigate the question thoroughly, it was the only survivor of a case of ipecacuanha plants which some time previously had been obtained from Brazil. The Government of India attached enormous importance to the introduction of ipecacuanha into that country, and looking at the almost specific character of this drug in the cure of dysentery, their desire to see it acclimatized was amply justified. The history of the plant was carefully recorded till it died in 1868. During that interval, however, nine plants had been obtained from it by propagation at the Calcutta Botanic Gardens, and five others which were cultivated at Darjeeling, so that in 1868 there was a total stock of fourteen plants in India. In 1871 the five plants at Sikkim has been increased to 100. Dr. Anderson, to whose intelligent [illegible] prise the cultivation of ipecacuanha was [illegible] etc., and who pressed the subject very [illegible] the Government of India, being then superintendent of the Botanic Gardens, Calcutta, came to this country in 1870, and used every effort to [illegible]

* Read before the Pharmaceutical Society of Great Britain at an Evening Meeting in London, Wednesday, November 9.

ipecacuanha plant which was to be had. There had always been a very distinguished pharmaceutical school at Edinburgh, under the auspices of Sir Robert Christison, where everything appertaining to pharmacy was a matter of great interest, and at the Botanic Gardens there was a notable collection of medicinal plants. Amongst others was ipecacuanha, and Dr. Anderson obtained all they could spare. He also obtained a supply from Kew; meanwhile, however, he died. But propagation had been carried on in Edinburgh, and 250 plants were sent out. This might be said to be the seed sown a quarter of a century ago, which had been quietly germinating in India, until that evening they were in a position to sample the first harvest. It had been an exceedingly arduous process, and rather a discouraging one. More than once those whose duty it was to cultivate the plant had been very much inclined to give up the task as hopeless. Ipecacuanha was perhaps more depressing to cultivate under adverse circumstamces than any other plant on account of its slow growth, and the general wiriness of its appearance; but at every point when the cultivators began to be despondent something had happened which encouraged them to proceed. The first difficulty met with was the extreme tardiness with which these plants could be propagated; in two years they only got fourteen from one plant. There were four original plants altogether in India, and up to 1873, with every effort and with all the additional supplies obtained, the total number was something under 7000. That represented something like eight years work, and of course, from a commercial point of view, it was not very encouraging. Then it was discovered by the late Mr. Mc Nab at Edinburgh, a very accomplished cultivator, that the rhizome of this plant could be cut into infinitesimal portions, and that every one of these would grow and form a plant, and when this discovery was applied in India it led to an enormous increase, so that in a short time the number of plants rose from 7000 to something like 63,000. At the Cinchona plantation, in Sikkim, there was a clever young gardener named Jaffrey who devoted himself to the ipecacuanha; and it was mainly through his exertions that this enormous advance was made. Another discovery was also made by the Edinburgh Gardens, by Mr. Lindsay, the present Curator, who found, what no one would have expected from such a plant, that a single leaf if plunged into damp sand would develope buds and roots. That method of propagation was not so successful, however, in India as from the rhizome, but still it was used to some extent. Up to about 1875, as far as methods of propagation were concerned, the future of ipecacuanha was secured, but the cultivation had to be carried almost entirely by artificial means, under glass in houses or frames, and notwithstanding all the pains devoted to it, it had not assumed anything of a commercial character, because of course, under such conditions medicinal plants could never be produced at a price which would make them available in such large quantities as the Government contemplated. However, it was found, as mentioned by Mr. Ransom, quoting from a short note he sent to one of the scientific journals early this year, that as cultivation under glass could not possibly be carried on extensively, the attempt was made in Sikkim to plant it in shady places under trees. It was a plant exceedingly sensitive to anything like fierce sunlight or dry atmosphere; it was in fact a characteristic kind of tropical undergrowth. This led in Sikkim to a very curious result. There was no doubt that the original Kew stock came from Brazil, and though he had not been able to ascertain exactly the channels through which it came, he had no doubt that pains were taken to get it from someone who would authenticate it as being the true ipecacuanha plant. It was rather doubtful what the history of the plants cultivated in Edinburgh was; about 1832 was the date of the first introduction of ipecacuanha into Europe, and one could not perhaps exactly say from what source the Edinburgh plants came, but probably from Brazil. But what the extremely intelligent superintendent of the Cinchona plantations at Darjeeling said was, that these plants, which were sent out as apparently the same thing, had certain tangible differences, by which to the trained eye of the cultivator they could be distinguished, and they could always tell which were the Edinburgh strain, and which the Kew strain. Probably, as constantly happened in cultivated plants, there were several forms or races of ipecacuanha, and they had been imported through two or three channels, and were not precisely the same kind. The curious fact was, that although in Dr. Anderson's importation the plants from Edinburgh considerably outnumbered those sent from Kew, yet the Kew plant happened to have greater constitution and vigour; it increased and multiplied, whilst the Edinburgh apparently eventually died out. He should be the last to say that that was owing to any merit on their part at Kew, but it was interesting with regard to the future of the drug, because knowing the trouble there was to critically determine the physiological differences in cinchona which accompanied small variations of a morphological kind, it would be more interesting to know that the ipecacuanha supply of India was derived from one definite source than from several varieties. He did not gather from the paper that the precise source of the present sample was exactly ascertained. He thought Dr. King as early as 1876 was able to submit to the medical service in India some dried root which had been grown in that country, which was tried in hospital practice, and found to be quite as good as the Brazilian drug. In 1877 Dr. King supplied 26 lb. of the root which had been grown in frames, and this was found satisfactory. No doubt the ipecacuanha would be kept alive in some suitable place in Sikkim, and in some places also in Southern India conditions would be found favourable for it; but the most promising thing in regard to its cultivation in the old world was a report from the Forest Department of the Straits Settlements for 1886. Mr. Cantley, who had the superintendence of affairs, wrote:—"The ipecacuanha is a native of Brazil, a plant which has been found generally very difficult to cultivate. It seems to grow in the Straits with all the luxuriance of its native country, when a proper situation is hit upon; it enjoys a very moist still atmosphere and somewhat dense shade. In that situation it forms a compact little shrub of about eighteen inches in height, and is very ornamental when well in flower. I lately visited a plantation of the plants in Johore, and saw thousands of plants in excellent health, protected from the sun by palm leaves laid on an artificial stage six feet in height, and the edges of the same a few yards apart. The soil is of a rich character." It would therefore appear to him that it was quite possible that in the State of Johore, and some other places in the Straits Settlements, there was a climate which was quite suitable for the cultivation of this plant on a large scale. In conclusion he would only say that it was extremely satisfactory to see the way in which the persistency which was so characteristic of the best English work had been rewarded in this case with ultimate success. He knew nothing in the whole field of botanic enterprise which exceeded the admirable persistence with which the Indian botanists and pharmacists had stuck to this business, and had gone on cultivating this plant for very nearly twenty years, with very little encouragement, until the last few years. Mr. Cantley, of the Cinchona Plantation at Darjeeling, when success seemed a little more in sight, wrote to him, saying that this illustrated the importance of never losing heart in work of this kind. You must not be disheartened by failures, but try new conditions, and adjust the circumstances to the varying places in which the plant is grown, and in the great majority of cases you would ultimately succeed. Being very much occupied he could not often hope to take part in these interesting discussions, and therefore he desired to add a word in support of what had been said by Professor Attfield as to the extreme usefulness of the work done there. He could assure the Society and the members there was no more assiduous student of the Journal of the Society than himself, and if he had not often

the pleasure of assisting at the discussions he had the advantage of reading them. He knew no scientific work in that great city which seemed more adapted to the end it had in view, or which more successfully attained that end, than the discussions and operations of the Pharmaceutical Society at its scientific meetings. He could not but admire the enthusiasm with which the work was carried on, and the ability with which its success was achieved.

Mr. Holmes said he had listened with the greater interest to the valuable account of the history of ipecacuanha which Professor Dyer had given, and his later remarks had thrown a flood of light on a point of great difficulty which he had experienced. When a fresh product came to this country the merchants who imported it were very reticent as to the exact locality whence it came, and very often tried to mislead one if possible—that was the case with this ipecacuanha. He was told that it came from India, but that nothing could be learnt about it. However, on seeking the drug broker, he was told that the packet which came over was about 10 lb., that it appeared to be a trial sample, but that instead of coming from India it came from Singapore. He had no doubt now that it came from that flourishing plantation which Professor Dyer had spoken of. As far as one could see from what had been said about the habit of the plant it might be grown equally well in Burmah. The broker who had the sample recognised the difference between it and Brazilian ipecacuanha by presence of the minute fibres, these being always removed from the Brazilian samples, and to commercial men minute differences of that kind often give a practical clue to the source of the drug. With respect to the ipecacuanha grown at Kew and that grown at Edinburgh he should be glad to learn if any record had been kept of the botanical characteristics of the varieties cultivated at either of those places. He believed the ipecacuanha was a dimorphic plant, and possibly either a long-styled or short-styled variety might have succeeded where the other did not. Again, the exact temperature and the conditions under which it flourished at Singapore would be no doubt published and made use of. He had to thank Mr. Ransom for the readiness and promptitude with which he undertook the examination.

Mr. MacEwan said he knew there was in the Library upstairs a paper contributed by the late Professor Balfour to the botanical Society, Edinburgh, with regard to the ipecacuanha in the Edinburgh Gardens.*

The Chairman proposed a vote of thanks to Mr. Ransom for this valuable paper. Ipecacuanha was a very important drug, and although it was not necessary to seperate the alkaloid as often as in the case of many other drugs, it was well to know the quantity present if one required to separate it. The paper would be especially valuable to those in India who were now cultivating it, and when it was found that the Indian was equal to the Brazilian article it would no doubt give an impetus to the industry. He would include in the vote of thanks the name of Professor Dyer, who had given such an excellent history of the cultivation.

The vote of thanks having been carried unanimously was briefly acknowledged by Mr. Ransom.

STROPHANTHUS.

Mr. Christy then drew attention to a quantity of strophanthus which had arrived from a new port, and thought it might be interesting to the meeting to know what had been done in this drug during the last year. The first year the quantity of seed which came from Africa was 1840 lb. with 450 lb. of pods, estimated to yield about 153 lb. of seeds, so that in the whole year there came to the United Kingdom [illegible] of strophanthus seed, and to the United States he had traced about 500 lb. Considering the very small use that was required, it would be seen with what great pleasure medical men had [illegible] this drug, and work with it. It had been [illegible] variety. At first it was thought the [illegible] over was the hispidus, and having received the first shipments, he was able to say that it was a variety which had been called hispidus, viz., the brown seed. Within the last fortnight he had received from the Niger the first shipment of pods and seed, which he sent specimens to Mr. Holmes, and these turned out to be a brown seed with a brown velvety appearance like hispidus, but not the same variety as received originally. Having been accustomed to taste the different seeds as they arrived, he could state that this hispidus variety was much more powerful than any of the kombé seeds, at any rate, much more intensely bitter; though whether it would obtain a greater percentage of the active principle had yet to be determined. He was informed that in the valley of the Niger large quantities of this were growing, so that further supplies might be expected. It would be also interesting to know that for some reason which at present he was unable to fathom, the French had decided that hispidus should be the standard variety, notwithstanding the many satisfactory experiments made both in this country and in Germany with the kombé. He had received from Sumatra a seed pod said to be a variety of strophanthus, and it was very singular that the plume was reversed, exactly the same as in the case of the seed sent from Natal, but quite a different shaped pod. The seeds of kombé which he had sent out to try and get cultivated were doing remarkably well on the West Coast of Africa, Java, Ceylon, and in Southern India, so that in the course of a few years they would not be dependent on the interior of Africa. Another collector of his, a native, had sent a plant which had a pod exactly like one of those sent to him of the kombé variety, stating that it was also one of the arrow poison plants. He sent one to Mr. Holmes, but the pod was in very bad order, and he thought the leaf was hardly like strophanthus. It would be very interesting to be able to get from medical men the results of experiments with the tinctures made from these different seeds.

Mr. Holmes said the seed of the specimen Mr. Christy had just referred to looked very much like that of *Strophanthus hispidus*, but the leaves were quite different in character, and probably belonging to some other species, although evidently nearly allied to *S. dichotomus*. The pod however was somewhat smaller than the strophanthus received before. The mounted specimens of strophanthus leaves on the table had been received from Mr. R. Lindsay, of Edinburg, to whom he had sent the seed of the different commercial varieties in January last. The specimens had been grown from the seed sent. Curiously enough he had obtained two different plants from what had been regarded in commerce as one kind of seed. It appeared therefore that collectors in Africa were not particular as to the species from which they collected, so long as they were strophanthus pods at all. Mr. Christy was mistaken in supposing him to say that the leaves of his plant were not those of strophanthus; they were evidently strophanthus leaves, but not those of *S. hispidus* or *S. kombé*. The exact species could only be determined by the examination of flowers and plants in good condition. Some roots Mr. Christy kindly sent to him a short time ago had a very peculiar undulating appearance, and a few days after from another source he, the Curator, had received some roots of *S. hispidus* which were exactly the same as those of Mr. Christy's plants, although the very different leaves of the second specimen were evidently those of *S. hispidus*. Whether the roots contained the same active principle as the pods, and in a larger or less quantity, would be a matter for experiment. A portion of the root had been handed to a chemist who was competent to [illegible] this point.

Mr. Collier said the strophanthus was an entirely new drug, and of course every one wished to try it, which accounted for the demand for it. He had the opportunity of observing its use, and he might say that at first a considerable quantity was used at Guy's Hospital, but its use has [illegible] very much. He was of the opinion it was likely to [illegible] to digitalis. They used remedies of this kind very largely, perhaps four pints of tincture of digitalis

* See *Pharmaceutical Journal*, [illegible], vol. ix., p 948.

in a month, but they certainly had not used two pints of tincture of strophanthus since it was introduced.

Mr. Robinson remarked that the dose of tincture of strophanthus being so much less than that of digitalis, it would be necessary to multiply the quantity used by three in order to make a comparison.

Mr. Collier did not think that in the last three weeks any strophanthus had been dispensed at all; although at present there were, he should think, forty or fifty patients who were taking digitalis.

The Chairman said this new drug might be very important, whether it was now used largely or not. It was being examined scientifically, and although all its uses might not yet have been discovered, the examination it was undergoing by different persons might lead to its use in some other direction. He heard Professor Faraday say once that he never regarded the commercial value of anything he was investigating, as generally there was no use to be found for it, but ultimately it during the investigation frequently became of great importance; and this remark might possibly apply to strophanthus. It was a new drug, of which he knew very little himself, but as a number of people were experimenting with it he had no doubt a use would be found for it.

Mr. Christy said he had now one or two hundred plants growing at Sydenham from all the different seeds he could collect commercially, and he had several different varieties growing from the same seed apparently, the leaves of which showed exactly the same characters as the leaves Mr. Holmes exhibited that evening.

The Chairman then proposed a vote of thanks to Mr. Christy which was carried unanimously.

DONATIONS TO THE MUSEUM.

Mr. Holmes then drew attention to the following specimens on the table:—A very fine collection of Chilian drugs, presented by the Director of the Royal Gardens at Kew. Amongst them were several which might be regarded as replacing in Chili various drugs or herbs used in Europe. In this collection there was a specimen of the drug recently introduced into this country under the name of pichi, and which consisted of stems and leaves of the *Fabiana imbricata*, a plant which had the appearance in leaf of the common heath, but in the flower was quite different in structure, and was intermediate in appearance between an *Erica* and a *Cestrum*. The specimen of spurious chiretta on the table had been presented by Mr. Elborne, who detected it as not being the genuine article. It had a general resemblance to the true drug, but the taste was perceptibly different, being much less bitter. The stem also was of a pale colour, and had four narrow-winged arylls, and the leaves, when they could be obtained entire, were evidently more obtuse. Amongst other specimens from Kew was a bark of a tree from the Cape Colony, used for making bitters in the same way as Angostura is in this country; this bark was derived from *Gonioma kamassi*. There was also a specimen sent him by the Rev. A. J. Lennard, a Wesleyan missionary in Griqualand of a root which was much used there for dysentery. The root appeared to be that of an umbelliferous plant, but as he had neither flowers nor fruit it was impossible to identify it. He was promised a large quantity of the root for chemical examination. There was also a specimen of sandal wood oil, which Mr. Umney had been kind enough to distil from a log of Fiji sandal wood exhibited at the late Colonial Exhibition, and subsequently presented to the Pharmaceutical Society. It yielded an unusual percentage of an oil which appeared to be of good quality. Dr. E. Harry Fenwick had promised to experiment with it and to report as to its therapeutic value as compared with the Indian sandal wood oil. Another specimen of sandal wood oil on the table was sent him by Dr. Bidie, of Madras. Usually, sandal wood oil was distilled in a very rough way by the natives in India, and sometimes had fixed oils mixed with it, and not being satisfied that the specific gravity given in the text-books was correct, he had asked Dr. Bidie if he could procure him a sample distilled by a chemist in Mysore which could be guaranteed as perfectly pure. This specimen had been specially distilled for the purpose. The Curator said that he would be happy to hand a portion of it to any one who would undertake to determine its specific gravity, and any of the physical and chemical properties of the pure oil. A specimen of strophanthin was upon the table, but of course was only in small quantity. He next called attention to a very liberal and valuable collection of rare chemicals, presented by Dr. Theodore Schuchardt, of Görlitz; amongst these were the new metal, germanium, also gallium, tellurium, crystalline selenium, keratin, large crystals of asparagin and vulpinic acid and other specimens that might be interesting to chemists. There was also a specimen of mannite in crystals, finer than any previously had in the museum. Some gentlemen present would remember the paper by Mr. Braithwaite at the British Pharmaceutical Conference on "A New Variety of Cantharides," in which it was stated that a sample of contharides sent to this country from Cape Colony, consisted of two species of *Mylabris*, *M. bifasciata* and *M. lunata*, the former being very active, and the latter containing very little cantharidin. Mr. Braithwaite had presented a sample of cantharidin obtained from the former insect. Dr. Schuchardt, who had since obtained some of these insects from the Cape, said that not only was the percentage of cantharidin larger than from any other source, but that it crystallized out in large crystals than he had hitherto obtained from Chinese cantharides. Mr. Williams had sent a specimen of crystalline aconitine from *A. Napellus*, and of pseudaconitine from *A. ferox*. Mr. Braithwaite had that evening brought in a specimen of *piperine* in fine crystals, which he and Mr. Farr had prepared. A valuable series of salts of one of the rarer of the opium alkaloids had been presented by Messrs. J. A. Wink and Co.; another series of specimens had been presented to the Conference by Messrs. Merck of Darmstadt, and by Messrs. Von Heyden and Co., through Mr. Helbing; these included all the new antipyretics, hypnotics and antiseptics. He would not detain the meeting by a detailed reference to their properties and uses, but would point out that two papers had been published in the Journal concering these new drugs, one by Mr. Helbing, the other by Mr. Dymond, the former being a paper read at the recent British Pharmaceutical Conference, the latter before the Chemists' Assistants' Association. The specimens of the oil of *Pinus Pumilio*, or mountain pine, well known as Carpathian balsam, upon the table, deserved notice from the fact that the use of the oil as an inhalation in throat diseases and external application appeared to be increasing. It was supposed to be superior to the oil of *Pinus sylvestris*, but that might be a matter of taste. It was, however, a difficult matter to obtain genuine oil of *P. sylvestris*; the oil sold under that name was often obtained from the wood of other species as a waste product in the manufacturing of paper from wood in Norway and Sweden. Another series of the specimens now exhibited consisted of herbs, roots, etc., largely used in this country, but which had hitherto been desiderata for the Museum. These had been presented by Messrs. Potter and Clark. Finally he called attention to specimens of saccharin. For this product many new uses were daily being found. It was stated to be two hundred and fifty times as sweet as cane sugar coffee. He was told that 3 grams were sufficient to pleasantly sweeten a pint of tincture, and that it was two hundred and fifty times as strong as sugar. Although pleasant when diluted, it was not advisable to taste the saccharin in its pure state.—*Pharmaceutical Journal.*

TEA BOXES.—Dr. Meyer, lecturer in Forest Botany at Munich, now—we believe, on his way to Japan—recently made a tour in Nothern India, where he was made acquainted with the scarcity of suitable wood for the formation of tea-chests. To supply this want, Dr. Meyer recommends the planting of Cryptomeria japonica on the Darjeeling Hills, and Paulownia imperialis on the plains, Terai, and Punjaub.—*Gardeners' Chronicle.*

THE OFFICIAL REPORTS ON THE COLONIAL SECTION OF THE EXHIBITION 1886, WITH REMARKS.

TROPICAL PRODUCTS: FRUITS, COFFEE, COCOA, SUGAR, TOBACCO, DRUGS, &c.,

BY G. H. HAWTAYNE, C. M. G., F. R. G. S.

Fruits are reported upon by Mr. D. Morris formerly of Jamaica, now assistant-director at Kew, who takes the greatest interest in the fruit of this and our neighbouring colonies. Mr Morris recently read a most interesting paper on the subject at the Royal Colonial Institute, and in a lecture given at the Exhibition last year, illustrated his remarks on the fruit of this colony, by the papier-mâché and wax models exhibited in the British Guiana Court, and by specimens of fresh fruit of various descriptions imported from here.

In the report before me, Mr. Morris states that "it "is now clearly demonstrated that by careful and "judicious treatment and storage in a cool chamber, "numerous tropical fruits from the West Indies can be "brought to England in a perfectly sound condition. "Bananas arrived from British Guiana, while such per-"ishable fruits as papaw, sapodilla, mango, avocado "pear were received from the West Indies (and from "this colony) in excellent condition. In the rich, allu-"vial soils of British Guiana all tropical fruits are "capable of being cultivated, and the dried and preserved "articles shewn in the British Guiana Court, no less "than the models of fruits produced in the colony, in-"dicate that a large and undeveloped field of industry "is connected with them."

As one of the Executive Commissioners, I have already reported to the Royal Agricultural and Commercial Society on the ready sale of our bananas in the exhibiton market, over £13 worth having been sold in penny-worths in one day; other fruits as sapodilloes, semitoes, &c., were in excellent order and were evidently an agreeable novelty. Souarrie nuts were also readily purchased, and from my own observation I am convinced that many, if not all the fruits which are or can be produced in British Guiana, would find a quick and profitable sale in England, where there is so large a demand at certain seasons. Of oranges and lemons or limes, for instance, there were imported into the United Kingdom in one year (1885) upwards of seven million dollars worth, of which only thirty thousand dollars worth came from British Possessions; indeed, of the £7,587,523 worth of all kinds of fruit imported that year, only £302,399 worth came from our colonies. With so enormous a demand for fruits, many of which are so easily grown here, it seems almost a culpable neglect of opportunities not to direct our attention to the cultivation and export of products with which nature has so bountifully provided us. Pines which will keep without special storage for 12 days, besides being shipped from the Bahamas in large numbers in a green state (455,965 dozen, worth over £50,000 having been exported thence in 1885), are also largely exported in syrup. Singapore, however, has established itself as the best source of preserved pines in the London Market.

The small island of Montserrat, the area of which is but 47 square miles, with a population of 10,000, is the head quarters of the lime industry in the West Indies, and in 1884 exported £10,300 worth of lime-juice. To Tobago belongs the credit of having in quantity and general representative character, the most complete exhibit of preserved fruits, 200 in number, of any in the tropical section.

Mr. Morris in his interesting report, says much that should cause attention to be directed to the development of an industry followed profitably in Jamaica and elsewhere, for which this colony with its abundant and fertile lands, easy communication with the United Kingdom and with America, is especially suitable.

The Fruit industry, moreover, whether confined to raising and shipping bananas, oranges, pines &c., or extended to the preserving and canning fruit and the manufacture of wines, syrups &c., would afford employment to a large class who now find it difficult to obtain the means of existence.

The Reports on coffee and cocoa were intrusted to Mr. Henry Pasteur, who, it will be recollected, was good enough to make the special report on the specimens of these products shewn by British Guiana, which was communicated to the Royal Agricultural and Commerical Society last year.

Mr. Pasteur reports that India is first and foremost amongst British Possessions both for the quantity and quality of its production of coffee in spite of the ravages of the leaf disease. He strongly advocates the shipment of coffee in parchment, to be peeled and sized in London, and gives instances of coffee from Costa Rica thus treated, realising from 10/ to 14/ per cwt. more than that cured in the ordinary way. The parchment not only preserves the colour and quality of the berry against damage, but allows the berry to mature more completely.

There were specimens of coffee shewn by Jamaica, the only island of the West Indies where cultivation is carried out on a large scale. This island, which in 1885 exported 80,600 cwt., possesses in the high lands of the Blue Mountains, one of the finest coffee growing districts in the world.

Mr. Pasteur evidently has an unfavourable opinion of Liberian coffee which has been to some extent tried in this colony. He says its quality is so poor, so deficient in strength and aroma, and so little appreciated in the home markets, that any material increase in supply must inevitably tend to a lower range of prices, which will fail to repay the outlay. The value set on the specimens shewn ranged from 140s. to 47s. per cwt. The Liberian was worth 50s.

Nearly all the other West Indian colonies sent exhibits of coffee, which in the case of most of them was an important article of export in bygone years, but is now scarcely cultivated. Dominica, which at one time, produced one of the best kinds in the market, suffered from an insect blight forty years ago, and now raises not more than equals the consumption in the island.

Trinidad, Mr. Pasteur considers, well fitted for the growth of coffee,—the shape and size of the berries showing that soil and climate are favourable, and that only labour, care, and skill are required to give the coffee its proper value.

The Reporter is of opinion that the samples from British Guiana tend to prove that excellent coffee can be grown in this colony. These specimens were affected by sugar, and if this product ever assumes its place as an article of export, it will be necessary to avoid its being so injured, either by shipping the bean in its parchment envelope, or by selecting vessels in which care is taken to prevent contact between coffee and other cargo.

British grown coffee is superior to that of other countries for reasons which Mr. Pasteur mentions. The increasing demand, and the diminished supply from Ceylon and elsewhere, should encourage the renewal of a cultivation, which, once a source of wealth to the older colonists of British Guiana, now exists only in small and scattered patches.

Cocoa was exhibited by the West Indies, British Guiana, Ceylon, and Mauritius. The world's production of this article is estimated at 100 to 120 million pounds, of which 25 millions are raised in English colonies. Its consumption is on the increase in Great Britain, and in 1885 amounted to 14,500,000 lb. Ecuador supplies the largest quantity, and its crop influences the market.

With regard to Trinidad cocoa, although it is not considered equal to that from Caraccas, which is the finest produced, the quality of the seed, and attention paid to its growth and preparation result in the attainment of great perfection. The samples shewed large size, weight, and solidity of the kernel of the cocoa, with fermentation carried to the point at which the bitter essence or strength and flavour can be obtained.

Grenada which produces 5 to 6 million pounds yearly, sent a few specimens which do not appear to have been of first class character, so that it was scarcely represented in the Grenada Court. The cocoa is inferior to that of Trinidad, being smaller, and coarser in flavour. It is however used in the

British Navy along with Trinidad cocoa to the exclusion of other kinds. The exhibits from Dominica, St. Lucia, and Jamaica, were of average quality, but had suffered from want of care in curing the last named colony, it would appear, has been unfortunate in the quality of seed used, which has resulted in the inferiority of the chocolate trees.

Mr. Pasteur says that the cocoa from British Guiana in quality, flavour, and size, was fully equal to the best from Trinidad, and the excellent character of these samples shews that the soil is eminently suited for the growth of cocoa, and that if the cultivation was taken up in a proper spirit, it would probably add greatly to the wealth of the colony.

It is interesting to note that Ceylon cocoa appears to have undergone a considerable change in becoming acclimatised. It has a fine flavour,—without, however, the desired strength,—and it does not stand the system of fermenting and drying without washing, as adopted in Trinidad. Whether this results from inexperience or from difference of climate or soil, Mr. Pasteur says must be decided by further experiment. It is doubtful, he adds, whether there is enough land in Ceylon combining the requisites for a good cocoa plantation, viz., fine, deep, rich soil, sufficiently moist, a good rainfall, and shelter from the wind, to justify the expectation that the culture will be extended much beyond what it is at present.

Mr. Neville Lubbock assisted by Mr. W. E. Halse and Mr. John McCarthy of Trinidad, sent in a report on sugar which has already appeared in print, and been well circulated. The subject is one of such importance to this colony, that it is to be regretted Mr. Lubbock has not more than half-a-dozen pages at his command. He states that about five million tons of sugar are yearly produced, but this does not include that raised and consumed in India, China, and other countries. The cane and beet produce 2,500,000 tons each. This quantity of cane sugar with the exception of 200,000 tons, is produced without subsidy or assistance from Government, while not a pound of beet sugar is raised without such artificial aid.

The largest consumers of sugar, as far as can be ascertained, are the United States of America and the United Kingdom, 1,200,000 tons being consumed by the former, and 100,000 tons more by the latter.

The sugar produced by British possessions, including 50,000 tons exported from India, is 500,000 tons.

Mr. Lubbock is of opinion that the Indian samples were of a high class, but unsuited to the English market, being wanting in brilliancy, and inferior in appearance to the loaf. It will be remembered, however, that Mr. Howell Jones considered some samples from the N. W. Provinces of India the finest in the whole Exhibition.

The Australian Colonies were represented by New South Wales and Queensland which produced 17,500 tons and 55,900 tons respectively. Fiji and Mauritius whose production is estimated at 12,000 and 120,000 tons, supply a large quantity to Australia.

The few lines in which the sugars of the West Indies and British Guiana are treated, tell us that these are all eminently suitable for the English market except the white crystals, which are wanting in a sparkling appearance produced by the home refiners at a trifling cost, but not attainable by those working on a smaller scale, except at an unremunerative outlay.

The report on Tobacco has been contributed by Dr. Watt, C. M. G., whose knowledge of East Indian products and manufactures is most extensive, and by Mr. McCarthy of Trinidad, to whom, not only that island, but the West Indies generally, were indebted for valuable services at the Colonial and Indian Exhibition. This paper is interesting, giving as it does a history of tobacco, with an account of the various modes in which it is used by different nations and races.

Of the fifty species of *Nicotiana* known, only two, or at most four, are cultivated for the leaf. The most extensively cultivated is *Nicotiana tabacum*, recognized by its long, pinkish flowers, and tapering oval-lanceolate leaves, a native of America, extending from Mexico to Bolivia. This is the species which grows in this colony. It is hardy and self-sown, which is rarely the case with the other kind, *N. rustica*, the leaves of which are coarser and more crumpled than those of *N. tabacum*. There are three other varieties, one said to yield the finer qualities of Cuban tobacco, and the others yielding Persian, and the strong tobacco of Chili.

Tobacco requires a rich or freely manured soil, the ash cotaining 16 to 17 per cent of inorganic constituents. It is practically immaterial what seed is used, it is the chemistry of the soil that can alone ensure good tobacco. Sugar, liquorice, or alcohol, are used in the manufacture of tobacco for the purpose of getting rid of certain organic materials, the combustion of which would yield an objectionable flavour, and in some parts of India the pulp of the *Cassia fistula*, which is not uncommon in this colony, is used for the purpose.

Dr. Watt considers climate to be a most important condition affecting the quality of tobacco, which has not hitherto been found apart from tropical and semitropical countries. The West Indies have always been famous for producing a tobacco richer in aromatic principle than that grown in most other countries, and this is due to their warm and moist climate. All attempts at producing a leaf of the peculiar quality of the Havana variety have hitherto failed elsewhere than in the West Indies.

The advantages which these colonies possess, in being the owners of a good raw material, are dealt with by Dr. Watt, who holds out much encouragement for this industry. He says that it is hardly creditable to Britons over the sea, that they should be so largely dependent on Manila and Singapore for supplies of cigar wrappers, and that the best cigars in Britain should be of foreign origin.

Jamaica, however, has done much to rival Cuba in this respect, and Trinidad cigars, which Dr. Watt says were made of tobacco as good in quality as that of Havana, were largely patronized at the Colonial Exhibition. It may be a reproach to us in British Guiana, where pipe tobacco to the extent of £16,000 sterling yearly is imported, to be dependent on the United States for an article, the raw material of which grows here like a weed. It is true that pipe tobacco is in every case the product of a milder climate than that from which cigar sorts are procured, but possibly some change in the mode of manufacture would lessen any difference which might be found to exist between the native and imported kinds.

The tobacco sent from this colony was not designed for market, but was exhibited more as a specimen of what we produced and used by the Indians of the country. It is gratifying to find that, nevertheless, it was reported to be of good quality and carefully cured. Its compressed state rendered it unfit for the British market.

Dr. Watt concludes with a "general note" of some value. He says that when seed is imported, a mongrel crop is produced, in the first season, partly flavoured with the soil. In the second year the crop is truer to the seed. Leaves keep in better preservation when ripe. They should not be green nor dead, nor should they be left open, but pressed to preserve the flavour. Stalks should never be sent with tobacco.

Dr. Paul's report on drugs, chemicals, and Pharmaceutical products deals with cinchona, which was introduced into Jamaica as an experiment by Government in 1866, and is now cultivated to the extent of 150 acres. Ceylon is the chief source of this valuable bark, from which quinine is extracted, and in each of the years 1884 and 1885, exported 11,000,000 lbs. Bebeerine at one time was proposed as a cheaper substitute, and greenheart bark from which it is obtained attained some value; but quinine is now produced at a price which prevents the necessity of employing any substitute.

Some of our Guiana Exhibits, such as quassia, copaiba, honey, castor-oil, lime-juice, and cane-juice vinegar, are merely mentioned, and are dumped together with similar products from other colonies. Our large number of astringent barks used for medicinal and tanning

purposes, are dismissed in a few lines, and one must have recourse to the more complete and careful notice of these products of Guiana afforded by the pamphlet of Mr. Holmes of the Pharmaceutical Society.

Perfumery is noticed by Dr. Paul, who reminds his readers that there are numerous raw materials in the West Indian colonies that might be turned to useful account for the manufacture of perfumes. In this connection, mention may be made of numerous essential oils available for perfumery purposes. Plants yielding fragrant oils are abundant, and there is a large field for their industrial application. A flower farm and perfume factory are being attempted in Jamaica, and there are other places, among them British Guiana, where this industry could be carried out.

There were no specimens of oils and fats from marine or land animals exhibited by British Guiana. Mr. Leopold Field, the reporter in this section, mentions that fish and whale oil have fallen into disuse as lubricants, being replaced by American, Scotch, and Russian hydro-carbon oils, just as kerosene and petroleum have supplanted sperm and colza as illuminants. British Guiana produces nothing in this way, and but three exhibits from the West Indies are mentioned. These were, a fine specimen of porpoise oil well fitted to make soft soap, and some shark's oil and a small quantity of whale oil. Nut, seed and fruit oils, with the exception of coconut oil, are not produced in this colony. Coconut oil is used chiefly in England for soap and night lights. In the manufacture of candles it has been superseded by acidified palm oil. It gives a white and brilliant light, and articles made from it are more cleanly and tempting than those made from other materials.

Coconut oil is largely used in soap making, but considerable prejudice exists against it on account of its rank and persistent odour. Its chief value appears to arise from the facility with which it can be adulterated. One of the tricks of the soap trade, it seems, is to crowd in silicate and carbonate of soda, sugar and water, and to hide any objectionable smell with mirbane and emon-grass.

The British Guiana coconut oil is described as very good and remarkably white, though slightly rancid and strong-smelling. These, Mr. Field says, are "accidents of circumstance," and he is of opinion that there is no reason why Guiana should not vie with other colonies as an oil-producing country.

The question is raised whether the kind of nut, and the method of cultivation may not have as much to do with the colour and odour of the oil as the mode of extraction, or perhaps more. This, it seems, is the case with palm oil. Mr. Field mentions as an instance of the effect which difference of soil will make in the quality of oil, the case of lavender. English oil of lavender produced at Mitcham, in Surrey, commands more than six times the price of that from all the south of France. The same, he says, is true of rosemary and peppermint, and he suggests that the point whether a different coconut or different soil be required, is worth attention.

There is one nut, the Candle-nut, *Aleurites triloba*, which, produced in Fiji, Ceylon, and elsewhere, yields 55 to 62 per cent of its weight in oil. This tree has been introduced into some of the West Indian Islands, and doubtless would grow well here.

Castor-oil is good as a lubricant for heavy machinery, but will in time yield to petroleum and shale oils. It has a peculiar and unique property. Besides its aperient qualities of being perfectly soluble in alcohol at ordinary temperatures, which causes it to be largely used in the manufacture of Brilliantine and other hair dressings. For soap making it has a special value, and is indispensable in the manufacture of cheap transparent soaps. Mr. Field, who, by the way, is a maker of soaps on a large scale, and, moreover, one of our best practical chemists, while admitting that these soaps cannot be recommended, as an excess of caustic soda is required, and that the smell of the castor oil becomes apparent in a few weeks, says their brilliant lustre and scouring properties possess great attractions for natives. Perhaps it was some such preparation that made the bishop of Wangaloo white, as is represented in certain illustrated advertisements.

Mr. Field goes on to say that it is a matter of surprise that with coconuts and castor-oil seeds to be had almost for the picking, these soaps are not made in Ceylon and the West Indies, where spirit is easily and cheaply obtained, where sugar (an important adulterant) is plentiful, and where, above all, essential oils abound. We know that in Trinidad there is a soap manufactory, but the qualities shewn were "poor, com-"posed of 'weak fats' and 'much resin'—of a dark "colour and alkaline, and indicating a large excess of "water in their original composition." These faults are of course avoidable.

