No reply has yet been received from Government, but, as I understand, that the work of prospecting in Morowak Korale will be at once undertaken by private enterprise, it is to be hoped that Mr. Dominico's exertions will not be unrewarded. He states that you may recollect his paying a visit to the *Observer* office in 1884, with samples of gold dust obtained from the Western Province. The same samples were shown to Mr. Leechman, of Messrs. Leechman & Co.

Referring to the remarks in your editorial on this subject, Mr. Dominico explains that the metal discovered near Akuressa is *not* Australian, but Ceylon gold; and he states it as a fact, that a nugget weighing 5½ sovereigns, and other smaller ones were secured by the diggers. Nuggets and pepitas were obtained, but there was comparatively little gold dust. He was confirmed in this opinion after washing the gravel on the occasion of his visit to Deurangalla.

TEA FOR AMERICA.

The prospectus of the Indian Planters' Company will be found given in full on page, 785, together with some very practical advice from a correspondent of the *Indian Planters' Gazette*, which is deserving the attention of Mr. Rutherford and our Planters' Association. Ceylon teas, no doubt, are more suitable than the bulk of Indian for distribution amongst the people of North America.

We have, besides, the pleasure of calling attention to the following address from Mr. Pineo to the planters of Ceylon. It will be a question to consider and decide at next meeting of the Association, how far action should be taken through, or in co-operation with, the Indian Tea Company and through Mr. Pineo's agency, respectively:—

To the Planters of Ceylon:

Gentlemen,—To many of the men to whom belongs the honor of developing and bringing to its present high standard the tea industry of Ceylon, I am an unknown quantity. To the old coffee planter and to those who furnished the sinews of war to carry on an industry that was, at one time, the backbone of the colony I am not, I trust, unfavourably known. Many a planter knows how earnestly I worked for his advancement, while proprietors and agents can testify to my zeal and energy in their behalf.

Bad times, adverse seasons, leaf-disease and other causes contributed to bring about a disastrous condition of affairs as respects coffee, and ignoring the lessons sought to be taught by a Taylor and Armstrong, we coffee planters concentrated our energies, thoughts, and best efforts in the development of an industry that we hoped would bring back to our coffers the many rupees lost or locked up in coffee. I allude to cinchona, which, doubtless, helped many of us very materially, but it did not restore prosperity—or what is essential to all commercial undertakings—confidence. Then, and not until then, did we turn to our teachers and salvationists, Taylor, Armstrong, and the Agars, and go in for the cultivation of that plant which is revolutionizing and recuperating the island. Then we discovered that Taylor at Loolcondera, Armstrong at Rookwood, Agars at Agarsland, Rutherford at Mariawatte, Leechman at Carolina, Scovell at Strathellie and others whom I cannot now remem-

ber by name,* were paving the way for Ceylon to be known as the home of the best of all tea, to be recognized as a community of planters that intended to nail the flag "Excelsior" to their mast, and to prove to the world that the planter would not countenance adulteration or injurious manipulation in any form or shape. The efforts and honorable intentions of planters have not, unfortunately, always been seconded and aided by the retail dealer, for we know that under cover of Ceylon tea much rubbish is sold by the retail tea dealer. Individual efforts of Ceylon planters who have entered the retail trade have not been crowned with deserved success, for the simple reason that they were not able to "stay," or, in other words, their capital was too small and limited.

I won't allude to the Ceylon tea trade of Great Britain, because that trade has already become familiar to you; but I wish to call your attention to a country—I mean America—where your tea is hardly known at all, and where there is room enough for well-directed, honest effort, backed by adequate capital, energy, push, and WAITING powers.

Mr. J. McCombie-Murray has been, and is, doing a noble pioneer's work, and the tea planter can thoroughly rely upon, and place confidence in, that gentleman's vigor and push, and, above all, upon his selling a *pure* Ceylon tea. Your interests in his hands are safe as regards the purity of the tea he may offer as Ceylon tea, and you may safely rest in the certainty that all that one man, with limited capital, can honourably do, by push, energy ,and indomitable pluck, will be done by Mr. Murray; but I submit it to you, can any one man, with limited means, however energetic he may be, occupy—satisfactorily to you—a field wherein live and have their being sixty millions of people? Early in 1885 I endeavoured to make pure Ceylon tea known to the people of Canada and the United States, and, in a limited way I did; but it was a drop in the bucket, and my means were too scanty to enable me to go on in a work that had few glimmers of brightness or satisfaction, and discouragements innumerable. Suffice it to say that three years of uphill, hard, unprofitable work convinced me that certain things were essentially necessary in order to place Ceylon pure tea properly before the American and Canadian consumer. I don't include the grocer, retail or wholesale tea dealer, but confine myself to the consumer, who must, if we want to attain success, be approached independently of any tea dealer or grocer whatever.

Now, I want you to have patience and permit me to tell you what I deem essential to success, and what to avoid:—

First.—A delicate, highly-flavored pekoe tea is an absolute desideratum.

Second.—A man with push, energy, an abundance of capital, and thoroughly versed in the art (?) of American advertizing.

Third.—To maintain a uniform standard of tea.

Fourth.—To refrain from sending strong, pungent, coarse teas until the more delicate varieties are known and recognized by the American and Canadian consumer.

Fifth.—To work independently of grocers, retail tea dealers and jobbers of teas; and

Lastly.—To see that only pure Ceylon tea is sold by your representatives.

Do these ideas commend themselves to you? Or are you of opinion that you know more about it than one who has interviewed the principal tea brokers and wholesale dealers in tea in the city of New York, in Philadelphia, and many other cities of the United States and Canada?

* Grave omissions are Elphinstone and Ceylon Company, Limited, and Abbotsford was earlier than some mentioned.—ED

The planters of Ceylon are not slow to see where their best interests lie. They are quick to adopt new and approved ideas, and I submit that my idea of going direct to the tea consumer is, if not new, something for them to take into consideration.

Are the planters and those interested in opening new markets for their tea inclined to help an old member who believes he is backed by an American gentleman of means, energy and push?

April 23rd, 1888. R. E. PINEO.

DISCOVERY OF A PROCESS FOR MANUFACTURING PURE SULPHATE OF QUININE AT MUNGPOO RESOLUTION.

(*Official paper*).

Apprehensions of the extermination, in their native forests, of the quinine-yielding Cinchona trees having reached an acute stage about thirty years ago, the Government of India decided to take effectual steps to introduce their cultivation into India. The collection of seed and seedlings in the wide tract of difficult country over which the best medicinal sorts are naturally scattered was no easy task. But it was successfully accomplished by Messrs. Markham, Pritchett, Spruce and Cross. Contemporaneously with these efforts on the part of the English Government, the Dutch authorities were at work on behalf of their Malayan Colonies, and by the year 1862 Cinchona cultivation had been successfully initiated in India and Malaya. The localities selected for the experiment of Cinchona growing in India were the Nilgiris and British Sikkim. And the excellence of this selection has been proved by the fact that the original nurseries in both localities have developed into large plantations which still remain in the hands of Government. From these two centres, seed and seedlings have been freely distributed to planters, and large tracts of land, especially in Southern India and Ceylon, have been covered with Cinchona trees by private enterprise.

2. The Cinchona trees thus introduced into India are practically of two sorts: (1) *Quinine* yielders and (2) *Mixed alkaloid* yielders. Of the quinine yielders there are two kinds, *viz.*, *Yellow* or *Calisaya* (including *Ledgeriana*) and *Crown* or *officinalis* barks. Of the mixed alkaloid yielders there are also two kinds, *viz.*, *red* or *succirubra* which has been in cultivation from the beginning and a kind which has come into prominence during the past few years, and which in Annual reports has been referred to as *Hybrid* bark. Red bark contains a comparatively small proportion of quinine with large proportions of cinchonidine and cinchonine. It had been chiefly used by druggists in the preparation of decoctions and tinctures, and had not been used by quinine makers as a source of quinine. This red-bark tree was however the kind which in the early days of the cultivation it was found most easy to propagate, and in all plantations both public and private it greatly preponderated over the other sorts.

3. The cultivation of cinchona trees having been pushed beyond the region of experiment, the next problem that presented itself was the utilization of their bark. For the private grower the most lucrative course up to the present time has been to sell the crude bark in London. The object of Government was not however to secure a financial success, but to provide the people of the country at the lowest possible rate with an efficient remedy for the most prevalent of all the diseases of the country. The first step for Government to take was therefore to discover whether it was really a fact that quinine is the only alkaloid worth extracting separately from cinchona bark, and whether cinchonidine and cinchonine might not each be an efficient febrifuge. It was true that quinine alone had got into use as a febrifuge, and that it alone of the cinchona alkaloids had found a place in the British Pharmacopœia. On the other hand tinctures, decoctions and various pharmaceutical preparations of red-bark, into the constitution of which all three alkaloids must undoubtedly enter, had for many years borne the reputation of excellent remedies

for fever. The presumption therefore appeared to be that the position claimed for quinine as the only real febrifuge yielded by cinchona bark would prove on careful examination, to be untenable; and that the other two alkaloids would also be found, to have value as frebrifuges. For the purpose of investigating this point, Commissions of medical officers of all three Presidencies were formed during the years 1866 to 1868. These Commissions were furnished with supplies of the three alkaloids, pure and unmixed, and after very extensive trials, their unanimous verdict was that cinchonidine and cinchonine are both excellent febrifuges, the former not much less efficient than quinine itself.

4. Having thus established the value of cinchonidine and cinchonine, the next point to be settled was how best to utilize the large stocks of these alkaloids contained in the bark of the trees growing in the Government plantations. To do this Messrs. Broughton and Wood, two professional chemists, were engaged in England and were located as Government quinologists on the Nilgiri and Sikkim plantations respectively. Mr. Broughton the (Nilgiri quinologist), as the result of his labours invented a preparation of red-bark which he called *Amorphous Quinine*, and which contained all the alkaloids of red bark in the form of a non-crystalline powder. Of this amorphous quinine no large amount was ever manufactured; and its preparation ceased when Mr. Broughton resigned the service of Government. Mr. Wood who did not arrive at the Sikkim plantation until 1873, concluded after much observation and experiment that the best way of utilizing the red bark was to make from it the preparation so well known as cinchona Febrifuge. This, like Mr Broughton's, is in the form of a powder, and contains the three chief alkaloids of red-bark mixed in the proportions in which they naturally occur in the bark. Cinchona Febrifuge was then a perfectly new product unknown to pharmacy, and it was not clear how it might be accepted by the medical profession.

Mr. Wood therefore adopted for its manufacture on a small tentative scale a simple and inexpensive acid and alkali process, requiring only the rudest apparatus. He intended, should the product be favourably accepted by the medical profession, to replace this simple process by one more efficient but more complicated, and involving the extensive use of spirit. During the first year of its manufacture (1874 75) only 48 pounds of this new drug were issued. At first and chiefly owing to a misapprehension as to the proper dose in which it should be given some prejudice existed against this drug. In 1875-76 however 1,940 pounds of it were consumed, and its consumption so materially increased during succeeding years that up to the present date no less than 87,704 pounds have been issued from the factory. A preparation similar to and avowedly an imitation of cinchona Febrifuge is now made and sold in London under the name of *Quinetum*, but until Cinchona Febrifuge had first been manufactured in India no similar preparation existed. It is therefore a remedy for which the world at large is indebted to India. Cinchona Febrifuge has been used in India as a substitute for quinine. It has been so used by Government in its own medical institutions and it has been freely offered to the Indian public. Its sale has, however, been restricted to the limits of India. From the beginning and until now its price has uniformly been sixteen rupees eight annas per pound, and in this respect it has presented a contrast to quinine, the price of which has fluctuated considerably rising at one time as high as 16s. 6d. per ounce. According, however, to statistics prepared by an English pharmacologist the average price of quinine in London from 1875 to 1887 (the period during which Cinchona Febrifuge has been in use) has been 8s. 4½d. per ounce. The sterling value (calculated at this average rate) of 87,704 pounds of quinine would be £587,616, while this quantity of febrifuge has actually been delivered to the Indian consumer for the sum of Rs. 1,447,116. The actual saving to India has therefore been very great, and the capital account of the plantations (about eleven lakhs of rupees) has been covered several times.

5. The preponderance of red-bark trees in the Sikkim plantation while he was attached to it naturally induced Mr. Wood to give his attention first to the utilization of their bark. But he by no means neglected the quinine barks. Of these barks only one—*Calisaya* and its variety *Ledgeriana*,—really thrives in Sikkim, the Crown bark or *Cinchona officinalis* tree having proved a comparative failure. Mr. Wood made many experiments in the manufacture of pure Sulphate of quinine, but up to the time of his retirement for private reasons, from the service of Government in 1879 he had not succeeded in discovering an efficient process. Mr. Wood was of opinion that good quinine barks could be grown in Sikkim, and that it might be possible to extract the quinine from them on the plantation. Dr. King, the Superintendent of the Plantation, was very strongly of this opinion, and in 1875 he recommended that all further planting of red-bark trees should cease. This recommendation was not acted upon for some time. Full effect has, however, been given to it of recent years, and *succirubra* has been supplanted by *calisaya* to the extent of about a million trees. The retirement of Mr. Wood did not put an end to the experiments on the manufacture of quinine. Mr. Gammie, the resident manager, took the matter up with energy, and encouraged and assisted by Dr. King he carried on a long series of experiments on an acid and alkali process of manufacture by which he succeeded in producing excellent quinine. He never, however, succeeded in recovering much more than half of the amount contained in the bark upon which he operated. The acid and alkali process had therefore to be abandoned as wasteful and inefficient. A process depending on the maceration of the bark in spirit was next tried; but after much experiment it was in turn abandoned. During a visit which he paid to Holland in 1884, Dr. King acquired some hints as to a process of extraction by means of oil. And now, benefiting by the advice of some chemical friends, Mr. Gammie has been able to perfect this process, with the result that the whole of the quinine in yellow bark can be extracted in a form undistinguishable either chemically or physically from the best brands of European manufacture. This can be done so cheaply that as long as the supply of bark is kept up quinine need never cost Government much above twenty-five rupees per pound. It is true that at the present moment quinine is obtainable in the open market at rates not very different from this; but that is due to entirely exceptional causes. For some time back the Ceylon planters have been up rooting their Chinchona trees both to save them from disease, and to make way for tea planting which appears now to be becoming the principal industry of that colony; and cinchona bark has actually been sold in London below the cost of its production in Ceylon. Indeed, so far as the fall in price gone, that South American bark has been practically driven out of the market. This is a state of matter which cannot continue very long, and which is not likely to recur. In the ordinary course therefore the quinine might be expected soon to rise to what may be considered its normal price. The object of making public the process now discovered is to check this rise in the price of a drug of such general utillty.

6. The cordial thanks of Government are due to Dr. King and his coadjutors—and especially to Mr. Gammie—for the patience, energy and resource displayed by them in their long search for the best method of utilizing these valuable medicinal barks. The Government has no desire to make a profit by the discovery, and the details are now produced in order that private growers of cinchona may be enabled to take full advantage of the process, and that a permanent reduction in the price of quinine may ensue.

By order of the Lieutenant-Governor of Bengal,
COLMAN MACAULAY.
Secretary to the Government of Bengal.

Method of extraction of the alkaloids from Cinchona Bark by cold oil as used at the Government Cinchona Factory in Sikkim.

In order that the oil may speedily and effectually act on the cinchona bark, the latter is reduced to a very fine powder by means of Carter's Disintegrator; and to get the powder of a uniform fineness, it is passed through a scalper, which is a machine commonly used for sifting flour. The scalper is in the form of a box enclosing a sloping, six-sided, revolving chamber, covered with silk of 120 threads to the lineal inch. It is driven at the speed of about thirty revolutions to the minute. Any particles of the powder which may be too coarse to pass through the silk meshes drop out at the lower end of the revolving chamber and are again passed through the Disintegrator.

2. A hundred parts of the finely-powdered bark are then set aside to be mixed with 8 parts of commercial caustic soda, 500 parts of water, and 600 parts of mixture composed of one part of fusel oil to four parts kerosine oil. If the caustic soda be of inferior quality, a little slaked lime (about 5 parts) may be used in addition to the eight parts of caustic soda; or caustic soda may be altogether omitted, and 15 parts of slaked lime may be used instead of it. The caustic soda is dissolved in the water and mixed with the bark. Then the oil is added, and the whole is kept thoroughly intermixed in an agitating vessel. Should lime be used, it is mixed in fine powder with the dry bark before adding the water and oil.

3. The agitating vessels in use at Mungpoo are barrels with winged stirrers revolving in them vertically, and with taps on the sides for drawing off the fluids. The first stirring is carried on for four hours, and then the whole is allowed to rest quietly in order that the oil may separate out to the top of the water fluid. When the oil, which has now taken up the greater part of the alkaloids has cleared out, it is drawn off by a tap placed just above the junction of the two fluids. The oil is then transferred to another agitator and is there thoroughly intermixed with acidulated water for five or ten minutes, the mixture being again allowed to rest for the separation of the oil. It will now be found (if sufficient acid has been used and the stirring has been thorough) that the alkaloids have been removed from the oil to the acidulated liquor. The oil is again transferred to the bark mixture and is kept intermixed with it for two or three hours; the oil is again drawn off in the same way washed as before in the same acidulated liquor; and this process is repeated a third or fourth time or until it is found by testing a small quantity of the oil that the bark has been thoroughly exhausted of its alkaloids. Each stirring subsequent to the second need not be continued for more than an hour. The quantity of acid required to take up the alkaloids from the oil will entirely depend on the quality of the bark operated on. If the bark contains 4 per cent. of alkaloids, about 2 lbs. of either sulphuric or muriatic acid mixed in twenty gallons of water should be sufficient, and so on in proportion.

4 The after-treatment of the acidulated water containing the alkaloids depends on the product desired, and on the kind of acid that has been used. Should sulphate of quinine be desired and sulphric acid have been used, the liquor is filtered (if necessary), heated and made neutral by adding a very weak solution of either caustic, soda or liquor ammonia. It is then allowed to cool, and as it cools the crystals form out. These crystals are afterwards separated from the mother liquor by draining through a cloth, [illegible] After they have been thus obtained the crystals are dried. They are next dissolved in about fifty times their weight of boiling water. The resulting liquor is filtered [illegible] charcoal [illegible] cooling after filtration the crystals again form out and they are separated as before from the m[illegible] liquor by filtration through a cloth. The [illegible] mass obtained by filtration is then placed in small lumps on sheets of white blotting paper stretched on slabs of plaster of Paris. By this means they are practically dried. They are afterwards thoroughly dried by being laid on blotting paper in a room heated to about 10 degrees above the temperature of the open air.

5 If Cinchona febrifuge is wanted, the alkaloids are exhausted from the oil by muriatic acid, the solution being neutralized and filtered in the same way. On an excess of caustic soda solution being added the alkaloids are precipitated. After standing some hours the whole bulk of liquor and precipitate is passed through cloth filters; and when the alkaline liquor has drained off, the precipitate is washed with a little plain water, dried and powdered. The powder is cinchona febrifuge ready for use.—J. A. GAMMIE, March 24, 1888.—*Indian Agriculturist.*

ROYAL GARDENS, KEW.

(From the Bulletin of Miscellaneous Information for December 1887.)

CUBEBS.

(Piper Cubeba, L.)

The rapid rise in value which in recent years has occurred in cubebs has drawn considerable attention to this pepper. It may be useful, therefore, to correspondents in the Tropics to have before them a brief summary of information on the subject. To this we are enabled to add drawings of the male and female plant of *Piper Cubeba*, L., taken from a Java plant, and one of Miquel's types, in the Kew Herbarium. This is *Cubeba officinalis*, Miquel, and *Piper caudatum*, Hort. non Vahl. There are good figures of this species given by Berg and Schmidt, *Officinellen Gewächse*, t. 29a, and in Baillon, *Histoire des Plantes*, Vol. III., fig. 508. The plant figured by Bentley and Trimen (except the details which are correct) in Med. Plants, plate 243, as from the Royal Gardens, Kew, has been proved to be *Piper Chaba*, Hunter [Chavica officinarum, *Miquel*], belonging to the long-pepper group.

The cubeb plant, like those which supply the black pepper and the long pepper, is a climbing shrub with smooth round stems, which are somewhat swollen at the joints. The leaves are alternate, on short stout stalks, with a lanceolate blade of about 5-6 inches long, terminating in a sharp point. The base of the leaf is often unequal and somewhat folded in drying. The flowers are unisexual, and appear on separate plants (diœcious). They consist of cylindrical solid spikes coming off opposite the leaves. The male spikes are long and slender, while the female spikes are shorter, thick, and fleshy, and provided with a short peduncle. The fruit (which appears only on female plants) is small, and very similar in size and appearance to black pepper. It is, however, provided with a stalk-like base, which is a little longer than the globular extremity. Numerous fruits, when approaching ripeness, are ranged horizontally on a common axis, forming a lax raceme. This pepper appears to be found wild only in Java, Sumatra, and Borneo. In the former islands cubebs are regularly grown, and they form an important (though irregular) article of export. They often come to this country through Singapore. According to Descourtilz, cubebs were at one time cultivated as an introduction by the French in the West Indies. At present they are unknown there. The produce of other species of Piper are sometimes called cubebs, as, for example, the native cubeb of Mauritius [illegible], which is [illegible], Cas. De Candolle. The cubeb pepper of West Tropical Africa is [illegible], Cas. De C[illegible] latter, according to [illegible] [illegible]iger and Hanbury [illegible] [illegible] Under the [illegible] [illegible] [illegible]. Among [illegible] *P*[illegible]. Kew [illegible] [illegible] described [illegible] XV. [illegible], and XVIII., p. 20[illegible]. The fruits of [illegible] A. Dietr., a plant of wide distribution [illegible] Malay Archipelago are [illegible]. They are smaller than true cubebs and have a stalk-like base

only half the diameter of the globular extremity. The cultivation of cubebs appears to be very similar to that of the ordinary black pepper. Trees are requisite for shade and for supporting the vines. At the foot of these the young plants are first started. When fully grown the cubeb vine climbs to the height of 18-20 feet, and forms a large bush. In Java small plantations are specially devoted to cubebs; but latterly they have been cultivated also on coffee estates by European planters. The fruits are gathered when full grown, but before they are quite ripe. They are then carefully dried with the stalk attached; hence on this account they are sometimes called "tailed pepper." Cubebs have a warm aromatic and somewhat "camphoraceous" taste. The smell is highly aromatic, and by no means disagreeable. Cubebs have stimulant and diuretic properties. The chief use of cubebs in European countries has been for various forms of syphilitic disease. Latterly they have been largely used in America in the preparation of asthm cigarettes. According to the *Chemist and Druggist* the price of cubebs has always been subject to sudden and violent fluctuations. In 1865 the price averaged 77*s.* 6*d.* per cwt.; from 1875 to 1880 cubebs could be bought at prices ranging from 25*s.* to 55*s.* per cwt. Since 1880 the price has steadily gone up, and "good genuine cubebs" in 1886 realised 20*l.* to 22*l.* per cwt.

In the Kew museums there are specimens of the fruits of *Piper Cubeba* from Nepaul and Madras, India Museum; these are probably bought in Bazaars, and not grown locally. Commercial cubebs from Java and Sumatra are represented by samples contributed by Messrs. Burgoyne, Burbidges and Co. West African cubebs, the produce of *Piper Clusii*, are represented by specimens from the Yoruba country by Mr. Barber; from Sierra Leone by Dr. Clark; from Bahia, brought from the West Coast of Africa by negroes, under the name of "Irrei," by Mr. J. Wetherell; and from the Sierra Leone exhibits at the Colonial and Indian Exhibition, 1886, under the name of "Yaray," by the Commissioner.

In addition to these there are samples of cubeb oil and cubebine, illustrating the products of *Piper Cubeba*; and samples of false cubebs as usually used for purposes of adulteration, which are probably the fruits of *Piper crassipes*.

Introduction of the Brazil Nut to the East Indies and Australia.

(*Bartholletia excelsa*, Humb.)

The plant yielding the common Brazil nuts of commerce is a lofty tree, locally known as "Castanea." native of the forests of Guiana, Venezuela, and Brazil. It grows regariously in large forests, and belongs to the tribe *Lecythideæ* of the natural order *Myrtaceæ*. The "nuts," generally from 15 to 25 in number, are contained in a spherical shell about the size of a child's head, but of an extremely hard woody texture. Inside this the nuts are closely packed round a central axis, and hence the wedge-shaped or triangular form assumed when ripe. The walls of the shell are about half an inch in thickness, and they are so firm and compact in texture that it is necessary to break them with an axe before the triangular wrinkled nuts can be extracted. This latter work is done by Indians, in the forests, and the nuts are then brought down the rivers in canoes to the port of shipment.

Brazil nuts form an important article of commerce, and about 70,000 bushels are annually imported into this country and used chiefly for dessert purposes. The ordinary kinds come from Pará and are sometimes called Pará nuts. The best nuts, styled "bold Manáos Brazils," which command the highest prices, come from Manáos, an inland town on the Rio Negro, and in the province of that name.

The nuts ripen and fall from the trees in February and March, and fresh nuts arrive in Europe in May and June.

While the nuts are largely exported they are also extensively used in Brazil, but chiefly as food by the Indians; the Tapejos, for example, subsist largely upon them. The oil contained in the kernels is used locally, and to a small extent in commerce.

The Brazil-nut tree is a native only of South America and it is scarcely known under cultivation outside the tropics of the New World. It was introduced to Jamaica as lately as May 1881, when 300 fruits, containing about 6,000 seeds, were obtained by the Botanical Department of that colony direct from Pará. Seeds were first of all distributed amongst cultivators and afterwards growing plants. The germination of the seeds, covered as they are with a dense woody testa, is a subject which requires some attention. If the seeds are sown in the natural state and without any preliminary preparation, the period of germination may extend from a few months to nearly two years. In the report of the Director of Public Gardens and Plantations, Jamaica, for the year 1883, it is stated, "Before being planted, it is advisable to take the nuts out of the pericarps or fruit cases and soak them in water for about a fortnight, otherwise they take several months or even a year or two in germinating. Some nuts planted in May 1881, without soaking, only appeared above ground in February 1883."

At Kew the results have been very much the same The assistant curator, in a memorandum on the subject, states that "if the seeds of Brazil-nuts are sown with shells intact, they remain in the soil a long time without germinating. They do not, however, perish, and we have succeeded in getting plants from seeds that have been sown over two years.

"By removing the shells from the seeds before sowing they will germinate in a very short time. At Kew, we had the young plants through the soil ten days after date of sowing. The shells, in this case, had been cracked and carefully removed from the seeds."

The introduction of the Brazil-nut tree into our Eastern and Australian Colonies was in every way so so desirable an object that this establishment, which has in many ways and for a long period, served as a "half-way house" between the two tropics, was very happy to take part in it. An application having been received from the Botanic Garden at Brisbane, Queensland, for seeds or plants of *Bertholletia excelsa*, about ½ cwt. of fresh seed was obtained in June 1885, and forwarded to the Colony. The first report received on this consignment was not encouraging. The superintendent, in a latter dated 22nd February 1886, states:—"I very much regret to say that the *Bertholletia* seed, respecting which you took so much trouble, has not been a success. Besides sowing large quantities myself without delay, I distributed it over a wide range of Nothern Queensland, but none of the seeds germinated." It was believed here at the time that some of the seeds would still germinate if they were kept in a suitable situation; but in order to ensure the introduction of the tree to Queensland, a second lot of seeds were forwarded in July of the present year. At the same time a lot was forwarded to the Botanic Gardens at Singapore. In acknowledging the receipt of the second lot of seeds, Mr. Oowan in charge of the Botanic Gardens at Brisbane, writes as follows:—"The previous consignment was submitted to such treatment as you advised, with the result that there are now available for distribution about 200 plants of this valuable tree. This second importation will enable a thorough trial to be made in all likely parts of the Colony."

Mr. Cantley, in reporting the arrival of the seeds at Singapore, mentions that those which were packed at Kew in moist peat had begun to germinate on the voyage. The other sent dry, had not germinated, but were placed under treatment at once. Mr. Cantley adds, "I have sent a few of the seeds to the native states, where they are very anxious to get anything of this kind."

The further introduction of the Brazil nut to Eastern Colonies is a matter which does not appear to require arrangements of an exceptional character. Fresh seed may be obtained in London from reliable merchants in June and July of each year, and these could be sent packed in cocoa-nut fibre or peat in an ordinary box as merchandise. On arrival, the seeds should be well soaked or the outer shell might be very carefully cracked and removed or cracked only, and the kernels sown in ordinary nursery beds. It is necessary to add

that the trees do not come into bearing for some years and they evidently require to be planted in deep alluvial soils, and in sheltered situations.

The germination of the seeds of Bertholletia in the wild state, while enclosed in the wonderfully strong fruit case (which, by the way, serves as an admirable protection against monkeys and other animals), was a matter which, for a long time, was involved in obscurity. This, however, has been cleared up by the observations of Mr. Barrington Brown, F.G.S., in British Guiana. Briefly stated, the process is as follows :—"In each fruit case, or pericarp, when lying on the ground, there is a small hole at the point at which it was attached to the stalk. Through this, after the fruit has been lying for some months in a moist situation, the shoot produced by one of the germinating seeds is able to effect an exit. When this is done, it gradually increases in size, but still uses the fruit case which indeed protects its roots and serves all the purposes of a natural pot. The other seeds, unable to find an outlet for their sprouts to reach the light and air, ultimately perish, and their remains probably go to nourish the solitary plant which is destined to represent the family. This latter, when it has grown to a certain size, bursts the shell in which its roots have hitherto been confined and grows up into a tree."

Castilloa Rubber of Central America.

(*Castilloa elastica*, Cerv.)

This is one of the earliest described of rubber yielding plants, but according to Sir Joseph Hooker (Trans. Lin. Society, Vol. 11., pt. 9, p. 209), it is probable that more than one rubber-bearing species exists in Central America under this name.

The Ule of British Honduras and Nicaragua is no doubt *Castilloa elastica* of Cervantes, but what is known locally as Tunu and said to yield a "gutta-percha," is so far undetermined owing to the absence of good specimens of the leaves and flowers. The species named *Castilloa Markhamiana* (Collins, Report on the Caoutchouc of Commerce, 1872, p. 12, t. 3) has been shown to belong to another genus, viz., *Perebea* (Genera Plantarum, Vol. III., p. 372).

Plants of *Castilloa* have been widely distributed from Kew to various tropical colonies, and seed-bearing trees are now found in Ceylon, Singapore, Mauritius, Jamaica, Trinidad, and the west and the east coasts of tropical Africa.

The original stock of Kew plants was obtained by Mr. R. Cross in 1875 for the India Office from the Isthmus of Panama, under the name of Caucho. The identity of the Ule of British Honduras with the Caucho of Darien appears to be not fully established. The points of difference so far noticed are, however, very slight. With regard to Ule, Sir Joseph Hooker mentions that "all the branchlets are clothed densely with substrigose buff-coloured hairs; the leaves are scabrid above, and densely hirsute or hirsutely tomentose beneath. On the other hand, Cross's indigenous specimens of Caucho, and those cultivated in Ceylon (derived from the same source), have the branchlets less clothed with hairs and the under surface of the leaves less thickly tomentose."

The above brief statement respecting the determination of the rubber-yielding plants of Central America will serve to show the present position of our knowledge of the subject.

The plants distributed from Kew, and now under cultivation in various tropical colonies, would be more correctly termed according to the place of origin *Darien Castilloa*. This would distinguish them from the Ule of Mexico, British Honduras, and Nicaragua, and sufficiently indicate their history. As regards the quality of rubber yielded by the Darien Castilloa, the Kew Report for 1882, p. 10, gives an account of the first sample of caoutchouc obtained from this plant in the Old World.

"In October 1882 the Director of the Royal Botanic Gardens, Peradeniya, Dr. Trimen, forwarded to Kew a sample of the rubber of *Castilloa elastica* grown in the Experimental Gardens at Henaratgoda, Ceylon. This was sent from Kew in 1876 (see Kew Report, 76, p. 9). The sample was submitted to S. W. Silver, Esq., F. L. S, who very kindly reported upon it:—'On working and drying a portion of this sample, the loss is 12·3 per cent; it is necessary to use warm water in washing this rubber; it becomes, on drying, much darker and shorter than Para rubber. It has a bitter taste, which is not removed on washing. The unwashed sample yields 1·9 per cent. ash, the washed sample gives 1·2 per cent. The shortness of this rubber would restrict its use to some extent where tensile strength or tenacity is required.' It was valued, Dec. 8, 1882, as worth 2*s.* 9*d.* to 3*s.* per pound."

The collection and preparation of rubbers as a forest product has hitherto been almost exclusively in the hands of natives, whose only object has been to obtain as large a quantity as possible of a marketable character, without any regard to the permanency of the industry or the quality of the article produced. In many localities the rubber trees have been so ruthlessly cut down or tapped, that they have been almost annihilated. In others, the preparation of the rubber is of so rude and unsatisfactory a character, that the waste must be enormous. Under these circumstances it is most important to extend knowledge of the subject, and it is to be hoped where rubber trees still exist under British influence, that careful steps will be taken to regulate the tapping or bleeding, and to re-plant areas already denuded of trees.

In the special instance of the rubber industry at British Honduras we have been lately favoured with the following correspondence :—

Colonial Office to Royal Gardens, Kew,
"Colonial Office, Downing Street,
"Sir, 11th November 1887.

"I an directed by Secretary Sir Henry Holland to transmit to you a memorandum on the cultivation and preparation of india-rubber, which has been prepared by Mr. Alvan Milson, who was formerly a district magistrate in British Honduras, and has now been appointed to be a district Commissioner in the colony of Lagos.

* * *

"I am to request that the memorandum, which is sent in original, may be returned with your reply.

"I am, &c.,
"D. Morris, Esq., (Signed) John Bramston."

Notes on Castilloa Rubber Tree of British Honduras, by Mr. Alvan Milson.

There is but little to be added to the admirable account given by Mr. Morris (now of Kew) of the *Castilloa elastica* in his book on the colony of British Honduras; but the cultivation and preparation of india-rubber is of daily increasing importance, and there is little doubt that information which in any way lessens the difficulties at present encountered in dealing with this article is worthy of statement and examination.

Cultivation.—The details I am able to give with regard to the cultivation of the rubber tree are mainly founded on hearsay evidence, but many of them have also come under my own observation. The present methods may be clasified under two heads :—

(i.) Cultivation as a shade tree or other crops, and
(ii.) Cultivation for its own sake.

(i.) The rubber tree is a tap-rooted tree, of small foliage area, a lover of deep, moist, clayey loam, well shaded by undergrowth, and appears to need surrounding low bush to force it to its full height.

The natural deductions from the above facts are that while it does not exhaust the soil in which the surface the rooting crop underneath it may be planted, it gives but little shade unless planted at very short distances. Until it has attained sufficient dimensions to shade *itself* (for it will not grow well if the sun gets at its trunk) and the plants beneath its branches, it must be protected by some other large tree, its natural habitat, like that of the Jamaica pimento, being in old plantations among the under brush that so rapidly springs up in humid soils. If planted sufficiently closely to shade its own stems, without which both the growth and flow of milk will be checked by the heat of the sun, it must of course ultimately damage the crop beneath it, and, in the case of cacao, when both crops come to maturity about the same time, both crops would be injured to an almost equal extent.

(ii.) If grown as a special crop, the seeds should be planted, I believe, at a distance not exceeding 15 feet from one another, should be left for a year or two in uncleaned ground so as to allow the underbush to shade them and stimulate their growth,—a small area of about a foot in diameter being kept clear round each plant,—and only when sufficiently large to shade one another to a certain extent should the plantation be thoroughly brushed with a machete.

On the plantation of M. Lefebvre (No. 7, Rue des Petits Hôtels, Paris), in the western district of British Honduras, several trees planted and treated as just described reached a diameter of nine inches at a height of four feet from the ground, and flowered and fruited in less than four years. Others in well-cleaned land did not make half this progress.

Stakes, if set in the ground, make more apparent progress than seeds (seedlings should not, I think, be planted, on account of the extreme length and delicacy of their tap roots), but two or three years suffice to show that the seeds make more certain and rapid progress.

I have reason to believe that the *Castilloa elastica* affects the neighbourhood of rivers chiefly, because the bush in such places is always stunted by the floods so as to allow the rubber trees to have full growth, and is yet sufficient to give the ground and stems full shade. Under these circumstances the trees will reach a great size, while in identical soil in the open savannah they make no apparent progress.

Preparation.—A great difficulty has hitherto been found in extracting the milk from the tree in a satisfactory manner. The method now employed is wasteful both of time and of the quantity and quality of the milk extracted. I append a rough sketch of a machine* invented by Mr. Blancaneaux, of the Cayo, British Honduras, which avoids all these disadvantages.

Coagulation.—The methods which at present prevail for coagulating the milk are well described by Mr. Morris. I cannot but think, however, that a plan suggested to M. Lefebvre by a series of experiments in the spring of this year (sample of the result of which I possess, and will forward at a later date,) offers decided advantages over any other.

M Lefebvre's method.—The milk is put into a barrel with a tap at the bottom, and three parts of pure limeless water are added to every part of milk. After standing for twenty-four hours the water is drawn off through the tap and the process repeated twice more. The well washed milk is then pressed slowly in a finely perforated vessel and yields a quality of rubber free alike from undue viscosity and brittleness. A sample of rubber thus prepared is difficult to distinguish from the smoke-coagulated Pará rubber which at present leads the market.

The above account, given by Mr. Millson, is printed without my expression of opinion as regards the value of the suggestions made. Experience alone can decide the circumstances best suited to the cultivation of this tree in different tropical colonies. There is also much more to be learnt and worked out as regards the best means to be adopted for tapping rubber trees, and for preparing the milk so as to yield the largest available amount of marketable rubber.

The preparation of Castilloa rubber is described by Morris (Colony of British Honduras, p. 76), as follows:—

"At the close of the day the rubber-gatherer collects all the milk, washes it by means of water, and leaves it standing till the next morning. He now procures a quantity of the stem of the moon-plant (*Calonictyon speciosum*), pounds it into a mass, and throws it into a bucket of water. After this decoction has been strained, it is added to the rubber-milk, in the proportion of one pint to a gallon, or until, after brisk stirring, the whole of the milk is coagulated. The masses of rubber floating on the surface are now strained from the liquid, kneaded into cakes, and placed under heavy weights to get rid of all watery particles. When perfectly drained and dry, the rubber cakes are fit for the market, and exported generallyin casks."

* Not reproduced.

The idea respecting the preparation of rubber, as suggested above by Mr. Milson, without the aid of the moon plant or of alum, which latter is also sometimes used, would appear to be not entirely new. In the Report on the Caoutchouc of Commerce, by Collins, published in 1872, it is stated that if the juice of plants is not procurable about two parts of water are added to one part of milk, and allowed to stand for 12 hours. The residue which separates from the water is poured into vats made in the ground and left to dry. This drying takes from 12 to 14 days. Sometimes the milk is simply poured on prepared ground, and the watery portion allowed to evaporate or otherwise disappear. The rubber, when dry, is subjected to pressure in order to get rid of the *bolsas* or packets of watery liquid."

TEA IN JAPAN.—Reports from the tea-growing districts continue to give a good account of the plants, and the first pickings will probably arrive at the end of the present month. The plants in Kagoshima and Kochi are said to be this season, as indeed they usually are, in advance of other districts. The Tea season is fairly closed, a few houses working off the last of the old leaf. A hand muster of new leaf has been shown, but it gives no clue to the quality of the crop. Reports from the interior are still good as to the quantity expected.—*Japan Weekly Mail*, March 24th.

FORESTRY ON THE NILGIRIS.—From Mr Gamble's Report on the Northern circle, Madras, we quote the passage referring to operations on the Nilgiris as affording hints regarding the trees likely to do well in Nuwara Eliya and its neighbourhood:—

In the Nilgiris, in Aramby reserve, 40,550 Bluegum, 700 shola trees and 7,000 Frenela were planted; casualties 5 per cent. Increase during the year is 10 acres. In Cairn Hill reserve 3,270 *Cryptomeria* were planted and 14,400 Bluegum, 330 *Pinaster*, 1,970 Cypress, 7,300 Acacia, 300 Grevillea. A large proportion of these were employed in filling up vacancies. The increase during the year was 7 acres. In Baikie 5,000 Bluegums were planted. In Governor's shola 1,000. In Lovedale during the year were planted:—

		Casualties.
Grevillea ...	567	5 per cent
Cedrus Deodara	20	none
Melaleuca ...	100	all failed
Tristania ...	20	none
Cedrela toona...	88	"
Acer oblongum	4	"
Pittosporum ...	137	"

In Coonoor sub-division 8,486 seedlings were planted in the Coonoor peak reserve consisting of teak and *Meliosma Arnottiana* in block I, *Planchoniana* and Bluegum in block II, *Cryptomeria japonica*, *Frenela rhomboidea*, Cypress and *Pinaster* in blocks III and IV, and *Acacia decurrens* and *Casuarina* in block IV. Vacancies in compartments 1, 2, 33 and 39 were filled with 4,099 basketted Bluegum. In Brooklands 919 shola seedlings have been planted to fill casualties. In the Ghat reserve 130 shola plants were added. The growth altogether is good, except in the case of a few oak and indigenous plants. *Eucalyptus planchoniana* is exceptionally striking. In the Kullar reserve 7,209 mahogany plants have been planted in gaps in compartments 5, 4, 3, 2 and part of 1 in block IV, 700 *Berrya Ammonilla* were planted between the mahoghany in compartments 4 and 5. Casualties are nearly 20 per cent, but the rest are flourishing. In Nilgiris 4,098 mahogany seedlings are planted in the Kullar nursery. Seeds of five or six kinds of Eucalyptus are germinating in the Sim's Park nursery. All the seeds of *Quercus Thomsoniana* failed to germinate and very few of *Acer Hookeri* germinated. Not a single seed out of ¾ oz. of *Pteroxylon utile* germinated. Of 1 lb. of dates sown in Sim's Park nursery on the 31st September 1886 not one has germinated up to the middle of July 1887. Seeds of ironwood, *Acer Campbelli Cupressus macrocarpa* and *torulosa* grow well.

THE EAST INDIA TEA PLANTERS' ASSOCIATION, LIMITED, FOR UNITED STATES AND CANADA.

CAPITAL—FIFTY THOUSAND POUNDS.

In 50,000 Shares of £1 each. First issue £30,000.

The object of the Company is to promote the sale of Indian tea in the United States and Canada, and it is intended, in the first place, to go direct to the consumer, instead of through ordinary trade channels, which latter system has hitherto proved futile.

Although the rapidly increasing production of British grown tea has thus far been absorbed, it now bids fair to outstrip demand in existing markets, with the results of a further decline in prices. Hence, the imperative necessity of opening out new markets, to relieve this pressure.

The annual consumption of tea in the United States and Canada is 110 million of pounds, increasing at the rate of nearly ten millions yearly, of which only a few hundred thousand pounds are British grown.

It is not the interest of the American trader to introduce and *push* the sale of Indian tea in his market; this must be done by the producer, and unless done by him, the market will probably remain closed.

Indian tea has never been really placed before the American people, who are known, moreover, to be less prejudiced than the British, and may accordingly be credited with a ready discernment of what is good.

The retail prices of tea to the consumer in America range from 30 to 75 cents or 1s 3d to 3s a lb., and there is no import duty, so that there is ample margin to work on, as a good Indian tea can be offered at the lower figure.

It is proposed to appoint a representative to establish depôts in one or more of the large centres, from which he would arrange for the sale of tea throughout the country by means of agents, by judicious advertisements, and by such other means as might seem from time to time expedient.

The amount of capital required will depend on the development of the business, but during the first twelve months a working capital of £10,000 will probably suffice, of which it is estimated one-fourth may be spent in providing depôts, advertising, &c., leaving the balance for stock-in-trade.

All expenditure under different heads would, of course, be submitted for the approval, and be entirely under the control of the Directors, with whom the American representative would be in close and regular communication.

As it is desired to obtain the support of all who are interested in tea, whether as Companies, shareholders in Companies, individual Proprietors, Managers or Agents, it is hoped that everyone so interested will subscribe in proportion to the stake he has in the Industry.

It is estimated that 2s 6d per acre of cultivation would provide the requisite capital, of which 1s per acre would probably suffice for the first year.

While those interested in the production of tea in India are invited to participate in this enterprise on the ground of the great indirect advantages that will accrue to them from the opening up of a large new market like America, there is every reason to believe that this undertaking will, if properly conducted, prove in itself a commercial success.

Unless at least £20,000 is subscribed, no allotment will be made without the sanction of the shareholders.

March, 1888.

As the above is only a draft and is subject to all sorts of revision at the hands of the I. T. D. A., it is premature to comment upon it, as any comment made here would return home too late to be of the least use in connection, and as the I. T. D. A. may revise it past recognition, comments upon it at this stage would serve no useful purpose in India either. It is an interesting document enough, however, as showing the first serious step towards the first serious attempt at combination, in the Indian tea interest, and is thus historical.

99

In my opinion, the very first step to take by any such association, when formed, should be to secure samples of the most popular teas consumed in the various States. We all know how much the quality of tea is affected by the water used, and that teas which are suitable for Liverpool water are quite unsuited for London water. We all know that climate affects taste; how many have found that the cheroots which pleased men in India became almost distasteful to them at home in England? Whiskey, on a moor or in the Scotch climate, is one thing; whiskey at Marseilles during a touch of the simoon is quite another. A country which has become partial to a tea having an extremely flavoury, straw-coloured liquour, has to be cajoled into appreciating a tea with a heavy, dark, full bodied, rather than flavoury liquours. It may be quite possible to make Indian teas (either by adding *namuna* hill teas, or some of the up-country greens teas) to come near to the *various* notions on tea held in America, without insisting upon dragging Americans over the ditch which divides Japan teas from ordinary India teas, at *one* stride. Bit by bit their taste may be educated doubtless; but, I hold that to attempt to force our ordinary black, heavy, full bodied teas upon America all round and *at once*, without any educational process—of taste as well as opinion—is rather too big a contract to be run successfully. The samples brought to England should be used as guides, of course to indicate the best way of preparing Indian teas to ensure their receiving the least possible amount of obstruction from local taste prejudice. To send over to America, ordinary Indian teas as prepared for the English market, is to court failure; as these teas are positively distasteful to many Americans, though not to all. Where *China* teas are consumed there, Indians have the best chance; where *Japan* teas are consumed the reverse is the case. These views I offer with all modesty as they may be in time to affect the policy of the new Association—if it should survive its request for so much money from the planting interest. They are not comments upon the draft prospectus: they are opinions based upon the personal experience of one who has seen tea made in Japan, China, Formosa, various parts of India, who has been an Indian planter, and who has traversed America from one side to the other with part of Canada thrown in.—*Cor., Indian Planters' Gazette.*

DR. TRIMEN'S REPORTS ON THE CEYLON GOVERNMENT GARDENS.

(See Supplement to this month's Issue.)

As painters are said to hang up a green cloth on which occasionally to rest their eyes, in order to alleviate the effect of intent gazing on glaring colours, so does rest come to the brain of the o'er-wearied publicist as he turns from the confused kaleidoscope of fierce political strife, lurid with shades of "blood and iron" to the greenery of well-kept gardens and grassy fields. There is no more pathetic and natural scene depicted by England's great poet,—the poet of human nature,—than that in which Falstaff on his death-bed is represented as "babbling o' green fields," the fields in which in his days of innocence he had wandered. We do not envy men who take no pleasure in the tree and plant and grass and flower pobes, in which so large a portion of our globe is clothed. For ourselves, we always turn with fresh relight to the beautiful objects which present themselves in gardens, fields, and forests, on patana knolls, and beside tanks and swamps and streams. Next to such delight is the interest felt in perusing reports of experiments to acclimatize in one portion of the earth the useful and beautiful products of other and distant portions, such as are described in the latest Reports of the Ceylon Director of

Botanic Gardens and his assistants, the larger portion of which (through the courtesy of the Government Printer) is given as a *Supplement* with this month's *Tropical Agriculturist*. Here we have accounts of the progress, position, and prospects of horticultural experiments under the most varied conditions of altitude and climate, from the base of the grand Hakgala at about 5,600 feet above sea-level, downwards to 2,200 feet at Badulla, 1,600 feet at Peradeniya, about 300 feet at Anuradhapura to only a little above sea-level in the case of "the tropical garden" at Heneratgoda. Surely we ought at Colombo to have gardens within the Municipal bounds, combining the botanical and the zoological, such as many smaller towns in India can boast of. As usual, what Dr. Trimen with his special knowledge of the life-history and properties of plants, records in the shape of fact or comment, and what he quotes from Mr. Nock (who has done so much to convert the precipice-crowned slope of Hakgala into an upland paradise, where flowers and ferns of all climates meet and mingle), are redolent of scientific and economic interest. We need only instance the elaborate notice of the until now obscure question of the identity of the valuable species of pepper known in commerce as cubebs. Like a true and honest scientist Dr. Trimen is as ready to correct his former mistakes, where materials for judgment were defective, as to speak decisively where the facts are cumulative and conclusive.