One oil was exhibited in the Jamaica Court which is highly extolled by Mr. Field. I refer to it, as the tree whence it is produced grows here easily, and is by no means uncommon. We know it as the horse-radish or seringah, but its botanical name is *Moringa pterygosperma*. Its seeds yield oil of Ben or Behen, described as an exquisite oil, and one which, though apparently devised by nature expressly for the perfumer, seems to have been singularly neglected. Mr. Piesse, in his "Art of Perfumery," is enthusiastic in its praise. It would be invaluable to the flower farmer, who by the process known as enfleurage, *i.e.*, submitting blossoms to the action of oils or lard, extracts their perfume. It is also said to be the basis of macassar oil which is, or was, so fashionable.

Referring to enfleurage, the Jamaica Court showed fine specimens of Tuberose and Jasmine pomades. Surely British Guiana could do likewise with Behen oil. These and other pomades and oils, for which the demand in England alone is enormous, could be manufactured here, and a profitable industry created. Mr. Field's remarks on this subject are worth laying to heart. "Why," he asks, "should not our own "colonies supply us? Why should all our citron, "bergamot, and orange oils come from Messina and "Spain, when the West Indies can grow these fruits "in any quantity?"

Carapa or Crab oil, it appears, would be a fine and valuable oil but for its sickly and persistent odour. It proved impossible to get rid of this defect—blowing hot air through a pint of it for 24 hours was ineffectual. It is, however, easily saponified,* and the smell becomes similar to that of fresh cider. It has, on analysis, been found to contain a bitter principle named Carapin, to which no doubt its insecticide properties are due. The association of its being used for this purpose might militate against its coming into general use, otherwise an acceptable pomade could be made from it by means of dexterous perfuming.

A considerable portion of Mr. Bolas's report on Gums, Resins, &c., is devoted to the Balata, or, as the writer prefers to call it, the gutta-percha of the Bullet-tree, and Gum Animi,—both products of this colony. His remarks have been already published in the *Argosy*, and it would be most interesting if his Cantor Lecture, delivered in 1880, on Indian rubbers, were also communicated to the public of this colony, which possesses one or more of the most valuable gums known. Mr. Bolas evidently appreciates our Balata. He believes it is of greater use and value than the average crude gutta-percha from other sources. I do not know how far he is justified in paying the people of the balata districts of this colony, the compliment of attributing this superiority to their higher moral character. Mr Bolas believes that high moral character in the workman ensures corresponding care to deal intelligently and honestly with the material, as well as abstention from adulteration; and so far he is no doubt theoretically right. Whether facts bear out his hypothesis in the case of the balata collectors of this colony is, however, questionable. Mr. Jenman's favourable report on the social condition of the people of the Baracarra district, has so impressed Mr Bolas that he claims it as supporting his view. But this as it may, balata is evidently a prof-

* A specimen of Crab-oil Soap, prepared by Mr Field and presented by Mr. Hawtayne, is exhibited in the British Guiana Museum.—Ed.

prized, and what is more, to be jealously guarded against exhaustion by indiscriminate and injudicious treatment of the trees which yield it.

There has been on this subject, as on others, a certain amount of legislation. I think British Guiana may well rank as one of the largest law-producing countries of the world. In it, to the making of laws there is no end; but when one takes up the Statute book and sees how few of a certain class of Ordinances are enforced, one is inclined to ask whether less theory and more practice is not desirable.

It may be also a question whether, not only as regards the preservation and proper collection of our natural products, but also the introduction, cultivation, and preparation of others, it may not be wise to create a department of Economic Products, by means of which the Government may employ a portion of the revenue in fostering certain industries, which, in all probability, would be the means of increasing both private and public prosperity. Much of our natural wealth requires to be protected and developed. The colony is fit and able to receive and adopt other products of great value. To depend on the spasmodic and short-lived efforts of individuals appears fruitless, while valuable results may flow from well directed enterprise.

Mr. Bolas says that the capabilities of supply of "gutta" in British Guiana seem to be enormous, and that if the misleading term "balata" were dropped, and relations opened directly with the manufacturer, a very large trade could be done in this article. Balata, or gutta, suffers from coming into the market as a different material from gutta, and under another and less recognised name. It has been bought by speculating dealers at a nominal price as bullet-tree gum, and sold to the manufacturer at the market price of the best gutta. It is also desirable to adopt some system of coagulation of the fluid gum which would advance the quality of the product, or minimise deterioration by oxidation. It appears that ozone, which, to a certain degree, is beneficial to human life, is the cause of rapid decay in gutta and rubber—a thin leaf of the former falling to dust in strongly ozonized oxygen. It is recommended, therefore, to mould the product into thick compact masses rather than into thin sheets.

The India-rubber shewn in the British Guiana Court was considered sound and of good quality. Mr. Bolas believes that much of it was obtained from the Touckpong tree, which is a variety of *Sapium biglandulosum*. Another sample shewn was from *Hancornia speciosa*. The rubber from *Hevea Spruceana* was submitted by Mr. Holmes to well-known brokers, who stated that it had never come into the London market, and that if well cured, it wou'd command 2/ to 2/2 per lb. The sample of Hancornia or Mangeibera rubber was cleaner than the samples usually sent to the London market, and was valued at 1/10 to 2/ per lb.

The samples of Gum Animi, or Locust gum, were considered exceptionally fine. Mr. Bolas remarks that the value of this material is quite understood by varnish makers. Mr. Holmes of the Pharmaceutical Society found that it was readily soluble in Eucalyptus oil and formed an excellent varnish. In the solid state it is capable of being worked up into an imitation of amber, and, mixed with that substance, becomes an admirable material for mouth-pieces of pipes, &c.

Dr. Schuchardt of Goerlitz informs me that he is engaged in chemical examination of our gums &c., and promises to communicate the results. Professor Wallack is also investigating their composition.

Karamanni also attracted the attention which it deserved. Mr. Bolas thinks it worthy of investigation. It is, according to Mr. Im Thurn, a compound of resin from a *Hevea*, bees-wax and powdered charcoal. A "wax gutta," something like the Karamanni, was shewn by an exhibitor in the Sierra Leone section.

Cotton, once one of the staple products of this colony, was but poorly represented at the Exhibition, as far as British Guiana was concerned. One of the samples shewn was, in the opinion of Mr. Butterworth (from whose report I quote), a Brazilian variety, retaining the features of that class of cotton in its harshness,—but well grown and of good staple. Another sample was evidently grown from Sea Island seed, and, if freer from leaf and dirt, would have been almost of a pure white. It had, however, one serious defect in irregularity in the length of staple, which is objected to by spinners, as it is difficult to manipulate.

Although Mr. Butterworth reports that our colony has extensive tracts of land "adapted for cotton "growing, which, with the improved methods of "cultivation, selection of seed and ginning would "produce an article in bulk and quality that would "be hard to beat," he is but speaking of a defunct industry which it appears impossible to revive. Cotton has died out also in the Islands, except in some of the Gren dines—small islands between Grenada and St. Vincent, where its cultivation, along with that of corn, affords subsistence to a sparse population, and where the remains of well built mansions, and other vestiges of an opulent proprietary testify to the prosperity which existed when "Cotton was King." It is interesting to learn from Mr. Butterworth's report that a hundred years ago, the Society of Arts of London granted a gold medal to a planter of Tobago for the best sample of West Indian cotton, and that the sample shewn in the Exhibition last year from that Island was of "an excellent colour, and capable of "spinning into number 60s, and in grade equal to good "Orleans—shewing the growing capabilities of the "colony to be maintained."

Silk, which formed a wonderfully interesting exhibit in the Indian Court, is reported on by Mr. Wardle, who is enthusiastic in his belief in this product as a source of wealth to many parts of Her Majesty's Empire. His work on the Silks of India is a most interesting book. Some Cocoons of a moth which is tolerably common here, have been sent by me to Mr. Wardle for examination and report, and there are some specimens of Attacus-moth under observation at the Museum. I understand that an attempt at sericulture was commenced by the late Mr. Oliver, which however did not go beyond raising mulberry trees as food. There are so many indigenous, or easily cultivable, sources of food for silk-worms other than *Bombyx mori*, that it might be far from difficult to establish silk-worm culture here.

There is probably no minor product of British Guiana from which greater results have been expected than from Fibres. There are so many fibre plants growing wild in this colony, samples of which it costs little to collect, and apparently possessing useful and valuable qualities, that people are often tempted to turn to these as a more than probable source of profit. Reports and quotations based on samples sent to London or elsewhere, often raise hopes and stimulate efforts, but hitherto there have been no satisfactory results. Nor is this confined to the products of British Guiana. Mr. Cross, the reporter on Miscellaneous Fibres, says this department of industry has been, perhaps, exceptionally fruitful of baseless enterprise—of abortive attempts to make into commercial undertakings that which careful antecedent investigation would have consigned to the long list of the unprofitable. The question also arises:—Is there any necessity for an extended application of the multitudinous vegetable fibres? Are not those fibres, now in possession, sufficient, not only in supply but in kind, *i. e.*, in variety, for all the possible purposes of vegetable textiles? Supposing the supply insufficient, are we not rather to seek the remedy in improved methods of producing and treating our present raw materials, than in introducing new ones? Especially since a new fibre means new methods and machinery for agriculturists and spinners.

It would take too much space to transcribe Mr. Cross's highly interesting remarks on the structure and properties of various kinds of fibre. They are grouped as materials for industry according to their application, and these groupings, it seems, follow their classification based on origin, structure, and chemical composition. Cotton, which consists of independent ultimate cells, differs from raw materials which are "fibre-aggregates," or bundles of ultimate fibres bound

together by contact or adhesion of the cell-walls, or cemented by a third substance. In the cases of straw and Esparto grass, the whole plant is regarded as a fibrous raw material.

A certain unit of length is required in spinning processes, and the value of a raw material depends on the length, fineness, or divisibility of the fibre bundles of which it is composed. Strength and durability are also qualities which determine its value, and these depend upon the ultimate structure and chemical composition—ascertained by laboratory investigation.

That portion of raw fibre material which resists the ordinary agents and alkaline solvents used in bleaching, is the cellular basis of the material, consisting of ultimate fibres or fibre cells, which vary in length according to the plant source from which they are derived. The lengths of these individual cells with their proportion in weight to the raw fibre, are taken as tests of value—"Constants," as they are technically termed.

Flax, hemp, rhea, and jute, which are the fibres of dicotyledonous plants, possess a percentage of cellulose varying only from 75 to 80 degrees, while the length of ultimate fibre, which in flax is set down at 25-40 mm. and in jute at 3m. rises to 60-200 mm. in rhea; and in monocotyledonous plants, furnishing a large proportion of rope-material such as manilla (*Musa*) or plantain, New Zealand flax (*Phormium*) and Agave, cellulose is from 63 to 76 per cent and the length of fibre from 2-8 mm. to 8-15 mm.

There are other fibres than the above which are used in *textile* manufacture, but these are unavailable for that purpose, and require to be broken up by chemical action in order to serve the purposes of the paper-maker. Bamboo, straw, and Esparto are entire stems or leaves of monocotyledonous plants, and are treated by boiling at high temperatures, for separation of fibrous portions, by washing and by bleaching. Mr. Cross refers, for details of the various chemical methods employed, to a paper in the Chemical Society's Journal for 1883. Much information is also to be found in Mr. Christy's "New Commerical Plants and Drugs" No. vi. "Spon's Encyclopædia of the Industrial Arts 1881," but the report made by Mr. Cross to the Indian Government will, when accessible, be of the greatest value to this and other colonies.

The real value of the fibres of the West Indies, (with which Mr. Cross includes those of Guiana), will be more appreciated when this work is published. No fibre exhibited by British Guiana appears to have presented any qualities greatly superior to those possessed by other and better known products. Megass from the sugar-cane has been considered worthy of attention as a paper material, and some machinery was erected in this colony for its conversion into "half stuff," but Mr. Cross declares it to be inferior to that yielded by bamboo, and not to be recommended to paper-makers. He doubts whether by any process it could be converted into a useful paper-making material at a reasonable cost.

Banana fibres are of fair length, and have been proved to possess good paper-making properties. Mr. Cross obtained by treating the raw material, 31 per cent. of a well bleached, clean, tough fibre. So low a yield however is to be regarded as prohibitory, a yield of 50 to 60 per cent being necessary before a fair price could be realized in Europe. Paper from Banana was shewn to the members of the R. A. & C. Society and this, among other qualities, could be written on without being sized.

The fibre of the silk-cotton (*Eriodendron infractuosum*) was exhibited from several colonies besides British Guiana, and some remarks on it have been already laid before the Royal Agricultural and Commercial Society. It differs in structure from true cotton; the latter is always somewhat flattened, and possesses a natural twist peculiar to itself, while silk-cotton fibres are straight cylindrical tubes. Silk-cotton has a peculiar absorbent quality, which may adapt it for surgical dressings. At present, its chief use appears to be for bedding, for which purpose it is well adapted.

The basts from this colony, of which two typical specimens, Enouroo and Kokoyoko, were analysed by Mr. Cross, gave results shewing them to be valueless.

Rhea grass is more likely to be a profitable subject for cultivation here than any fibre-plants we possess, and a large number of pamphlets about it have been distributed in this colony. In hemp substitutes and "unenumerated fibres," the West Indies now play an inferior part, but Mr. Cross thinks that a large proportion of this commerce can be wrested by them from those now holding it.

The commercial issue as to the value of a fibre-product entirely depends on the cost of putting down the treated material at the several ports, in a condition which would ensure its conversion into pulp at no greater loss than 40 per cent., and such a product, Mr. Cross estimates, to be worth £8 per ton.

It must be remembered that the foregoing estimate is based upon a purely laboratory valuation; and though "sida" from the West Indies will compete with jute, and "grugru" is capable of competing with hemp, the cost of production and freight, and extent of regular supply are not taken into consideration. If those latter conditions are favourable with regard to any one fibre, and the analysis shews the assistance of a superiority of quality, there may be prospect of success; but calculations have to be carefully and thoroughly made, before any dependence should be placed upon the introduction of any fibre, at present comparatively unknown.

Leather, Furs, Hides, and Tanning materials were not represented in the British Guiana Court, with the exception of some ocelot, baboon, otter, deer, and other skins, which, from want of proper preparation, were in bad condition.

I regret that this was the cause, because in the Local Exhibition of 1885, we had such excellent specimens from Mr. Frank of Eliza and Mary, and others of well prepared leather from goats. So extensively are crocodile and alligator skins used at home, that one would think it worth while to kill and export the skins of the caymans which are so numerous in our trenches. So-called "Porpoise-skin" is, I believe, the produce of the horse, or, at all events, horse-hides are dressed and sold as porpoise-leather. Some years ago I sent home the skins of porpoises captured during a short cruize "among the Caribbees," and they were converted into excellent leather. Porpoise-catching might be followed as an adjunct to other fishing, since the oil and the skin are both valuable.

The Tanning barks of British Guiana were passed over in the Report now under notice. There are other sources whence much useful information as to the qualities of the several barks grown here may be obtained. The Chamber of Commerce in London took notice of such materials exhibited from other parts of the world. Some of these, however, are to be found here or are capable of cultivation, and with encouragement, a fair supply could be raised and exported from this colony.

Mr. Lastell's paper on Timber is somewhat disappointing as far as this colony is concerned, because, although he visited our Court and closely examined our numerous and varied exhibits, he has offered no opinion as to their suitability to the English market or English requirements. His observations on each specimen are repetitions of those descriptive remarks which when, compiling the catalogue, I borrowed from Mr. McTurk's list of specimens in former exhibitions, and of those furnished by Messrs. Park & Cunningham. It would have been more satisfactory if one could have gained from the report the opinion of English experts as to the value of our timbers.

Mr. Lastell says the timber of the colony was well represented, and that there is quite a mine of wealth in our forests. That is so; but our exhibits were sent not merely to attract attention to the quantity and variety of our timber products, but to elicit from home consumers some opinions founded on their experience and their requirements.

It is true that Messrs. Ransom invited the Commissioners to send specimens of prescribed sizes, which were longer than British Guiana could supply, for the purpose of their being worked up by the machinery

of these gentlemen. The invitation, I confess, appeared to be issued more in the interests of the manufacturers of wood-cutting tools than in those of timber exporters, and I do not think British Guiana lost much by not having put in an appearance.

In conclusion, I trust that these extracts may prove interesting and of some value. All that I can claim to have done is to have picked out from the Reports, what I considered of value to the readers of *Timehri*.

I think that from these Reports one may learn much of what is wanted by consumers in England, and (which may be of equal value)—what is *not* wanted. It is better to discourage undertakings which, however, promising and attractive to an enterprising colonist desirous of tapping new sources of profit, nevertheless belong "to the long list of the unprofitable." It is well to know what is wanted, and then to see how this colony can supply that want easily, and cheaply. All this requires study, and knowledge of markets, and acquaintance with technical modes of analysis and valuation. These are not always possessed by the producer or collector: often are they ignored by the commercialist on the other side, who is only anxious to secure a new customer, and to speculate with some new product. It is depressing, no doubt, to feel difficulty in developing the resources of one's land: it is, however, more discouraging to see time, energy, and capital all thrown away upon some unsuitable, or comparatively useless product for want of previous enquiry.

The Society of which *Timehri* is the Journal, can, it is true, aid greatly in supplying this necessary information; but it may be suggested that our Colonial Government could more easily institute enquiries, and foster experiments with respect to our undeveloped resources—and this would probably be no unprofitable investment of Colonial Revenue.

The following are the reports, written for Mr. Hawtayne, on the subjects specified:—

BRITISH GUIANA COFFEE.

38, Mincing Lane, E., 13th Nov., 1886.

I have carefully examined, roasted, and tasted the samples of the British Guiana coffee you have been kind enough to send me, and I now have the pleasure of giving you my report upon them:—

No. 15, marked ordinary, J. P. Murphy, is a rather small, pale, even and nicely picked coffee, clean in taste, but thin and weak. Value 58s. to 60s per cwt.

Sample marked Colonial Co., Pln. Mara, is a bold pale yellowish even sample, clean and pure tasted, but wanting in strength. Value 63s.

No. 16, marked N.G.D. Elephant, is a common dull brownish Liberian, it roasts badly, and taste badly, oily, and unclean. Value 45s.

Sample marked N.G.D., C. Arabica, pale greenish native kind, good size but bricky and tasting like Santos. Value 58s.

No. 17, Liberian, W. Smith, appears to be a mixture of pale native kind, and of the ordinary Liberian sort, it has a common oily taste though not so bad as No. 16. 52s.

The Liberian samples are so common, and roast and taste so badly, that I cannot sufficiently caution your colonists against growing this sort. It sells fairly well now, owing to the great reduction in the stocks of coffee and the rising tendency of the article, but with a full supply of Liberian (which I am afraid we shall see before long, as everyone seems to have been going for it,) I have no hesitation in saying that Liberian will become very difficult of sale, and that prices will go down materially, even if other sorts keep their value. There is an oiliness in Liberian which, when roasted, becomes most offensive to smell and taste.

The N.G.D., C. Arabica, the ordinary, J. P. Murphy, and the Pln. Mara are a very successful class of coffee; the first seems to have suffered a little in preparation but has all the elements of good coffee, and with good preparation would probably be greener and nicer looking, and might be worth 5/ to 8/ per cwt. more; the 2nd and 3rd are nice looking, well picked, the Pln. Mara, especially, of very good size.

I think planters should be warned that sugar is an enemy to coffee in all its stages from its growth to its preparation, and the utmost care should be taken to keep the two at a distance from each other; especially in shipping coffee, care must be taken not to put it in the same vessel which carries sugar, as the effluvium from the sugar almost invariably ruins the coffee which is in the same part of the vessel. The Royal Mail Steamers alone can be trusted, as care is taken, if any sugar is on board, to place the coffee in a totally different part of the vessel; this is a matter of very great importance.

If there are no appliances to peel and prepare the coffee for shipment at Georgetown or on the estates, I would recommend planters to send their produce to London in parchment. The pulp, of course, must be removed on the estate as quickly after picking and as carefully as possible, and the parchment *must* be perfectly *clean* and *dry*: when in that state, it can be sent to London, not only without risk, but with the certainty that it will preserve the berry during the voyage. Highly successful and encouraging experiments have been made here during the present year, which show that coffee peeled and sized in London has kept its colour and quality extremely well, and has so far, in every case, realised more than the same kind of coffee prepared and peeled abroad. Suitable machinery has been put up at "Red Lion Wharf" and at "Metropolitan Wharf," and I believe that some of the Dock Companies contemplate erecting similar works.

I trust that the above remarks may be of some interest, and perhaps of use to the planters in your colony.

H. PASTEUR.

BRITISH GUIANA COCOA.

Mincing Lane, London, 18th Nov., 1886.

It is with much pleasure I hand you a report upon the samples of Cocoa exhibited in the British Guiana Court.

They at once attracted my attention from their remarkable quality and fine growth. No other cocoa in the Exhibition could compete with them except Trinidad, to which they bear great resemblance.

It seems to me that the soil and conditions of temperature and climate must be quite adequate to the production on a good scale of a very superior cocoa, especially fitted for the use of English manufactures. I find on going through the samples again that there is a difference on the part of three of them compared with the other seven. No 9, a bright red, unfermented, and rather small in size, is evidently the produce of an inferior tree. No. 5, some accident in the curing had deprived of its proper value. No. 11, which I understand is grown in Berbice, has also a distinct character, more allied to the growth of Surinam than to Trinidad, the flavour good, superior to Surinam, but differing from that of Trinidad.

Of the remainder, Nos. 7 and 8 are very large size, fine flavour, and the breaking up of the bean shows the color a *red brown* that is generally liked. No. 6, 6a, 7a, 12, and 13 are all after the style of Trinidad in their quality and flavour.

The seven samples I have seperated from the rest are in colour and appearance of the outside shell, good; and one essential, the fermentation, has been very carefully carried out, producing an even colour in the breaking up of the fruit, which manufacturers like in their preparations. I should suggest the trial on the estates, where the seven samples came from, of the latest mode of curing used in Trinidad, that is, after the fermentation (carried out to the extent *only* as you have now done it), instead of washing the pulp or mucilage away from the shell, it should be dried upon the surface, and only slightly rubbed, just to get a reddish colour.

In giving this advice, I wish you to avoid the very high fermentation to which they subject Trinidad cocoa. The drying of the mucilage on the surface has the effect of sealing the shell, and thus not allowing any of the flavour of the fruit to escape.

The extent to which France and the United States now compete with England for Trinidad, will ensure a ready sale for all cocoa that you can produce of this character.

WILLIAM PINK.

No. 5 ZG in Diamond R (Charles Ross) dark, brownish, dull break, no flavour, value per cwt.

No. 6 Noitgedacht, bold red, fine flavour, would bear higher fermentation, 85s. per cwt.

No. 6, Ariba, N. G. D., red, fine flavour, evenly fermented, 84s. per cwt.

No. 7, Caraccas Weber, (Vryheid) bold bright red, fine flavour, 87s. to 88s. per cwt.

No. 7a, Caraccas, Wm. Smith (Vryheid) bright pale red, fine flavour, wants strength, 85s. per cwt.

No. 8, White, Weber (Vryheid) very bold red, picked, fine flavour, fine colour in the break, 87s. to 88s. per cwt.

No. 9, Honston, bright red, rather small, unfermented, 65s. to 66s. per cwt.

No. 11, Mara, red with a bloom on it, good flavour, red break, 82s. per cwt.

No. 12, Le Desir, red, fair size, red break, good flavour, 83s. to 84s. per cwt.

No. 13, Le Desir, white, red, little greyish, fair break, 80s. per cwt.

PRESERVED FRUITS, ETC.

113, Edgeware Road, London, Nov. 18th, 1886.

In response to your request to present to you a report on the food products of British Guiana and their commercial value in the English Market, I must confess at the offset that the circumstances under which the samples are shown prevent me from arriving at an estimate as to the true value of these products. The samples are too small to test the market, and the mode of package is unsuitable to a good class trade to which these goods are adaptative; but from the data before me I will offer these conclusions, the value of which must be left to your good judgment.

It must be borne in mind that although there is a demand for this class of products, that demand is governed by price. As the London market is the centre for all the world's products, these goods are naturally brought into competition with articles of a similar character, and the trade consequently goes to the best and cheapest producers. There can be no doubt that you are favourably situated for producing goods, such as I detail below, as well as any country. The fruits growing in great quantities, sugar being plentiful and labour cheap, consequently it only rests with the method of your packing so that the articles come into the market in a reliable form. For this purpose I should advice that, in each class of goods, a brand be established which will serve as a guide to reliability, which, for the successful purpose of trade, you must endeavour to impress upon your clients, must be always maintained, for goods varying in quality have a fluctuating value.

The following products come under my experience. I should be glad to open commercial relations with any of your clients and advise them on the methods of sending them to this market.

Cassareep, Limes, Papaws in syrup, Tamarinds in Syrup, Guava Jelly, Limes in Syrup, Guavas in Syrup, Pine Apple Jams, Preserved Ginger and Tamarinds.

Cassareep.—There is a demand for this as it is the basis of many sauces and condiments. I think a good trade could be made in this article. I should suggest that it be packed in open stone jars, well corked, containing about a gallon each, and made of uniform strength. If there is any difficulty in obtaining earthenware utensils, I could ship to you proper jars for this purpose. I could then ascertain the London value for your product, for it is impossible to arrive at this in the absence of [illegible] from you.

Tamarinds in Syrup.—There is always a market for these in London; the most [illegible] package is usually in small earthenware pots containing about half a pound of fruit and covered with a preserving paper; the sample you show is equal in quality to any on the market; they also might be packed in tins.

Guava Jelly.—The sample shown is very good and could command a good price if suitably put up.

Limes in Syrup.—A very good sample is shown, but I think there is a little too much sugar used. I am certain business could be done in these as they are very scarce; if attention is given they will lead to success; great care should be taken that they are air-tight as they are so liable to evaporation. If these were sent in gallon jars they will pay for labelling and bottling here. I should suggest that this plan be adopted, but send sufficient quantities to show results.

Limes and Papaws in Syrup.—The sample shown is very good; the same remarks apply to these as to the Limes in Syrup. Oranges in Syrup, these ought to be turned to advantage, they should be in a good clear syrup, not too sweet, and in glass jars containing about 2 lb. of fruit. Care should be taken that the flavour of the orange should not be lost by too much sweetness; if they are carefully packed there is a certain market for them.

Pine Apple Jam.—The sample is good, but unless you are prepared to compete in this product, I should not advice you to send, as great quantities come to this market from Straits Settlements; and they are put up in a showy style and are sold very cheap.

Preserved Ginger.—If this is preserved in Syrup as the Chinese pack it, there is a good sale for this article and it fetches good prices.

West Indian Pickles.—If you can send these in bulk and the prices are low, they are saleable; but it would be necessary to bottle them afresh here, and price is the chief consideration.

Fruits.—I am sure you have great facilities in your colony for bringing the fruits as cheaply to this market as any country. I am prepared to bring your products prominently to notice and would ask you to send me at your earliest convenience such samples that I may be prepared to offer them for sale and suggest improvements, if necessary; but again I have to draw your attention to bringing your consignments as cheaply as to be remunerative to you and establishing a firm trade in them. If there are any utensils that you consider necessary, I shall be pleased to consign them to you, or any information I can get for you I shall be yours to command. I may remark that there is a great demand for *crystallised fruit* here and with your cheap sugar and good fruit there is a splendid opening.—S. GOVER.—*Timehri.*

PLANTING REPORT FROM THE HILL COUNTRY OF CEYLON;

THE CEYLON PLANTING ENTERPRISE—SAD RETROSPECTS—VARIOUS JATS OF TEA—TIMBER TREES.

UPPER DIMBULA, Dec. 13.

I suppose that on other estates as well as on that whence I write new light is being obtained as to the comparative merits of various jats of tea. Of course, a medium hybrid, with a strong leaning to Assam, is the best, provided it yields abundant flush, such flush being distinguished by a bright golden tinge. It would be well if all the plants were of this description. But with all the care that may be taken in the selection of seed, there will be departures to the China type on the one hand and to what looks like the indigenous on the other. Some of the former, especially those showing a bronze tinge, are excellent flushers. But there are hard-leaved China plants which, the sooner they are ousted and superseded, the better. They look bad and are what they look. There are others in the very opposite direction, the quality of which entirely belies their impotent looks. In foliage, size and appearance, even silkiness and serrated edges, they resemble closely indigenous Assam jât, and while the bushes are young the planter plumes himself on their high quality. As they advance in age, however, they become sources of disappointment, and require to be rooted and superseded by "supplies," equally with the most miserable look

ing China. The plants referred to, often one-stemmed and with large-looking foliage, seem normally incapable of developing "flush." Successive pairs of leaves open in a "banjy" or hard state, unsuitable for tea-making. The leaves of such plants are generally *stumpy*, disproportionately wide in comparison with their length. One lies before me, quite of the indigenous type, but its breadth is exactly one-half its length, 2½ inches broad against 5 long. By its side lies a leaf from a bush of our best flush-yielding jât, which is long and sharp-pointed, the dimensions being in this case only 2¾ inches of breadth against 6¾ of length. The bush from which this leaf was taken had ten separate stems, and some of our very best plants with the largest expanse of plenteous flush-bearing surface have a score of stems and occasionally even more. Where a good flusher rises from the ground with one stem, we always find that the primaries spring from it at seldom more than 4 inches from the surface. In our moist, warm climate the tendency is for trees which would be one-stemmed in India, to send up 6 or 12 or even 20 stems, and their value is in proportion as this propensity is followed and encouraged. The general result is, that while to an Indian planter the stems of our tea plants are contemptible, he soon learns with astonishment to appreciate the superior yielding qualities of the flush-surfaces supported by multitudinous thin stems. Exceptions there are, of course, and I have seen stems as well as leaf surfaces in Ceylon equal to anything India can show. It is possible, of course, that at lower elevations the short and disproportionately broad-leaved plants to which I have referred may give better results than they do at our altitude, ranging about 5,000,—from 4,600 to 6,000. I deem it right, however, to mention what I have observed. Happily the great bulk of our bushes are of the many-stemmed, long and sharp-pointed leaves and free-flushing variety. But when we come to the work of supplying good instead of objectionable plants, it seems probable that the cumberers of the ground which must be ousted will be to a great extent plants regarding which a casual onlooker would express admiration on account of their large, indigenous-like foliage. More of those which lean to the China type will probably be spared than of this deceptive variety.

Eucalypti of all species, from blue and red gums to stringy bark and jarrah, flourish here; but our favourite amongst trees of Australian origin is *Grevillea robusta*, with its luxuriant fern-like foliage, silvery on the under side and the noble stems of good timber it forms. Once in the ground and grown appreciably, we have never known a grevillea die, although a fine specimen was blown down the other night. Only a small proportion of the seeds seems to be fertile, and grub (bred in a manure heap) has played havoc with some of our nursery beds, just as rats are inimical to plants of *Cryptomeria japonica*. Toon (*Cedrela toona*, the "red cedar" of Queensland), which is our favourite equally with if not above grevillea, seems able to resist both grubs and rats. The three trees above-mentioned seem the most desirable to cultivate for firewood and timber purposes, and we are inclined to think well of a variety of casuarina which grows thin and tall, with branches at wide intervals, and with rough corky-looking bark. The one with fine dense foliage is liable to die off.

IMPROVED (RICE) AGRICULTURE IN CEYLON.

Office of the Director of Public Instruction, Colombo, December 17th, 1887.

To the Editor of the "Ceylon Observer."

SIR,—I have the honor to annex for your information copies of letters No. 359 of 22nd October and No. 402 of 7th instant, addressed by me to the Hon. the Colonial Secretary concerning work done at the Minuwangoda and Panapitiya branch Agricultural Schools.

As the subject is interesting to many, I should be glad if they could find a place in your columns.—I am, sir, your obedient servant,

H. W. GREEN, Director.

Copy of my letter No. 359 of 22nd October to the Colonial Secretary.

Sir,—I have the honor to report that the Minuwangoda Agricultural Instructor reports his first crop result from the use of the improved plough.

2. He arrived at the village too late to cultivate the lands allotted to the school for the harvest just over. Those lands are now cultivated, but their crops cannot be judged of till next spring.

3. He at once, however, ploughed an acre of paddy land for a Mr. Joseph Croos at Minuwangoda, and this ploughing alone, without "planting out," or manure, has now given a crop of 30 bushels for this acre, which Mr. Croos certifies. Two bushels of seed paddy were used. Mr. Croos also certifies that he never had more than 15 bushels from this field before, and usually only had ten bushels.

4. The large yields which I have previously reported were obtained by "planting out" the paddy, in addition to ploughing with the new plough.

5. The present experiment shows, what I have frequently demonstrated, that the mere use of the plough should about double the crop, while if other methods are added the increase is enormous.—I am, sir, your obedient servant,

(Signed) H. W. GREEN, Director.

Copy of my letter No. 402 of 7th December to the Colonial Secretary.

Sir,—I have the honor to report that the Agricultural Instructor at Panapitiya in the Kalutara district has reaped his first paddy crop.

2. The results are:—(*a*) For four bushels of paddy sowed broadcast, but cultivated with the improved plough and using 2½ cwt. bone dust manure, 99 bushels of crop, which is within a fraction of 25-fold. I had the land surveyed and it came to 2 acres, 1 rood 23 poles. The *yield per acre* was thus about 41½ *bushel an acre*.

(*b*) On an exactly similar extent of land immediately adjoining this, sowed, manured and cultivated in exactly the same way, *but without the improved plough*, four bushels of paddy produced 60 bushels, or 15-fold, the *yield per acre being* 25 *bushels* and a small fraction. The use of the improved plough, therefore, made a difference of rather over 16 bushels an acre crop.

(*c*) A very small piece of land was planted out with ¾ of a seer after using the improved plough, and the yield was 4 bushels and 8 seers crop, or 204-fold, but this is not of much value as an experiment per acre, the quantity sown being so small. This could not be avoided as there was too much water at the time for planting out to enable a proper extent to be thus cultivated.—I am, sir, your obedient servant,

(Signed) H. W. GREEN, Director.

LEAF-CUTTING ANTS: REMEDY.

I have heard occasionally of cases in country districts where it has been impossible, or has been deemed impossible, to grow fruit-trees and vegetables owing to the depredations of the leaf-cutting ants, which, in a very short space of time, strip the plants of all their foliage. Mr. Belt in "The Naturalist in Nicaragua" relates how, in a district where the ants were very abundant, and where complaints where rife and gradens barren, he was enabled to grow, in spite of the ants, large quantities of fruits and vegetables that were particularly appreciated by them. On finding the ants in his garden beginning their work of destruction, he followed their track to their nest, and here he began his war against them. Making a mixture in the proportion of one pint of common brown carbolic acid to four bucktets of water, he poured this down

and over the nest in sufficient quantity to saturate it. The result was striking. The ants left the garden to protect their home, and for the next few months were occupied in other districts building a new nest. Again they returned, however, and following them to their nest, he treated them as before, and with a similar result. They attempted a migration to their former nest, but being checkmated in this direction, betook themselves to fresh fields and pastures new. By carefully watching the garden, so as to detect the first approach, and by warring against the insects with his mixture in their very home, he succeeded in keeping them at bay, and in reaping his harvest of fruit and vegetables.

He found also that crystals of Corrosive Sublimate (Bichloride of Mercury) had a most wonderful effect on the ants in the dry season. At such times, sprinkled in or across their track, it maddened the insects, which, rushing about, attacked their fellows and caused a war of extermination all along the line even to the very nest. Sprinkled in the openings of the nest, the crystals would naturally have a still more marked effect. Coal-tar was also effectively used to break the course of a track. Necessarily, constant attention is required, so that remedial steps should be taken *before* the mischief is done. *Le jeu vaut la chandelle.—Timehri.*

A PROFITABLE SUGAR-PALM.

The following passage from Wallace's "Tropical Nature" seems worthy of more than a passing notice—particularly at this time when every possible attempt is being made to lessen the cost of sugar production from the sugar cane, often by means of experiments entailing very considerable expense. It seems a good opportunity for some of our wealthy capitalists to at least begin experiments with this palm—although no immediate returns could be expected. The diminution of expense in the cultivation of the palm as against sugar cane, would be due not only to the saving in manure and in the cost of cultivation (as pointed out by Wallace), but also in the fact that elaborate and costly machinery would, to a great extent, be done away with:—

The sap which pours out of the cut flower-stalk of several species of palm when slightly fermented forms palm-wine or toddy, a very agreeable drink; and when mixed with various bitter herbs or roots which check fermentation, a fair imitation of beer is produced. If the same fluid is at once boiled and evaporated it produces a quantity of excellent sugar. The *Arenga Saccharifera*, or sugar-palm of the Malay countries, is perhaps the most productive of sugar. A single tree will continue to pour out several quarts of sap daily for weeks together, and where the trees are abundant this forms the chief drink and most esteemed luxury of the natives. A Dutch chemist, Mr. DeVry, who has studied the subject in Java, believes that great advantages would accure from the cultivation of this tree in place of the sugar-cane. According to his experiments it would produce an equal quantity of sugar of good quality with far less labour and expense, because no manure and no cultivation would be required, and the land will never be impoverished as it so rapidly becomes by the growth of sugar-cane. The reason of this difference is that the whole produce of a cane-field is taken off the ground, the crushed canes being burnt; and the soil thus becomes exhausted of the various salts and minerals which form part of the woody fibre and foliage. These must be restored by the application of manure, and this, together with the planting, weeding, and necessary cultivation, is very expensive. With the sugar-palm, however, nothing whatever is taken away but the juice itself; the foliage falls on the ground and rots, giving back to it what it had taken; and the water and sugar in the juice being almost wholly derived from the carbonic acid and aqueous vapour of the atmosphere, there is no impoverishment; and a plantation of these palms may be kept up on the same ground for an indefinite period. Another most important consideration is, that these trees will grow on poor rocky soil and on the steep slopes of ravines and hill sides where any ordinary cultivation is impossible, and a great extent of fertile land would thus be set free for other purposes. Yet further, the labour required for such sugar plantations as these would be of a light and intermittent kind, exactly suited to a semi-civilized people to whom severe and long-continued labour is never congenial. This combination of advantages appears to be so great, that it seems possible that the sugar of the world may in the future be produced from what would otherwise be almost waste ground; and it is to be hoped that the experiment will soon be tried in some of our tropical colonies, more especially as an Indian palm, *Phœnix sylvestris*, also produces abundance of sugar, and might be tried in its native country.—*Timehri.*

TO DESTROY THE TURNIP FLY.

To the Editor of the "Tropical Agriculturist."

December 8th, 1887.

SIR,—I have great pleasure in communicating to my brother cultivators through the medium of your valuable paper, that I, after perusing an article on the cultivation of turnips in one of the agricultural magazines, tried and found that gas lime sown upon turnips, before their coming up, is a sure preventive against the ravages of the fly. When gas lime cannot be obtained, gas tar reduced with common lime may be successfully applied between the lines carefully avoiding the plants. I discovered by my own experience that a mixture of one part of flour of sulphur with about one hundred parts of lime will also produce a beneficial effect.

J. A. GNO RODRIGO,
Agricultural Instructor.

POONACK WITH LIME AS MANURE FOR PADDY.

Bandaragama, December 9th, 1887.

SIR,—I should feel particularly obliged if any correspondent to your valuable journal, or you, Mr. Editor, can give me information as to the use of this substance mixed with lime as manure for paddy. I have a large quantity of poonac with me, and I make only a little use of it, but if information can be elicited to show how it can be applied and what other ingredients may be mixed with it to form a compost suitable for paddy, it will be of infinite service to many, who now like myself, make only a little use of it and pay vast sums of money for bone dust, &c.—I am, sir,

J. A. GNO RODRIGO.

[Poonac will no doubt be a good manure for paddy; but lime should never be mixed with fresh nitrogenous manure. The effect of lime on organic manures is to hasten decomposition, whereas the natural rate of decomposition is quite rapid enough for the wants of most cultivated plants.—ED.]

FRUIT IN SOUTH AFRICA.—The farmers of the Albany district are beginning to recognise the soundness of the advice given by some of the lecturers at the late Exhibition. The other day, consignments of Marie Louise pears from that district realised 15s. per 100 in the Kimberley market, while for a large variety of other fruit prices were obtained which would rejoice the hearts of the fruit growers of Europe, who pay five or ten times the price per acre for the land on which their orchards stand, and are otherwise taxed much more heavily than Cape cultivators. Ever since the opening of the line to Kimberley, oranges have netted prices to the growers far in excess of the rates realised in the London market, while lemons have been realising almost the price of hot house fruit, and the demand for pine-apples (the bulk of which are of very inferior quality) has only been limited by the supply.—*Cape Times.*

TEA IN FIJI.—Mr. Barratt, of the firm of Mackinnon & Barratt, Masusa Plantation, Wainunu, an experienced Indian tea planter, who has been engaged in the culture of the shrub for the last three years in Fiji, has written an able article in the *Fiji Times* recommending it as a suitable industry for men of moderate means. He declares that it will give returns in Fiji 25 per cent. better than any which have come under his notice during his Indian experience.—*Colonies and India.*

COCOA ADULTERATION.—Amsterdam, Nov. 23rd.—Our leading cocoa manufacturers have lately been pestered by invitations from a London firm of dealers in colours and chemicals to try a new cocoa adulterant. In their letter the firm in question say, "We hand you herewith sample of a finely levigated brown which we are supplying for the purpose of bringing up the colour of cocoa; it is perfectly harmless, and being of light gravity and rich colour is particularly well adapted for the purpose." The sample is a mineral brown, and upon analysis was found to consist simply of oxide of iron and a little alumina—certainly not very desirable ingredients in cocoa or chocolate.—*Chemist and Druggist.*

THE CHANGE FROM COFFEE TO TEA: ROTATION OF CROPS!—An experienced Manager writes of a recent trip he took through upland districts he had not seen for some time:—"Queer changes one sees now-a-days. —— was a fine coffee estate with no end of cinchona when I saw it last, less than three years ago, and now it is a grand sheet of tea with a most palatial-looking factory which contains everything complete for turning out the tippy stuff we are in duty bound to drink nowadays whether we like it or no. I counted exactly 13 coffee trees, and I saw a few scrubby looking shrubs which I was told were cinchonas. Who will say the *Tropical Agriculturist* does not cultivate the land in the most approved fashion by rotation of crops after this I should like to know. ——, ——, ——, ——, ——, are now all in tea and the nicest looking tea estates, in my opinion, in the four districts, but then I am probably prejudiced. The jât on —— is not quite so good as on the rest of them, but then the soil isn't so good either, and it is soil that very frequently makes or mars jât, but I have no fear but it will do well by and bye."

CHINA TEA EXPORTS AND PROSPECTS.—A correspondent, writing before our correction on the export comparisons, says:—"A mistake has been made in your China tea figures: the total shipments last year from China to England were 147 million pounds not 127, the latter had been shipped by this time, as the statement you published show, the decrease will therefore be 33½ millions and not 13½; it is now 31 millions and will be larger. In fact it will be nearer 40 than 30 millions probably. It is wonderful what nonsense people write, when they expatiate on subjects they do not understand. The Foochow merchants think the cultivator should produce tea for their benefit, not for his own. They nowhere propose to subscribe the capital to make the changes in cultivation they recommend. They say that India and Ceylon can lay down dust &c. at 2d per pound, whilst they admit that the cost of tea is 6d, or it will be that in a year or two. as if dust and fannings were not a part of the whole yield. Planters sell dust &c. at 20 cents because half a loaf is better than no bread, and it is better to take 20 cents for dust than throw it away. Their suggestions based on absurd ideas of the life of the plant might have been put forward by children. They should offer to make good the loss of revenue to the Chinese Government, if it does away with the lekin and export duties—and then their recommendations will be attended to."

TEA EXPERTS AND TEA GARDEN MANAGEMENT.—Reading over Mr. Armstrong's paper in its reprinted pamphlet form, we feel that our friend "Peppercorn" (page 459) (though no doubt "kinder sarkastic") was unduly severe in his criticism. Sentences detached from their connection no doubt may afford puzzles, but the paper read consecutively cannot fail to be followed, at least by those for whom it was specially intended, tea planters (not excepting "Peppercorn") acquainted with the technical language necessarily used.—A more serious matter in connection with Mr. Armstrong's paper is the evidence he affords of the special necessity for careful supervision of the work done in the tea fields, in "plucking" especially, as well as in the factory. Is it not clear that there will be a wide cry for additional help when all the tea now growing is being fully cropped, and is there a sufficiency of suitable factory or field assistants now in training. Are Ceylonese parents with sturdy sons not afraid of work, looking forward, as they ought, to getting their sons into factories? We learn that Mr. Barber has been the means of training several factory assistants of the type we refer to, who have readily found employment. As regards field-work, the hardest-worked man we have heard of is a wellknown Kelani Valley proprietor who, unlike his neighbours, despises "breakfast in the bungalow," when "plucking" is fully on, keeping out rather all day to see after this important work, and breakfasting as in the busiest days of old with coffee, "in the field." May the shadow of this hard-working planter of the old school never grow less!

INDIGO TRADE IN SAN SALVADOR.—The quantity of indigo produced annually in San Salvador varies from 9,000 to 15,000 bales of 150 lb. each. Indigo seeds are sown broad-cast like wheat and oats, and ploughed in. Every seed germinates twice, and thus there are two annual crops. Prices fluctuate greatly and the natives are capricious in their demands and fancies. The crop, as prepared for market, is graded like cotton and wheat in the United States, and the numbers "6," "7," "8," and "9" on the bales define the class or grade to which the bale belongs. The last of the figures designates the best, and the first the lowest grade. The absolute cost of production is about two shillings and eightpence per lb. while in India the cost is stated to be about one shilling. In San Salvador the indigo is cut with *machetes*, instead of reapers. When cut, the indigo is soaked in vasts, "puddled," boiled, strained, and dried, and this is all done by the simplest means, and by manual labour. The natives convey the indigo to the market towns in packs on their backs. Samples are spread on mats, beside which the farmer sits awaiting customers, and these are attracted from many parts by the annually recurring indigo fairs of Salvador. These market periods in each city commonly last from eight to fifteen days. The particular saint of each of these indigo markets is specially invoked during the continuance of the sales, and thus the priests and churches share in the profits incidental to these gatherings of the people. The first great indigo fair of the year begins on August 30, at Santa Rosa, the next when the first closes, at Chalatenango, the next at Sesuntepeque, and then follow those, attended by vast numbers of people, at San Miguel, near the harbour of La Union, which begins on the 17th and lasts until the 25th of November. Formerly consumers of indigo in the United States bought and imported their supplies from India through Liverpool or London, but they now buy largely from San Salvador, and instead of four or five hundred bales, as in former years, it is expected that one-sixth of the whole crop of 1887 will be taken by New York and Boston, and by cotton-mill owners of the South. There is an export duty on indigo in Salvador amounting to about 14s. per bale.—*Chemist and Druggist.*

ON IRRIGATION.

To the Editor "Tropical Agriculturist."

I shall feel obliged if you, or some one of your correspondents would state why the subject of irrigation is so little attended to; and on what grounds some of the wealthy and intelligent cultivators of the soil abandon a practice which appears to me to produce the most plentiful crop upon a given part of the ground, and at the least possible expense with the least permanent injury to the soil? *

My little experience in this art enables me to say, that where paddy land is favourably situated, it will, by the effects of water, regardless of seasons, produce a sufficient crop which may cover all the expenses of the cultivator, and would leave a sufficient quantity for his consumption without impoverishing the soil from whence it came. This, with other concommitant advantages, shall be more particularly enumerated if occasion requires, but entertaining, as I do, an idea that the island Lanka is suffering an enormous loss by the subject not being more fully understood, I trust an apology for troubling you will be unnecessary.

J. A. JNO. RODRIGO.
Agricultural Instructor.

ON LEAVES AS A MANURE FOR PADDY.

Sir,—As the season for the cultivation of the yala harvest is approaching, I am desirous of calling the attention of your numerous readers and their friends who are preparing to cultivate their fields to the consideration of the leaves of the common Pila plant, *Indigofera purpurea* and Magulkarande, *Pongamia glabra* as a manure for paddy. The great facility that every cultivator has of obtaining them from his neighbouring gardens free of cost, warrants their trying a series of experiments in sowing their seeds and putting on the leaves before the fields are puddled by the buffaloes, as it is the custom among most of the native cultivators, or ploughed with the native or English ploughs. These leaves can be used as a substitute for bone and other manures which are costing ten or twelve times as much.

Experiments have been tried, but not extensively enough to warrant its being said how much is saved in expense, and what quantities per acre ought to be used to render the best returns.

It is to this point that I wish attention to be directed and as Sir Humphrey Davy in his *Elements of Agricultural Chemistry*, writes:—"Nothing is more wanting in agriculture than experiments in which all the circumstances are minutely and scientifically detailed." Would some of your readers or their friends assist this object, and sow a small portion in each of their fields of paddy with these leaves as manure, and report the result in your paper; that is, the quantity of other manure used, the respective cost for manuring an acre, the yield, and the quality of the ground experimentalized upon.

J. A. JNO. RODRIGO,
Agricultural Instructor.

THE GROUND-NUT TRADE OF INDIA.

Pondicherry lately enjoyed the advantages of a monopoly of the Indian export ground-nut trade, but from a comparatively insignificant beginning three or four years ago, Bombay has now divided, about equally, the bulk of the trade with the port of Pondicherry. The total number of lakhs of bags (164 lb. each) exported from India during each of the last three years in round numbers was as follows:—

	1885.	1886.	1887.
From British Indian Ports...	4 6-10th	6 7-10th	7 6-10th
,, Pondicherry... ...	7½	9¼	6¾

It will be seen from these figures that while the shipments from British India (chiefly Bombay), between the years 1885 and 1887, increased by 66 2-8th per cent., those from Pondicherry fell nearly 48¾ per cent. The crop in Southern India for the current year has been a bad one, but at the same time it is said to have been below the average in the sister Presidency, so that the vagaries attributed to the season have had little to do with the rise and fall in the quantities of kernels exported from the two rival ports. Taking the actual number of bags shipped during the three completed quarters of the present year, and assuming the ratio of increase for the remaining three months to be at the same rate, the total for Bombay will approximate to half-a-million of bags for the twelve months, and it is estimated that this quantity will be doubled for the season of 1888. Already Marseilles merchants are discussing the situation in regard to next year's prices, and the opening market rate is expected to rule unprecedently low. So far, the crop prospects for earth-nuts are unusually good in both Presidencies, and the amount available for export from the whole of India is likely to reach two millions of bags. The sudden development—approximating to a rise of about 100 per cent. in two years,—of this trade must materially affect both buyers and sellers. The Bombay kernel is greatly superior to that usually produced in South Arcot, and it is, as a rule shipped in much better condition. It also weighs more, and consequently occupies less space, and is more economically manipulated, while the facilities for shipping, the rates of freight, are all in favour of the Western port; and there is a much more direct relation with between the exporter and the cultivator than exists generally in this part of India. Unlike cereals, or at least food grains, the demand for earth-nuts is confined within rather narrow limits, and it remains to be seen whether manufacturers will pay a price for comparatively surplus stocks that will yield a margin sufficient for the producer to work upon. The tillage of the nut costs very little, and land well nigh useless for other crops can be utilised for its growth. In ordinary favourable seasons the cultivator has but to sow the seed and reap the harvest.—*Madras Mail*, Dec. 5.

* We suppose, that, as a matter of fact, fields are occasionally left fallow to provide pasturage for cattle, their droppings preparing the land for future cultivation. Unless ground is manured or fallowed, we fancy irrigation will not prevent exhaustion after a time.—ED.

PROCEEDINGS OF THE AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA FOR NOVEMBER 1887.

Lemons at High Elevations.—Mr. Angus Campbell, writing from Mussoorie, referred to a statement of Dr. Bonavia's, that "Orange and Lemon trees can be successfully grown wherever tea and coffee can be grown." Mr. Campbell remarks as follows:—"In the Doon, at 2,000 feet elevation, tea grows well, but coffee does not, as the frost destroys the trees, but lemons and oranges grow well; here, at 6,500 feet Tea grows well, and I have seen it growing at higher elevations, but I cannot find that lemons or oranges grow here, though limes grow in the valleys at about 1,000 feet below this. I have heard that some 500 feet below this, lemons have been planted, but the growth is slow, and the bushes have not fruited yet. I have some young lime trees that I intend to plant out next spring, but I am afraid that they will not prosper. Do you know of any of this family of trees being grown so high upon the Himalayas? According to the Flora of British India, Vol. I, pages 514-515, Citrus medica *Linn.* ascends to 4,000 feet, and C. Hystrix *D. C.* to 5,000 feet. Mr. Campbell's remarks will, however, it is hoped, lead other members to record their experiences of growing any of the Citrus group at high elevations.

Erythroxylon Coca.—The following further letters have been received on this subject with samples of leaf:—

From Messrs. Cresswell & Co. we have received the following report regarding the Cocaine from Mr. W. S. Cresswell in reply to the questions the Society desired answered:—

1. District, Dooars.
2. Elevation, 2,200, rainfall 180 to 200 inches.
3. Soil, virgin forest, chocolate colored leaf mould.

4. Plants received from the Agri-Horticultural Society's gardens this year, planted out in the month of February, in all 152 plants, out of these 9 died. They were planted out 4 ft. × 4 ft.

5. Leaf was collected this month (October) also seed; did not like to collect leaf before until the plants were well set in the new soil; piece of land planted 33 ft. × 58 ft. No very particular care taken with them; average height of plants 3 ft. They look very healthy and are again shooting out leaf and flowering.

6. The leaf, after being collected, was dried in an airy room.

7. Weight of dry leaf 3 lb. Owing to my absence, the green leaf unfortunately was not weighed.

I can see it is a mistake to plant so far apart, 18 inches distant would be ample.

As regards the yield, I will take care next time that the green leaf be weighed, and next year will let you know how many pluckings we can get off the present number of plants. The seed has been picked off the bushes and will be put into a nursery to supply vacancies, and to fill up the existing plot of ground planted; on Monday or Tuesday, the leaf will be packed in a tea-lead case and forwarded to Calcutta.

From G. T Peppe, Esq., Ranchi.

Answers to Questions.

1. District, Lohardugga, Chota Nagpore.
2. Elevation, 2,200 feet.
3. Very ordinary loam with much iron in it, of a light chocolate colour.
4. The plants are now two years old from time of sowing seed, which was got from Paris: sown in boxes in December and planted out in June two feet apart, half was watered in dry season which was a particularly dry one, but the half that was not watered seemed to do just as well; they were shaded with basket shading. Out of 200 plants I lost 30 in two years.
5. Leaves collected in November.
6. Dried as described in letter sending them.
7. Yield, only a few were taken off; more can be sent if desired.
8. The plants now are very vigorous and seed constantly for the last four months. I find they take readily as cuttings even in the open; white ants do not seem inclined to injure it; the roots do not seem to go deeper than one foot. It does not do well under dense shade of trees. They have been once manured with cow dung.

I shall be glad to hear what percentage of alkaloid the leaves give that I sent, and if you would care for more leaves as the plant gets stronger. I showed the plants to Mr. Finucane when here, and he seemed to think them very promising.

PADDY CULTIVATION AND MANURING: CATTLE DUNG AND BONES.

So much has been discussed of late about paddy cultivation, yet there were no conclusions made on manuring, which is considered to be indispensable in the cultivation of soils, and especially when a land is taxed of the same materials over and over again. Thus in our paddy fields season after season and year after year we see the same thing grown. In most cases the goyas never use manure; therefore a system of manuring will be a useful addition to the improvements in the cultivation of paddy. Manuring is not very easy; the manures should be adopted according to the character of soils. There is another thing to look for in manuring paddy lands. Paddy lands are made lower than the surroundings to catch water, and, if the depth is lessened by degrees, the land will suffer. Thus manures which are bulkly, will in time, shallow the depths of the beds, thereby will not enable it to hold a sufficient quantity of water for the use of paddy plants. This is the case with cattle manure. In the category of manures, cattle manure comes to be the foremost, as it is suitable for all soils, but there is no proper treatment of that manure in Ceylon. In almost all countries and ages cattle stand first in the cultivation of soils, not only on account of their manure, but also in being useful in tillage operations. Cattle in Ceylon are miserable, and they can be improved if they are treated as they ought to be. This improvement can be done without the expense of importing foreign cattle. Some of our native cattle are very good and well formed; but the want of care and proper management has degenerated them. The Ceylon goya does not understand what a fodder crop is; he has never gown a fodder crop for his cattle. If the cattle be kept properly and the manure collected carefully, what a host of benefits would be done. Though cattle manure is beneficial for all descriptions of soils, it is invaluable for sandy soils, as your Siyane Korale correspondent justly remarks, a patch of paddy plants in a sandy soil is an eyesore indeed; no bone manure nor any other fertilizer can improve it, because it is a hungry soil. But *well rotten* cattle dung if applied in quantities can change its aspect to a great extent. Cattle dung, though a good manure for any soils, is known to give out its fertility sooner than any other manure, more so to because it contains a lot of nitrogenous or leaf-forming materials; where this manure is applied to a paddy field, the plants begin to grow luxuriantly at first, but in a few months' time the growth is stopped. It stops for two reasons: first, as the leaf formation goes on only during the first few months, and second, as the manure does not last long. Cattle dung, however, is known to be good for those varieties, which take only three or four months to produce. As a manure for paddy, *bone dust* comes next to cattle manure. Some goyas consider that the rice obtained by using bone dust is inferior in quality. This may be quite true, as in most cases when the quantity gets higher, the quality goes down. Bones have none or little power to luxuriate leaves; its action is direct on the ears. The pollen of a flower consists mostly of phosphoric acid, and to fertilize and get a good crop we require that material. In Ceylon it is only supplied in sufficient quantities, in the form of bone or animal refuse. As the abovementioned two kinds of manure viz., catttle dung and bones perform more or less two different functions; one the formation of leaves, the other that of ears; it is always advisable to have a mixture of these two for our paddy lands. But some may object to this mixture as bones contain lime, and that lime, when mixed with cattle manure, volatilize a great portion of the nitrogenous matter. In this case also, the action will be formed, but not to a great extent to be of any consequence, as the lime in the bones are not very free.

W. A. D. S.

Minuwangoda, 6th Dec. 1887.

[We referred the above to an experienced European agriculturist, of long residence in the low-country of Ceylon, who writes:—"I have read the letter you sent me with much interest, as it is quite a new thing for a native to have attained even so much theory as to write about nitrates and phosphates. He may keep his mind quite easy about raising the level of his fields with cattle manure. I will warrant him against ever accumulating enough to raise the level the tenth of an inch. He is wrong, too, about cattle manure lasting only two or three months, it continues to develope plant food till completely decomposed. This will take place quicker in this climate than in Europe, but it has been known to last twenty years before being utterly exhausted. I know no reason why bone dust should deteriorate the quality of a paddy crop, nor do I admit that a large crop is necessarily of inferior quality to a small one. Lime has no injurious effect on nitrogenous manures when in combination with phosphoric acid."]

CONSULS' REPORTS.

AFRICA (EAST-CENTRAL).

The first report of our consul at Zomba, East-Central Africa, contains particulars of the trade of the Ayassa territories, which form a very imperfectly defined district. As yet both the export and the im-

port trade are insignificant; the latter, in fact, "does not amount to the ordinary business of one company." As to the former, the consul thinks that there may be room for competition, for, if lower retail prices were established and goods made regularly obtainable, settlers who now import supplies for their own requirements would then, in all probability, purchase on the spot; and if, in addition, the tastes and wants of natives were sufficiently considered, a portion of the ivory which now finds its way to the coast, either through the hands of Arabs or by direct exportation on the part of the chiefs, would undoubtedly be sold in the established local European markets.

Oil Seeds.—Oil seeds grow freely in the lowlands of the Makololo country, and, if freights were sufficiently low and the communication on the River Shiré better organised, this export would doubtless become a paying one. So far the possibilities of opening up this industry do not appear to have received full attention.

Indiarubber.—Under proper treatment, indiarubber also might become a profitable export. It is now found in very small quantities only, and indeed can scarcely be considered worthy of mention. This is, undoubtedly, owing to the destructive method the natives have of extracting the juice. At Mount Zomba, the *Landolphia Florida* species were found in plentiful quantities, but now the plant is almost exterminated. Rubber of this species sold in Africa last year for 1*s.* 6*d.* per lb. The cultivation of rubber by Europeans now appears to attract attention. A *Ficus elasticus* plant is growing most successfully in a private garden, and the owner tells me he proposes to propagate extensively from it.

Indigo.—Indigo grows wild all along the slopes of Mount Zomba. It forms a large bush, and is perennial; its growth is luxuriant, and its cultivation and manufacture might possibly be undertaken with advantage.

Cinchona.—Cinchona has been introduced, and there is every prospect that its cultivation will be a success, plants three years old being now 6 feet high. It remains to be seen whether the quality of the bark will justify the planter's investment of capital, and whether the state of the market will offer encouragement. A small plantation of 1,000 plants has been formed this season at Zomba.

Strophanthus.—Strophanthus (native name, *Kombe*) is a climbing plant, from the seeds or fruit of which a strong poison is extracted. It has attracted notice in England through the experiments of Professor Fraser, to whom the plant was introduced by Mr. J. Buchanan, of Zomba. During the last year over 1,100 lb. exported from these districts, realised in the London market 9*s* per lb.

The consul gives the following notes which he has obtained from Mr. Buchanan in reference to this plant:—"Strophanthus is considered the most powerful poison the natives possess. It is found at a low level, and, as far as I can gather from personal observation and native sources, is not to be had on the high land. The supplies hitherto obtained have been drawn from the right bank of the River Shiré, below the Murchison Rapids. There is, apparently, more than one species, or, at least, variety; the distinguishing feature being a much smaller pod and fewer seeds. At present information relative to these other varieties is scant. The strophanthus is a strong climbing plant, and is always found in the vicinity of high trees, on which it supports itself. The stem varies in diameter, but has an average of a few inches. It lies on the ground in folds, the branches supporting themselves on the nearest trees. The young branches have a rod-like habit, and are in appearance not unlike elder. The fruit grows in pairs, and has a peculiar appearance, very like a pair of immense horns hanging to a slender twig. The fruit begins to ripen in July, and lasts till the end of September. Judging from the few plants I have reared here, it would appear to be a strong growing plant. The natives are quite ignorant of its age, or how old a plant may be before it bears fruit. The native method of preparing the poison is very simple. They first clean the seeds of their hairy appendages, and then pound them in a mortar until they have reduced them to a pulp. A little water is then added. To the pulp is added the bark of a tree containing a gummy substance, which helps to keep the poison on the arrow, in event of its striking against a bone. The poison thus prepared is spread upon the arrow and allowed to dry; game wounded by arrows poisoned with strophanthus die quickly. The flesh is eaten without evil effect. The only precaution taken is to squeeze the juice of the baobab bark on the wound made by the arrow, and this counteracts the evil effect of the poison. Buffalo and all smaller game are killed by this posion."—*Chemist and Druggist.*

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

PARIS, November 30, 1887.

France is not only sincerely bent on making the two blades of grass grow where only one grew before, but of doubling the yield of corn per acre as the best means of competing with foreign cereals. In the latter aim, three plans are open to agriculturists, viz., the application of chemical fertilisers, the judicious preparation of the soil, and the selection of good seed. It is impossible that farmers can keep their eyes closed to the efficacy of mineral manures in augmenting the yield of wheat. The tests are within their reach: they can visit the practical success of these complimentary agents on well-known farms or at certain agricultural stations. By indulging in an essay themselves, they will help much to precise the influences of soil, climate, seed, and culture in the relative yields obtained, and thus permit of fixing the conditions for a wider surface of success.

Marked interest continues to be taken in the employment of dephosphorized scoriæ and insoluble phosphates as compared with superphosphates. The second is one-half less dear than the third in point of insoluble phosphoric acid, the fertilising body therein. A matter not to be overlooked is the importance of adding to the soil on which the experiments are to be made with a special manure a sufficient quantity of other fertilizing substances, in case the land does not contain them in the requisite proportions for producing good crops. Scoriæ, it should be remembered, are the product of steel preparation subjected to the action of a very elevated temperature. A natural phosphate found at Ardennes has been subjected to an elevated temperature. Like the Scoriæ or clinker, it also proved that phosphates so calcined are more assimilable by plants. In the case of oats the difference was as much as 25 per cent. The heat, both in the case of the clinker and the mineral or rock-phosphate, has modified favourably the phosphate they contain. As the plant can only feed itself by the direct action of its roots on the particles of earth they immediately touch, the more the manure will be disseminated the greater are the chances of the rootlets reaching it. Theoretically, then a fertilizer in a state of impalpable powder ought to be preferred to that in grains more or less coarse. But in practice the economical view must be remembered, because if in reducing a manure to a state of dust, the price is tripled by the process the farmer will fall back on the coarser substances.

And this is virtually what he does. In the case of the Scoriæ even when in small bits, they in due time, crumble into powder easily and spontaneously. The lime, the iron, and the manganese they contain by absorbing water and re-oxydising, separate, and ultimately become dust. The Gilchrist clinkers [illegible] disintegrate and produce all their effects even [illegible] first year. At Armainvilliers, near Paris, the co[illegible] screened Scoria have been spread on stable manure at the rate of 156 lb. per cubic yard: this [illegible] enriches the manure heap in phosphoric [illegible] fixes the odors of decomposition even when [illegible] are dosed with it. Nothing can be better for a [illegible] to the liquid manure tank, and contrary to what

might be expected analysis has shown there is no loss of nitrogen.

In Spain it is related that when cherries are served on the tables of the rich, if the fruit be small, magnifying spectacles are also supplied; the illusion secures pleasure just as a wig deceives none but the wearer. It is something of the same principle which actuates some farmers, who to impart volume to the udder of a cow when going to be sold, allow the milk to accumulate for twelve or more hours: occasionally the teats are scourged with nettles or rubbed with red pepper, to produce an inflated appearance. In French Switzerland these tricks of trade will soon cease, as at the entrance to every market and fair, a cattle inspector examines the milch-cows: if doctored, they will be excluded from the sale ground.

A curious experiment in connection with the rearing of calves has just taken place at Rötha, in Saxony, with two lots of calves of the Dutch and Friesland breeds, and that were immediately separated from their mothers after birth. The calves were unable to support at this stage of their existence, sour or acid milk, so they were kept on sweet milk for a fortnight, then given only creamed milk, but not sour. Ten other calves after the fortnight received the creamed milk, but soured and thrive much better, in the sense of putting up more uniformly their 1½ to 2 lb. of flesh daily on 12 quarts of such milk, whereas the unacid milk fed calves, required 15 quarts. It would be desirable to test the matter more fully; a difference of six sous per day, when the milk sells at two sous the quart, is an economy not to be despised.

In Germany, farmers are coming round to the cheaper practice of supplying their land with nitrogen by means of rationing their stock on concentrated aliments, and thus having a richer farm-yard manure rather than purchase direct fertilizers. M. Stutzer asserts it is not possible to obtain nitrogen cheaper than by employing ground nut, lin, and cotton seed cake, &c., which contain seven per cent of nitrogen, and that will be found in the solid and liquid excrements of fat stock to 65, and for milch-cows eighty per cent. If the manure be well cured and dosed with the fashionable scoriæ, a substantial economy will be felt. The farmers' Syndicate of Hesse follow no other plan now.

Some experiments undertaken in Germany are not at all favourable in any marked manner to the preservation of green-soiling-vetches, &c. in stacks, and tightly roping or chaining down, as the agent of pressure. The stacked forage was found on analysis not to be so rich in all round nutritive matters. Perhaps were the experiments conducted in autumn instead of summer, the loss in richness would be comparatively less. One important fact is that freshly cut forage can be preserved in the stack form if well weighted down as well as in the silo—the end in both cases is the same—exclude the air. Also the stuff can be heaped in wet weather with perfect safety.

STICK-FAST FOR FLIES.—We find the following paragraph credited to the *Fruit Growers' Journal*:—"Mix together equal parts by measure of melted rosin and castor oil. Stir until thoroughly mixed—which will take only a minute, while yet a little warm spread thin and evenly on any strong paper that is not porous. We use foolscap, writing papers, catalogue covers, showbills. Spread with a case-knife or any straight-edged instrument slightly warmed. Leave a narrow border to handle with. Lay the papers on tables, shelves, or any spare places where flies are numerous. They will soon cover the papers. As soon as they alight they will stick fast and soon pull themselves down. When the papers are covered two or three flies deep, put in the stove and replace with another one. Be sure to use no water. The oil prevents the rosin from hardening, and has the peculiarity of not evaporating. The oil leaves no odour when cool. Ten cents will buy enough material for all the flies in the house."

A NEW BRANCH OF THE DRUG TRADE.—The celebrated firm of Dr. Theodor Schuchardt in Görlitz is about to extend the sphere of its activity by undertaking the delivery of all the most modern medicinal plants. For this purpose a connection has been established with all the most famous foreign firms, and in Dr. Schuchardt's next list a variety of new drugs from Ceylon, Queensland, Guiana, West Africa, etc., will appear. The aim of the firm is threefold: the obtaining of materials for the discovery of new alkaloids, glycosides, etc., the subsequent introduction of the same into the *materia medica*, and the perfecting of our national botanical and pharmacologial museums and collections. There is no doubt that Dr. Schuchardt's new enterprise will receive energetic support from all who are interested in the drug trade.—*Kuhlow's German Trade Review.*

CEYLON TEAS IN LONDON AND THE PROSPECT OF AMERICAN CONSUMPTION.—We have been permitted to make the following extracts from the letter of a London correspondent well up in "tea" to a Ceylon planter: the date however of the letter was in the first half of November, but the interest is not lost we think:—

It will not pay to ship to Australia so long as London rates are so high for low grades as they are now. The movement of prices must be puzzling to you, as it is to us; quite common tea which in the summer was selling between 5d and 9d. is now worth from 9d to 1s. This is due to the small import, and the demand "for price," the bulk of the tea now sold retail in England being between 1s 9d and 2s 3d. duty paid. On this the grocer requires to make 4d or 5d., sometimes more; the "blender" or wholesale dealer also wants 1½d, 2d. The consequence is a range of price quite inconsistent with intrinsic value: for while common tea has gone up, fine has come down. This only holds good when supplies are short. Indian tea, for example, which is very abundant and good all round this year, shows a very low price for low and medium qualities, while finest still fetch a good price. The average of the Indian sales in Calcutta for two or three months past has been little over the equivalent of 10d or 10½d. in London, and you would open your eyes to see the good Pekoe Souchong selling at 7½d. and Pekoes at 10d and then look at Ceylon tea at 1s. and 1s 1d. The moral of course is—that producers must not be carried away by present prices, but must prepare for a much lower scale in a year or two, unless China is shut up. Do impress upon everyone that fine quality, not large crops, is what is required to keep the prestige of Ceylon tea. Of course those who make the heaviest yield regardless of quality have the laugh on their side *now*, but it is only once in a decade that common tea runs up to the price it is now.—Latterly we have been getting some remarkably good teas from various gardens, especially small ones; a feature is their excellent firing and condition, turning out here with an aroma on the leaf which can be smelt a yard off—among them, Poengalla, Sogama, Tunisgalla, Kelliewatte, Elkadua, Carolina Factory, Oonoonagalla and Gallaheria, Elbedde (this must be a good garden), Rookwood (making choice tea again), and each one maintaining month after month its distinctive peculiarity, or individuality, so that the habitual taster can spot almost at a glance where the tea comes from. This is one of the curious and interesting features about Ceylon and Indian teas, their wonderful variety, and power of reproducing same characteristics, and we attribute to this more than anything else the rapid displacement of China tea by Ceylon and Indian. You produce teas to suit all tastes, all waters and all markets. Oh, if we could only tickle the palates of the Yankees and Canadians—then, tea planters would have a high time, but despite continuous efforts from this side, (numbers of the large dealers have travellers and agents pushing the tea in the States) we cannot overcome the prejudice of the American storekeeper, though they own to netting a large profit on the Indian teas they buy here.

Correspondence.

To the Editor of the "Ceylon Observer."

TRANSPORT OF TEA LEAF.

DEAR SIR,—Can you or any of your correspondents inform me what is the greatest length of time that green tea leaf can be transported in baskets (containing from 50 to 60 lb.) without the leaf deteriorating? ENQUIRER.

[It depends very much on the weather and district, we believe: in comparatively dry Uva, the distance and time would necessarily be less than in Ambagamuwa or the Peak districts; but perhaps some of our planting readers will give their exact experience.—ED.]

FRUIT CULTURE IN CEYLON.

DEAR SIR,—I have been reading a recent Kew Bulletin on Tropical Fruit Culture and a despatch from the Colonial Office calling for reports on the subject. Could you not make public the reply elicited from this colony? Considering that portions of our great Empire are scattered over the face of our planet, there is no doubt that Morris's initiative in this matter is both practical and far-seeing. At any period of the year fruit of all kinds should be procurable in our wealthy European cities. Trade is so conservative and so apt to run in the same grooves that persistent action is required to accomplish any improvement. The fruit trade could be developed in Ceylon, but it will always be a small auxiliary.

To begin with, we want better varieties of oranges &c. than we now have for our own consumption, and the nursery is not yet made at either Peradeniya, Henaratgoda, or Hakgala.

OLD PLANTER.

ERYTHROXYLON COCA AND ITS CULTIVATION IN CEYLON.

DEAR SIR.—In answer to your correspondent, I have been growing coca for some years, chiefly for the seed, and am now extending the cultivation in view of leaf harvest which promises to be most remunerative.

Germination commences on the tree, as may be ascertained by dissection of the fruit, of which I send a few under another cover. Seeds should therefore be sown while quite fresh, on the surface of good loam and shaded from the sun. After this no special cultivation is required. The plants can be put out like tea, three to four feet apart, in good land and sheltered, which, in common with most other products with which I am acquainted, they prefer to poor soil and exposed ridges.