As we take it for granted that all our readers will peruse our Supplement with care and interest, our own further remarks may be few and brief. The central gardens at Peradeniya renowned all over the world for their combination of flower and fern beds, and drives through forest trees and by a noble river bordered with grand groups of giant bamboos, have been improved, and can now be inspected by the observant visitor with the aid of a Hand-book and an elaborate Catalogue of the plants indigenous and imported which are grown within its bounds. It is curious to notice that here, at 1,600 feet above Colombo, the average rainfall should be almost exactly the same as that of the sea-level station. The figure for Peradeniya is 87·33 inches on 144 days. There was a considerable excess in 1887, the figures being 90·06 inches on 169 days. The average of four years at Hakgala (with an Uva climate) is not very different, 86·68 inches, but the average of rainy days is much higher, 217. Different ideas of what constitutes a rainy day must surely account for some of the large difference, considering the nearness of the totals of rainfall. We have already noticed the oak seedlings so successfully grown and ready for distribution at Hakgala, as also the beautiful *pinus longifolia*, but how can we convey an idea of the fernery with its specimens varying from tall tree ferns to "maiden-hair" of such minute leafage, that a lady of our party, during a recent visit, followed many others in going into raptures over them, only to be told that as those ferns were grown lower and lower down, the leaves increased in size. So with roses and other flowers: some which flourish at Hakgala are failures at Colombo and *vice versa*. One of the great delights of a visit to these mountain gardens, is the number of European forms which exiles can salute within their bounds. Even the emerald turf in which the brilliant flower-beds are set like gems is a sight of beauty. But there are qualifications everywhere, and it will be seen that much damage was done to the gardens at the end of last year by the abnormal rain-floods, 33·77 inches falling in December, while porcupines and rats proved serious plagues. We are not surprised to learn that the number of visitors to this beautiful scene with its magnificent view of Uva, is increasing. Nearly all who visit Nuwara Eliya take a trip to Hakgalla. The number inscribed in the book in 1887 was 1,170. The history of the subsidiary gardens at Anuradhapura and Badulla, includes difficulties from droughts followed by excessive floods, such as we trust will not recur for many years. In the case of the capital of the North-Central Province there ought now to be a perennial supply of water.

What Dr. Trimen writes about the Australian wattle acacias as fuel trees will receive special attention from planters. Trees 51 feet high from the seed in six years, with stems over 1 feet at the base, in the case of the silver wattle at Hakgala, exceed, we suspect, anything known in the native habitat of the plant. The silver wattle, *acacia dealbata*,—if its character as a good fuel were certainly established—would, probably, be the best to cultivate for the supply of tea estate furnaces. Of blue gum as a good fuel tree we have already had testimony and it coppices freely. What we desiderate are reports of trials in the furnace of the wood of each of the four leading wattle-acacias cultivated in Ceylon. They all send up shoots from their spreading roots, but in varying proportion. *Acacia melanoxylon* (the "blackwood," and, curiously enough, the "lightwood" also, of Australia,) has, perhaps the least tendency in this direction, although individual trees differ greatly in this respect. We have been advised to cultivate this species exclusively, because of the superiority of the well-grown trees for timber purposes. But we should like to know if, meantime, plenty of good fuel can be got from the subsidiary shoots and from the lopped branches. This species is liable to be specially infested by the *loranthus* parasite, but a cooly with a hook or knife on a long pole could easily clear away the inimical growths. The "blackwood" must not be confounded with the "black wattle," *acacia decurrens*, which is a smaller species than the three others common here. *Acacia pycnantha* is a most ornamental tree, from the profusion of golden blossoms which gives it its name of "golden wattle." Plantation for fuel and timber might well be formed of "blackwood," the silver wattle and the golden, if the latter is good for firewood. Trials of each of these three, if the fourth is not worthy of inclusion, ought to be made in the furnace, for it is fuel more than timber which the planters want. The *Grevillea robusta* (not an *acacia*, we find, but belonging to the natural order PROTEACEÆ and distinguished by its large coloured flowers,) is an excellent timber tree and grows well in our hill regions. This will be obvious by a look at the long row of now noble 30 and 40 feet high trees which the late Mr. George Smith put down along the road-side through Lorne and Dessford, and which, to our knowledge, cannot be more than seven years old. The late exceptional drought has forced many of these fine trees into blossom. We believe these trees can be improved by the gradual lopping off of the side branches for fuel, but we must repeat the hope that some planter, (and all will think of Mr. Rutherford, to whom his brethren on estates owe so much already,) will institute careful trials and report the result, of the *comparative fuel values* of the timber of the blue gum, of Grevillea, and of the three or four wattles chiefly grown in Ceylon: *A. melanoxylon*, *dealbata*, *pycnantha*; and *decurrens*. We once had an Australian Nurseryman's list, in which the best fuel plants were specified, but even if we could refer to it, trials here would be useful, because in our hot-moist climate the charcteristics of the trees may possibly have been considerably altered. The specimens of timber might be tried green and in a dried state. For

fuel purposes the *eucalypti* can be grown close together and on very poor soil, even.

Dr. Trimen's remarks on cinchona here and in Java ought to be qualified by the statement that the Ceylon planters were unable until the enterprise was well-advanced to obtain seeds of *Ledgeriana*, and that while the soil of Java, if not the climate, seems eminently suitable for that superior kind, it has been found to flourish only in a few places in Ceylon. We wish we had back all the money we spent on it. Planters in Ceylon cultivated what would grow and the result, though not profitable to them has resulted in enormous good to suffering humanity. With reference to what we said yesterday about Viticulture in Uva,—and with reference to many other places in Ceylon where grapes could well be grown, we draw attention to what Dr. Trimen says about the Cochin-China tuberous-rooted vine. The main facts observed by Dr. Trimen on his botanical tours could not but be interesting to those who wish to know where certain species of vegetation predominate. A notice of the visit to "the mysterious Ritigalla" in the North-Central Province, believed to have been at one time the refuge of the aborigines who fled from the Wijayan Conquerors, and said to have interesting monuments scattered over and around it, ought, certainly, to be given somewhere, and in some shape by Dr. Trimen, or his accomplished travelling companion, Mr. A. P. Green of Colombo, or by the two conjointly. A paper is, probably, in course of preparation for the local Asiatic Society.

There is much else suggestive of remark in Dr. Trimen's interesting and comprehensive Report, but nearly all of it, except the catalogues of plants and the accounts, is given in our supplement and considerations of time and space compel us to conclude. But before closing we must bear testimony to the value of the Botanic Gardens of Ceylon to the Colony not only from the scientific and æsthetic standpoints, but in an economic and strictly utilitarian sense.

COTTON CULTIVATION IN SOUTHERN INDIA.

A merchant-shareholder in the new Company writes :—"I enclose a memo. relative to cotton cultivation in Southern India. There they plant in the North-east Monsoon. If we put April to May for August to September, it will apply to Ceylon for the South-west, and we may be able to get a crop in the North-east as well."

"Operations are commenced in August to September when manure, chiefly sheep and cowdung, is spread over the ground. The ground immediately after is ploughed twice, and when the rains come in Sept. to Oct., and while the ground is quite wet, the seed is thrown broadcast, and then at once ploughed in. The seed is previously prepared by being mixed with buffalo dung and water, the proportion in weight being 3 of seed to 1 of the dung liquid. Each seed should be coated with the mixture and allowed to remain so in shade 3 days, and then bagged. this assisting germination before being sown. Three days or so after sowing the seed should appear above ground. In November the plants should be 5 to 6 inches in height, and at this stage the ground should be weeded and the plants hoed and thinned, 2 to 3 inches space being allowed between the plants. In December, the soil is furrowed between the plants, and they are then left until they are ready for picking in March. Tuticorin, 20th April.

BARILLA. The Indian Government has been endeavouring to have certain soda plants growing in various parts of the country identified, and to see if barilla could not be profitably extracted from their ashes. Though plants, however, have been found available for the purpose, yet it has not been practicable to so economically extract the barilla from them as from the very abundant native natron earths themselves, the product even, of which cannot favourably compare with the European chemically made article from common salt.—*Com.*

GREVILLEA ROBUSTA.—In our article (page 785) on the Report of the Botanic Gardens, we wrote that this tree was "distinguished by its large masses of comb-shaped, orange coloured flowers." These words are necessary to a proper description of the very striking Grevillea flowers, forming such a contrast of vivid colour to the wealth of green, graceful, fern like foliage with which the tree is clothed. *Grevillea robusta* is one of the most ornamental as well as one of the most useful sylvan gifts which Australia has bestowed on Ceylon. Here, the tree does not compete with the blue-gum in rapidity of upward growth, but in thickness of stem in an equal number of years, it excels most of the *eucalypti*. Many of the latter which have thick stems within a few feet of the ground, have a habit of tapering away almost to a point as they get up higher and higher, some of them attaining 100 feet, or even 150 in ten years. In its own native habitat (New South Wales and Queensland), the Grevillea tree (the "silky oak" of the settlers), attains on rich alluvial banks of rivers a height of 100 feet. Specimens fourteen years old in Ceylon are about 60 feet in height, judging by the eye, but careful measurements may correct this estimate. Of course, the trees in the loose, accumulated soil on the sides of the Lorne Road, to which we alluded as having become fine trees in seven years, are in very favourable circumstances for rapid growth. But like most other trees, they ought to be planted in groves and pretty close together to secure perfectly straight trees. A good many of the trees in the single row along the Lorne Road have indulged in some curious bends and contortions under the influence of winds and loose soil. But we suppose that even crooked timber is useful for "knees," wheel tires and so forth. We may repeat that in Australia the timber of *Grevillea Robusta* is the favourite for staves of its low casks. It might, therefore, be useful in Ceylon for oilcasks. The order to which this tree of equally beautiful foliage and inflorescence belongs, is described as "a very large genus, comprising some beautiful and interesting Australian flowering shrubs and trees. Nearly 200 species have been described all with one or two exceptions, indigenous to Australia, and two-thirds of that number belong to Victoria. They are chiefly admired and cultivated for their flowers; some of them are of a dwarf, heath-like habit; others are trees of considerable size." By the way we may now supply an omission in our notice of Dr. Trimen's report by drawing attention to the fact that amongst the *Eucalypti* which have made the best growth at Hakgala, and on poor soil, is *E. marginata*, the grand jarrah, which gives the finest timber of all the species, vieing with oak in quality and with mahogany in beauty of colour and polish. This noble and useful tree seems to take more kindly to the Ceylon hill regions than most of the *eucalypti*. The red gum, (*E. rostrata*) with its clean stems and elegant drooping foliage is very beautiful, but it seems difficult to grow, and has an unfortunate habit of dividing into two or more stems. The most ready grower is the blue gum (*E. globulus*), and the more we learn about the timber of this tree, the more favourable is our impression, if *only the timber is well seasoned*. Darkened with oil the wood resembles fine satin.

Correspondence.

To the Editor.

CINCHONA IN JAVA.

Tjikoraï Estate, Garoet, 31st March 1888.

DEAR MR. EDITOR,—I thank you for sending me the *Ceylon Observer* of March 8th, in which I found two letters on Java cinchona which interested me. Still my opinion differs greatly from that of your correspondents'.

I do not think 12,000 acres are all there is under cinchona in Java. The Government gave out in fee farm about 62,000 acres for cinchona, and about 33,000 acres for cinchona and other produces.* How much of this expanse is planted up now I cannot tell, but I am afraid 20,000 acres would be a very low estimate. All cinchona estates in this island I know of, but one, have more than 120 acres in cultivation. An estate of 300 bahos or 500 acres is considered in Java of middling extent.

J. C. Bernelot Moens gave as his experience† in Java, that cinchona fields of 8 years old and in good condition produce about 180 kilogrammes of bark per acre per year, which would make for Java 3,600,000 kilogrammes or about 8,000,000 lb. yearly. Bark renews beautifully in Java. Fresh acreage is being added continually.

I don't know what Mr. Rivers Hicks considers to be the average of the Ceylon yield of quinine, so I can't say much about his estimate of Java bark being 50 per cent richer than Ceylon bark. What I know is that Java planters do not consider 5 per cent of sulphate a high analysis for stem, and that one of my last invoices of about 5,000 lb. analysed nearly 8 per cent for stem and root.

This bark was harvested from a plot of six year old trees that has since been replanted with grafts of little less than twice that yield. There certainly goes some inferior bark into the market, and this will continue to go as long as it pays planters to harvest it; young branches and twigs always have a poor bark, but this says nothing for the ripe stem-bark.

Your correspondents greatly mistake in thinking that Java planters would like your Ceylon estates to ship all their bark at once. If they did, prices would fall to a mere nothing, which would make our poor branch unsaleable at a time that Java not being in full produce yet, inferior barks ought to sell well. Afterwards we shall be our own worst enemies. The time of being afraid of Ceylon, is pretty well past by this time. We are afraid of Java now.

How angry Mr. Hamilton is with the Chairman of the Java Planters' Association. He even gives him the kind epithet "astute" for telling what is going on in Java. I don't think Mr. Hamilton pays himself a compliment by his insinuations. The chairman in question is a *tea*-planter *nota bene!*

As to what trees can produce I beg to direct your attention to the Government tree, No. 89, mentioned in the same number of your *Ceylon Observer*. The tree when harvested was 20 years old, and yielded a crop of 72 half-kilogrammes of dry bark of about 14 per cent sulphate.

I address to you by this mail a description of barks sold in Amsterdam on the 23rd February last; perhaps the analyses will interest you.—I remain, dear sir, faithfully yours,

ANTON: KESSLER.

TROPICAL CULTIVATION IN THE WEST INDIES: FOOD FOR TURTLE, &c.

Nuwara Eliya, 6th April 1888.

DEAR SIR,—I annex extracts from letter received by last mail which may be of some interest to you.—Yours faithfully, A. M.

Antigua, W. I., 20th January 1888.

"Both your kind favours of the *Tropical Agriculturist* have been received, and much appreciated..... The fearful depression in the sugar markets, during the last three years, nearly brought the West Indies to the brink of ruin, and paralyzed all trade connected with that industry: an improvement is now established and more confidence is everywhere visible, especially in London. This is partly due to the partial failure of the beet crop and to the attitude assumed by the late Conference, of which you know, to the diminished stocks and the probable increase of consumption, and we hope to get £12 per hhd. this year instead of £7 the average for last year's crop. It was well for us that good seasons prevailed since you left us, or there would not be a sugar-cane here now.....

"Ceylon must be a fine country and flourishing too. The *Tropical Agriculturist* tells well for it; for a periodical of its ability could never be supported there otherwise, and I find that it is only one of its many literary products. By-the-bye see page 223 of the *T. A.* Oct. 1st, 1887, a note beginning, "In Mauritius there is a cactus &c." Such a cactus is quite common here, and is named the *French prickly pear*; it is said to be eaten by cattle in dry weather, and is the only food we give turtle in kraals'. It supports them and keeps them in fine condition for months, and improves their flavor also; it is much used by the natives for headache and all sorts of pains, the little branches, about the size of a lady's hand, being slit through the middle, parallel to the flat surface, and applied to the part affected, the inner part next the skin; they do not possess the slightest trace of a prickle or anything to injure the most delicate hand. They grow to the height of 8 ft. or more, and can be propagated by sticking any small portion the size of a half crown in the ground, and keeping watered until it throws out half inch shoots (in a few days, after that it will look after itself: it will live for months on the ground without being planted. If the ground is anyway moist it will grow at once by merely scattering it about on the soil, and when once started will flourish anywhere. If you have any turtle will send you a plant *via* London for them."—Yours, &c.

(Signed) M. BROWN.

POOR TEA.

Kandy, 13th April 1888.

DEAR SIR,—In looking over last Wednesday's local sales, I was surprised to see the number of estates that did not fetch satisfactory prices. I for one being of the number; I have tried all sorts of withering and rolling, but with a bad result. Would it be much to ask if any of the gentlemen honourably mentioned, would give us an idea of their manufacture through your valuable columns?

WILLING TO LEARN.

[Our correspondent should invest in the several manuals and pamphlets in which our tea authorities have already given the required information, and if that does not suffice, pay a fee to a competent authority to come and give him a lesson or two in tea-making.—ED.]

CENTRAL TEA FACTORIES.

Udapussellawa, 19th April, 1888.

DEAR SIR,—Some remarks in *Observer* today remind me of a theory I have wanted to try, but have not the chance here: Central Tea factories are no doubt the most economical. The great trouble seems to be the transport of green leaf, which must be done twice a day. My idea is to have

large boxes, airtight if possible, either wood or iron, the fresh leaf to be closely packed and pressed, the firmer the better. This I expect will carry without change for 12 hours, and would lessen cost of transit very much. I consider a basket of leaf in the loose state it is carried from a distance has the very best chance of fermenting and deteriorating on the way. In the packed box no doubt some leaves would be bruised, but they could be picked out and cured separately, if necessary. Please get someone to give this a trial. Weather simply perfect, crop coming in, and as yet very little bug. UVA.

TROUT IN CEYLON: MAHSEER AND LULU.

G. O. H., April 19th.

SIR,—I have lately returned from a shooting trip in the Anuradhapura district, and having been laid up for more than a fortnight at a place on the Kurunegala road far out of the reach of postal communication, was naturally glad enough to look at the papers when I arrived at Colombo.

It may be in the memory of some of your readers that some time ago when the first trout was caught in Ceylon, I wrote a letter to your journal, congratulating Mr. LeMesurier on the successful result of his experiment, and suggesting that if further acclimatization were tried, it would be desirable to get some ova of the species of the trout which are found near Tetuan in Morocco; as fish from a similar climate habitat would be more likely to succeed here than ova imported from the colder waters of Scotland or England where they could only be expected to survive in the hill streams, and not be of general benefit to the whole island. In answer to my letter Mr. Cross, who was the gentleman who was fortunate enough to catch the first Ceylon trout, wrote rather questioning my statement that there were trout at all in Morocco. It was, therefore, a rather curious coincidence that on taking up the *Field* of March 3rd, almost the first thing I saw was the interesting article by that experienced angler and well-known writer to the *Field*, Sarcelle, on "Some African Trout." I do not wish to re-open the discussion with Mr. Cross for the petty object of proving that my facts were correct, but I have been asked in the public interest to call the attention of Ceylon sportsmen generally, and Mr. LeMesurier in particular, to the letter I refer to, for the following reasons:—

1st. That, if an importation of these splendid fish could be successfully introduced here as the climate of Tetuan is, even in the winter, far hotter than the average climate of Ceylon, there is no reason why these fish should not people not only the hill streams, but also spread over all the large rivers of the island, thereby not only affording sport and healthful recreation to the Europeans, but also an addition of valuable food supply for the natives.

2nd. That Morocco is nearer than England, and consequently the week less of time required for the transit of ova would materially diminish the risk.

3rd. That the present British Minister at Tangier, Mr. Kirby-Green, is a near relative of one of your best-known merchants in Colombo, so would naturally take an interest in giving his utmost assistance. Further, Sarcelle, who is an enthusiastic piscaculturalist and who is, I believe, well known to be no other than H. M. Consul at Mogador, would doubtless assist with his experience and advice. Obeying, therefore, the expressed will of some Ceylon residents, I again venture to call the attention of Mr. LeMesurier to this point, and I hope that if tried, the experiment will be a successful one, and that I may live to return to Ceylon and catch a *Salmo Macrostigma* in its beautiful and sunny streams. One word of warning I would venture to give, and that is that great care should be taken when importing these ova not to lower the temperature with ice *too much*, for just as our northern trout are bred in the icy streams of Wales and Scotland, and any sudden rise of the temperature above a certain point becomes fatal to them, so these fish bred in the almost tepid streams running down from the Atlas range, any excessive lowering of the temperature would be as fatal to them as excess of heat to the others. The temperature should be lowered very *gradually* to a certain point, and then kept as steady as possible.

I see there was a discussion also as to the mahseer being identical with the Ceylon lulu. I cannot say whether the mahseer is found in Ceylon, but I took particular pains to procure specimens of the lulu, and I can positively assert that the lulu is not the mahseer, or in the slightest degree resembling it. The lulu is one of the great loach tribe, but more nearly allied to its European congener (the *Silurus Glanis*), while the mahseer belongs to the carp tribe, and more nearly resembles a huge chub than anything else. L. T. GRAHAM-CLARKE.

SOME AFRICAN TROUT.

The existence of undoubted trout in the neighbourhood of Tangier, in certain streams among the Anghera Mountains, was, I believe, made known some years ago through the columns of *The Field* by an English gentleman resident at Tangier. But now that the picturesquely situated town on the Straits of Gibraltar appears to be coming into some fame and favour as a winter health-resort, and that travellers in the empire of Morocco are yearly becoming more numerous, some little additional information on the subject of these interesting Salmonidæ may be found useful. The principle places where they are caught are the said Anghera Mountains, near Tangier, and certain affluents of the Marteen river, near Tetuan, on the Mediterranean side of the Straits. From the latter place I received last year a huge bottle, containing what I should have called, had I caught them in a mountain stream, a very pretty dish of trout. They were from a quarter to three-quarters of a pound in weight, some brown and golden with large red spots; some silvery sea-trout-looking specimens, with small black, and a few small pink spots. I fondly hoped that some of the latter might prove to be anadromous; but on examination by Dr. Günther, that eminent authority stated that there was not a migratory specimen among them, and that they were "without doubt the *Salmo macrostigma*," precisely similar to specimens previously received from Algeria and Tangier. Algerian travellers should make a note of this.

Information about the Anghera trout streams can doubtless be obtained from the hotel keepers at Tangier. With reference to Tetuan, I have received from an intelligent resident the following interesting particulars, which I translate literally from the Spanish —

The trout are caught in the affluent of the river Martin (Marteen), called Kitan, and in another called Buglad (probably Bow Jdad). They are also caught in an abyss (pit?) full of water from a spring, called Zarkan, in the village of Yarghitt. It is supposed that both in Kitan and in Yarghitt they are bred because the water, passing through the mills, carries along some of the flour ground in the mills which are near these places. Yarghitt is distant about four miles from Tetuan toward the mountain Beni Hosmar. Buglad three miles from Tetuan on the side of the same mountain; Kitan is two miles off, and is between the orange groves which bear that name. The trout are never caught at the mouth of the river near the sea, but only in the places I have stated above. They are caught always by some four or six individuals, only with hooks, not with nets or any other tackle.

ments. Very few are caught, and not when the river is very clear, for there are few of them, and they are quick at seeing the fisherman (lit., "they see much the fisherman"). Nor can they be caught in all seasons. They are mostly taken in the spring and on the first rains of winter. The literal name which is given to them here is *essemh*, and many Moors do not know this name.

There is a *hiatus* in the above quaintly interesting account, in that my kind informant makes no mention of the bait put on the hooks with which the "four or six individuals" (doubtless professional fishermen), bring to bank the spotted beauties amid the orange groves of Kitan, and by the mill-tails of Yarghitt. But surely there is a new and luxurious sensation for the Globe-trotting angler—trout fishing among orange groves, with sweet suggestions of wetting the first fish on a hot day with a juicy orange instead of a drop of the crathur.

Apropos of baits, I heard from some travellers who paid a brief visit to one of the districts in question, that they, trying various flies, were unsuccessful, and were laughed at by the natives who told them that the fish would not take anything of that kind, and proceeded to catch some with worms, grasshoppers, or grubs. I am not quite sure which. Dr. Günther states that the stomachs of most of the Tetuan trout which I sent him were "crammed full with the larva of some Dipterous insect unknown to me." I should imagine that they would, like most other trout, take the right fly when offered to them at the right time, and in the right way, and that they would prove far less highly educated than the inhabitants of the crystal chalk stream waters which "Detached Badger" and other masters of the great dry fly school are so successful in beguiling.

Were the place not so far from this southern district of mine, I would soon try conclusions, with fly, minnow, and *faute de mieux* worm. But I hope that ere long some of the numerous sportsmen visiting Morrocco may be able to give in these columns satisfactory accounts of interviews with the bonny essemh of the Anghera hills, the Kitan orange groves, and the Yarghitt flour mills. The Anghera streams can be reached from Tangier, where there are plenty of hotels, and guides, tents, &c., can be obtained. The other waters are within easy distance of Tetuan, where there is a small hotel, the proprietor of which speaks English, and can give a necessary information. SARCELLE.

Mogador, Morrocco, Feb. 8th.
—The *Field*.

SPECIAL TEAS FOR AMERICA.

KELANI VALLEY, 20th April 1888.

DEAR SIR,—Don't you think that Mr. Rutherfords scheme would be far more likely to succeed if we *studied the tastes* of our American cousins, instead of sending them a tea they are wholly unused to?

Tea, like many other good things (pickled olives for instance), is an acquired taste, and the people used to the harsh bitter flavour of green tea will be long before they learn to appreciate the rich malty flavour of our black teas.

But, apart from this, green tea appears to promise far better results as regards prices than we can hope to obtain for our black tea, besides the advantage to the latter.

I have lately had an opportunity of tasting samples of China green teas (some of the lower grades literally rubbish) which fetched in New York the splendid average of 31 cents of a dol. per lb., or about 93 cents of Ceylon money taking the dol. at 4s 6d and the rupee at 1s 6d sterling. Ceylon black teas sold in the Lane about the same time averaged barely 70 cents per lb.; here then is a difference of upwards of 20 cents per lb. in favour of green tea, even if we cannot hope to beat China in quality.

One planter, at least, has, I hear, decided to try a shipment of green tea to New York, but, unless he is supported by his brother planters as he deserves to be, he is sure to have an uphill fight in the 1st place. An individual planter could not put a sufficient quantity of tea in the market to draw and fix the attention of the trade, nor can he afford to push his teas by means of paid agencies, advertising and giving away of free samples.

If others do not care to join in the fight, by manufacturing a sufficient quantity of green tea to keep the pot boiling, the least they can do in my opinion is to render assistance by means of the Ceylon tea fund. In bringing these teas prominently before the American public, the Indian planter would also do well to send a certain amount of green tea only. In dealing with an enlightened people, they might dispense with the use of soapstone, though (judging by the China samples above alluded to) the Americans do not appear to object to a little colouring matter.—Yours truly,

GUNPOWDER.

PATANA FLOWERS AND THE SUPPOSED STICK INSECT.

DEAR SIR,—I always read "On the Hills" with pleasure: the description of scenery and little remarks on natural history, animate and inanimate, must be welcome to many readers. I noted the account of the violet with saggitate leaves and the beautiful daffodil-like ground orchid, both great favourites of mine, and have had them for years in my garden, but I find neither of them likes shade or rich soil, and they are gradually dying out. The orchid seems to do best in a few inches of poor patana soil on a slab rock, so would grow in a pot. I have had three blossoms on one stalk, but rarely. It is a common plant in many places on the higher Uva Patanas, its scents always reminds me of the primrose. These flowers will keep fresh in a jar of water for about three weeks. The violet is quite a weed in places in Haputale, and is generally found growing freely on the soil thrown out of the drains cut between the patenas and cultivated ground. I think the supposed stick-insect referred to will prove to be a caterpillar, as I have met with many of the latter well agreeing with the description given, and I know of no species of stick-insect which can spin a web. The last caterpillar of the kind I met with was being captured by a mason-wasp; the first sting paralysed it, and it then deliberately stung it in every joint, and then carried it off to its nest. KOSLANDE.

[Thanks for the interesting information about the patana flowers. Our "stick-insect" proved on final examination to be a veritable bit of twig, one end of which was inhabited by a creature capable of emitting a spider-like thread. The creature was active when originally caught, but after a night in a tumbler all signs of life had so utterly disappeared that friends were sceptical of any having been ever connected with the stick. But we could not possibly be mistaken: we saw a head protruding and hauling its body and the stick up by the thread. — ED.]

THE JAVA CINCHONA ENTERPRISE.

DEAR SIR,—I have been reading with interest the accounts of the extent of the Java cinchona enterprise, and the probable outturn from the bark during the next few years. The estimates are sufficiently alarming to one who still has a small interest in the article. It is, however, with surprise that I have waited for the views of someone more largely interested, commenting upon the state-

ments from their experience gained from the cultivation of considerable quantities of seed imported from Java and *guaranteed* pure Ledger seed, and sold at enormous prices. Now what has been the result from this fine seed. My own experience that they are worthless as to growth and from published analysis worthless as to results. I have a few Mattakelle ledgers planted at same time, which have grown with vigour, the Java ones have struggled to exist. It would, however, be well to have the results from others, but if my experience is general, we can form a pretty good idea of the quality of the Java ledger trees.

The results of the analysis from Java bark must be received with caution just now, for there is considerable jealousy between London and Amsterdam to secure the future market for this bark, which leads one to doubt the *bona fides* of the actual outturn.—Yours truly. CINCHONA.

THE TEA ENTERPRIZE IN TRAVANCORE.

Colombo, 21st April, 1888.

DEAR SIR,—I was agreeably surprised to see in your *T. A.* for April, page 689, that some friend, who signs "M., Travancore," had thought it worth his while to notice my letter on the tea enterprize in Travancore, which is in the *T. A.* for February. I thank him for the epithet "cheery" which he has applied to my report, and I hope that our prospects will continue to deserve the same.

But your correspondent requires a little friendly correction for his intimation that in my report I gave "only *hearsay* information.' On seeing this, I felt bound to refer to my report; and, after reading it over again, I could not avoid the conviction that anyone who thought its information to be "only *hearsay*" must be characterized more by length of ears than by clearness of eyes. In reply to his aspersion, I refer him to that report, only asking him to read and learn, remembering also that the same report was as a supplement to tabulated statistics which accompanied it, and which will appear in your new Directory. Your correspondent is pleased to refer to a small field which I planted with tea so long ago, that on account of it he would bring me into prominence as the oldest tea planter in South Travancore. But I deserve not that honour, and humbly decline it. He also shows some desire to know the result of that little field, but I object to admit anything of a personal nature into consideration; and even if I were to tell "M" that the aforesaid little field of tea is not in existence, it would not in the least affect the general state and prospects of the tea enterprize in Travancore. To bring these into more general notice was my only object in writing; and these, notwithstanding whatever "M" or others may write or think, are, and will be, "cheery" still.

It is true, that I was silent as to "yield," and I gave good reasons for being so. I look with confidence for the proper time to give them, not as "M" in his letter brings up some "hearsay" tales, but by carefully collected facts.

By a happy coincidence, on the same day that I saw "M's" letter when I was upcountry, I saw also your Supplement to the *Observer* for 11th April, and for the encouragement of poor "M," I cannot do better than refer him, and any others (if such there be) who agree with him, to the following extracts from that supplement.

"FROM GEO. WHITE & CO'S. ANNUAL INDIAN, CEYLON, AND JAVA TEA REPORT.

London, 33 Fenchurch St., E. C., March 19th.

Comparative Quality of the outturn of the different districts for the past three seasons.

NEILGHERRIES AND TRAVANCORE.

"1886 CROP.—Only a limited quantity has been received, and this generally of worst description. It is said that most of the best tea in the former district is used for local requirements.

"From the latter, some very desirable parcels have come to hand, similar in flavour to Ceylons.

"1887 CROP.—Most of the shipments from the former have been of the inferior makes, and it is evident that the best teas are used locally.

"From Travancore, however, some *choice flavoured* parcels have *again* been received; and this comparatively new district promises well."

The above confirms the reports from other experts which I gave before, and while I do not accuse "M" of a desire to run down the country Travancore, I feel sure that it will run up without his aid.—Yours truly, JOHN COX.

THE FRENCH VINEYARDS (like our coffee estates with green bug after the leaf fungus.—ED.) are in for another pest. It would seem as if they were getting completely worn out, and were useful only as breeding-grounds for animal and vegetable parasites. The new pest, which has attacked the vines in the south of France, is a fungus known to botanists as Coniothyrium diplodiella. Its direct action is to attack the grapes and cause them to shrivel and dry completely up.—*Australasian*, March 10th.

COTTON SPINNING IN INDIA: A DIFFICULTY OVERCOME.—One of the great difficulties Indian cotton spinners have to contend with in the hot dry weather is the electrical disturbance of the air inside the mills, owing to which the fine cotton dust raised by the working of the machinery takes a very long time to settle. An ingenious apparatus, called the Aerophore, which has recently been introduced, overcomes this obstacle by damping the air. Jets of water are forced through a series of minute holes and turned into an almost impalpable spray, which spreads through the room or mills, and has a wonderful effect in laying the cotton dust. Not only do the rooms become more pleasant and healthy, but there is a great improvement in the working of the machinery. The same apparatus, charged with a disinfecting liquid in place of ordinary water, is found very useful in hospitals or other places where pure air is essential. Of course a disinfectant could in case of need be use in mills, and thus serve a double purpose.—The *Englishman*.

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, 12th April 1888.)

FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.
BEES' WAX, White	Slightly softish to good hard bright	£6 a £6 10s
Yellow	Do. drossy & dark ditto	85s a 105s
CINCHONA BARK—Crown	Renewed	5d a 1s 6d
	Medium to fine Quill	8d a 1s
	Spoke shavings	4d a 9d
,, Red	Branch	2d a 6d
	Renewed	3d a 1s 6d
	Medium to good Quill	6d a 9d
	Spoke shavings	3d a 7d
	Branch	2d a 4d
	Twig	1d a 1½d
CARDAMOMS Malabar	Clipped, bold, bright, fine	2s a 2s 6d
and Ceylon	Middling, stalky & lean	8d a 2s
Alleppee	Fair to fine plump clipped	1s 3d a 2s
Tellicherry	Good to fine	1s 6d a 2s
	Brownish	6d a 1s 3d
Mangalore	Good & fine, washed, bgt.	1s a 2s 4d
Long Ceylon	Middling to good	8d a 1s 4d
CINNAMON 1sts	Ord. to fine pale quill	3d a 1s 5d
2nds	,, ,, ,, ,,	7½d a 1s 4d
3rds	,, ,, ,, ,,	6½d a 1s 1d
4ths	Woody and hard	5½d a 10½d
Chips	Fair to fine plant	2⅜d a 8d
COCOA, Ceylon	Bold to good bold	80s a 90s
	Medium	74s a 78s
	Triage to ordinary	60s a 72s
COFFEE Ceylon Plantation	Bold to fine bold colory	90s a 105s
	Middling to fine mid.	77s a 88s
	Low mid. and Low grown	72s a 76s
	Smalls	69s a 74s
Native	Good ordinary	60s a 70s
Liberian	Small to bold	50s a 69s
East Indian	Bold to fine bold	90s a 104s
	Medium to fine	77s a 88s
	Small	69s a 73s 6d
Native	Good to fine ordinary	60s a 70s
COIRROPE, Ceylon & Cochin	Mid. coarse to fine straight	£5 a £15
FIBRE, Brush	Ord. to fine long straight	£13 a £32
Stuffing	Coarse to fine	£9 a £18
COIR YARN, Ceylon	Ordinary to superior	£13 a £35
Cochin	Ordinary to fine	£13 a £35
Do	Roping fair to good	£11 a £15
COLOMBO ROOT, sifted	Middling wormy to fine	8s a 24s
CROTON SEEDS, sifted	Fair to fine fresh	10s a 15s
GINGER, Cochin, Cut	Good to fine bold	83s a 87s 6d
,, Rough	Small and medium	28s a 49s
	Fair to fine bold	25s a 45s
	Small	16s a 23s
GUM ARABIC, Madras	Dark to fine pale	30s a £6 10s
NUX VOMICA	Fair to fine bold fresh	10s a 12s
	Small ordinary and fair	7s a 9s
MYRABOLANES Pale,	Good to fine picked	5s 3d a 7s 6d
	Common to middling	3s 6d a 4s 9d
Pickings	Fair Coast	4s 9d a 5s
OIL, CINNAMON	Burnt and defective	2s 6d a 3s 3d
CITRONELLE	Fair to fine heavy	8d a 2s 6d
LEMON GRASS	Bright & good flavour	¾d a 1d
ORCHELLA WEED	,, ,, ,, ,,	1¼d a 2d
PEPPER, Malabar blk. sifted	Mid. to fine, not woody	35s a 37s
Alleppee & Cochin ,,	Fair to bold heavy	7¾d a 8¼d
Tellicherry, White	,, good ,,	
PLUMBAGO Lump	,, ,, ,,	none here
	Fair to fine bright bold	12s 6d a 17s
Chips	Middling to good small	7s a 12s
dust	Slight foul to fine bright	6s a 10s
RED WOOD	Ordinary to fine bright	5s a 9s
SAPAN WOOD	Fair and fine bold	£4 15s a £5
SANDAL WOOD, logs	Middling coated to good	£8 a £9
Do. chips	Fair to good flavor	£20 a £44
SENNA, Tinnevelli	Inferior to fine	£5 10s a £22
	Good to fine bold green	7d a 10d
	Fair middling medium	3d a 6d
	Common dark and small	½d a 2½d
TURMERIC, Madras	Finger fair to fine bold	7s a 8s
Do.	Mixed middling [bright	6s a 6s 6d
Do.	Bulbs whole	5s a 5s 6d
Cochin	Do split	5s a 5s 3d

FUEL FOR ESTATES.

A correspondent, writing to us from London, expresses the interest he has felt in the several letters which have appeared in our columns dealing with the above subject, and specially, as regards the calculations made by Mr. Rutherford and communicated by that gentleman in his letter to the *Observer*, as to the annual rate at which our present sources of supply are likely to be used up. It is a subject, our correspondent thinks, the importance of which cannot be too highly rated; and he adds to the discussion his own view that, however widely and speedily Mr. Rutherford's advice to plant quick-growing trees on and about our tea estates may be followed, the result is not likely to be soon enough obtained to avert, what he terms, a fuel famine occurring, which will do much to hinder the economical preparation of our island teas. He thinks that a remedy for this apprehended evil must be sought in another direction, in the provision of some efficient, but cheap means of transporting firewood from the lowcountry. There can be no doubt, that long before all the present available supplies are exhausted, or even approach exhaustion, the cost of fuel on our estates will have reached a rate which must be almost prohibitory of successful competition as to price with the cheap varieties of tea from China and Java; and, if we are to avoid being exposed to this difficulty, it may be wise to look early for other sources of supply to supplement that which is now close at hand, but must soon rapidly diminish. Our friend suggests to us that there is every probability that wire tramways—as they are somewhat illogically termed—are the means best adapted for tapping the abundant resources which the base of the hill-country can furnish, and he believes that large groups of neighbouring estates should combine to erect such wire-rope railways, by which not alone firewood, but timber for tea-boxes also, could be brought up from the lowcountry at a cheap rate.

It is doubtful, he thinks, if our main line of railway could be an economical carrier of wood fuel. Already, our railway management experiences a dearth of supply sufficiently contiguous to the lines to enable it to keep down working expenses, and it is manifest, therefore, that it can hardly afford to carry material, the provision of which would be in direct competition with its own needs. Beyond Matale, no doubt, there exists ample forests to be drawn upon, fuel cut in which could be transported to the distant station to be built at Haputale; but the cost of transport over such a mileage and up the steep inclines of our mountain railways, must prohibit such a source of future supply being considered available; and, with the heavy traffic already existing on our line and the large development we may expect it to receive, it would be impossible for the railway to carry up fuel at any rates which would render supply from such a source practicable. Some time back, we wrote as to improvements made in the construction of wire rope tramways which seemed specially to fit them for adoption as branch feeders to our railway, for the conveyance to the stations, or to specially constructed sidings, of our estates produce. We think that there is every possibility that some day or another, we may see that suggestion acted upon very widely, and we can realize that the improvements we there referred to, would greatly facilitate a further adaptation of the idea to the object of bringing up fuel, at certain points, from the low country, as we have above suggested.

The cost of such an aerial line is not great, and the construction of say, 20 miles of it, would not be an overpowering burden for a considerable group of estates to undertake. Such a length of line would probably tap ample reserves of forest in which firewood in any quantity could be cut. It would be possible, we should say, in nearly every instance of such lines being erected, to obtain water-power for working them. The precise localization of their termini would not be matter of importance, so long as they delivered their supplies within the neighbourhood of the group of estates subscribing to erect them, and therefore, there would be a wide latitude available in so placing them that water-power could be utilized in every case. We by no means want to discourage the following of the wise advice of Mr. Rutherford and of other correspondents who have obliged us on the subject with their counsel, to plant quick-growing trees wherever land available for doing so can be found; but we are inclined to agree with our home correspondent in the view he takes that, long before such planting can largely supplement our existing supply, the cost of wood fuel must be very seriously enhanced. His suggestion, therefore, that rope tramways should be utilized as above described, is not without its value, and we should be glad if those interested in the matter would think the proposition over, and communicate to us their views relative to it.

The proprietors of each large group of estates, might form themselves into Limited Companies for the purpose of raising capital to construct and work the lines. One such aerial railway would probably suffice to work an area of some 5 000 or 6,000 acres, and water-power being, as we have said, available more or less in every case, the cost of working would be little more than the wear and tear of the line itself, for the bundles of fire-wood could themselves be slung to the travelling carrier. Everyone seems to be agreed that it is only by maintaining the present low cost of production, that our tea can in the future meet the competition sure to have to be faced, and cheap fuel must constitute one of the chief items of insurance of success in that competition.

There is, however, one fact left out of view by the home correspondent who deals with this subject, namely, the prospect of some other cheap fuel being supplied. Let us hope for the realization of the expectation entertained, as mentioned by us recently, that good lignite from Siam may be laid down in Colombo at R5 per ton, specially low railway rates rendering it available for estates.

CEYLON TEA FOR AMERICA.

We call attention to the forcible remarks (page 801) on this subject of our Uva correspondent in his lively series of "Mountain Echoes." The feeling is evidently growing stronger that the milder Ceylon teas—so well suited to the American palate—should be worked separately from the stronger Indian teas, so that the best thing our planters can do is to go in for supporting Mr. Pineo and Mr. MacCombie Murray. Let Mr. Pineo have the 6,000 lb. tea required for distribution in packets, sharp, at least. Mr. Pineo writes to us as follows, and we especially call attention to the very concise announcement of his "plan of campaign" given by Mr. Elwood May in his letter to his Ceylon representative. This experienced New York capitalist evidently means "business":—

The Club, Colombo, 24th April 1888.

The *Ceylon Observer* has done me a very great kindness, in pointing out the grave omission of

names so interwoven with our new industry that occurred in my appeal of yesterday, and I am deeply grateful to it for doing so.

None know better than myself that Abbotsford, Elphinstone at Windsor Forest, the Ceylon Company, and Messrs. Shand and Symons, in Rakwana, did noble service as pioneers; and to them the tea planters of the present day are infinitely indebted.

It may not be out of place if I now give an outline of what my principal proposes to do:

Our present intention is to buy our supplies in the local market. Every parcel will be subjected to examination by a local expert, in whom all planters have confidence.

Until our teas become known, only the more delicate flavored kinds will be handled.

We propose gratuitously distributing a large quantity of tea in attractive quarter or half-pound packets. With each packet instructions for the correct infusing of the leaf will be given; and also original, telling advertising matter, stating where our pure Ceylon tea can always be had, will go out with every packet.

This, as you are aware, will involve, at the very outset, a large expenditure of money and much ingenuity in the getting up of suitable advertising matter.

For nearly three years my attention has been directed to making myself acquainted with the tastes and views of the American and Canadian consumers, and in learning the views of leading brokers and dealers in tea. In addition thereto I traced the manipulation of Indian tea in the American market, and know results obtained and how far Indian tea has become known to the consumer.

If the Planters' Association and the Planters of Ceylon feel that I am not entitled to their confidence and support, or if they view my scheme and proposed method with suspicion and distrust, they will be doing me a real kindness by frankly and at once saying so. Or if they can be induced to recommend improvements on my scheme, I shall be very grateful.

I am, and have been working conscientiously for the advancement of our great industry, and time alone can prove whether my efforts have availed anything or not. R. E. PINEO.

On second thoughts, I consider, that it may be well to publish the letter handed to me by Mr. Elwood May before leaving America, on this subject.—R. E. P.

[S. ELWOOD MAY, MANUFACTURER AND EXPORTER

Established 1876.]

155 Fulton Street, New York, U.S.A., Jan. 12th, 1888.

My Dear Sir,—When you arrive in Ceylon and interview the tea planters you cannot too strongly urge upon them the likelihood of a great success for their tea in the United States under the proper management and with a man at the head who has the peculiar traits to successfully handle and introduce a new article.

After the fullest and most careful investigation, I have concluded to take hold of the sale of this tea, and I mean to put it firmly upon this market. This you well know, and can explain, involves large sums of money for advertising, etc. and the tea growers should be willing to contribute some tea to give away as specimens.

My successful experience in handling several specialties has necessarily opened up to me the many ways to be tried to reach the consumer and the discouragements that wipe out the many I am proof against.

There is very much more I could state, but I think our many interviews must have posted you well and you can convey to the planters all necessary information.—I am, dear sir, yours faithfully, S. ELWOOD MAY.

To R. E. Pineo, Esq., New York City.

GOLD IN THE SOUTHERN PROVINCE OF CEYLON.

(From Our Galle Correspondent.)

Galle, 24th April 1888.

Mr. Dominico informs me that he was at Dewurangala for three days, during which time he was unable to work any pits himself for want of coolies.

The pits are from 7 to 8 feet deep. The gold obtained is of a dull colour, from which he infers that it is not brought down from a distance, and it may belong to the spot where it is found. He saw many nuggets which were quite spongy, but there was no trace of quartz in them. This shews that the matrix is quite decomposed having been reduced by rain water to bi-carbonate of lime, alum, potash &c. During his visit the place was well occupied with gemmers and gem pits. While washing out the products of the latter, nuggets and pepitas were generally found. One of the diggers (a native) had 23 coolies working under him. He was informed that this man had collected from time to time a good quantity of gold. He was ostensibly gem-digging, but Mr. D. noted that the ground (about one or two acres) had been carefully gone through without leaving an inch undug, which would not have been the case if he were only looking for gems. Another party got a nugget weighing 5½ sovereigns.

Dewurangala is 36¼ miles from Galle, 13 from Akuressa resthouse, and 3 from the Morawaka resthouse. It is reached by the highroad with only half a mile of foot paths. With relays of horses on the road, the return trip can be made in 3 days, or possibly two days. From the river the land up to 20 to 25 fathoms has been dug. The monsoon rain will no doubt interfere with digging operations, though Mr. D. seems to think that the flow of water can be prevented. He adds that in 1879, gem-digging was extensively carried on higher up, and probably the wash with gold were thrown away by the diggers who were no aware of its value.

TEA-FLUSHING AND COOLIES UPCOUNTRY.

(From a V. A.)

The rains are making the tea bushes flush like mad. People can hardly keep up with the bushes. I am glad to see new coolies passing through Kandy. They report that many are coming over in immigrant vessels and that want of rain is affecting crops in India, so I trust Ramasamy will come over accompanied by the lovely Meenatchy and the gentle Carpie. When will we get news of the prospect of new China season's crop? The buyers were leaving London about 5 weeks ago.

[The season opens next month and we hope to have the news pretty sharp.—ED.]

NEWS FROM NORTH BORNEO.

A letter from an old Ceylon resident dated Sandakan, 5th April, reports:—Tobacco and pepper are the trump cards here, though a good thing is being made of timber and other lines not agricultural. I am pleased with the flattering notice in the *Observer* of our go-aheadness." There is no word of disturbances, so the riots on West Coast don't appear to affect them much. Mr. Callaghan on West Coast writes that an English Company with £50,000 is starting in his district Silam. He leaves soon for a four months' trip to the old country.

GOLD IN THE SOUTHERN PROVINCE: THE DEWURANAGALA GOLD FIELDS.

(From a Planting Correspondent.)