Markham, in his cinchona book, chap. xv, tells us that the average yield of leaf in Peru was 800 lb. per acre, and that the profit from a coca farm was 45 per cent. This seems too good to be true; but I do not think he exaggerates the yield, and, even at 9d per lb., present prices of leaf in London averaging 1s 3d, the profit should be considerable. Machinery is not required, and, as far as I can judge at present, the trees may be allowed to run at their "own sweet will," leaves being taken off as fast as they arrive at maturity.

Fruit-bearing commences at eighteen months, and, when seed is no longer required, can of course be checked and the energies of the plant directed to producing leaf.

To return to Markham, he tells us also that Joseph de Jussieu, a confrere of La Condamine, and in whose honour the shrubby variety of C. calisaya was named C. josephiana, spent fifteen years in Peru making a large collection of coca plants, of which he was robbed by a servant. This had such an effect upon the savant that he returned to France bereft of reason. This was in 1771. You may give my name to your correspondent, to whom I shall be willing to give any other information which it is in my power to supply.—Yours &c.,

W. C. W.

JAFFNA YAMS IN THE UNITED STATES.

Chunnakam, Jaffna, Oct. 17th, 1887.

SIR,—Five years ago when I studied Hughes' Physical Geography in Jaffna College, I came to understand that plants originally confined to one hemisphere could grow equally well in the other under favourable conditions of soil and climate. At that time a thought of sending our Jaffna yams to other parts of the world entered into my head. I waited for an opportunity of doing so. When I became acquainted with an American friend (living in Georgia) by letter-communication I mentioned these yams to him. He was anxious of having them, so last February I sent to him some yams in each of the following varieties:—

1. Rasavally —Royal yam.
2. Ratthavally —Blood yam.
3. Karany —Medical yam.
4. Mullan —Rice yam.
5. Vally kelangoo—Garden yam.
6. Oolakky vally—Pounder yam.
7. Battaly —Sweet yam.

My friend says that the yams grow well there. I enclose herewith that part of his letter which gives an account of the yams, and the post-card which he sent some time after writing the letter. I have no doubt that you will like to read them since you give much attention to this department also.

I was induced to write this thinking that it will do some good to the public.—I beg to remain, sir, your obedient servant, ISAAC PAUL.

(Letter from America referred to).

The yams have reached me at last They came this morning, and I write at once to let you know of their arrival, and to tell you what great curiosities they are to us all. Some of them are immense, and it is hard to realize that a plant, related to our potato, can grow to such a size. The yams have all sprouted, and a sprout from one of the largest grow, through one of the holes in the box, to a height of about five feet or more. All the clerks at the freight depot here were anxious to know what kind of a plant that box contained and you can imagine how astonished they were when I told them it was a box of yams. I have shown them to a number of friends today and they were all glad and astonishd to see them. Some of the yams, I am afraid, will not grow, as they have been packed so long, but the greater part of them seem to be in a tolerably good condition, and I think they will grow nicely. I will plant some at my home, and I have promised to send some to friends of mine. I do hope we will succeed in raising them. One friend, to whom I have promised some of the yams, has a very fine garden and is quite a successful fruit grower. He lives in South-Western Georgia, about 70 miles from here. I was at his home some days ago, told him about these yams, and promised to send him some as soon as they arrived. I think the soil there is well adapted to them, and am sure he will do the best he can towards cultivating them.

Chunnakam, Jaffna, Oct. 18th, 1887.

After mailing the letter, I received another post card from my American friend. He says the yams grow finely. The tree yam is a great curiosity. [illegible] is the karany yam which I call in the letter as the 'medical yam.' Sometimes this grows to the size of a pumpkin.

I did not write you in the letter the way of cultivating and taking care of these yams, thinking that you are acquainted with it

Aug. Oct. 7th

436 Washington Avenue, Macon, Georgia, U.S.A.,
Aug. 24th, 1887.

My dear friend,—I thought I would write you a few lines this morning to tell you about the yams. I am astonished to see how well they are growing. They are all alive except one very small one. The vine from the largest yam has grown about three feet in the last four days, and everybody is astonished to see it.

You say that No. 5 has fruit on the *vine* as well as in the ground. When you write next please be sure to tell me if the fruit that grows *on the vine* is used *for food*. Please tell me also if *all these different varieties* of potatoes that you sent are used *for food*.

CEYLON TEA AT THE MELBOURNE EXHIBITION.

Yandrit, Victoria, Australia, 16th Nov. 1887.

SIR,—Kindly allow me space in your valuable paper to give the Ceylon tea planters a hint *re* the Melbourne Exhibition. I take it for granted that they purpose being represented and would suggest that if possible their accredited representative bring a native or Tamil to serve at the tea stall, a tidy smart boy.

I may mention that I received a box of your tea, and as "the proof of the tea is the drinking of it," I frankly confess that at first I did not like the flavour, to me it tasted as if sweetened with brown or ration sugar. But before I had finished the cup I pronounced it *the best* tea that ever, I had tasted in my life. It seemed to have a body in it, and one felt that it was doing one good, just such a difference as one feels when partaking of a good glass of port wine beside the logwood rubbish that is often sold for port.

I gave away several pounds of the tea, and all my friends soon came to like it and eagerly asked for more. Your tea is very different from what is sold here as Indian tea by the Calcutta Syndicate, and my advice to your agent is bring a good supply of *good* tea and you will soon find a market. Let the agent employ a reliable person to distribute samples in such places in Melbourne, as the police stations, the soldiers' barracks, and so forth, and best of all through the bush in the rural districts and townships, *not at the stores*, but amongst the people at their homes.

I may be wrong, but I think, the time is not far distant when you will be receiving large supplies of our butter (which we are now selling at 6d per lb.) and cheese, and in return we can take supplies of tea, cocoa, fibre and other products of your lovely island.

I shall only add that I feel so confident of your ultimate success that I will gladly render any assistance in my power to your representative, and should you require an agent in Melbourne, I could not name a better than the Hon. James Balfour, if he would undertake it.

I enclose my name and address for references if required.—Yours, &c.

A LOVER OF CEYLON TEA.

CINCHONA AND QUININE.

London, 30th November 1887.

DEAR SIR,—I wrote you last on this subject on 26th October. I told you then I thought the cinchona had touched bottom, but I hardly expected the market would so soon take a turn for the better.

The auction of bark held on 22nd instant, showed an advance of nearly 20 per cent from the lowest point touched. The next auctions will be on 6th proximo, the advance will bring out a larger quantity of South American, which has been held for some time, also some 3,000 bales Java—good. I hope it will be all sold, the quicker the present stocks get taken off the market the better for Ceylon. Quinine has made a considerable advance also. On 27th October German was offered out of second hands at 1s 3½d. No buyers. Last week 130,000 oz. changed hands at 1s 4d to 1s 6d, while yesterday and today a large business has been done at 1s 7d to 1s 9d. Market strong.

The sole cause of this rise has been the falling-off of exports from Ceylon,—nothing else. Ceylon has the regulating of the price of bark in her own hands; and I trust therefore the holders of bark will keep back their supplies; by doing this they will be amply rewarded in the future. The market is a very sensitive one, and if shippers press forward shipments, we will relapse into former low rates.

Those interested need not fear Java or Indian exports. They no more affect the market, than Ceylon coffee does the coffee market.

The "boom" is sure to come if planters will only keep back supplies. This cannot be impressed too strongly on them.—Yours truly,

E. T. DELMEGE.

Since writing above, market closes firm at 1s 10d for German quinine.

CUBEBS.—At the drug sales this month some excellent samples of genuine cubebs were on show, accompained by others of a pale colour, not unlike that of "yellow berries," and which evidently consisted of the unripe fruit. Both the ripe and the unripe berries gave the beautiful carmine rose colour with concentrated sulphuric acid, characteristic of the genuine drug, but the unripe ones, when bruised and boiled in water, did not give the deep blue coloration with tincture of iodine, although it was readily obtained with the ripe berries. The unripe berries possessed, however, a considerable amount of aroma, and would doubtless yield essential oil on distillation. It would be interesting to know whether this absence of colour on the addition of iodine to the decoction of the unripe fruit is due to the presence of a compound analogous to glycosuccinic acid, which according to Messrs. Brunner and Chuard (*Pharm. Journ.*, [3], xvi., 917) occurs in unripe fruits, and forms with iodine a soluble and colourless compound.—*Pharmaceutical Journal.*

PATCHOULI LEAVES.—Mr. J. R. Jackson, the Curator of the Kew Museum, remarks (*Gard. Chron.*, Nov. 19, p. 617) concerning a sample of patchouli leaves lately received from Penang, as the result of an experimental trial in cultivating and harvesting the plant, that one sample consisted of the leaves of *Urena lobata*, var. *sinuata*, which it seems is largely used to adulterate patchouli for the market. Mr. Jackson also points out that *Pogostemon suavis*, Tenore (*Kew Journ. Bot.*, 1847, p. 328, t. 11, excl. syn.), and *Plectranthus Patchouli*, Clarke ('Flora of British India,' p. 624), have the same odour. Selected leaves were reported by a firm of manufacturing chemists to be worth £80 to £100 per ton, and the demand for the leaves and essential oil is being steady and continuous. The leaves of *Urena lobata* (of which there is a specimen in the Herbarium of the Pharmaceutical Society) bear a strong resemblance to the second form of adulteration of patchouli leaves, figured by Dr. Paschkis (*Pharm. Journ.*, [3], xi., p. 814, fig. 4), and agree with the latter in the presence of stellate hairs. Dr. Paschkis, however, does not mention the oval slit gland which is characteristic of the leaves of *Urena lobata*, and may be found near the base of the central nerve at the back of the leaf. In true patchouli the hairs of the leaves are all simple and four-celled.—*Pharmaceutical Journal.*

THE KINMOND-RICHARDSON TEA ROLLER.

The public trial of this machine was held at the Lebanon Group factory, Madulkele on the 3rd inst., the following gentlemen being present:—Messrs. Bewley, Cuff, Hastings, Clarke, W. G. Dickson, Clench, Ferguson, Joseph Fraser, Kynaston, Melville White, Patterson, Prance, Reid, Spencer Shelley, Smail, Tait, Throckmorton, Walker, T. C. Owen and T. Dickson, Manager.

At 1-30, the three rollers were charged as follows:—The "Excelsior" with 250 lb. wither, the Blackstone, No. 2, with 100 lb., and the Robey's with 364 lb. These figures represent the normal charge for each machine.

The three machines were started and worked simultaneously, each roller was run for a full hour and the charge then taken out and sifted.

The weights of these teas, from the roll sifter, in proportion to the charge are given below:—

The "Excelsior" out of 250 lb wither gave 24 lb Tea
" "Blackstone" do 100 do do 10 do
" "Robey's" do 364 do do 18 do

The balance of the roll was then returned to the respective rollers and re-rolled, and after firing in the "Victoria" and sifting in the "Eureka," the percentages of fine and coarse teas were as below:—

	Bro. Pek.	Pek.	Pek. Sou.	Sou.	
The "Excelsior"	26 p.c.	38 p.c.	24 p.c.	12 p.c.	=100
" "Robey's"	19 p.c.	43 p.c.	19 p.c.	19 p.c.	=100

The Barber's roll after fresh rolling was not kept separate, the machine being required to continue the day's work immediately. In considering the above percentages, it must be borne in mind that the Robey's machine had 46 per cent more work to do in the same time than the "Excelsior," for a consumption of 40 per cent less power.

PLANTING IN NETHERLANDS INDIA.

(*Translated for the Straits Times.*)

Sugar is not the only article in which Russia seeks to compete with planters in Java. They have suffered much from the quantities of Russian beet root sugar flooding the market. The Russian Government has made up its mind to try cinchona growing. Plantations of this valuable tree have been started near Tiflis. They have taken so kindly to their novel environment, that the extension of the plantations has been decided upon.

Indigo growers in Java have become so alarmed by rumours of that article having been artificially manufactured in Europe, that they have set on foot enquiries into the matter. The result has been somewhat tranquillising. The artificial product known by the name of Alizarine has only recently come into the market, and shews all the characteristics of a permanent dye, and admits of shades of colour pretty similar to those of indigo. It still does not yet come up to the standard of the latter, and has yet the drawback of dearness. There is some prospect of Alizarine proving a formidable competitor to indigo from its suiting woollen goods, its permanence of colour, and its simpler manipulation in dyeing. The low prices now ruling for indigo lessen still further the chance of Alizarine gaining command of the market.

MAURITIUS.

(From the *Mercantile Record and Commercial Gazette*

(18th November.)

PORT LOUIS, 18th November 1887.

THE WEATHER AND THE CROP.—Some ten days since, the weather has been much finer and the manipulation is going on very actively. The yield is not very satisfactory and generally it is inferior to that of last year. It is to be feared, as we have already said, that it will be difficult to cover the present deficiency of 87,135 bags

VANILLA.—There has been a brisk demand for fine qualities and the market closes very firm. A few lots of first quality offered for sale this week fetched R24·20 per kilo, above 6 inches. A lot of about 300 kilos from Seychelles (Forêt Noire) was publicly sold at R18 per kilo above 6 inches and Vanilloes R5 per kilo, from 5 to 6 inches. We entirely confirm the remarks we made in our last issue as regards the present crop. The 1888 crop however will be short at least one third as compared with the present one, and the reason may be attributed to an abnormal loss of flowers for which no definite cause can yet be traced.

FEVER AND ITS CURE: QUININE FOR THE MILLIONS.

TO THE EDITOR OF THE "PIONEER."

Sir,—In your issue of 15th instant in the leader, "England and India in 1885," you state that in India, "of the 5 millions of recorded deaths, fever accounted for 3½ millions;" and again, "the Army Sanitary Commission point out that the four main epidemic diseases have in the course of ten years swept off no less than 38 millions of the inhabitants, and that the 30 millions of fever deaths registered during this period must be taken to indicate attacks of fever several times over the entire population and a really incalculable loss of working power to the country." Medical opinion confirms the latter part of this statement, as the doctors all agree that the deaths from fever do not average at most more than 10 per cent of the sufferers from fever. You then enforce the Army Sanitary Commission's advice as to the enforcement of sanitary measures at large while admitting the pecuniary and other difficulties of so doing. But if these difficulties will prevent our dealing with the four main epidemic diseases as we would wish, with the worst of them, fever, we can deal without any of these difficulties. You do not allude to the fact that as against fever there exists a specific remedy, now very abundant and very cheap, which it is only necessary to put for sale in every village in the country to afford immediate relief in 99 out of every 100 cases of fever.

On the 27th of January 1885 I sent in to the Madras Government an offer, if they would give me the aid of their officials (without which it would be hopeless to attempt it), to place within four months, without any expense to them, an ounce of the best quinine in every village in the Madras Presidency to be sold in doses of 5 grains each by the village moneghar to every one having fever, at an anna a dose, with further stocks of the same quinine at each tehsildar's office and at each collector's office to renew the supply to each moneghar on his paying for the last bottle supplied to him. For Madras alone this would have required 75,000 ounces of quinine. My belief was and is that as soon as the people knew that they could always get as many doses as they required from the moneghar of their own village at their own door, every fever-stricken ryot or coolie would find somebow one anna, or less than half a day's wage, wherewith to shake off his fever and restore himself to the power of working. In an ounce of quinine there are 109 doses of 5 grains each, which would thus give 109 annas to the moneghar. I proposed to give him 13 annas as his reward for selling and to supply him from the stock at the tehsildar's office with another ounce of quinine on his paying 96 annas or R6 to the tehsildar. The tehsildar would refill his stores from the collector's store by forwarding to the collector R6 per ounce, and the collector, on forwarding that to my office at Madras, would at once have his store refilled from there. My expectation was that by degrees this would lead to a large consumption, to an enormous saving of life, and to a still more enormous reduction of the loss of working power to the country.

The Madras Board of Revenue recommended that my offer should be at once accepted, but the Madras Government refused on the ground that they meant to apply the bark from their own chinchona gardens to the making of a febrifuge by their own quinologist for

distribution to the people at a cheaper rate than I proposed. My proposal of one anna a dose was based on various considerations. While giving a good profit at the then price of quinine, it was still not more than the poorest coolie could easily afford to be cured of his fever even if it had to be repeated two or three times, which, with the best quinine, would be the probable utmost requirement. Quinine is a thing that no one buys, however cheap, except when suffering from or anticipating fever, but which everyone who has once been cured by it buys, however dear, when again attacked. Again, what I considered as of immense importance was that the price of it to the coolie should never vary, and as it was then thought that the price of quiniee would soon again rise, though not to its former excessive price, an anna a dose would have allowed, even at some rise in price, of the continuance of the supply at least without loss. At the same time I stated that I asked no monopoly, and that if private trade would supply it cheaper, I should make no opposition. But the Government of Madras, in refusing my offer, apparently did not realise the impossibility for them to make febrifuge in India in the quantities required, or of the quality necessary to induce the coolie to buy. Nearly three years have elapsed, and the people of Madras are now no nearer having febrifuge within their reach in each village than they were at the time when, if my offer had been accepted, an ounce of the best quinine would have been placed for them in each village. Even if the Government did supply each village with its own locally made febrifuge, it is doubtful if they would buy it, however cheap, as it is not known to and appreciated by them as quinine is. Nothing but quinine, and that the very best and purest standing the test of dissolving without any sediment in three times its weight of ether, would have such effects on the first village purchasers from the moneghar as would lead all the other villagers to buy it when attacked by fever.

The consequence is that since January 1885 from 200,000 to 300,000 lives yearly have been sacrificed, and intense suffering and loss of working power has afflicted ten times that number yearly from fever which my proposal to the Madras Government would, if not have saved, at least, have diminished. Since 1885 the continued fall in price would make the application of this remedy easier and at a cheaper rate. Though I could not now work it myself, the Government, not only in Madras but all over India, could do so easily and without the smallest risk. The money invested in purchasing the quinine for the first start would be perfectly safe, as all of it which the villagers did not buy would remain in the hands of the officials for use in the hospitals and dispensaries. And if, as is to be expected, it was largely bought in the villages, even half-an-anna a dose would now give Government a profit while saving millions of lives. But the essential condition of success must be the abandonment of the idea of locally prepared febrifuges, and the purchase in the European market of the best and purest quinine standing the test I have mentioned. In your article you say: "Let us hope that the present Viceroy may among other honours of a successful reign be able to achieve some material contribution to this beneficent results." If His Excellency would take up this subjects, although I am not a Government servant, I should be proud to place my knowledge and experience of the bark trade at his disposal, and for that purpose to go to Calcutta at my own expense this next winter to meet him.

J. W. B. MONEY.

Devah Shola, Nilgiris.

BRAZIL COFFEE NOTES.—A S. Paulo paper says that in the municipality of Araraquara the coffee blossom is such as has never before been seen. The trees are absolutely bending under the weight of the blossoms! The story is said to have been overheard. A party asks his friend whether he is a "bull" or a "bear" on coffee. The friend replies that he is an "ass," for all his money had gone. If it was invented, we must offer our congratulations to the concocter. —A S. Paulo paper prints the following:—The yellow coffee ripens earlier than the red. When the latter is only half-way to complete ripeness, the yellow is entirely ripened. In years of very short crops, trees of the yellow coffee are seen well covered. The branches are stiff and do not break under the weight (of the crop), which does not happen with the other varieties. The harvesting of the yellow coffee is much easier than of the others, for the berry is softer. It dries more rapidly than the red. And beyond this it is much heavier than the latter. Two new native products have recently been patented. One is a "Consolidator of coffee trees" and the other an "Ant Destroyer." Now, if some one would patent a "consolidator of coffee prices," operators would all take a hand.—*Rio News*, Nov 1st. [This is the first time we have heard of "yellow coffee" as a distinct variety. All the coffee we have ever seen passed from green to yellow and from yellow to red in ripening.—ED.]

THE MANUFACTURE OF JAPAN SOY.— At a recent meeting of German chemists a Mr. Erich communicated a paper on the preparation of Japan soy, a product of which the details of manufacture are as yet imperfectly known. Soy has been manufactured in Japan for over a thousand years, and forms a very considerable article of consumption in that country and throughout the East. There are many factories of the condiment in the country, one of the largest being at Tokio, where considerably over one million gallons are specially prepared for export every year. The principal ingredients known to be used in the manufacture of soy are a very hard long-awned variety of barley, common salt, soya beans (*Dolichos soya*), a specially prepared ferment, and water. The soy beans are roasted like coffee, the barley is partly roasted and partly malted. The roasted parts of the barley and the beans are soaked in cold water, cooled, and preserved by the addition of a liberal dose of common salt. To this are added first a distase solution, and afterwards a specially prepared ferment, which causes an extremely slow fermenation, but without any considerable formation of carbonic dioxide or alcohol. The degree of strength of the soy depends upon the time used in the process of manufacture, which varies from one to three years. If kept cool and out of the light soy can be kept good for a very long time, but the action of light and the free access of air cause fermentation.—*Chemist and Druggist.*

NORTH OF INDIA TEA NOTES.—A sprinkling of rain in Cachar. Tea prospects good in Sibsagar and Lukhimpore. The prospects of all crops are good in the Garo, Khasi and Jaintia Hills. Rice had also suffered from drought in Cachar but the tea season was closing. Weather is reported "fine" or "seasonable" in all the tea districts except one. In Nowgong, the weather was a little dry, and rice was suffering from drought. Rajmai.—On the night of the 11th March a most destructive hail-storm visited the district and did much harm to the bushes, taking off whole shoots, and otherwise committing great damage. This storm was followed on the 15th of the same month by a second that proved equally damaging in its effects on the pruned tea. This unusual event, of two hail-storms one after the other in such quick succession, is sufficiently peculiar to be worthy of note; affecting, as they did, the tea prospects in no small degree. At the present time fogs are very prevalent in the mornings, lasting for four and five hours at a time, and foreboding an early close of the season. The rainfall has generally speaking, been behind that of last year, but more evenly distributed, and hence, though most gardens are likely to be behind the outturn of last year, they have still done very fairly well. Health has, been pretty good, and one item worthy of notice is that notwithstanding the short rainfall, the musquito blight has been pretty prevalent. One garden in the Luckhimpore district was completely "shut up" on this account, not making its estimate by a long way.—*Indian Planters' Gazette*, Dec. 6th.

PLANTING REPORTS FROM THE HILL-COUNTRY OF CEYLON:

ABSENCE OF FOSSIL FUEL IN CEYLON—COAL AND WOOD FOR TEA ESTATES—THE WEATHER.

NANUOYA, 20th Dec. 1887.

The entire absence of fossil fuel (for the peat formations of Muturajawela and other localities can scarcely rank as such) places Ceylon, in regard to its railways and tea estates as well as other enterprises, at a great disadvantage compared with many parts of India and especially with Assam, where coal of very good quality is abundant, in addition to vast tracts of forest. Although much of the coal which reaches Colombo from Britain (only a small portion comes from the Australian mines) is carried almost as ballast, yet the cost price and the inland carriage have made it so expensive that even on our railways it is used only in exceptional cases, as on steep inclines, and merely, we believe, as an aid to the staple wood fuel of the engine furnaces. On many old coffee estates converted into tea plantations there are no fuel reserves either in the shape of felled or standing forest, and what with the demands of tea estates for buildings, boxes and furnace fuel, and those of the railway, timber is disappearing at a rate which is calculated to create concern. Close to the railway terminus here, for instance, an estate which some time ago showed a large extent of fine unbroken forest is being rapidly denuded, not merely for store timber and shingles, but from the operation of a contract to supply the railway. Of course it is immediately advantageous to be able, while clearing for ultimate cultivation, to turn timber into money, but lookers-on cannot but remember that while trees left to decay on the ground yield fertilizing matter for tea as they did for coffee, wood has, in the case of tea cultivation, additional value for fuel purposes, as well as for buildings and tea boxes. No doubt the proprietors of the estate in question have well weighed all the *pros* and *cons* of the matter. They know that our clayey soil up here is rich in potash and iron, elements in which tea delights, and that phosphoric acid is in fair proportion. With such a soil and with our moderate climate the contingency of exhaustion of fertility may be regarded as a very distant one, but the question of wood fuel is a serious one, unless importance is attached to the recent reduction in the rate of carriage of coal, or that my neighbours are as sanguine as I am that science will ere long provide an artificial fuel, which will enable railways and tea estates alike to dispense with the fearful waste of wood which now takes place, and justify the Government in unlocking for cultivation forests which they now reserve as stores of fuel for the railway engines. As the retention of forest on the sides of mountains which rise to 6,000 and even over 7,000 feet above sea-level, as rain-compellers, is wholly unnecessary, the question of lands fitted for tea cultivation being disposed of along large portions of the railway line from Nanuoya to Haputale depends on a cheap supply of coal, or what would be still better, the discovery of an artificial fuel in which the maximum of caloric would be compressed into the minimum of bulk. If, as seems possible, crude kerosine or like substance can be deodorized, say by being intimately mixed with charcoal or coke, and compressed into brick, the want might be supplied. Meantime I should like to know how the reduction in the price of coal is likely to increase the use of that fuel, either alone or mixed with wood. many estates having no wood with which to mix coal or coke. Some time ago, I met Mr. Rutherford in the train, and felt much concerned to learn from him that the result of experiments he had tried was that coal fuel for tea factories was twice as expensive as wood. No doubt Mr. Rutherford referred to cases where reserves of wood fuel existed: he said nothing about a mixture of coal with wood, and I presume the coal he used was charged a much higher price for carriage on the railway than the rate which has now been conceded. If the concession, added to the condition of a large number of estates with reference to timber fuel, leads to a largely increased use of coal in tea-house furnaces, I need not dwell on the extent to which this fact will add to the already great proportion of up traffic to down on the railways. Not in the carriage of coal any more than in that of rice-can carts possibly compete with the engine-drawn trains of goods vans. To meet cases where coal will have to be carried appreciable distances from railway stations, I have no doubt that special modes of packing will be resorted to. It seems likely that pounding and pressure of the article will be resorted to? Then with reference to the cheaper rates of carriage now offered, the question may arise whether coal inferior to that used for marine and land steam engines, and therefore considerably cheaper in first cost, may not suffice for the furnaces of tea driers? Of course, estates which use steam instead of water for motive power will always require a supply of good steam coal. As the time has already arrived or is fast approaching, when timber will be absolutely absent or scarce and dear, whether in logs or as charcoal, this question of coal is a very interesting and important one, and I trust that what I have written may elicit valuable information on the subject of its use as fuel on tea estates, either alone or mixed with blocks of wood.

RAINFALL—POOR PEATY SOIL OF NUWARA ELIYA PLAINS—MR. WHYTE'S RHUBARB PLANTS—FOREST AROUND NUWARA ELIYA.

NANUOYA, 23rd Dec.

It looks as if the north-east monsoon of 1887 would be memorable for abundant rainfall all over Ceylon. Yesterday, up to 4 p.m., we had nothing worse than drizzle, but from the hour mentioned it has never ceased raining steadily, with an occasional gust of wind, and the atmosphere seems still charged with moisture. The rain gauge this morning indicates a fall of 1·19 inch in the 24 hours. I wrote recently that up here we were largely exempt from rain storms, and in support of that statement, I may mention that in the records of this year 2 inches of rainfall in 24 hours were never exceeded or even reached, except once and that was on the 17th-18th of this month when 2·18 were measured. Our even distribution of rain deprives us, of course, of a certain amount of sunshine, but the small amount of wash and land slips is much in our favour. I spoke of our soil as tenacious although fertile, and on my recent visit to Nuwara Eliya I was struck with the contrast of the black but poor soil of the Plain. Of course I am speaking of the grass land, bare or dotted over with rhododendrons and a few similar growths. Mr. Whyte in showing us over his extensive flower and vegetable gardens, had the same tale to tell which we have often heard from other cultivators of the black, peaty soil. It had to be repeatedly trenched and manured before anything would grow in it and for a long time every green thing which got above-ground became a prey to black grubs. Even now Mr. Whyte has to protect his rhubarb plants in their young stage by coverings of wire gauze over the propagating boxes. When the leaves get beyond the tender succulent stage they are safe from the attacks of the fly which at an earlier

stage of their growth would choose them as depositaries for its eggs. As regards the origin of this black soil, I have always been astonished to find Tennent following Baker in attributing it to materials washed down from the sides of the mountains which rise over the upland plain. No doubt the peaty soil at the very base of the mountains is mixed with such degraded material to its great improvement. But over the expanse of the plain itself, we have but peat poor in proportion to the poverty of the grasses, rushes and sedges which have, in the course of ages, rotted in what was once a mountain lake. The excavations connected with alterations in the race course present a favourable opportunity of examining this almost purely vegetable formation, which presents so striking a contrast to the vividly-coloured clays, shading from white and yellow to rich pink,—turned up in the construction of the new road to facilitate access of the carts from the Kandapolla and Udapussellawa side to the road to Nanuoya station which starts from the opposite side of the Plain. Equally striking is the contrast between the poor peaty soil of Nuwara Eliya Plain and that of the forest which rises around it. The result, unfortunately for scenic effect is that while the grass lands are neglected, or only small portions converted into sward, the forest trees are gradually disappearing.

CEYLON UPCOUNTRY PLANTING REPORT.

DOES PROLONGED STORAGE AFFECT THE QUALITY OF CINCHONA BARK?—CROTON PESTS—COMPETITION FOR HUSK COFFEE—WEATHER AND TEA FLUSHING.

21st December 1887.

Now that there is a hopeful movement in the *cinchona* market, it is an interesting question how far the quality of bark is affected by a prolonged storage. There are few estates, I fancy, whose Cinchona is still growing that have not more or less quantities of bark on hands which have been held for that rise, the beginning of which, let us hope, we have but seen. The mind of planters has been pretty easy in regard to deterioration through lapse of time, as we have all been led to believe that provided the bark was kept dry, the analysis would turn out pretty much the same, whether the sample were drawn today, or this day twelve months. Is this a fool's paradise we have been living in? It is to be hoped not; all the same I have heard of one lot of cinchona which after a year or more storage, has brought the startling result on a second analysis of a loss of one per cent of quinine? I was not able to learn if the bark in question had been exposed to damp, or any other condition likely to affect its mercantile value, but if it had been kept dry and the presumption is in favour of this, the loss in question reveals a state of things, which would be deplorable if it turns out to be general. Of course as "one swallow does not make a summer," neither should a single example of a loss such as I have mentioned, establish that the holders of bark have been unwittingly "let in." All the same it would be well to know more of the matter; for if there should be a chance, here and there, of such an unlooked-for conclusion, it would introduce a fresh factor in our calculations as to how far it was wise to hold harvested bark even in the face of a glutted market. Cinchona has of late been a dark enough puzzle, without this new element of uncertainty, and I certainly hope that we will hear no more of such disappointing results. By the way I understand that light is found to be detrimental to store bark, so that that has to be guarded against as well as damp, if the percentage of quinine is to remain unchanged.

A friend of mine who takes some interest in that despised and neglected product *croton*, has, kindly sent me his views regarding it which I gladly epitomise and reproduce. Although classed among our new products, he says, there are already a lot of old exploded notions connected with it forming a chapter, of what may now be regarded as ancient history, doubtless compiled by some unfortunate, who had had the temerity of experimenting on the croton bean as food. Anyhow whoever has the honour, we used to be told that food could not be cooked with safety, if the fuel used had been got from the croton tree; that birds could hardly fly over a field where they were growing; and that they certainly would not build their nests in their branches. It was death to the wandering buffalo and was to effectually put an end to cattle trespass. The old upas tree, with its legendary train of horrors was the only thing the modern had to compare with it. Now all this or most of it has become as I have said ancient history, for instead of killing off every form of animal and insect, that came within its baneful influence, croton has become the favourite feeding ground of a most destructive grub, which in turn has been devoured by birds, fowls, lizards and frogs, without any apparent harm having been done them. And last of all the rats have taken to eating the bean. In one store which is swarming with these vermin, several bushels of croton seed have been destroyed and the rodents are livelier than ever, and more numerous! Except in such questionable quarters, croton is at present very much despised. People won't give any kind of price for it either at home or here. Even at the late Matale Show there was neither prize nor welcome awarded to it; allowed to languish in neglect, "shunned" as Burns would have said "alike by saint and sinner." When it is known that the croton is only used for medical purposes, and that a little of it goes a very far way, it is not to be wondered at that with the much increased supply, there should be the old result.

The competition for husk *coffee* has begun again and the Moormen are busy outbidding each other. R5 a bushel for strippings, and what was picked from the ground, not by any means a very superior lot, is the best quotation I know. Even when coffee was at its highest, I cannot remember of a higher figure ever having been given for ordinary husk.

The weather is awful. Rain, constant rain; the ground sodden; roofs leaking; and rooms smelling as if you were growing mushrooms in them. It is proving too much for tea flushing, which wants more sun to start it again. PEPPERCORN.

LOWCOUNTRY PLANTING REPORT:—

SIYANE KORALE.

PADDY CULTIVATION AND PLOUGHING—PROFESSOR WALLACE ON PLOUGHS—PADDY AND MANURE.

In continuation of the subject of my last communication I wish to offer a few remarks on the vexed question of ploughing as bearing on paddy cultivation. As far as my knowledge on the subject goes, which I candidly admit is limited, the objects of ploughing are mainly to break up a soil so as to aerate it and also to mix up the different particles composing it. In other words, to improve its mechanical condition. The much decried native plough affects these objects, though clumsily and at a great and useless expenditure of man and animal power. As far as I know, no one ever intended to run these primitive machines in competition

with the improved machines for which I believe we are indebted to Mr. Howard, senior, of Bedford, the father of the members composing the firm of that name. Messrs. Howard say that "Before the first meeting of the Royal Agricultural Society of England, held nearly half a century ago, iron ploughs with wheels had not been made in England, wood ploughs being in general use." I never joined in the wholesale condemnation of the native plough, which some with more humour than truth describe as a pointed stick with an iron tip, used for scratching up the ground. Though its work is not perfect, it answers to a great extent the requirements of a plough. There is an old adage that we must learn to walk before we attempt to run. Therefore I say the attempt to at once wean the natives from the use of their primitive ploughs, held sacred by them as having answered the requirements of their ancestors, and to familiarize them with the perfect machines of European agriculture, renders necessary a revolution too violent for a notoriously conservative people who cling with feelings of reverence to customs having the sanctity of age. Educate them gradually, I say, to an improvement on their primitive machines, and gradually lead them on to the use of the improved ploughs for which we are indebted to Mr. Green's public spirit. One of the objections I have heard repeatedly made to the native ploughs, is that it does not plough deep enough. This is an objection made by people who are, it is only too evident, ignorant of agriculture. Those practically engaged in agriculture have a wholesome dread of bringing to the surface, subsoil which in many cases is sour and poisonous but in every case poorer than the surface soil. Those engaged in planting upcountry know by experience the disastrous effects that sometimes follow the spreading on the surface the soil removed in cutting drains, while those in the lowcountry know that in very many cases even the ubiquitous and not choice-feeding grasses refuse to grow on soils brought to the surface by cutting trenches. By one, whom it is hard to convince that subsoil is generally poor stuff, and who in his public writings spoke of "the rich and unexhausted subsoil," a row of very healthy coconut plants growing on the road boundary of Mr. J. F. Drieberg's estate at Jaela, on soil thrown up by the cutting of a boundary ditch, is pointed out as proof that subsoils are not poor. But there are soils and subsoils, and everything under a certain given depth cannot be rightly called subsoil. We speak of deep and shallow soils in regard to soils that have an admixture of vegetable matter to an appreciable depth or on the surface merely. The particular soil in question has been formed by the decay in successive periods of vegetation growing in what originally must have been a bog. The soil therefore must be almost entirely composed of vegetable matter. It is perfetcly friable and is of the porosity of sponge. We know that on such soils roots roam unrestricted and that such soil are very absorbent. Because vegetation thrives on such soils, we are not justified in saying that all subsoils are rich and can be beneficially brought to the surface. Before we resort to deep ploughing we must study the composition of our soil. If we have a tenacious clay which is invariably sour, or sand which is always poor, for our subsoil, it will be wise not to bring either to the surface, for the former "would render the surface soil unproductive till physical and chemical agencies had again restored it to a condition fit for the growth of crops," while the objection to ploughing deep in sand is that "it will bring to the surface a soil which is poorer than the surface soil."

During the recent discussion on the merits of ploughs, Professor Wallace was quoted against the use of iron ploughs as tending to bring to the surface a good deal of soil that was deleterious. It was also stated on his authority that as paddy was a surface feeder, two inches of soil were quite sufficient for the roots to feed on. He is not alone in this opinion. Professor Sanbourne of the Missouri Agricultural College says that as corn is a surface feeder it is a mistake to plough deep and that a layer of undisturbed soil ought to exist between the ploughed soil on the top and the damp soil at the bottom. It is but too apparent he speaks of dry cultivation, but his objections to deep ploughing are worthy of note. The field I work is sandy and in my last I mentioned that those portions which have not a stratum of mould on them, present a very sorry appearance. I lately in conversation mentioned to a gentleman that with the iron plough I never went below three or four inches, yet with these bad patches staring him in the face, he was of opinion that I might with advantage plough deeper. I pointed out that that would bring the sand to the surface and that the whole field will be like the bad patches. "Oh, but soil improves by being brought to the surface," was the reply. His evident belief was that this was almost instantaneous, while those practically engaged in cultivation know that it is a matter of time. The ideas some people hold on the benefits of deep ploughing arise from their confounding deep ploughing with deep cultivation, and their being under the impression that they are one and the same thing, which they are not. In European agriculture a plough is used to turn up the soil and prepare it to the necessary depth, and a subsoiler to stir or loosen the soil below it, without bringing it to the surface so as to increase the tilth. The subsoil being thus loosened allows of a free passage of air and water into it and it is gradually quickened into a "live soil." As time rolls on this is brought to the surface by deeper ploughing. This is a work of time. Agriculture in Europe having assumed the position of a science this can be carried on with precision, while with the rough and ready methods in vogue here, one incurs a certain responsibility in recommending deep ploughing. One advantage of the native plough is that you can work it deep without much fear, for from its construction it cannot bring to the surface the subsoil. Like a subsoiler it simply breaks up and loosens the soil. On a loamy or clayey soil you can with advantage work the native plough deep, not so on sandy soils where the aim of the cultivator should be to superimpose loam on the sand. As bearing on this subject I may mention that I have in my employ people from the village where an Agricultural Instructor is stationed. I asked a man whether he had seen the field cultivated by the Instructor. "Yes," he said, "but it was a huge failure. The paddy is not coming up as well as that in our fields cultivated according to our methods." "How so?" I naturally enquired. "It is a mistake to use the iron plough in our sandy fields. It brings to the surface all the sand, and the field is permanently injured." So you see, sir, that the goyiya of whom we are too prone to speak sneeringly is not deserving of sneers. In conversation with villagers, I was struck with the amount of the knowledge of agricultural chemistry possessed by them as a result of intelligent observation. What this goyiya told me may be true, or may be the result of prejudice. The crop results when published in time will show this; but this much is plain that they know what they are about, and their prejudices cannot be pushed aside with a contemptuous wave of the hand.*

The usual manure for paddy is bones, which possesses a high value as a crop producer. I have heard it stated that the effect of fish manure is better. One feels inclined to attribute this to the phosphorous (phosphates) fish admittedly contains, but, according to Hughes, fine bone dust contains three times as much phosphoric acid as the best fish manure he analyzed at the request of the Planters' Association; over three times as much of lime, and about the same quantity of alkaline salts; but about half the quantity of nitrogen. From this analysis it is but too apparent that bones are a better crop producer than fish, while the latter will perhaps be found a less stimulating manure than bones for the cultivation of perennials, owing to it containing more organic matter and nitrogen than bones and owing to the disparity between nitrogenous and phosphatic compounds not being as great as in bones. In other words, because the balance between leaf-forming and fruit-forming constituents is properly main-

* Since writing the above Mr. Green's letter giving the results of the use of the iron plough at Minuwangoda proves that my informant was prejudiced.

tained. All this on the assumption that the chief action of nitrogen is to form leaf and that of phosphates to form fruit.

QUININE: SMALL *V.* LARGE DOSES.

LONDON, Dec. 2nd, 1887.

It so chanced that, being in company with Mr. Thomas Christy, the wellknown drug importer, a few days back, it occurred to me to mention in connection with some matter or other that came under our discussion, my own experiences in the use of quinine. My statement to the effect that as the result of that experience I altogether disbelieved in the efficiency of the small doses of the drug usually administered, awoke in Mr. Christy an immediate interest, and he at once asked me on what ground I had come to such a conclusion. In reply I told him that many years back a severe attack of fever wholly prostrated me, and that treatment persued by a wellknown doctor in Ceylon for several months wholly failed to eradicate it, although quinine was taken by me under his advice at least three times a day. Finding his treatment altogether useless, Dr. —— advised me to try a change to the hill country. The very first night of my arrival at Nuwara Eliya the fever returned with as great violence as before, and I sent a messenger off in haste for the Military Surgeon then quartered there. On his joining me, the question as to previous treatment was immediately put, and my new adviser quite laughed at the idea that the ounces of quinine I had been made to swallow could have had any effect in eradicating a fever of so serious a type as I had suffered from. He at once called for a glass of sherry, and to my surprize,—and, it must be said, horror—put half a teaspoonful of sulphate of quinine into it. The decoction was almost as thick as mud, but down it had to go. "You're to take another like that directly you wake in the morning," was then said to me, "and I will come and see you about 10 o'clock, but I don't suppose you will want me to do so again." I repeated the dose as directed, and surely enough the fever left me never to return, though within a week from its doing so I traversed the whole of the malarious country between Nuwara Eliya and Batticaloa, merely taking rather lighter doses of quinine early in the morning to ward off the possible effects of the unhealthy country I was passing through. Mr. Christy was so struck by this tale of my personal experience that he got me to put it into writing, and submitted it, as I have since learnt to several home experts, among them being Messrs. Howard, the well-known quinine manufacturers. Mr. Howard said he well knew that the doses of sulphate of quinine as given were ridiculously small, and that he had of late advocated their being largely increased, but that he had never had direct evidence before of such large doses as half a teaspoonful being prescribed. I was asked if I could furnish any further evidence of the beneficial application of such quantities of quinine. In reply I furnished details of two cases in which my advice had been followed with perfectly marvellous results. One of these was an officer who had contracted malarious fever at Chatham, and when I saw him a twelve-months after his leaving that place, it recurred daily with undiminished violence. I counselled his taking half a teaspoonful of Howard's sulphate in a wine-glass of brandy and water every morning before he got up. He was cured in less than a week, and has experienced no relapse since then. The second case was of a more recent date. A friend, a lady who had suffered much from fever in the tropics and who I chanced to meet only after she had been more than two years in England, told me she never felt free of fever. Even in the hottest day in our late summer she always felt, as she expressed it, "chilled through and through." An internal ague always distressed her and affected both her appetite and power of sleep. I told her to take about a third of a teaspoonful of Howard's sulphate of quinine before she took her morning cup of tea in bed, and in the same vehicle as above described, viz., brandy and water. After the third morning the feeling of cold and ague entirely left my new patient, and by perseverance with the treatment, though with largely reduced doses, she has been enabled to bear the severe cold we have lately been experiencing with no more discomfort than other Englishwomen who have never been in the tropics can do. I deem it best to let you know what I had to impart to my questioners, because there is reason to believe from the correspondence which ensued upon my interview that some effort will be made to diffuse the knowledge of the effects of such treatment very widely. What first stimulated Mr. Christy's interest in my narrative was the fact that in dealing with a very noxious drug, invaluable for certain complaints but very dangerous if used by inexperienced persons, he had been counselled to restrain its use to the very early morning, before the person taking it rose from bed. He told me he had never heard of such a dose as half-a-teaspoonful of quinine being taken without very distressing results, and there was a striking analogy, he said, between my experience and what he had heard about the administration of the drug in which he was personally interested. He lost no time in mentioning the facts named by me to those interested in the drug trade. Messrs. Howard, of course, might well be expected to view such a matter with favouring interest because of the probability of inducing practitioners at home to use quinine more largely than they do. It is a fact that it is rarely used in England save as a tonic for weakly persons, children especially. As I am informed, the treatment with the mild doses prescribed by home doctors lasts over such a length of time that quinine is regarded somewhat in the light of a failure in domestic practice. Now if Messrs. Howard can persuade the medical men in the fenny counties of England to increase their doses after the fashion recommended by me because of my own experience they will succeed in greatly stimulating the use of the drug, and of course that is an object they as manufacturers must have strongly in view. What will be good for them will be good for Ceylon. What you need to make your cinchona cultivation a paying thing instead of a losing one is the popularization of the use of its product. I have long felt certain that this could never come about so long as medical men restrict their application of it to the tiny doses they only think it safe to employ, and any course which will awaken them to the fallacy of their present treatment is sure to have beneficial reflex effect on the industry of Ceylon. I hope soon to hear of the steps Mr. Christy and Messrs. Howard may purpose to take in this matter. I am assured such are in contemplation, and it will be curious and interesting to learn if they produce effect in the direction desired, that of increasing the consumption of quinine. People in England don't know, indeed, what quinine can do for them. They would soon find out what its real powers are if the suggestions I have given receive any wide adoption.—*London Cor.*

CEYLON TEA AT GLASGOW.

The following Circular has been issued by the Ceylon Committee of the Glasgow Exhibition to all Firms in London interested in Ceylon, Mr. Shand

writes that the "Exhibits especially equired from Ceylon are those of Natural History, birds, beasts, butterflies, &c." and is desirous that Government be persuaded to send back all the decorations and exhibits returned from South Kensington:—

CEYLON AT THE INTERNATIONAL EXHIBITION AT GLASGOW.

It was considered by several gentlemen largely interested in Ceylon of importance that the colony should avail itself of the opportunity of the Glasgow Exhibition to extend the knowledge of the superior quality of its pure teas from this great centre outwards. Several months ago, Mr. Edward Aitken of Colombo was asked by the Council of the Glasgow Exhibition to assist in the matter and a Committee was formed, but beyond arranging that a certain sum should be expended by the Glasgow Exhibition Council in the purchase of exhibits, little seems to have been done.

The Planters' Association then took the matter up and appointed a Committee to make the best possible arrangements, that Ceylon should be properly represented especially in Ceylon tea in the Glasgow Exhibition:—the Association has obtained a money grant of R2,000 from the Ceylon Government, and they expect to have at our disposal R6,000 towards the expenditure of the Ceylon Court, and a telegram from Mr. Edward Aitken announces our appointments to represent Ceylon at the forthcoming Exhibition. As soon as possible we placed ourselves in communication with the Exhibition authorities in Glasgow, and we found that Mr. Muir, Chairman of the Indian section, and who is very largely interested in Indian teas had arranged that a joint building should be erected in which Indian and Ceylon teas were to be sold.

We pointed out that we considered it absolutely necessary that Ceylon should have an identity of its own as it had had at South Kensington and Liverpool Exhibitions, but the difficulty was presented to us that the schedules for tenders for refreshment contractors in which the Council had reserved the right to themselves of selling Indian and Ceylon teas in a joint building, had now been printed, and the authorities feared that it would be impossible to make any alteration. We pointed out that Ceylon did not desire to make a profit by the sale of tea for any individual benefit, but that we would withdraw altogether from the Exhibitions, unless we were allowed to have a Ceylon Court and Tea-house entirely of our own, and under our own management, that we would account to the Council for a minimum of R6,000 (a maximum of £600) to be expended upon the Court and Tea-house, and that we would hand over at the close of the Exhibition any profit which might be derived from the Ceylon Court. and the sale of tea.

This was agreed to and we have selected an excellent site in the grounds near one of the band stands, and the illuminated fountains upon which the Kandyan tea home, which was at the Colonial and Indian Exhibition last year, and at Liverpool this year—will be erected.

We feel sure of general support from Ceylon, and our desire now is to obtain the aid and sympathy of many in London largely interested in the success of Ceylon tea, and the maintenance of prices:—

1st. By adhesion to a scheme started by the Planters' Association of Ceylon, whereby tea estates in Ceylon consent to a voluntary assessment of one rupee per 1,000 lb. of made tea to form a fund for the pushing of Ceylon tea, wherever opportunity may arise, but with special present reference to the Exhibitions to be held in Glasgow, Melbourne, and Brussels.

2nd. By subscriptions toward a fund of the nature of a guarantee fund, which we do not expect will be called for, but which will enable us to do justice to the Ceylon Court; without undertaking the entire personal responsibility, for this purpose we hope to raise a guarantee fund of £[illegible] or £500 in London.

3rd. By the loan of Ceylon Exhibits which may prove of interest in the Court.

It is generally admitted that however great the intrinsic value of Ceylon teas, the zeal with which it has been pushed has to some extent contributed to the remarkable position which it holds in the market.

There can be no possible better advertising medium than an Exhibition, and as the Glasgow Exhibition has a guarantee fund of £300,000, and will be, par excellence, the Exhibition of next year, we cannot, but look upon it as an opportunity for Ceylon, which all interested should combine to take advantage of.

Kindly address communications on this subject to Mr. J. L. Shand, 24 Rood Lane, London.

In this appeal the Oriental Bank Estates Company, and the Scottish Trust and Loan Company, have responded by enrolling their estates. It is to be hoped the Ceylon General Limited Company, in its new form, will also give the scheme every support.

Mr. D. Reid writes he has called on nearly every firm in London connected with Ceylon, and they have all promised their hearty support not only to the Glasgow Exhibition, but also to the "Rutherford Tea Fund Scheme."

THE NEW DIMBULA COMPANY, LIMITED.

THE COFFEE TRADE.

The Coffee trade of the world has undergone some remarkable changes during the last fourteen or fifteen years, and it may be of interest at the present time, just after a considerable fall in prices has occurred, to inquire to what extent transactions in the United Kingdom have influenced the great rises and falls that have from time to time taken place in the value of Coffee. Roughly speaking, it will be found that the total imports of Coffee into the United Kingdom have during the last two years been [illegible] per cent less than they were fourteen or fifteen years ago, that exports have been about [illegible] per cent less, and that the quantity left for home consumption, although not showing a marked decrease, has, on the other hand, shown no increase, in spite of the large addition that has been made to population during that period. We have here, then, a Coffee

trade showing enormous decreases in imports and exports as compared with so long a period as fifteen years ago, whilst concurrently there has been a complete stagnation in home consumption. As a matter of fact, when the increase of population is taken into consideration, the consumption per head of Coffee will be seen to have fallen from 0·98 lb., in 1872 to 0·86 lb. last year, and this, in face of a long-sustained stirring impetus given by advocates of temperance to the working classes, towards substituting such a beverage as Coffee (amongst others) for alcoholic drink. On turning to the figures of other countries, it will be found that the Coffee trade of the United Kingdom forms a very small part of the Coffee trade of the world, and, moreover, that whilst the consumption in England has declined so perceptibly, Coffee drinking in most Continental countries and in America has increased materially. Our home supplies and home demand have really very little to do with the marked fluctuations that have been going on, but could any record be obtained of the large transactions that have taken place in England, in Coffee which either has no existence anywhere, or is lying in one or other of the American or Continental ports, some light could no doubt be thrown upon the subject, as the tendency to speculate in Coffee has surprisingly developed during the last year or two. The Yankees have probably gambled in it to a much greater extent than other people, but for a long time past the Coffee exchange at Havre has been forced into much greater relative prominence by speculative transactions, carried on by all sorts and conditions of foreigners and Englishmen than has ever before been the case, whilst concurrently in America, transactions on a gigantic scale have also from time to time been reported. The special Coffee exchanges existing at New York, and at Havre and other Continental markets, virtually rule prices, both there and elsewhere, without much reference to the existing state of supply or demand, or of stocks at any one particular port, so that the chance statistical position of any single market, such as that of London, has not now, and has not had for a very considerable period, any material influence on London prices. Holland has of late gradually ceded to Havre the position of first importance as a Coffee centre; but this, it will be seen, is due, not to the fact that the French have of late become larger Coffee consumers than the Dutch, but because more speculative transactions have been passing through the French exchange of late years. The Havre and New York Coffee exchanges were only established in 1882, whilst the special Coffee exchange at Hamburg has only commenced business during the present year.

The popular adulterant to sell as a mixture with coffee is still Chicory, and there cannot be the smallest doubt that its use has been more largely resorted to for the purpose of producing a low-priced so-called "Coffee" during the last year or two (since Coffee became so dear) than was ever before the case. On the other hand, it is argued that the class for whom these mixtures are prepared would probably have ceased to buy Coffee in any shape, unless mixed with the cheaper Chicory, and so brought, as a mixture, within their reach; thus to say, as is often said, that Chicory has probably prevented an increased consumption of pure Coffee, may be far from correct. If these mixtures had been sold at the average of the price of the two component parts, there might be something in this argument, but the admixture is, of course, made not only to lower price and meet the demand for cheap Coffee, but also in order that a higher profit may be obtained; indeed, 75 per cent. of Chicory is often, we are told, mixed with Coffee "mixtures."

The following tables show the relative rates of consumption of Coffee and Chicory during the last ten years:—

Consumption of Coffee and Chicory in the United Kingdom during the ten years 1177-1886.

	1877	1878	1879	1880	1881

The decline in values which has taken place during the last month seems to have come as a surprise to nearly all engaged in the trade here, and there is of course a division of opinion as to the probable future of prices. There are still many who think that rates must again take an upward turn, and that they will touch a much higher range than has been reached at any period of this year. In order, however, to justify an advancing market, stocks must either be decreasing, or there must be an absolute certainty that in the near future this will happen. At the present time the stock in Europe and Brazil is in excess, but in the United States it is about 4,000 tons less than last year, although in America more than two months' supply is rarely held. In some measure to show the uncertainty of all forecasts of prices in relation to existing stocks in various ports, it may be mentioned that on October 31st last the stock in the United States was in relation to her deliveries, sufficient to last barely two months, and in the Continental markets as follows:—Holland, eight months; Antwerp, two to three months; Hamburg, three to four months; Havre, five months; Trieste, two to three months; and London, five months. As a matter of fact, the European deliveries during the first ten months of this year show a falling-off compared with the previous year equal to 16½ per cent., and in the United States, where adulteration has a freer course even than here, the decrease has doubtless been considerable. As between November and March the European stocks are usually the lightest, it may be well to inquire what will be the probable position on March 1st, for by that date the 1887 crops from most of the producing countries (Brazil alone excepted) will be rapidly arriving, and it is expected that many of these will turn out above the average. It will probably be difficult long before that period to maintain a high range of prices, especially as the coming Brazil crop bids fair to be a very large one. Looking first then at consumption, to arrive at any fair estimate of what will be taken from the principal European ports during the next four months, it will probably be overstating the case if an amount is deducted from the total deliveries of that period in the previous year, in the same proportion as the falling-off has been this year, namely 16½ per cent. But with prices still 50 per cent higher than they were at this time last year, it is certain that the reduction will be much greater. Upon a falling-off, however, of only 16½ per cent in general consumption, there will be required during the next four months 104,830 tons,

which, deducted from the entire stock on the 1st inst., would leave 22,050 tons only, to which the probably arrivals during this period have to be added. From November 1st, 1886, to February 28th, 1887, the imports amounted to 128,250 tons, but as both the Brazil and Java crops have this year proved exceptionally small, nothing like this quantity can be expected. On the whole, it is clear that in the present state of most uncertain statistics and heavy speculation, and the impossibility of even the best-informed persons forecasting the actual out-turn of the Brazil crop, on the weight of which so much hangs, opinions from any quarter cannot be worth much in prophesying the possible course of the market, and under such circumstances the practice of steadily buying from hand to mouth, to fulfil immediate requirements, is the one usually adopted, and is certainly the safest.—*Produce Markets' Review*, Dec. 3rd.

PRODUCE IN MINCING LANE.

The "boom," to use an expressive though by no means elegant, Americanism, which has stirred up our produce markets since the end of November shows signs of waning. Few who looked at the sudden and unreasoning development of speculative tendencies from an unbiassed standpoint could fail to be struck with the absence of solid foundation for such enormous advances as took place in some articles within a few hours' time. When once the drug market began to move with quinine and quicksilver it was thought that the high-price times were about to return, and speculators wildly seized upon whatever article they considered "low priced," regardless of other considerations, and proceeded to gamble it up as high as possible. Chillies and cassia lignea are cases in point. If ever there was an article in which a decided advance appeared unwarranted, cassia is one. Our stock here is sufficient to cover three years' average consumption, and is still accumulating. Consumption does not increase, but the production, according to trustworthy advices from China, is decidedly growing, and is capable of almost unlimited extension. Yet this article was drawn into the whirlpool of speculation, and forced up about 20 per cent from its lowest point within a few days' time. The result, of course, was that at the weekly auctions an unusually large quantity was brought forward, and the advance obtained will probably be lost altogether in a few days. Chillies, the statistical position of which is the reverse of inviting, shot up like a sky-rocket, only to come down again with almost equal rapidity. Shellac has always been the pet article of speculators, and the violent fluctuations which it has experienced within the last fortnight are by no means rare in its history; but it is admitted by the speculators themselves that, although the reports concerning a short crop of sticklac and the statistical position of the article may have warranted a slight increase, its recent advance, retrogression, and renewed forward movement have been governed by quite other than statistical considerations. It is too early yet to estimate how much of the excitement in quinine has been justified by legitimate demand, but there are already indications of an ebbing tide in this important product. In London, on Thursday, there was much confidence on 'Change in the future of this article, and a further advance was actually established; in Amsterdam, at the same time, large quantities of bark were being sold, as our cablegram shows, at a fractional reduction of the rate per unit of quinine. There has been probably some actual increase of legitimate orders for quinine, due to the reduction of the large stocks stored two years ago on the sudden breakdown of the syndicate which had then been formed; but it must be remembered that there are large stocks of bark in Ceylon awaiting shipment, and that the report of the improvement of the market is certain to bring some of these forward.

Speculative movements and sudden fluctuations in the prices in articles of consumption cannot be beneficial to the business community at large, although they may put money in the pockets of a few Mincing Lane brokers, unless it be that some of the money thus secured has been lost by those outsiders who, not knowing quicksilver from quinine or borax from shellac, periodically invade the drug market when they hear that there is "something good going on" in Mincing Lane.—*Chemist and Druggist*, Dec. 10th.

PLANTING IN NETHERLANDS INDIA.

(Translated for the "Straits Times.")

In the Residency of Palembang, planting enterprise has of late been speeding apace. It has been extending considerably without any check save from the scarcity of labourers owing to the scantiness of the native population. Coolie immigration under these circumstances is the only resource available to meet the need. The Netherlands India Government has this time taken action before hand and has promulgated an Employers' and Labourers' enactment almost like that in force on the East coast of Sumatra. There Chinese coolies are becoming dearer and dearer. It has become high time indeed in the interest of the planting community to remove the hindrances in the way of the free immigration of Tamils thither. It is rumoured that after all the Netherlands Consul-General at Singapore will be despatched on a mission to India for the purpose.

A new field of enterprise will shortly be available for tobacco planters. Trials with the cultivation of that produce article are about to be taken in hand in German New Guinea. The New Guinea Company lately sent one of its directors to Deli to investigate thoroughly tobacco cultivation there in all its bearings, so as to gain information preparatory to starting plantations in New Guinea. The *Locomotief* says that unhappily not much could be made of his experiences. He died of malarious fever after his return before he was able to make any use of the theoretic knowledge he had gained.

The *Surabaya Courant* says that in Java, owing to favourable advices from British North Borneo, many enterprising planters have decided upon trying their luck there.

MANILA NEWS.

(Translated for the "Straits Times.")

The Minister for the Colonies has directed the Governor-General of the Philippines to take steps to bring home to the inhabitants of the islands the advantages of cultivating a variety of crops. Model farms, of which several have already been started, are expected to offer the best means for the purpose, by showing them the working of improved agricultural machinery and appliances. Economic plants will be tried in cultivation so as to show the natives which of them would pay when grown. The cultivation of Rameh will be especially experimented with.

WYNAAD COFFEE AND CINCHONA.

A South Wynaad correspondent writes:—"Besides the east-wind and its usual accompaniment of lumbago and colds in the head, one is sorely troubled as to whether one is going to get in the estimated amount of crop. In spite of the coffee market being favourable, the unseemly rain that fell late in the season in this district is beginning now to show its results; and, with a few exceptions, most of the planters will consider themselves lucky if they realise but half of their original estimates. To add to their misfortunes coffee thieves are particularly lively this year; stripping off an acre of coffee in one night is an ordinary occurrence, in spite of our having from four to six watchmen patrolling an estate. In fact, stolen coffee is simply being carried away. This state of affairs is undoubtedly owing to the fact that every petty bazaar man is allowed to issue coffee passes. One may catch a thief on one's own estate carrying away a bag of coffee, and yet the rogue will have the audacity to produce a 'pass,' and say that he was simply going through your estate, as it was a short cut to the bazaar; and that he was afraid to go round

by the road for fear of meeting bears, as the evening was on the wane! Heaven help the planters, for neither the Police nor the 'diel' will. Those unfortunates who relied upon the equivocal 'last straw'—cinchona—to enable them to stem the overwhelming tide of misfortune, must now be in a very sore strait indeed, considering that at the present depressed state of the market, it hardly pays the expenses of harvesting. At the last Planters' Associaton meeting statistics were given as regards shaving *C. Ledgeriana* trees, and the result can hardly be called satisfactory. It was found that after the second shaving 15 per cent of the trees died, to say nothing of the indifferent analyses of the bark thus taken from the trees, so that one can only come to the conclusion that the least bad variety of cinchona one should attempt to cultivate is the old and much abused *C. Succirubra*. This will at least stand the abominable ballyragging of a Canarese cooly with a pruning knife in his hand, and at the same time it will pay its hard-worked owner for relieving it of its skin 'without dying to spite him' even though it cannot at present bring him in a profit."—*Madras Mail.*

JAVA COFFEE CROP.

AMSTERDAM, Dec. 7th.—According to a private telegram from Batavia the Government's coffee crop for this year, which is now harvested, amounts to 257,000 bags while the next crop is estimated at 500,000 bags. Some new joint stock companies in connection with Netherlands India have been formed. The prospectus of the Rotterdam-Siak-Kultuur Onderneming, of Rotterdam, has been published, from which it appears that the object of this company is the cultivation of produce on certain lands granted by the Sultan of Siak to the company, and on such other lands in Sumatra as may be obtained by the company hereafter. Further, the sale of its own produce or of produce purchased in Sumatra, or received in consignment, and to grant advance on such consignments. The capital has been fixed at fl.600,000, divided into three series, each of 200 shares amounting each to fl,1,000. Provisionally but one series has been issued, which was promptly taken up; and the remaining shares will be issued in five years from the date of the Royal sanction to the statutes, viz., Sept. 14th, 1887. The Rotterdam-Borneo Maatschappy has been established at Rotterdam for the purpose of working certain lands on the territory of the British North Borneo Company and the sale of the produce obtained therefrom. The capital is fl.500,000, divided into 500 shares each of fl. 1,000, of which one series only has been issued and taken up. The remaining shares will be issued in five years.—*L. & C. Expess.*

IMPROVED TEA-PREPARING MACHINERY.

The machines which Mr. Dalgarno (acting on behalf of Messrs. Jackson) has specially to bring to the notice of our tea-planters on the present occasion are an improved Tea Drier and a new improved and cheapened Tea Roller. The latter is "Jackson's new Patent '*Rapid*' Tea Rolling Machine," made in two sizes and styled the "24 inch Rapid Roller" and the "32 inch Rapid Roller," the capacity of the first being 200 lb. leaf, of the second 400 lb. The prices, we understand, are not yet decided, but a reduction of about £10 on the previous machines of the same capacity is anticipated. One of the new Rollers is coming by P. & O. steamer, and arrangements will, no doubt, be made for a trial in Colombo, soon after its arrival. This roller, of which a photograph is before us, is said to be much easier to drive through an improved action, the saving in motive power as compared with the "Excelsior" being over 30 per cent or fully one horse-power. It is also said to do better work, more especially in giving a capital twist and finish to the leaf. Another comparative new Roller is the "Rajah" introduced in 1886, of which 50 are now in use, 5 or 6 in Ceylon. We need say nothing of the substantial character of Jackson's rollers; 700 are now in use and so strongly are they made that in no single case yet has a complete set of duplicates been called for.

In the case of Jackson's Tea Driers, the great drawback at least to the "Venetian" was the difficult of getting at the flues, built as they were in masonry and below ground. This is entirely obviated in the new 32 and 42 inch self-delivery Venetian Driers for which no firepit is required. Its further advantages are described as follows:—

The Machine, including the Stove, is now placed on the ground floor of the Tea House, no pit requiring excavation or building up being necessary, thus saving much labour and expensive brickwork, and at comparative little cost or inconvenience the Machine could be moved from one part of the Tea House to another, or changed from one Factory to another. Access to stove: This is now made very simple and easy. Any tube can be taken out and replaced in a few minutes, even when the fire is on, and without disturbing any part of the masonry or other part of the apparatus. Economy in fuel: An arch of refractory material has been introduced between the fire-grate surface and the tubes, which enables the combustion to be completed before reaching the tubes, and as a better circulation of the gases will result, a considerable saving in fuel will be effected, and the durability of the tubes prolonged. Self-delivery: The lower portion of the drying chamber is now constructed so that when the lowest drying surface is opened the dry tea thereon descends on a shoot which conveys it outside of the drying chamber altogether, and delivers it into a tea chest placed to receive it, thus dispensing with the Trolly hitherto used. Drying Chamber: This is now constructed of steel or wrought iron, which minimises the risk of breakage in transit, and reduces the freight. Erection: This is simplified by an arrangement which enables all the iron work of the Stove and Drying Chamber to be fixed up together, and set in a line with the driving pulleys, and the brick-work built round it afterwards: Method of working The top feeding tray is drawn forward on rollers. A charge of fermented leaf is spread over it by hand, when it is returned to the drying chamber. The crank handles are then turned consecutively, beginning at the bottom, when each stratum of tea will be moved down from one tray to another, the lowest being delivered by the shoot direct into a tea chest outside the machine. The smaller Machine has a drying chamber 32 inches square, and is capable of putting out about 70 lb. dry tea per hour. The larger Machine has a drying chamber 42 inches square, and is capable of putting out about 90 lb. dry tea per hour.

Prices of these and the other new Machines will be duly advertised, and it is evident that the Messrs. Jackson are determined to keep up their high reputation as makers of tea-preparing Machinery in the Ceylon market.

COCONUTS IN FIJI.—Says the *Fiji Times* of Nov. 9th:—An old "copra man" under fire of cross-examination, informs us that, in 1885, he manufactured on his estate, copra to the extent of 50 tons; in 1886 he secured but 20 tons, and in 1887 the total result decreased to 12½ tons. Next year, with a considerable increase of coconut area, he expects but to reach the output of 1885. He further states that most of the old trees, such as those from which the natives collect their taxes, are now in full-bearing, while trees of from 10 to 12 years old have not nearly recovered from the effects of the blow. This will afford a pretty fair indication of the severity of the strain on coconut growers during the past two years.

PRODUCTS: BRITISH & FOREIGN CONSULS, REPORTS.

CHINA.

Ginger Preserving at Hong Kong.—Though most of the preserved ginger sold at Hong Kong is made in Canton, a considerable quantity, which is steadily increasing, is now prepared in the colony itself. The process is simple. After first boiling the fresh root until it becomes soft, it is punctured all over with a fork, and then boiled in syrup until the proper consistence is obtained, when it is placed in jars for market. Other fruit and vegetables are preserved in substantially the same manner, holes being pricked into them to allow the syrup in which they are boiled to penetrate them in every part. A favourite preserve is made of small oranges, called *cumquats*. The fruit is preserved whole, after being scraped all over to free the essential oil from its containing vesicles. It is then punctured and boiled. Young bamboo shoots are largely preserved, as are snap-beans, tomatoes, and most of the vegetable roots.

DUTCH COLONIES.

Java Indigo.—The indigo crop of 1886 was satisfactory both as regards quality and quantity. During the year 612,000 kilos. were exported from Batavia, against 601,000 kilos. in 1885, and an average export of 422,000 kilos. from 1880 to 1884. The high prices which ruled at the commencement of 1886 could not be maintained, and the season closed at decidedly lower rates than the one preceding. Prices, in fact, were so low that the planters would not sell outright, but preferred to ship the bulk of the crop to Holland for their own account. The finest varieties are becoming more and more scarce. The 1887 crop does not look favourable as regards quantity, having suffered from excessive rains and insects.

Spice Exports.—The following figures relate to the quantities of the principal descriptions of spices exported from Batavia:—

		Average		1885	1886
		1875-9	1880-4		
Cassia	kilos.	30,900	71,000	4,800	10,000
Cloves	„	150,000	45,000	42,000	37,000
Mace	„	203,000	87,000	10,000	3,130
Nutmegs	„	425,000	280,000	160,000	42,000

The falling-off in the exports of cloves, mace, and nutmegs is not due to the decrease in the production, but to direct exports from the producing islands (Amboina for cloves, Banda for mace and nutmegs) to Singapore and to Holland direct. Cassia is the produce of the islands of Flores and Timor, east of Java.

Lampong Pepper.—In the Lampong districts of Sumatra the export of pepper in 1886 was almost treble that of the preceding year, the figures being: 1886, 2,487,000 kilos.; 1885, 970,000 kilos.; average of 1875 to 1884, 1,370,000 kilos. Of the shipments, Holland receives 30½ per cent, Italy 25 per cent, Singapore 18½ per cent, Trieste 14 per cent, and France 12 per cent. White pepper is exported in very small quantities; in 1886 2,500 kilos., mostly from Bencoolen, were shipped to Singapore.

HAYTI (SAN DOMINGO).

Logwood.—The logwood trade has been much depressed lately, mainly in consequence of excessive competition. There is a very good demand, larger in fact than the supply, for the better varieties of logwood. In consequence a good deal of inferior wood is brought down from the interior, and these shipments give rise to claims on the part of the receivers in Europe. Exports from Hayti fell from 293,548,750 lb. in 1885 to 273,626,277 lb. in 1886. The decrease is principally owing to reckless destruction of the woods and to the haste with which young trees are felled before they have attained maturity, and by the wretched condition of the roads in the island, which are never repaired, and have now become so bad that it is impossible to bring down the fine trees which are still found plentifully in the interior. In the coast districts there is no wood left.

Cocoa.—The cultivation of the cocoa plant is steadily increasing, the high prices which have lately prevailed in Europe having caused many farmers to take up this industry. If proper attention were paid to the cultivation the island could produce an excellent quality of cocoa, but as it is, the gathering and treatment are most carelessly effected, the beans being brought to market mixed with earth and imperfectly dried. The crop in 1886 was only a medium one —3,304,305 lb. were exported against 3,156,957 lb. in 1885. On the local markets the average price is about 31s. per cwt.—*Chemist and Druggist.*

ON ALLEGED DEGENERATION OF TEA SEED THROUGH CHANGE OF HABITAT ONLY.

The question as to whether or no a degeneration takes place with indigenous tea seed by a mere transfer of site or change in locality, is one that interests a great many engaged in this industry. It is frequently asserted that a change of habitat alone seems to produce a marked effect, that the seed of an indigenous patch of tea, in hills or plains, when transfered to another district, or habitat, produces a plant less vigorous than the parent. It is presumed that, of course, in all cases the effects of intercrossing with lower varieties as "Hybrid" and "China," is carefully avoided, and that the indigenous flowers are in all cases fertilized by their own pollen. The difficulty then is to see how such a change for the worse can arise. There is generally supposed to be a cause for everything, and hence *if it is true* that change of site alone causes distinct degeneration in tea seed, that cause with a little care and investigation should become apparent.

In the first place, it is very difficult to find reliable cases where distinct degeneration has undoubtedly taken place. Few patches of really indigenous tea have been cropped for leaf, or pruned like the cultivated tea, or statistics kept showing the outturn in lb. per acre and recording the qualities of the manufactured leaf and liquor. And until we have data to go by—not in a few isolated cases, but in a fairly large number—can we have reliable means of judging this question? Simple assertion that tea degenerates by change of habitat is worse than useless; in fact, when looked into is probably untrue, for the simple reason that transfer to a site, where the normal conditions of growth are improved, should, and indeed *would*, give an improvement in the growth and vigour of the indigenous *jat*.

To those who understand the doctrine of evolution and development, the origin of species by natural selection, it will be needless to point out that every change in habitat probably produces some effect. If the change in the surroundings is slight, the change in the animal or plant will be slight also, and if the change is great in the surroundings, the effect produced will be great also, and may cause death even.

Small annuals of the temperate zone become arboreal and perennial in the tropics, and *vice versâ*. A change of habitat with indigenous tea, may, therefore, be expected to produce some slight change in the plant, though not at all necessarily one for the worse. If taken from a hill, and planted in the open in level land, or perhaps land having a different soil or drainage, the change may be for the worse. If taken from the plains and planted in a rich hill soil, there may be a very distinct improvement, as there also would be if transferred from an average hill soil to a *better* one in the plains. The conditions necessary for growth are various: good soil alone is not enough. We might have magnificent soil in Greenland, and a temperature of only 45°; or a fine soil and quite suitable temperature in the vicinity, say, of Bivouac, where the rainfall is often 200 for the year. Where the change of habitat is not great locally, i.e., is within the same province, or district, where rainfall and temperature do not vary greatly, the change would mainly be one of soil and drainage. If these latter were good, therefore, we might safely say the chances of degeneration were reduced to a minimum, and where soil was better, there would probably be an —actual improvement

We are so accustomed to look on indigenous tea as the best, that it is never noticed that even improvement in it is quite possible. It is the best (in certain respects) of our present varieties. No one as yet has attempted to breed on a large scale a conspicuously good leaf-bearing variety, which is what the industry requires, and which would probably be found among the better class Hybrids.

As a rule, the indigenous plant does not give crops of 8 and 10 maunds per acre. It forms a more open bush; whereas the Hybrid is wellknown to give even over 10 maunds per acre, and up to 900 lb. per acre over large areas, the bushes having denser growth or many branches, and hence many more shoots for plucking from with a given size of stem. One can *see through* an indigenous bush, but not through a Hybrid, so to speak. Occasionally most planters see bushes in their gardens that yield persistently quite an abnormal amount of leaf. What is needed is to select from such, and by crossing with its own pollen, secure a new variety that will give heavier leaf crops.