I have read up "Lyell," and also turned up the article "Gold Mining in Ceylon" in your Directory. The latter has very much enlightened my darkness, and is already a guiding light how and where to proceed on the spot.

The man Dominico (who is he?*) appears to have been the real pioneer, or discoverer of the dark doings of the constable Arachchi. Your maps, or plans obtainable from the Survey Department will probably furnish the best guides to what is Government Waste Land and what is not. [No doubt.—ED.]

The first applicants who prospect and apply in a hurry are not the most likely to get the best grants, especially those who go to work quite ignorant of the teachings of geology. What should be first ascertained, if possible, is whether the mother veins exist in subjacent rocks or in more elevated distant ridges: the finds being so far, I understand, in the alluvium only. This is a clue, but only a clue, to the situation of the veins (though the deposits themselves *may* be found to be rich enough to work) as upheavals, subsidences, and denudations may have altered the direction of the water-shed since the remote times when the auriferous alluvium of Deurangalla was deposited. Time spent in a little preparation to understand the subject by study will not be lost time.

By the *Observer* to hand since penning the above, I see a Colombo Syndicate has sent Mr. George Armitage to prospect, and gives also the position and distance of Akuressa. I fancy he will form an opinion more on what he can exact of the truth of past finds than on the results of actual digging himself, but we shall see. If he digs and digs for a week and finds nothing, that will be no dispro f. Nor will a nugget turned up with the first cut of the mamoty with nothing after it, be proof of much wealth. I fancy the first eager pioneers, in this as in other things, will only show the later comer how to improve upon their proceedings. Besides, I see that Government restricts the leases and licences to very meagre lots, so that there will be plenty of land left.

(From an old Australian Digger.)

I got your note about the new "Gold Field," and had arranged to start en route this morning, but learned by the *Observer* that came in last night, that the distance is much greater than I had anticipated, being 36 miles from Galle, so I must re-arrange for longer time. About these nuggets I fear they are too many and two heavy to be reliable. If such finds can be got with their unskilled and unsystematic way of working, it is time we were off to peg out a claim. I shall go and see what is to be seen and hear what is to be heard; but first shall call at the Kachcheri, and see what assistance or information Acting Government Agent can give me.

To the Editor, Ceylon Observer.

27th April 1888.

DEAR SIR,—With reference to your para on quartz specimens in your issue of 23rd inst., it might be of some importance to those who think they have auriferous quartz in their properties to know that they need not call to detect gold by the naked eye in quartz if it is there. Nothing could show more distinctly, whether you are experienced or not than gold does in quartz. The least speck, though not larger than a needle prick in a sheet of paper, if enough to be visible, cannot be mistaken. Iron pyrites, mica, or other metallic substances show different shades of colour as you turn the stone in your hand. Gold will never change its shade; turn it or look at it as you like. It is also worth noting that if there is gold in paying quantity in quartz you are certain to see it by breaking up some of the stones and examining them carefully, even with as little as 6 penny-weights to the ton, you will see a great many specks. If the quartz is difficult to get 6 penny-weights is not a paying quantity; you will see it in many of the stones with little trouble if in payable quantity.

I remember many years ago good Mr. John Anwardt showing me a cooty sack full of *road metal* from a quarry near Galle, and asking whether I would take shares in a Gold Reef Company that he intended getting up to work it. The stone was full of iron pyrites. Had there been as much gold, the outturn would have been enormous; but not a speck of gold was to be seen, and as unlikely stone to find gold in as you could imagine. I told him so, but his expectations had been raised, and he wisely resolved to have it tested, the result of which led him slowly and sadly to realize the fact that his fortune did not lie in the quarry at Galle.

Quarts may be very simply tested, thus:—Take 10 lb. or more (the greater the quantity, the more reliable the evidence), burn it well, then grind it to powder, next put it in a strong iron vessel, and apply great heat and stir it. The particles of gold will melt like lead and run altogether in one piece at the bottom. Or instead of heat, water and quicksilver could be used, but as no one is likely to try the experiment, I need not give details.

—Yours, &c. EXPERIENCE.

*An Italian who came here some years ago after red coral.—ED.

CEYLON TEA PLANTATIONS COMPANY, (LIMITED).

INCORPORATED UNDER THE COMPANIES' ACTS, 1862 TO 1883.

OFFICES.—21 Mincing Lane, London, E. C.

DIRECTORS.—David Reid, Esq., Thomanean, Kinross-Shire, CHAIRMAN; Donald Mackay Esq., Hereford; Henry Tod, Esq., 21 Mincing Lane; David Reid, Esq., 7, Mincing Lane.

SECRETARY.—Henry Tod, Esq.

MANAGER IN CEYLON.—Henry Kerr Rutherford, Esq.

BANKERS.—The Chartered Mercantile Bank of India, London and China. The Commercial Bank of Scotland, Limited, 123, Bishopsgate Street.

SOLICITORS.—Messrs. Murray, Hutchins and Stirling, 11, Birchin Lane, E. C.

AUDITORS.—Mr. R. H. Miller, 10, Coleman Street, E.C.

REPORT OF THE DIRECTORS to be submitted at the First Annual General Meeting of Shareholders to be held at the Offices of the Company on Friday, 13th April, at 12 noon.

The Directors have the pleasure to submit the General Balance Sheet and Profit and Loss Account for the year ending 31st December, 1887, duly audited.

	£	s	d
The net profit, after providing for the General Expenses, including Directors' Fees, Income Tax, &c., amount to	13,257	18	3
An interim dividend of 6 per cent. was paid on 18th July, 1887, absorbing	4,005	8	0
A second interim dividend of 1 per cent was paid on 14th January, 1888, absorbing ..	5,003	12	0
It is proposed to pay a final dividend of 8 per cent (making 15 per cent in all, free of Income Tax) which will absorb	3,751	10	0

			£ s d
To write off on account of "Preliminary Expenses"		265 6 8	
And to carry forward to next year a balance of	..	1,729 1 7	
			13,257 18 3

The Directors trust that the results of the first year's working of the estates and appropriation of profits will be satisfactory to the Shareholders. The gross average price realised for the tea crop of 1887, sold in London, was 1s 1d, while the average from the estates for 1886, was slightly *under* 1s 1¼d. The annexed tabulated statement, prepared by the Ceylon Manager, gives full and detailed information as to the position of the Company's estates, their yield per acre, and the cost of tea, f. o. b. Colombo. The Directors are fully satisfied with the result, and think the Shareholders are to be congratulated on the possession of such a valuable property, which, in spite of an adverse season, has returned them large profits. The ability and energy displayed by Mr. Rutherford in the administration of the Company's affairs in Ceylon, is highly appreciated by the Board, and they further acknowledge most heartily, the zeal and intelligence of the Superintendents and staff on the estates. Under clause No. 69 of the Articles of Association, Mr. Henry Tod retires from the Direction, but, being eligible, offers himself for re-election. It will be necessary to appoint an Auditor for 1888, and Mr. R. H. Miller again offers himself for the office.

DAVID REID, Chairman.

London 5th April, 1888.

For the Ceylon Tea Plantations Company, Ltd.,
H. K. RUTHERFORD,
Manager in Ceylon.

6th February, 1888.

THE FIRST CEYLON TEA COMPANY AND ITS FIRST ANNUAL REPORT.

The very full and interesting Report published by the Ceylon Tea Plantations Company given above, deserves prominent notice, although there is really no room for comment, so complete is the information afforded by the Directors and their able Ceylon Manager, Mr. H. K. Rutherford. The most interesting part to the fortunate shareholders in this prosperous Company is, of course, the successive dividends, aggregating 15 per cent for the past year. But to those outside the Company interested in what can be done under the most favourable circumstance with tea in Ceylon, the best news is that the Company's tea from four different estates cost f. o. b. an average of only 5½d per lb., Mariawatte's portion being indeed so low as 4¾d. To realize the profit we have to compare this with the average realized in London, namely, 1s 1d per lb. for over half-a-million lb. Of course, various charges have to be accounted for, but the wonder is that the dividends did not even amount to more than 15 per cent. It must be remembered, however, that a good deal of the tea is still too young to give full bearing crops. Everything promises well for this Company, and we congratulate the shareholders on having their affairs so well looked after. Fifteen per cent casts even our Colombo Wharf and Hotel Companies into the shade.

THE TEA ENTERPRISE AND SUPPLIES OF FUEL.

Some of the sentiments expressed by our correspondent "X.Y.Z." (page 809) we have long entertained and strongly expressed. We hoped and we still cherish the hope that both for railway and tea estates purposes, some artificial fuel will be invented which will supersede both coal and wood fuel. When Sir Arthur Gordon was on one occasion looking over the trace of the railway from Nanuoya to Haputale, we drew his attention to the vast expanses of forest along the route, reserved avowedly to supply the railway with fuel, and we expressed the hope abovementioned. His Excellency expressed his full concurrence in this hope, as well he might, for we can conceive of few more barbarously wasteful systems than that of denuding forest lands, especially upland forest lands for mere fuel purposes. The fad about the denudation of forest, in a mountain country lessening the amount of rainfall, being once abandoned, as it ought to be by all sensible men, the hill and mountain forest lands, with generally good soil and in a specially salubrious climate, will be unlocked for profitable cultivation, and no one can doubt that it would be more profitable for planters to devote all their attention, land and capital to tea, rather than preserve indigenous forest or plant portions of estates with forest trees. But men for whose opinions our correspondent expresses great respect insist that one or the other alternative must in general be resorted to. Indeed, the Visiting Agent of a well-known group of tea estates in Ambagamuwa, did not hesitate to say to us that he considered the proper proportion of forest reserve for timber and fuel to be one-third of the acreage devoted to tea. This is very different to our correspondent's off-hand and we fear many will hold comical solution of the difficulty, by making over to each cooly employed on an estate, (one per acre, as a rule,) as sufficient for purposes of warmth and cooking, the prunings of an acre of tea! Our experience of Ramasamy is that he is much too particular about the lasting as well as the burning qualities of the fuel he uses, to be put off with anything so unsubstantial and evanescent as tea twigs, which, some may think ought to be returned to the soil in which they grew. They may not restore much fertilizing matter to the ground, but if any manurial matter is added, the buried twigs will make it doubly effectual by keeping the soil open and so securing its aeration. As to permitting the coolies to burn cow dung as fuel, all planters who know how readily and largely tea responds to an application of this substance, will receive the proposition as we do with groans of incredulity and condemnation. To talk of burning cowdung on a tea estate is equivalent to throwing rupee paper into the fire. We believe most planters will agree with us that tea prunings would not be acceptable to the cooly as fuel, and that as regards the valuable product of cattle sheds, the coolies ought to be stringently restricted to limited supplies for the necessary, cleanly and salubrious process of coating the floors and inner walls of lines and their verandahs with a substance so wholesome, clean-looking and so calculated to cause insects to *flea* away. We feel sorry that a writer whom we esteem so much should so little appreciate two things: the Tamil coolies' appreciation of good solid firewood; and the almost incalculable value of cow dung as a fertilizer for tea. To coffee in latter days this substance too often merely carried a fresh access of destructive white grubs. To tea it always adds a fresh and luxuriant growth of flush. Should grubs happen to be present, they turn up their noses at the feeding rootlets of tea and die of inanition, while the tea continues to flourish. If only a greater demand existed for well fed beeves, cattle establishments on tea estates might become far more profitable than they were on coffee plantations. Tea prunings and cow dung cakes for fuel, being out of the running, fuel of some kind is a necessity, and we should really like to have details of the mode in which the difficulty arising from the absence of firewood on Rothschild and other old estates has been overcome. Our correspondent's off-hand statement that the coolies have not only existed without firewood for a score of years, but put on abundant adipose tissue, belongs to a form of logic for which he would have been "ploughed," had he passed at Marischal College, Aberdeen, or wherever he studied the

science of stating facts and drawing inferences. His idea of the coolies on Rothschild and similarly situated estates getting fat without fuel for warmth and cooking being supplied to them in some form and at considerable expense to somebody, reminds us of the inference drawn by John the Minister's man from the text, "The ass sniffeth up the east wind." One of the inferences was "He may sniff lang eneuch or he gets fat on it." John was certainly a better logician than "X. Y. Z." No one doubts that there are enormous supplies of firewood in Ceylon. Including the jungles of the low country, we think the estimate of the late Col. Fyers was that seven millions of acres in Ceylon were covered with trees of all sizes, from low jungle to lofty forest. Nevertheless wood fuel is scarce and daily becoming scarcer, where it is imperatively needed: it or a substitute. And neither the transit of wood nor charcoal, or the provision of a substitute for wood fuel, is a problem so easy of solution as our correspondent seems to imagine. Transit is costly in proportion to distance, and even the railway has to give weight to this consideration by having depôts of firewood at various centres along its route. Mr. Rutherford's calculation was that coal for tea factory purposes would be twice as costly as wood. This was when coal cost R20 per ton at Colombo. The proportions on the railway could not be very different, as we believe the present calculations are that the wood consumed by the railway department costs up to R12 per ton against R18 for coal: the latter having recently fallen in price. We have always hoped much from the residuum of kerosene, deodorized. But the article is not produced, and now our hopes point to the promised cheap lignite from Siam. Meantime, in opposition to preconceived strong opinions and determination, we have felt compelled to go in for what our correspondent regards as "a curse," a steam engine. "Only a little one," however, as yet. We are also acting on the advice of those who think it wise for tea planters to devote some portions of their land to the cultivation of firewood and timber trees. To be compelled to resort to a steam engine was a deep mortification to us; for, some years ago we ridiculed such a proposition in regard to an estate so well-watered as to be named the *Aruvitotum*: the waterfall estate. But the waterfalls are in the lower portion of the estate, at from 5,000 feet down to 4,600, while the factory is at 5,800 feet. Its site was decided on with reference to tea grown as a subsidiary product and at a time when, like the vast majority of planters, we refused to recognize the fact that by *hemeleia vastatrix*, the coffee on which so much had been spent, was fatally smitten, so that not even as a subsidiary product could it be profitably grown. Had we known all we now know, of course the site of the coffee store down in the lower portion of the estate and where the "water privileges" are centred, would have been the position chosen for a great central tea factory for the whole estate. For the present the most and best must be made of the extensive establishment above, contiguous to the larger area of bearing tea. For eight months of the year and generally nine the supply of water is ample, and provision has to be made for an overflow from the dam. It is in the first three months of the year, generally amongst our best flushing months, that we feel the pinch, and as the tea yield increased, we were compelled to obtain a small steam engine, which, we suspect must shortly be superseded by a larger. The fuel thus consumed, in addition to that required for tea drying, involves considerable expenditure which we should be glad to avoid. Our correspondent would say to us and others similarly circumstanced, get the power which exists in one part of the property transmitted to where it is wanted; but, according to a way he has, and which is not so satisfactory to the advised as to the adviser, he does not tell us how. That is for the engineers to settle and the thing can be done, either by electricity or by a long belt or series of belts over 2,000 feet in length revolving on drums and worked by a powerful steam engine (out of the question) or an efficient turbine. The question has engaged attention and Mr. John Ferguson brought from England on the occasion of his latest visit, plans and specifications for transmission of power by electricity. What has answered for large mines is, we fear too expensive for a tea estate. *Ab initio*, we should have to provide a powerful turbine to generate the electricity, and the obvious question is whether the power of the turbine had not better be applied direct to machinery erected within easy a ach of it. We must have *a* factory down below, if, in time, the whole of the upper buildings and machinery are not moved down. As this would be a work of time and very expensive, the question is whether it would pay better than having a steam engine, above to have an eight-horse power turbine below, from which power, (all not lost in friction) could be transmitted upwards by belting. We quite agree with our correspondent as to the undesirability of using steam engines, but we have ventured to state our own case as a typical one and as showing that in some cases resort to steam cannot be avoided. The alternative in our case is to have a turbine of about 8 horse power set a-going two or three years in advance of a factory on the spot and for the sole purpose of transmitting power from its site at 4,700 feet above sea level to a point 1,100 feet higher. The endless belt needed would certainly require to be 2,300 feet in length, and besides the first cost of this (sure to be heavy), drums would have to be erected at intervals and there would be a good deal of wear and tear. Can any correspondent furnish an approximate idea of what the cost of the turbine and necessary apparatus would be, and the proportion of the eight horse-power which would reach the point 1,100 feet above, after allowing for loss by friction? Such a calculation would help us to estimate the cost of water power transmission which our correspondent apparently thinks so feasible. Transmission of force is one engineering problem, possible undoubtedly, and we should, personally and for the sake of many brother planters, be very glad if the possible can be attained at a moderate cost. Another question for engineers especially to decide is, if in machinery intended solely to convey dessicating heat to damp tea leaves, it is possible to economize fuel, as is now done in regard to fuel, the purpose of which is to generate steam? The cases may be analogous, but to our lay mind there seems a difference? We shall, however, be glad to hear that sensible economy of fuel in the drying process is possible, although we think our correspondent very sanguine indeed in anticipating that the small quantity of timber in a tea box can ever suffice to roast tea equivalent to its contents, say from 80 to 100 lb. dried tea, equivalent to 320 to 400 lb. of green leaf. Meantime, let us be thankful that tea boxes, like ships, can be made of metal as well as wood, and that Japan is able to send us an apparently unfailing supply of wooden shooks to be converted into boxes. But all said and done, may it not be judicious on the part of those who possess reserve forest to set some of it aside for timber and firewood, and may it not be still more advisable for others to devote portions of their land to the cultivation of fast growing timber and firewood trees?

As to poor soil Dr. Trimen's report shows the satisfactory progress made by *Eucalypti* in such soil, and the immense growth of the Australian silver wattle in six years. Artificial forest can be grown much closer than natural, and with reference to frequent thinning and coppicing. The eucalypts coppice well and so do the wattles (*a. dealbata and a. melanoxylon*) besides the habit of the acac ias to form dense groves by sending up shoots from every pore of their roots. The cubic contents obtained from such plantations on the Nilgiris have been enormous and we have a right to believe that in our warm moist climate the result will be still greater. The question is no doubt finally one of the comparative cost of such plantations and that at which timber and fuel from a distance can be supplied, and as regards firewood of course we have to face the probability of that discovery, so long delayed of a good and cheap artificial fuel. As to the "thousands of acres of virgin forest on elevated positions which can be cut and sent down shoots," all within easy reach of the railway are reserved for railway purposes, and we have been astonished and alarmed to see how rapidly the originally sparse forest on private land near Nanuoya has disappeared in response to the Moloch demands of the railway engine furnace, while the reserved Government jungle above Inverness, is also being thinned at a rate which gives concern to those who understood that the mountain forest belonging to Government was to be carefully preserved, on both sides of the road leading to Nuwara Eliya. Our own belief is that in a well cultivated forest of toons, grevilleas, eucalypts and wattles, more trees could be grown on and more timber or fire wood obtained from one acre, than will be yielded by ten of the virgin forest on which our correspondent so greatly depends. In the forests referred to we know that trees of any kind and especially of any size, are few and far between amongst the prevailing undergrowth of *nillu* or *strobilanthus*. The luxuriance of the latter was the redeeming sign of good soil when the lands around Nanuoya were chosen for cultivation. How toons, eucalypts, grevilleas and acacias grow in such soil, we shall show further on. Dr. Trimen has given a list of trees suitable for growing at low elevations, and we may add that for railway firewood the favourite tree to grow now, is not the *Waa* or *cassia florida* (C. Siamea,) described to us by Mr. Strong as the best, but the marvellously quick growing *Lueu-medilla*, which has been known in six years to attain a height of 40 to 60 feet, with a girth of 18 inches. The timber is the favourite for house ceilings and for the outriggers of canoes. But the great point is its rapid growth for firewood. We take it for granted it coppices. We do not know the upward limits of this tree, but we saw some noble specimens on "Gang Warily" in Dolosbage, about 2,000 feet above sea level. We should think it would succeed considerably higher up, for we see the Great Rangit Valley, Darjiling, specified as one of its habitats. We are giving this information of course, for the sake of those who may deem it wise to cultivate timber and fire trees, notwithstanding the elaborate arguments and emphatic protests of "X. Y. Z."

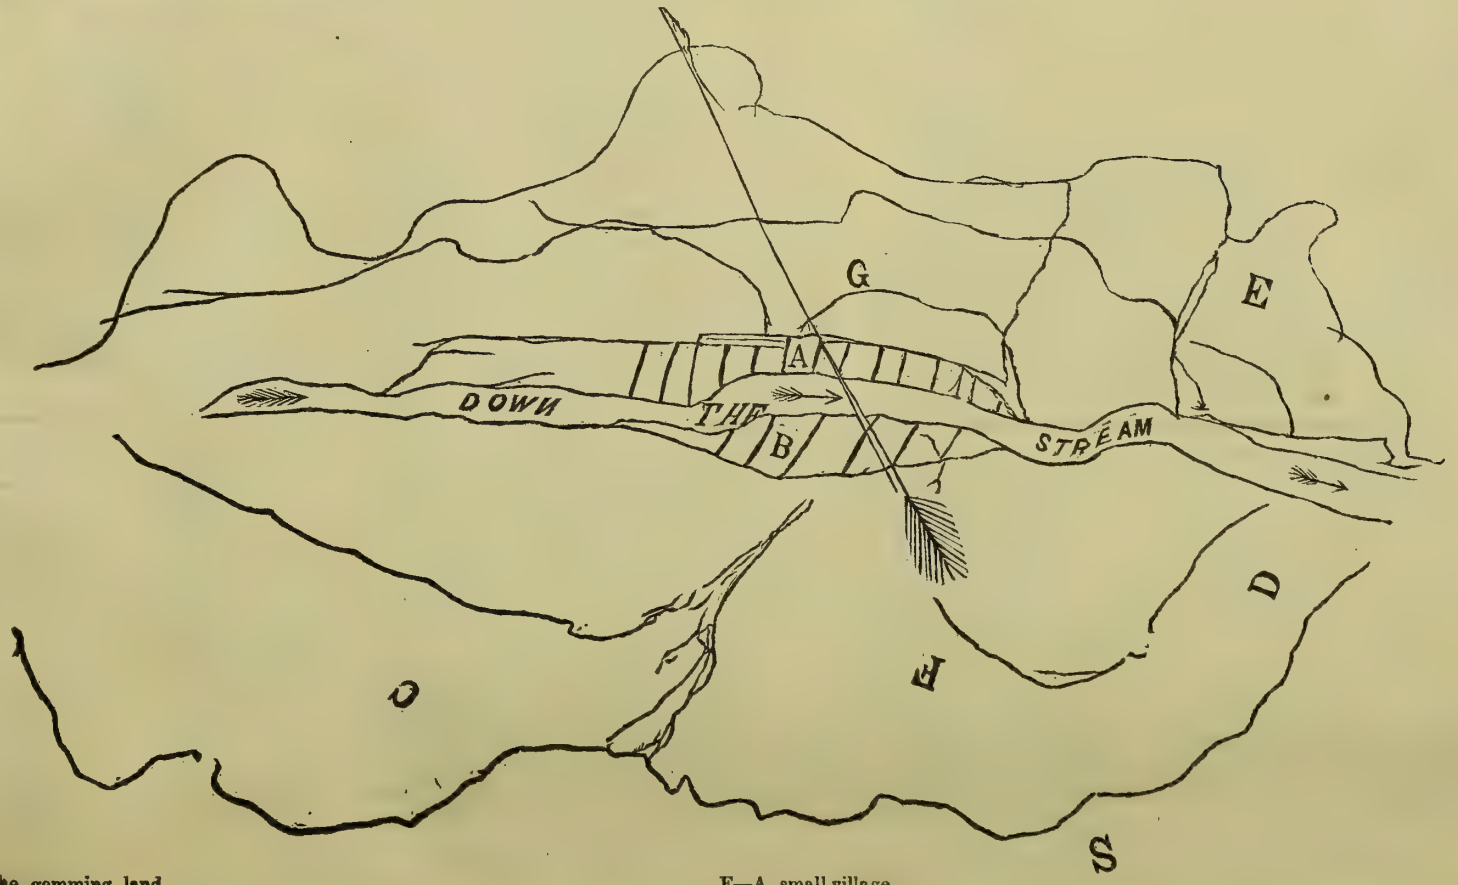
Quinine Pills.—A correspondent of the [illegible] calls attention to the [illegible] of [illegible] of pill [illegible]. One patient to whom he was administering quinine pills [illegible] for it, and he found that the pills had actually been avoided by the patient "substantially the same as when swallowed." The dispenser explained that the pills were freshly made with tragacanth paste and coated with French chalk. To this excipient the correspondent attributes the insolubility of the pills, and it is just possible that he is right, although the coating may have something to do with it. Nevertheless the use of tragacanth paste for quinine pills is unnecessary as long as so effective an excipient as sulphuric acid is in the field.—*Chemist and Druggist*, April 14th.

Quinine as a Hypnotic.—In the last number of the *Medical Press and Circular*, Dr. Weaver, of Southport, calls attention to the efficacy of quinine as a hypnotic in cases of insomnia. His own experience leads him to regard it as a remedy of remarkable value in all cases of insomnia arising from debility or nervous irritability, and much preferable to the bromides. Moreover, the taking of quinine is not likely to become habitual or to be productive of the fatal effects frequently attending the use of other hypnotics. It will not act, however, in cases of sleeplessness arising from a congested condition of the brain or its blood vessels. In such cases its administration has been found to produce headache and to intensify the insomnia. Dr. Weaver has found that a dose of quinine at bedtime invariably gives him relief, though a bad sleeper with a nervous temperament, and that it does so without any of the disagreeable feeling experienced after taking bromides or chloral, etc. On the contrary, he wakes in the morning refreshed and ready for food as well as for the fatigues of the day.—*Pharmaceutical Journal*, March 31st.

Amsterdam, April 11th.—The Royal sanction has been granted to the statutes of several limited companies connected with shipping and trade between Holland and Java. The establishment of the Steamship Company "Holland" is now officially announced. This company intends to open a regular service between Amsterdam and Netherlands-India and other ports. The capital has been fixed for fl7,200,00 in shares of fl6,000, and to be issued in two or more series, the first series of 240 shares having been entirely taken up by the Netherlands-India Steam Navigation Company at the Hague and some private persons. The company will bring into the Steamship Company "Holland" three of its steamers, viz., "Bantam," "Borneo," and "Celebes," for the value of 200 shares. The directors are Messrs. Bogaardt, Hooy, and Fraser, and a board of seven commissioners will be appointed at a meeting of shareholders. The service will very probably be opened in July next with four steamers, of which one steamer will be despatched every month, and this will create again a strong competition with the existing companies, Nederland and Rotterdam Lloyd. The statutes are also announced of the Coffee and Cinchona Agricultural Company Pagilaran, established in this city for the purpose of working certain lands in the district of Pekalongan (Java). The capital amounts to fl1,000,000, divided into two series each of fl500,000 in shares of fl[illegible], and of which the first series has been taken up. The Siak Tin and Agricultural Company has been established here, with a capital of fl2,400,000, in 20,000 shares each of fl120, divided into preferred and ordinary shares each [illegible] shares. The purpose of this company is the working of mines in Siak and the cultivation of produce [illegible] that [illegible] in Netherlands-India. At the [illegible] of [illegible] in the Amsterdam [illegible] Company a dividend of [illegible] per cent. was declared for 1887. [illegible] it appears that the [illegible] capital written off, [illegible] the [illegible] the amount of the [illegible]. A proposal was adopted to increase the capital [illegible] and to transfer the profit to be earned on the [illegible] new shares to the reserve fund, which, however, may not exceed fl[illegible].—*L. & C. Express*, April [illegible].

Plan of the Dewurángala Gold Diggings.

The scene of the diggings is in a valley between high and low hills; a stream running right through it as in the plan. Farther up there is tributary which has a course of about 3 miles. It crosses the Morawak Korale road, and joins the Akuressa river.



A—The gemming land.
C—Mountains.
D—Road to Morawak Korale.
E—Old pits.
F—A small village.
G—Hill where diggers live.
N—North.
S—South.

MOUNTAIN ECHOES:

CROPS—MR. PINEO AND THE AMERICAN TEA MARKET AND CEYLON TEAS.

Uva, 18th April, 1888.

Pallam is ripening, tea is flushing, the weather is lovely with lots of forcing showers, things in general wear a smiling aspect, and altogether, we are having a fine time hereabouts. We are happy for the simple reason, that we have no time to be miserable. For misery in its pure perfection, you must go to the unfortunate individual who has "got no work to do-oo-oo." You won't find him in this corner, so you need n't look.

Mr. R. E. Pineo seems to have got hold of the right end of the stick this time. Give him a firmer grip of it, and he means to tickle up our American brethren to a lively measure. His scheme has, doubtless, more of the elements of success about it than anything yet brought forward. Let it not be said that it died a natural death for lack of support. He asks for 6,000 lb. of tea. Out of the united bins of the island, this is but a flea-bite and will make no difference to anybody. Handed over to Mr. Pineo, it means that the members of 48,000 (forty-eight thousand—note!) American families will become acquainted with the taste of Ceylon tea. If that is not something very much to be desired, I am sorry I spoke. At present, the Americans who are, I believe, the greatest liquid-imbibing people on the earth's surface, do not know what good tea is like. From a moral, not to speak of any other, point of view, it is our duty to bring a good healthy beverage within their reach. Let us, therefore, obey the pleasing call of duty, and if weonce got the Americans started on Ceylon tea, the whole crop of our island will not satisfy them after a bit.

Mr. Rutherford's latest scheme is a credit to his ingenuity and public spirit. It is doubtful, however, if it will meet with the unanimous approval accorded to his "Tea-fund." At the first glance, there is a one-sided look about the proposal that further consideration only tends to intensify. Indian planters are to subscribe R60,000 and Ceylon planters R30,000, and the united fund is to be spent in pushing Indian and Ceylon tea *conjointly* in America, which means, that there is to be no distinction made between the two. Ceylon, which subscribes one-third of the capital, is to stand on the same footing and have exactly the same advantages as India which subrscribes two-thirds of the money. I think there will be considerable difficulty in bringing Indian planters to see the exact force of this arrangement. But why should we go and mix ourselves up with India anyhow? Up to date, we have managed to shove along pretty well on our own merits. Is it not because our teas have been always regarded as a speciality that they have attained their present position in the market? I think that is the general impression. It is, therefore, on its own merits and as being distinct from other teas, that Ceylon tea will command success in America as it has done in Great Britain and Ireland. If in this matter the Ceylon Planters' Association goes and joins itself to all the Planters' Association in India, whose name is legion, it will not be long before our identity will be utterly absorbed, and Ceylon tea instead of having a distinct name and record of its own, will simply be regarded and bought up as a tea from some obscure district of India. This is n't the sort of thing we want, and what 's more, we won't have it. At any rate, "them 's my sentiments," and I think they will be found to be pretty nearly identical with those of most of my brethren.

This American idea is a grand one, and should be entered into heart and soul by all who have the smallest interest in our island. So far as I can remember, superintendents (as distinct from proprietors) have done little or nothing towards pushing the sale of our tea. The reason for this, I reckon, is that they have never been specially called upon to do anything. Now, there are none of us so blind as not to see that the success of the tea enterprise is as vital to the interests of the superintendent as to those of the proprietor, and I am certain there is not one of us, who would not give his quota towards a fund for pushing our teas in America. It would be one of the best investments going. I would like to make a suggestion, which is:—that a fund, to be limited to estate superintendents and assistants, be started under the auspices of the Planters' Association, for the special purpose of introducing our tea into America. I feel certain that such a fund would be a grand and glorious success. I do not think there is one of us who would not gladly give, say *one per cent* of his yearly salary, and that simply means that a sum running well up among the thousands, would be the result. Let proprietors do their duty at the same time, and we can afford to do something that will make the Americans' hair stand on end, and simply compel them, through sheer admiration, to submit to our advances. We must have America on the brain for the next few years, for let our tea be once established on the Western Continent, and the future of our island and all that is therein will be assured for evermore.

CEYLON UPCOUNTRY PLANTING REPORT.

GRAFTING IN A NEW LIGHT AND THE "T. A."—WHAT IS CINCHONA COMING TO—CACAO—NATIVE COFFEE—TEA FLUSH.

30th April 1888.

I got "a wrinkle" the other Sunday regarding a promising new field for the circulation of the *Tropical Agriculturist*. The preacher we had been listening to had for his text "the engrafted word," but he "fooled around" very considerably; his knowledge of grafting being of the haziest, and far from accurate. Yet all he had to say depended for its force and point on the correctness of his information regarding grafting. One who certainly desires to see the pulpit a power in the land hazarded the remark, when the service was concluded, that he thought the preacher would do well to become a subscriber at once to the *Tropical Agriculturist*. Now I hardly fancy that when summing up your prospects of successat the time you launched that useful periodical, you calculated anything at all from clerical support. And yet if the pulpit is to keep up with the times, and go in for the expounding of "natural law in the spiritual world," it won't do to be "all out of it" in such a simple matter as grafting. I would commend, therefore, to your thoughtful consideration the pushing of the *Tropical Agriculturist* among the clergy for their own sake as well as ours. It is rather hard to have your spiritual pabulum spoiled by an admixture of nonsense for the mere mental act of noting the presence of the worthless matter makes you feel so worldly. However, if you manage to get your able monthly to be taken up and read by the clergy, so that in matters horticultural they may speak with no uncertain sound when the explanation of a passage calls for it, then, there will be before the world another proof of the power of the pulpit, a sermon not preached in vain. *

* The Scottish farmer's advice to the new padrè going to see his ploughman was to say "nothing about sawin' or reapin'; for that the ploughman would soon see his pastor's ignorance and would then never after believe anything else from him!—Ed.

What CINCHONA is coming to is a subject which interests a lot of us. That certain rise which was ahead, and which was calculated on by most growers is evidently ahead still, and looks as if it would keep there. And yet bark is not altogher despised, for it was but the other day I heard of one enterprising Moorman who was nibbling round a box stored for the rise which does not come. It thrilled the seller when the Moorman on being told that the planter was willing to trade asked the price of the bark, *per hundredweight!* And it has come to that at last. To me there seemed at first something unholy in the idea of a priceless article being disposed of in such a gross way, but that is a kind of feeling easily got over. If buying by the hundredweight comes more kindly to the Moorish mind than by the avoirdupois pound, well let us suppress our emotions and suit ourselves to our buyer.

The CACAO blossom, which was so full of promise, has passed off in many places without leaving much fruit behind. Some districts have not anything to show for it at all, but there is a pretty general opinion that the June and July blossom will be all the better of the present failure, and that the prospects for a bumper autumn crop are very good. Certainly the vigour and healthiness of the trees are such as to attract the attention of even the unobservant. How this wealth of leafage and sturdiness of growth come about at the end of the driest season Ceylon has had for many years, is somewhat of a hard problem to solve? It may be that much of the cacao in bearing has past that critical stage which is said to end with its eighth year, and now that it has passed through its adolescence, it is going to do something for us in a manly way, and be done with infantile complaints for good. Whether this be the right reason or not, it is highly satisfactory to note in the meantime that cacao never looked better.

GOLD IN THE SOUTHERN PROVINCE.

(*From a Correspondent.*)

We learn that the local authorities are somewhat incredulous as regards the recent gold fields. Some weeks before the announcement in the papers, the Assistant Agent at Matara, was told of the finding of gold in small quantities at Dewurangala and was shewn a small piece, but it was so small that he did not make a fuss over it, though he duly recorded the fact in his diary and informed the Agent. Mr. Dominico *subsequently* brought the matter to the notice of the Government Agent with a view to a sum of money being entrusted to him for exploration. (Mr. Dominico had previously claimed to have found gold in the Pasdun Korale and made a similar application which had not been acceded to.)

Inquiry made on the spot does not confirm the reports in the papers, though the local gemmers adhere to the story of small finds. If the larger nuggets shewn in Colombo were found as stated, the secret has been well kept, but there is no local rumour of a rush such as there is when there is a good find of gems. Orders have been given, we hear, to offer Mr. Armitage every facility in his enquiries and search, and Mr. Allen of the Survey Department, who is a qualified geologist, will probably proceed there also. So the truth will soon be known.

THE PRICE OF FUEL.

We gave R12 per ton yesterday as the rate paid by Government, for wood fuel delivered at railway stations up the line. This we learned on good authority; but we begin to think that our informant meant this as the price of the quantity of wood which is equal to a ton of coal? In Colombo, we learn on mercantile authority, that wood fuel is delivered at the mills (through the facilities for water carriage by the Kelani and canals doubtless) at the rate of 20 cents per cwt. or R4 per ton, and, as three or four tons of timber are required to make an equivalent to one of coal,—the cost of the latter in Colombo being R18 (to R20) per ton, the comparison would be generally taken as R12 or R16 to R18. Wood fuel is, therefore, still considerably cheaper than coal. This, of course, applies to Colombo; the conditions in the planting districts must vary according to their distance from the railway, local reserves of forest and chena, &c., while the cost of coal or coke is largely enhanced by distance of railway carriage.

HIGH-GROWN CEYLON TEA.

The following is the opinion of Mr. F. Street on a sample of tea grown in the Nuwara Eliya district, sent him by the proprietor :—

"The sample sent me this morning possesses exceedingly fine flavour. I know of none better in Ceylon. Had you asked me the district in which it was grown, I should have unhesitatingly said Haputale: the tea possessing the characteristic flavour of that district. I think if the tea-maker withers less and rolls more, it will give the liquor more *body and fullness*, which, in my opinion, is its only deficiency in the cup. The leaf is too mixed, choppy, and brownish, but this can be easily altered. The leaf is a little highly-fired, but *not* burnt, and should arrive in London in prime condition. The tea in its present unassorted state is worth about 1s per lb. in Mincing Lane."

THE TIMBER AND FUEL SUPPLY QUESTION.

So long as a good artificial fuel is not discovered and the cheap lignite from Siam is not available, and so long as the chief dependence of the railway rests on wood fuel as the cheapest procurable (coal being only partially used), so long, no doubt, the Officers of the Forest Department will be expected to pay special attention to securing full supplies of wood within easy reach, say two miles on each side, of the railway. Native chenas and even abandoned estates so situated might well be purchased and planted up. We have no doubt that Col. Clarke and the Forest Officers are devoting close attention to this matter. We quite believe in the duty of Government conserving and growing forest for the service of the public, but this does not certainly mean what "X. Y. Z." (see page 809) seems to consider legitimate, that estate coolies should be at liberty to collect "firebrands" from Government forest, "virgin" or artificial. We have never been able to see any distinction between stealing from private parties and from the Government,—the latter holding all property in trust for the community. As a general rule we must depend on Government to supply the market with such timber as is grown in Ceylon. Forest growing would require too much capital, which would be for too long a period unproductive, to render the pursuit profitable to private individuals. We speak generally, for we can quite imagine a tract of chena or an abandoned estate, below 2,000 feet altitude, and not far from a railway station, yielding a little fortune to a man with capital enough to enable him to wait until the fifth or sixth year of a closely planted hundred or two hundred acre tract of *lunumedilla* trees. We do not know that good patana at a high elevation, planted closely with blue gums and wattles, might not also turn out a good speculation. The

proprietor of "Albion" estate near Hakgala, ought to be able soon to test the question as far as wattle cultivation at least is concerned. But what Mr. Rutherford and other writers advised and what "X. Y. Z." has questioned, is the propriety of planters growing timber and fuel trees on a portion of their own land for their own use, instead of trusting to possible outside supplies, when their own are exhausted. What the probabilities are of successful growth of timber and fuel trees at high elevations, we are able to indicate to some extent from our own experience, reference to which, we trust, will be excused. Last year the old bungalow, at 4,800 feet elevation on Abbotsford, had to be rebuilt and blue gum trees of from 12 to 13 years old, were largely utilized for timber. The quality of this timber is excellent, provided time is available for thorough seasoning, so as to prevent the strong tendency to warping, especially when exposed to the sun. Mr. John Fraser who superintended the building of the bungalow and the cutting down of the trees needed for timber purposes, supplies the following figures for a blue gum which grew, amidst others, on a knoll near the bungalow and which certainly was under rather than over 13 years old, when cut down. The figures will enable engineers and mechanics to compute the large cubic contents in timber of this one tree:—The large blue gum tree was 103 feet high: (8 feet per annum for the whole period), but from the ground to the highest point, the height was probably 110 feet. This tree (which was exceptionally well grown) was 80 inches (6 feet 8 inches) in circumference at the base; at 10 feet above the base, 63 inches (5 feet 3 inches); at 20 feet, 58 inches; at 30 feet, 49 inches (or over 4 feet); at 40 feet, 42 inches; and at 50 feet, 33 inches. There was nothing exceptional in soil or exposure in this case, but as a general rule gum trees have a habit of tapering as they grow upwards, a habit which close planting would probably cure. This tree shows what can be expected on an average for timber purposes, taking a ten years' period and considerably lower figures for measurements.—For timber purposes as well as for firewood, we should plant so close as 6 × 6 so as to allow for thinning out, while for firewood, coppicing (which the blue gum bears well, the secondary growth being luxuriant), could be resorted to in the sixth or even the fifth year. *Grevillea robusta* is superior to blue gum in the quality of its timber and in its better mode of growth,—the trunk not tapering beyond the ordinary rate. We have not cut down any specimens of this tree, but we are satisfied that in the shape of lopped branches it will supply a good deal of firewood in its progress towards the timber yielding period. The largest of several 14 year old grevilleas which we have cherished for seed-yielding (as yet with but slight results) is 60 feet high, not bad, seeing that the extreme height to which this tree attains in its native country, and when growing on the rich alluvials of rivers, is 100 feet. Our tree is 5 feet 4 inches in circumference at the base, and as there is no special tapering, it is obvious that from such a tree a very appreciable amount of timber could be obtained in the shape of beams, planks, or cask staves. If any well grown specimen of grevillea has been cut down and utilized for timber in Ceylon, we hope the results will be published. Our grevillea has been excelled in perpendicular and lateral growth by a specimen of the Australian "Blackwood" (*Acacia melanoxylon*). No wonder if Mr Fraser is inclined to regard this "wattle" as the best to cultivate whether for timber or fuel purposes. The *main tree* has, in 14 years, attained a height of 66 feet, and a circumference of 6 feet 6 inches at the base, with no special tapering in the stem. We have purposely italicised the *main tree*, because this main tree has had to care and provide sustenance for seven or eight subsidiary plants which sprung up from its roots (after the fashion of the wattles) and which are now themselves very respectable looking and promising trees, straight and clean growing, in imitation of the parent tree, to which underground they are still attached. One, we believe the largest, was recently cut down to make room for the building, but there are still at least half a dozen from 12 to 20 feet high, and with stems of good diameter. Had this handsome and well grown tree been treated from the first, so that the whole of its strength might have been concentrated in one stem (the subsidiary stems being removed as they appeared), we think our readers will justify our belief that the dimensions would have reached 100 feet in height and eight in circumference at the base. It is obvious that this valuable timber tree, with dark, ebony-like heartwood, can be grown exclusively for timber, or entirely for firewood (the growth of subsidiary plants being encouraged), or for both purposes, the finest specimens in a grove being reserved for timber. The history of our Abbotsford blackwood tree and its progeny is very curious. In 1874, we believe it was, that our good friend, Mr. Hector, then on Agrakande (?) sent us a present of a wine case filled with earth in which were growing Australian tree seedlings. The box was placed on the ground near one of the entrances to the old bungalow, and one "blackwood" plant was allowed to grow *in situ*. It made rapid growth, speedily splitting and destroying the box in which it began life, and producing progeny, early in its career. It may be now an interesting question whether the original tree and the subsidiary ones would not thrive better, if their root connection were severed and the seven or eight trees allowed to grow independently? The results of experiments in this direction would be interesting and probably valuable.

Next in value to *A. melanoxylon* and perhaps its equal or even superior for firewood purposes is *A. dealbata*, the silver wattle, of which Mr. Kellow of Albion estate and Dr. Trimen in his report have spoken so highly. The roots of this tree, if uncovered, send up shoots from every pore, so that a dense grove is soon formed. Large specimens of this wattle afford good timber, but its chief value seems to be for firewood, as it grows so densely and luxuriantly, coppicing also so readily.

At elevations between 4,500 to 7,000 feet, we believe *Cedrela toona* will be a good tree for timber exclusively; blue gum, Grevillea and blackwood trees for timber and firewood and the silver wattle for firewood exclusively. There are, however, other eucalypts which seem to do better at high elevations and in exposed positions than *Eucalyptus globulus*. From purchases and presents we have on Abbotsford from twenty to thirty different species of eucalyptus, besides other Australian trees, many of which we are unable to identify. Amongst our acquisitions are acacia trees of enormous growth, the tender flush of which is golden or silvern, but no blossom has yet shown, and there is no tendency to send up shoots. We should much like to know what these truly magnificent trees are, as well as many others which are flourishing with us? One very handsome eucalypt, with oak-like foliage is now bursting into blossom. Of our true English oak, received from Mr. Cunningham of Glencairn, fourteen years ago, we have already given the measurements: 21 feet 2 inches high and 2 feet 2 inches circumference at the

base. Treated properly from the first (all extra shoots being pruned away), this tree might now be 30 feet high and 3 feet in circumference. Mr. Fraser writes :—"There are cinchonas here still 40 feet high, but they are not so good as you have had, and they are more ornamental than useful now-a-days." Too true, and Dimbula can show no such cinchonas as we saw the other day on Roehampton estate, Haputale. Measurements of tea trees, grown for seed bearing, up to 32 feet high (are there any loftier in Ceylon?) we reserve for a separate notice, but we venture to quote from the letter which accompanied the measurements we have given and commented on. Our correspondent, who knows as much about trees as most people in Ceylon, writes:—

"I note what you say in the *Observer* of the 26th about the different fuel trees, and I shall send——— a sufficient quantity of each to experiment with in the Venetian. I doubt if you have any of the *A. decurrens* on Abbotsford as from the description given, I imagine it is the one so common about Nuwara Eliya, of which there is not a single specimen here. This is no loss, however, as the dealbata is a much more free grower and shoots readily when coppiced, and I am doubtful if the former will do so.

"The *pycanthus* is, I suppose, the golden wattle growing near the bungalow here in such profusion. It is a nice looking and very hard wood, but not a particularly fast grower, and when coppiced the stools and roots die off. At any rate a dozen I cut down here some months ago, some of which were not more than a couple of inches in diameter, are all dead. If, however, this is the true golden wattle, what then are the handsome golden foliaged trees on the ridge which throw no suckers from the roots?"

This refers to one of the noble acacias we have mentioned, the young foliage of which is in one case golden, in the other silvern, while the gum exuded is lovely ruby colour.—Now, as previously, we have given the public the benefit of our personal experience, and we hope others who have anything to tell about trees economically useful, or likely to be so, will be equally communicative. So shall "X. Y. Z." and other planters be in a position to draw interences more correct than that coolies can live and get fat while destitute of firewood for purpose of warmth and coooking. Timber for tea boxes we may be able to obtain from Japan apart from the use of metal; but fuel and other estate purposes, it would seem judicious that we cultivate some well-selected trees on belts and ridges and corners of estates.

WHERE GOOD COFFEE GROWS.

SOME VARIETIES COST SEVENTY CENTS A POUND ON THE PLANTATION.

At the Coffee Exchange recently several well-known speculators were discussing the new boom in that market, when the subject of the Mexican product came up. Said one broker: "Probably the best coffee in the world is raised about Jalapa, but it never reaches the markets of the United States, for the reason that it is bought up seasons in advance by resident English buyers for the English market. The resident German buyers contract for three or four years in advance for the crops raised in the States of Vera Cruz, Tobasco, Colima, Michoacan and Guerrero. The little State of Colima has probably exported more rich coffee beans than all the other Mexican States put together, and at the astounding price of seventy cents per pound. A friend of mine went down to try to secure some of this delicious product, even at the price mentioned, but he found himself forestalled by the English, French and German resident buyers, who watch with hawk-like glance that the letter and spirit of their contracts with the Mexican planters are carried out even to a single pound of the bean.

"Jalapa is connected with Vera Cruz by a steel railway sixty miles long, and this country is described as an Eden. The coffee plantations are interesting, and always slope toward the east. When the plants are one year old they are transplanted into squares ten feet apart, with banana trees between, to protect the coffee shrubs from the fierce rays of the sun. At this age they are about two feet high, and they are never permitted to attain a growth of over six feet. The plant bears from the age of three years, and, unless blighted, continues to yield up to its fifteenth year, when it is usually uprooted and supplanted by a one year old sprig.

"The leaf is olive-green in color, the blossom white, and the berry itself a pea-green. Each berry contains two beans, which, when ripe for picking, turns carmine. The average earnings of the six-year-old coffee shrubs are forty cents, and a plant between twelve and fifteen years of age yields from $1 to $1·25 worth of beans yearly. Coffee is picked much the same as cotton or hops, and the peons earn about twenty-five cents per diem during the season. Upon the coffee plantations, bananas and castor-oil beans berries raised between the coffee shrubs to shelter them are sold at absurdly low prices. Last year the value of coffee exported from Vera Cruz was $1,900,000; Colima, $240,000; Chiapas, $96,000; Gurrero, $15,000; Michoacan, $153,000; Morelos, $83,000; Tobasco, $69,000; Oaxaca, $88,000. No we don't know in New York what really good coffee is. Coffee at seventy cents a pound on the plantation would cost a pretty penny here, even if we could get it."—*N. Y. World.*

"GOLD IN CEYLON."

In the matter of gold, Ceylon would seem to present a very tantalizing problem, and the wealth beneath its soil to be as unequally distributed, and as uncertain as that which we try to extract from the cultivation of its surface. I have no doubt rich gold deposits and prolific gem beds do abound if only they could be found; but just as tea will grow from the sea to Nuwara Eliya, but not flush everywhere the same, so may, and, I believe, does gold everywhere abound, though only here and there in "paying quantities." So far as "nuggets" and "pepitas" are concerned, their existence, generally in the country so long worked for gems, must be very strongly doubted, or their existence must have become well-known in all the long past during which gemming operations have been carried on. On the other hand auriferous dust may well abound in such land quite invisible to the unsuspecting and inexperienced native diggers. If, however, it can be authenticated, that an occasional large "nugget" has been found here and there in the gemming lands, but not many, then the presumption is that a gold "reef" exists somewhere in the adjacent hills, or did exist at some remote period; and that free auriferous dust, in paying quantities, would be found lower down the watershed in the opposite direction. For "nuggets," then, the country so long worked for gems is *the last place* I should look for them in. This is only a deduction from what I conceive to be logical reasoning, and is open to confutation by anyone able to confute it. DEWURANGALA may be a new gemming field, and not far from rocky eminences, and so not come within these remarks and conditions? In 1854 Bradley and his mates prospected in the MAHAOYA, and found only "grains" of gold. They were satisfied with the prospects this dust held out to them, till that excitement collapsed, as it did most effectually, for in his report the then Government Agent, C. P. Layard, declares that "8 cwt. (say 16 cooly loads) of soil washed in his presence only yielded ½ grain of gold" ("Gold in Ceylon" page 91). True, unofficial rumours flew about of far richer yields than this,

but the fact remains that the pursuit of gold in that locality was abandoned, notwithstanding the fact that exploitation was pushed up the river to its source nearly, as well as along its tributaries with the same reported "success." The reflection upon this is that the gold is there still as it is also in Dolosbage and Nuwara Eliya, where it was "discovered" at the same time or immediately after. It was also "discovered" near Negombo, near which place the Mahaoya river, the natives said, "was so impregnated with gold, that the very waters taste of it." ("Gold in Ceylon" page 16.) Again in 1868 ("Gold in Ceylon" page 58) gold was discovered "in paying quantities" in Saffragam and in 1881 by Mr. Auwardt (!) at Galle. Here then, are *proofs* of its presence from Nuwara Eliya to the sea. What is to be done? Government will not assist if it does not obstruct the search for it. Ceylon has a wide reputation for the energy of its colonists yet in a country famed from the remotest antiquity for its gems and gold, and with all these *evidences* staring us in the face, no action—not even the feeblest, is taken to secure this abounding wealth, nor to *prove* its existence "in paying quantities." Is the present movement to collapse as all previous searches have done? I confess there is not much evidence yet of the existence of prolific gold-diggings at Akuressa, not enough to cause any rush to the place to peg off claims. Syndicates are very useful "institutions," but are often too small and select as "Companies" are often too large and unwieldly. Instead of a "private" syndicate, consisting of nobody knows who or in addition thereto,—for the more the better! and the sooner we shall *know*, or be put out of the misery of uncertainty,—let there be at once inaugurated a *public* Syndicate with a capital large enough to employ an experienced European, with a sufficient labor force to prospect, or exploit all likely fields, with the sanction, and, if possible, the assistance of Government so far as the promise or concession to it of a *free grant* of the *first* claim made for *regular* operations. If Government can be induced to grant this "concession" of say 1,000 acres or more when found under a Government license to search anywhere and everywhere, there should be no difficulty in raising a couple of thousand pounds for immediate operations. The capital should be large enough to enable the Syndicate to offer a substantial reward to native diggers who should report as to its likely ground based on genuine discoveries made by themselves. In likely localities the Syndicate should instruct the villagers in the art of prospecting for gold, and furnish them with the few simple utensils necessary for that purpose. This, backed by the offer of a reward in the event of success, would set a good many of them at work openly, and others to imitate them on the sly, and mutual jealousy and self-seeking would prevent anything like concealment for long together.

I don't think much more remains to be said in a first paper on this subject. Practical and experienced gold-diggers are to be found in Ceylon, and anyone has only to turn to your publication, "Gold in Ceylon", to find all that geology has to teach about it, in a condensed practical and handy form.

The word "reef" would appear to be a miner's term not used in the science, which speaks only of "veins" and "rocks" and "lodes." But "reef" is a very expressive term as indicating the rocky ridges in and through which the auriferous veins penetrate. But spangles of free gold exist also diffused through certain quartz without any veins, while auriferous quartz has to be crushed by heavy and expensive machinery. I doubt if much of this exists in Ceylon, and if "veins" of gold or gold ore existed in *exposed* rocks, somebody would have spotted them before now. The probability is that the gold bearing reefs are covered with more or less soil, except in unexplored and unexplorable ravines and gorges, and all that can be done with much hope of success is to prospect for rich deposits in the "alluvium" (*i. e.* the *subsoil* lying between the *surface* soil and the rocks below), and to follow these *upwards* for nuggets and *downwards* for dust, and to dig for the "reef" if not visible in the country around.

J.

CORAL REEFS AND ISLANDS: LECTURE AT THE ROYAL INSTITUTION.

Mr. John Murray, of the Challenger Expedition, recently lectured at the Royal Institution on "The Structure, Origin, and Distribution of Coral Reefs and Islands." Coral reefs, he said, were the most colossal and striking accumulations of organic life in the world. They were found in certain tropical regions, and were masses of carbonate of lime secreted from ocean waters by countless myriads of marine organisms. The bulk was made up of dead skeletons and shells, the margin only being clad in a living mantle of plants and animals. This was specially the case on the outward and seaward face of the reef, where gaped millions of hungry mouths at all times, and to whose power of secreting carbonate of lime from sea water the coral reef owed its origin. So striking was the result, that it seemed at first sight impossible to deny designing genius to the tiny architects of these coral worlds. There was, however, another force ever at work in the ocean, in a sense antagonistic to the secretion of carbonate of lime by organisms, which had much to do with fashioning the more characteristic features of coral reefs. This was the power of sea water to dissolve all dead carbonate of lime. No sooner did life quit coral structures than there was a silent but sure burial of their carcasses in a state of solution. There was no more certain oceanographic fact. The state of solution varied with temperature, with pressure, and with the amount of carbonic acid present in the water. It was on the reciprocal play of these two opposing forces, the one vital and the other chemical, that science could alone rely in solving the problems connected with oceanic deposits and coral reefs. Coral formations were essentially structures, as Mr. Murray showed, belonging to the great oceans and oceanic basins. They were dots of land within the oceanic areas that might be compared or contrasted with the small salt lakes found scattered over our world's continental areas. Accordingly, a rapid survey was taken of the more generic phenomena of the great ocean basins, leading on to a better appreciation of the questions connected with coral reefs. These great ocean basins were found to occupy over two-thirds of the earth's surface, and to have a mean depth of over two miles; their central spaces took up about one half of the globe's surface, and the average depth of these abysmal regions, as they were termed, was over three miles. The areas thus designated were vast undulating plains, sometimes rising to less than two miles from the ocean surface or again sinking to a depth of four or five miles. Volcanic cones were found to rise singly or in clusters from the submarine plains. When these lofty cones shot up above the ocean level, they formed island groups such as the Azores, the Sandwich, the Fiji, and the Society Islands. But many more of the volcanoes were submarine. When the "Challenger" sounded along the west coast of Africa, there was no suspicion that she was sailing over submerged [illegible] more than the soundings of telegraph ships had correctly mapped out so few

than seven such peaks between Lisbon and Teneriffe. On one of these at 400 fathoms, two species of coral (*Lophohelia prolifera* and *Amphihelia oculata*) were growing luxuriantly. In all, about 300 such submarine cones were already known. All the agencies at work above the lower limit of wave action tended to level down these cones, and thus to form banks. The lecturer instanced Graham's Island, thrown up in the Mediterranean in 1831, which, although three miles in circumference, was washed away in a year or two, leaving the bank formed on the spot with eight yards of water over it. Many parallel instances must often have happened in the great ocean basins. On the other hand, all the deeply submerged summits were built up to the lower limit of wave action by the accumulation of the remains of their animal population and by the fall of shells upon them from the surface waters. In this way were foundations laid for the true reef-building species, which could flourish in the shallower depths only. In the Solomon Islands group, there were upraised coral islands, each with its central volcanic cone already strewn with thick layers of marine deposits, and like deposits must now be forming over hundreds of submerged mountains. The lecturer spoke of the icy coldness of the bulk of the ocean waters at the bottom, even at the equator. But on the surface, there was within the tropics a relatively thin film of warm water, the temperature being from 70 deg. to 84 deg. Fahrenheit. This film of warm water was much deeper towards the western parts of the Atlantic and Pacific Oceans than in the eastern, by reason of the trade winds, which blow over from the East, carrying all the warm surface-waters to the westward, and drawing up cold water from beneath along the western shores of Africa and America to supply the place of that driven westward at the surface. Hence, there was at all times a very cold temperature along these western shores. There were no coral reefs along the western shores of Africa and South America, a circumstance evidently connected with the low temperature, wide range, and—more directly with the food supply resulting from these conditions. It seemed a confirmation of this view that on the eastern shores of Africa, about Cape Gardafui, from off which the south-west monsoon blows, there were likewise no coral reefs, though they flourished to the north and south of this region, where cold water was also drawn to the surface by wind action. Coral reefs flourished in mid ocean along the eastern shores of the continents, where the coasts were bathed by the warmest and purest currents of water coming directly from the open sea. If we excepted Bermuda and one or two other outlying reefs, it might be said that reefs were never found where the surface temperature of the water at any season of the year sank below 70 deg. Fahrenheit, and where the annual range was greater than 12 deg. Fahrenheit. In tropical countries, however, the temperature was higher, and the range much less. The food supply of the coral reef and the other interesting points of the problem were next discussed, leading up to the fairy vision of the coral archipelago emerging from the waves in all its manifold loveliness and grace.—London *Times*.

PLANTING IN MANILA.

(*Translated for the Straits Times.*)

The growing deterioration in the quality of the Manila Hemp brought to market, has induced the authorities to take action to improve matters in this respect. Three hundred dollars have been assigned for the purchase of living hemp plants for cultivation in the province of Zambales. Other useful produce plants will also be obtained for similar purposes. Something of the kind was tried years ago by the then Governor-General. That official took so much to heart the development of the productive resources of the islands, that he did all he could to further the planting of cocoa and coffee. Vast numbers of coffee and cocoa plants were in consequence put under cultivation. The start once given, private enterprise was left to do the rest. Public indifference and neglect ensured the failure of the undertaking.

AUSTRALIAN EXPLORATION: RUBIES.

A RUN THROUGH THE AUSTRALIAN CONTINENT.
A CHAT WITH EXPLORER LINDSAY, DISCOVEROR OF THE RUBIES.

Mr. David Lindsay, our own South Australian explorer, is to be seen in the city streets again after having for the second time crossed the Australian Continent. He has brought a new curiosity—a minute but very lively specimen of the blackfellows of our interior country. When Mr. Lindsay came down last time he placed on view an 18-year-old "boy," who measured 6½ feet, and who with his 6 feet odd of master formed a great attraction for folks when the couple walked in the streets. But this Anakite "Dick" of Mr. Lindsay's is now working on the ruby-fields, putting his money into the Savings Bank like a Christian, and feeling himself animated by some sort of an ambition to ultimately exhaust the treasures of learning stored up at Prince Alfred College. In the meanwhile he is adding cubits unto his stature. Mr. Lindsay's new attendant is about 4½ feet long and 8 years old, and answers to the name of Teddy. He is a smart little bundle of mischief, as full of frolic as a kitten is, as fond of his master as fond can be, and so jolly that he is perpetually on the grain, and when he grins he shows a singularly beautiful set of teeth, worth £50 of any dentist's money. Teddy comes from a station at Borrow's Creek, and says that metropolitan life is so greatly to his taste that he has no wish to go back amongst the unenlightenedy savages of the interior.

The explorer got into town late on Wednesdai-week, and thus completed his second transcontof nental journey. He left Adelaide in the latter half m last year, and reached Port Darwin by steamer. Frord Palmerston to Adelaide he has followed the Overla in Telegraph line. He bade good-by to Palmerston or the middle of September, and having spent two or three weeks upon the gold-fields started for the South. He had four horses, and his only human companion was a blackfellow. This little party ran over the country at a rate of speed probably unprecedented. They traversed the 900 miles from their starting-point to the ruby-fields in five weeks and two days! The journey was without special incident. They saw no natives except a few at the stations. They were not in special jeopardy, and they even enjoyed themselves after a mild fashion. Once or twice hasty rushes had to be made from water to water, as they travelled just before the beginning of the wet season. They went one stage of 75 miles without a drop of water, and the distance would have been 104 miles had not a providential thunderstorm brought rain between the permanent supply points. There were one other thirsty stage of 65 miles and two of 40 each. The horses kept up capitally all the way. Mr. Lindsay stayed upon the ruby-fields three and a half months surveying claims for Adelaide Companies and prospecting, and so in due course he arrived in Adelaide again.

"Should a Transcontinental Railway be made?"

"Yes," said Mr. Lindsay.

"But people say the country is too bad to warrant the cost."

"I was exceedingly pleased," continued he, "with the country along the telegraph. Speaking broadly, it is all fit for occupation by pastoralists. Some parts certainly are poor, and it is patch, just as all country nearly everywhere in the world is. But a railway should be made. There are no engineering difficulties worth speaking of. There would be an ample supply of

water perfectly good for the engines. There are along the route several springs, good soakages, and permanent waterholes and waters might be obtained almost everywhere, probably at shallow depths. As one who has crossed and recrossed the country, I believe most thoroughly in the railway for developing our interior. If the railway were made it would open up a belt running right through the heart of the continent, some 300 miles on each side of the line; virtually all of which could be profitably occupied. Feeders to the railway could be found from that occupied country by means of roads, in the construction of which there are no ranges to act as obstacles to easy traffic. The lay of the country is nearly all east and west. There have been some new waters discovered lately 50 or 60 miles west of the telegraph on this side of Powell's Creek, and plenty more will reward the search. There is only one well of bad water on the whole road, and that is at Taylor's Creek, about 40 miles north of Barrow's Creek, and even that is good stock water. I would not like to express an opinion whether the land would be good for agriculture. If artesian water could be found for irrigation, no doubt a great deal of stuff would be grown, but without irrigation no agriculture will probably be profitably attempted south of Powell's Creek.

"You were the original discoverer of our South Australian rubies, were you not?"

"I was. On March 8th 1886, I was following the Elder River down in search of water. Whilst scratching a hole under a rocky cliff I found a lot of gem sand and concluded that it contained rubies, a great bulk of the stones being garnets. I mentioned my opinion to some of my party as they came riding up on the camels. Latter on on the same day were we at the now famous Glen Annie George—I named the glen after my wife—on which are now the claims of the original Companies. I left the party for a day and a half whilst I started looking for a new road over the ranges to the eastward. During my absence my men gathered a lot of these red stones. Before I left the place I took some with me, and afterwards submitted them to experts in Adelaide, Melbourne, and England, but only got a report that they were garnets. Therefore I did not do anything further in the matter."

"You want to know my own opinion about the prospects of the ruby-fields? I think that a great quantity of stones which have been gathered from the different parts of the district will prove to be of no value, but a fair proportion have been pronounced to be rubies. The latter may be found in many different parts of the field, which extends altogether some 25 miles long by 20 miles wide, taking in the Elder, the Florence, and the Maud Rivers. There is a range about 1,500 feet high running on one side of this field. That is Hart's range. All the country at the foot of this range answers to the descriptions I have read of the Burmah ruby-fields—gneiss peaks, mica schist, schistose rocks, crystalline limestone, diorite, granite, sandstone, &c. The heavy rains in denuding the hills wash the rubies into the creeks, and the floods carry the stones down into the main creek (the Elder), and at the entrance to and in the gorge, Glen Annie, to which I have previously referred—5 chains wide, with cliffs from 300 to 500 feet perpendicular—there are heavy boulders, coarse gravel, and the detritus washed from the low hills at the foot of Hart's Range. This wash contains great quantities of precious stones, garnets and others. Here are the claims of Lindsay's Prospecting, the MacDonnell Ranges, the Hale River, and the Elder River Companies. These claims all join, and all have precisely similar deposits. Stones have been discovered, and claims taken out some 25 miles further down the Elder. I discovered some stones in the creek further to the eastward, but still coming out from the low hills at the south of Hart's Range, and I secured claims for my Company. A month afterwards other prospectors found a few other patches in the same locality, but at present these are the furthest eastern points at which any of the stones have been found. All the way up the Elder, Florence, Maud, and Illuricka, wherever this course gravel is seen, there too the precious stones are discovered. Hart's Range has been examined by myself and others, but not thoroughly. We have only found course dark garnets there. On some of the spinifex rises wherever we could see surface stones, we found, and by sinking and washing could get stones. The deepest hole so far is 4 ft. 6 in., and that is in the creek bed. In no other part of the country traversed in my extensive travels across and zigzagging the continent have I found any ruby country."

"I would like to impress on the public one or two facts about the ruby fields. There have been no stones sent out from the range south of the Elder. They all seem to be found in the valley between Hart's Range and the Elder River. No doubt the matrix is in the low hills striking Hart's Range, and formed of primitive rocks and mica schist. The supply of good sound stones of fair size and quality will be large, but it is a mistake to suppose that every red stone picked up is valuable. I have tested a great many of them and found numerous different varieties, showing varied degrees of hardness, even amongst stones which to the ordinary observer appeared to be the same. The largest true ruby I have seen has about a diameter equal to that of a shilling were it stretched into an oblong shape. Up till the last month only the original Companies had sent stones which they could be certain were from their own claims. You cannot blame any Company for that, or charge them with dishonesty, because no Company was sure of the position of its claims, and consequently the stones were gathered from other parts of the field.

"On my way down I visited the auriferous field at Maude Creek, near the Catherine River, 200 miles from Palmerston, and 7 miles off the telegraph line. This place will be on the most direct route for the railway on account of the favourable gradients and the shorter distance. I was much struck with the richness of the stone. About twenty-five men were working when I was there. They had got to a depth of 28 feet. The reef crops out upon the surface. There are, indeed, dozens of parallel reefs. The country is very settled, and the run of the lode seems to be continuous. The width varies from 1 to 5 feet, and the prevailing rocks are ironstone and quartz. The country is similar to that of the famous Charters Towers in Queensland. Gold is to be seen in nearly every piece of stone broken. As showing the vast extent of gold country in the Northern Territory, let me mention that I noticed whilst at Maude Creek a strong resemblance between the land there and that which I had seen in three places between 80 and 50 miles apart in my Arnheim Land expedition, and it is clear to me that what I saw so far north was the continuation of the same line of country. Its farthest north-eastern point in Arnheim Land is at the Liverpool River, and its southerly extent seems to be about 12 or 15 miles below Maude Creek."

"This South Australia is a very valuable country from north to south and from east to west. The railway already made will have a wonderful effect in developing various places. Take the MacDonnell Ranges for instance. It is only the difficulty of sending cattle over the dry strip of country which the railway is now bridging which has prevented much magnificent pastoral land being profitably occupied. The land is clothed with splendid grass and our best Australian herbs and bushes. Water can be easily obtained and conserved by sinking at a moderate cost. Eventually all that travel will be occupied. So I believe will be nearly all our vast interior lands, excepting patches of sand hill and spinifex, which may be said to be almost unfit for any kind of occupation, and, so far as I could see by a cursory glance, no use for minerals. But as to the MacDonnell Range country I have very good authority for saying, that gold and various minerals, is developed to the west of the telegraph line. Our ruby claims, as you are aware, lie to the east. I rest once more from my travels a greater believer than ever in the wealth of South Australia."—*S. Australian Register*, April 9th.

TEA.

The following figures show, in millions of pounds, the deliveries (both for export and home consumption) of Tea in the United Kingdom coming from China, India, Java and Japan respectively, during the past ten years:—

	FROM			
	China.	India.	Java and Japan.	Ceylon.
1878 ...	157	37	2½	Not separated.
1879 ...	160	34	2½	,,
1880 ...	160	44	2	,,
1881 ...	154	48	1	,,
1882 ...	160	50	1¾	,,
1883 ...	155	59	2	,,
1884 ...	152	63	3	,,
1885 ...	152	65	3½	3
1886 ...	143	66	4	6½
1887 ...	120	82	3½	10

When it is remembered that the export of tea from the United Kingdom has diminished from 45½ million lb. in 1886 (the largest export trade done in any one year during the decade above referred to) to 34¾ million lb., to which it had sunk last year, it will be seen that the lessened quantity of tea required from China—whose teas almost alone figure in our export trade—to supply deliveries, is very considerable. At the same time, there can be no doubt that China can, and will, send us better teas than she has lately, and there can also be very little doubt that, notwithstanding the enormous strides which have recently been made in India and Ceylon towards supplying this country, there will always be a demand for good Congou, such as China has sent us liberal supplies of in the past.—*Produce Markets' Review*, March 31st.

BRITISH NORTH BORNEO NEWS:

INTERESTING ITEMS.

(From the *North Borneo Herald*, April 1st.)

We understand that the Borneo Planting Company are making rapid progress. Mr. A. Walker, their Manager, has felled 160 acres on the Segaliud River for Liberian coffee, cocoa, Manila hemp, pepper, coconuts &c. At Bocara 60 acres are planted with Manila hemp and pineapples, and further land is being cleared for this purpose. We wish this Pioneer Company every success.

Great progress is being made in the erection of the Saw Mill of the British Borneo Trading and Planting Company. The two powerful Boilers are fixed in their places and all the earthwork in connection with the levelling and raising of the site is finished, upwards of 2,000 tons of each having been cut from the hill at the back and taken to the site a distance of 700 feet by the portable railway and tipped on the ground. The tunnels for the main and intermediate shafts are finished, and we understand that the erection of Saw Mill Buildings will be started at once. Mr. Boultbee and his energetic staff are to be congratulated on the rapid strides they have made in so short a time.

Mr. Lind of the German Borneo Company, has finished sorting his Tobacco and was to ship it in the "Paknam" leaving Banguey about the 25th March.

By the "Paknam" arriving on the 16th March, Messrs Jonkher A. van Citters and R. Doorn, both of Java, arrived at Sandakan. These gentlemen propose to take up land for Tobacco planting.

We hear that Mr. Jan C. Teves has formed a Company in Holland with a Capital of 1,000,000 guilders to work his concession on the Sugut River. We also hear that the Capital will be fully paid up and that the working capital of the Company will be least 750,000*f.*

The Government of British North Borneo has decided to limit the area of Land to be taken up by one Company to 10,000 acres. The large amount of land applied for by Tobacco Planters has rendered this necessary, and it is quite possible in the face of the continued application for lands, that the area to be allowed in such cases may be yet further diminished.

Price of British North Borneo Tobacco.—The *Indische Mercurier* of the 31st December, 1887, contains a review of the prices obtained during 1887 for Tobacco, and among the quotations we notice:—

	Borneo Cover Tobacco.	
15	B. N. B. (Ranow 1886)	185 c.
12	do. Bando	65 c.
27	Average.	132 c.

We have received a valuation of Cotton obtained by Mr. W. B. Pryer from Domingal, on the Kinabatangan River, which is as follows:—

"The Sample of cotton you forwarded to us is a very good useful cotton, is well cleaned, without injury to staple which is good, and worth 5½d. per lb; if equal to sample would sell readily. W. J. & H. Thomson."

The Cotton plant here referred to is a shrub, not unlike Fiji cotton, but somewhat taller, say eight feet high.—*Straits Times*, April 24th.

CEYLON TEA IN AMERICA.

The following appears in "The Literary and Society Journal" of America received by the mail:—

A short announcement of an interesting nature has been made to the élite of this city in the shape of a postal card which reads as follows:—

"On the 17th day of December, 1887, at a meeting of a joint committee of the Chamber of Commerce and the Planters' Association of Ceylon, it was resolved:

"That the sum of two thousand rupees be voted for the purpose of buying tea to be sent to Mr. J. McCombie Murray for free distribution in America.

"Please call at St. George's Hall building, No. 60 N. Thirteenth street, and receive a sample of our tea free of charge, in accordance with the above resolution. Tea will be served from three to five o'clock every afternoon.

"THE CEYLON PURE TEA & COFFEE CO.
"J. M. MURRAY & CO."

It is very interesting to note that Ceylon tea is fast becoming first favorite at our fashionable afternoon teas, as it has been for some time past in England. We cannot do more than congratulate Mr. Murray, himself a teaplanter and proprietor in Ceylon, for the success he has met with in his endeavours to introduce a pure, wholesome and fine flavored tea in this city. The independent position he has taken up, and the energetic way in which he has gone about his work, is in itself a recommendation of the quality of the article he is introducing to our best families, and we are glad to see that his efforts are acknowledged by the Chamber of Commerce and the Planters' Association of Ceylon. We understand that among the number of appreciative drinkers of Ceylon tea are President and Mrs. Cleveland. [The fact of the President's sister and family, Dr. and *Mrs.* Hastings, having devoted their lives to missionary service in Ceylon affords another reason for interest in our island.—ED.]

INDIAN TEA NOTES.—Sylhet has had 4·73 inches of rain. More than 2 inches have fallen in Sibsagar and Lukhimpoor. The weather in most districts of Assam has been hot and windy. Tea plucking has become general, and prospects are good. The hot weather has begun in earnest at Dehra Doon, and they are all busy making tea. The gardens on the whole are looking very well indeed for this time of year. A note from Dibrugarh, dated the 18th April, says:—"Still more rain to chronicle——

Total to date	..	...	20·15
In 1887	...	...	15·50
In 1886	...	..	11·90

"Plucking is now general. Fine plucking and high fermentation is to be the rule this season. No new machinery appears to be coming to this district this year, but several improved Victorias are on the way out."—*Indian Planters' Gazette*, April 17th.

Correspondence.

To the Editor.

THE ANALYSIS OF BONES.

21st April 1888.

DEAR SIR,—Can your Hapitigam Korale correspondent be in jest when he expresses a wish for a recent analysis of bones? I must confess to an ignorance of Forcroy and Vanquellin and to the date of their analyses of bones, but surely your wide-awake correspondent was not asleep during Hughes' visit amongst us, and must be aware that his table of the analyses of different manures is extant. Here is his analysis of bones:—

Moisture	7·20
Organic and volatile matter* ..	25·30
Phosphoric acid	2 25
Lime	32·36
Alkaline salt, &c.	6·49
Insoluble silicious matter.. ..	4·40
	100·00

* Containing nitrogen 3·69 ammonia 4·48.

I also enclose the analysis of one of the leading scientists of the day;—

(Raw bones).

Water	6·20
Organic matter	39·13
Containing Ammonia 4·80.	
Calcic phosphate (insoluble) ..	48·95
Lime	2·57
Magnesia	·30
Sulphur teroxide	2·55
Silica..	·30
	100·00

In boiling or steaming bones there is said to occur a loss in nitrogen in the gelatinous matter which is removed, but an increase of phosphates and bones to be soluble must be boiled to remove the fat in them, which retards decomposition.—Truly yours, SIYANE KORALE.

THE TEA FOR AMERICA.

Colombo, 26th April 1888.

DEAR SIR,—*Apropos* of Mr. Pineo's letter in your last evening's issue, I may mention, that, when Mr. Gow was last at Rakwana, he expressed his opinion, that, if Ceylon tea-planters wished to push the consumption of their teas in America, they should manufacture the descriptions suited to the American taste.

He was kind enough to teach my son how to make Oolong tea, and he having made some sent me samples, which Mr. Gepp reported upon as being suitable to the American market, consequently I recommended that three or four thousand pounds should be made experimentally.

There are now a few hundred pounds on the way to Colombo; they will be offered for sale at the auctions, and, if anything near Mr. Gepp's valuations are obtained, will be sold.

I make the matter known, because there is no probability that, if even the experiment proves to be successful, such a quantity will be made and exported to America as to over-supply that market. There will be plenty of room, not only for all we can make, but for all that can be made by others, who may desire to follow the lead. If the pale and ripping liquor of these teas is suited to the American taste, I do not wonder at Mr. Pineo and other gentlemen experiencing much difficulty in introducing the dark and flavoury liquoring Ceylon pekoes and pekoe souchongs.—Yours truly,

C. SHAND.

TEA FOR AMERICA: MR. PINEO'S APPEAL.

Kandy, 25th April 1888.

SIR,—Mr. Pineo's appeal to the Ceylon planters appears, to me worthy of support, and as far as it lies in my power, I shall be very pleased to contribute my "mite" of tea towards his fund for distribution in America. To my mind, the sixty million inhabitants of that great nation, and the vast population of Russia, are the "citadels" we should attack with our tea forces and tea samples. "At home" every shop window is placarded with advertisements of "Ceylon tea," and so there is less need to spend our capital upon tea-houses and at exhibitions. Let Ceylon planters get our great staple once properly introduced into such countries as America and Russia, and we need have no fear of *over-production*, though Ceylon were to put forth 40, 50, ay even 60 million lb. annually! In supporting Mr. Pineo's scheme, I would suggest his sending subscription lists to the several District Associations, to be returned to him by a certain date (the sooner the better), as no doubt time is of importance.

The quality of tea, I gather from Mr. Pineo's letter, is not to be lower than *Pekoe*. To make the parcel he intends sending to America as uniform and perfect as possible, the whole of the contributions should be "bulked" at some Ceylon factory before being despatched, as we are well aware how gardens differ in pungency and appearance etc., and it would be as well to place ONE "Ceylon Blend," of say, Orange Pekoe and Pekoe *mixed* before our American friends, and not confuse them with the many hundred contributions, which I trust are to come in to Mr. Pineo's fund. The modest request for 6,000 lb. from Ceylon planters as a sample for America will no doubt be doubled, or even quadrupled, and in my opinion undoubtedly "go to a good market" if placed in the hands of so old, tried, and trusted a member of our planting community as Mr. R. E. Pineo who tells me that powerful and influential friends will advertise our teas in America very extensively if Ceylon planters will only start the "initiative" with a few thousand pounds as samples to be distributed on say ½ lb packets.—I am sir, &c.,

SHELTON AGAR.

FUEL SUPPLY FOR TEA.

26th April 1888.

DEAR SIR,—It is highly undesirable that the public of Ceylon, and the good folks of other countries should be led away by the idea that starvation, as far as fuel is concerned, stares Ceylon in the face. Writings from men, for whom I have the greatest respect, however point so. I think it is incumbent on anyone possessing other notions to state them, and I shall endeavour to do so. Mr. Rutherford's writings and calculations are theoretically good and sound, but practically, in my opinion, bad, and calculated to give our *now* "tight little island" a character it far from deserves.

The future three starvation points are apparently to be 1st the Railway, 2nd the Coolies up-country, and lastly the Tea Factories and Estates.

1st. The RAILWAY.—Can anyone believe that a Government Railway, running from a large shipping port through a fairly well-wooded country, including vast reserve forests of its own, can starve from want of fuel? I cannot. It can, worked on mere economical principles, afford to burn *nothing* but *coal*, transporting its own reserves of fuel if so desired to those who desire to purchase, but I fancy in the end purchasers will be few. The Railway, I do not consider, deserves another thought

2.—There was a cry nearly 20 years ago that the coolies on many estates could not exist for another 12 months for want of fuel. Take Rothschild estate for instance: it and its coolies have managed to exist through this famine and grown fat, too, and, I have no doubt, intend to live through another 20 years—one cooly per acre, working fairly regularly, is now, I believe, considered about sufficient for a tea estate. It is a very poor estate indeed that the prunings of 1 acre would not supply a cooly with sufficient for his inward and outward wants for a year. However, the poorer the prunings the fewer coolies required on such estate. He can also fall back on cinchona sticks, roots, cow-dung and, lastly, *to him* a never-failing source of firebrand, the Government. Taking all in all, I think we can dismiss the cooly!

3. TEA FACTORIES.—This is not so easily dismissed, but the difficulties exhibited are largely, I consider, reduceible. Fuel is said to be necessary for two purposes, power to drive the machinery in some cases, and for drying the tea in all:—

Power.—In almost all the tea districts that I am acquainted with, in Ceylon, in the centre, or thereabouts, is provided a natural and immense water power. Some estates adjoin such power, others don't, and few, if any, utilize it. Our resident engineers have evidently been brought up to understand one thing only:—"Take the water to the wheel or turbine and we will give you so many horse-power; if you cannot do so, you *must* have a steam engine" (a heavy deduction from the yearly profits of a garden). Nine cases out of ten allow the power to go by, and the valuable fuel to disappear in smoke. This sort of thing, if Ceylon is to succeed as a rival to other tea producing countries, will not last. The power so mercifully provided throughout the country must be transmitted, as it is in other countries, and our worthy engineers must recommend something else than always the steam engine, and if they do not know that "other thing," they must learn it. It is not for me here to say how power can be transmitted, but every one knows it can. Estates, too far from the power, must seek nearer quarters for their factories, and place them as often can be the case, *off* their own lands, even if they have to carry their leaf two or three miles; it sounds bad, but no worse than is being done on many places in the Island. Estates within reach of power will, after their own wants are supplied, generally if the "consideration" be sufficient, sell rights to their neighbours. Estates beyond all reach of power, and with no fuel, must be content to sell their leaf, and the competition for the manufactured article will ere long become so keen, proprietors will readily sell, and accept what an unfortunately situated estate can show as profit, but such estates will be few. It is all nonsense to think every estate *must* have its own factory *on* its own lands; if such is to be, undoubtedly fuel will be at a premium, and present calculations would be correct. Estates desirous of manufacturing their own tea, must, if necessary, either go to the power, bring the power to themselves, or sell their leaf; the three means are in all cases available, and no alarm need be felt on this score. Rather more scientific engineers than the island boasts of are, however, requisite to work out the system, and because it is something *new*, it must not be pooh-poohed. It is an extraordinary fact, however, that many estates I know of possess both available water-power to drive anything, and a steam engine besides. I have no mercy on such properties, throwing away money and burning others. Such peculiarities are often gone in for, rather than move, perhaps an old coffee store, or even set of lines to be near the bungalow or cart road, etc.; all I can say is when next your boiler bursts, move to the water! So much for motive power, and if the resources of the country were utilized by 1-10th of the supply, little fuel is required as motive power for a tea garden. Avoid steam engines; they will prove a curse.

FUEL FOR DRYING.—I hold the opinion that erelong when actual necessity arises, dryers will be introduced, so economising heat, that the fuel required will be reduced to a minimum. I have quite as much right to believe in this as any one ten years ago, to say that the P. & O. "Britannia" would have made the run she did with the quantity of coal consumed. I believe the weight of fuel in a tea chest, say 22 or 25 lb., ought to be sufficient to dry the 100 lb. of tea contained *in* such chest, so that if tea chests are available, so is fuel, and we can take to steel boxes. We have oil to fall back upon, and it too if necessity arises, can be supplied without the enormous profits at present netted by sellers of the article. But go to any of the high points of our higher districts, and look round; thousands of acres of virgin forest stare one in the face, all available to shoot down to the valleys beneath, either in wood or charcoal. Government must and will unlock its reserves, and make them pay handsomely, must not encroach on its hill reserves for itself for fuel, but seek the low-country as its supply for the railway. Tea can be dried by oil equally well to the delicate pastry baked in a "Rippingille" cooking stove which is a good model for a tea dryer.

Therefore, "taking one consideration with another," my own opinion is, Ceylon has no fear to apprehend as regards its fuel supply; there are heaps of it in the island, and for transport, the ever energetic planter will find the means. Motive power must be economised and sought for, and no one has far to seek. Take almost any tea estate you like to name in the island, using a steam engine, and you will find that with a little ingenuity and forethought, it could have found water power, even if, as I said before, leaving its own boundary by a mile or two, and the carriage of leaf to such factory would have been compensated for over and over again by first the transport of fuel to the engine; second, the value of the fuel itself. Water power to an estate is worth all in all, and few know how very little water is required with a good fall to develop 6 or 8 horse-power from a turbine.

Tea driers will be brought before the public ere long, using one-eighth of the fuel required for a "Sirocco," "Victoria Drier," etc.; the "Desicator" has already made a great start in the right direction. If not, oil will come into use, and charcoal is light and of easy transport for railway or otherwise. The planting up of parts of estates with timber for fuel, I do not believe in for one moment, and, as far as I hear, few do. No piece of land to grow fuel to pay, but what will grow tea to pay. Twelve to fifteen years must be reckoned on as the shortest time to get any return from an acre of fuel, and, after all, what would it be? And compare it with the returns such an acre of tea would have returned, remembering that 7 or 8 years' purchase is about the limit of estate value in the colonies. It is the exception to find estates in our higher districts at any rate, but what every acre of land would grow tea, and if it would not grow tea, it would grow uncommonly poor fuel. I think you will find the tea-planter of the day will believe in looking to being able to purchase fuel for his time, and not plant it for posterity. I

think our fuel resources in Ceylon are like coal-mines in England. I remember, thirty years ago, an outcry at home that coal would run short in three years! In conclusion, let us take heart and don't cry "stinking fish."—Yours, X. Y. Z.

THE SIROCCO TEA DRIERS.

Kalutara, 28th April 1888.

DEAR SIR, Considering the number of Sirocco driers in Ceylon, it seems a great oversight on the part of Messrs. Davidson & Co. that duplicate parts of their machines cannot always be had in Colombo. Few Siroccos reach estates entirely free from damage, some of the weaker castings, especially being almost sure to get broken.

If a machine is much wanted, it is bad enough in such cases to have to leave it unused till the damage can be replaced by sending to Colombo for extra pieces; but, when reference to Messrs. Davidson & Co.'s authorized agents shows that the duplicate castings are not in their hands, and that they have no advice as to when these may arrive, the case becomes serious.

This has been my experience and that of another in this district, and I think it well to make the fact known for general information.

But the difficulty is almost entirely in the weaker castings (especially Nos. 850 and 851). It seems to me that the remedy is in the hands of the makers. What simpler than for them to send with each machine a few duplicates of those castings?

This would cost them a mere trifle, and it might save some of their constituents from serious loss.—Yours faithfully, R. MORISON.

TOBACCO CULTIVATION.

DEAR SIR,—In reference to the inquiry for land for the cultivation of tobacco in Ceylon, I may mention that some years ago Mr. Steele reported a fine field for the growth of tobacco to exist on the banks of the Walawe river at places from seven to ten miles distant from Hambantota. We wonder whether this field has been occupied. The land is said to be extremely wet and fertile, and water (a prime requisite in tobacco cultivation, as the plants require watering regularly twice a day) was to be had in ample supplies from the river. Produce of all sorts (it was also said) might be grown in abundance along the banks not only of Walawe, but of Magama and Yala rivers as well. Mr. Steele added:—"The banks of the Walawe are much preferable, and the nearness of Hambantota as a port of shipment, where dhonies and a coasting steamers touch, is of great importance."—Yours truly CULTIVATOR.

THE PUSHING OF CEYLON TEA.

DEAR SIR,—In Mr. Pineo's scheme for pushing Ceylon tea in America, is proposed the distribution of ¼ or ½ lb. packets. The success of the scheme seems to me to greatly depend upon the size of the samples distributed. Almost everyone's experience has been that the first cup of Ceylon tea is decidedly unpleasant. The change from China, and what one has been accustomed to for years, is too sudden. The palate requires gradually educating up to the pungent flavoury taste of Ceylon growths, and one's former liking cannot be eradicated under two to three weeks daily drinking Ceylon tea.

I maintain, therefore, that the selling of Ceylon tea in the cup at Exhibitions is a very hazardous experiment, and the verdict after the first cup is liable to be "What nasty stuff" "It tastes of herbs" "I don't believe it's tea at all." Give people at first go off, sufficient Ceylon tea to keep them going for three weeks, and they will never willingly buy an ounce of China tea afterwards; give them but one cup of Ceylon tea, and they will not be inclined to ask for a second

The distribution of samples should be undertaken most carefully, and regulated, if possible, according to the number in the household, sufficient being given for 3 weeks' supply and if possible no chance of getting at China tea during that time. The trick will then be done, and the shadow of the Peak will appear insignificant compared with the golden mantle that will thenceforward rest upon Lanka's shoulder. ANTICUPEKAI.

MR. PINEO'S AMERICAN TEA SCHEME.

MR. RUTHERFORD'S SUGGESTION AS TO FUNDS.

SIR,—The Planters' Association, however desirous it may be to help Mr. Pineo in carrying out the scheme he has proposed for introducing tea into America, is certainly not in a position to grant him any money from the tea fund for this year.

I have had a long interview with Mr. Pineo on the subject, and he is of opinion that unless the proposal he has made be adopted *now*, his principal, Mr. Ellwood May, would in all probability give the scheme up. I have seen Mr. Shelton Agar's suggestion as to sending out district lists and collecting tea for Mr. Pineo, and having it bulked in Colombo, while it is very gratifying to find Mr. Agar so heartily supporting Mr. Pineo's scheme, I scarcely think the manner in which he proposes to raise the necessary funds is quite satisfactory.

There is now a Tea Fund scheme in existence, framed and organized with the very object of dealing with such cases as Mr. Pineo's. The scheme was well considered, and has met with the hearty support of practically the whole of the planting community. I deprecate very strongly any departure from the principle laid down in this scheme, which is an assessment of 25 cents per 1,000 lb. of green leaf. What Mr. Agar suggests is, I understand, an *extra* subscription to the fund already in existence. Now, I do not think planters will subscribe to this, and I consider it would not be fair to ask them to do so as an *extra*.

To get over the difficulty (should the Planters' Association decide to support Mr. Pineo) I would suggest that the necessary funds be raised by those enrolled in the "Ceylon tea fund scheme," who see in Mr. Pineo's proposal a hope of great advantages accruing therefrom. This could be done by their subscribing a certain sum in advance and this amount would be deducted from the subscription which would otherwise be due by them for 1889. We have nailed our colors to a particular scheme for providing funds for pushing Ceylon tea, and I do not think we should depart from the means we have so unanimously agreed upon as the only fair principle whereby all interested in the tea enterprize are equally taxed for finding new outlets for our staple product. Should the scheme proposed by Mr. Pineo for introducing our teas into America be supported by the Planters' Association, then this method I have suggested is the only one that occurs to me by which the necessary funds could be raised to give *immediate* effect to what appears to be a very favorable opportunity of bringing Ceylon tea before the American people. H. K. RUTHERFORD.

MATARA, May 7th.—Tea in the low-country here is flushing exceedingly well. At first here is about double the size of one's fingernail. I noticed this on an estate about ten miles from town; and the quantities plucked must certainly be very much greater than up-country, though the flavour may not be so good. Not a drop of rain yet, and the place is getting unbearably hot.—Local "Examiner."

COFFEE PLANTING IN HAWAII: REPORT OF MR W. J. FORSYTH, ON THE SUITABILITY OF LANDS FOR COFFEE AND CINCHONA CULTURE.

HON. L. A. THURSTON, *Minister of the Department of Interior:*

SIR,—According to instructions of 15th of August last received from your office, I proceeded to the Islands of Maui and Hawaii on a visit of inspection with a view to report upon the suitability of lands for the cultivation of cinchona and coffee. The following is my report:—

ISLAND OF MAUI.

Landing at Kahului, I went to Makawao; thence to the department of Kahiki Nui visiting on my way the uplands of Kula and Ulupalakua. From there to Kaupo, Kipahulu, Hana and Koolau. I returned again by the same route to Makawao and visited Hamakuapoko and Hamakualoa, which completed my survey of East Maui. I then rode round West Maui, passed through the departments of Wailuku, Kaanapali and Lapaina, and made excursions into the Interior whenever I thought advisable.

ISLAND OF HAWAII.

From Lahaina I crossed over to the Mahukona landing, Hawaii. Thence to Kohala district and the districts of Hamakua, Hilo, Puna, Kau, North and South Kona, and returned again to Mahukona. Thereby making the complete circuit of the Island. I went inland at various places in every district, wherever I thought it necessary to do so.

The elevations I ascended never exceeded 3,500 feet above sea level, for reasons which will appear ater on. The general characteristics of both closely resemble each other.

The district of Koolau, part of Hamakuapoko and Hamakualoa, on the Island of East Maui, are in general very like the districts of Kohala, Hamakua and Hilo, on the island of Hawaii, so that what I have to say of the one applies equally to the other. I could also add a section of the department of Kau above Naalehu, but there is more exposure and wind than in any of the aforementioned places. These districts have a great depth of soil, strictly volcanic, a chocolate colored loam, and subsoil drainage.

In the same way the districts of Puna, North and South Kona, on the island of Hawaii, resemble each other, except that Kona proper may be more regular in its seasons.

SOIL ON HAWAII.

The soil formation is chiefly *aa*, more or less decomposed; pahoehoe lava too is quite frequent, mostly bare, or coated thinly with a layer of soil; at other places the layer of soil attains to a thickness of several feet. The general lay of the land is sloping ridges, rarely steep or precipitous, which is excellent for surface drainage. In seasons of heavy rainfall where the land is closely cultivated, surface drains are made at regular intervals to receive the surplus water and convey it to neighboring ravines. This method is always employed in the cultivation of both cinchona and coffee, and effectually prevents the washing away of top soil, which is always the richest. All that I have said and what will follow has reference only to lands which range between 1,000 and 4,000 feet elevation above sea level—seldom under 1,000 and rarely so high as 4,000.

RAINFALL AND CLIMATE.

I regret exceedingly not being able to obtain a good rainfall record from each district; as rain and the distribution of rain exercises a great influence on the cultivation of the products under notice. Hamakua has a rainfall of from 85 to 149 inches nicely distributed, taken from a record kept at Honokaa plantation for two years. Hilo has a rainfall of 127.75 observed at Hilo for ten months of present year. On the island of Maui, district of Makawao, there is an average rainfall of 81.10 observed at the homestead of Mr. W. P. A. Brewer, for three years ending 1881. These all show very good distribution. There is no record observed in the district of Kona, but I should judge the average would range from 80 to 110 inches. I form this opinion from the way the coffee is reported to crop. If the rainfall was in excess of 150 inches the coffee tree would likely blossom and ripen all the year round. The crop I am informed is nearly all gathered within a period of three months, which indicates a distinct season, and lower rainfall. The rainbelt of the islands is confined to a range of elevation from about 500 feet to not over 4,000. Above this elevation there is very much less rainfall, and along the shore line, also, the climate is much dryer.

The districts of Hamakua and Hilo, on Hawaii, and those districts on East Maui, including Hana, which I stated are very much alike in all their conditions, are exposed to the regular trade winds. They never blow violently, except only on very exposed places near the bluffs, and where the land slopes to windward. Further inland their influence is almost entirely gone, and at an elevation of 2,000 feet and upwards, there is very little wind at all. The upper part of Hamakua is subject to strong Kona winds, which pass over the Waimea gap, or plains, with considerable violence. The lower, or windward part of this district, or that portion adjoining Hilo, is protected by the mountain of Mauna Kea from all such visitations. The districts of Puna and Kona, so far as I could learn, are blest with perpetual calms. The greater portion of the lands within the range of the altitudes mentioned, are more or less forest clad. The bush upon the lower part of the forest lands of Hamakua and Hilo, is somewhat thin. The underbrush has been killed off and the largest trees are rapidly dying away. These bare sections have paved the way for the celebrated Hilo grass,* which abounds everywhere, flourishing with great vigor. I noticed very little fern, which is in marked contrast to both Puna and Kona districts, where the ground is equally well covered with timber but without Hilo grass. Ferns never impoverish land, and are at all times desirable to encourage, as they cast a dense shade on the surface of the ground, preventing the growth of all foreign weeds, notably Hilo grass, which latter draws from the soil the properties required for coffee.