The reaction from China and Hybrids in favour of indigenous seed is most natural. The evenness of the flushes is thereby attained, which is impossible in mixed gardens; but the scientific breeding of tea, for the purpose of producing an even and heavy leaf-cropping variety, has not begun. The true habitat of the indigenous tea tree has been only vaguely settled. Many so-called "indigenous" gardens or plots are obviously where early Shan settlers planted the tea not as we do in rows, but irregularly scattered; and indeed in most of these sites there are reasons to think this "indigenous" has not been introduced more than some 60 or 80 years. Few indigenous plots can show tea trees 35 feet high, and 3 feet 6 inches round at 4 feet up, dimensions that are found occasionally in Upper Assam, and are apparently greatly exceeded in Upper Burmah. So that one of the prime conditions in the case has an element of uncertainty in it. Where, however, we find virgin forest extending over large areas, with a considerable per cent of tea therein, the chances are it is "indigenous." It is found both in the hills and plains, and as the original tea drinkers of these parts were mostly hill tribes, living for the most part on hill tops and spurs, the fact of its being found in such places is quite natural. That it can, and does, grow on level, or even low land, near water level, is also certain. The general idea is that it is confined to hills, but this, as is well known locally, is not true. Occasionally it is said that the seed of any garden should not be again sown on the same plot, or it may be near it, or used to fill vacancies therein. The reason for this is not at all obvious, and generally speaking, when looked into, there are no facts to support the statement.

There is also a prejudice against the seed of plant raised from so-called "indigenous:" it is considered in some way or other to have deteriorated. But there is generally one way alone by which this can have been effected, *i.e.*, by crossing with Hybrids growing near or not far off, this crossing is so common, that to it we may safely trace the supposition that pure indigenous degenerates by change of habitat. Thus *crossing with inferior kinds and transfer to inferior soils* are the only conspicuous causes of degeneration. If the former is avoided, and indigenous seed, or seed even off plant from it, is put in to good soil, there is no reason to expect it may degenerate. The chances are equal that it may even improve.—*Indian Planters' Gazette.*

A CHEMIST'S HOLIDAY IN MYSORE.

By DAVID HOOPER.

Last July I visited the native province of Mysore, in Southern India, and I thought that some notes of my tour in this interesting country might be acceptable to the readers of your journal.

Mysore is an undulating tableland lying between the Eastern and Western Ghauts. It is 3,000 feet above the sea, but elevations occur in Malnád, on the western and mountainous side, ranging from 2,000 to 6,000 feet. The region botanically is characterised by bamboo, and the rather dry climate is favourable to the production of gums, resins, and other exudations from plants. The earliest accounts describe the country as covered with forest, and it is only within the last century that the cultivation of cereal crops, areca, and date palms has partly displaced the wooded tracts. There are a few of these forests left, considerably reduced in size, but the names of the districts indicate the character of the trees once grown, as, for instance, Chandanaranya (Sandal Forest), Gangajaranya (Abrus Forest), and Kundaranya (Jasmin Forest). The language almost universally spoken in Mysore is Canarese, from the country of Canara bordering on the north-west.

The large European and military station of Bangalore was my first destination. Here were an extensive native town, or *pettah*, two bazaars, and the bungalows of the English residents scattered in the suburbs among tropical vegetation. The Government Botanic Gardens, called "Lal Bagh" (Red Garden), are ably superintended by Mr. J. Cameron, F.L.S. They represent all the indigenous and naturalised trees and shrubs, both economic and ornamental, grown in this part of India. The most handsome in the collection is undoubtedly the "Flame of the Forest" (*Cæsalpinia pulcherrima*). The umbrageous tamarind, with its dark green foliage made up of delicately pinnated leaves, is also a prominent tree; its green acid pods, not unlike broad beans, are preserved and exported. *Cathartocarpus fistula*, another large tree of this order, is well named the "Indian laburnum" from its resemblance when in flower to the attractive *Cytisus*; the long cylindrical pods or lomentaceous legumes have suggested to the natives two other names—"Candle" and "Long-pudding tree."

The chief article of commerce in Mysore, and the most important item in the Forest Revenue, is the sandal wood. The *Santalum album* is from 30 to 60 feet high with not a very robust habit; the colour of the stem is darker than that of the figs and cassias in its vicinity, the flowers are small and red, but neither the bark sap-wood, leaves, nor flowers have that fragrance which is found in the duramen or heart-wood. The sandal is propagated by seeds, and as both the wood and the tree are a Government monopoly, the fruits are carefully collected by servants, whether from forests or from the compounds of private houses. Natural grown sandal is being attended to by having a system of special men called "sandal monegars" to look after their cultivation, as there is a doubt if the artificially grown trees will have the same amount and quality of perfume as the self-sown. The wood is sold by auction once a year, the larger portion being purchased by merchants of Bombay. Until the sales it is stored in depôts called "Kotes," situated in several towns in the province. Mysore sandal is appreciated above all other kinds, especially in the China market, and it has a steady net price of 45*l.* per ton at the place of production, showing it to be the most valuable wood in the world. During the year 1886-1887 a better sale of the wood realised about 46,000*l.*, a substantial increase to the Mysore Forest Revenue of one lakh of rupees, or 10,000*l.*, over the sales of the previous year.

The Lal Bagh contained many other trees noted for affording medicinal products:—*Strychnos Nux vomica*, with its round green fruit sheltered under the branches; *Mallotus Philippinensis*, with its drooping inconspicuous inflorescence, like most of the Euphorbiaceæ; *Erythroxylon Coca* in a healthy condition although overrun by black ants; the climbing *Arbus precatorius*, with its dusky pods and scarlet seeds. *Pterocarpus marsupium*, the Malabar kino, and *Butea frondosa*, the Bengal kino, grow side by side, and form a trio of timber trees with *Pterocarpus santalinus*. A few species of *Eucalyptus*, from Australiya, were not flourishing at this altitude. Besides these may be seen *Dichopsis gutta*, from the Straits Settlement; *Manihot Glaziovii*, from Brazil; *Araucaria Cookii* from California; *Artocarpus incisa*, from the South Sea Islands; and *Dammara robusta*, from New Zealand—all yielding secretions used largely in the arts.

The Mysore Government Museum, Bangalore, is also under Mr. Cameron's supervision. It has a most varied collection of products and antiquities of the country—coins, minerals, stones, fibres, rubbers, dyes, tanning agents, besides a number of gums and resins taken from trees in the Lal Bagh. Dr. Kirkpatrick has given a case of specimens illustrating the medicines used by the "Nakeems," or native doctors of India, together with their uses and doses.

The teaching of scientific chemistry is carried out at the Central College, and in a few minor schools. The laboratory in the former place has accommodation for about thirty students, where, for the matriculation of the Madras University, they undergo a course of practical work that has been denominated "test-tubing." For the F. A. (First in Arts) and B. A. degrees the pupils are instructed in elementary quantitative analysis. The laboratory, like those in Madras, has the disadvantage of having no gas, and the light, which is here accompanied by heat, is not liberally admitted; in other respects, with its teak counters, side benches, and water-supply, it is well appointed.

The pharmacies in Bangalore are held mostly by Europeans, but Parsees, Muhammadans, and Hindus, who have obtained a certificate as "Chemist and Druggist," retail drugs and chemicals, and dispense medicines. The certificate is given to those who attend a course of lectures in chemistry, pharmacy, botany, and materia medica during a curriculum lasting two years at some medical college, usually Madras, and who pass an examination at its close. Each pharmacy is well stocked with proprietary preparations, which are well advertised in all Indian newspapers; the bottles and drawers, forming so prominent a spectacle in shops in England, are here usually kept out of sight in the dispensing department. In one store I noticed a stock of the flat Calisaya bark from South America, some gamboge from Siam, gum arabic from Kordofan, powdered opium and "ext. cannab. ind.," obtained from a London wholesale house, but all of which could be obtained or prepared in the country. The official *Cinchona succirubra* is cultivated in South Mysore, and in the neighbouring territories of the Nilgiris, Wynaad, and Coorg *Garcinia Morella* and *Acacia Arabica*, both indigenous, yield, respectively a gum-resin and a clear gum quite equal to the Pharmacopœia characters and tests; while opium in a very pure state can be purchased in the bazaars. The British Pharmacopœia of 1885 is now official all over India; the Indian Pharmacopœia of 1868, built upon the B. P. of 1867, although a useful compilation, is hardly commensurated with the present state of pharmacognosy.

The manufacture of castor-oil is carried on extensively in the villages by the class *Ganigas*. The mill for crushing the seeds and pressing the oil is in the form of a large stone pestle and mortar worked by bullocks. Two kinds of oil are made; the better is obtained from small seeds, and is the kind used in medicine; the inferior is pressed from large seeds, and is used for lamps. Castor-cake is usually burnt as fuel, but is well adapted as a manure for exhausted soils. Of the other kinds of oil made gingelly or jesame oil, called "Woll ellu," from *Sesamum Indicum*, is universally regarded as the best. "Hippe," a fatty oil from the ripe kernels of *Bassia longifolia*, is used in lamps burnt before gods, and the cake acts as a soap to wash oil out of the hair of those who anoint themselves. "Honge" oil, from the seeds of *Pongamia glabra*, consumes very quickly when burnt; it is employed as a remedy for rheumatism and for cutaneous diseases. "Kobri" oil, or coconut oil, from the kernel ("kobri") of the coconut, is a common illuminant, and is often resorted to by the doctor and the cook. "Huch ellu," or "Ram til," a thin oil from *Guizotia oleifera*, is a lubricant for delicate machinery.

The town of Seringapatam, so well known for the defeat of the great Muhammadan "Tiger," Tippu Sultan, in 1799, might be considered more the resort of the historian or antiquarian than of the chemist; but many objects of interest among the ruins were here found and made a note of. I had the privilege of being conducted over the town by Mr. S. Busappah, the native apothecary in charge, and the author of a "Guide to Seringapatam." As the guide was out of print, the alternative of the author's services was willingly accorded and as gratefully received. Seringapatam is an island on the river Cauvery, and the inhabitants, exclusively native, find employment in extensive paddy cultivation. It is considered to be very unhealthy, fevers and cholera often prevailing. When occupied by the British it did not appear to be unsalubrious. The inhabitants attribute this to the destruction of the sweet flag (*Acorus calamus*), which formerly grew in great profusion on the banks of the river, and was supposed to possess febrifugal properties. The palace, within the fort has now disappeared, with the exception of the rooms previously occupied by the servants of Tippu's harem, which are converted into a "sandal kote."

The "Summer Palace," outside the fort, was decorated in true Oriental style with scenes of battle and everyday life depicted on the wall, and most gaudy colours, red, yellow, purple, thrown together with the usual artistic taste. It does not seem to be generally known that the "false gilding," at one time largely used in ornamenting this and other palaces, was made from aloes. A country-made aloes, called "Musambra," was boiled and mixed with some thick oil and gum. This paste was applied to pieces of paper cut in the shape of flowers, and made to adhere to the wood work of the building. The "musambra" I have examined is a very impure article, but it contains a large quantity of orange-coloured material which in thin strata would well imitate brass or goldware.

A neglected temple in the fort showed a "Brundavana" within the outer court. This is a square brick structure built on a raised piece of ground upon which is planted the purple-stalked basil (*Ocimum sanctum*) or "Tulasi" of the natives; it is preserved and worshipped in honour of Vishnu. These Brundavanas are occasionally seen outside the houses of high-caste Hindus. As the fragrant leaves of tulas (of the natural order Sabiatæ) are sacred to Vishnu so the leaves of the "Bilpatri" (*Ægle marmelos*) are held in veneration of Siva or Eswara. The papaw (*Carica papaya*), although a native of the West, has long been domesticated in India. It has been used for years as an anthelmintic and emmenagogue, but the administration of the juice of the fruit as a "vegetable pepsin" is, even now, little known. It is satisfactory to find the papaw tolerably abundant in these parts. What with the chupatties, the buffalo steaks, the goat-mutton chops, and the curried dishes the Anglo-Indian has at times to devour, the digestion very often stands in need of artificial assistance, and it is a source of comfort to know that such an effective remedy is at hand.

The residents of Seringapatam place arrack and toddy at a discount, as they take their narcotic like the Chinese, by fumigation. They meet together in the evenings and indulge in the soothing influence of the ganja-pipe. The ganja used for smoking is the dried leaves and stalks of the *Cannabis sativa* sometimes mixed with tobacco leaves. Other preparations of the plant are "white and black marjoon." The former is made by grinding the leaves of Indian hemp with milk and adding sugar and spices; it is a mild preparation, and is given to children. The latter is a stronger confection, used by adults, and made with "jaggery," or country sugar. For criminal purposes an extract is sweetened with sugar and flavoured with spices; a piece of this about the size of a pea is quite sufficient to render anyone unconscious for several hours. The first effects of ganja are very exhilarating, and afterwards sedative, or, as described to me by a native gentleman, "It was first like heaven and earth going round on a wheel, and myself with them, and then one gets as sleepy as an owl."

A Kengah Kopalu, on the northern bank of the Cauvery, above Seringapatam, there is a quantity of "red and yellowish quartz," or what to me appeared like porphery. The native doctors here and elsewhere

attach a high value to the mortars and pestles made from this stone, and "kilbuths," or stone vessels used by the natives, are prepared from it. It was anxious to procure a pestle and mortar, but there were difficulties in the way. The proprietor of the quarry resides at Mysore, and when an order is placed with him he sends for the stone, and it is brought back to be worked. As he never keeps anything in stock he cannot be credited with an enterprising character.

I next visited Mysore, the city of palaces and dirt, but have little to report from here. The *Acacia Arabica* or "Kari Jali," the mulberry, *Ficus Indica*, and a species of *aloe* were growing in the suburbs, while *Androcotyle Asiatica*, *Hemidesmus Indicus*, *Rubia cordifolia*, and *Euphorbia pilulifera*, all having great virtues, grow as weeds among the grass. The *E. pilulifera* is allied to the *E. Drummondii* of Australia, and may be found to have the same constituent, viz., an "alkaloid" possessing the properties of calcium oxalate.

The following are some of the exported articles from the districts of Tumkur, Kolar, Kadur, Shimoga:—Gall-nuts, gum, honey, kamala (kapile rung), orris root, areca-nuts, marking-nuts, tamarinds, tobacco, turmeric, cotton, lac, poppy-seeds, coconuts, oils and oil seeds, cummin, fenugreek, capsicum, sugar, coriander, mustard, coffee, ginger, safflower, and cardamoms. Such produce as honey, gum, certain fruits and seeds are gathered by a wild race called "Karumbas," living in the jungles on the south and west of the province. The produce of the country is exported by way of Mercara, to Mangalore on the western coast, or from Mysore and Bangalore by rail to Madras and other stations on the Madras and South Indian railways.

I was unable to visit the gold mines in Kolar, the iron-works in the north, the Astragram sugar refinery (now a distillary), and the tanneries and dye factories, in which a chemist could take delight. But these must be left for other pens to describe. If I have the fortune on another occasion to draw a month's privilege leave, I hope to go to some other part of India, where, if it be as interesting as Mysore, I may be induced to notice other resources of our vast "Empire in the East."—*Chemist and Druggist.*

CHEMICAL NOTES ON TEA.

BY DR. B. H. PAUL AND A. J. COWNLEY.

So far as the chemistry of tea has been studied its most important constituents appear to be an essential oil to which the aroma is due, theine, legumin, and an astringent substance analogous to tannin. With the exception of theine, however, little is known of the chemical characters and relations of these constituents or of the mode in which the quality of tea is influenced by them. For instance, what is commonly spoken of as the "strength" of tea is a tolerably vague quality in itself, and no relation has yet been ascertained to exist between it and the amount of any particular constituent. Considering the physiological properties of theine it might be supposed that the "strength" of tea depends to a considerable extent upon the amount of this substance, and some probability is given to that opinion by the great variation in the published statements as to the proportions that have been obtained from different kinds of tea. According to the earlier determinations by Mulder, Chinese and Java tea were represented to contain less than 1 per cent. of theine. Subsequently, Stenhouse found from 1 to 2 per cent. in a number of samples examined by him, while Peligot obtained from 2·5 to 4, and in one case as much as 5·84 per cent. of theine. On examining the methods by which these results were obtained they all appear to be open to suspicion of inadequacy to meet on the one hand the difficulty of obtaining theine in a sufficiently pure condition, and on the other hand that of extracting the whole of it in such a condition.

The method of sublimation by which Stenhouse* sought to determine the amount of theine in tea is not capable of furnishing correct results, since the greater part of the theine is decomposed, and this circumstance will account for the low results obtained by him. Peligot's method* of treating an aqueous infusion with basic lead acetate, and evaporating the filtrate after separating excess of lead, was equally unsuitable for the determination of theine, since its extraction by water is incomplete, and while the quantity thus obtained cannot be rendered pure by crystallization without loss, there is also a risk of obtaining too high a result if the product is not sufficiently purified before weighing. Consequently the data of both these experimenters cannot be relied upon for accuracy, and the results of some preliminary experiments furnished us with evidence that a further investigation of the subject was desirable. Even Zöller's† more recent examination of a sample of tea from the Himalayas, in which he found 4·94 per cent. of theine, does not sufficiently remove uncertainty as to the amount of theine in average tea, for his memoir suggests that the tea examined by him was of exceptional quality. Moreover, his method of extracting the theine by thoroughly disintegrating the leaves with strong sulphuric acid does not appear well adapted for the purpose. Liebig was of opinion that theobromine was also obtained from the Himalaya tea examined by Zöller, though this point was not settled conclusively, since the quantity of material was too small for the purpose. In two other samples Zöller was unable to find any trace of theobromine. In our analyses of tea we have always endeavoured to trace the presence of theobromine, but so far we have in every instance obtained only negative results. It must, however, be mentioned that as the quantity of tea operated upon for the determination of theine is but small, a minute proportion of theobromine might in that case escape detection, and we, therefore, propose to operate upon large quantities to decide this point.

In the course of an inquiry undertaken for the purpose of ascertaining the circumstances that determine the differences of "strength" in tea, one of the points to which we directed our attention was the extraction of the theine in such a way, that precise analytical results could be obtained, admitting of a comparison of different kinds of tea in regard to the percentage of theine. After several trials we found that the method we had previously adopted for coffee‡ was capable of furnishing satisfactory results, and that with careful manipulation the amount of theine in tea could thus be determined with considerable accuracy.

For this purpose 5 grams of powdered tea is moistened with hot water, well mixed with 1 gram of hydrate of lime, and the whole dried on a water-bath. The dry residue is then transferred to a small percolating apparatus and extracted with strong alcohol. The clear liquor is to be evaporated to remove alcohol, and the remaining water solution, measuring about 50 c. c., mixed with a few drops of dilute sulphuric acid, which separates a trace of lime and partially decolourizes the liquid. After filtering the slightly acid solution, it is transferred to a separator and well shaken with chloroform, which gradually abstracts the theine. This part of the operation requires particular care, for though theine is freely soluble in chloroform it is necessary to shake the acidified water solution with several successive quantities of chloroform in order to remove the whole of the theine. Unless the quantity of theine is very large, about 200 c. c. of chloroform will be sufficient for 5 grams of tea, and that should be used in 5 or 6 separate portions, testing the last portions by distilling off the chloroform in a weighed flask until it is found that there is no more theine taken up. The whole of the chloroform solution is then to be placed in a stoppered separator and shaken with a very dilute solution of caustic soda. This will remove a small quantity of colouring matter and render the theine solution

* *Phil. Mag.*, xxiii. (1843), 427.

* *Ann. Chim. Phys.*, [3], xi., 138.
† *Ann. Chem. Pharm.*, clvii., 185.
‡ *Pharm. Journ.*, [3], xvii., 921

quite colourless, so that on distilling off the chloroform from a weighed flask the theine remains in a condition fit for weighing. When the operation is carefully carried out the theine will be perfectly white. In this way we have been able to obtain results of great uniformity.

Our first experiments were made with Indian and Cingalese tea, the general result showing that both kinds contained a much higher percentage of theine than has hitherto been generally supposed, and that the variation in the amount of this substance was not considerable. In this respect, however, there seems to be a marked difference between tea and coffee; the amount of theine in tea is by no means a constant quantity, and so far as the tea of India and Ceylon is concerned, it varies from 3·22 to 4·66 per cent. This is taking the tea in the ordinary air dry condition in which it met with in commerce. The following table gives the results of our determinations in twenty-eight samples that were selected for this purpose as representing a wide range of quality, as may be understood from the fact that the prices realised by the corresponding parcels in public sale varied from 7*d.* to 3*s.* per pound. The sample No. 10 was tea of exceptionally fine quality, that was valued at 6*s.* or 7*s.* per pound, and the sample No. 4 consisted of the hairs detached from the leaves in sifting:—

		Approximate elevation of place of growth.	Moisture per cent.	Theine per cent.

At present we have not had an opportunity of examining many samples of Chinese or Java tea that could be accepted as authentic, but so far as we have been able to judge the amount of theine is less than in the tea of India and Ceylon. We intend, however, to continue the inquiry in that direction as soon as we can obtain suitable samples. But, so far as the tea of India and Ceylon is concerned, it is at least evident from the data above given, as compared with the prices mentioned, that the marketable value of tea is not to any great extent dependant on or proportionate to the amount of theine it may contain, however important that constituent may be in other respects. Neither can the "strength" of tea, as that term is generally understood, be taken as proportionate to the amount of theine. This is evident from the results of the analysis of the two samples, 26 and 27, which were selected by experienced judges of tea to represent extreme cases of difference as to strength. The amount of theine in 27 is greater than in 26, but to such a small extent that the difference in strength of the tea represented by those samples could not be ascribed to the theine they contain.

It appears to be much more probable that the "strength" of tea is chiefly determined by the amount or condition of the astringent constituent, the precise nature of which is at present only partially known. Moreover, when the mode of preparing tea is considered it is also probable that this quality of "strength" may be largely influenced in degree by the manipulation of leaves in the process of manufacture, which comprises stages of fermentation and heating in the moist state in contact with atmospheric oxygen, both of which are conditions likely to induce alteration of material analogus to ordinary tannin. But before any definite opinion of this point can be offered in place of the general probability above suggested, it will be necessary to acquire a better knowledge of the chemical nature of that constituent of tea leaves which in some respects resembles ordinary tannin.

The commercial value of tea is at present estimated by a combined consideration of several factors, among which appearance counts to a considerable degree. In this respect the size of the leaves, indicating their age, and likewise the presence of what is termed "tip," consisting of the unexpanded leaf buds, serve as indications by which tea is classed partly as Souchong or Pekoe, and partly also as varieties of those kinds of tea. In addition there is also the process of tasting procured by tea brokers. This consists in preparing infusions of the different samples, much in the same manner that tea is commonly used, and then forming a judgment as to the value of the samples according to the aroma, flavour and other characteristics of the corresponding infusions. This is an art that is practised with a surprising degree of precision, so that the results arrived at by different operators agree in a very remarkable manner. In carrying out the broker's test, tea is infused for five minutes in boiling water in the proportion of about 43 grains to 3½ fluid ounces of water. The infusion is then poured off from the leaves into a cup and the value of the tea estimated by its taste, in this operation the soluble constituents of the leaves are only partially extracted, and while more perfect exhaustion of the leaves will give about 35 per cent. of extract, the amount taken out in the ordinary broker's method of testing does not amount to more than 20 per cent. on the average. Hence it is evident that attempts to value tea on the basis of the total amount of extract obtainable by treatment with boiling water must be entirely fallacious and useless for any practical purpose. In respect to the amounts of extract thus obtainable from tea of different qualities, there is not in reality any such difference as would afford indications of the actual differences in value. Peligot and others have made determinations of this kind, showing that different kinds of black tea yield from 24 to 47 per cent. of extract, or on the average 34 to 40 per cent., but these data have little practical value. It is indeed not by the perfect extraction of tea that its value can be estimated. This must be sought for within the limits of extraction which obtain in the ordinary methods of using tea, as is the case in the broker's method of testing, which fairly represents ordinary practice in the use of tea, though the infusion is then made stronger than it is generally drunk.

To obtain some idea of the extent to which the constituents of tea are extracted under those ordinary

conditions we have made analyses of the infusion thus prepared, and have ascertained as a general result that the 20 per cent. of extract taken out by the infusion will contain about one half af the theine present in the tea used. An ordinary breakfast cup of equally strong tea infosion, measuring about eight ounces, would therefore contain two grains of theine, or thereabouts. The rest of the theine is left in the spent leaves, and it requires repeated treatment with boiling water to extract the whole quantity. This is no doubt one of the reasons why the amount of theine in tea has been underestimated in so many instances, since experimenters have operated upon a water extract for its determination. In one instance we found that the residual leaves of tea which had been used in the customary manner contained as much as 1·7 per cent. of theine, and in another case leaves exhausted as far as practicable by percolating with boiling water still contained as much as 0·13 per cent. calculated on the original tea.—*Pharmaceutical Journal.*

THE POSITION AND PROSPECTS OF QUININE.

It is not unnatural, in view of the enormous depreciation in the market value of quinine during the past few years, that it should come to be considered by some that the cost of manufacturing that alkaloid is a factor which bears but an insignificant relation to the cost to the consumer. It has been stated, on apparently good authority, that twenty-five cent quinine was only a question of time, and the inference has been thrown out that the market price of the commodity might even go below that limit and still leave a comfortable margin for the manufacturers. Some attempts have been made to show how very small is the actual cost of manufacturing and marketing quinine, but until last week the lowest estimates we had seen did not go below twenty-five cents. A few days since a circular was issued by a firm in the trade, who, from their connections, might well be supposed to know whereof they speak. The circular reads as follows: —

"From reports of the sale of Java bark at Amsterdam, October 20th, 1887, (see London *Chemist and Druggist* of October 22nd), it would appear that our estimate of the probable future price of sulphate of quinine [25c] was too high. It is noted in the above journal that the 1,717 packages of Java cultivation bark sold at lower prices than at previous auctions, the price obtained averaging one and one-twelfth pence per unit. As this is equivalent to about thirteen and a half cents per ounce for sulphate of quininein the bark, it would seem that further comment on the future is unnecessary other than to note that the sale shows a marked decline in prices since our recent advices to you."

The inferences to be drawn from the above statements are plain, and it is quite probable that the increased weakness, noted in the market a week ago, was attributable in part to their acceptance by outside holders of quinine. At any rate, they drew forth a vigorous denial from a leading firm of jobbers, and a clear exposition of what they consider the actual circumstances from the agents in this city of one of the German manufacturers. The substance of these circulars was given in our market report last week, but we were unable to give in detail the facts from which the conclusions given were drawn. The first mentioned reply to the above quoted circular, referring to the belief that there is no stop to the decline in the price of quinine, that it may be made for a mere nothing, cites some of the expressions which are made as the basis of this belief, among which is the following—"Java bark, containing 11 per cent. of quinine, was sold in London at 37½c, and that planters realize a good profit at present market value." Commenting upon this the writer of the circular says:—

"Upon careful inquiry at headquarters in London, we find that a small lot (11 bales) of Java bark was sold at 1s 6d to 1s 7d, which contained a fraction over 9 per cent. of quinine, not 11 per cent. as stated. If planters could rely on producing such high test bark, it would probably pay them very well to cultivate the cinchona trees; but such bark is very rare, the great bulk testing on an average only about 2 per cent., and realizing about 4d per lb., which can be verified by looking at the result of the London bark sales."

In regard to the recent sale in Amsterdam upon which the estimate of the market value of quinine is based in the circular quoted at the beginning of this article, the jobber who answers it says the average unit value realized was one and a half pence, not one and one-twelfth pence, and consequently the cost of quinine in the bark would be eighteen and three-quarter cents. The cost of manufacturing quinine in Germany was formerly about fourteen cents per ounce but this has been reduced somewhat of late years. If calculated at ten cents this would make the cost of manufacturing and marketing the alkaloid about twenty-eight and three-quarter cents per ounce. These calculations, the jobber says, are based on the recent lowest price of bark, but the manufacturers have been buying bark for the past few months at two pence per unit, equal to twenty-five cents, and, adding ten cents to this as the cost of manufacturing, the actual cost of quinine to the manufacturer would be thirty-five cents. The cost of their present stock must average that, argues the jobber, and it can readily be seen that they must lose money when the market is declining, and profit very little when it is steady. Regarding the probability of a further decline in bark, the writer goes on to say that it costs equal to five and a half cents per pound to market Java bark, and it would therefore require about two per cent bark to pay these expenses, leaving nothing to the planter for cultivating the plantation for six or seven years before the bark is ready for the market. A lower grade of bark would not pay the expenses, and consequently a large portion would not be shipped at all at present prices. The circular concludes with the statement shipments for October have fallen off considerably, and must continue to decrease if prices remain so low as at present. The average unit value at the London sale in 1885 was five and a half pence per unit, in 1886 four pence, and this year about two pence. The writer concludes that it is safe, therefore, to assume that the bottom has been reached. In this statement of the case there is certainly much food for thought, but it appears to us that the immediate future of quinine does not so much depend upon the cost of production. While the decline in bark has necessarily affected the market value of quinine, the most potent factor in the situation is the overproduction of the alkaloid itself. There is a surplus stock of about seven hundred thousand ounces of quinine in this market, and on good authority we learn that there is a surplus of one million ounces abroad. The present stock of bark in Europe and America represents, according to the same authority, three million seven hundred and forty thousand ounces of quinine, giving a total visible supply for the world of five million four hundred and forty thousand ounces, or enough to last ten or eleven months. These figures present even more food for thought than the careful calculations of how much it costs to produce an ounce of quinine. The foreign manufacturers of the alkaloid have striven hard to get a foothold in this market at considerable pecuniary loss to themselves at times, and having not only gained a foothold, but a considerable slice of trade, which as a whole represents an annual consumption of over three million ounces, it does not seem reasonable or likely that they would relinquish any of it. Therefore it would seem hardly probable that so long as present conditions prevail—that is to say, so long as the foreign manufacturers can secure bark at prices that will enable them to place quinine on this market at about present figures—any permanent improvement in the quinine market will occur.

There is, however, one contingency that may arise to change the current of events. We refer to the possibility of a combination of the interests of the European and domestic manufacturers. Until recently there appeared to be no ground for believing

that such a contingency were likely to occur, and there may be now even less ground for such an expectation, but in some quarters the belief, or at least a suspicion exists that the subject is being canvassed by the manufacturers, and recent events, small in themselves perhaps, have tended to strengthen it.

Whatever may be the future course of the quinine market, the fact remained that a firmer tone has been infused into it during the past few days, and there is no doubt, in the absence of any more tangible reasons appearing on the surface, that it is attributable to some extent at least to the discussion created by the bear circular of the Philadelphia parties referred to above, and possibly to the indications, slight as they are, that the manufacturers are considering the matter of an international agreement to regulate prices.—*Oil, Paint and Drug Report.*

NOTES ON PRODUCE.—New markets for Indian and Ceylon tea are wanted, and they will be found; but who is to be first in the field? The United States and Canada should be won over. They drink Japan tea in America because they are used to it, and for the reason that interested persons natually do their utmost to retain the trade in Japan tea. The Ceylon planters are going to make a raid on the American markets and the Indian planters must do the same. It is absurd that this market should be practically closed to the best teas grown, simply because the consumers have had their palates spoiled. The Americans and Canadians may not be tea drinkers, but if they could be persuaded to acquire a taste for Indian and Ceylon teas they would take kindly to tea. The scheme in India for promoting the sale of Indian tea amongst natives has not hung fire. It is announced from Calcutta that shares in the Association to the amount of 100,000 rupees have already been subscribed for, and that the Provisional Committee have resolved to register a company forthwith.—*H. & C. Mail,* 16th Dec.

ESSENTIAL OIL OF SHADDOCK.—Certain West Indian planters who visited this country at the time of the Colonial and Indian Exhibition have since been turning their attention to the cultivation of sundry minor commercial articles which, though still promising a fair profit, had hitherto been neglected, partly because the time of the cultivators was fully occupied in looking after "staples," and also because the requirements and capacities of the European markets for minor products were but very imperfectly known. Among the articles thus recently introduced is essential oil of shaddock *(Citrus decumana)*, of which we recently saw an excellent sample in the hands of a London firm of essential oil merchants. This oil is obtained by the sponge or Ecuelle process from the rind of the shaddock, known in this country as "pompelmousse," or "forbidden fruit." The sample which we inspected is of pale yellow colour, excellent aroma, and pungent, bitter taste, very like orange oil of the finest quality. No attempt has yet been made to extract this oil in quantities large enough to make it a regular article of commerce; but under favourable circumstances the West Indian planter who sent over this trial-consignment would be in a position, we believe, to send over more important consignments. At present a few pounds only are obtainable at a price approaching that of oil of bitter orange, as a substitute for which the shaddock oil is especially recommended. The fruit was brought over to the West Indies more than a hundred years ago from its original habitat, China, by an English captain, named Shaddock, who has thus immortalised himself in one of the largest fruits extant, a single one of which occasionally weighs as much as twenty pounds. The shaddock has a smooth pale yellow skin, and a white or reddish sub-acid pulp. The Chinese "cumquats," frequently sold in Mincing Lane, belong to the same tribe. We should think that the oil might find employment, though the market could easily be glutted, in the manufacture of perfumery, liqueurs, and confectionery.—[illegible]

DOES CINCHONA-GROWING PAY?—A well known Berlin wholesale druggist, Mr. J. D. Riedel, in a recent number of the [illegible], offers his view of the question at what lowest sale-price of bark cinchona-growing can be made to pay. Mr. Riedel asserts that from 1880 to 1882 cinchona exporters in Columbia did not find it profitable to ship any bark for which less than 5*d.* per lb. was paid at the London auctions. It should be noted, however, that at the time the London charges and allowances on cinchona were very much heavier than they are at present, deductions for difference in weight alone amounting to about 10 per cent. During the same period the cost of production of a cargo (equal to 250 lb.) dry cuprea bark in the forests of Santander, where that variety had just then been discovered in immense quantities, was 2¼*d.* per lb., taking into account the loss on the Spanish exchange and the fact that nearly 6 lb. of green bark were required to yield 1 lb. of the dry article. Carriage of the bark through the woods and by the Magdalena River to Savanilla, the port of shipment, amounted, in 1880, to about 2*d.* per lb., but afterwards, when the rate were increased, to as much as 6*d.* per lb. As soon as the London price for this variety averaged below 6*d* per lb., the export of cuprea bark must, therefore, have ceased to be profitable. With the decline in the value of cinchona the exportation of bark from South America to New York and Paris receded to a minimum, and the shipments to London were mostly limited to old stock on hand. The increase of East Indian bark supplies, collaterally with the diminution in the South American shipments, is, in Mr. Riedel's opinion, evidence that cinchona can be produced much more economically in the British and Dutch colonies than in its original habitat. Labour being cheaper in Ceylon than in South America, the cost of collecting bark in the former country may be estimated at 1*d.* per lb. of dry bark, or per 100 lb., 8*s.* 4*d.*; carriage to railway station, per 100 lb., 6*d.*, railway freight and cartage to the mills in Colombo, 1*s.*; repacking, pressing, export duty, and other charges at Colombo, and freight to London, 3*s.* 6*d*; cartage, sampling, storage, and sale expenses in London, 1*s.* 9*d.*; insurance (on 40*s.* per cwt.), broker's commission, interest on money advanced, &c., 5 to 5½ per cent. of 40*s.*, 2*s.* 5*d.*; total costs and charges per 100 lb., 17*s.* 5*d.*, or 2 1-10th *d.* per lb. It follows that if the average price at the London auctions is less than 2 1-10th *d.* per lb., the planter loses money absolutely, and it will pay him better to leave his trees alone or to burn them down, as the cheapest way of destroying them, than to harvest the bark. The cost of turning cinchona bark into sulphate of quinine, Mr. Riedel estimates (for London) at 1¾*d.* to 1 9-10th *d.* per lb. of bark, and the average proportion of quinine in the bark at 1¼ to 1½ per cent. Calculating on this basis, he arrives at the conclusion that if the planter is to receive back the mere cost of collecting and shipping bark, not allowing for any profit, the producing price per oz. of quinine is 1*s.* 3½*d.*—*Chemist and Druggist.*

LOWCOUNTRY PLANTING REPORT:

COCONUTS, CACAO, &c.

SEASONABLE WEATHER—S.-W. MONSOON FAVOURABLE TO THE YIELD OF COCONUT CROPS—PRACTICE OF PERIODICAL DIGGING OR PLOUGHING OF COCONUT LAND DEFENDED—CHEAP LABOUR—PLANT FOOD: THEORIES OF DIFFERENT SCIENTISTS CRITIZED.

Hapitigam Korale, Dec. 1887.

November began and ended with rainy weather, but the two spells were separated by a fortnight of dry weather. On the whole it has been seasonable and satisfactory.

It is during the S.-W. monsoon that coconut trees put on more than two-hirds of the crop of the year. The flowers developed during the N. E. season are either scantily supplied with germs or drop a large proportion, as soon as they begin to make any important demand on the common resources of the tree, and if it has put on more crop than it can carry through the dry season, it keeps on dropping germs and formed nuts till it has no more than it can maintain after a fashion. Thus, though the coconut tree is weakened by the dropping of immature leaves in a protracted drought, it never suffers from overbearing.