REMARKS ON COFFEE AND CINCHONA.

Having described the leading characteristics of those districts from which I should select lands for the cultivation of either coffee or cinchona, I shall now explain why they are adapted for cultivation, by describing the requirements or natural conditions, best suited for the growth of these products, indicating the localities or sections of those districts which I am of opinion are richest and best for the purpose. I assume that Your Excellency had in view the desirability of encouraging only such products as are strictly tropical and those best suited for volcanic soils, and not any that find a genial home in a wider range of latitude. This policy is extremely wise, for it narrows the circle of prospective competition and increases the possibilities of continued success. With regard to coffee and cinchona, their proper and only home is here and in other tropical countries which are blest with the same natural conditions. There is not any territory under the control of the Government of the United States of America, suited for the cultivation of either coffee or cinchona. I speak with certainty upon this point, having had extensive correspondence with the Minister of Agriculture, Washington, upon the prospects of cinchona as a likely industry to introduce into some portion of the Southern States.

CINCHONA.

In selecting lands for the cultivation of cinchona, great care must be observed, as the success or failure of first efforts will assuredly either encourage an extension of the field of operations or effectually damp all future attempts. Trials have been made in two instances, to introduce the cultivation of cin

* The iluk of Ceylon, alang-alang of the Straits and Java.—ED.

chona on these islands, both of which have so far been successful.

ANALYSIS OF ULUPALAKUA CINCHONA.

The first was on the property of James I. Dowsett, Esq., Ulupalakua, Maui, where a few trees were planted some twelve (12) years ago, by the late Captain Makee. About three months ago, at the request of Mr. Dowsett, I saw these trees, and by his desire one of them was cut down and the bark brought to Honolulu for analysis. The following is Mr. Smith's letter to Mr. Dowsett, containing analysis:—

"Honolulu, H. I., July 27, 1887.

"Hon. James I. Dowsett.—*Dear Sir*: I beg to acknowledge receipt from you of 23 lb. of cinchona bark, selected by Mr. W. J. Forsyth, from a tree of the variety of cinchona robusta, growing on your Ranch at Ulupalakua, Maui, and to append herewith analysis of same, viz:—

No. 1. Total Alkaloids	12.180
Sulphate of Quinine	5.632
No. 2. Total Alkaloids	12.582
Sulphate of Quinine	5.660
No. 3. Total Alkaloids	12.643
Sulphate of Quinine	5.581

"This analysis shows even greater results than the analysis of bark from the cinchona robusta growing in Ceylon and Southern India. I take pleasure in offering to purchase this parcel, for which I will pay you 75 cents per lb., this price being based on the latest London quotations for first class bark. I remain Sir, yours very truly, Geo. W. Smith."

The percentage of sulphate of quinine alkaloids always regulates the commercial value of cinchona bark. Accordingly, when the above return is compared with the results obtained from these barks in India, the planters of Hawaii have good reason to congratulate themselves in anticipation.

According to the returns of the government cinchona plantations of India, and those conducted under private enterprise, the analysis of barks seldom shows more than an average of 2.70 to three per cent of sulphate of quinine alkaloids. This result is almost entirely owing to the lower classes of cinchonas planted. From figures taken three or four years ago, the total number of cinchonas planted out in India, viz., 26,490,000, there are 20,676,000 Succibras, the balance are made up from Officinalis, Pubescens, etc. There is very little or scarcely any at all of the higher classes grown, viz., Ledgeriana, Calisaya, and Calisaya Verde. The reason of this is very easily explained. When the Indian Government resolved to father the cultivation of cinchona in India, the botanist charged with the collection of seeds in South America, was unable to obtain any of the higher grades; hence the prevalence of the Succirubra, in the plantations referred to. I go out of my way somewhat to make special mention of this important matter, since it bears strongly upon the future of these Islands as producers of cinchona. I specially recommend the Ledgeriana and Calisaya types of cinchona to be grown here, yielding as they do all the way from five to over ten per cent of sulphate of quinine alkaloid.

CINCHONA IN HAMAKUA, HAWAII.

The next effort at introducing Cinchona was made by Mr. Purvis of Kukuihaele. This gentleman made a special visit to Ceylon for the purpose of gathering information about the cultivation of this valuable product. He spent three months there and returned with seeds of the choicest kinds, and planted a small block of land at an elevation of about 2,000 feet above sea level, some 12 acres in extent. His exertions were rewarded with success, and he now has about 12,000 trees close upon three years of age. At the time of my visit to Kukuihaele in October last, these trees were in a very healthy and thriving condition. The foliage is of a deep green color, and altogether showed evidence of thrift vigorously. In cinchona cultivation the great difficulty experienced is to raise the seed to plant from, after that the rest of the work is comparatively easy. I am of opinion that the whole of Hamakua and Hilo, of the island of Hawaii, also, the districts which I have noted as corresponding to them on the island of Maui, are eminently adapted for the cultivation of cinchona. The elevation selected to ensure success must be above 1,500 and not more than 4,000 feet above sea level.

SUGGESTIONS ON CULTIVATION.

The pahoehoe lava formation, particularly where it crops up near the surface of the ground, is suited for planting cinchona. Cinchona of all kinds are sensitive to "wet feet" and will assuredly die off if planted in fatty soil, or in ground that has no subsoil drainage. The soil does not require to be very rich, but must be friable and free. The ground should be thoroughly cleared of all forest and undergrowth, and kept perfectly clean for the first three years. After this time the branches interlace together, and cast a dense shade on the ground, which effectually prevents the sprouting of all foreign weeds or shrubs. The following is a list of the work to be done in opening a clearing: Raising nurseries will cost about $5 per 1,000 plants.

CLEARING OF LAND.

Lining 5+5, = 17,000 to the acre. Holing, 18 inches by 18 inches.

PLANTING.

By "clearing of land," I do not wish to be understood to mean to clear it in the same elaborate way that is done for cane. No uprooting of stumps of trees being required. It is always better to hole in the dry weather and in advance, because the work greatly facilitates planting, when the proper season arrives. Cleaning every two months for two years, then every three months. I know of no reason why cinchona cannot be grown equally well in the choicest parts of Kona and Puna on the old *a-a* formations, as districts mentioned, but as I have never planted on similar land, cannot say positively.

CINCHONA IN CENTRAL AMERICA.

In the Republic of Guatemala, Central America, I raised in nurseries, 3,000,000 of cinchona trees, and delivered to planters 2,500,000. The balance, 500,000 was lost from various causes. These trees are of the types which I have enumerated as the lower kinds of cinchona, viz., chiefly Succirubra, then Robusta, Officinalis and Pubescens. I had no seed of the higher grades. These trees comprise nearly all the cinchona planted in Mexico or Central America.

COFFEE.

To select lands for the cultivation of coffee, a thorough knowledge of all the requirements of the tree is necessary, as a maximum return to a given area is the object to be gained, and where any of these requirements are wanting, coffee had better not be tried. There are a few coffee patches on the Island of Maui. One near Huelo, East Maui, planted by Mr. Anneslay, about 800 feet elevation, another on the ranch of Mr. Burchardt, about 1,500 feet, and a third on a property belonging to Mr. Campbell, on West Maui, about five to seven miles up the Honokohau Canyon, elevation 400 feet. These several patches of coffee trees range all the way from ten to fifteen and twenty years of age. There are all very vigorous indeed; foliage and other indications show all the evidence of health and a continuance of life. They have, however, been terribly neglected. Totally abandoned in some cases, and jungle has been allowed to grow up and completely choke the lower primaries, so that the tree is lost, and has been for years, solely dependent on the tops for reproduction, or crop. I am very much surprised to see them live at all under these conditions which speaks volumes for the extreme richness of the soil. Mr. Anneslay informs me that from one tree he has picked as much as twenty pounds of clean coffee, and thinks there is little doubt but an average of three to four pounds can be gathered annually from each tree.

COFFEE ON HAWAII ISLAND.

On the Island of Hawaii, [illegible] there are several small portions of land planted with coffee. The plantation of Honoka, at an elevation of [illegible] feet has about an acre of coffee planted. The trees are in the neighborhood of twelve years of age. I

estimate the crop on them to be nearly ten hundred weight per acre. This is over and above what has been already picked off this season. Mr. Richard is of opinion that from three to four pounds of coffee per tree could be gathered yearly. The trees were in excellent condition, very little shaded, and free from blight, except only in the case of a few isolated trees which were almost completely choked with Hilo grass, and in a sickly and dying condition. Diseases and plagues of all kinds are less apt to attack trees of vigorous health, and free from objective influences. Weakly trees and those exposed in consequence of neglect in the way described, are sensitive to all kinds of pests. Mr. Kinney, formerly manager of Onomea, Hilo, has planted quite a large quantity of coffee on that plantation. I am informed by him that he has planted out fully 50,000 trees, which are now being uprooted to make way for sugar cane. Elevation about 1,000 feet above sea level. These trees have been planted far too close together, a very common error, and allowed to grow naturally. The effect is patent; at the age of three to four years the branches interlace, a shade is cast on the lower primaries, which become, in consequence, weak, spindly and unproductive. To make matters worse, the coffee trees have been planted under too dense a shade. In fact sunlight and daylight have been more than semi-excluded. Accordingly the tree is drawn up to seek the light, which hampers it as a producer. Coffee never blossoms freely under shade, and without blossom there can be no crop. Daylight, and all the daylight, is absolutely necessary for coffee. Nowhere in the world are shade trees planted among coffee, except only to protect it from the scorching rays of the sun, and in localities only where there is an insufficient rainfall, *and* where there are long periods of dry weather. Shade, under these conditions, is always *planted*, and that judiciously and with care. Mr. Kinney informs me that from three to four pounds of clean coffee could be reckoned as an average annual return from trees grown under the best auspices, which agrees with all the other accounts that have reached me.

KAU COFFEE VERY FINE.

In Puna I saw very little coffee. In the district of Kau, above Hilea Plantation, there are several patches of coffee, by far the best I have seen. Exposed to sunlight and daylight and quite free from blight. But again too closely planted to return their best results. I should estimate the crop on these patches to be at the rate of twelve to fifteen quintals (100 lbs.) per acre. The soil is very similar to that of Hamakua and Hilo; deep friable loam, chocolate colored, and a subsoil drainage. These trees were totally free from any indications whatever of bright.

COFFEE IN KONA.

In Kona there has been a great deal planted, but nowhere did I see an intelligent effort. No one appears to have had any knowledge of the requirements of the coffee shrub. All attempts are alike. One person appears to have copied the method of his neighbor, without any regard as to whether he was right or wrong. Throughout the whole of Kona I saw but very little blight; indeed only in the case of isolated trees surrounded and choked with Hilo grass, or overshadowed and touched by the guava tree. Everywhere, removed from these influences, the coffee was as fine as coffee can possibly be I never saw better conditioned trees than the majority of those in Kona. Nowwhere is coffee machinery employed of any kind. This is very much to be regretted, as a single pulper can do as much and better work than a hundred men, with the primitive methods used. Peeling and sizing machinery too, is quite unknown. In regard to coffee blight, which I was told would for ever prevent coffee being a paying industry, I may say that this experience is not confined alone to these Islands.

BLIGHT IN CEYLON.

The Dimbula district of Ceylon, was at one time, threatened to be exterminated as a coffee country. The plague was so bad that planters contemplated abandoning their estates, but looked forward hopefully to the eternal "next year," for a prospect of a new order of things. Their perseverance was rewarded. The trees became acclimatized, and today, in fact, for many years past, there has been scarcely a vestige of the pest to be seen. Dimbula, when I left, was the largest sheet of unbroken coffee in the world. * My opinion in regard to the coffee at present planted here, is that the trees, as was the case in Dimbula, are acclimatized, or be coming so very fast. In confirmation of the abve statement I beg to quote the following extract from Ferguson's Directory, Ceylon:—"In the early days, black bug or blight affected the coffee plant very seriously. Whole fields were prevented from cropping by this evil, and it was mainly on accunt of the prevalence of bug that any extension of cultivation to Dimbula and Dikoya was condemned. But who ever hears of blight now? One hundred thousand acres have been planted in the wilderness of the Peak since then, and the area affected by bug there or elsewhere in the island, has been most trifling. But the place has been more than filled by the most terrible of all diseases, *Hemilea vastatrix*, or coffee leaf disease." Of the terrible effects of this coffee scourge, I need only say that since the year 1869, when it made its first appearance, the coffee crops of Ceylon fell off during the first decade of years, more than one-half of their greatest production.

DANGER OF BRINGING THE DISEASE HERE.

In a letter which I addressed to the President of the Planters' Association, Honolulu, from Honokaa, Hawaii, I urged upon them, at this meeting, the necessity of drawing the attention of the Minister of the Interior to the danger to this country of would-be benefactors, bringing plants of coffee from the East Indies, with a view to change the seed here. I desire to embody a similar warning in this report, so that it may reach every one interested in planting on Hawaii. There may be even now plants on their way for the very purpose suggested; I would strongly advise them being destroyed before landing. The pest was introduced into the Fiji group of Islands in this way, where I saw it and reported upon the matter. It has also extended its ravages to Southern India and Java. These Islands are quite isolated, and it is easy to keep them free from contamination. A great industry undeveloped, has as much right to be protected as those already established. Scientific men shake their heads at the idea of leaf fungus disappearing in the same mysterious way that it began. "It has found its food, and why should it go, so long as there is a coffee tree left for it to live on," fairly represents the opinion of Dr. Thwaites, Dr. Trimen or Marshall Ward; the eminent mycologists have not given the planters much more comfort.

HOW TO PLANT COFFEE.

As I have before stated, the first qualification is rich, deep soil, as coffee is a large producer and calls equally largely from the soil. The amount of return of crops is regulated according to the fertility of the soil; like cinchona, it rejoices more in sloping, and even steep lands, than flat. I would strongly advise caution being observed in selecting *pahoehoe* formation covered with a layer of soil. Like cinchona, coffee is also very sensitive to "wet feet," and any land of a spongy nature that retains water will assuredly kill coffee. *A-a* formation containing a sufficiency of soil is best adapted to the requirements of the coffee shrub, as it takes very kindly to stony or rocky land, if accompanied by a subsoil drainage. The degree of decomposition, however, of the *a-a* must be taken into consideration. The older the flow the better; I do not need to enlarge upon this, as everyone will easily understand my meaning who has the least knowledge of the formation of this country.

DISTRICT OF PUNA.

The district of Puna is a vexed question to me.

* If Mr. Forsyth returns in a few years he will find it a sheet of tea.—ED.

I cannot say positively if the decomposition of the *a-a* has far enough advanced to ensure a permanent success to coffee, as beneath the surface, say three or four feet, the *a-a* is not packed with soil, but lies somewhat loose. The trees I saw, however, upon the whole, were very good indeed. The proper distance apart to plant coffee, must not be less than 9×9 feet, which gives 540 trees to the acre.* This distance ensures the light of day to circle round the tree. Grass lands are universally acknowledged to draw from the soil the food necessary for coffee, and plantations open on old pastures have always been unsatisfactory. Therefore it will be well to avoid lands which are overrun with Hilo grass. I am of opinion, however, that if Hilo grass has only recently established itself on virgin lands, the harm cannot be great.

CHOICEST DESCRIPTION OF LAND.

The choicest lands are those which are fern-clad and covered with bush or forest. I would also advise raising nurseries of plants, and not to propagate from seedlings which have grown from seeds dropped off the coffee trees. Plants taken from a dense shade, are always weak, spindly and difficult to raise, whilst those propagated in nurseries possess clusters of roots, and from the very beginning, when planted in the open, will form themselves into well shaped trees. After lining 9×9, the next work in the order of progression is to prepare the holes for transplanting. These holes should, as in the case of cinchona, be dug beforehand, and can be done in any weather, thus facilitating planting when the proper season begins. The season for planting is during the rainy weather, and care must be taken not to plant until the ground is well saturated to a considerable depth. Plants put out in semi-dry soil are likely to fail. Coffee, to succeed financially, must be planted in the way described, in proper plantation form, and on a scale large enough to take advantage of machinery for the purpose of pulping and curing.

ACREAGE AND ESTIMATED RETURN.

I should advise not planting less than 200 acres. This area will yield about 3,000 quintals (one quintal 100 lbs.) of clean dry coffee, annually, allowing that each coffee tree will yield an average of say three pounds per tree. In making this estimate I take 500 trees per acre, whereas the total amount of trees to the acre planted 9×9 is actually 537. The proposition will stand thus: 500 trees per acre ×200 100,000, the number of trees planted on 200. 100,000 ÷ 3 300,000 ÷ 100 3,000 the number of quintals per acre annually returned.

COMPARATIVE YIELD OF OTHER COUNTRIES.

I beg to draw attention to the comparison of yield of other countries of which I have personal knowledge and experience. In an article addressed to the President of the Planters' Association, Honolulu, I gave some information on coffee culture, and beg to refer you for further information to that letter which is published in the *Planter's Monthly* for November. I therein stated that, where all the natural conditions for the cultivation of any product are in the highest degree of perfection, a planter can begin the cultivation of such product with confidence in his ability to compete successfully with the whole world, and that the high price of labour holds a very lame, secondary place. This, of course, has special reference to tropical agriculture where the articles produced are chiefly, if not altogether consumed in the temperate zone, and where no argument of local production and consumption can be raised.

COFFEE IN GUATEMALA.

To substantiate this statement I referred, in my letter, to Guatemala, Central America, where coffee is raised very extensively, and placed the rate of charges against coffee in transport from the chief coffee districts to the steamers. They are as follows:—

From the plantation to the railway station, about $2 per quintal. The railway has a concession from the Government which gives it a monopoly and right to charge sixty cents per quintal. The wharf company have another concession which entitles them to charge thirty cents per quintal, and a still further charge of thirty-two cents, to deliver from the wharf to the steamer. In addition to all these charges the Government have an export tax of twenty-five cents per quintal, making in all, $3.47 per quintal, or at the rate of nearly $70 per ton. I also stated that alongside of the high price of labor which is paid here, I think it only fair to mention the great facilities of transport in this country, which would proportionately cheapen the cost of production. I beg also to add further testimony in support of my position, because the price of labor appears to be the great stumblingblock in the eyes of many people here.

COFFEE RETURNS IN CEYLON.

The largest export of plantation coffee, and the maximum average rate of production per acre, (5½ cwts, per acre for the country) were attained in 1870.

COFFEE IN GUATEMALA.

To return again to Guatemala, which is a volcanic country, and has all the natural requirements for the coffee tree in the highest degree of perfection, the average yield of coffee per acre ranges from ten to fifteen quintals, that is, on the choicest plantations. An important factor in estimating labor cost, is to consider at the same time, quantity produced. For instance on a plantation which produces but four quintals to the acre, a coolie can pick only about one-third of the quantity that he could on an estate that has a crop of fifteen quintals per acre. And as the picking of the crop is the principal charge against the plantation, the saving is accordingly proportionate.

COMPARISONS—GUATEMALA, INDIA.

Further, table No. I shows the return of all India to be 354,898 cwt. of coffee, whereas Guatemala, with its enhanced charges, exports nearly 600,000 quintals. This, to the ordinary observer, is very remarkable, when it is considered that the latter country pays nearly three times the price for its labor. The high charges of transport and export duties, mentioned above, and worst of all, a most fickle, uncertain and thoroughly corrupt government, where tyranny prevails, and the administration of law is a complete dead letter, makes the case still more remarkable. And yet notwithstanding this drawback, the coffee plantations pay handsome returns; a result unattainable in either India or Ceylon. I have gone more fully into this matter than is perhaps necessary, but have done so in order to satisfy those who are not familiar with these matters, and moreover who have preconceived ideas concerning coffee, and how its future may be affected by the price of labor prevailing in this country.

I may also mention, before dismissing this section of my subject, that a man unused to coffee picking, may work steadily all day long, and gather less than one-half the quantity of an expert picker. Continual practice is necessary to attain efficiency in this respect.

RAINFALL.

Rainfall exercises a great influence for good or evil upon coffee culture. The rain is accepted to be from 70 to 150 inches, nicely distributed throughout the year. Below seventy inches the trees requires care. Above 150 the effect on the tree is to cause an over growth the whole year round, making wood every month, and for want of rest, added to excessive moisture, the blossom is apt to [illegible] the trees are the tree. The fruit too, becomes deteriorated, being insipid and watery. The tree will exhibit a most luxurious foliage and great size, which is very deceiving to one not thoroughly acquainted with the culture. These observations [illegible] personal observation, and are accepting by planters of wide experience.

*This is more than Java and Brazil as a rule, than that of Ceylon, where about 1,280 trees to the acre was the rule.—ED.

COFFEE YIELD IN BRAZIL.

The world's production of coffee reaches about 900,000 tons, nearly one-half of which is produced by Brazil. Brazil may fairly be called the coffee barometer of the world, consequently what effects that great country, will naturally be felt throughout the whole coffee world.

AGE OF COFFEE TREE.

The life of a coffee tree whilst productive, cannot be reckoned longer than twenty-five to thirty years, and as coffee can never be planted twice on the same land, the question naturally arises, where is the worlds consumption of coffee in the future to be derived from. The culture is confined to the tropics, with all the conditions I have enumerated above, so that the area in the whole world is limited. I attribute the rise that has recently occurred in the price of coffee, partly to an increased demand, but mostly to the gradual failure of the oldest plantations throughout the world, as well as the fact of new countries suited for the cultivation of this product, not being opened fast enough to meet the demand. In conclusion I would mention that the report now submitted, has reached dimensions not contemplated when beginning my remarks. The fact, however, of cinchona and coffee cultivation being new in the country, and to planters generally, I was induced to enter into greater detail as my subject proceeded. I shall at a later date, after having visited other parts of these Islands, supplement this report with a review of what may strike me as being worthy of notice. I beg to subscribe myself your obedient servant,

Honolulu, November 29, 1887. W. J. FORSYTH.

KEROSENE AS AN INSECTICIDE.

EDITOR PLANTERS' MONTHLY:

In the last "Biennial Report of the State Board of Horticulture" of California, a copy of which I herewith send you, there are accounts of processes for exterminating insects, some of which might well be tried against the white aphis, "Dactylopius destructor," which has seriously checked the culture of coffee in our Islands. If this insect were overcome, coffee might probably be cultivated wherever sugar cane grows.

In this report it is remarked that experiments conducted by the Agricultural Department at Washington, as well as by State Inspectors of fruit pests in Florida and California, have demonstrated that the most effectual destroyer of all kinds of insects, and particularly of the *Icerya Purchasii*, which resembles our white aphis, is an emulsion of kerosene oil sprayed over the trees. I have formerly found this to be true in regard to our aphis.

On page 26, the following recipe is given for preparing a good emulsion:—"Five gallons best kerosene, 1¼ pounds good common soap, 2½ gallons water. When using, dilute 6½ gallons of water for each gallon of oil, and to this mixture add 2½ pounds of good home made soap dissolved in boiling water. All the mixing is done in hot water. We usually have 140° in the tank from which we spray."

In regard to applying these emulsions, it is remarked that "the essence of successful spraying consists in forming the emulsion as a mist from the heart of the tree first, and then from the periphery, if the tree is large." It is recommended that "a No. 1 Hooker pump be used, with a 4½-feet lever and 50 feet of hose. Two men in a wagon with a tank can pump 700 to 800 gallons per day." The "Cyclone Nozzle," which can be procured in San Francisco, is the best for making the spray. "A bunch of four nozzles can be arranged at the end of the piping, so that working from the centre of an ordinary sized tree they will envelope it in a perfect ball of mist."

The State of California employs an Inspector of Insect Pests, whose investigations and suggestions are invaluable to the fruit industry of the State. It is very desirable that a competent person be employed to make similar investigations and experiments in our Islands.

Oakland, Dec. 10, 1887. J. M. ALEXANDER.

BLACKBERRY CULTURE.

Mr. Walter Ellis, of Seaford, Sussex County, Delaware, writes to us as follows:—Your Note on blackberry culture, in the *St. James's Gazette* of the 23rd of January, induces me to send you a short account of the industry as carried on here. It is by no means a novelty, having been successfully prosecuted for nearly twenty years. There appears no good reason why it should not be a success in England in suitable localities and worked on the American plan. The method of cultivation described in your paper is, no doubt, suited to the climate of Wisconsin, but is certainly, as to the winter covering and consequent wire supports, quite unnecessary either here or in England. There are at the present time within a few miles of this place considerably over a thousand acres in blackberries; and, on the whole, they are a profitable crop, requiring little cultivation and no manure. The plants are set in rows at varying distances, according to the soil and the fancy of the grower: 6 ft. by 4 ft. is a convenient distance and gives 1,750 plants to the acre. They are planted either in the fall or spring: preferably the former in this latitude. The setting out is usually as follows:—The ground, having been ploughed and harrowed, is "crossed out"—*i. e.*, furrows are run with a small one-horse plough 6 ft. apart and afterwards crossed with other furrows at right angles 4 ft. apart; the point of intersection being the mark for planting. The plants, previously trimmed and prepared, are dropped by boys at these intersections, and following come the planters armed with a hoe sufficiently light to work easily with one hand; the plant is picked up with the left hand, the bottom of the furrow scraped out the plant set well down, the earth drawn round it, and a stamp with the feet on either side completes the operation. Two thousand a day can be done by any fair hand. The plants will in the first season make a good growth; the first operation in the following spring is cutting back the canes to about 30 in. and the removal and burning of the brush. The ground between the rows is then ploughed with a small one-horse plough, and afterwards cultivated, usually three times during the season, with a tool much resembling a small Kentish hop-shim. The variety usually grown here is the Wilson; but it would be quite unsaleable in England, as it is absolutely tasteless, its size being its only recommendation. Other varieties more suited to England are the Early Harvest, Early Cluster, Kittatiny, and Snyder. The average yield is a quart to a plant; the cost of producing and putting on the market is under 2½*d.* per quart. It would be necessary to use American tools; they are cheaper to buy and much cheaper to work than English ones. A suitable plough cultivator and harness would cost about £3 10*s.* delivered in England. But in order to successfully market the fruit, proper berry-crates must be used; the ordinary size holds thirty-two quart baskets in four tiers, divided by removeable decks. The fruit is picked into these baskets in the field, and the pickers are paid by this measure. Berries of any kind, even raspberries, properly packed in these crates are shipped 200 miles and more and handled by the common American railroad fiend, and yet arrive in good condition. The crates, fully fitted with baskets, cost about 3*s.* a-piece and last for years; the bent-wood baskets cost under 1*s.* 2*d.* each by the thousand.

TEA AT FOOCHOW.—The Foochow *Echo* learns that this year the amount of treasure obtainable by the natives for the purchase of the new season's tea up country, will be far below that of last year, and earnestly hopes such will be the case, believing that nothing will improve the trade but a severe cut down of the usual liberal advances generally made to natives, which enable them to purchase even the roots of the tea plant. In a later issue, the same paper states that the Chinese Banks will advance very little to the teamen this year, and that it will not reach half of the amount advanced last year.—*Hongkong Daily Press*, April 18th.

PADDY CULTIVATION:

PULVERIZING AND CONSEQUENT CHANGES IN THE SOIL—CLAY SOILS—ALUMINA AND DOUBLE SILICATES—POONAC AS A MANURE—COCONUT AND CASTOR-CAKE, &c.

25th April 1888.

In connection with Mr. Cochran's analysis of paddy soils a new face on the question of pulverizing soils has been opened, and your Siyane Korale correspondent has drawn some valuable deductions from the same. It is quite true that the injurious ferrous compounds in the soil is made innocuous by exposure to the air; but I don't think it as the principal cause for the increased results obtained by ploughing with English ploughs. In some soils there is no ferrous oxide at all; and in others we find only very little. The real value of thorough ploughing is the yielding of more plant-food for the use of the growing crop. By oxidation and carbonification caused by the air and accelerated by the sunheat many of the dormant compounds become active or soluable in water. When the injurious ferrous, compounds such as (Fl_2-O_2) are exposed to the air, oxygen is readily absorbed, and the insoluable compound of ferric oxide (Fl_2-O_3) is formed. This compound also plays a great deal in fertilizing a soil. Though it is insoluable in water (and hence not entering the plant), it has the power of absorbing nitrogenous matter and yielding it to the growing plant, and sometimes it readily parts of its oxygen also when required by the plant. Ferrous oxide is not the only injurious substance found in the soil and improved by aeration. There are the foul organic acids; these acids are present to a large extent in most of our paddy soils formed by the decay of grass and stubble. Such substances are also improved by thorough aeration and turned into valuable plant-food. However, no one as far as I am aware has determined the amount of materials in a soil turned into the active state by aeration within a given period of time. Some such results would be very valuable as showing the difference between thorough ploughing and ordinary ploughing. The whole amount of active matter generally found in a fertile soil is not above four per cent of its whole weight.

Most of our Ceylon paddy soils consist of clay to a more or less extent. Clay soils contain a deal of alumina and silica generally in the form of aluminum silicate. It is quite admitted that alumina does not enter into the composition of plants, and silica too only in very small quantities. These apparently useless compounds occur in the soil to a large extent, sometimes above fifty per cent of the weight of a soil, though they are apparently useless, and some may suppose, 'playing no part in the vegetable economy.' Alumina and silica play a great deal in the growth of a plant and is of great service to the crop. The silicate of alumina forms compounds in the soil called double silicates, and the nature and importance of the double silicates may be gathered from the following paragraph from Prof. Tanner:—

"Although it (alumina) forms no portion of plant-food necessary for the structure of our cultivated crops, it has other duties devolving upon it which unavoidably associate it with the plant-food itself. (The double silicates) are silicates of alumina and some second substance. The silica has two partners; the one alumina is a permanent partner, whilst the other may either be soda, lime, potash, or ammonia; and in consequence of the silicate having two partners, these compounds are known as double silicates. It may be as well to call to remembrance the fact that when the double silicate of alumina and soda meets with lime in the soil, the soda is thrown out of partnership and the lime is taken in, and the new product is a double silicate of alumina and lime. If this double silicate comes in contact with potash, then the lime is turned out and the potash is admitted as a partner, and the new item is known as double silicate of alumina and potash. But if ammonia should be brought in contact with this double silicate, then the potash has to give place to the ammonia. Thus it will be seen that ammonia is the highest favourite, the potash the second, the lime the third, and the soda the fourth; and a higher favourite always puts aside any other of lower rank. At length a period arrives when another agency is brought into action, and that is the 'demand made by the growing plant.'"

Thus we see alumina playing a great deal in the vegetable economy and supplying plant-food to the crop, and this is the reason why many of the clay soils containing above fifty per cent of alumina are richer than other soils.

The value of poonac as a manure for paddy has been discussed lately, and the relative value of castor cake and coconut poonac; the former is by all means better, but from the following table got from the analysis of Mr. Hughes, it will be seen that castor cake contains from ½ to ¼ more of nitrogen than coconut poonac.

Contains	White Castor Cake.	Brown Castor Cake.	Coconut Poonac Mills.	Coconut Poonac Chekku.	
Nitrogen	7·13	4·39	3·35	3·02	per cent.
Digestible fibre ...	11·26	21·89	41·25	43·06	„
Mineral water ...	10·68	6·12	10·46	7·80	„

But I was surprized at a statement made by your Siyane Korale correspondent that castor cake contains *one twenty times as much nitrogen* as coconut poonac. If it is not a mistake made by him through some slip of the mind, we would be glad to know from where he got the information.

The cultivators of paddy if they go to employ poonac at all will resort to their village chekku stuff, instead of going for the trouble and expenses in getting down castor cake. The only deficiency in coconut poonac is its less percentage of nitrogen; brown castor cake contains about 1 per cent more of nitrogen. Therefore 1¼ cwt. of coconut poonac will contain nearly the same percentage of nitrogen and a great deal more of digestible organic matter and mineral water than one cwt. of castor cake; and a 1¼ coconut poonac will be cheaper and convenient for our goyias than a cwt. of castor cake.

W. A. D. S.

INDIGENOUS TEA PLANTS.

What is an "Indigenous Tea Plant?" I think there is a good deal of confusion regarding this subject, and therefore purpose giving a short sketch of what I really consider to be such. To commence with, the tea we term indigenous, and which the Natives call "junglee," shows pretty plainly that the plant is part of our virgin forest or scrub land, which has never been subjected to cultivation. The plant may be divided into various classes according to the district it is found in, such as Assam indigenous, Cachar indigenous, Tipperah indigenous, &c., but as to whether any of these plants differ from one another, is much to be doubted. I for my part take them all to be one and the same plant, not as yet generally known by their botanical name among the majority of planters, and for this reason they go by the names of the districts in which they are found. That the three districts by which I have named these indigenous plants may slightly vary, owing to different local surroundings, soil, temperature, &c., there is no room for doubt. Some are hardy, others are the reverse, but all the same they are one and the same *jat* of plant.

I must make a slight digression here, and refer to what is generally termed Munipore indigenous. That such a plant exists there is no doubt, but it is one and the same class as those already mentioned by me, its foliage being the same, a light greenish yellow. A word as to the dark leaf plant, which is much smaller in the leaf, and which, to my mind, is only a hybrid, having been the offspring of the light-leated plant, hybridised by China

plants, which I believe to be plentiful in Upper Burmah which adjoins Munipore, and it is, therefore, a decided mistake to call it indigenous. The very growth of these plants is enough, to those acquainted with true indigenous, to show that by the number of small branches it developes, it cannot be a pure indigenous plant, whose branches are very sparse and far apart in comparison with any plant tending to the hybrid class. Most people are aware how easily one plant can hybridise another by its pollen being carried by insects, and as tea has been made in the north of Burmah, I see no reason to doubt the possibility of the light leaf plant having perhaps become so impregnated whilst in flower, and so give us the dark leaf plant and seed. These light-leafed plants are longer in leaf, I believe, and what is generally termed the small leaf plant, is simply nothing more than a second or third remove from the first plant self-planted in the large tracts of jungles or even planted out by the Munipores after they learned the demand for this class of seed. That this class of plant is a hardy one, no one doubts for a moment, and if it yields well, so does a good China; but it is deficient in strength of liquor to be really pure indigenous, which is invariably a more tender plant to handle.

Now to return to my former subject, indigenous tea seedlings put out from the pure plant are delicate, and from various causes, such as the parent plant having grown in the shade and then planted out in the open, it will always be found that when indigenous seedlings are planted in the shade or on the cool side of a *teelah*, they thrive better than if on the hot side without any shade. It may also arise from the seedlings not having sufficient mineral food whilst in fruit stage on the mother plant, or from being in poor land, heavily washed land, or any other cause, as the first plant was a self-sown plant and naturally had not the amount of care bestowed on its planting that we bestow in planting exotic, the first remove shows signs of delicate health. Now indigenous once removed is, as a rule, a good yielding plant, and hardy, and simply because it has been once transplated, and so able to procure all the nourishment requisite to keep it in a robust state of health. Plants twice removed are often termed indigenous; but this is a mistake, as in nine cases out of ten the plant has not been planted is an isolated spot and has beceme hybridised.

It is absolutely necessary for any person growing an indigenous seed crop, to isolate the plants from all possible chance of contamination from other plants, and where this is done a really high class plant will be got; not till then. A great deal can yet be done towards improving indigenous plants, or, correctly speaking, high class hybrid plants: such as panting out Cachar indigenous and Bazalonie, or any other two kinds, alternately in the rows, and so introducing a new class of *plant* that will yield well and give strength of flavour at the same time. To ensure a good seed crop, the bushes should be deeply turned round every cold season and lime applied to the roots, with good cow manure on the top. If a liberal allowance of lime* be given, it may go for three years, and only heavy manuring with cow-dung carried on every year in the cold season, with the deep trenching, and provided the land be sandy, a good crop will be the result, anything from 10 to 40 maunds of seed per acre.

Another mistake people make at present, who grow seed, is cropping it for leaf. The bushes do not yield well for either crop, and seed from such bushes should be avoided as much as possible. It is also a mistake many people make when a bush gets too big to pluck, to leave it for seed, as invariably such a bush has not got free sap channels to permit of a full and vigorous flow of sap. A full flow of sap for a fruit crop is quite as essential as for a leaf crop. I might even go the length of saying more so, as the mineral substances exhausted from the soil harden up the wood very considerably, more on a fruit bearing tree than in a tree grown for its leaf. A tea plant can grow to a certain height with advantage for a leaf crop, but after constant plucking and pruning the channels get stopped up, and with a poor, feeble flow of sap, the bushes throw out poor small leaves and degenerate very rapidly; but if these very plants are cut down low and allowed to form new wood and consequently new sap channels, the bush regains its former vigour and we get a fine luxuriant foliage in place of the small puny leaf it yielded prior to its being cut down, and though the bush may be half or quarter its former size, I am prepared to say it yields more per acre. If this is so with a leaf crop, it also surely holds good with a seed crop, and such bushes also, after a certain stage, can with advantage be pruned down.

In conclusion, let me say to all concerned in tea, when making new extensions go in for high class plant. Don't be over-ruled into buying seed by the name of it, without satisfying yourself: *first*, that it is a really high class plant; *secondly*, that it is isolated from all contamination from an inferior *jât* of plant; *thirdly*, that the bushes are in a robust state of health; as with a falling market none but the finest yielding plants will recoup one for putting them out. And don't, above all things, be misled by the term indigenous, as unless it is procured from the jungles, nine out of every ten gardens selling their seed as "Munipore Indigenous" sell nothing more than a moderately fair class of hybrid. Its being a hybrid in its first stage won't make it more an indigenous, because Tom and Dick sell it as Muniporee, Cachari, or Tipperah once removed.—CACHARI.—*Indian Planters' Gazette.*

[Except for lowcountry places, 3000 feet and under, we suspect high class hybrid plants are preferable.—ED.]

* But most writers on tea state that it requires the minimum of lime.—ED.

NOTES ON ESSENTIAL OILS.

(From Messrs. Schimmel & Co.'s Half-yearly Circular.)

Since last autumn, Messrs. Schimmel & Co. state, the trade in essential oils has been of a fairly satisfactory character, although not an exceptionally favourable one. The increased stringency of the protective duties, and the tariff-wars which have lately marked the commercial policy of Continental states, have adversely affected the export business of the Leipzig firm, and the sale of essential oils to liqueur manufacturers in Germany has been greatly hampered by the Spirit Law, which has had the effect of disorganising the liqueur industry, and of decreasing its output to the estimated extent of 25 to 30 per cent. The perfumery trade has apparently suffered no injury through the action of the new law, although its provisions with regard to the official control and inspection of the stock of alcohol in the hands of manufacturers are exceedingly irksome.

CINNAMON OIL.—In Colombo higher prices are now asked. The bulk of the exports from that island consists of bitter, low-class oils, or of cinnamon-leaf oil, only a small percentage of the shipments being of fine and pure quality. The most practical and certain test of the purity of cinnamon oil, and one which is preferable to all chemical tests, consists in simply pouring a few drops into cold water, when cinnamon oil sinks, as its specific gravity is higher than that of water. When touched with the tongue, pure oil immediately creates an extremely sweet taste, far surpassing that of sugar. This purely sweet taste should be maintained throughout. Ordinary oils first cause a clove-like taste, which is only succeeded by sweetness after a long interval. Such oil has no higher value than ordinary oil of cassia.

CLOVE OIL.—Until now only small shipments have come to hand of the clove oil distilled in Mauritius from green cloves. This oil, though it is said to answer the requirements of a good quality of clove oil, is of a very low specific gravity (1.048 at 18° C), against 1.060 s.g. at the same temperature for clove oil distilled by Schimmel & Co.

GERANIUM OIL.—In October last the price of African geranium advanced by about 10 per cent., and this increase has been fully maintained for the better brands. The stock of the latter is now much reduced, and the future course of the quotation will depend upon the yield of the first crop, which is distilled in the month of April. It is worthy of note that freshly-distilled African oil, if exported in tins, nearly always has a pronounced disagreeable flavour when first opened, but this is quickly lost when the oil is decanted in bottles and brought in contact with the air. Quite recently the quotation for fine Spanish oil have been somewhat reduced. It is proposed to establish in the south of Spain a large distillery, fitted on the French plan, especially with the object of producing oil of geranium. There is no doubt that, in case of only a small difference in price, Spanish oil deserves the preference over the African product. The production of geranium oil in Corsica does not appear to have gained much ground.

GINGER OIL.—Cheap ginger for distilling purposes has been obtainable in abundance, African ginger especially being frequently obtainable at very advantageous rates in Liverpool and Hamburg. In China, whence hitherto only preserved ginger has been exported, a company has recently been formed which treats the root by special machinery and dries it for export. It is said that no less than 90 per cent. of the weight of the fresh root is extracted in the form of water and starch, while the remaining 10 per cent., which is obtained in a powdered form, contains the valuable aromatic part of the root. A sample of the powder proved far superior in aroma to all known varieties of root, and the first large trial shipments of this powdered root are looked forward to with much interest.

LEMON OIL.—The prices of the new oil in Sicily ruled at an advance on those paid for old oil at the close of the season, and owing to heavy and pressing orders from America a large proportion of the crop changed hands at full prices since the beginning of the year. Recently business has become rather slacker, and a decline in the values may not improbably occur with the advent of warmer weather. One of the principal manufacturers is steadily engaged in elaborating a machine for the manufacture of oil of lemon, and the complete solution of this problem appears likely to be realised soon. This would do away with the now largely prevailing sophistication of the oil during the process of squeezing it from the rind by hand. According to official Italian statistical returns the number of lemon, bergamot and orange trees in Sicily is 10,115,796, and in the province of Reggio 1,211,377, yielding in 1885 a total of 2,329,622,600 fruits, a quantity much below the average. About 1,500 fruits are required for the manufacture of one kilo. of essential oil.

LIGNALOES OIL.—The production of this oil in Mexico has been increased to a perfectly senseless degree, considering the limited consumption, and consignments upon consignments are accumulating on the European markets. Under these circumstances values have steadily fallen, without thereby enlarging the use of the oil to any considerable extent, and the exporters will have to prepare themselves for heavy losses. The principal employment of oil of lignaloes is in the manufacture of a perfume which has already gone more or less out of fashion, and thus the field for consumption has shrunk, while the production has increased tenfold.

MATSU OIL.—This oil, which is a novelty imported from Japan, is probably obtained by distilling the tar of a variety of birch or beech-tree. The oil is quite different from that yielded by the German birch-tree. The latter has a s.g. of 0.965 and contains about 40 per cent. of phenol derivatives. The part which is insoluble in alkali boils at 170° to 288° (between 170° and 280° about 20 per cent.) The s.g. of the Japanese oil is 0.875, and it contains 4 per cent. of phenols of an agreeable guayacol flavour. The bulk of the part insoluble in alkali boils below 180°, viz., about 40 per cent between 160° and 170°, and 40 per cent between 170° and 180°, only about 10 per cent requiring a temperature of over 200°. The low boiling parts of the oil would probably be worth a careful chemical investigation.

NEROLI OIL.—The expectations that the frosts which have occurred in Southern France have damaged the orange-trees have not been realised. It is stated from a reliable quarter that although the temperature has been as low, if not lower than in 1883, yet no evil effects of the frost are noticeable, as the young buds were not yet sufficiently developed to be damaged. Only quite young plants, which do not yet bear fruit, and sweet oranges have suffered, and a normal result of the neroli crop may therefore be anticipated. The prices upon which the flower contracts have been based are the same as last year.

PETITGRAIN OIL.—The high prices which were realised by fine Paraguay oil a year ago have unfortunately brought about over-production, which, in a short space of time, has thoroughly ruined the trade in this oil, and quotations have now fallen to a point which can scarcely leave a margin to the manufacturer. The consumptive capacity of the market for this article, it should be recollected, is strictly limited, and any transgression beyond its boundaries usually avenge itself. The manufacture of the oil, also, is no longer confined to a few persons, as it used to be, but quite a number of people, mostly new to the business, are engaged in it, and are in the habit of consigning their goods, on good luck, to the first European market they can think of. The formerly-practised adulteration of the oil with alcohol does not seem to be resorted to any longer, and, on the whole, laudable care is now given to the preparation of the article. The competing French oil, of course, suffers greatly from the glut in the market.

ROSE OIL.—The plantations of centifolia roses in Germany only show to a very slight extent the damage caused by the severe winter, and the loss is comparatively no larger than in former years. A few hundred rose plants of the variety cultivated in Bulgaria have reached Leipzig by a détour, and high expectations are formed of their successful propagation. They will flower in the coming season, and it may then be judged whether they will serve the purpose better than the centifolia plants. The cultivation of roses for distilling purposes can of course only be resorted to with advantage in the immediate vicinity of Leipzig, so that the freshly-gathered roses can be at once forwarded to the works in the morning. Meanwhile, however, the price of otto of rose has fallen so low that the German distilled otto, although in commerce it commands a higher price than the Turkish article, does not leave a profit to the distillers. German rose oil will be exhibited for the first time at Brussels and Barcelona this year. The cause of the extraordinary depreciation of the Turkish oil is generally said to lie in the fact that the prevailing fashion is not favourably disposed towards the article, and that the enormous extent to which adulteration is resorted to has made people lose confidence in the article. If no improvement should occur in this respect the future of the article may almost be despaired of, for if a favourable crop should come to reinforce the stock left over from previous seasons, the accumulation of supplies must further depress the price, and even threaten the continued existence of the Bulgarian industry on its present scale.

WINTERGREEN OIL.—During the past half-year prices have only slightly varied in America, and they now again approach the lowest quotations of the latter end of 1886. The action of gaultheria oil has recently been investigated by H. Wood and H. A. Hall. They found that large doses caused violent irritation of the mucous membrane of the stomach and severe vomiting, but no diarrhœa. Paralysis of the heart only occurred after the injection into the blood of very large doses, and in this respect the effects were weak as compared to that of other liquid oils. It is surmised that the oil is entirely

changed to salicylic acid in the body, as all attempts to prove its presence in the urine were fruitless. The statement made by MacEwan, to the effect that winter-green oil is very largely adulterated with camphor oil, seemed so improbable to Messrs. Schimmel & Co. that they made inquiries on the subject in New York, and received the answer that their New York firm had never met with any such adulteration within their experience.—*Chemist and Druggist.*

ANNUAL REPORT OF THE ROYAL BOTANIC GARDEN FOR THE YEAR 1886-87.

Calcutta, the 21st May 1887. From—Surgeon-Major G. King, M.B., LL.D., &c., Superintendent, Royal Botanic Garden, Calcutta, to the Secretary to the Government of Bengal, Financial Department.

I have the honour herewith to submit the Hundredth Annual Report of the Royal Botanic Garden.

It may not be inappropriate to begin the hundredth annual report of the garden by giving a brief account of its history, which is, to a very great extent, history of Indian Botany.

1. The suggestion to form a Botanic Garden here was first made to the Government in Calcutta in June 1786, by Colonel Robert Kyd, then Superintendent of the Hon'ble Company's Dockyard at Kidderpore. The proposal was favourably entertained by the Governor-General, and its adoption was recommended to the Supreme Board in London during the same month, practical effect being given to it during the following year by the selection, as a site, of a large piece of land immediately below Colonel Kyd's private garden at Shalimar. This piece of land, besides the Botanic Garden as it is now limited, included about fifty acres which form part of the grounds of the present Engineering College. Colonel Kyd was himself an ardent horticulturist, and he had brought together in his private garden at Shalimar a large collection of exotic plants, chiefly from the Straits. He was therefore very appropriately appointed the first Superintendent of the Botanic Garden which had been founded at his suggestion. Colonel Kyd continued to perform the duties of Superintendent until his death in 1793. On Colonel Kyd's death, Government decided to put the garden under the charge of a special officer who should have no other duty. Dr. William Roxburgh, the Company's Botanist in Madras, was therefore transferred from that Presidency, and was installed at Seebpore in November 1793. No better selection than that of Dr. Roxburgh could have been made. Dr. Roxburgh, for many years prior to his transfer, had been engaged in studying the then little-known Flora of the Northern Circars in the Madras Presidency. He was a most ardent and enthusiastic botanist, and a good gardener. Dr. Roxburgh continued to be Superintendent until 1814, when he was obliged to proceed to the Cape on account of his health. From the Cape he went on to St. Helena, and from thence to England, where he died during the following year. Dr. Roxburgh was the first botanist who attempted to draw up a systematic account of the plants of India. During his busy life in this country he prepared a *Flora Indica*, which contained systematic descriptions of all the indigenous plants known to him, as well as of many exotics then in cultivation in the neighbourhood of Calcutta. The manuscript of this work he took with him when he left India, intending to publish it during his residence in England. His death prevented the execution of this plan; and, with the exception of the first volume, which was printed with some additions and interpolations by Drs. Wallich and Carey in 1820, the book remained unpublished until 1832. In the latter year it was printed, exactly as the author had left it, by the piety of his sons, Captains James and Bruce Roxburgh, neither of whom was a botanist. This book is the basis of all subsequent Indian botanical works. It is an admirable production: the descriptions are accurate and graphic, and its authorship justly entitles Roxburgh to his title of the Father of Indian Botany. Until the year 1872, when the publication of the "Flora of British India" was begun by the distinguished botanist Sir Joseph Hooker, Roxburgh's was the only single book through which a knowledge of Indian plants could be acquired. A second edition of this excellent manual was issued by Mr. C. B. Clarke in 1874 at a merely nominal price, Mr. Clarke's desire being to put the book within the reach of the poorest student. Besides the *Flora Indica*, Roxburgh published, at the expense of the Honourable Company, in three large folio volumes, his *Plantæ Coromandelianæ*, being descriptions with figures of three hundred of the most striking plants of the Coromandel Coast. Dr. Roxburgh was immediately succeeded in the Superintendentship of the Garden by Dr. Francis Buchanan (afterwards Hamilton), who at the time was on special duty in connection with an extended enquiry into the agriculture of India and in the collection of materials for a Gazetteer. Dr. Hamilton, who was an accomplished botanist and zoologist, collected a vast mass of material, part of which was published in his own name, but the bulk of which, after many years' suppression, was published under the title of Montgomery Martin's History, Topography and Statistics of Eastern India. Dr. Buchanan-Hamilton held charge of the garden for only a short time, and he was succeeded in 1817 by Dr. Nathaniel Wallich, lately Surgeon to the Danish Settlement at Serampore. Dr. Wallich was an able and most energetic botanist; and, during the earlier part of his term of office, he organised collecting expeditions into the remote and then little known regions of Kumaon, Nepal, Silhet, Tenasserim, Penang, and Singapore. Dr. Wallich in fact undertook a botanical survery of a large part of the Indian Empire. The materials (in the shape of dried specimens of plants) thus accumulated were taken by Dr. Wallich to London, and, after being named there by himself and by other botanists, they were distributed in numbered collections to the leading botanical institutions in Europe. In this great distribution, Dr. Wallich included the collections of several other botanists which had been made over to him for the purpose. The liberality with which these specimens was given away was so extreme that, in the garden report for the year 1843, we find Dr. Griffith (who had been appointed to officiate for Dr. Wallich during his absence in England) complaining that the herbarium had been completely denuded of every specimen collected during the first fifty years of the existence of the garden. Besides distributing these enormous collections, Dr. Wallich was enabled, through the munificence of the Honourable Company, to publish, under the title *Plantæ Asiaticæ Rariores*, three superb volumes illustrated by coloured figures of a high degree of excellence. Dr. Wallich retired in 1846 and died in 1854. During the lengthened absences of Dr. Wallich in Europe, his place at the garden was filled by Dr. W. Griffith, whose premature death deprived Botanical Science of one of its ablest and most industrious votaries. Dr. Griffith's extensive notes and numerous drawings were, after his death, published by Government in nine volumes. Dr. Wallich was succeeded by Dr. Hugh Falconer. Dr. Falconer was a Palæontologist, well known by his researches on the Sivalik Fossil Mammalia. In 1855 he left the country on account of ill-health, and was succeeded as Superintendent by Dr. Thomas Thomson, a traveller and botanist of much ability, the coadjutor of Sir Joseph Hooker in the collection and distribution of an extensive and well known herbarium of East Indian plants, and the joint author of the first volume of a new *Flora Indica*. Dr. Thomson retired in 1861, and was succeeded by Dr. Thomas Anderson, whose untimely death in 1870 was caused by disease contracted during his efforts for the introduction of the quinine-yielding Cinchonas into the Sikkim Himalaya. For the two years subsequent to Dr. Anderson's departure from India, Mr. C. B. Clarke acted as Superintendent, and during his incumbency he began the series of botanical publications which has earned for him so high a scientific reputation.

2. From the first foundation of the garden, it was understood that it was to be made a source of botanical information for the possessions of the Company, and at the same time a centre to which exotic plants

of economic interest could be imported for experimental cultivation, and from which, in turn, they could be issued for distribution in the Company's possessions. It was also intended to assist in introducing indigenous Indian products to new markets. It was intended that it should not only be a botanical, but also a horticultural and agricultural garden. The preceding paragraph shows how the botanical work laid out for the garden has been accomplished. But the economic side has by no means being neglected. At first, great hopes were entertained that the spices which rendered the trade of the Company with the Moluccas and other of the Malayan Islands so valuable, might be cultivated in Bengal. The earliest efforts of Colonel Kyd were therefore directed to the introduction of the trees which yield nutmegs, cloves and cinnamon, and of the pepper vines. It was, however, speedily proved that the climate of Northern India is quite unsuited to these equatorial species. The equatorial fruits, such as mangosteen, langsat, dukko and bread-fruit, were also tried with a similar result; and so were the temperate fruits of Europe. In fact, no small part of the benefits conferred on the country by the garden in its early days was the demonstration by practical experiment that certain natural products, many of them of a most desirable kind, cannot be grown in Bengal; much money and bootless effort being thus saved to the country. The introduction of exotic timber trees also received early attention; and in the garden there still remain a few of the original mahogany trees introduced in these early years. The introduction of tea was one of the items put down in Colonel Kyd's original programme; and in the final establishment of what has now become one of the most important industries in Northern India, the garden bore a most important part. Potato growing was introduced through its agency, and the cultivation of the quinine-yielding Cinchonas of the Andes was initiated and carried to a successful issue under the direction of Superintendents of this garden. In the improvement of Indian cotton, and in the introduction both of that and of jute to the markets of Europe, the garden authorities worked cordially hand in hand with the Agri-Horticultural Society of India, with what success it is unnecessary to point out. By the introduction of some of the best kinds of sugarcane from the West Indies, and the dissemination of these to all parts of the country, a considerable improvement was effected both on the quality and quantity of the sugar crop of the country. In this matter also the Agri-Horticultural Society worked hand in hand with the garden authorities. Very soon after the establishment of the Society just mentioned, a considerable piece of land in the garden was made over to it rent-free, and on this land the Society conducted the greater part of its operations for forty years. In fact, it was not until the year 1872 that the Society's garden was transferred to its present site in Alipore. It is unnecessary to discuss in detail the numerous experiments in the cultivation of economic plants which have been conducted in the garden since its beginning. A few of the products tried may simply be mentioned. Chief among these are flax, hemp, tobacco, henbane, vanilla, coffee (Arabian and Liberian), cocoa, ipecacuanha, aloes, sarsaparilla, jalap, India-rubber, cardamoms, tapioca, and coca. As regards horticulture, it may suffice to say that a large proportion of the kinds of exotic plants now found in private gardens in India has been introducted to the country though the agency of this garden, and that the improved methods of cultivation which now obtain were to a great extent initiated here.

3. In 1820 about fifty acres of land belonging to the garden were made over by Government to the Society for the Propagation of Christian Knowledge. And on this land the Society founded the institution so long known as Bishop's College, but since 1880 (owing to its retransfer to Government) as the Government Engineering College. In the year 1864 the garden was devastated by a cyclonic storm of extraordinary violence, which either uprooted or broke to pieces the majority of the trees in it, and, by blowing down all the plant-houses, hopelessly crushed their contents. The few trees which escaped on that occasion were sadly reduced in number by a second cyclone which passed over the garden in 1867; and, at the present time, almost the only trees dating from before 1867 are the great banyan and a smaller tree of the same sort, some peepuls and country almonds, about twenty mahogany trees and some palms. It is almost a pity that the occasion of its destruction by these cyclones was not taken to remove the garden to a site on the Calcutta side of the Hooghly. For, although there are certain advantages in the garden being so remote from the town, there can be little doubt that the balance is in favour of a site more easily accessible to the residents of Calcutta. The destruction of all shade, which resulted from the removal of the trees, allowed the inveterate weed known popularly as ooloo grass and botanically as *Imperata cylindrica* to take possession of the whole of the ground not occupied by roads or flower borders; so that when I took charge of the garden in 1871 it presented rather a sorry appearance. The liberality of the local Government, under whose control it soon thereafter passed, has made it possible for me to lay out the garden entirely anew. The whole of its area has since that date been treated for landscape effects, sheets of ornamental water having been formed, and, with the earth so obtained, undulations having been thrown up. New roads and footpaths have also been made; a building for the Herbarium and three handsome conservatories for the more delicate kinds of living plants have been erected; nursery buildings have been put up; and the garden staff have been furnished with comfortable houses.

4. Botanically the most important feature in the garden is its Herbarium, or collection of dried plants. As has already been explained, all the collections prior to Dr. Wallich's visit to England in 1828 were distributed by him to scientific institutions abroad. The commencement of the present collection dates, therefore, from his return to India in 1832. It consists of plants contributed by almost every worker at Botany in India since that date, and of considerable contributions from Botanists in Europe. It is first and foremost an Indian Herbarium, but the plants of South-Eastern Asia, of Japan, of Persia and of Asia Minor are fairly well represented. Those of Europe also excellently represented; but in African and American plants the collection is comparatively poor. Constant communication and interchange of specimens have been kept up for the last fifty years with the great national collection at Kew; and to the distinguished Directors of that institution, Sir William Hooker and his son and successor Sir Joseph, the Calcutta Herbarium is indebted for invaluable contributions. Interchanges have also been kept up with other European Botanic Institutions, such as the Herbarium of the British Museum, of the *Jardin des Plantes*, Paris, the Imperial Gardens at St. Petersburg and Berlin, the Royal Botanic Gardens at Buitenzorg in Java, at Peradeniya in Ceylon, and at Saharanpore; and with many other institutions. Amongst the private contributors in past times from whom the Herbarium has received the most valuable collections must be mentioned Vicary, Edgeworth, Griffith, Wight, Simons, Low, Gibson, Stocks, Dalzell, Kurz, Miquel, and Maingay. The most important contributions received during recent years have been duly mentioned in my annual reports.

5. The year which ended on 31st March last presented little of novelty. No new works were undertaken in the garden, and the time of the staff was occupied in the ordinary routine of cultivation. The show of orchids was unusually fine, and the general condition of the plants, both in the conservatories and out of doors, was satisfactory.

6. The collection of dried plants received several valuable additions during the year. Chief amongst these was a set of the plants collected by Dr. Aitchison during the Afghan Boundary Commission. Dr. Aitchison's collections were taken by himself direct to Kew, whence, after having been named and numbered, a set was issued to Calcutta. From Kew were also received a named set of plants collected by Dr. Giles

during the Gilgit Expedition; and a quantity of plants collected some years ago by Dr. G. Watt while he was on duty with the Commission appointed to settle the boundary between Munipur and Burmah. From Kew were also received a quantity of interesting specimens made by various collectors in the Malayan Peninsula, in Singapore and in Penang. For all these contributions from Kew we are indebted to the good offices of Mr. Thiselton Dyer, its present distinguished Director. Dr. Regel, of the Imperial Garden, St. Petersburg, presented a large number of most interesting plants from the Russian possessions in Central Asia. Three excellent named collections from Natal were presented by Mr. Medley Wood of the Botanic Garden, Durban. From Mexico, Mr. Pringle sent four hundred named species; and from New Guinea Mr. H. O. Forbes forwarded a large box filled with dried plants. Of contributions received from within the limits of India, I have to acknowledge—from Sikkim a quantity of plants from Mr. G. Gammie, as also a collection made by a Bhotea employed by Mr. Pantling in the Lachen valley; from the Khasia Hills many fine things chiefly trees, from Mr. Gastav Mann; from the Naga Hills a fine collection made during his short residence there by Dr. D. Prain, now Curator of the Herbarium; from the North-Western Himalaya some interesting plants sent Mr. J. F. Duthie, of Seharampore, and by Colonel H. Collett, C.B.; from Manbhoom a collection made by Reverend J. Campbell; and from Southern India a few most interesting plants from Mr. J. S. Gamble, Conservator of Forests.

7. During the month of November last the Herbarium was visited, for the purpose of study, by the Reverend Father Scortechini, the Government Botanist of Perak, who had been deputed by Sir H. Low, the British Administrator of that State, to proceed to Calcutta in order to name and arrange his collection of Perak plants. It was Father Scortechini's intention to have remained here for three or four months; but unfortunately he died shortly after his arrival. During the year there was issued from the press the first part of a monograph of Indo-Malayan species of *Ficus*, in which I have been engaged for some time.

8. I have to acknowledge, with thanks, the assistance freely afforded whenever asked, by the Indian Assistant in the Kew Herbarium, Mr. W. Botting Hemsley. Mr. Hemsley, with the permission of the Director, Mr. Thiselton Dyer, is always ready to settle any knotty point in nomenclature, or to check any doubtful identification—a kind of work that can only be done with accuracy in a perfectly equipped Herbarium like that of Kew.

9. The interchange and distribution of plants and seeds has gone on actively during the year. Of plants, 8,064 were received against 46,104 given out. Of seeds, 903 packets were received and 2,534 distributed. The names of all donors and recipients will be found in the appendices to this report.

10. The Lloyd Botanic Garden at Darjeeling has during the year been under the charge of Mr. W. Kennedy. And the Municipality having agreed to continue the vegetable garden which lies wedged in between the Botanic Garden and the grounds of the Sanitarium, that garden also has been under Mr. Kennedy's care. At one time the Municipality threatened to convert the vegetable garden into bazar; at another they resolved to turn it into a washing-place for the dhobies of the station. Its maintenance as a sightly spot is a matter which concerns not only the Municipality, but the visitors who frequent Darjeeling and the patients in the Sanitarium. It is well, therefore, that both these proposals have for a time at least, been shelved. I regret to have to report that the acclimatised English potatoes turned out badly, the produce having been tasteless and waxy. This was also the experience of private growers.

11. The budget allotments of both the Calcutta and Darjeeling gardens were spent in full. At Calcutta R1,373 were realised by the sale of surplus plants, and at Darjeeling, from the sale of garden produce of sorts, R1,180 were collected as against R741 last year.

12. In May last Mr. L. J. K. Brace, Curator of the Herbarium, retired from the service of Government, and Surgeon D. Prain, of the Indian Medical Service, was appointed in his stead. Owing, however, to the exigencies of military service, Dr. Prain was not able to join his appointment until 24th January last; and during the interval the Herbarium work devolved upon myself. Dr. Prain had on a previous occasion officiated for Mr. Brace, and had shown himself to be a highly competent man. Mr. W. Mc Hardy, from the Royal Garden, Kew, having been appointed to the post of Assistant Curator, vacated by promotion of Mr. H. Bahr, joined on 15th June 1886. He has worked well. Messrs. Bahr and Kennedy have also conducted their respective duties in a satisfactory manner.

[The Government resolution we do not reprint, as it is merely an abridgement of Dr. King's most interesting centenary Report.—ED.]

TEA PLANTING IN NATAL.

(From the *Natal Mercury*.)

Natal has been called in scorn, with just enough truth perhaps to sustain the epigram, "a country of samples." We produce a little sugar, a little tea, a little coffee, a little of everything in fact, but nothing in large quantities; so say our detractors. Not till recently at any rate could Natalians meet thi somewhat serious charge with a direct negative; for did not some ugly facts stare us in the face? Was it not true that on one celebrated occasion a man-of-war which put in with orders to ship Natal coal, had to be sent empty away as far as the colonial product was concerned? Natal's best defence was that her industries are in their infancy; that every beginning is difficult, as the German innkeeper said: Natal's beginning doubly so, on account of the wars on her frontier, which, while enriching her in one way have greatly impeded her in another, by taking away her young men, and generally disturbing the repose so necessary for the internal progress of every country. At length, however, a brighter day seems to have dawned. With some reason we may claim to have changed all that, for lately Natal's coal has been sold in Durban at two shillings and sixpence a hundredweight. Natal coal is being used throughout the railway, and travellers from upcountry state that a really large transport business is going on between Dundee, Newcastle, and Ladysmith; and all this points to a hope that in the near future talking of carrying coals to Natal may sound as ridiculous as carrying coals to Newcastle in England. Take next the cultivation of tea, which, according to the great authority of Mr. Hulett, has been proved to be an industry capable of a large development in this colony; so far, tea has been produced of most excellent quality; but not in such quantities as to have much effect in keeping down the importation of the same. This year, according to Mr. Hulett, the yield may be estimated at 150,000 lb., something over 4 lb. a head of our white population. This is not a very large amount, inclining as we do to take a somewhat more hopeful prospect than Mr. Hulett of the expectations of the Natal Tea Company's gardens at Isipingo, whose Managing Director is known to be a gentleman of capacity and experience, acquired in another great tea-producing country. We cannot but hope that this estimate will turn out to be rather under than over the actual yield of Natal tea for the current year. At any rate, 150,000 lb. cannot be called a sample, especially when we remember that it has grown from a yield of 2,000 lb. in 1881. While on the subject of tea, it will be interesting to examine the returns of another country with far greater facilities certainly than Natal possesses in the matter of labour as well as other things, but not more than five years her elder as a tea-producing country. We refer to Ceylon. In 1877 the amount of tea exported from that country was also some two thousand pounds; in ten years the amount has grown to nine million pounds, while there are some hundred thousand acres under cultivation. By a calculation based upon those figures the yield per acre would appear to be far greater in Natal than Ceylon; but allowance must be made for

the amount grown for home consumption in the latter country, which it is not easy to estimate with any certainty, in the absence of information; yet it is unlikely that it would amount to a very large proportion. In quality we certainly need not fear comparison, and assuming Mr. Hulett to be correct in stating that "at least for a distance of twelve miles from the sea coast tea will give a maximum yield," there would seem to be nothing to prevent our Natal tea industry from equalling, or even surpassing in its dimensions that of Ceylon as at present established. The coffee and sugar industries of Natal cannot be said to be in a flourishing condition. The farmer will probably be able to produce enough for our own wants; and we have no doubt that Sir Donald Currie was correct in saying that it was better than that he had tasted in the Red Sea, though whether this remark involved any great compliment to Natal coffee is doubtful, for we imagine that most of the coffee drunk in the Red Sea has been bought in London and served better or worse, as the case may be, on board the various steamers traversing that dangerous and disagreeable portion of Neptune's domains. But a blight seems to have fallen upon the industry here, as in other countries. Sugar growing also is in a bad way all over the world, and in Natal no better than elsewhere. The produce of sugar is assuredly more than a sample. Coming to gold, the reproach is justified in a manner, however entirely unmeant by the jester, and it thus affords another instance of the manner in which jesters do oft prove prophets. We have as yet produced only sufficient gold to give great hopes for the future finds of that precious metal in more abundance; and if the Capetown people could find as much gold in the "Lion's Head" as has been already unearthed at Umzinto, they would assuredly be not ashamed of their sample. With regard to wool, tobacco, &c., the first-named we have recently discussed in these columns. Tobacco is not much more than a name. On the whole, we think we may fairly state in conclusion that Natal no longer deserves the reproach of being a country of samples.

THE TEA INDUSTRY:

INTERESTING LETTER FROM MR. HULETT.

SCHEME FOR SMALL SETTLERS.

A GOOD OFFER: EUROPEAN OR COOLIE?

We have received the following interesting and instructive letter from Mr. J. Leige Hulett, M.L.C., of Kearsney:—

Permit a few remarks upon your sub-leader in last Friday's issue regarding tea culture, &c. You say it "has been proved to be an industry capable of large development in this colony; so far tea has been produced of most excellent quality; but not in such quantities as to have much effect in keeping down the importation of the same." It is self-evident that every pound of tea of home growth consumed must displace a like amount of the imported article. Upon the surface of things, in view of Customs returns, it would appear that we are making no impression upon the importation whatever; but the fact is the other way. The importation during the past two years has been abnormally large in consequence of increased demand for the Gold Fields, &c. Had there been no special demand, the present season's output would have materially affected the importation, and as far as the colony itself is concerned, I reckon that now out of every three pounds used at least two pounds are of colonial growth. The normal importation of tea was between 250,000 lb. and 300,000 lb., of which perhaps 100,000 lb. went across the borders; that would leave about 150,000 lb. to 200,000 lb. for Natal. The actual amount of Natal tea used during the past year 1887 would be from 80,000 lb. to 85,000 lb., so a considerable reduction in amount of imported tea consumed must have taken place. The quantity of Natal tea which may be estimated for the year 1888 will amount to probably 17,000, this is judged by the year, and not the season; the latter may be considered as from October to following June. The year 1889 will probably give a return of 250,000 lb., or an amount equal to what was generally used before the Gold Field trade set in. Unquestionably the need for care on the part of merchants will be necessary in regard to future importations of tea. The flooding of the colony and interior states with low qualities of China growth will not advantage the merchant or grower. The grower will be obliged to sell, and the merchant also. If the importations are regulated with care, so as to gradually give way before the home-grown article, no loss to either interest need accrue. It is worth noting that on 1st January, 1887, only about 9,000 lb. weight of tea was in bond, and on January 1st, 1888, the large amount of about 165,000 lb.

Natal has a future before it in the tea enterprise that the public generally little dream of, especially if we are able to secure the whole of South Africa's trade by free entry of all colonial produce into the neighbouring colony and states. Both sugar and tea, together with various other products, will be stimulated and largely increased in supply. The advantage to the mercantile community must be very great. The saving effected by keeping large sums of money at home instead of in advance sending the same to a distant foreign country will be considerable, and the becoming exporters in the place of importers will bring a corresponding advantage.

To return to your article. You compare Natal with Ceylon. I fear Natal will not be able to take its position side by side with Ceylon not for want of capability, but for want of push on the part of its people. Our back country drains away so many of our young men, the Zulu war demoralised them, and the excitement of gold keeps them unsettled. The Ceylon planters had to face ruin in connection with coffee failure, and were forced into tea growing, and all at once, so that the country became a tea-producing one almost by magic. They had the land ready to hand, under the best system of culture to be found anywhere, the buildings and bungalows all to hand, no preparatory work; out with one crop and in with another; their knowledge of planting and the characteristics of climate they were accustomed to. The consequence was that with a bound they sprang forward and took the first place as a tea-growing community, and they will hold and keep it too. The class of cultivation pursued in Ceylon is scientific, and the result is that their yield per acre surpasses that of North India and Assam to an enormous extent.* As far as cultivation and yield is concerned we in Natal may hold our own. The result of the past two dry springs proves that we have nothing to fear; but it will depend upon care in the cultivation of the soil. I am certain that with proper management and ordinary seasons, after the plant has arrived at five years' growth, not less than 1,000 lbs. per acre of made tea should be obtained. Indeed I fully expect to pick and make over 1,000 lb. per acre on a block of 32 acres of land this season; if the season continues good this block will give me 1,200 lb. per acre. Requisites necessary—average land, good culture (and all that is contained in that term), and liberal scientific pruning, and above all things, not too close planting.

Natal possesses a climate suitable for Europeans, and advantages can be taken of circumstances peculiarly suitable to the colony. I refer to the Central Factory system. One plant of machinery, &c., for 20 to 40 small growers. The maximum yield per acre can be thus obtained by individual attention to small areas of cultivation, and the manufacture of large quantities of leaf together insures a better average turnout of tea. No difficulty as to proportion as in sugar, a fixed price for the green leaf per lb. The Chinese grower sells his leaf to a manufacturer. With the introduction of small settlers, no reason exists why Natal should not in a few years' time produce its 40,000,000 lb. of tea, as Ceylon expects

* Not to "an enormous extent" as an average, tea being grown here on so many old coffee estates. Perhaps 400 lb. per acre in Ceylon against 200 lb. in India (average of all districts) may be near the mark. If Mr. Hulett's rate is sustained as an average, it is to the yield in Natal that the word "enormous" will apply. ED.

to do in two years' time. This enterprise thus conducted, means the support of thousands of white people.

Feeling assured of the desirability of this central factory system, I am prepared to throw open 4,000 acres of land to settlers of small means on some such terms as the following.—To each settler a block of 50 acres of suitable land for a term of 10 or 15 years. No rent for three years; afterwards a rental of 1s. per acre per annum; at the close of the period, purchase can be effected at £1 per acre, half of the amounts previously paid in rents to be allowed on account of the purchase. Should the lessee desire not to purchase, two-thirds of the value of improvements below a fixed amount to be paid to the lessee. A reserve block of 50 acres adjoining each occupancy to be laid off for purchase or lease by the occupant ata fixed rate. On the estate only 20 settlers to be located in various parts, the remaining 2,000 acres to be held by myself as owner for purposes of the estate generally—grazing rights allowed within certain restrictions to the tenants. I would erect suitable buildings and machinery for making the tea, and agree to purchase green leaf at a price fixed according to the market price of the article. I will find tea seed for planting *gratis*.

The occupiers would be required to plant five acres of tea the first season, and each following season the same quantity for five years, unless special circumstances prevented. Each occupier would be required to plant one acre a year with forest trees. All other cutivation at option of the occupier, which would doubtless consist of food supplies. No occupier would be allowed to keep a regular store or canteen. Each occupier would have to prove his capability to carry out the conditions. The amount of money necessary would greatly depend upon the individual. From £150 to £400 would be about the minimum that an industrious man could do with. The estate in question is situated about nine miles from this place, on the Tugela. I have one of my sons upon it opening out 40 acres of tea. All occupiers would receive the practical advice of one capable of giving the same. If white settlers can be obtained so much the better; but if not I intend getting Indians who will pay rent at once.

I consider the principle embodied in the above scheme worth the attention of landowners in various parts of the colony.

NATAL AND CEYLON COFFEE.

Mr. J. L. Hulett, M. L. C., of Kearsney Tea Estate, Nonoti, writes us:—

The following appears in the article headed "Tea in Ceylon and Natal," in Monday's *Mercury*. Speaking of coffee, the writer says:—"Many of these estates have for years given from £10,000 to £30,000 profit annually; but the owners were too greedy, and killed the goose that laid the golden eggs. Successive heavy crops weakened the trees, which were again revived by heavy pruning, only at last to succumb to a virulent disease, which has found its way even to Natal—another case of the sins of the fathers being visited upon the innocent children."

With regard to the first portion of the above quotation, I have nothing to do; but when a slur appears to be passed upon a community of planters, who have been proverbially known as the most energetic and painstaking to be found anywhere, and the serious blow given to their industry by causes beyond their control, laid at their door as being too greedy, it requires a protest. The question of coffee disease is one that in past years has exercised the minds of many of us, and the reason of the same, and attempts at cure, have been examined most minutely. The planters of Ceylon and Natal have done everything possible to find a remedy for this coffee failure, for the coffee is subject not only to one disease but many. The present leaf disease is new to Natal, but the *borer* and bark diseases is what ruined Natal coffee, and Ceylon also to a great extent. Everything possible has been tried, both here and in Ceylon. High cultivation, low cultivation, manuring and no manuring, light soil and heavy soil, pruning and no pruning, topping high, medium and low, not topping at all. Soils have been scientifically analysed, both here and in England, and under all and every circumstance the result has been the same.

Not Ceylon and Natal only, but Java, Jamaica, and now Brazil is threatened with destruction. I have my own theory, which is that the tender character of the coffee tree will not bear cultivation, and will yield in a semi-wild state a precarious crop of berry; but in that condition will not pay as an enterprise. I have a strong feeling against any attempt being made to foster a careless style of cultivation in anything. A practical experience of 30 years in Natal leads me to the conclusion that in the present day of keen competition the only way agriculture will be made to pay is by intelligent attention to the cultivation of the soil, and taking care to keep it in good order, and crops perfectly free from weeds. My experience has a range over all coast products, and it is a case of the "survival of the fittest" throughout. Ceylon planters are so far, to my mind, the fittest for us to follow, and we may do our best to excel. Every country has its peculiarities, and those of Natal are not a few. I do not consider that Ceylon planters killed their goose, though it was laying golden eggs, and neither did Natal kill its goose. The coffee goose died though every means was tried to keep it alive. Yet I would rather have a goose to lay a few golden eggs, than a goose that lays no eggs at all.

[Mr. Hulett has, with candour, good sense and correct information, vindicated the Ceylon planters from a most unfounded charge often recklessly preferred. Coffee fell before a fungus against which science, skill and liberal manuring alike were powerless.—ED.]

ADIANTUM FERGUSONI.—We (*Gardener's Chronicle April* 21st) have received the following communication from the Director of the Royal Gardens, Kew, with reference to this plant:—"The interest which this fine Fern has excited, induces me to think that it may be worth while to place on permanent record in the *Gardeners' Chronicle* the account which was given me in a letter by the late Mr. W. Ferguson of its first discovery. *W. T. Thiselton Dyer.*

"Extract from a letter from W. Ferguson, dated Colombo, April 28th, 1885:—'On my return from Puttalam, about 85 miles north of Colombo, in November, 1881, I stopped a night at Negombo, about 21 miles north of this, and by a curious coincidence the next house to the resthouse in which I put up, was that of your acquaintance, T. G. De Livera, Esq., District Judge of that place. On walking over to call upon him, I found this Fern, for the first time, in a small pot between plants of Adiantum tenerum and A. Farleyense, and said to Mrs. De Livera that I thought it was A. Farleyense, which had taken a great bound and gone back to be a fruitful Fern. I went on purpose to Negombo a short time ago to trace out the history of this Fern; but I am sorry to say it is involved in obscurity. Mrs. De Livera got the plant from a family of De Silvas close by, a member of whose family is said to have got it at a sale of plants at Colombo, and this is all its history in the meantime. Here, in Kelvin Grove, it is a tall, stiff Fern, about 2 feet in height and 4 feet in expansion, growing in coir fibre and in a tub. It has seeded freely here in the walls of wells, and in crevices in walls round my house; in fact it has no barren fronds at all, and the tiny seedlings show no difference from the parent plant when they are quite young. It is surely too robust a plant to be squeezed into any form of A. Capillus-veneris, and the nearest to it that I can suggest is A. concinnum, of which several forms are in cultivation here. But after I get a photo taken of this giant Fern, I shall take up good specimens, with roots and all on, for Mr. Moore, and Kew. I feel very grateful to Mr. Moore for the honour he has done me in naming this rare Fern after me, and for Mr. Baker for all the trouble he took respecting it.'"

CINCHONA BARK PROSPECTS.

We think it may be inferred from the following reports of the English, American and German bark and quinine markets given in the *Chemist and Druggist* received by last mail, that the large stocks of quinine held by speculators—money-lenders chiefly—and the gradual working off, of such reserves, has had a good deal to do with the depression in the bark markets. Manufacturers could not possibly go in for increasing their stocks of an article which they knew to be already held by middlemen extensively, and accordingly they have been buying the raw material after a languid fashion. It is not a very pleasant fact to contemplate that—apart from the steady though gradual increase in consumption, especially in the United States, and what has to be done in promoting new demands,—the factor that would more than any other, favourably affect quinine, is the breaking out of the great War in Eastern Europe which Russia has been, and is still, threatening. Armies in the field during summer in South-eastern Europe would require an enormous quantity of quinine. Meantime, we quote as follows :—

London, April 12th. CINCHONA.—At Tuesday's sales there was a dull tone, and prices marked a decline averaging 5 to 10 per cent. The unit is calculated at 2¼d to 2½d, and nearer the lower than the higher figure. Heavier shipments from Ceylon account for this decline. The packages catalogued included 1,158 packages of South American, of which only about 120 sold. Calisaya quill (Bolivian cultivated) sold at 7d to 7½d for broken (one package at 5½d), to 8½d to 10½d for fair to good. Of Ceylon and East India there were 2,243 packages, of which nearly two-thirds sold. The average quality was, however, very low. Succirubra realised 1½d to 3d for siftings, 1d to 1½d for branch, 1½d to 4½d for chips, some of which were largely mixed with branch; spoke shavings, 2½d to 5d; root, 2½d to 4½d, and a small supply of special quality, 8½d; renewed, 2d to 3d; ordinary to fair, 4½d to 6d; good to fine, 7d to 10d. Crown brought 2d to 3d for branchy and small, and 5d for fair; stem chips, 3½d to 5½d for shavings, 6½d for root, from 3d up to 1s 1d for renewed. Ledgeriana was sold at 10d to 1s for stem chips, and 3d to 5d for branch. Of 31 cases of Java sold, long bold red realised 8½d to 9½d, dull short quill varying from 4½d to 9d.

QUININE has had a rather eventful week. Before the sales German makers had offered their product at 1s 7d, and second-hand holders did business at 1s 6d. After the sales large transactions took place direct at 1s 6d, and second-hand holders quoted a halfpenny less. Over 30,000 oz. of BS. and Brunswick brands were bought at 1s 6d, after which, however, makers declined to go on. On Thursday there was a much stronger feeling, and after 25,000 oz. had been booked for forward delivery at 1s 7d, makers refused to quote. Messrs. Howards, who intimated on Wednesday an inclination to accept lower terms than they had been quoting, were firmer again on Thursday, but apparently not disinclined for business at their old rates, 2s 2d per oz. in vials. It is generally thought that the article has touched bottom—indeed, a much better feeling prevails, and if it were not for the fear that a few lots held by money-lenders on account of speculators recently gone to grief are likely to be put upon the market, a larger advance would probably forthwith take place. There seems to be an intent on the part of the manufacturers jointly to do their utmost to keep prices down. They have doubtless profited well this year, as they have managed to buy back the bulk of their sales at reduced prices, without importing new stuff to any appreciable extent.

TAMARINDS are in strong demand, with advancing rates. A parcel of new season Barbadoes, consisting of 205 packages, sold under the hammer this week at 21s 6d to 26s per cwt. for slightly dark to fair bright, and some old Montserrat at 15s to 17s 6d.

IPECACUANHA.—The arrival this week of 87 packages by the "Horrox" from Monte Video is a welcome reinforcement of our much shrunken stock.

THE AMERICAN MARKETS: NEW YORK, March 26th.—Quinine.—While the American manufacturers have steadily maintained their price for some time back at 49c. (2s 0½d) for bulk, foreign has been selling at 43c. (1s 9½d), to 45c. (1s 10½d) according to brand, even in the face of quotations from abroad of 2s. Some large holders increased their price immediately upon receipt of the advices of advances abroad and the advance in prices of bark at the London sales, but they were not sustained by others, who being anxious to realise, still continue to offer at previous prices, at which moderate quantities can at present be obtained, showing a weakness in the market here, which is attributed to large stocks in speculators' hands, and a belief in the minds of many that there is a good profit in manufacturing the article at present selling prices.

THE GERMAN MARKET:—Hamburg, April 10th.—Barks.—Cinchona (Porto Cabello): Fine qualities are rare and command high figures. Very extreme prices, 140m. (6½d) asked by owners. In spite of the high prices there has been a regular demand for this bark. Maracaibo was sold at 30m. (1½d), a very low price. Lima, in large supply, met with no demand. The new cultivated Calisaya bark was realised at 3.60m. to 4m. (1s 7d). Condurango very steady at 3.25m. Quillaya bark is arriving in considerable quantities and depressing the market. Second-hand holders have reduced their price to 25m. to 26m.

SALT AS A MANURE.

It is a well known fact that common salt (chloride of sodium) is a valuable fertiliser when used in small quantities or diluted with about 300 times its own weight or water—though destructive to plant life if used with only, or less than, 30 times its own weight of water. I use salt for manure in special cases while the price is eleven measures (about 16 lb.) per rupee; if it was about 20 or 24 measures for rupee—I would use hundreds of pounds for every one that I now use. May it not be possible for Government to enlarge the present Customs Department, or to create a new one, specially with reference to the use of salt for agricultural purposes, whose duties would be to collect a light tax of say 8 as. or 12 as. per maund, and to see that the salt was mixed with other manure on the soil beyond the possibility of extraction for human consumption. It seems monstrous that agriculture in so poor a country should be handicapped by a tax on manure while the Government is apparently desirous of improving it—the present revenue from salt must be the reason. The present system prohibits the use of salt for agriculture—and this letter is to propose that Government should raise a reduced revenue on it, just sufficient to cover the cost of the extra establishment required, and perhaps even to yield a small revenue. The quantity of salt that would be used for agricultural purposes would be so large that a very small tax per maund would realise a large sum. The manufacture of the salt would find employment for much of the increasing population, and would enable the land to produce more for their support. This matter ought to be taken in hand by Government without delay as a means of obtaining revenue as well as a relief to agriculture, for any less tax than the present will be a corresponding boon to agriculture. The accompanying extract from the Tea Cyclopædia, well describes the situation.

"Salt (chloride of sodium) being a direct constituent of plants, is a valuable fertiliser. Salt stimulates the organs of plants to more active vegetation. It promotes the decomposition of the animal and the vegetable matters of the soil. It prevents evil effects from changes of temperature. It causes the soil to attract more moisture. It destroys vermin and weeds. It prevents mildew and helps to eradicate blight. All plants take up salt with the greatest avidity, and if the Government of this country could only be made to see through the spectacles of the German Government, and allow methylated salt, unfit for human consumption, though not unclean to the caste prejudices of the natives, to be sold for a nominal figure, such as it is

sold for out of the salt ships, to agriculturists and planters it would be conferring a far greater and more real boon than by the creation of agricultural and statistical and irrigational *et hoc genus* Directorships. The sour, ill-cultivated fields of India would, if each had a tongue, cry with such a lamentable howl for salt as would drive the Government and its empirical advisers into a fit—of sense." TEA PLANTER.
—*M. Mail*, April 21st.

[Is salt really so valuable as represented? If so, kainit, which consists largely of common salt combined with potash, ought to be a valuable application to tea.—ED.]

TEA CULTURE IN ASSAM.

Miss E. M. Clarke contributes to the *Asiatic Quarterly Review* an article on the Indian Tea Trade :—

In this, as in all other forms of husbandry, large profits are dependent on high culture, and an annual expenditure of R100 an acre will amply repay. Constant, that is to say monthly, hoeing is the most beneficial treatment for the plant, the demands on the vitality of which require to be met with a constant stimulus. Its productiveness depends on the frequency with which it "flushes," or sends out new leaf-shoots, and "the more hoeing, the quicker the flushes," is an axiom of tea culture. From February or March to the middle or end of November, the season in Assam of the activity of the plant the flushes succeed each other at irregular intervals, varying between seven and twenty days. A small crop and scant profits are represented by a total of 18 flushes; ample production and large gains, by 25. A tea-garden in full flush is a very pretty sight, as its thickly planted bushes then appear as if crowned with gold.

As the young shoot must be plucked while still callow and tender, an army of leaf-pickers is required to carry on the operation simultaneously. The leaves are daintily nipped off by the thumb and index finger, half the last one always being left so as to draw the sap upwards towards the new growth. In the first plucking of the season, only the bud and half the leaf next it are taken, the maximum of three and-a-half leaves in addition to the bud being progressively reached as the season advances.

The quality of the tea is determined by the position of the leaf it is made from. Thus, the closed bud and half-open leaf next it, forming the head of the flush, alone give true Pekoe ; the two succeeding leaves Souchong ; and those still lower down Bohea and Congou, the latter, however, being a quality rarely manufactured in Assam. The production of "Pekoe tips," which owe their silvery or orange grey bloom to the down on the callow bud, is also generally neglected, the separate treatment they require being too costly to be repaid even by the high price they command.

Each bush yields a yearly average of 2 oz. to 3 oz. of finished tea, representing four times that weight of green leaf. This figure is, of course, largely exceeded by individual plants, and one has been known to give 13¾ oz. The gross production throughout India of 256 lb. to the acre is surpassed by that of Assam, reckoned at 280 lb. The latter is the minimum of profitable production, taking expenses of cultivation at R40 to the acre, R100 being required for really high culture. A profit of £20 ought, according to estimates, to accrue on a crop of 400 lb. to the acre, but is found in practice to shrink to £10 or £15. Well-cultivated gardens produce 500lb. to 800lb. per acre. While the figure of 920 lb. has been reached in Upper Assam, and 1,000 lb. per acre is hoped for among possibilities of he future.

Plants grown for seed, blossom in the spring, the flower resembling that of the white dog-rose, and the seed is ripened in October or November. That of the indigenous plant sells for R200 to R300 the maund, or chest of 80 lb.; that of the hybrid for R50 to R80. The vitality of the seed is injured by travelling, and a large proportion fails if transported to any distance.

All the operations hitherto recorded are purely agricultural, but no sooner has the Assam tea-planter gathered his fermented to the saccharine stage, as it is drunk without the extraneous sweetening demanded by the European palate.

"Sunning," in which the fermented leaf is exposed to the drying influence of sunshine, is counted as a fourth process, and is preliminary to the fifth and last, that of "firing." The fuel used is generally, though not necessarily, charcoal, and the tea is crisped by being exposed to its heat on wickers drawers or shelves. It only remains to sift it, in order to separate the coarser and finer qualities, after which it is packed in 80 lb chests, and leaves the plantation in the same state in which it reaches the market.—*Pioneer*, April 26th.

GOLD IN THE SOUTHERN PROVINCE OF CEYLON :

THE DEWURANGALA GOLD-FIELD :

PRACTICAL INFORMATION.

(*By a Special Correspondent—an old Australian Gold-digger.*)

3rd May, 1888.

The situation of Dewurangala has already been described in the *Observer*. The part being worked for gems, and where gold is said to have been found, is a flat of a few acres only, possibly about five acres. It is bounded on the south by a long high ridge, thickly covered with jungle. On the north side there is a succession of little hills. The features of the place—not altogether discouraging—would drive the experienced miner to the conclusion, that if leads of gold are found about there, they must be very patchy. That there is gold there, would almost appear to be a settled question, and the prospects already secured, if real, are more than ample to warrant its being thoroughly prospected. On the 30th ultimo I accompanied Mr. Geo. Armitage to the spot. Mr. Armitage was kind enough to show me several pieces of gold, and outline sketches in his note-book of the nuggets previously noticed in the *Observer*, and pointed out the holes out of which they were said to have been taken. One small piece, about 1 gr. or 1½ gr., he had washed out himself. This looked an important indication that gold was scattered about and to be found at no great depth. A remarkable feature about it is that with the exception of this little bit, all the gold found should have been in such large pieces before reaching the bottom, and that there was no fine gold found at the same time. Light and scaly gold is often found near the surface and all the way down to the bottom, but *pieces* are generally on or near the bottom. If there were fine gold which one would have naturally expected with the nuggets, the question arises what became of it? No one has heard of it. If thrown about their gem pits with the debris, a shower of rain would have made the particles show up. Only very fine particles could go through their gem-washing baskets. I noticed that they were very closely woven. The gold itself too is peculiar, rough and rugged. It does not appear to be up to the fineness of virgin gold. I would take it to be under the standard value 22 carats.* This may be a deception, however, caused by circumstances.

* Mr. Armitage made it 17 carats?—ED.

I should smelt it, and see whether it would then show like virgin gold.

Mr. Armitage was hard at work with a gang of coolies trying to get to the bottom, which I was anxious to see, but he had too much water to contend with to be able to reach the bottom during my limited time.

The word "bottom" as used by gold-miners is generally one of three sorts: First, pipe (pure white) clay; second, blue, soft, shelvy slate; third, sandstone. The auriferous stratum or washing stuff of the miners is found on either of these: pipe clay, I believe, is the most common. The washing stratum may be 18 inches thick, or any number of inches down to a mere seam. The miners have no difficulty in knowing it when they get down to it, and they know in sinking their shafts that so long as they have gravel, they have not reached the bottom.

There may be bars of clay found in sinking in which there may be some fine gold. These the miners call false bottoms. They try whether these are payable to work, and if not, they are left for another process. Whether this Deurangalla will turn out a gold field or not, it is impossible to say yet. The little hills about that I should have liked to have seen hard and quartzy, are good tea land. The quartz turned out where they are gemming seemed the right sort, but I saw no specks of gold in it. The whole place for many hundred yards round in the flats, gullies, and rising ground, should be prospected by sinking shafts and determining the bottoms, a work which will occupy several weeks.—More anon.

THE CEYLON TEA PLANTATIONS COMPANY.

Sir Grœme Elphinstone, writing by last mail from London on April 13th, says:—

"This forenoon the Ceylon Tea Plantations Company held their meeting, and thinking you might like to have as early information as possible as to what has taken place, I got from Reid the accompanying report, and he kindly also sent me the enclosed telegram, so that I might let you have the latest by this mail. There was to be a reporter at the meeting to take down what was said, and by next week's mail I'll send you the account in detail. I feel sure you and your readers will be highly pleased with the results of the year's working as set forth in the accompanying report, and I must say I consider it of very great importance to our tea enterprise that such a satisfactory result should have publicity. I consider the whole of the working and management of the Ceylon Tea Company to be most satisfactory, and published results, such as the Ceylon tea plantations can show will, I feel sure, influence fresh capital to Ceylon. There is a very fine field in Ceylon for small Limited Liability Tea Companies similar to the one under notice, and I believe myself it is the proper way for capital to be invested in Ceylon."

CHEAP CINCHONA FEBRIFUGE FOR THE MILLION IN INDIA:

AN EXAMPLE TO THE CEYLON GOVERNMENT.

From M. A. Lawson, Esq., Government Botanist and Director of Cinchona Plantations, Nilgiris, to the Secretary to Government, Revenue Department, dated Ootacamund, 6th January 1888.

I would suggest that small packets or bottles of the febrifuge, varying perhaps in value from 1 anna to 1 rupee, should be sent to every Postmaster or other local official, who should be authorized to sell the drugs retaining a small commission for his trouble, as for instance is done in the case of the sale of postage stamps. It might be well to consider if the febrifuge could not be brought to the notice of the people in out-of-the-way parts, by distributing it also through the tahsildars and deputy tahsildars of the taluks, and through the headmen of villages.

From G. Bidie, Esq., M.B., C.I.E., Surgeon-General with the Government of Madras, to the Secretary to Government, Revenue Department, dated Fort St. George, 6th March 1888, with reference to the measures to be adopted to render the local special preparation of cinchona bark more popular, and to bring them within easy reach of all classes of the people.

I am still of opinion that for some time they should be liberally distributed gratis to the poor in all feverish districts, such as Ganjam, where the people continue to suffer from malarial fever of a severe and fatal type. This gratuitous distribution should be carried out through District Surgeons both at head-quarters and in the minor dispensaries; and tahsildars and other subordinate revenue officials, living in feverish districts, should also have supplies to give away to the poor free of charge, and at cost prices to those able to pay for the drugs. As already pointed out in paragraph 6 of my letter mentioned in paragraph 1, the efficacy and cheapness of the preparations should also be brought specially to the notice of Local Boards and Municipalities, with the view of their substituting them in their hospitals for a certain proportion of the imported alkaloids. This measure would also help to familiarise the people with the appearance and value of the articles, and this will be another advance towards their more extended use.

The next step will be to get the febrifuges pushed into the hands of bazaar shopkeepers for retail, and this would best be done through the Revenue Department, discount being allowed on all sales of five or more pounds of the fluid and half pound or any larger quantity of the solid. The prices proposed to be charged by the Director of Cinchona Plantations for his preparations, viz., R12 per pound for the solid and R1 per pound for the fluid, are moderate; but to these will have to be added the cost of bottles, packing, carriage, &c., which will be considerable. For the present, I think the Government might forego the latter and charge only the net prices as given by Mr. Lawson. For convenience of distribution both preparations will, to some extent, have to be made up in small packages, say the solid article in phials holding 30 grains each and the fluid in bottles each containing half an ounce. For gratuitous issue some 400 or 500 pounds of the solid and 2,000 or 3,000 pounds of the fluid might at once be issued. On the 15th December last, I gave orders for the issue of 25 lb. for experimental trial in each of the following districts, viz., Calicut, Vizagapatam, Berhampore, Trichinopoly, Coimbatore, Tinnevelly, Ootacamund, and General Hospital, Madras. The district medical officers were requested to distribute the supplies amongst the minor dispensaries, and a blank form was issued which will secure the uniform record and tabulation of results.