Having decided on digging over a field of twelve acres if it was to be managed during the current rainy season I found some little difficulty in getting people to do the work at the rate I decided to give, namely R7 per acre. That difficulty has been overcome, and I have now enough of labour to get over half an acre daily. As the practice of periodically digging or ploughing coconut land has been assailed and declared opposed to agricultural rule, I feel called on to defend it as best I may. In the first place, I have not before heard of the rule in question, and secondly I would not have been influenced by it, if it had been familiar to me from my childhood, while my own experience did not confirm it. I have never said that cutting the primary roots of coconuts was directly beneficial to the tree, but I want a depth of seven or eight inches of the surface soil for the operations of cultivation, and I sacrifice all the primaries that intrude on that space. Moreover, if the young plant be regularly dug round, in a widening circle as its roots extend, the primaries will be kept at their proper level from the first. The secodary roots that branch out into innumerable ramifications, each bearing an absorbing surface at its extremity, are in a different category; the oftener the soil is turned, the more perfectly it is pulverized and aerated, the quicker will they branch out and multiply the absorbing points with or without the application of manure, but more with than without.

As the absorbing surfaces by which the food of plants is taken up in solution are individually mere points, that act only on such soluble matter, as they are in direct contact with, that mechanical condition of the soil, that presents least impediment to the extension and ramification of the roots is that in which the absorbing points are most multiplied, and the healthy growth of the plant most aided. Nor is this the only advantage of frequently breaking up the soil, a loose soil absorbs many times as much moisture as a stiff and compact one, and renders it up very much slowly either to evaporation or percolation. As plants take up that part of their nutriment obtained from the soil in solution, it is only some part of the elements specifically necessary to the plant that are immediately soluble, of which the roots can avail themselves. But in all soils, there are portions of the elements that enter into vegetable organization that are and continue insoluble till chemically acted on by the atmosphere, but the actions of the air is almost entirely excluded from a compact unbroken soil. Thus, breaking up the soil not only gives greater freedom for the extension of roots, but supplies additional plant food.

That water was the sole food of plants was held a century and-a-half ago by the first ranks in science of the day, and that in the name of inductive reasoning. Yule having observed that the roots of plants travelled fast and far in pulverized soil, seized on that one truth as a complete solution of a complex problem, ond taught that the whole art and science of agriculture consisted in the manipulation of the soil. Only thirty years ago the great chemist Liebig thought that plants derived nothing from the soil, but the constituent elements of their ashes. It has been since demonstrated that nitrogen, the most universally present element in vegetable tissues, is not derived from the air but from the soil, and the agricultural chemists of today value manures by the measure of nitrogen they contain. These and many other exploded theories had either some fragment of truth or show of likelihood to rest on. Water is necessary to all vegetation, and some plants flourish in water alone. Almost all cultivated plants grow better on wrought than on unwrought soil, and it required agricultural experience, as well as chemical skill to decide whether plants obtained their nitrogen from earth or air. We have lately heard a theory ascribed to a Welsh gardener, that has neither fact nor likelihood to base on, namely, "that the roots of plants within a circle round the stem" (diameter undefined) "supply fruit-forming material, while all that extend beyond the circle supply only leaf and wood-forming material." This theory was advanced in support of the system of applying manure to coconut trees in a circular trench round the stem, because in that region alone are the fruit-feeding roots. Now in my experience, I have generally found that if I have a good stout stem and a heavy head of leaf, I have a heavy bearing-tree; therefore I manure for wood and leaf, and leave the fruit crop to shift for itself.* The most generally accepted theory on this branch of phytology is that all the absorbing surfaces alike select from the general mixed solution of all the elements in the soil in definite proportions, just those that the species requires and no others, that the crude sap so obtained is passed along the proper vessels till it reaches the leaves, where the air converts it into the specific sap or blood of the plant, and that it then circulates through all the parts for the nourishment in due proportion of all the tissues, root, wood, bark, leaf, flower and fruit.

OYSTER CULTTRE IN FRANCE.

Some remarkable statistics showing the progress of the oyster trade in France have just been published. It appears from them that during the past twelvemonth the beds have produced no fewer than 600 millions of oysters, or ten times more than in 1876. The progress does not concern quantity alone; the quality also shows an equally noteworthy improvement. In 1883 France exported 31 millions, this year the exportation will not be less than 50 millions. The culture of what is known as the Portuguese "naissain" has been eminently successful in France. Formerly France imported great quantities of them; for example, in 1883 she imported 154,647 kilogrammes, representing a value of nearly 2,000,000 f. Instead of importing, she now exports them: thus, for the present year the exports of Portuguese oysters amount to

* This is a rather off-hand way of treating the matter, but when one was to deal with nonsense why be particular?

over 500,000 kilogrammes. The extension of the oyster trade in France during the last ten years is one of the most extraordinary gastronomic features of the times. Not long ago the oyster was eaten only by the bourgeoisie; nowadays the working classes indulge in the succulent bivalve daily, and every wineshop, even in the poorest quarters, has its oyster-stand outside.—*P. M. Budget.*

MINUWANGODA, 6th Jan.—The rain has ceased since the advent of New Year. Most part of the maha paddy crops are ripening just now and a few late sowings are flowering. The common and most formidable enemy of the paddy plant is the fly, it has the characteristics of a bug, and is destructive to the paddy in the flowering stage, as it sucks the sap from the young ovaries. Many remedies are employed in preventing their attacks. The common method employed among the goyas is the drawing of a string steeped in resin oil through the field. The peculiar smell of the resin oil is very disagreeable to it. Several other remedies are applied and generally those are connected with superstitions also. They believe this fly to be the incarnation of a devil and employ charms &c. I have seen these performed both upcountry and lowcountry, and when they are questioned as to the effects they show that it is effective. The reason is, they do these charms when the flies have nearly finished their work, and of course they leave the field after that. Rainy and calm weather is very favourable for the settlement of flies, but in dry weather they cannot frequent open fields. Any insecticide in general use has the effect of driving away this fly; but in selecting one it must be easily procurable and of little cost, and at the same time it must have a power of improving the fertility of the soil also.—*Cor.*

GREEN BUG is referred to in the Planters' Association proceedings, but not much if anything seems to have been done in meeting the request to secure the interest of English scientists and observers. Mr. Isham, we believe, had no response while at home, although he was prepared to get Miss Ormerod to examine and give her opinion on our latest coffee enemy. Still stranger to say, no copy of Mr. E. E. Green's paper and accompanying coloured drawings has been sent either to Kew or to the British Museum authorities! Mr. D. Morris knew nothing of it the day we saw him, and the following is the answer to an inquiry we made respecting "green bug" specimens which we heard Mr. Gow had sent to the British Museum National History authorities:—

British Museum (Natural History), Cromwell Road,
London, S. W., October 22nd, 1887.

J. Ferguson, Esq.

Dear Sir,—Dr. Günther wishes me to say that your letter arrived just as he is leaving town for a short time. Some specimens of coccus were recently brought to me which I presume are the green bug, but I was unable to name the species. They differed somewhat from any we have in the Museum. I shall endeavour to see Mr. Green's monograph, for although the scale insects are not in my department specially; I take an interest in them. The subject, however, is one for a specialist and must be worked moreover by persons on the spot.—Believe me, yours truly,

CHAS. O. WATERHOUSE.

Surely the Government which published Mr. Green's monograph might have sent copies through the Colonial Office to the Kew and British Museum authorities as well as to Miss Ormerod and other specialists. But the Colonial Secretary may say that it was for the Planters' Association to suggest this transmission.

CINCHONA BARK HARVESTING IN CEYLON:—FUTURE PROSPECTS.—We call special attention to the letter of the Chairman and Secretary of the Sockaboemie Planters' Association, Java, published on page 513, with the advice it tenders to the Cinchona Planters of Ceylon. There can be no doubt of the force of the argument in reference to the shipment of inferior twig bark which selling under 4d per lb. sometimes scarcely covers expenditure if all charges are counted. But there is one fact Mr. Mundt overlooks—(apart from the cry of so many of our planters of late years—

My poverty and not my will consents,

and that is the desire of so many men to shave off original bark, in order to get "renewed" as soon as possible. Such harvesting once taken off, can be sold for very little to cover transport charges. Again, in the past many planters have stripped their twigs and branches in order to give employment to women and children while their tea bushes were growing, and the rate per lb. at which this work can be done is very moderate indeed. However, we certainly do believe that there will be a great falling-off in the shipment of such inferior bark as Mr. Mundt and his colleague aim at, in the future from Ceylon. Tea-planting is more and more encroaching on the available labour supply of the country, and there will be soon no hands to spare to strip inferior branch and twig cinchona bark. Messrs. Mundt and Eckhout would have pleased us more, if in addition to their counsel, they had in their letter, told us a little more about Java cinchona. What has become of the 35,000 acres over which shaving was to proceed 18 months ago according to Mr. Mundt's expectation when here in April 1886? Are our Java friends still waiting till their trees are all seven years old?

"MAZAWATTEE CEYLON TEA."—What is to be done to put a stop to the sort of thing brought to our notice by a mercantile correspondent:—"When I was upcountry a few days ago, I was given the accompanying cuttings from home papers about the '*Mazawattee Ceylon Tea*,' and I send them on to you, in case you may wish to show them up a bit. The tea is doubtless mostly rubbishy China stuff, and the sale of it as Ceylon tea is calculated to do Ceylon harm. There is fraud on the face of the advertisement, for, evidently the object is to make people believe that there is a Company of the name in Ceylon." The advertisement is in the Plymouth *Western Morning News* is as follows:—

MAZAWATTEE CEYLON TEA.

This new luxury is a high-class tea, richer and more mellow than Indian or China tea. It is also far less astringent, and, consequently, peculiarly suitable for those of weak digestion. Thousands now drink no other tea, an overwhelming testimony to its dietetic value.

See Medical and Analytical Report.

I certify that I have analysed samples of Ceylon tea submitted to me by the Mazawattee Ceylon Tea Company.

A detailed analysis is appended.

I find that the theine upon which the refreshing properties of tea depend is quite equal to that in the finest teas imported, whilst the tannin, which, from its astringency, makes ordinary teas disagree with many constitutions, is in very much smaller quantities in the Mazawattee Ceylon tea.

Many dyspeptics who are obliged to avoid ordinary tea find they can drink this with great relish, and feel no nervousness or distress after its use.

W. L. EMMERSON, M. D.,
Member of Society of Public Analysts;
Analyst for Counties of Leicester, Northampton, Rutland, &c.

To be obtained from leading grocers, in lead packets only prices, 3s, 2s 6d, 2s 2d, and 2s per lb.

Applications for the Agency for these teas will be entertained from any place in which there is at present no Agent.

MAZAWATTEE CEYLON TEA COMPANY, EASTCHEAP BUILDINGS, LONDON.

Can the "Ceylon Tea Fund Committee" not take some action, in the way of warning the English public through advertisements, about such mixtures as "Mazawattee Ceylon"?

REPORTS ON PRODUCTS OF THE STRAITS SETTLEMENTS.

Gums, Resins, &c.

In these Settlements there appears to be a possibility of some considerable development of trade in gutta-percha and india-rubber, although at present the production is not very great; and in reference to the existing output the following extract from a letter by Mr. N. P. Trevenen, the Assistant Executive Commissioner, and dated October 6th, 1886, will be read with interest:—

"Referring to the wish expressed by you for information as to the places whence the india-rubber and gutta-percha exported from the Straits Settlements are derived, I have the honour to send you the following:—

From British North Borneo:—			
Gutta Percha 549 piculs,	value...	...	$22,924
India Rubber 12 „	„	...	542
From the East Malay Peninsula:—			
Gutta Percha 1,527 piculs,	value...	...	$69,480
India Rubber 61 „	„	...	4,101
From Java:—			
Gutta Percha 584 piculs,	value...	...	$27,250
India Rubber 38 „	„	...	$ 2,240
From Labuan:—			
Gutta Percha 245 piculs,	value...	...	$12,280
From Sarawak:—			
Gutta Percha 2,115 piculs,	value...	...	$125,719
India Rubber 358 „	„	...	$ 14,826
From Sumatra:—			
Gutta Percha 24,966 piculs,	value...	...	$705,843
India Percha 358 „	„	...	$ 14,826
From other islands under Dutch rule:—			
Gutta percha 22,081 piculs,	value...	...	$823,873
India Rubber 110 „	„	...	$ 5,385

The above is taken from the trade returns for 1884, and show the quantities and values from the different places named during that year.

"One picul if 133 lb. avoirdupois weight, and one dollar, at the present rate of exchange, is worth 3*s.* 2*d.*

"Sticklac is obtained almost entirely from French Cochin China and Siam, the values from these countries during 1884 being 8,693 dols. and 42,816 dols. respectively.

"It is of course impossible to give any decided opinion as to whether this rate of production can be largely increased, but considering the extent of the two countries in question there seems no reason why it should not. It was on this point that you were more particular in your inquiries."

The white gutta-percha exhibited was of excellent quality and remarkably clean. Some of it was made up into fantastic shapes, clubs, &c.

From Palembang there was a rather fine sample of hardish india-rubber of a kind which appears to be very suitable for the manufacture of ebonite. This material, although it is, like ordinary rubber, permanently softened and destroyed by sufficient heat to melt it, has when heated a small rather like gutta-percha than like india-rubber. It is exhibited under the name "Gutta Grek," but no particulars as to the output are to hand.

A vegetable juice sent over in sealed tins and marked "Gutta Horfoot," yields a caoutchouc-like material of fair quality, but it appears that the trade in this is by no means developed. It need scarcely be observed that to send the juice to Europe would involve an enormous waste of freight.

Three samples of a sort of caoutchouc similar to the "Gutta Grek" were shown, but no particulars were obtainable. One of these—marked "Gutta Lumbut, Java, from native states," is hard and sound, while another sample marked "Gutta Jettong, from native states," is soft, sticky, and much oxidised. Another sample, simply marked "33," is hard (that is, hard for rubber) and quite sound, although not very clean. The first and third—like the sample referred to as "Gutta Grek"—when cleaned and mixed with a trifle under an equal weight of sulphur, give, on curing, a very sound and satisfactory vulcanite.

The Dammar from Larut, Perak, although rather dark—indeed decidedly dark in colour and mixed with foreign matters, is of good quality and exceptionally hard. This material is said to be form a Dipterocarpous tree and seems to be known indifferently as *Damar degon*, *Damar rookong*, and cat's-eye Dammar. There is no statement as to price and quantity available.

Sticklac was exhibited by the Government of Perak, and if the samples shown fairly represent the average material available, it would seem that the source of lac is well worth attention; the twigs are thickly coated, and the resin is of good quality.

Vegetable tallow (Meinyah Tunkawang).—This name is applied generally to a number of fats which, as before remarked, spasmodically pervade the English markets. The tribe of fat-yielding trees is very large and widely dispersed, and no doubt, could one certain species be fixed, and its product well identified and put to thorough practical tests, it would tend greatly to clear up the existing haziness as to these tallows.

Lant Carpenter,* who has treated this subject pretty exhaustively, as one having considerable practical experience in the matter of soap-materials states that the two distinct vegetable tallows coming from Asia are:—(1) Chinese tallow, from the *Stillingia sebifera*, a white, brittle fat, chiefly produced in the Chusan Archipelago; and (2) Vegetable tallow, from a species of *Hopea*, also *Tetranthera laurifolia* (growing in the Malay Archipelago). The latter appears to be identical with the samples exhibited in bamboo cases as collected by the natives. It is greenish-gray when crude, but after boiling with dilute acid a few times, becomes nearly white. No experiments were undertaken with the actual exhibit, the samples being too small—but previous experience of the writer and others show that this fat is a glycerine of a high solidifying point (85° to 90° Fahr.), yielding hard and white fatty acids, and a good soap. In a dearth of palm-oil, or even as a white substitute, vegetable tallow should have a ready sale. The supply is said to be all-sufficing, but the natives are too lazy to collect and treat the nuts or berries.

Regret may be here expressed that the Hongkong Court did not exhibit either Chinese wax or tallow. Considerable hopes had been entertained that this would prove an opportunity of negotiating a commercial quantity of this beautiful material, the annual production of which is valued at £600,000. Hardly a hundredweight finds its way to England now: perhaps because, in the golden days of spermaceti, Pela was coldly received. Its highly crystalline structure and intense hardness (180° Fahr. m. p.) present some obstacles, but of a noble kind, and doubtless surmountable. Spermaceti appears to have had its day: every year new witnesses an increasing scarcity, and elevation of price (now 2*s.* per lb). An efficient substitute would be highly welcome. The Chinese formerly used all their supply themselves for "lobchoks" &c., but as many tons of cheap scarlet paraffin candles are imported for the same purpose, it may be supposed that a corresponding amount of Chung-pela is to be had.

The Straits Settlements, although including the Cocos Islands, exhibited only a few desultory specimens of copra and coconut oil on which an opinion can hardly be given. The oil does not appear in the English market under a distinctive name.

In the Straits Settlements some very curious soap was displayed. The finer quality was white, and covered with fine crystalline efflorescence. The coarser was dusky red, very gritty, and also coated with alkali. These soaps were evidently composed of coconut oil, saponified directly with the carbonated alkali derived from wood ashes. As a specimen of original soap, possibly typical of the "sope" of the Old Testament, this exhibit was very interesting

Mining Industry.

The Government of Perak, a Malay State under British Protection, sent a collection of specimens and tools to explain how tin ore is dug and washed. At present none but alluvial ore is worked: the deposit of stanniferous sand varies in thickness from 18 inches to 10 feet, and is covered by 6 to 50 feet of overburden.

* "Soap and Candles," E. and F. Spon, London 1885.

This is stripped off by Chinamen using a hoe, with the blade set at an acute angle to the handle and the stuff is carried out of the pits in bamboo baskets by means of a yoke. The tin ground is dug out and brought up in the same way, and then subjected to a first washing in long wooden troughs; the rich concentrate is finally cleaned in a round wooden dish about two feet in diameter and 2 inches deep in the middle—a *batue*, in fact, to use the Spanish name. The clean tin ore is sold to the smelters.

The wash-dirt contains on an average 1 to 2 per cent of tin ore.

The water in the pits is raised by endless chain pumps worked by over-shot water-wheels though some of the larger mines employ centrifugal pumps driven by steam power.

With the aid of the specimens of tools exhibited, and with a little knowledge of the working of alluvial deposits, one could readily form a very fair mental picture of the Pêrak tin diggings.

The total quantity raised in Pêrak in 1884 was 10·190 tons, valued at 3,640,924 dols. independently of what was obtained in other parts of the Straits Settlements. A little fine gold is washed out of the tin sand.

The pamphlet entitled "Notes on the Straits Settlements and Malay States" (Price 3*d.*) has many pages devoted specially to Pêrak and its mines.

Minerals and Gems.

The Hon. D. F. A. Harvey, Malacca, exhibited specimens of stream tin and tin sands and specimens of ironstone &c. from Johor and Geminchi gold-pit. The Government of Pêrak showed wash and tin sand from various regions, gold bearing tin sand from Batang Padang, and specimens of gold dust washed from tin sand from the same locality.

Fruits.

In the notes on Pêrak it is stated that tropical fruits are supposed by the great majority of English people to be far finer, richer, and better in every way than those grown in colder climates; but according to the writer of the notes, such is not really the case. Malayan fruits are admitted to exceed English fruits in size and often in strength of flavour and odour, but it is claimed that the English strawberry, pear or peach (or a green-house pine) is quite unequalled by anything grown in tropical countries. This after all is purely a matter of opinion; and the fact cited that Europeans in the tropics ignore local fruits and fall back on tinned and bottled English fruits, is merely another way of saying that Europeans have certain set habits and tastes, and a love of "home" things, which they will not or cannot give up. It must be remembered, however, that tropical fruits have not, as a rule, received that careful and scientific culture which has been expended on European fruits: in fact that they are practically wild fruits, more or less indigenous to the country, and suited to be used only under the special circumstances in which they are found. A pine-apple grown in a tropical country and costing only a few pence may not be equal in size and flavour to a pineapple grown in an English hot-house and costing twice as many shillings. But what English fruit is so refreshing and so suitable for the composition of a really well-cooked dish in the tropics as the lime?

Opinions may differ as regards the special merits of the mangosteen, "fig"-banana, mango, cherimoya, freshly-gathered date, litchi, a really good orange, or a dozen other tropical fruits that may be named; but if we take each one on its merits, and use it according to the circumstances and habits of the country in which it is found, there are few, if any, English fruits that are so well adapted to refresh and revive flagging physical energies those we meet in the tropics.

Having said this much by way of defence of tropical fruits, I turn to the varied and interesting collections shown in the Court of the Straits Settlements.

The chief price is taken by the pineapples of Singapore, which, preserved whole in syrup, have entered into commerce, and are now regularly supplied by London stores. The pineapple is canned and shipped in a similar manner from the Bahamas, Fiji, and Natal; but owing probably to the greater enterprise shown by Singapore firms such as Bastiani, Tye Seng Bee, and Nethersole & Co., each of whom have London agents, the Singapore pineapple has established itself as one of the best in the market. There were stalls with a tasting-bar maintained at the Exhibition, which no doubt greatly contributed to make the Singapore fruit widely known. The Singapore Preserving Company, the Chasseriau Land and Planting Company, C. Favre & Co., J. Graham and others, exhibited an excellent series of tropical fruits, which attracted considerable attention. Many of these fruits, unfortunately, had only the native names both on samples and in the Catalogue, and hence were difficult to recognise. But the mangosteen, durian, mango, papaw, guava, pumelow, rambutan, banana, lemon, and bread-fruit were easily recognised.

Tea. (Johor.)

The nine samples exhibited comprise specimens of Souchong, Pekoe Souchong, Pekoe and Orange Pekoe. The teas possess fair flavour, but are capable of improvement both in the infusion and in make of the leaf. This will doubtless follow as the process of manufacture becomes better understood.

About 300 acres are at present under tea cultivation, these appear to have been planted with Assam Hybrid seed not many years since. A few parcels of tea have recently been shipped to London and sold in the market.

The climate on Johor is hot and damp, with an annual rainfall of about 90 inches. The soil, except in parts, is not rich. Labour is now chiefly imported from India.

Coffee.

Coffee does not appear to be grown in the British Settlements of Singapore, Penang, and Malacca, except in gardens and on a very small scale; but in the three Native States of Pêrak, Sungei Ujong and Selângor, taken under our protection in 1874, its cultivation has been introduced, and some interesting exhibits from Pêrak testify to the adaptability of the soil and climate for its production.

In Pêrak, where mountain-ranges, reaching to 7,000 feet, occupy a large portion of a well-watered country, a considerable acreage, above 1,000 feet elevation, is reported to be suitable for coffee cultivation, whilst the Liberian sort thrives on the lower slopes and the plains. In Selangor, planting has only been introduced during the last few years, whilst in Sungei Ujong, estates have been established on the slopes of the Berumbun range which rises to a height of 3,000 to 4,000 feet, and the cultivation of Liberian has been introduced on the lowlands. Of the fourteen exhibits from Pêrak five are from the experimental hill gardens opened by Government; the sample marked *hillgarden* is strong and full flavoured, and worth 90*s.*; those marked *Waterloo* and *Hermitage* have probably suffered somewhat in drying, being coarse and musty in the cup, and worth 70*s.* and 76*s.* Such kinds, if properly prepared on the spot, or in London, should the necessary appliances not exist at the plantations, and if perfectly sweet and clean, should supply an extremely good quality, suitable for home consumption as well as export, the coffee being for size, colour, and general appearance, on a par with good Ceylon plantation. The climate, soil, and rainfall are all that can be wished on the Pêrak hills, but the great drawback hitherto has been the cost of labour, which, however, has now been arranged satisfactorily, and the difficulty of transport. One sample of large pale berries, very smooth, but out of condition and mildewed, would be worth 60*s.* if sound; two of Liberian viz., Lindum Estate, in Sungei Ujong, and Waterloo, were very large, and worth 53*s.* to 55*s.*; and three of ordinary Liberian quality 48*s.* to 52*s.* per cwt.; the remainder consisted of parchment and cherry.

The growth of Liberian is not to be encouraged for the reasons stated under the head of Ceylon.

Samples of Bali, Bonthyne, and Philippine coffee, exhibited in the division of the Straits Settlements, were probably not British-grown, but the produce of some of the Dutch islands in the neighbourhood in the Straits.

Tobacco and Cigars.

Guthrie & Co., Singapore.—Tobacco.

Luneberg, Penang.—Cigars and Cigarettes.

Westerhout, J. E., Malacca.—Tobacco.

The short thick Cigars made in these Settlements scarcely deserve more than a passing consideration. Their Chinese character and peculiar flavour preclude them entirely from any possible European trade. The tobacco of which they are made is however admirable, but it is feared that it is imported, and not grown in the Straits.

Silk.

I can find no trace of the existence of any sericultural industry in this Colony.

There was exhibited in the Straits Settlements Court a collection of silk sarongs of interest, from Sumatra, made of silk from Siam. One was of a plaid pattern with representations of flowers printed upon it with gold, the borders having serrations like many of the fabrics of Java. There were also some with gold thread woven along with the silk.

Some of the silks were dyed in purple, blue and magenta, with aniline dyes.

There was also exhibited a case of Singapore sarongs and handkerchiefs.

I am without any information respecting silk-producing Lepidoptera in this Colony.

Timber.

The Timber Exhibits in this Court were trunks of trees, sections, &c. The Forest Department exhibits specimens of wood, fifty-six in number; Dr. T. I. Rowell, specimens of Straits timber, 114 in number; Chi Bun Hong, specimens of timber, fifty-two in number; the Government of the State of Sungei Ujong, ornamental and other woods, twenty in number; and the Government of Perak, woods, forty-five in number—there being, as per Catalogue, a total of 287. Further, there are for Selangor, a collection of timber from the jungles, and some specimens of timber with scientific notes sown by Mr. H. Newton. These exhibits consist for the most part of small pieces, half-sections varying from 12 to 15 inches in length stems of small trees and shrubs, some short cross sections the full growth of moderate-sized trees, upon which, unfortunately, the labels were in many cases damaged, and the names not legible. There were also some prepared specimens about 1 inch by 4 inches by 6 inches, and Mr. H. Newton's specimens 1½ inch by 3 feet of woods in ordinary use in the Straits Settlements, which he had tested experimentally for transverse strength.

These several lots were set out in six parcels, but after looking into them, over and over again, Catalogue in hand, it was found impossible to identify more than a few of the woods. Upon one occasion the Assistant Executive Commissioner joined in the effort, anxious to help, but after working for some time without making satisfactory progress, he came to the conclusion that errors must have occurred in packing the exhibits for shipment.

The following are the woods made out from the parcel shown by the Forest Department:—

Dyera costulata, Hook. f., native name Jelutong; *Eugenia zeylanica*, Roxb., Kelat; *Ingera*, Nipis Kulit; *Litsæa*, Kandis; *Lophopetalum*, Sapah Petei; *Shorea*, Durian Daun; *Terminalia*, Keradei; *Tetranthera*, Melang Telor and Nyatoh. Several of these appeared good in quality, and doubtless would be useful for many purposes.

The "Notes on the Straits Settlements" make no mention of timber as an article of produce; it seems therefore likely that the Colony is dependent, for many of the woods in use there, upon supplies from Borneo and Australia.

The following are a few of the principal woods referred to in Mr H. Newton's notes:—

Afzelia palembanica, Baker, native name Miraboo. A large tree, plentiful, yielding timber of a close fine grain, hard, tough, rigid-taking, a good polish, and suitable for furniture.

Apodytes, Darroo. A moderate-sized tree, yielding timber of a straw colour, having a peculiar aromatic smell; it is easy to work, and suitable for carpentry purposes.

Artocarpus, Kladang. Also a tree of moderate dimensions, yields a light yellowish-brown coloured timber close-grained, and moderately hard, flexible, takes a fine polish, suitable for furniture and ship-building.

Calophyllum inophyllum, Linn. Bintangore or Poon, is of moderate size, and yields timber of a reddish colour, coarse-grained, and moderately hard small masts and spars are made of this wood for prahus and junks. It is suitable for carpentry.

Canarium, Damar Laut, is a large tree, plentiful, yielding timber of a brown colour, close-grained, and very strong; large scantlings for constructive purposes can be obtained from it.

Dialiumindum, Linn., Krangie. A large tree, yielding timber of a dark colour, finely veined, hard, and suitable for furniture and building purposes.

Hopea, Seriah. A medium-sized tree, yielding timber of a reddish colour, close fin grain, moderately hard, suitable for carpentry and general purposes.

Sloetia Sideroxylon, Teysm. & Binn, Tampinnis, is a moderate size tree, yielding wood of a brown colour, close grained, moderately hard, it takes a good polish, resembles Mahogany, and it is suitable for furniture and civil architecture.

Vatica Rassak, Blume, Rassak. A tree, of a large size, yielding timber of a dark colour close-grained, moderately hard, suitable for bridges, piles, carpentry, &c.

The following have native names only:—

Ballow. A large tree, attaining a height of 60 to 100 feet, and 4 to 6 feet diameter. It yields timber of a brownish colour, close-grained, hard, and heavy, very suitable for architecture, and for most purposes where strength is required.

Billian. A tree of large dimensions, yielding timber of a brown and dark colour, close-grained, very hard and difficult to work. It is sometimes called iron-wood, and is suitable for bridges and piles, or any purpose in carpentry where great strength is required.

Damar Putih. A large tree, yielding timber of a brown colour, close in grain, hard and heavy, it resists sea-worms, and is suitable for piles or bridges.

Tambaga. A tree attaining 100 to 150 feet in height and 3 to 5 feet diameter. It yields a strong, rigid wood, suitable for the stoutest scantlings required in either engineering or architecture.

Tanning Materials.

INDIA AND SINGAPORE.*

At present our supplies of tanning material from India are limited to myrabolanes, of which from 20,000 to 25,000 tons reach this country annually. As however, Singapore is subordinate to the presidency of Bengal, we may include gambier in our enumeration, and of this as much as 25,000 to 30,000 tons annually are received, the combined value of these two articles being fully three-quarters of a million sterling. Both were represented in the specimen cases exhibited in the Indian Court, in addition to which there were many varieties of bark, gall-nuts, &c., which possess the greatest interest for leather manufacturers here, and show how rich India is in tanning agents.

The inspection of these serves to account for the development of tanning in India, and the important increase that has taken place of late years in tanned kid, goat, and sheep skins, sent to this country and the Continent, and also to the United States.

By the kindness of Dr. George Watt, C. I. E., the special officer in charge of the Economic Court, many specimens of the under-noted barks have been obtained, and he has also given many valuable and suggestive comments thereon. In some cases only an extract from the notes in the Official Catalogue is given.

1. *Acacia arabica*, or the Indian gum arabic tree, a small thorny tree common everywhere in India. The bark is a powerful astringent, and is one of the tanning substances most extensively used in India. If sent to this country, chopped or ground like mimosa, or as an extract, it would no doubt find a certain market, which would become important, if it were found a desirable addition to the tanning substances used in this country.

* These have been admitted for the sake of comparison.

and could be delivered here at a moderate cost. The pods of this tree when the seeds are removed, are also rich in tannin. If ground to a powder like sumach, and packed in bags, there would be no difficulty in obtaining for it sufficient trial in this country to determine the question of its probable commercial value.

2. *Acacia catechu.*—Cutch, a tree 30 to 40 feet high, abundant in the forest of India and Burma. Its extract, similar to gambier, is well known, but it is not so well adapted for tanning purposes as for colouring and preserving the nets, lines and sails of our fishery industry. The bark, being of pale colour and rich in tanning-property, might find favour with tanners here as a rival to mimosa.

3. *Acacia leucoplœa.*—A tree met with in North, South, and Western India and Burma. The bark is of pale colour, and is valued as a tan, giving a pinky tinge to the leather produced from it, similar to that derived from the bark of another tree of this family (*A. Jacquemontii*).

4. *Arogeissus latifoia.*—This tree is found in the sub-Himalayan tract from the Ravi eastward, and in Central and Southern India. It is very plentiful in Melghat. The bark and leaves are extensively used for tanning in India, and if found suitable for the European market, could be more largely and cheaply supplied, as stated by Dr. Watt, than any other Indian tan. The leaves would have to be ground into dust like sumac, and the bark treated like Australian mimosa, to make them available for export.

5. *Cassia auriculata.*—A common shrub in South and Central India, the bark of which is one of the most valuable of Indian tans. The same remarks apply to this as to the acacia bark above-mentioned.

6. *Cæsalpinia coriaria.*—This is the American divi-divi or sumach. It has been successfully introduced into India, especially in the Madras Presidency, and as it has been found to have a salutary effect on the soil where it is grown, it will doubtless be more largely introduced The pods are not equal in quality to the divi-divi imported from Rio Hache, but there is no reason why with intelligent treatment they should not become so.

7. *Ceriops candolleana.*—Often called a mangrove, a small evergreen tree met with on the muddy shores and tidal creeks of India and the Andaman islands. This and *Ceriops Roxburghii*, are of much the same character, and both are said to yield a bark which is an exceedingly valuable tan, imparting a good red colour to the leather, and which ought to be brought more prominently to the notice of European tanners.

8. *Eugenia jambolana.*—A moderate-sized tree found wild or in cultivation all over India, from the Indus eastward. The bark is a powerful astrigent, and might be a useful tan, but is used chiefly by druggists.

9. *Hymenodictyon excelsum.*—A large deciduous tree with smooth bark, met with on the dry hills at the base of the Western Himalayas, throughout the Deccan, Chutra Nagpur, and Central India. The inner bark is astringent, and might be adapted for tanning.

10. *Mallotus phillippinensis.*—A small tree of the sub-Himalayan tract from the Indus eastward, the bark of which is largely used in tanning in the North West Provinces.

11. *Mangifera indica.*—The mango tree, a densely branched tree, wide on the Western Ghats, the Chutra Nagpur Hills and the Naga Hills cultivated all over India for its fruit. The leaves are used for tanning by the poorer classes in Oudh, and the bark is said to be used as tan in the Dacca district, Bengal.

12. *Phylanthus emblica.*—A moderate-sized tree in the dry forests of India and Burma. The fruit is the emblic myrabolane used in dying and tanning. The leaves are also used in tanning in most parts of India, and are regarded as one of the best tans by the Bengal tanners. If ground to a powder, they would be more likely to be serviceable here than the nuts.

13. *Quercus lamellosa.*—A large handsome tree, with broad serrated leaves, met with in Nepau and eastward to Sikkim, Bhutan, the Naga Hills, and the mountains on the Burma-Manipur frontier In Darjeeling the bark is used for tanning, and it has the appearance of being well adapted for that purpose.

14. *Rhizophora mucronata.*—The mangrove tree, a small tree frequent in tidal forests. The bark is used for tanning, but does not make good leather.

15. *Soymida febrifuga.*—The Rohun tree found in the hilly districts of North-West, Central, and Southern India. The bark is astringent, and a powerful febrifuge, being an excellent substitute for the Peruvian bark. It is of a desirable pale colour, and appears to contain a high amount of tanning principle. Experiments are likely to be made with this bark to test if it is as serviceable as its appearance would indicate.

16. *Tamarix.*—Tamarisk of which these are six species in India, the gall-nuts of which are highly prized on account of the great amount of tanning they contain. They are regarded as one of the most valuable of India tans.

17. *Terminalia.*—Several species of trees belonging to this genus afford valuable tans. The bark of all is rich in tanning material, and the fruits of at least two constitute the so-called myrabolanes of commerce—viz., *chebula*, the black myrabolane; and *belerica*, the beleric myrabolane.

A few other interesting specimens, all more or less useful for tanning purposes, might be added to the list; but they are generally in smaller supply than the above, or not so well adapted for exporation.

The Rev. A. Campbell, Santul Missionary, Chutia Nagpur, exibits an interesting series of myrabolanes, terminalia galls and terminalia bark. The various forest officers throughout India have also contributed largely, and with the special show case furnished by the Chamber of Commerce of Bombay, the collection of India myrabolanes now on view is one of the largest and most complete ever exhibited.—*Straits Times.*

POISONOUS PROPERTIES OF RHODODENDRON LEAVES.

To the Editor of the "Pharmaceutical Journal."

Sir,—In the supplementary note upon Trebizonde honey by Mr. E. M. Holmes (*Pharm. Journ.*, 1887, p 400), it is recorded that Mr. H. Clark states that eight sheep which ate rhododendrons in Syndall Park, Laversham, were found dead the next morning with rhododendron leaves in their stomachs. In the discussion upon the paper I mentioned that a case of suspected poisoning of sheep by rhododendrons had occurred in my own neighbourhood. I have since quite satisfied myself that the stomachs of the sheep contained considerable quantities of rhododendron leaves, and there appears to be little doubt that the sheep were poisoned by these leaves. It is noteworthy that the description of the symptoms of the sheep closely correspond with the effect of the honey upon Xenophon's army. It appeared to me desirable to confirm my previous statement, for apart from the interest it might have as connected with Trebizonde honey, rhododendrons are very frequently cultivated in parks, and their poisonous properties appear not generally to be known (even such botanical works as I have speaking doubtfully on the subject), therefore I do not think that their dangerous character can be too widely published.—J.C. SHENSTONE.

INSECT PESTS.—Pears, Plums, and Apples, are often infested with scale and other insects which, unless the trees receive an occasional dressing when the pruning is completed prove very injurious. The stems and branches ought to be painted over with a solution of Gishurst Compound, at the rate of 4 oz. to the gallon of water, the required consistency being given to it by adding a little clay, lime, sulphur, and soot; and this should be put on with a brush.—*Gardeners' Chronicle.*

SILK CULTURE.

Pen and Pencil in Asia Minor; or, Notes from the Levant. By WILLIAM COCHRAN. Illustrated with eighty-nine engravings, made chiefly from water-colour sketches by the Author. (London: Sampson Low and Co., 1887.)

This well-printed volume of over 450 pages is one of a class that we had thought had become extinct. The notes begin with the arrival of the author at the Alexandra Docks in Liverpool, and are continued almost daily, in some instances hourly, until the close of a five-months' tour through the Mediterranean to Smyrna, Constantinople, and then, with some slight journeys inland, back again by the same route to Liverpool.

No doubt the journey was pleasant, and we feel sure that the note-taking and the water-colour sketching were very agreeable occupations for the tourist; but probably even the author's friends would admit that as now laid before the world the text contains nothing either very novel or attractive, while of the many scenes sketched, omitting the sketches from photographs, we may say that it would be hardly fair to criticize them from an art point of view. The volume is not, however, without its merits. The author deserves credit for the earnest way in which he has called attention to the importance of encouraging the tea and silk industries, and we sincerely hope for the good of our colonies that his efforts in the direction of silk culture in Australia and New Zealand may eventually be as successful as tea-farming has been in Ceylon.

One chief object of the voyage to Smyrna was to see the result of Mr. John Griffitt's silk-farming in Asia Minor. At one time the silk industry was one of great importance in and about Smyrna, but owing to the silk-worm disease it became almost extinct, so that even the very mulberry-trees were used for firewood. Now, through the philanthropic zeal of Mr. Griffitt's in supplying silkworm eggs not only free from disease but raised from carefully-selected varieties, the industry is being restored, and large numbers of mulberry-trees are being planted.

Several chapters in this volume are devoted to the subjects of the rearing of silkworms, and of the treatment of the mulberry-trees. From the hatching out of the larval forms to the reeling off of the silk, only some forty to forty-five days elapse, but though the labour be short, the care and attention required are very great, and the successful silk rearer learns various lessons of method and cleanliness which are of permanent value.

In chapter ix. we have a summary of Mr. Griffitt's valuable report on the silk trade, furnished to the Department of State, Washington. From it we learn that at one time in Smyrna there were three large silk-reeling factories, driven by steam, where hundreds of female hands were employed. When, on the failure of the indigenous worms, Japanese worms were introduced, it was found that it required double the number of cocoons to yield the same weight of silk. With Mr. Griffitt's improved native race of silkworms, the quality of the silk is better, and the produce much heavier than before. To those interested in silk culture we can recommend the perusal of this volume, which, indeed, would be better described as "Notes on Silk Culture in Smyrna."—*Nature*.

A NEW HARDY PAPAW.

Thanks to the courtesy of M. Van Volxem, of Brussels, we have been enabled to see some fruits of a hybrid Carica raised by him. The parentage is complex. First Carica pentagyna was pollinated by C. candamarcensis. The plants of the hybrid offspring were again pollinated by C. candamarcensis, C. candamarcensis, and the seed known but not named by Mr. [illegible] and M. de Melin in a paper in the [illegible] Belgique, vol. x., 1881, and wherein it is mentioned as the common Carica of the Bordering Andes, where it is cultivated up to an elevation of 9000 feet for the sake of its edible fruit. Mr. Spruce adds, that in February he found the ground strewn with the ripe and rotting fruits of this species which were 8—9 inches long, smaller and sweeter than those of the common p aw, and which were the favourite food of the bears whic infest the forests of the mountain of Tunguragua. Growing at such a height the tree in question is comparatively hardy, and it has, indeed, flowered in the open air, but it requires at least greenhouse temperature to ripen its fruit.

Sir Joseph Hooker, who gave a coloured figure and full description of the plant in the *Bot. Mag.*, 1875, t. 6198, vouches for the delicious scent and grateful taste of the fruit, in both of which qualities it differs from the common Papaw. C. candamarcensis is a "graceful little tree," almost hardy, with oblong obovoid, ribbed, yellow, fragrant fruit, the size of a large egg, or larger in its native country.

C. porphyrocarpa is a tender stove tree, which dies off after flowering, and produces scentless red ovoid fruit. The hybrid between the two species named, raised by M. Van Volxem, is as hardy as C. candamarcensis, and produced a dark red scentless fruit larger than that of either parent. The flowers of this last-named hybrid, pollinated by C. candamarcensis, yielded a metis, the fruits of which are now before us.

They are about 4 inches long by 2¼ at the greatest diameter, oblong obovate, slightly ribbed, 5-sided, of a rich red colour, and fragrant. As for the flavour of the fruits we cannot speak favourably, as, before we tasted them, owing to their ornamental qualities they had been allowed to remain on the plant for a twelvemonth, and even then they had to be cut off.

Here, then, we have an ornamental greenhouse plant of the first rank, and one which moreover, produces edible fruit.

As happens occasionally in other fleshy fruits, the seeds sometimes begin to germinate while still within the fruit, so that on cutting open the fruit it may be found filled with young seeding plants. In the natural state the seed is filled with white perisperm or albumen, which surrounds the embryo and provides a store of food for it. This is well illustrated in some of the sprouting seedlings in the fruit before us, which have used up the albumen of the seed, and left the empty husks. In some cases the young rootlets may be seen attacking the albumen, and when that is used up they avail themselves of the pulp in the fruit. A similar occurrence happens in Pernettya mucronata very frequently, and we have seen a similar occurrence in Tomatoes, Melons, and other pulpy fruits.

The Papaws (Carica) are interesting for another reason. It was long ago alleged that tough meat could be rendered tender by enveloping it in leaves of the Papaw, or by hanging it amid the branches of the tree. We fear these statements were either looked on as travellers' tales, or an explanation was provided by the heat of the climate, Nevertheless, modern chemistry has proved the accuracy of the statement by demonstrating the presence in the milky juice of the plant of a substance called papain, which, like pepsin, really has the property of softening and ultimately dissolving albuminous substances, on which account it has been introduced into medicine as an aid to digestion, and as an application for the purpose of dissolving the skin like membrane which forms in the throat in cases of diphtheria. It is as well to mention that the leaves and unripe fruit are filled with a milky juice which has acrid properties, which disappear as the fruit ripens.

As to the name candamarcensis, that, it appears, was first given in Belgian gardens, and adopted by Sir J. D. Hooker in the [illegible] before cited, but the name is sometimes written cundinamarcensis, from the name of the province in which it grows (CUNDINAMARCA).

FOR INSECT BITES.—Three parts of olive oil to two parts of peppermint, one part ammonia and one of glycerine. To be well shaken before applying to the hands or face. Avoid getting the mixture into the eyes.—*Chemist and Druggist*.

TEA CULTURE IN THE CAUCASUS.—A wealthy firm of tea merchants, one of the largest in Russia, has acquired extensive tracts in the neighbourhood of Soukhoum Kaleb, and along the Circassian coast, on which they are about to raise tea plantations. These will shortly be placed under the care and direction of Russian experts, who have been sent to China to study the tea culture, and are now about to return.—*H. & C. Mail.*

WYNAAD PLANTERS' ASSOCIATION.—14th December.—Cinchona.—Mr. Lamb at the Honorary Secretary's request gave the following figures with regard to the Ledger trees, from which the barks of which the analyses were given in the September Proceedings, were taken. 36 trees, 5 years old gave an average of ½ lb. original dry stem bark shavings per tree; six months after they gave 3 1/3 oz. renewed bark per tree from uncovered stems, and 4 2/3 oz. per tree from covered stems. The trees suffered considerably from shaving, and 10 to 15 o/o died down as far as they had been shaved. 161 five years old double stemmed Ledger trees of which one stem was coppiced gave 425 lb. dry shavings of stem branch and twig bark.

PRUNING FOR A CROP.—Pruning is one of the most important factors in hardy fruit culture, and where the knife is used with judgment, other conditions being equal, the results are invariably satisfactory, but when used indiscriminately, without regard to the nature or character of the tree, the reverse is more often the case. The following remarks of our correspondent, Mr. Watson, of Englehurst, on this subject are well worthy of attention:—Take bush or pyramid Apple trees, for instance; we frequently see the trees cut hard in every season to the old stems, with scarcely a fruit spur on them, the branches disposed regularly all round, and of uniform shape and height—pretty to look at when in growth, but when fruit time comes the crop is small or none: the few fruits they do bear no doubt being of good size and quality. This close pruning may answer with some varieties but not with the greater number of the varieties of Apples. Young trees by careful root-pruning may be brought into bearing without much use of the knife, but too frequent pruning of the roots has a tendency to stunt the trees, and fruit of best quality cannot then be expected. A moderate healthy growth is necessary to produce a full crop of fine fruit, and this should be the object in all pruning. Trees having made healthy shoots from 1 to 3 feet in length, and having few or no fruit spurs among the older branches, should have the terminal shoots on all the main branches left their entire length, while all the inner growths should be cut back to an eye or two. The shoots left will, during the following season, form fruit-buds at almost every eye, and these buds invariably grow into fruit-spurs, and bring the tree into a fertile condition. The tree having got well furnished with bearing wood, the annual growths may then be cut back to an eye or two, leaving the leading shoots a little longer. Some varieties form their flower-buds towards the ends of their shoots; such should only have the branches thinned out when they are too thickly placed, and those branches that are getting extended too far should be chosen for removal. There are some varieties, amongst which may be named Northern Greening, that form fruit-buds and spurs, no matter how hard the trees are pruned; but where satisfactory results are expected, fruit trees must be allowed a fair amount of natural development. The same principles of pruning Apples apply also to Pears and Cherries. Plums may be pruned in closely, and still bear fair crops, but where fruit of high quality is required, a considerable amount of annual growth must perforce be left Gooseberries and Currants were formerly spurred in hard, but now we simply thin out the branches, and get better crops and finer fruit. These remarks apply, of course, to fruit trees grown in the open, but the principle applies with equal force to trees on walls. Pear trees on walls which only bear a few fruits at the extreme end of their branches (and that is mainly where the young wood is left) are often got to bear all over by leaving at intervals on the branches a few strong shoots, which can be fastened in neatly in a line with the main branches, afterwards cutting away the old bar ren spurs to let in sunlight; such shoots will form fruit-buds during the following season, and will carry fruit the next.—*Gardeners' Chronicle.*

QUININE PRODUCTION.—I very recently gave you the substance of a foreign opinion upon the cost of quinine production in England: since that date I have met with further remarks on the same subject from a totally different quarter, viz., New York, a trade journal of which centre contains the following statement which may be of some interest to your planting and commercial readers:—A controversy over the cost of producing quinine has been started within a few days, through the issuing of the circular, the tendency of which was to create the impression that this cost is a very small item, scarcely worth consideration as a factor in establishing a market value for the alkaloid. This has brought forth statements regarding what are considered the actual facts from at least two houses in the trade here, and further literature on the subject may be expected. One of these statements, issued by the agents of a German band of quinine, referring to the wrong impression which is gaining ground regarding the cost price of the article, says that the principal error in all of the calculations regarding the cost of making quinine is based on the supposition that cinchona barks coming in auction contain 11 to 12 per cent of quinine. The writer of the circular expresses doubt if ever a single package was found to test as high as that. It is true, he says, that the Java barks are running much higher in their percentage of alkaloids than those of Ceylon, but the Java barks sold for manufacturing purposes run also far below 11 and 12 per cent. At the last auction in Amsterdam the 119,500 kilos. of bark contained 8,947 kilos. of quinine, or about only 4·14 per cent. Further, the consumption of quinine cannot depend on the Java product alone. Not a tenth of the actual demand could be supplied by it. The writer then submits statistics of the quinine strength of the bark sold at the London auctions since May 26th, which show an average of 1·85 per cent. of quinine. The actual cost price of barks, regarding which erroneous impressions also prevail, is then discussed, and statistics are given to prove that the bark as it comes into London, to the auction, is charged with actual expenses of 2 02d per pound, and this does not include the cost of cultivation, nor any benefit due the planter. Therefore, if the barks do not bring more than 2d per lb., the planter loses not only his bark but does not even realize the actual cost of getting his product to market. At the auction of October 29th, the price was below 2d per pound. From this the conclusion is to be drawn that there is certainly no justification for basing calculations for a staple market price of quinine on such a state of affairs as now exists, at least not so long as fundamental changes occur in the condition of bark supplies. The other circular to which reference has been made, coming from a leading firm of jobbers, comments upon the same false impressions, which it endeavors to set straight by producing convincing evidence as to the actual state of affairs. The circular covers the ground fully, but we regret that we have only space for a few extracts. Regarding the cost of producing quinine, the writer says that, in Germany, it was formerly estimated at 20 marks per kilo, or about 14c per ounce, but improvements of late have reduced this. If this cost is calculated at 10c per oz. including commission for bying bark, shipping charges, and freights to factory, actual cost of manufacturing, packing, and commission for selling the product, interest on plant, wear and tear, etc., and calculating cost of the bark at 18¾c. the actual cost of production is found to be 28¾c. These calculations are based on the lowest cost bark, the prices paid for the bark during the past few months being such as to raise the result to 35c as the actual cost of production.—*London Cor.* Local "Times."

Correspondence.

To the Editor of the "Ceylon Observer."

MR. JOHN HUGHES ON TANNIN IN TEA; THEINE; AND TEA ANALYSES GENERALLY; "THE JUBILEE VOLUME ON CEYLON."

London, E.C., Dec. 2nd, 1887.

DEAR SIR,—Since you left I have determined the amount of theine in the Naseby tea, the mean result of the determinations being ·625 per cent, the actual figures in each case being ·60 by one method and ·65 by another method. This is certainly low* when compared with published results, for according to Stenhouse two per cent is the average found in teas of commerce. In certain green teas Peligot found as much as six pounds in every hundred pounds of dried tea; but so large a proportion as this is very rare. In another Ceylon tea, however, grown at the comparatively low elevation of 2,500 feet, only ·26 of theine was found while there was 15 per cent of soluble tannin and the liquor produced was considered decidedly strong. The proportion, therefore, of theine found in the Naseby tea if small was yet twice as much as that found in the low-ground tea. We must remember that theine is an extremely volatile alkaloid, so that no doubt a certain proportion is frequently expelled during the process of firing, and the higher the temperature the greater the loss. Theine has no smell and only a slightly bitter taste. It has, therefore, very little to do with the flavour of the tea from which it is extracted, and it is much more reasonable for us to regard the peculiar essential oil as the chief factor in producing the fine aroma of good tea. At the same time the strength of tea is doubtless dependent upon the amount of tannin present. Consequently, we may expect that in hot countries, such as India and Australia, Indian and Ceylon teas containing much tannin will be greatly preferred to ordinary China tea on account of their greater astringent properties. Indeed, we might from this argue that strong tea will generally be preferred in hot climates, and the finer quality tea possessing less tannin in more temperate zones. I know myself that Anglo-Indians who have been accustomed to give their children comparatively strong tea in India find it necessary to reduce the strength when coming to reside in England.

For old or very young persons the less tannin the better, hence the value of high-grown tea, such as that of Naseby. Tea acts not simply as a beverage, but as a food, the soluble extract being specially rich in nitrogen compounds. No wonder therefore that tea should be a favourite—on the one hand with the poor, whose supplies of substantial food are scanty—and on the other with the aged and infirm, especially of the feebler sex whose powers of digestion and whose bodily substance have together begun to fail.

Again in the case of strong tea how useful is the astringent power of the tannin in bracing up the body for special exertion or in checking internal disorders. How common it is to hear of the recovering patient ask for "*a cup of tea*" and to prefer to drink it without milk or sugar so as to enjoy the full benefit of the natural beverage.

In conclusion I think planters who may wish to know something definite respecting the properties of their tea, which affect their sale in the public market, will find it useful to have the proportion of *tannin* rather than *theine* determined as well as an estimation of the amount of *essential oil* present. It would also be useful to ascertain to what extent the proportion of these constituents may be influenced by the processes of manufacture such as withering and firing, for these operations are, or should be, conducted on chemical principles to produce certain results.

The splendid Jubilee copy of "Ceylon in 1887" reached me last week and is a volume of great interest and of great value to all who may intend visiting the island or who already have important connections with it.—Wishing you the compliments of the season, believe me, yours faithfully,

JOHN HUGHES.

* It has been suggested that the low proportion of tannin in this case may be due to the tea-bushes being specially young—the first plucking. Further analyses later on may throw light on this.—ED.

GOOD, PRACTICAL ADVICE FROM JAVA TO CEYLON CINCHONA PLANTERS.

Java, 12th Dec. 1887.

SIR,—If, in submitting the following remarks to the attention of those of your readers that are interested in cinchona cultivation, we intrude upon the valuable space of your paper, we trust the importance of the subject under consideration may excuse us for so doing.

When, some fifteen years ago, leaf-disease dethroned Ceylon's popular "King Coffee," a great many planters went in for the cultivation of "new products," in order to make up for the loss of their gradually dying-off coffee shrubs. Amongst those new products cinchona held a prominent place, *et pour cause*, for if only a tenth part had come true of the calculations which in those times were made as to the probable profits this product was to yield, cinchona-planting would have been a first-rate business indeed.

But, unhappily, those have proved right who prophesied, that in a case as of this drug, which only commands a limited market-field, overproduction of bark would soon be sure to come and force prices down, to an extent of which in those times few people ever dreamt. In fact, the unit, which four years ago was 1s 4d and more, now stands at 2¾d after having been at 1d and 1½d in October last.

Still we think—and we are able to corroborate our opinion by facts—that this tremendous fall in prices must principally be ascribed to many Ceylon planters having harvested and exported barks, which at their sale did not realize prices sufficient even to repay the *direct* expenses of harvesting, *i.e.* of collecting, drying, packing, transporting and selling put together. So they have swamped the market with inferior barks without sensible profits—if indeed any—to themselves, and to the great prejudice of those who exported barks of finer quality (amongst these our Java planters), but only got these paid for at unit prices in every respect disappointing the most prudent calculations made beforehand.

In looking over the regular market reports of London broker firms of the last two years, we find constantly that a great part, and, in later times in fact from a third to a half, of the bark offered has been disposed of at prices ranging under 1d per lb. We are unable to exactly estimate the cost of production per lb., which Ceylon planters have to pay for the bark as delivered at the London market, but according to information which our President, Mr. Mundt, collected on his visit to your beautiful and hospitable island in April 1886, we suppose that near this price of 1d per lb. lies the limit, where planters in your colony are able to sell their barks with a profit on the *direct* expenses. An estate which is devoted to cinchona planting exclusively, will of course,

have to fetch much higher prices in order to cover its general expenses, and even for estates where cinchona is planted as a bye-product, the aforesaid limit must in our opinion be put at a higher point, because of the part of general expenses, which falls in that case to the cinchona side of the account.

Be this as it may, the fact remains that considerable quantities of bark have been sold at from 1d to 2d per lb., whereas a few months ago some lots of bark were sold at Colombo for even 1-5th d. per lb. We fail to understand the motives which may have induced managers of estates to throw away their money in harvesting and selling such very inferior barks. Ceylon planters have greatly injured themselves and others by so acting, for a simple calculation will, we think, tend to show that if they had kept down their exports of bark, only harvesting the really paying qualities, they would as a whole have made larger profits than now have been their share.

From 1st October 1885 to 30th September 1887 Ceylon has produced about 29 million lb. of bark which have averaged about 2 per cent of sulphate of quinine. Now amongst these exports have been about 12 million lb. averaging no more than ¾ per cent of sulphate, so the remaining 17 million lb. have averaged about 2·88 per cent of sulphate of quinine.

Supposing these 12 million lb. of inferior quality had not been exported, a quantity of about 90,000 lb. or 1½ million ounces of sulphate of quinine would never have entered the market, and we think we may safely assume, that in this case we should not be suffering under low prices as a consequence of overproduction of the drug. This being admitted, there is no reason why prices should have fallen below those reigning in 1885, the less so, because at their rate a daily dose of quinine (15 grains) did not cost more than 1 1-5th d.

Now unit-prices in the last three months of 1885 averaged about 4½d, whereas in the three months ending with September last they averaged no more than 1 9-10th d. During the whole of the two years mentioned the average was about 3d.

The 29 million lb. of exported bark therefore realized a sum of 29,000,000 × 2 × 3d = about £725,000 from which amount the direct harvesting expenses for 29 million lb. must be deducted in order to arrive at an estimation of the profits made.

But if the 12 million lb. of inferior bark mentioned above had been sacrificed, the exports would have amounted to 17 million lb. only, which, sold at a unit of 4½d. would have realized a sum of 17,000,000 × 288 × 4½d = about £920,000 from which amount the direct harvesting expenses for 17 million lb. only would have to be deducted in order to calculate the profits made.

We do not pretend these ciphers to be mathematically exact, but as a whole they may, we think, be accepted as showing the situation as it has been and as it would have been if some planters had not continued to export bark of very inferior quality without any profit to themselves and indeed to the detriment of all, and this notwithstanding repeated advice to the contrary from European brokers.

We beg to put these facts before every cinchona planter and every cinchona-planting company, and think, they prove conclusively that by adopting the method of having each lot of harvested bark analysed by sample, before deciding to send it off or not, and by holding strictly back all barks, which are not *quite sure* to pay the direct expenses, we may arrive perhaps at forcing the market up, but certainly at steadying it to the advantage of all concerned.

Allow us, Mr. Editor, to offer you our sincerest thanks for the insertion of this letter in the columns of your paper, and believe us with best wishes for the prosperity of your splendid colony,—Your obedient servants,

THE SOEKABOEMIE PLANTERS' ASSOCIATION,
G. MUNDT, *President*,
J. N. ECKHOUT, *Acting Secretary*.

"A CHANCE FOR CINCHONA PLANTERS."

Kensington W., 15th Dec. 1887.

SIR,—Owing to the large sales of quinine during the past 3 weeks for forward delivery by the foreign manufacturers at the late reduced prices, the price for this commodity has naturally risen to a very large extent, varying from 80 to 85 per cent.

As is always the case with these speculations the growers of the crude article pour their stock on the market while they can get a shade better price for their goods, forgetting that, by so doing, they break down a market that would help to repay them for the long term of bad prices.

If the agents here would only exercise their influence in advising growers to limit their shipments and allow the bark to remain on the trees, they would not only improve the quality, but reap the benefit of high prices, which the enormous sales of quinine for forward delivery in January, February and March must command, thus reducing their expenses in freight, labour etc. at least 100 per cent. On the other hand by selling double the quantity (or I might say giving away) for the same returns, they not only knock down a market which has been made for them, but bring about a state of things worse than before.—I remain, yours truly,

AN EX-PLANTER.

CINCHONA HARVESTING.

Colombo, 31st Dec. 1887.

SIR,—The subject touched upon in the letter from the Soekaboemie Planters' Association of Java appearing on page 513 is, I think, deserving of the fullest attention of Ceylon cinchona planters at this time. As you point out the officers of the Java Association have taken no account of the great advantage to the labour force of Ceylon that the harvesting of cinchona branch bark was a year or two ago—to which cause a large proportion of the export to which they take exception is attributable; but as matters have turned out there can be no question that that advantage was purchased dearly. The only thing to be done now is to profit by experience. There is no plethora of labour for which employment must be found, and therefore no excuse for harvesting unprofitable barks. The officers of the various District Associations should constitute themselves a sort of Vigilance Committee, and "jump on" any man found harvesting bark not likely to contain at least 1 per cent. of quinine.

ROBUSTA.

["Robusta" adds:—A Happy New Year to you, and to all readers of the *Observer* except those (if any) who won't throw away their low class bark. His limit of one per cent, however, is a safe one, for during the recent depression 2 per cent crown barks realized no more than 3d per lb!—ED.]

TEA EXPORTED FROM RUSSIA (BATOUM)?

4th Jan. 1888.

DEAR SIR,—In *Public Opinion* of the 2nd ultimo, there is an article extracted from the *Pioneer*, on Indian tea in China, and in that article it mentions, *inter alia*, the shipment of 6,800 lb. of tea from Batoum on the Black Sea "of all places in the world." When I was in England last autumn,

I saw Russian tea advertised largely in the Liverpool and Manchester grocers' shops at 4s 8d per lb! I thought this was just another instance of the gullibility of the British public, who will take anything extensively advertised. The Russian tea I took to be China tea, shipped to Odessa originally, or brought overland, and shipped from some Baltic port to London, but probably it may be the real article grown in Circassia, as I have seen it stated in the papers more than once that the Russians were trying to grow tea in their southern possessions, where doubtless it is hot enough in summer. Can you throw any light on this?—Yours faithfully, A. L. C.

[We believe our correspondent was right in supposing the so-called "Russian" tea to be the China article packed after the Russian fashion, and we cannot think that the tea said to be shipped from Batoum (the port last annexed by Russia) can be otherwise than of foreign growth—a quantity re-shipped in fact. Tea is said of late to be experimented in on the Caucasus, but even if the bushes had come into bearing, the product would scarcely be sent away from the country—ED.]

RUST.—All steel articles can be perfectly preserved from rust by putting a lump of freshly burnt lime in the drawer in which they are kept. If the things are to be moved (as a gun in its case), put the lime in a muslin bag. This is valuable for specimens of iron when fractured, for in a moderately dry place the lime will not want renewing for years, as it will absorb a large quantity of moisture. Articles in use should be placed in a box nearly filled with thoroughly pulverized slacked lime. Before using them they should be well rubbed with a woolen cloth.—*Florida Dispatch.*

THE DIVI-DIVI TREE.—At the beginning of the year the Secretary of State, says a contemporary, brought to the notice of the Bombay Government an offer made by a firm of tanners in Glasgow, if steps were taken to extend the plantation of the Divi-Divi tree, to take over 8,000 tons of pods yearly at £7·10 to £8 per ton delivered at Glasgow. The subject has since been thoroughly gone into, and the India Office has just been informed that the terms offered are not favourable enough to encourage the free cultivation of the plant. The Bombay Government, however, is willing to grant concessions in the way of remission of assessment with the object of encouraging cultivation.—*Pioneer.*

LIBERIAN COFFEE.—A Northern Australian paper says: Mr. Holtze who has returned from a trip to the Adelaide river has kindly showed us a specimen of the Liberian coffee plant taken from the block of land experimented on by Fisher and Lyons. To us it appeared a perfectly healthy plant, entirely free from say traces of the ravages of insects and Mr. Holtze describes it as a fair average specimen of some 10,000 plants growing on the plantation. He had taken from the plant no less than 320 berries, and as it is only about three years since the plantation was started, and during the major portion of that time it had been utterly uncared for, the bush gives an excellent idea of what might be done by careful cultivation. The whole of the plants are said to be in a fine healthy condition, with an average height of three feet, and many are already bearing luxuriantly. It is the intention of Mr. Holtze to send the plant to Adelaide as a practical proof of what the territory can do in the way of growing coffee, and if such a result can be furnished by a plantation that is allowed to run wild, we think it is only a fair assumption that the industry would well repay a little care and attention.—*Adelaide Advertiser.*

THE VIRTUES OF BORAX.—The washerwomen of Holland and Belgium, so proverbially clean, and who get up their linen so beautifully white, use refined borax as washing powder instead of soda, in the proportion of one large handful of borax powder to about ten gallons of boiling water; they save in soap nearly half. All of the large washing establishments adopt the same mode. For laces, cambrics, etc., an extra quantity of the powder is used, and for crinolines (requiring to be made stiff), a strong solution is necessary. Borax being a neutral salt, does not in the slightest degree injure the texture of the linen; the effect is to soften the water, and therefore it should be kept on every toilet table. To the taste it is rather sweet, is used for cleaning the hair, is an excellent dentrifice, and in hot countries is used in combination with tartaric acid and bi-carbonate of soda as a cooling beverage. Good tea cannot be made with hard water; all water may be made soft by adding a teaspoonful of borax powder to an ordinary sized kettle of water, in which it should boil. The saving in quantity of tea will be at least one-fifth. —*Exchange.*

CACAO ADULTERATION.—Although we have heard a great deal at various times about the adulteration of coffee and the shameful tamperings with tea, very little has been said or written about frauds with cocoa, the worst that has ever been reported of this article being its admixture with sugar, arrowroot, &c., but I notice that, in a trade circular from Amsterdam, complaints are made of the attempts by a London firm to induce the cocoa manufacturers of that city to give them orders for chemical adulterants to blend with their goods. Here is what in their letter the firm in question say:—"We hand you herewith sample of a finely levigated brown which we are supplying for the purpose of bringing up the colour of cocoa; it is perfectly harmless, and, being of light gravity and rich colour, is particularly well adapted for the purpose." The sample is a mineral brown, and upon analysis was found to consist simply of oxide of iron and a little alumina—certainly not very desirable ingredients in cocoa or chocolate. The object in recommending a rich brown coloring matter is doubtless to enable the manufacturers to add more rice flour and other ingredients without reducing the color of the cocoa too much, and, though the additional quantities of adulterants may not be very objectionable in themselves beyond the fraud practised upon the consumers, the blending of chemical colouring matter is certainly objectionable. Cheapness, which in these days of competition is the backbone of most trades is assuming many harmful features.—*London Cor.* Local "Times."

"COCO" AND "COCOA."—Under Science Gossip in the *Athenæum* of December 10th we read:—

In the new number of the *Annals of Botany* Prof. Bayley Balfour writes on a current mistake to which the *Athenæum* has more than once called attention, namely, the erroneous spelling by which the *coco-nut* is confused with *cocoa*, the product of the cacao tree. Prof. Balfour shows that the early authorities never made this blunder, and that its beginning was probably in Johnson's 'Dictionary,' where, under the heading *cocoa*, Dr. Johnson erroneously confounds the two articles, one of his quotations from Miller applying to the coco-nut while the other from Hills refers to cocoa. But botanists long after this stuck to the right form (as does Lord Tennyson in 'Enoch Arden'); and Prof. Balfour calls upon them to range themselves under the "careful writers" and those who know, and to spell "coco" correctly. A curious circumstance is that Dr. Johnson appears subsequently to have learnt that the coco-nut was not the source of cocoa, since in his 'Life of Drake,' 1779, he correctly used the form of *coco*, pl. *cocoes*; but this was too late for correction of his unfortunate mistake in the 'Dictionary.'

Tennent, in his book on Ceylon, adopted the correct spelling "*coco-nut*" and we have done the same in our various publications; but in speaking it is impossible to distinguish between *coco* and *cocoa*, and the latter word has, unfortunately, obtained too great currency in Mincing Lane and other home markets, to be got rid of. The Dutch have adopted the Malay name of the coconut, *kalapper* (spelt by them *klapper*).

HOW DRAINAGE AFFECTS VEGETATION.

If a sample of common soil is examined with a magnifying glass, it is found to be composed of numerous fragments of minerals of various kinds, humus, muck, and often of undecomposed vegetable or animal matter. These fragments are very irregular in form and size, and are in contact only at their more prominent corners. They might be compared to a mass of coal of various sizes mixed together, the difference being that the fragments of coal are all of one substance, whereas the soil is composed of various substances. Now we know that if we pour water over a basket of coal, a thin layer of water adheres to each fragments and the rest passes off through the meshes of the basket. Just so, when a soil is wet by the rain, each tiny fragment is surrounded by a thin film of water, and the rest, if the soil is in a normal condition, filters through and flows away. As the fragments of the soil are very much smaller than those of the coal, while the film of water that adheres to the particles is perhaps just as thick, it follows that the amount of water, retained by a given bulk of soil is vastly greater than by an equal bulk of coal.

Suppose we put the coal in a light pail instead of a basket, and then pour on water. Of course the water fills the interstices between the fragments and the air is all driven out, except a few bubbles that become entangled. This is precisely what happens when heavy rains fall upon a soil that has an impervious clay subsoil. The spaces between the particles become almost all filled with water, and the air with the oxygen it contains, is mostly driven out.

Botanists tell us that the root-hairs, that supply the roots with water and its nourishing substances in solution, cannot live without oxygen. If the oxygen is shut away from roots, therefore, the roots will die. In dying they not only injure the plant to which they belong, but the matter of which they are formed soon undergoes decomposition, and generates gases which are injurious to other healthy root-hairs in the neighbourhood.

To be sure, the rain-water, as it falls upon the soil, is charged with oxygen, but in passing downward a part of this is filtered out; another part unites with organic matter in the soil, so that after the water remains for a time it becomes deficient in the life-giving oxygen. Hence it is that when a soil is filled with water the roots of land plants cannot live in it in a healthy condition.

When, however, we provide an outlet for this surplus water, it slowly flows away, and in doing so the air forces itself in from the top of the soil, and the roots are abundantly supplied with oxygen. From time to time rains come, and, temporarily filling the cavities of the soil, drive out the air within them that has given up a part of its oxygen. As this water passes off through the drainage, fresh air enters again, and thus the roots are kept supplied with oxygen.—Prof. E. S. GOFF, of N. E. L. Station, in Philadelphia *Weekly Press.*

THE STUDY OF VEGETABLE PHYSIOLOGY.

A great change has of late years come over the subject of botanical teaching in this country. Up till recently much stress was laid upon the investigation of the outward conformation of flowering plants especially, and upon their orderly classification according to the natural system. Minute anatomy, such as requires the aid of the compound microscope, and of chemical reagents, was less attended to, while vegetable physiology or the investigation of the mode of action of living plants was almost entirely neglected. The lower orders of plants, so called, were little studied—so little, indeed, that even A. Berkeley thought it requisite to state in his celebrated *Introduction to Cryptogamic Botany*, that the student of cryptogams need not blush for the subject of his choice! Of late years, chiefly owing to the introduction of German methods of tuition, and to the mode of instruction by means of specimens selected as types of each principal group, matters have greatly altered. The system of instruction from type specimens was introduced into this country by Huxley and Rolleston in the case of animals, and adopted by Dyer in the case of plants. The plan, in general terms, consists in the lecturer detailing to his audience the salient features of each group, illustrating them by diagrams or black-board illustrations, and then placing in the hands of the pupils, specimens of the plants, in order that they may for themselves work out the details sketched in outline by the lecturer. The pupil, according to this method, is compelled, not only to use his ears and attend to what the lecturer or the text-book may tell him, but also to prove its correctness by his own individual extertions. The efforts of the student in following out this plan, and especially the necessity incumbent upon him of making drawings of what he sees, are especially valuable as discipline; and for those who wish to gain a general idea of the whole subject no better plan can be conceived. For the acquisition of special knowledge, however, there is nothing to equal the preparation under the master's eye, of a comparative monograph of a single group. It is a question whether the pupils of the present day, though better trained as general biologists, are as likely to turn out such good botanists and naturalists as were their predecessors, for once out of sight of their "type" they are more at sea than were their predecessors, who learnt their grammar systematically.

Vegetable physiology proper—a subject of profound importance to the cultivator—still lags in arrear in this country. We have had our Grew, our Hales, our Robert Brown, our Thomas Andrew Knight; but since the time of the latter—if we except Darwin, who is exceptional in all ways—we have had few men who could claim to occupy a foremost rank as vegetable physiologists. The fact is, that vegetable physiology, apart from the investigation of the miscroscopic structure of plants has become chiefly a matter for students of physics and of chemistry, and students of these sciences have preferred to study the abstract sciences in their laboratories rather than follow up their applications in the living plant. Chemists, indeed, have told us a good deal concerning the chemical constitution of dead plants. They cremate them and then study their ashes—an odd method, it would seem, of studying the life-action of plants. Combined, however, with practical observations and well devised experiments in the laboratory and in the field or garden, such a method renders invaluable assistance. We earnestly hope, therefore, that the younger school of botanists now coming forward will see the great need there of their services, and actively take upon themselves the task of unravelling the problems of plant life. As a precious aid in this direction we may call attention to Professor Marshall Ward's lately published translation of Sachs' *Lectures on the Physiology of Plants.* * Those who are familiar with the *Experimental Physiology* of the celebrated German author and with his *Lectures*, as here translated, will know how greatly superior those works are in grasp and lucidity to his *Text-book*, and hence students will feel specially grateful to Professor Ward for this translation of the *Vorlesungen*, and for the admirable way in which he has accomplished it.—*Gardeners' Chronicle*

AGRICULTURE IN SOME OF ITS RELATIONS WITH CHEMISTRY.

Agriculture in some of its Relations with Chemistry By F. H. STORER. Two Vols. (London: Sampson Low, Marston, Searle, and Rivington, 1887.)

This work, by the Professor of Agricultural Chemistry at the Harvard University, is based on a course of lectures delivered annually by the author. It is addressed to students of agriculture and persons fond

* *Lectures on the Physiology of Plants.* By Julius Von Sachs, translated by H. Marshall Ward, Professor of Botany in the Forestry School, R. I. E College, Cooper's Hill. Oxford: Clarendon Press.

of rural affairs, rather than to students of chemistry. Free use has been made of German publications in agricultural chemistry, and of the writings of Prof. S. W. Johnson, of Newhaven, Connecticut. Some of the matters treated of in his two well-known books, "How Crops Grow" and "How Crops Feed," have been omitted, or only lightly touched, in the present volumes, which are therefore, to a certain extent, a supplement to those books.

The present volumes treat of the chemistry of the atmosphere, of waters, of soils, and of manures, and of their several relations to plants; the chemistry of animal life and nutrition, is not dealt with. A large amount of valuable information, partly of historical interest, has been brought together; and much of it is presented in the somewhat old-fashioned English of the best writers of New England.