The arrangements here proposed for popularising the Nilgiri febrifuges are very similar to those that were adopted in the case of chlorodyne on its first introduction, and if energetically pushed, they will, I feel sure, be equally successful. I trust, therefore, they will now commend themselves to His Excellency in Council and that it will be in my power to take further early action.

Order—dated 10th April 1888. The Government agree with the Surgeon-General in considering that gratuitous distribution of the febrifuge to the poor in feverish districts is desirable. They accordingly direct that supplies of the febrifuge be sent to tahsildars in feverish localities for issue by themselves and through village heads, free of cost. Each bottle should bear a label containing directions in the vernacular as well as in English. 2. The proposal to give a small commission—say 10 per cent.—on purchases by local bazaarmen is also accepted, the drug being supplied to them by tahsildars. 3. The Local and Municipal Department will be requested to bring the febrifuge to the notice of all Presidents of District Boards and Chairman of Municipal

Councils. The supply to them, however, will be on payment of the cost of manufacture, but the charges that will be incurred by the Medical Stores for bottles, packing, carriage, &c., should be foregone until the usefulness of the drug has become generally recognised. The price will then be raised to the full cost of supply.

GIANT TEA TREES IN CEYLON.

Of course the term "giant" is used only relatively, the bushes grown for leaf-yielding purposes ranging under four feet. In contrast we give the measurements of some grown on Abbotsford estate, Dimbula, for seed-yielding purposes,—purposes which, owing to the high jât of the tea, as well as the high altitude at which it is grown, have not in some cases been yet fulfilled by trees which are twelve to fourteen years old. The elevation in which the trees are grown ranges from 4,700 to about 5,200 feet,—that is the trees which have been measured, for there are trees reserved for seed purposes up to 6,000 feet. At an elevation of 2,000 feet or thereabouts such trees (high class Assam hybrids) would be in full seed-bearing in their fifth year. Few with us yielded much seed before the eighth year.

MEASUREMENTS OF 20 SEED-BEARING TEA TREES ON LOWER ABBOTSFORD ESTATE.

No.	Height. ft.	Height. in.	Circumference of Stem. in.	No.	Height. ft.	Height. in.	Circumference of Stem. in.
1	30	0	48*	11	24	6	32
2	28	6	40½	12	31	3	31
3	26	0	39	13	27	0	30
4	24	9	37½	14	32	0	21
5	22	0	35	15	32	0	13
6	28	6	34	16	31	3	25
7	24	6	34	17	30	6	23
8	21	6	33	18	30	6	28
9	29	6	32	19	30	0	29
10	27	9	32	20	30	0	24

* Circumference of tree 84 feet; greatest diameter 30 feet.

Mr. John Fraser, who took the measurements, writes:—

"As these measurements of the tea trees have been taken rather hurriedly, I may have omitted several of the larger trees on the estate, as there are a larger number of them from 20 to 30 feet in height with a girth of stem of from 20 to 30 in.; but I do not think there are any which will be found to exceed in size the first 3 or 4 on the list.

"The first 13 are given on account of their large circumference of stem, and the last 7 on account of their height. No. 15 is one of the original plants left in the nursery, where they are all extremely tall, but very spindly trees owing to their having been grown so close together. The trees are all single-stemmed ones, but No. 1 appears to have originally had several stems, which have, however, combined and now form a single stem which would make a great many forest trees hereabouts feel rather small. Looking at this tree one feels inclined to ask why not grow the fuel required for tea-making on the tree itself?"

No. 1 on the list is our "giant," *par excellence*, in succession to the original big tree which was wrecked in a storm, but which is again growing freely. The present giant has, it will be seen, a stem 4 feet in circumference. It is only 30 feet high, but then look at the enormous area covered by its mass of branches, 84 feet round with a diameter at one place of 30 feet. No other tree quite equals this in umbrageousness, though it yields in absolute height to one of a number of trees, left to grow close together (far too close) in a nursery of December 1874. The greatest height of any tree, it will be observed, is 32 feet. In the jungles of Assam ancient trees were found 45 feet high, and we believe 60 feet is the extreme height to which a tea tree has been known to attain. Are there any in Ceylon with better growth every way than those of which the measurements are given? If so what is their history? The room occupied by the giant and many other trees like it is very great, and ought to be calculated when estimates of yield of leaf per acre are made in regard to the leaf-yielding bushes amidst which the seed-bearers (about a couple of thousands) are scattered. As yet, however, the big tea trees are too valuable to be used as firewood. Tea bushes allowed to grow up would, it is evident, make excellent fences and even break-winds. Our big trees, when no longer required for seed-bearing purposes, will yield leaf well when cut down. Meantime, they are exceedingly ornamental, some of them closely resembling the finest nutmeg trees, in beauty of foliage and elegance of form.

THE COFFEE LEAF-DISEASE.

A PLAN FOR COMBATING IT.

[Translated from the *Soerabaia Courant* of the 19th March 1888, by J. D. Y. for the *Ceylon Observer*.]

The following plan proposed for combating the coffee-leaf disease has been received from Heer Chamberlain Mak, residing at the Hague:—

The report of Dr Burck, Joint-Director of the National Botanical Gardens at Buitenzorg, which appeared in the *Bataviasch Handelsblad* of the 13th Dec. last, kindly sent me by a friend, I have read with great interest. Desirous to co-operate heartily in contending against the disease, I wish to record certain facts in hopes of their furthering the discovery of its cause, and facilitating the search for a remedy.

I have been earnestly endeavouring for several years to trace out the cause of the potato disease known under the name of *Péronospora infestans*, allied to the fungic mildew known as *Peronospora viticola* and *Hemileia vastatrix* on the vine and on the coffee plant.

This disease has generally been attributed to important atmospheric changes occurring chiefly in the month of August, at a temperature of 20 deg. to 25 deg. centigrade during wet weather. True it is that the pest spreads widely under these circumstances, but it seems to me an error to assign them as its cause.

Repeated experiments made with various kinds of fertilizing matter, and compared with one another, have confirmed my opinion. Potato fields, manured with phosphate of ammonia and carbonate of ammonia, showed all the symptoms of the disease to such an extent, that in six weeks two-thirds of the potatoes were entirely decayed. On the other hand potato plants manured with phosphate of soda, carbonate of potash, and gypsum, displayed no vestige of the disease, and the crop of potatoes was abundant and perfectly sound.

I was now in possession of proof that the origin of the disease was to be sought for in the nutriment of the plant. Seeing that unsuitable manure had brought it on, this I look on as an important phenomenon, and consider my success complete.

The nutrition of plants stands in close relationship to their whole organization, and is a consequence of the limited space to which they are confined. A plant has within itself the faculty of producing oganic combinations, such as starch, albumen, &c., out of the inorganic matter which it absorbs such as carbonic acid and water. The substance indispensable for this physiological function, and which alone is endowed with the power to exercise it, is the parenchyma. The conversion called "assimilation" of the inorganic matter takes place only under the influence of sunlight. The work thus performed by the sun is stored up in the assimilated vegetable matter. This can now supply the strength necessary for the exercise of vital functions by the plant itself, or it can serve as food if consumed by man or the lower animals.

The chlorophyll which, in the form of granules, is elaborated in the parenchymatous tissue of the leaves and stalks, is always present in ordinary green plants, and is indispensable to their life, science having proved that this substance is charged with the important functions of absorbing carbonic acid, decomposing oxygen, and forming starch and sugar. At the latter part of the year when the leaves fall, it is converted into a colorless sap, and is returned towards the roots, to be stored up during winter.

Should the action of the chlorophyll be disturbed by any injury of the parenchyma, the process of assimilation stops, the plant sickens, the green color of the leaves pales, parasites appear, and the leaves fall off. I have recorded my success in the discovery of the cause of a disease which had raged with destructive effects for fully 40 years, and have labored to help nature in her unchangeable laws, principally by a supply of suitable nutrition, as the best means to obtain robust plants, from which alone a plenteous supply of good fruit can be hoped for, and it now remains for me to bring forward my suggestion for combating a disease of the same kind which is destroying the coffee plant.

The simplest, and, as I believe, the best experiment consists in sprinkling the coffee plantation with a solution of one kilogramme of carbonate of potash in a hundred litres of water, which will suffice for 100 square metres of ground, the sprinkling to be repeated after an interval of 14 days to insure the extirpation of all the spores. This experiment can be made at a trifling cost. Out of the fertilizers abovementioned, viz. phosphate of potash, phosphate of soda, carbonate of potash, and gypsum, which were used with such signal advantage already described, I have been induced to give preference to carbonate of potash by the consideration that the fully developed foliage of the potato plant, elm &c., has been found to contain a considerable quantity of potash, as much as 17 to 18 per cent, and in the experiments made the chlorophyll granules were elaborated in great quantities; and, as this substance is indispensable in the physiological functions of plants my choice was fixed.

[By a later report from Java we learn that all the carbonate of potash in the place had been used in this coffee experiment, but that it was too soon to judge of results.—ED.]

NATIVE TEA—TOBACCO—COTTON—IN UVA.

(From a Correspondent.)

Your instructions are certainly explicit enough. "Go back 30 years or so of your life, but retain in mind your past 25 years' experience of Uva." Very well, my dear sir, "morally wrong and physically impossible," and why should I do it if I could? Oh well, just to say whether in such case you would look elsewhere for better native tea gardens than you will find in Uva, say five years hence, and cotton for the Colombo mills, and fruit for the Colombo market, and pasturage for cattle on 1,000 hills, and—"Hold on please—your order is big enough in all conscience without any more 'ands.'"

It is difficult to say what the villagers of Uva may or may not do; but I think in all probability they will require full five years, perhaps double the time, to make up their minds whether it was a sufficiently profitable cultivation to be worth their while to go in for it. Then again it is a moot question, and one to be solved only by experience, whether or not the greater part of native Uva is too dry for profitable growth of tea. The rainfall mostly results from storms which, commencing in the Bintenna country, gather up around the Madulsima and Namunakula ranges and then work round by Haputale to New Galway, whilst some of them strike Naranglala and cross to Udapussellawa. A great deal of moisture is discharged on the hill tops and ranges, whilst the central plateau and valleys are very dry. All the ravines and nullahs near the villages in this central portion of Uva are already occupied by paddy-fields, and it is only when you get to the foot of the ranges that you find chena and jungle, and along the Walapane side from the Elephant Plains and through the Madulla villages. Outside the Haputale range a different condition obtains, but then comes the question of wind and drought. On the Wilson's Bungalow side the same difficulty arises, and down by Passara and Lunugala the soil is poor and the climate dry. I am told that the old coffee gardens should and would be utilized as tea gardens, but I cannot see it. The greater part of the coffee was grown under the shades of "kekuna," "kitul," and other native trees, and in turn gave shelter to the cattle of the villager. It was grown in a semi-jungly condition, and required no cultivation; almost all the attempts at gardens, topped and cultivated after the fashion of the estates, were failures, or lasted but a very short time. Of course I mean the small gardens amongst the villages; not such large estates as those opened by the estate kanganies near Narangalla and Spring Valley.

Tea could be grown under the same conditions, but would have to be pruned, and the plucking would be tedious and expensive. The best soil left in the central plateau of Uva lies in the saddles, and well up towards the tops of the hills, and not along the lower slopes. For untold ages the surface of the country has been periodically denuded by fire, and the heavy storms of rain falling on the hillsides cause a heavy wash which accumulates in its progress, and by the time it gets well down the slope cleans off everything in the shape of vegetable deposit, leaving in many places the subsoil and slab rock fully exposed to the sun and wind.

For native tea gardens we shall have to look to the wetter districts; those which are exposed to the wet monsoons, Dimbula, Kotmale, and Balangoda, all round by Ratnapura, and the western face of the Adam's Peak range.

Referring to Udakinda, there is a great want of trees. When living near Wilson's Bungalow many years ago, it appeared to me that the jak, kitul, kekuna, and other village trees were cut down or died from natural causes, and none were either planted by the villagers, or seemed to grow spontaneously as they do in wetter districts. As far as I know the same conditions obtain at the present day, and Uva becomes more bare and treeless every year.*

There is little doubt the Tamil and Moormen boutique-keepers will plant up tea gardens, and get their debtors to work them free for nothing as they used to do with coffee, and if they grow at all they will pay, as they cost nothing.

Tea, to do well in Uva, will have to be planted on the mountain ranges and not amongst the "untouched patanas," so you need n't estimate any great addition to the exports under native-grown tea from that part of the island.

How about Tobacco? Udakinda has, I believe, the credit of growing the finest tobacco in Ceylon, and far back in the Sixties we used to get commissions for Badulla cigars, and send considerable quantities to England.

I believe myself that the natives could be educated into growing tobacco very profitably in Uva in small patches highly cultivated; the style of culture would suit native ideas to a T, and if the headmen would only interest themselves in it, a large profit would accrue to the native population. Of all the propositions that have appeared for cultivation of paying products in Uva, I consider tobacco far away the most likely.

As for Cotton I have never seen the cultivation beyond the limits of a garden, but from what I read and hear, I don't think any large extent of land in Uva would be suitable. The flat tracts east of the

* This is a most serious statement and describes a state of things urgently demanding attention. We do not believe that cutting down trees [illegible] lessons rainfall; but we have a vivid sense of the value of trees producing shade, conserving moisture and gradually accelerating soil and climate. Tree planting on the patanas ought to be carried out vigorously and extensively.—ED.

Dambulla country as well as its equable climate point to the great cotton growing country in Ceylon. Uva has grown, and I suppose is growing, some fine specimens of Long Sea Island cotton; but the crops cannot be relied on, simply because the weather can't be relied on. One would think it was a cultivation to suit the villagers if they could only be induced to make a start, but knowing them as I do, I don't think the natives of Uva will take to it. The Sinhalese villager is body and soul in the hands of the Moorman bontique-keeper and the low country loafer, and they will never do anything for themselves or anybody else as long as they get enough to eat, and even that they extract with difficulty from their owners. The action of the Governmant of late years in wringing the taxes from these unlucky people has been the last straw to break their spirit as well as their backs, and it will require some very radical measures of reform and relief before they produce tea, tobacco, cotton, or anything else except murderers and cattle-stealers.

A NEW INDUSTRY: PAPAW MILK.

Have you heard that papaw milk, after undergoing a certain process of drying, is being shipped to England by some firm in the Fort? I have had some natives coming round my place this morning, offering to pay me 15 cts. per tree to allow them to extract the milk. Four men came over and they tell me they are employed by the day for this special work at 50 cts. per diem.—*Cor.* [Well done; for a digestive mixture doubtless, like pepsine.—ED.]

CINCHONA IN JAVA.

We owe an apology to Mr. Anton Kessler for throwing doubt on the statement he made in reference to the ability of the Government Cinchona Gardens in Java to place 2 million lb. of bark per annum on the market. We went by Mr. van Romunde's official reports, which have never estimated or hinted at more than one million for any one of his future annual exports. But, undoubtedly, the double quantity was given out at a public meeting as likely to be harvested in the way Mr. Kessler stated. Here is the translation of what Mr. Kessler sends us:—

Yikovai Estate, 12th April 1888.

Dear Messrs. Ferguson,—At last I am able to send you a copy of the articles of the assembly of superintendents of estates in Bandoeng, held on the 9th of July 1887. You may find in it what I told you about the 2,000,000 half kilogrammes of bark; the Dutch Government estates covering about 1,000 bahoes would be easily able to throw on the market every year.—I remain, dear sirs, yours faithfully, ANTON KESSLER.

Report of the proceedings at the meeting of the directors and managers of agricultural undertakings, held on the 9th July 1887 at Bandoeng.

Present—The Honorary member, J. Heijting, the President, vice-President, Secretary, and 20 others [all men of well-known names and good standing.—NOTE BY TRANSLATOR].

The report of the Secretary, and the remarks thereon made by the members of the meeting show clearly the position at the time of the Government cinchona plantations, mentioning the fall in prices, cost of cultivation, and all that could interest the cinchona planters in general, holding out no hope of any rise in price for many years to come.

The following is a translation of what is said regarding the extent and production of the Government cinchona plantations:—These cover an extent of about 1,000 bouws, of which extent a great part is not yet in full bearing.

The harvest of 1885 came to 432,000 ½-kilogrammes.

That of 1886 came to 525,000 ½-kilogrammes.

Whilst that of 1887 will be about 700,000 ½-kilogrammes.

It is shown by the above figures which give the produce of the original Ledgeriana plantations of Tjinjiroean, that we have hardly arrived at the first beginning of the regular full harvests, and that when the whole extent shall have reached maturity. The produce may, without any extraordinary effort, be brought up to 2 millions of ½-kilogrammes a year. The report is signed by the Secretary, A. H. Berkhout.

[Translated for *Ceylon Observer* by J. D. Y., Kotagala, 4th May 1888.]

LONDON NOTES ON PRODUCE.

The recent improvement in the coffee market appears to have had a very favourable influence on the market for Java securities. There has latterly been considerable animation on the Amsterdam Bourse, attention being specially given to the shares and bonds of Netherlands Indian plantation, financial and trading companies.

DIGESTIVE TEA.—It would be interesting to learn a little more about "digestive tea." Bread of that description we know, and pills with a similar title are to be met with, but "digestive tea" is a novelty. A company entitled the Universal Digestive Tea Company, Limited, has recently been registered, with a capital £20,000 in £10 shares. Its object is to carry into execution an agreement intended to be made between the company and Harrison Jackson for the exclusive sale by the company of tea prepared by the said Harrison Jackson in accordance with the letters patent obtained, or about to be obtained, by him for the preparation of tea; to purchase tea to be prepared by the said Harrison Jackson, and generally to carry on the business of wholesale and retail dealers in tea so prepared as aforesaid, or not prepared at all, or any business of a character similar or analogous thereto. The first subscribers are:—

	Shares.

T. K. Walton, Shallcross Hall, Whaley Bridge...	20
W. Pollard, Oak Cottage, Eccles ...	50
W. Jackson, Shrewsbury Street, Old Trafford, Manchester	20
C. Watts, Horner Terrace, Old Trafford ...	20
H. Jackson, Sitch House, Tascal, Whaley Bridge	20
A. S. Booth, 53, Brockley Road, London, S. E....	50

The first directors of the company shall be Alfred Scrivener Booth, Harrison Jackson, William Jackson, and Joseph John Sparkes, and Harrison Jackson shall be first managing director.—*H. & C. Mail*, April 13th.

EXPORTS OF JAVA AND MADURA.

According to a statement published in the *States Gazette*, the export trade of Java and Madura considerably increased during the preceding year. The following details are mentioned of some of the principal articles:—

	1886.	1 87.
	Liters.	Liters.
Arrack ...	2,267,399 ...	4,218,596
	Kilos.	Kilos.

At the annual meeting of the Deli Langkat Tobacco Company the directors presented their report, which was satisfactory. The condition of the undertakings and the prospect of the crops were very favourable. After approval of the balance sheet a proposal was adopted raising the capital to fl. 1,000,000.—*L. & C. Express*, April 20th.

[It will be seen that while sugar has largely increased, coffee, tea, and pepper have decreased considerably. - ED.]

GOLD IN THE SOUTHERN PROVINCE OF CEYLON.

THE DEWURANGALA GOLD FIELD.

PRACTICAL INFORMATION.

(*By a Special Correspondent—an Australian Gold-digger.*)

12th May 1888.

Referring to the Dewurangala gold field, the peculiar appearance of all the pieces of gold, with their ragged edges that I have seen, look more like pieces spurted from a smelting ladle than gold dug from the earth, and the quality more like jewellers than virgin gold. These considerations, together with the fact that no fine gold had been found in the pits out of which these pieces had been taken, force a doubt on one's mind as to the finds being genuine. On the other hand what cause could be assigned for the owners of the pits trying to play off any deception? Had they wished to sell their claims, and for that purpose tried to make out that they were rich in gems and gold, there would be reason to suppose that the gold had been melted-down jewellery, and made use of to try to catch buyers. There seems to have been nothing of that sort however, so there is reason to believe that the finds were genuine; also that there is considerably more gold to find thereabouts. Nature may and sometimes does play queer freaks, but it is most unlikely that she would have deposited eight or ten ounces of gold in that narrow spot, and not scattered some of her precious treasure as profusely in other parts of that neighbourhood. In addition to prospecting all the flats, gullies, and rising ground over a wide circle round the gem pits, I would be inclined now that there is abundance of water to sluice in longtoms a piece of that flat from top to bottom where the gold was found, taking a good slice of the latter. I suspect when the pits are worked over and abandoned, their claim to them lapses. According to the prospects (if genuine) out of these old holes it would pay handsomely. The longtom is simply a long trough, into which all that is to be washed is thrown and puddled till all the clay is dissolved. It is then run out with a good rush of water through wide flat-bottomed spouts. Across these spouts there are 2 inch bars or ripples placed at three to four feet apart for catching the gold. The heavy gold is caught by the first ripple, and if any fine gold should reach the last ripple, it is considered necessary to add another spout with more ripples. The miner reasons that if any gold has got so far as the last ripple, some may have got away altogether.

It is to be hoped Mr. Armitage will drop on to something to reward his enthusiasm. He had made fair progress when I saw him at what was then castles in the air. These structures are by no means to be despised. Next to money in one's pocket, I know of nothing more helpful to the gold prospector.

Mr. Dommico, "full of high hope," and with the air of a man who was losing treasures every hour he was off his claim, was hurrying up to set men to work. He (like some others I met) seems to think if he got on to a lead of gold, it would guide him to the matrix: that attained, they evidently think, their fortune is no longer matter of speculation. The man of experience does not trouble himself about the matrix: whoever yet managed to connect a single alluvial lead of gold with a quartz reef, or say with any degree of certainty to what reef it owed its existence?

Science has probably done less for the goldseeker than for any other individual. Auriferous reefs are often found in the ranges that intersect the gold fields, but what about the plains of hundreds and hundreds of acres rich in gold and far from any reef? How did the gold come there? and what about the matrix? Reefs run parallel, alluvial leads run in all directions. It is common enough for men to be sinking shafts all along for a mile or more ahead of where a lead has been struck, believing they were on the line of it, but to find it had turned a right angle to suit those who could not get on to the line. There has been no reliable theory ever yet got to bear on gold finding. The plodding man with his pick, shovel, and tin dish discovered most of the old rich gold fields of Australia. The scientific man followed up afterwards, but too late to be useful.

A VALUABLE MEDICINAL OIL, a sort of wool said to be obnoxious to moths, and a strong, cheap, matting, are among the products now made from pineapples.—*Home paper.*

ONE of the oldest industries in Egypt is artificial egg-hatching, principally engaged in by Copts. There are said to be 700 establishments of this nature in the country.—*Ibid.*

PLANTAINS have greatly risen in price, owing, principally, I think, to all the lands, as far as Polgahawela being cleared and planted out. Bum boat men now go about the gardens in town paying very fair prices for inferior kinds of plantains unfit to be cut in order to supply the shipping.—*Cor.*

LARGE GOVERNMENT ORDER FOR FOREST TREES.—We note in the *Dumfries and Galloway Standard* that the firm of Messrs. T. KENNEDY & Co., nurserymen, Dumfries, were recently invited by Her Majesty's Commissioners of Woods and Forests to tender an offer to supply 600,000 young forest trees of specified varieties for planting on the Crown lands in the Isle of Man. Their offer has been accepted for over a quarter of a million plants, which have to be straightforth delivered to the Crown Receiver at Douglas. The order consists of Birch trees, Beech, Sycamore, Alder, Silver Fir, Corsican Pine, Austrian Pine, Douglas Spruce, Scotch Firs.—*Gardeners' Chronicle.*

CHINA GRASS AND COCA.—The Société d'Acclimatation heard at its last meeting a very interesting paper from Dr. Bélances, presented G. M. Geoffroy St. Hilaire, the celebrated naturalist. Dr. Bélancés, has made a study of the cultivation of "China-grass and Coca" which plants he has introduced into Porto Rico and San-Domingo. He says these plants are destined to be of immense value to the Antilles, where they have been definitely acclimatised. The lecturer showed two stalks of [illegible] ft. 11 in. long, cut after one month of cultivation by M. D[illegible] at Porto Rico and a beautiful branch in flower, covered with leaves, which had been sent to him by the Archbishop of San Domingo. "In the deluge of economical perturbations threatening this country, [illegible] may be shown to the people as a token of salvation." Dr. Bélancés likewise exhibited [illegible] at Porto-Rico, [illegible] at San Domingo and [illegible] at Venezuela. The latter is easy of cultivation, is possessed of the same nutritive qualities as the potato, and contains a large proportion of tecula.

Some of this fruit has been forwarded to the Starch Manufactory at Palinges with a view to ascertaining the proportion of starch they contain. The Society decided that an attempt should be made at the Algiers Gardens to acclimatize the plant, which may become a staple of culture and be utilized in industry. This interesting communication was listened to with great attention. Endeavours are being made in the French West India possessions to form a company with the object of introducing and cultivating the coca plant.

CEYLON TEA FOR CHINA.—The latest we have received is an order for 200 lb. Ceylon tea from a firm in Shanghai. This is right into the enemy's camp, I think! Do you think they want to imitate our Ceylon make, if so, they couldn't have chosen a better mark than ours eh?—*Merchant.* [No doubt the tea is for "foreign" consumption at Shanghai. —ED.]

COFFEE NOTES.—The correspondent of the *Journal*, writing from Ouro Preto, Minas Geraes, under date of the 5th inst., says: "Farmers, in view of what is occurring (emancipation), are abandoning the old, worn-out coffee orchards, and are applying themselves to the planting of new, and the development of these in full bearing. This will diminish greatly the coffee crop this year. Some persons declare that not over two-thirds of the crop will be secured."—*Rio News.*

BUG ON BEET.—A recent exchange says that a destructive and voracious enemy of the beet-root has appeared in Germany. It is a black bug, and was first seen in Silesia, where in the district of Leopschutz, upwards of fifty acres of beets were completely ruined. One cultivator, on a patch of less than ten rods square, killed 1,800 bugs. This unexpected falling off in the outcome of the beet sugar crop in Germany this year, may be owing in part to the ravages of these pests.—*Planters' Monthly.*

THE TEA BUG OF JAVA AND CEYLON.—At a meeting of the Entomological Society of London on April 4th, Mr. Waterhouse read a paper entitled "Additional Observations on the Tea-bugs (Helopeltis) of Java," and exhibited a number of specimens of these insects. He said that the species infesting the chinchona in Java was supposed to have been introduced from Ceylon in tea, but that he had discovered that the species on the tea and on chinchona in Java were distinct, and that both species were distinct from *Helopeltis antonii* of Ceylon.—*The Athenæum*, April 14th.

CINCHONA BARK.—With another fall in price, this time of a farthing per unit, it would really seem as if "other countries" learning that Ceylon was slacking off, had begun to "rush" their bark to Europe. If so, they will find Ceylon is waking up too, for apart from rising exports, here is the railway return for week ended 8th April giving 148 tons bark against 94½ same week last year! The 8th instant closed the week just before the rain began.

CEYLON ARROWROOT FLOUR.—Mr. R. P. Jayawardana of Cotta sends us a packet of "Jayawardanapura Arrowroot," which is "guaranteed pure, and free from all chemical impurities." According to a contemporary,

"It appears that he picked up the mode of preparation when attached, many years ago, to the Agricultural and Industrial School under Mr. Thurston. On his transfer to Kurunegala, he attempted to grow the yam, but the soil there was not favourable to it. Since his re-transfer here, he has been making experiments in Cotta and has induced the people thereabouts to undertake the cultivation, making small advances against the crop. The result is that there are now about 10 acres of land under the product in that district and its neighbourhood. Mr. Jayawardana at present works a small Hand-mill, which gives employment to about half-a-dozen hands; but he will undertake operations on a more extended scale when the samples he has distributed for analysis are reported upon."

The sample looks very good, and we wish Mr. Jayawardana all success in his new enterprise.

HARDINESS OF EUCALYPTUS COCCIFERA.—You have been good enough on one or two occasions to insert in the *Gardeners' Chronicle* some remarks of mine relative to the hardiness of Eucalyptus coccifera. About three, or perhaps nearly four years ago, I had planted in the garden of the Atkinson Morley Hospital at Wimbledon, four small plants of this Eucalypt; one perished from drought, but the other three, notwithstanding the exceptional severity of the late three winters, have withstood snow and frosts remarkably well. They are now from 8 to 12 feet high, in an exposed site, and look (I saw them this day, March 27), in perfect health and vigour. Of all the tribe, E. coccifera is the one which will best bear our winters out-of-doors. It is quite a mistake to plant E. globulus for such a purpose. It might grow, in fact I have seen it grow, in the open air in winter in Cornwall, and in a secluded sheltered spot in Dorsetshire and Hastings Old Town: whereas the E. coccifera will flourish in any season, and its culture should be encouraged and promoted by all means.—JOHN COLEBROOK.—*Gardeners' Chronicle.*

PLANTING IN BORNEO.—We understand that the Borneo Planting Company are making rapid progress, Mr. A. Walker, their Manager, has felled 160 acres on the Segaliud River for Liberian Coffee, Cocoa, Manila Hemp, Pepper, Coconuts, &c. At Bocara 60 acres are planted with Manila Hemp and Pineapples, and further land is being cleared for this purpose. We wish this Pioneer Company every success.—*Borneo Herald*, April 1st.

JAFFNA TOBACCO.—The tobacco cultivation is of deep interest to all people in Jaffna. In fact, this is the chief article of export. Whilst we have to buy from foreign markets our articles of food and clothing, as well as other articles of necessity, not to speak of those of luxury, the principal means of bringing money into the country from abroad is tobacco. It is now in various stages of growth, and in a few weeks more, it will be gathered and cured. Probably, the extent grown with tobacco this year is greater than any previous year. The care and the trouble taken and the work done by the cultivators in raising the crop, are very great. But where is the market for a good sale? There is more than the demand of the markets in Colombo, Kandy and Galle; and more than the demand of the Indian market. Now, it behoves every man of patriotic feeling to find out the ways and the means of sending the Jaffna tobacco to the European market. The process of curing should, of course, be in a superior manner. This is well worthy of the attention of such good men as Charles Morrison, the banker, or some metropolitan merchants. If among the drawbacks, bad curing be one, the remedy can be had. Persons versed in the act of curing may be got out for a time, to teach the cultivators, or instructions may be obtained from wheresoever they can be had. It would be a great service to the country, if the cultivation of the chief article of export can be encouraged. From the year 1857 to about 1870, sales of tobacco were very encouraging and satisfactory; but since then, there has been a decline. It is certain that there is a large acreage fit for such cultivation, and what is wanted is larger demand. To develop the resources of the country is of the utmost importance for its prosperity. Our people have to direct their attention towards finding out the ways and the means of advancement and improvement. Selfishness is an evil and a disgrace. It is man's duty to be useful for himself and others. It is a good idea to form an agricultural association, hold meetings at stated times, and have communications with similar institutions in other parts of the world, with a view to introduce new modes of cultivation and adopt all that is good and useful. Are there not men of leisure, means and talents in our midst to form such a useful association?—*Com.* "Morning Star."

PLANTING AND TRADE IN FIJI IN 1887.

The crushing hurricane of 1886 developed the depth of depression to which it was possible for the colony to sink. The effects of gradual decline in the fruits of the sugar industry were beginning to be felt in the results inevitable to the reduction of staffs, the lowering of salaries and the cutting down of expense wherever that was possible.

It may be fairly hoped that the suffering of 1886 and the effort of 1887 will receive something like tangible reward in 1888. Sugar has taken a turn commercially for the better. Not only is the market firmer, but the Conference on the sugar bounties now organized can but effect a result beneficial to the cane-grown article. The year 1887 is entitled, however, to such advantage as has accrued from this stiffening of prices; to the extent, at least, of the output for the season just closed.

The copra yield, the paucity of which in 1887 is to be distinctly traced to the blow in the preceding year, is assuming tangible proportions and recovering its vigor. During the last four months, about seven hundred tons of this article of export have come into the hands of the Government contractors. That quantity may be expected to be largely increased during the first months of the coming year; but the value of such as may be then brought in should distinctly be carried to the credit of 1887, of whose production it evidently must be part.

Tea is apparently holding its own. Its growth and preparation are in the hands of skilled men who have thoroughly established the claim of the Colony to be classed among tea-producing countries. Other matters being equal, there is nothing to prevent Fiji from assuming a very considerable pride of place in this direction. That she has maintained her position is certain, and 1887 may be regarded as fairly satisfactory to that extent at least.

The Fruit Export has grown to large proportions and has consequently had a material effect upon the trade of the Colony. The tonnage employed by means of the development of this source of industry is very considerable and figures substantially in the revenue. There is a whisper that another steamer will be added to the number of those already employed and that March will see that brought about.

Altogether, the outcome of 1887 may be regarded as affording fair cause for congratulation. With some few exceptions, people have succeeded in breasting the wave of depression and stout hearts and busy hands, actively employed, have enabled them to avoid being submerged. That they have so far succeeded is full of promising presage for 1888. It may be considered that the shore has been reached, and although some few may have lost their cloths in the struggle, at least they have escaped with life and with sufficient energy to enable them to face anew the conditions of existence.—*Fiji Times.*

TREES FOR CULTIVATION.

SEEDLING, TIMBER AND ORNAMENTAL TREES AVAILABLE FOR DISTRIBUTION AT THE NURSERIES, CINCHONA.

(From the Bulletin of the Botanical Department, Jamaica.)

The YELLOW CYPRESS of N. W. America and California (*Thuja gigantea*) is a good timber tree, suitable for building purposes. The wood is bright yellow, and fine grained. The inner bark is soft and pliable and useful for making mats, sails, ropes, &c. This graceful tree generally grows from 50 to 70 feet in height, and in favourable situations attains 200 feet. It will probably do well on the hills in Jamaica. Although called a Cypress, it is in fact an Arbor-Vitæ.

LAWSON'S CYPRESS (*Thuja Lawsoniana* B. & H.) is described by Murray as the handsomest tree seen by him in his expedition in N. America, the habit being most graceful, with the branches at first curved upwards, as in the Spruce, and towards the ends hanging down like an Ostrich feather; the leading shoots when young, droop like those of the Deodar. The tree attains a height of 100 feet, and a diameter of 2 feet. The timber is good, easily worked, with a strong odour. Murray described it as a true, Cypress. (*Cupressus Lawsoniana*, Murr.)

THE CHINESE ARBOR-VITAE (*Thuja orientalis*, L.) is a native of China and Japan. The name Arbor-Vitæ is derived from the Chinese and Japanese names for the plant. In China it is known as "Hak," everlasting life, and in Japan as "Hiba," tree of life, so called from the evergreen nature of the shrub.

The LARGE FRUITED CYPRESS (*Cupressus macrocarpa* Hartw.) is one of the finest of the true Cypresses. It is a native of Upper California where Hartweg discovered it, growing to a height of 60 feet, with a trunk 3 feet in diameter. It resembles in habit a Cedar of Lebanon, having a far spreading, flat top.

Another beautiful CALIFORNIAN CYPRESS (*Cupressus Goveniana*, Gord.) also discovered by Hartweg is much smaller, growing only to a height of from 6 to 16 feet. It is very ornamented with spreading slender branches.

The HORIZONTAL CYPRESS (*Cupressus sempervirens*, L. var. *horizontalis*) is only a variety of the common Cypress of South Europe and is so named from its horizontal spreading branches.

The above plants are on sale at 1d. each or 7s. 6d per 100.

FREE DISTRIBUTION OF ACORNS AND SEEDLING OAKS, (*Quercus Robur*)

In 1885, Mr. Morris obtained a barrel of acorns from the Royal Gardens, Kew, which have done well in the nurseries at Cinchona, and there are now some hundreds of plants available for free distribution. Carriage of plants must be paid for. Another barrel has lately arrived from Kew and Acorns will be sent free by Post to those who make application for them. The bags should be returned. There is also a limited number of plants of the Turkey Oak (*Quercus Carris*) available. Both these species of Oak are likely to do well on the hills, and would be an important addition to our supply of timber. There is a fine tree at Whitfield Hall, the property of DeB. Spencer Heaven, Esq.

ARROWROOT CULTIVATION AND PREPARATION.

From the Director of Public Instruction, to the Hon. the Government Agent, Central Province, Kandy :—

Colombo, 4th April, 1888.

Sir,—Referring to your letter No. 9 of the 3rd ultimo, I have the honour to annex copy of a report from Mr. Rodrigo, the Agricultural Instructor, who has been so successful with arrowroot. This report gives information as to soil, method of planting, and preparation of flour. (2) To this report I add a further report showing the method of cultivation, if roots or tubers are commenced with instead of shoots. This further information is given because, if arrowroot does not already grow in a district, roots or tubers can be sent by parcel post without damage, whereas shoots might die in transit. (3) Regarding rainfall, the exact rainfall at Mr. Rodrigo's garden is not ascertainable, but the Surveyor-General gives the average rainfall at the neighboring station of Gikiyanakanda in the annexed table. (4) Mr Rodrigo makes about 16 lb. of arrowroot flour from 100 lb. of arrowroot tubers. He can sell his arrowroot flour locally to villagers at 25 cents per lb., whereas the average price of 1 lb. of arrowroot tubers in his portion of the land in a district is one cent. (5) The Principal Civil Medical Officer, however, reports Mr Rodrigo's arrowroot on analysis to be equal to the best imported arrowroot which is sold by Messrs. Cargill & Co., at R1·12 per lb. while in the Pettah, I believe, it is sold at 75 cents per lb. Mr. Rodrigo is therefore arranging for the sale of his arrowroot in tins through the Pettah shops, a proceeding which

should bring in a still more handsome profit than the more local sale.—I am, &c., (Signed) H. W. GREEN.

(*Copy of Report Referred to.*)

Sir,—With reference to your letter No. 132 of 31st of January, I have the honor to afford the following information:—(1). *As to the nature of the soil* where you (*sic*) have succeeded with arrowroot:—I have grown arrowroot on a piece of land where the upper layer of the soil is open, sandy, and light and not moist at all, but I have observed that on a moist land arrowroot grows better, but the tubers yield a less quantity of flour than on dry ground. (2) *Method of Cultivation.*—There is not much to be said, the cultivation being so very simple. The great thing is to select rather light, open soil, and to break it up thoroughly before planting, so that the tubers may have room to grow easily. Then the earth is made into beds, and the shoots of arrowroot, two in each hole, are planted at a distance of 12 to 18 inches apart, and are covered with leaves to prevent the earth being dried up, and the leaves when they are decayed serve as manure, and also hinder the growth of weeds. Unless in a great scarcity of rain it is not necessary to water the plantation. Care should be taken to plant them in a rainy season, say in April, May, June, October or November. The deeper the ground is dug, and the more the soil is stirred, the larger the tubers become and healthier the plants look. Nothing more is required beside frequent weeding and keeping the land clean and sweet. I do not think the crop needs much manuring, but a dressing of rotten old dung and leaf mould will do good. The soil is not disturbed after planting till the tubers are dug up, which is done 8 to 10 months after planting. (3) *Rainfall, if ascertainable.*—The Surveyor-General gives the average rainfall at Gikiyanakanda for 14¾ years at 139·36 inches. (4) *Method of converting the Arrowroot into Fine Flour.*—First the tubers should be cleaned of all the scaly leaves by washing them in water, and then reduced to powder by pounding in a mortar. Then pour a sufficient quantity of water to make it a liquid, and, after stirring well, filter through a very rough cloth, in which the threads are set apart into another vessel, and keep that vessel unshaken for a time till the powder settles at the bottom; then remove the water and stir the powder again with fresh water and filter this time with a finer cloth to another vessel, and keep as before. Repeat this process of washing once more, and, when the powder is settled, remove the water and dry the powder in the sun on clean white paper. Whilst being dried the powder, which will be in lumps, should be continually reduced to bring them to a fine state.—I am, &c., (Signed) J. A. G. RODRIGO.

(*Copy of further report.*)

Sir,—With reference to the additional information you required on my letter, P. S., of 10th of February, I beg to state that arrowroots will grow wither they are sent with the shoots or tubers alone. In the latter case it will be advisable to plant them in a separate patch of ground till the shoots come out, before they are planted in the required ground at the usual distances. Care should also be taken to water the tubers till the shoots come out, and to protect them from exposing too much to the heat of the sun.

I am, &c., (Signed) J. A. G. RODRIGO.
Local "Times."

THE FLOWER INDUSTRY OF GRASSE.

A Paper on this subject was read before the Chemists' Assistants' Association on March 8 by Mr. F. W. Warrick, and was listened to with much interest.

The population of Grasse is about 12,000, and the flora of its environs represents almost all the botany of Europe. Among the splendid pasture lands, 7,000 feet above the sea, are fields of lavender, thyme, &c. From 7,000 to 6,000 feet there are forests of pine and other gymnosperms. From 6,000 to 4,000 feet firs and the beech are the most prominent trees. Between 4,000 and 2,000 feet we find our familiar friends the oak, the chestnut, cereals, maize, potatoes. Below this is the Mediterranean region. Here orange, lemon, fig, and olive trees, the vine, mulberry, &c, flourish in the open, as well as any number of exotics, palms, aloes, cactuses, castor-oil plants, &c. It is in this region that nature with lavish hand bestows her flowers, which, unlike their compeers in other lands, are not born to waste their fragrance on the desert air or to die "like the bubble on the fountain," but rather (to paraphrase George Eliot's lofty words) to die, and live again in fats and oils, made nobler by their presence.

The following are the plants put under contribution by the perfume factories of the district, viz., the orange-tree, bitter and sweet, the lemon, eucalyptus myrtle, bay-laurel cherry-laurel, elder; the labiates, lavender, spike, thyme, &c.; the umbelliferous fennel, and parsley, the composite wormwood and tarragon, and, more delicate than these, the rose, geranium, cassie, jasmin, jonquil, mignonette, and violet.

THE PERFUME FACTORY.—In the perfume factory everything is done by steam. Starting from the engine-room at the bottom, the visitor next enters the receiving-room, where early in the morning the chattering patois-speaking natives come to deliver the flowers for the supply of which they have contracted. The next room is occupied with a number of steam-jacketed pans, a mill, and hydraulic presses. Next comes the still-room, the stills in which are all heated by steam. In the "extract" department, which is next reached, are large tinned copper drums, fitted with stirrers, revolving in opposite directions on vertical axes. Descending to the cellar—the coolest part of the building—we find the simple apparatus used in the process of enfleurage. The apparatus is of two kinds. The smaller is a frame fitted with a sheet of stout glass. A number of these, all of the same size, when placed one on the top of the other, form a tolerably air-tight box. The larger is a frame fitted with wire netting, over which a piece of molleton is placed. The other rooms are used for bottling, labelling, &c.

The following are some of the details of the cultivation and extraction of perfumes as given in Mr. Warrick's paper:—

ORANGE PERFUMES.—The orange tree is produced from the pip, which is sown in a sheltered uncovered bed. When the young plant is about 4 feet high it is transplanted, and allowed a year to gain strength in its new surroundings. It is then grafted with shoots from the Portugal or Bigaradier. It requires much care in the first few years, must be well manured, and during the summer well watered, and if at all exposed must have its stem covered up with straw in winter. It is not expected to yield a crop of flowers before the fourth year after transplantation. The flowering begins towards the end of April and lasts through May to the middle of June. The buds are picked when on the point of opening by women, boys, and girls, who make use of a tripod ladder to reach them. These villagers carry the fruits (or, rather, flowers) of their day's labour to a flower agent or commissionare, who weighs them, spreads them out in a cool place (the flowers, not the villagers), where they remain until 1 or 2 A.M.; he then puts them into sacks, and delivers them at the factory before the sun has risen. They are here taken in hand at once; on exceptional days as many as 160 tons being so treated in the whole province. After the following season, say end of June, the farmers prune their trees; these prunings are carted to the factory, where the leaves are separated and made use of.

During the autumn the ground round about the trees is well weeded, dug about, and manured. The old practice of planting violets under the orange trees is being abandoned. Later on in the year those blossoms which escaped extermination have developed into fruits. These, when destined for the production of the oil, are picked while green.

The orange trees produce a second crop of flowers in autumn, sometimes of sufficient importance to

allow of their being taken to the factories, and always of sufficient importance to provide brides with the necessary bouquets.

Nature having been thus assisted to deliver these her wonderful productions, the flowers, the leaves, and the fruits of the orange-tree, at the factory, man has do the rest. He does it in the following manner:—

The flowers are spread out on the stone floor of the receiving-room in a layer some 6 to 8 inches deep; they are taken in hand by young girls, who separate the sepals, which are discarded. Such of the petals as are destined for the production of orange-flower water and neroli are put into a still through a large canvas shoot, and are covered with water, which is measured by the filling of reservoirs on the same floor. The manhole of the still is then closed, and the contents are brought to boiling point by the passage of superheated steam through the coils of a surrounding worm. The water and oil pass over, are condensed, and fall into a florentine receiver, where the oil floating on the surface remains in the flask, while the water escapes through the tube opening below. A piece of wood or cork is placed in the receiver to break up the steam flowing from the still; this gives time for the small globules of oil to cohere, while it breaks the force of the downward current, thus preventing any of the oil being carried away.

The first portions of the water coming from the still are put into large tinned copper vats, capable of holding some 500 gallons, and there stored, to be drawn off as occasion may require into glass carboys or tinned copper bottles. This water is an article of very large consumption in France; our English cooks have no idea to what an extent it is used by the *chefs* in the land of the "darned mounseer."

The oil is separated by means of a pipette, filtered, and bottled off. It forms the oil of neroli of commerce; 1,000 kilos. of the flowers yield 1 kilo. of oil. That obtained from the flowers of the Bigaradier, or bitter orange, is the finer and more expensive quality.

The delicate scent of orange-flowers can be preserved quite unchanged by another and more gentle process—viz., that of maceration. It was noticed by some individual, whose name has not been handed down to us, that bodies of the nature of fat and oil are absorbers of the odour-imparting particles exhaled by plants. This property was seized upon by some other genius equally unknown to fame, who utilised it to transfer the odour of flowers to alcohol.

Where oil is used it is the very finest olive, produced by the trees in the neighbourhood. This is put into copper vats holding about 50 gallons; 1 cwt. of flowers is added. After some hours the flowers are strained out by means of a large tin sieve. The oil is treated with another hundredweight of flowers, and still another, until sufficiently impregnated. It is then filtered through paper until it becomes quite bright; lastly it is put into tins, and is ready for exportation or for use in the production of extracts.

Where fat is employed as the macerating agent the fat used is a properly adjusted mixture of lard and suet, both of which have been purified and refined during the winter months, and kept stored away in well-closed tins.

One cwt. of the fat is melted in a steam-jacketed pan, and poured into a tinned copper vat capable of holding from 5 to 6 cwt. About 1 cwt of orange-flowers being added, these are well stirred in with a wooden spatula. After standing for a few hours, which time is not sufficient for solidification to take place, the contents are poured into shallow pans and heated to 60° C. The mixture thus rendered more fluid is poured on to a tin sieve; the fat passes through, the flowers remain behind. These naturally retain a large amount of macerating liquor. To save this they are packed into strong canvas bags and subjected to pressure between the plates of a powerful hydraulic press. The fat squeezed out is accompanied by the moisture of the flowers, from which it is separated by skimming. Being returned to the original vat, our macerating medium receives another complement of flowers to rob of their scent, and yet others, until the strength of the pomade desired is reached. The fat is then remelted, decanted, and poured into tins or glass jars.

To make the extrait the pomade is beaten up with alcohol in a special air-tight mixing-machine holding some 12 gallons, stirrers moved by steam-power agitating the pomade in opposite directions. After some hours' agitation a creamy liquid is produced, which, after resting, separates, the alcohol now containing the perfume. By passing the alcohol through tubes surrounded by iced water, the greater part of the dissolved fat is removed.

These are the processes applied to the flowers. The leaves are distilled only for the oil of petit-grain. This name was given to the oil because it was formerly obtained from miniature orange fruits. From 1,000 kilos. of leaves 2 kilos. of oil are obtained.

The oil obtained from the fruit of the orange, like that of the lemon, is extracted at Grasse by rolling the orange over the pricks of an *ecueille*, an instrument with a hollow handle, into which the oil flows. The oil is sometimes taken up by a sponge. Where the oil is produced in larger quantities, as at Messina, more elaborate apparatus is employed. A less fragrant oil is obtained by distilling the raspings of the rind.

THE EUCALYPTUS, MYRTLE, &c.—Of later introduction than the trees of the orange family is the *Eucalyptus Globulus*, which, not being able to compete with the former in the variety of nasal titillations it gives rise to, probably consoles itself with coming off the distinct victor in the department of power and penetration. The leaves and twigs of this tree are distilled for oil. This oil is in large demand on the Continent, the fact of there being no other species than the globulus in the neighbourhood being a guarantee of the uniformity of the product.

Whereas the eucalyptus is but a new-comer in these regions, another member of the same family, the common myrtle, can date its introduction many centuries back. An oil is distilled from its leaves, and also a water.

Associated with the myrtle we find the leaves of the bay-laurel, forming the victorious wreaths of the ancients. The oil produced is the oil of bay-laurel, oil of sweet bay. This must not be confounded with the oil of bays of the West Indies, the produce of the *Myrcia acris*; nor yet with the cherry-laurel, a member of yet another family, the leaves of which are sometimes substituted for those of the sweet bay. The leaves of this plant yield the cherry-laurel water of the B. P. It can hardly be said to be an article of perfumery. It also yields an oil.

Another water known to the British Pharmacopœia is that produced from the flowers of the elder, which flourishes round about Grasse.

The rue also grows wild in these parts, and is distilled.

THE LABIATES.—The family which overshadows all others in the quantity of essential oils which it puts at the disposal of the Grassois and their neighbours is that of the Labiatæ. Foremost among these we have the lavender, spike thyme, and rose-mary. These are all of a vigorous and hardy nature and require no cultivation. The tops of these plants are generally distilled *in situ*, under contract with the grasse manufacturer, by the villagers in the immediate vicinity. The higher the altitude at which these grow, the more esteemed the oil. The finest oil of lavender is produced by distilling the flowers only. About 100 tons of lavender, 25 of spike, 40 of thyme, and 20 of rosemary are sent out from Grasse every year. Among the less abundant labiates of these parts is the melissa, which yields, however, a very fragrant oil. In the same family we have the sage and the sweet or common basil, also giving up their essential oils on distillation.

THE UMBELLIFERÆ.—Whereas the flowers of the labiate family are treated by the distillers as favourities are by the gods, and are cut off in their youth, those of the Umbelliferæ are allowed to mature and

develope into the oil-yielding fruits. Its representatives, the fennel and parsley, grow wild round about the town, and are laid under contribution by the manufacturers. The Compositæ are represented by the wormwood and tarragon (*Estragon*).

THE GERANIUM.—Oil of geranium is produced from the rose or oak-leaved geranium, cuttings of which are planted in well-sheltered beds in October. During the winter they are covered over with w stra matting. In April they are taken up, and planted in rows in fields or upon easily irrigated terraces. Of water they require *quantum sufficit*; of Nature's other gift, which cheers and not inebriates—the glorious sunshine—they cannot have too much. They soon grow into bushes 3 or 4 feet high. At Nice they generally flower at the end of August. At Grasse and cooler places they flower about the end of October. The whole flowering plant is put into the still.—*Chemist and Druggist.*

THE POETRY AND IDYLLIC LIFE OF TEA PICKERS IN CHINA.

We are greatly indebted to a friend who spent a portion of his holiday at home in making extracts for us from Williams' "Middle Kingdom," bearing on the tea enterprise in China. Amongst the copious extracts there is the pretty, coquettish and yet pathetic ballad of the tea picking girl, the literary merit of which is so great that we have resolved first to give it a place in these columns. While we cannot doubt that the sentiments are genuine Chinese, our readers will see that the translation is in polished and elegant verse. There is much of human nature in the Mongolian maiden's mingled self-pity amidst her hard work of picking and manufacture of tea and household work and of truly feminine self-appreciation in regard to her pearly finger-tips and rounded arms. We might feel regret that the Indian and Ceylon planters should be rapidly interfering with the industry described, but we fancy the tea exported from China is as nothing to the quantity consumed by the people, so that the tea-pickers will not be thrown out of employment. The allusions to the ascent of "the high Sunglo" shews that tea in China, as in India and Ceylon, is mainly grown on hills. The Sunglo range of mountains is the scene of the idyll embodied in the ballad. The maiden who manufactures, firing "to a tender brown" has her weather troubles just as we have in Ceylon, and other troubles cause her bosom to "rise and fall like a bucket in a well," a homely but not unpoetic image. The maiden as a tea manufacturer shews *esprit de corps* and is proud of her "golden buds," and of the bitter tea which beats the sweet!

"I only wish our tea to be superior over all,
O'er this one's 'sparrow tongue' and o'er the other's 'dragon ball.'"

And pickings limited to three in a season seem indicated in the lines :—

"When all are picked we' ll leave theshoots to bud again inspring,
But for this morning we have done *the third, last gathering.*"

We may add with reference to the love expressed by the Chinese maiden for flowers wherewith to deck her hair, that on the Darjiling tea eatates, the Indo-Mongolian women, Nepalese and Bhuteas, shew the same pleasant propensity. To see a woman at work, with magnolia blossoms, pink or white, as big as saucers, in her hair, and perhaps a necklace composed of one hundred strung rupees round her neck, was a sight to interest and amuse.

(From "The Middle Kingdom." by S. Wells Williams. L.L.D., 1883.)

Among the best of Chinese ballads, if regard be had to the character of the sentiment and metaphors, is one on picking tea, which the girls and women sing as they collect the leaves.

BALLAD OF THE TEA PICKER.

1.

Where thousand hills the vale enclose, our little hut is there,
And on the sloping sides around the tea grows everywhere;
And I must rise at early dawn, as busy as can be,
To get my daily labour done, and pick the leafy tea.

2.

At early dawn I seize my crate, and sighing, Oh, for rest!
Thro' the thick mist I pass the door, with sloven hair half drest;
The dames and maidens call to me, as hand in hand they go,
What steep do you, miss, climb today—what steep of high Sunglo?

3.

Dark is the sky, the twilight dim still on the hills is set;
The dewy leaves and cloudy buds may not be gathered yet:
Oh, who are they, the thirsty ones, for whom this work we do,
For whom we spend our daily toil in bands of two and two?

4.

Like fellows we each other aid, and to each other say,
As down we pull the yielding twigs, "Sweet sister, don't delay:"
E'en now the buds are growing old, all on the boughs atop,
And then tomorrow,—who can tell?—the drizzling rain may drop."

5.

We've picked enow: the topmost bough is bare of leaves: and so
We lift our brimming loads, and by the homeward path we go;
In merry laughter by the pool, the lotus pool, we hie,
When hark! uprise a mallard pair, and hence affrighted fly.

6.

Limpid and clear the pool, and there how rich the lotus grows,
And only half its opening leaves, round as the coins, it shows—
I bend me o'er the jutting brink, and to myself I say,
"I marvel in the glossy stream, how looks my face today?"

7.

My face is dirty; out of trim my hair is, and awry;
Oh tell me where's the little girl so ugly now as I?
'Tis all because whole weary hours I'm forced to pick the tea,
And driving winds and soaking showers have made me what you see!

8.

With morn again come wind and rain, and though so fierce and strong,
With basket big, and little hat, I wend my way along;
At home again, when all is picked, and everybody sees
How muddy all our dresses are, and drabbled to the knees.

9.

I saw this morning through the door a pleasant day set in;
Be sure I quickly dressed my hair, and neatly fixed my pin,
And fleetly sped I down the path to gain the wonted spot,
But, never thinking of the mire, my working shoes forgot!

10.

The garden reached, my bow-shaped shoes are soaking through and through:
The sky is changed, the thunder rolls, and I don't know what to do;
I'll call my comrades on the hill to pass the word with speed
And fetch my green umbrella-hat to help me in my need.

11.

But my little hat does little good; my plight is very sad!
I stand with clothes all dripping wet, like some poor fishing-lad;
Like him I have a basket, too, of meshes woven fine—
A fisher-lad, if I only had his fishing rod and line.

12.

The rain is o'er: the outer leaves their branching fibres show;
Shake down the branch, the fragrant scent about us 'gins to blow;
Gather the yellow golden threads that high and low are found—
Oh what a precious odour now is wafted all around!

13.

No sweeter perfume does the wild and fair Aglaia shed,
Throughout Unu-yuen's bounds my tea the choicest will be said;
When all are picked we'll leave the shoots to bud again in spring,
But for this morning we have done the third, last gathering.

14.

Oh, weary is our picking, yet do I my toil withhold?
My maiden locks are all askew, my pearly fingers cold;
I only wish our tea to be superior over all,
O'er this one's "sparrow-tongue," and o'er the other's "dragon-ball."

15.

Oh, for a month I weary strive to find a leisure day;
I go to pick at early dawn, and until dusk I stay;
Till midnight at the firing-pan I hold my irksome place:
But will not labor hard as this impairs my pretty face?

16.

But if my face be somewhat lank, more firm shall be my mind;
I'll fire my tea that all else shall be my golden buds behind;
But yet the thought arises who the pretty maid shall be
To put the leaves in jewelled cup, from thence to sip my tea.

17.

Her griefs all flee as she makes her tea, and she is glad; but oh,
Where shall she learn the toils of us who labour for her so?
And shall she know of the winds that blow, and the rains that pour their wrath.
And drench and soak us thro' and thro', as plunged into a bath?

18.

In driving rains and howling winds the birds forsake the nest,
Yet many a loving pair are seen still on the boughs to rest;
Oh, wherefore, loved one, with light look, didst thou send me away?
I cannot, grieving as I grieve, go through my work today.

19.

But though my bosom rise and fall, like bucket in a well,
Patient and toiling as I am, 'gainst work I'll ne'er rebel;
My care shall be to have my tea fired to a tender brown,
And let the *flag* and *awl* well-rolled display their whitish down. *

20.

Ho! for my toil! Ho! for my steps! Aweary though I be,
In our poor house, for working folk, there 's lots of work I see;
When the firing and the drying 's done, off at the call I go,
And once again this very morn I climb the high Sunglo.

21.

My wicker basket slung on arm, and hair entwined with flowers,
To the slopes I go of high Sunglo, and pick the tea for hours;
How laugh we, sisters, on the road; what a merry turn we 've got;
I giggle and say, as I point down the way, "There look, there lies our cot.

22.

Your handmaid 'neath the sweet green shade in sheltered cot abides,
Where the pendant willow's sweeping bough the thatchy dwelling hides;
Tomorrow if you wish it so, my guests I pray you 'll be!
The door you 'll know by the fragrant scent, the scent of the firing tea."

23.

A while 'tis cold, and then 'tis warm, when I want fire my tea,
The sky is sure to shift and change—and all to worry me:
When the sun goes down on the western hills, on the eastern there is rain!
And however fair he promises, he promises in vain.

24.

To day the tint of the western hills is looking bright and fair.
And I bear my crate to the stile, and wait my fellow toiler there:
A little tender lass is she—she leans upon the rail
And sleeps, and though I hail her she answers not my hail.

25.

And when at length to my loudest call she murmurs a reply,
'Tis as if hard to conquer sleep, and with half-opened eye;
Up starts she, and with straggling steps along the path she 's gone;
She brings her basket, but forgets to put the cover on

26.

Together trudge we, and we pass the lodge of the southern bowers,
Where the beautiful sea-pomegranate waves all its yellow flowers;
Fain would we stop and pluck a few to deck our tresses gay,
But the tree is high, and 'tis vain to try and reach the tempting spray.

27.

The pretty birds upon the boughs sing songs so sweet to hear,
And the sky is so delicious now, half cloudy and half clear;
While bending o'er her work, each maid will prattle of her woe,
And we talk till our hearts are sorely hurt, and tears unstinted flow.

28.

Our time is up, and yet not full our baskets to the mouth—
The twigs a-north are fully searched, let 's seek them in the south;
Just then by chance I snapped a twig, whose leaves were all a pair;
See, with my taper fingers now I fix it in my hair.

29.

Of all the various kinds of tea, the bitter beats the sweet,
But for who never either seeks, for him I'll find a treat
Though who it is shall drink them, as bitter or sweet they be,
I know not my friend—but the seeds and of my fingers only see!

[* The *kê*, or "flag" is the term by which the leaflets are called when they just begin to unroll. The *tsung* or "awl" designates those leaves which are still wrapped up and which are somewhat sweet.]

30.

Ye twittering swallows, rise and fall in your flight a-
round the hill,
But when next I go to the high Sunglo, I'll change my
gown, I will;
And I'll roll up the cuff, and show arm enough, for my
arm is fair to see:
Oh, if ever there were a fair round arm, that arm
belongs to me!

THE FUEL SUPPLY FOR TEA ESTATES.

Sambo came from the field in a state of great excitement, exclaiming, "Massa an' me great 'spute. He say sandy ground good for squash pumpkin an' me say de same ting; an' we 'spute all day long!" It is much the same with "X. Y. Z." (see page 841) and ourselves. It was notwe who raised the alarm about firewood for tea estates, but a planter so largely interested and experienced as Mr. Rutherford. He, no doubt, had in view the requirements of steam engines as well as of the furnaces of tea driers and stoves for warming the air of withering sheds. But the Visiting Agent who gave the strong opinion that an estate should have one-third wood to two-thirds cultivation is specially connected with the well-known group of estates in Ambagamuwa, which are so well supplied with water-power. He, therefore, had in view the requirements of Victoria and other driers, and of stoves or other appliances for warming the air of withering sheds. We had and have the greatest possible objections to steam engines, if the use of them can be avoided. Not that we undervalue this great triumph of engineering invention, but we object simply on the score of expense. We always hoped that water-power would be available in the vast majority of cases, and that the invention of a cheap artificial fuel would supersede the wasteful use of wood. But the inexorable logic of facts is as yet against us. On the larger number of the lowcountry estates steam engines will be absolute necessities, and so, apparently will be fuel reserves. On a great number of hill estates too, while there is abundance of water for eight or nine months of the year, the supply is insufficient for one-fourth or one-third of the year. We have advocated central factories, and we believe great economy could be secured by the larger adoption of this expedient. But here again, the logic of facts must be regarded. Each proprietor of an estate of any size thinks he can do more justice to his own tea than it can receive from outsiders, and so the tendency is to separate establishments for estates, except, perhaps where a group is owned by an individual or a company. We have also written strongly in favour of utilizing great waterfalls, such as those of Craigie Lea and St. Clair in Dimbula, conjuring up visions of tea factories supplied not only with power but with the electric light from such centres. But actual plans and estimates prove that the cost of generating and transmitting electric force would be very heavy. Then comes the question of transmitting power by mechanical means, —belting or steel wire rope revolving on drums. We certainly did not mean to cast ridicule on this mode of transmission by adducing the case where the power of a turbine was wanted 1,100 feet above it. There can be no impossibility in such a feat. It is a question of expense in machinery, and of loss of power from friction and perhaps in overcoming gravity. We have seriously asked for a scientific opinion on the subject. If the turbine gave 12 horse-power say, and if only half this power was available at the factory 1,100 feet higher up, that might probably pay by superseding the use of a steam engine. An estate owner having an excess of water power might be able to help his neighbours who were less favoured by some scheme of transmission, but we suspect the idea of several factories being built on the favoured estate, the leaf from more or less distant estates being carried there and prepared, is utopian. On the whole we suspect that what with the requirements of inevitable steam engines, and those of tea driers and stoves, the fuel question assumes a graver aspect than our correspondent is willing to admit, and so long as wood is chiefly burnt on our railways, even railway extension will add to the difficulty. Our correspondent will, of course, argue that wherever the railway goes, it supplies the means of conveying firewood and charcoal, from places where wood is plentiful to where it is scarce. But the very lowest rates at which the railway can afford to carry coal, coke, firewood, or even charcoal,—say from Matale to Hatton,—makes the cost heavy if not prohibitive. The railway itself finds it better to have firewood depôts along the line than to carry any considerable quantity of reserve fuel. We have no more desire to create undue alarm than Mr. Rutherford had, but we must face facts, and that after a different fashion to that of the divine who looked scriptural difficulties boldly in the face and—passed on! We must consider what is to be done, and in view of the differences of opinion which have arisen as well as the importance of the question, we submit that the whole subject of the timber and fuel requirements of tea estates, and how such requirements can be best met, whether locally or from foreign sources, ought to be thoroughly investigated by a Committee of the Planters' Association, such Committee to be composed of the most experienced representatives of various districts. The Planters' Association might also, perhaps, offer a bonus to the discoverer and introducer of a really good and cheap artificial fuel, suitable not only for use in steam engines, but in tea drivers and therefore destitute of odour which might injuriously affect tea.

FIRST ANNUAL GENERAL MEETING OF THE CEYLON TEA PLANTATIONS COMPANY, LTD.

(*Special Report for the "Ceylon Observer."*)

The first annual general meeting of this Company was held at their office, 21, Mincing Lane, E. C., on Friday, April 13th, at 12 noon. There were present Mr. David Reid, Milnathort, in the chair; Messrs. David Reid of Sevenoaks, P. G. Spence, G. White, W. M. Leake, A. W. Starey, E. Walker, and Henry Tod, Secretary.

The Secretary having read the notice calling the meeting, the CHAIRMAN asked the shareholders if they consented that the report should be taken as read, and this having been assented to, he proceeded to address them as follows:—Gentlemen,—Before I move that the report and accounts be received and adopted, I daresay you will expect me to give you some account of your properties. Generally the first thing a shareholder wants to know is what property he has got, and what it has cost him. By referring to the statement of acreages which has been placed in your hands, you will see that, speaking in round numbers, you have 1,600 acres of tea and 1,600 acres of jungle. The cost of this may be readily found by taking the first item on the creditor side of the balance sheet, by cost of estates, including buildings &c., £56,863 3s 5d, and adding to it the £1,260 mentioned in the note to the statement of acreages as having been paid for land included in the statement though not purchased till the present year. This gives us, again speaking in round numbers, £68,000 as the total cost of the Company's estates. Here then is a simple calculation which each shareholder may easily carry away in his head:—

1,600 acres of land planted with tea, and fully provided with buildings and machinery at £40 per acre	£64,000
1,600 acres of jungle at £2 10s... ...	4,000
Total ...	£68,000

The jungle land, although adding greatly to the value of the property, gives no return, and if you add its cost to that of the dividend-yielding portion, you have a total of £42 10s per acre. This is a little over 10,000 pence—a hundred hundreds—so that for every 100 lb. per acre of yield and for every penny per lb. of net profit on that yield, the estates should give 1 per cent of dividend to the shareholders. Thus a yield of 450 lb. per acre and a nett profit of 4d per lb. would show a dividend of 4·50 × 4=18 per cent. There is one point which I explained at the last general meeting, but which, as I see many shareholders here who were not then present, it may be desirable to go over again. I daresay, every shareholder may not take the trouble to go over the Memorandum and Articles of Association of the Company, and may wonder how these estates come to cost less than the amount paid to the vendors, viz. £75,000. The explanation is that what the vendors sold to the Company was not only the four estates of Mariawatte, Dunedin, Dewalakande, and Sembawatte, but these estates along with their profits for 1886: they handed over to the Company not only the estates, but £11,361 5s 3d in cash, and this cash balance has formed the working capital of the Company. I may state that by the Memorandum and Articles of Association the Directors cannot use this money to pay dividends with, as it is part of the capital of the Company, and can only be used for capital outlay, such as planting new fields, purchasing additional land or machinery, or erecting additional buildings. Part of this capital, amounting roughly to £4,000, has been already expended in this way. Such, gentlemen, is the general position of the Company, but I have no doubt you will expect me to give you some particulars regarding the individual estates. I will begin with the first in the statement, which, by the way, is also the most interesting not only to us shareholders, but also to Ceylon tea planters generally—Mariawatte. I think I may fairly say that this estate is unique in the history of tea-cultivation, and that the splendid results obtained from the original 100 acres so early as 1884 gave a marked stimulus to tea-planting in Ceylon. In 1883 these 100 acres gave 550 lb. per acre; in 1884 the yield suddenly jumped up to nearly 1,100 lb., an unprecedentedly high level which the estate has since very well maintained, the exact figures for the past 4 years being as follows:—

1884	.....	1,092 lb. per acre.
1885	.....	1,170 ,, ,, ,,
1886	.....	1,059 ,, ,, ,,
1887	.....	1,126 ,, ,, ,,

The younger tea is not yet mature, and I cannot say if it will ever equal the original 100 acres, but one field in 1887 gave 700 lb. per acre. The soil is a deep rich ferruginous loam, eminently suited for the growth of good tea. In January of this year an addition was made to Mariawatte by the purchase of Atgalla estate for £1,300. This land is not of the same kind as Mariawatte, but the purchase has added considerably to the value of the property: half of the new land will grow very fair tea, while the timber enhances the value of the estate. The climate of this whole plantation is perfect for tea growing. I know the climate well. It was a source of great loss to me as a railway contractor, but a bountiful Providence has many compensations, and my compensation for the Nawalapitiya railway slips has been the Mariawatte tea—what was death to the railway contractor has been life to the tea planter. Mariawatte is situated in a hollow surrounded on all sides by hills which intercept the vapour-laden clouds of both monsoons. The fury of the storms bursts on the outward slope of these hills, but the "tail-ends" as one may say pass over and fall upon Mariawatte, giving just the kind and quantity of rainfall required for tea. The factory is, as most of you know, a very large and fine one. When the original owners of this estate erected so large a building, they were thought very extravagant, but I believe it will be found none too large in a few years. The young trees are coming on very well, and we are doing a large and increasing manufacturing business.

Turning now to Dunedin and Dewalakande, I may tell you that the crop on these estates has been very short owing to the drought; the rainfall from Nov. 1886 to March 1887 inclusive was only 2-5ths of the average for the same 5 months in the 5 previous years. For my own part, I am never concerned about shortness of crops from abnormal drought; it gives the trees a wintering, and we will get the tea when the weather changes as it must do some time. The superintendents report that they never saw the trees looking better. I will now say a word about Sembawatte and its daughter Mudamana. The shareholders would notice that a new estate had made its appearance in our statement. This is how it happened. The Government wanted to recover possession of 400 acres on the crest of the hill for climatic reasons and offered us acre for acre elsewhere. To this proposition we readily assented, as this part of the estate was of quite inappreciable value to us. The land we have got in exchange is good and as it adjoins a block of 60 acres which we owned and which by reason of its smallness was of no value to us, we have practically got land for a new estate of 507 acres without any outlay at all, and one which, I hope, will some day be a fine tea estate.

I will now make a few remarks about the cost of production and price obtained for our teas. These I consider highly satisfactory to the shareholders as well as highly creditable to the management in Ceylon. In view of the enormous development of the tea-growing industry, I think it is as plain as the nose on a man's face, that we must make every effort to keep the quality of our tea high, and the cost of producing it low. I do not think, however, that we will ever be able to put before you results much more favourable than those shown in the statement for this year. Possibly many small economies may be effected, but on the other hand we cannot expect to go on getting these large crops without manuring. I have the authority of Mr. Hughes, the analytical chemist, for stating that an average crop of tea takes as much out of the soil as an average crop of barley or oats, and in view of this, I think that manuring cannot be long deferred, and that, when it begins, we must look for increased cost in the production of tea. In the short time we have been in existence as a Company, we have built up a considerable commission business which has this year gone a good way towards paying our London expenses, and as this is a growing business, I have no doubt that next year the whole of these expenses will be defrayed from this source. Before concluding, let me say a few words about the administration. And first, about the constitution of the Board of Directors. When this Company was inaugurated, the men who were chiefly interested in it and who formed the original Board, were not tea-planters, nor yet commercial men, but engineers and railway contractors. We soon felt that there was an element wanting in our body. We wanted a man of good standing in the City of London with a thorough knowledge of commercial and banking business, and we unanimously agreed to ask Mr. David Reid, of 7, Mincing Lane, to qualify and join the Board. This he agreed to do, and his appointment was effected by the method of procedure laid down in clause 52 of the Articles of Association. To pass to another point:—my colleagues and myself think that however important it may be to have a good Board of Directors, a matter of still greater importance—I may say of vital importance—to the shareholders is to have in Ceylon a Manager in whose judgment and probity they can place entire confidence and superintendents of character and ability. I can assure the shareholders with the most unqualified confidence, for I speak from the best personal knowledge, that in Mr. Rutherford and his staff these conditions are well fulfilled.

HOW TO TREAT SHOLAS (PATCHES OF FOREST IN PATANAS).

In an inspection note on the Nilgiris, Mr. Gamble, Conservator of Forests, Northern Circle, throws out some suggestions in regard to the treatment of *sholas* in that district. Referring to the Dodabetta reserve he says that it contains 1,015 acres, of which about two-thirds is *sholas* and one third grass land, at an elevation of from 7,500 feet to 8,600 feet above the level of the sea. During the last year or two the Woodcock *sholas* have been cut for the Public Works Department fuel supply, and the results show that the growth from coppice is a great deal slower than it is at lower elevations, and that the reproduction from seed is not so good. [The Nilgiri sholas are in 11° North against 6½° around Nuwara Eliya and Horton Plains, the wind on the region around Ootacamund being often fearful and the frost sometimes intense. Our mountain climate in this island is altogether milder.—ED.] He therefore recommends the following system of working which would tend to improve the forests; (1) that the whole be gone over by degrees and cleared of creepers, low bushes and straggling shrubs and dead wood; (2) that one or two years after the above a cutting be made on what is technically known as the Jardinage system by selection of the largest and oldest trees; and (3) that blanks be filled up by degrees by planting partly indigenous trees partly conifers. In regard to (1) the work will be done, as the similar works in Coonoor range, and the wood will be removed under permit by the cutters of head-load fuel. If 100 acres yearly can be gone over so much the better, and it will be completed in about ten years, the cutting (2) may be arranged by felling 1½ tree per acre yearly over the whole, when the plan may be modified if it does not answer expectations. This will give, say, 1,000 trees annually. Instead, however, of cutting indiscriminately, Mr. Gamble advises that the forest be divided into ten compartments of about 100 acres each, and the compartments be gone over in ten years, cutting 1,000 trees in each compartment in rotation, that compartment being then closed against grazing for five years, so that there will be always one-half of the area open to cattle. By the term "Jardinage," which we have mentioned above, is understood the removal "here and there of the oldest trees, such, as are in a state of decay, spoilt or dried, and other trees in a good state of growth but which are demanded for purposes of trade or for local consumption. On this method of working a forest, which has generally been applied to resinous trees, the principle is never to remove more than very few trees at the same point, and to extend the Jardinage as much as possible over the whole forest. It results from this method of working that the forest presents at all points trees of all ages mixed together in confusion, from the young seedling to the old veteran, and that the trees which are biggest and highest interfere with those which are beneath their crowns and retard their growth. Moreover, since the trees are not close together they branch greatly."

Mr. Gamble's note having been, in the first place, submitted to the Board of Revenue, they are of opinion that the advice of the Conservator on this point is professional, and as it would, if carried out, amount to the felling of all the largest and oldest *shola* trees over an area of more than 1000 acres in the vicinity of Ootacamund, and their gradual replacement by planting indigenous trees and conifers, they do not approve the recommendation, while the removal of all creepers, low bushes, and straggling shrubs, they think, may have an important effect on the power of the *shola* to retain moisture in the soil, and should, they think, be closely watched. Mr. J. H. Garstin, a member of the Board, dissenting from the views of his colleagues, points out that there is a slight misconception of the effect of Mr. Gamble's proposals. He says, that if any work at all is to be done in the *sholas* the method of Jardinage should be adopted to prevent any sensible alteration in the appearance of the *shola*. The result of felling a tree here and there is not to cause a blank in the *sholas* for there are always some undergrowth which spread out their branches and ultimately refill the cover, but it refers to spots not covered by trees at present. Mr. Gamble, therefore, proposed to plant up the blanks and not to plant up where old trees had been cut down. As regards the cutting up of creepers, low bushes, and straggling shrubs, the effect of this operation will be only to make the *sholas* more dense, as young seedlings of the larger trees will have a better chance of growth. In conclusion, Mr. Garstin adds: If my presumption is correct, that the object aimed at by the recommendation of the Board is to preserve this characteristic appearance of certain *sholas* for scenic effect, I would submit that this object would be attained by an order that *sholas* within a certain radius should be treated only on the Jardinage principle, and that, too, very sparingly; and that the trees to be felled should always be marked by the District Forest-Officer and not by subordinates. Outside the radius the treatment of *sholas* may be left, if possible, unfettered by restrictions.

The matter having been referred to the local Government the following Resolution has been issued:—The Government fully share the misgivings evidently entertained by the Board of Revenue in regard to the effects of the action proposed in Mr. Gamble's note. The Cairn Hill and Aramby *sholas* have been inspected by the members of Government, and the fellings there appear, from the ornamental point of view, to have been anything but a success. The further destruction of these and other fine pieces of woodland scenery is to be strongly deprecated, and his Excellency the Governor in Council is therefore pleased to direct that no natural *shola* in the settlements of Ootacamund, Coonoor, Wellington, or Ketagiri shall be treated on the "coppiced under standards" or "Jardinage" systems without the previous and special sanction of Government. The clearing away within the limit specified of creepers, under-growth and bushes, and the removal of dead-wood are unobjectionable and such work may be carried out without reference; but His Excellency in Council looks to the District Forest Officer and Collector to see that this is done in such a way as not to mar picturesque effect in prominent localities. The blanks in *sholas* should be filled up with indigenous trees or conifers, and never with acacias or blue gums. Outside the limits of the settlements there may be special *sholas* which should be dealt with in the same manner as those within. The Collector should be consulted with regard to these and a list of them drawn up. The Government are further of opinion that the treatment of *sholas* outside the settlements on the "coppice under standards" plan should be regarded as an experiment, and should until experience has shown it to be a success, be limited. The "Jardinage" system is one in regard to the working of which his Excellency in Council has no desire to fetter the discretion of the Conservator provided that operations are carried on outside the boundaries of the settlements.—*Indian Agriculturist*, March 31st.

CINCHONA AT DARJEELING.—At the Government Cinchona Plantation at Darjeeling the work of substituting yellow and hybrid trees for red bark trees is being steadily carried out. The reason for the change is that the bark of the first-named two trees yields quinine, which is the most valuable of the cinchona alkaloids used for fever. Financially, the plantation was not as profitable as it has been in other years, although the balance to credit on the year's operations was R18,500. The cause of the difference was the unusual exports of bark from Ceylon, which were due to a special cause, and may not occur again to interfere with the Indian industry. On the other hand, the year's crop, amounting to 225,631 lb., was collected at less than half of the cost of the bark produced in the Nilgiri plantaton of the Madras Government. The year 1886-87 was memorable for the number of landslips in Darjeeling, by which no fewer than 300,000 cinchona trees were hopelessly destroyed. That catastrophe followed on the loss of 20,000 promising trees through a hailstorm of unusual violence.—*Bombay Gazette.*

Correspondence.

To the Editor.

CINCHONA SUPPLIES AND PROSPECTS.

England, 10th April 1888.

DEAR SIR,—I am very much obliged to you for giving in the *Observer* some very valuable information *re* cinchona in Java. As practical planters are aware, the produce per acre is much the same whatever may be the number of trees, so what we require to know is the acreage of the private plantations. If we could ascertain this, we could guess fairly at the total annual yield, as the Java Government are good enough to publish full particulars of their estates.

I give below the heads of information we require. I am sorry I am unable to give you the yield per acre of estates in Wynaad; on my own estates there the cinchona is mixed with the coffee.

The price of bark in London is very low, and is likely to continue so, while stocks and imports remain so large at each sale; the quantity offered is beyond requirements, so that the buyers can purchase at nearly their own price.—Yours faithfully,

W. T. HODY.

We require the following information:—

1. Of the Java Government estates, (*a*) acreage, (*b*) number of trees exclusive of those in nursery, (*c*) yield, (*d*) price obtained.
2. Number of private estates.
3. Their acreage, average of each if exact acreage cannot be obtained.
4. Proportions of the kinds of trees, (*a*) Ledger, (*b*) other kinds.

FUEL SUPPLY: "X. Y. Z." IN DEFENCE NOT DEFIANCE.

8th May 1888.

DEAR SIR,—My letter of 26th ultimo has been pretty strongly commented upon in your leading articles of 2nd and 4th instant. I am glad of it for the subject cannot be too well ventilated, and my humble efforts have brought forth statements and figures which must be interesting to all.

I addressed you with the object of showing that in my opinion at least

1st. The quantity of firewood, as stated to be necessary for continuing the tea enterprise in Ceylon was *not* necessary.

2nd. That, if it were necessary, the means proposed to find it were not the best calculated to pay the planter.

As regards No. 1, I am under the impression Mr. Rutherford, for instance, based his calculations on the supposition that every tea garden was to manufacture its own tea *on its own ground*, and that knowing how few estates could boast of having sufficient water motive power, a large quantity of fuel was reckoned as a *necessity* for generating steam. I endeavoured to show that much might be done by the natural motive powers our tea districts are possessed of, and that it would be found more judicious for many estates to seek other sites for their factories than their own land offered. Transmission of power by electricity, I daresay, is too expensive to the thought of, though I think I saw the same once advocated in the *Observer*, and with reference to the waterfalls in the districts of Lower Dikoya and Ambagamuwa. The question of transmission of power is rather cast into ridicule by you in speaking of transmitting up the power of a turbine over 1,000 feet, by means of belts, though I do not know that it is impossible.

Everything in reason, Mr. Editor! I daresay you are well acquainted with the fact that water power is transmitted for *long* distances in the mother country by means of wire ropes. Do you not consider that with our fine falls and rivers, much could be done in Ceylon by similar means? If so, will you not admit that the number of steam engines, said to be necessary for tea gardens, might be greatly reduced, and if so the quantity of fuel reckoned on as absolutely necessary be likewise reduced? Estate A may have a river frontage, but cannot raise the water to its factory: by wire rope could the power not be transmitted to the machinery? B adjoins A, but has no river frontage; could not B for "the consideration" perhaps secure a site from A, and if it could, and had even to carry its leaf one or two miles, would it not be better off to do so than erect a steam engine, and either purchase fuel for same, or plant up one-third of its available area for tea? There is no reason why A should not supply half-a-dozen sites for factories if each man must make his own teas. Though, how about central factories which you have always so wisely advocated? Will you not agree that the estimated quantity of fuel said to be required can be reduced in this way? And that the difficulties the tea planter in Ceylon has in prospect can be, to a great extent, obviated by such means?

My sole object in writing these letters is to *reduce* the prevailing fear that starvation, as far as fuel is concerned, stares Ceylon in the face, a fear which I still maintain has been exaggerated, and to a great extent unnecessarily raised.

You set your face against the idea of coolies burning prunings and cow-dung, and perfectly right too, for an estate which can afford to let them burn *anything else*; but these points were merely brought up, to show that an estate having "nothing else," its coolies *could* pull along with such supplies, and therefore that such estate could modify the difficulty of how its labour could exist. You consider the burning of cow-dung as a great sin; so do I; but do you or I ever give a thought to the indiscriminate waste of cow-dung on our estates for the enamelling the walls and concreting the floors of our cooly lines? Prunings are better buried no doubt, but if you *require* them for cooking either your tea or your pudding, you cannot drink or eat these luxuries and have them too.

An estate plants 20 acres of fuel trees; would such an estate, do you consider, allow its labor supply a stick of such fuel for its own purposes, if *any* other article for burning is available? which it always is.

You do me an injustice in hinting that I recommend the cooly to steal from Government forests; far from it; but that such an impression was formed by you, I admit I have myself to blame; my expression of "a never-failing source of firebrand the Government" was not explicit. My meaning was that Government had been for so long a source of "firebrand" to the cooly, that if he were likely to suffer from want of fuel, the Government would look after his warming and cooking comforts, as they have so wisely or unwisely pestered him with their medicinal remedies. It may be too, that some day the Government will reserve for the emigrant cooly forests for fuel as they do for his more lazy and indolent friends, the Sinhalese.—Steam engines on estates (unless supplied with immense stocks of fuel), I still maintain, will prove a *curse*, and I honestly and humbly give my opinion, that unless a tea estate can drive its machinery by water-power, it ought to *seek* that water-power within any reasonable distance, and I think

in 90 cases out of 100, such can be found. I note that the late Col. Fyers reckoned Ceylon contained some seven million acres of forest of different qualities. This is far better news than I expected, and I think the question resolves itself into, will it pay the tea enterprise of Ceylon best to seek means of transporting the necessary fuel in some form from these Eldorados of forest, or grow fuel on land, which it hopes will give a profit of from R30 to R50 per acre?

You have named "Abbotsford;" therefore I may take the liberty of alluding to it as an example. I know the estate well; I have had the pleasure of inspecting most corners of it both in the company of my worthy criticiser and that of its efficient manager, Mr. John Fraser, and my only difficulty in alluding to it as an example is, that I consider before many years are added to its age, it will be considerably above the average of tea gardens in Ceylon in quality. I know no ridge or corner on Abbotsford, but what I consider will grow tea to pay, say a profit of R40 per acre. Now take any 20 acres of it, and transfer it into a forest for fuel. Take the cost of such transformation, the R40 per annum per acre the tea would have paid you, add on interest and compound interest, and see the cost at say the end of 10 years of that 20 acres of land bearing 20 acres of fuel. I fear, Mr. Editor, the result will rather surprise you, and you will be inclined to agree with me that you and I and most of us, must try to extract from the mines of fuel the island possesses (7,000,000 acres) fuel to, *we will only say*, *fire* our tea. If such fuel *cannot* be got, we must all plant and reduce our estimates of returns accordingly, but I think we will make a big try first. For building purposes, we must look to stone and iron, supplies of either not being likely to run short. For tea boxes, surely we are all safe; if the 7,000,000 acres are not transportable for fuel, surely tea boxes will be got out of it. I believe tea boxes of pine could be supplied from England or America at lower rates than supplied from Japan. I must not trouble you further, and I take the consolation in return for the "cutting up!" that between us we have shown the public of Ceylon, and more especially outsiders, that 1st, the estimated quantity of fuel required has been modified; 2nd, that if required, it actually *exists in* the island, and if not available for transport, it can be easily and readily grown, thanks to experiments and proofs positive, as shown the public by the worthy editor of the *Ceylon Observer*, and drawn forth by the humble efforts of, yours,

X. Y. Z.

A QUESTION OF QUAILS.

DEAR SIR,—It is difficult to form an opinion as to the species of quail seen on Horton Plains by your roving editor "On the Hills." In the first place, were they quail? It is very likely they were. At the same time it is quite possible, I don't say probable, they were not; for, about the time they were seen, the little chicks of jungle-fowl and of spur-fowl would be abroad in that locality, and I need hardly remark that they might closely represent on the wing both small and large quail. I merely point to this to show how difficult it is to arrive at any conclusion on the subject, from just seeing the birds on the wing for a minute. Had an old jungle-or spur-fowl been seen near, it would have been strong evidence of the birds in question being chicks as suggested; but not conclusive, as they act in different ways according to the circumstances of the case, and in this case the parent might have *run* off, first giving her chicks notice to *fly*, which they well understand. On the other hand they might have been quail, either *Coturnix climensis* or *Turnix aigoor*: the former is a very small pretty bird of dark plumage, which I have seen as high as 5,000 feet, and it might easily venture up to 7,000 feet especially in the fine weather; but this species delights in damp rushy places. Were the birds flushed from such a place? And they look so much smaller on the wing than the other species, as did the birds in question, this the writer remarks, so they may have been this species. Again, as there were several, the season points to the bevy being composed of old and young—a family party. So it is possible for them to have been chicks of the black-breasted quail, *T. tigoor* which look darker on the wing than their parents, though quails cannot be common at such elevations, or they would oftener be met with one would suppose. Yet, as I have flushed quail near the church at Nuwara Eliya many years ago, there is no reason why they should not be found on Horton Plains, though I have never heard of quail being seen there before. It would be interesting to have the matter settled; but nothing definite can be arrived at on the present information. If any sportsman have shot them on Horton Plains, perhaps he would kindly send a note of it for publication. S. B.

[We have seen jungle-fowl chicks, but they were lighter-coloured, longer-legged, and longer-necked than the covey or bevy (why bevy and not covey?) of little, dark (almost black) round birds we disturbed on Horton Plains, just in such a locality as our correspondent describes—only instead of rushes we should say tufts of tall grass. We are pretty familiar with lowcountry quails and their habits, and first the short flight, and then the run of the little dark (*very* dark) birds on the Plain caused us at once to exclaim "Quails!" We have in our own mind no doubt they were quails,—of a species common lower down probably (the same as our correspondent flushed on the Nuwara Eliya Plains), but dwarfed and darkened by being bred at an elevation so extreme? But, after all, if a bird exists at 6,200 feet, there seems no good reason why its range should not extend 800 feet higher,—the cover on the edges of swamps and streams being undoubtedly better in the loftier than in the lower locality? We now recollect that only two or at most three of the seven birds took wing, while the rest of the seven ran. There was no disparity of size—all were very small and very dark in plumage: quails, we firmly believe, and we hope to obtain the credit of having made their acquaintance at the highest level they have been known to attain in Ceylon. They and the patana moths were the only living things we saw on the Plains,—for we only heard the hawk. By the way, we cannot help thinking that if there were fewer hawks in our mountain regions, there would be more non-predatory birds? We certainly feel this very strongly.—ED.]

GOLD IN CEYLON: PRACTICAL HINTS.

DEAR SIR,—In your article of 4th instant on "Gold in Ceylon," your correspondent doubts the existence of gold (heavy) in a country so long worked for gems, but acknowledges that his reasoning may be confuted by anyone able to do so.

As I, some years back, had a good deal of practical experience in gold-digging, I think I can confute his statement, and show that it is quite possible that gold, especially heavy gold, may exist and not be found by the gem-digger. Gold from its specific gravity is always found close to or even imbedded in the "bottom" or primitive

rock. Gems from what little I have read of them are of much less specific gravity than gold, and lie in layers or veins of gravel *always above* (frequently many feet) what diggers call "bottom." I have known many instances of gold-diggers of some experience, working their claims out as they thought, and leaving all the heavy gold in the "bottom," from where it was afterwards taken out by others.

So that if gem-diggers have found heavy gold (?) I would rather say that by accident their mamoties cut deeper than was their intention, or than is customary or necessary for gem-diggers to dig, and thus they dropped on the gold by accident, than conclude that heavy gold could not be left in a shaft or pit worked alone for gems.

It must not be inferred that all coarse gold lies deep in the earth, but only that gold lies in or in close proximity to the "bottom" or primitive rock. Frequently, indeed, *heavy* gold is found an inch or so below the surface, but then you will always find the "bottom" has risen also. One of the most necessary experiences for a gold-digger is to know "bottom" when he sees it, and experience even won't teach one in all instances, for every gold field differs in some respects from others, so a man has to learn something on every new field he goes to. Now a native gem-digger knows nothing whatever about "wash dirt" or "bottom," and would never desire to sink his shaft below the drift in which he finds gems. *All* drift lies above "wash dirt," and wash dirt lies on the "bottom," and gold is found intermixed with "wash dirt" and the "bottom,"—so you can well understand how a gem-digger might leave gold behind him.

It is well-known that the country is auriferous, but what is wanted is to find gold in paying quantities, and this can only be found by prospecting or by accident as at Akuressa?

I myself found gold in a cutting on a road near Nuwara Eliya some seven years ago. I gave what gold I found to Mr. Geo. Armitage, who, I have no doubt, will remember the circumstance, as he saw me wash it out of the dirt.

I believed at the time that gold could be found around Nuwara Eliya to pay! But I had neither the time nor inclination to prosecute the search, besides I doubted very much if the finding of gold in paying quantities would be beneficial to the planters, as it would be sure to demoralize our labour force.—Yours, &c., OLD DIGGER.

CHINA TEA EXPORTS IN 1850 AND SINCE.

10th May 1888.

DEAR SIR, I find in a book dated 1850 that the total export of tea from China at that date, and therefore presumably the total quantity consumed in extra-Chinese countries, was only 40 millions of lb. Can this have been correct?

The present export from China, Japan, India, Ceylon, and Java is, I think, about 250 millions of lb., or more than six times as much as is said to have been exported only 38 years ago.—Yours faithfully, X.

[No, there must be some mistake: China exported over 60 million lb. in 1850; 64 million lb. in 1851; and practically all but a small portion of China's exports then went to London. Still a certain proportion of tea was carried overland to Central Asia, Russia &c. The development in the 38 years in respect of tea consumption is chiefly in the United Kingdom and its dependencies, and the result is much more startling than "X." supposes, for China gave 234 India 85, and Ceylon 14 millions, or a total of 323 million lb. last year against 60 millions in 1850 from China alone. The rapid development of the Indian tea trade is very wonderful; only 2½ millions exported in 1861-62; 13½ millions two years later; 46½ millions in 1881-82; and now 95 millions! But Ceylon will do still more: 348,000 lb. in 1881; 14 millions in 1887; and probably 40 millions in 1890.—ED.]

PLANTING TREES ALONGSIDE STREAMS: THE OTHER SIDE OF THE QUESTION: EVAPORATION BY ROOTS AND LEAVES *VS.* FROM THE STREAM DIRECT; SWAMPS AND THEIR DRAINAGE; QUICK-GROWING TREES.

May 11th, 1888.

DEAR SIR,—I do not think planting a thick fringe of quick-growing trees along the course of a stream, as suggested by a planter in your issue of the 8th instant, would have any effect in increasing the water supply, but rather the reverse: the roots of the trees would take up water which would be evaporated from the leaves, and increased evaporation would be the result. The fact of a stream sheltered by thick trees nearly drying up is mentioned in "Popular Scientific Recreation," page 7, and is accounted for by leaf evaporation, and an experiment mentioned on the same page seems to prove it. It is well-known that trees planted in marshy places assist in draining the ground, and this seems to bear out the above theory, which, if it is correct, rather stultifies the Government reserve strips along ravines and streams. The thorough way in which swampy places and ravines have been drained on most estates has no doubt contributed to the short supply of water in dry weather, as these places in former days acted as reservoirs, gradually yielding up the water absorbed in rainy weather. If all swamps on the upper parts of estates were embanked so as to retain as much water as possible, it would do more towards keeping the ravines full in dry weather than any amount of tree planting. Water holing the tea on a large scale would also do a good deal to retain much of the rainfall which now runs to waste owing to drainage; if the whole of, say, Dimbula had been waterholed, the amount of water held up when the January drought began would have been enormous. They would also assist in retaining the thunder-showers which sometimes occur during the droughty season, and most of which run to waste. The most suitable place to plant trees for fuel purposes would seem to be the exposed ridges on estates: tea seldom does much good in these places, and the trees when grown would form a shelter to the tea to leeward of them, and would thus cause increased yield in the sheltered places, compensating for the ground taken up by the trees, whereas, if trees are planted in ravines, they occupy the best land to the exclusion of tea and are useless, as a rule, for shelter. Of course, the trees to be planted on ridges should be such as can stand wind, and would grow in comparatively poor soil. For estates at an elevation of 3,500 feet and under kekuna will be found a very quick-growing tree. I give below the measurement of one 8 years old from seed. The wood is easily split, but I am unable to say whether it is a good firewood or not: perhaps some other of your correspondents will be able to decide this. The kekuna, from its habit of throwing out large branches at a low height makes a good tree for lopping firewood. The kekuna is ornamental and seeds freely, oil is made from the nut or seed, it grows readily at stake.—Yours truly, B. J.

Kekuna tree 8 years from seed, height about 30 feet, circumference 9 inches from ground 54 inches.
Do. at 60 inches do. do. 47 „
At 6 feet from ground a branch lopped off last year measured 30 inches in circumference, and with

a few smaller branches gave about 4 cooly-loads of firewood.

This tree is at an elevation of 3,500 feet in old coffee, and exposed to the monsoon at a lower elevation, growth would be greater.

LONDON *V.* LOCAL TEA SALES.

DEAR SIR,—I am glad "Tea Buyer" has publicly discussed my objections to patronizing the local market, as only good can result one way or the other. If *we* have prejudices, let them be removed; if the brokers and buyers have faults, let them be amended.

To my first objection "Tea Buyer" replies:—"Planter must have little confidence in his own brokers and their valuations of his teas, if he supposes the latter would be allowed to sell below value." Upon this I have to remark that what we want is a market in which competition is always keen enough to offer the *full value* of the tea *in the sales-rooms* quite independent of any broker's valuations. Brokers are neither better nor worse than any other hungry class of middlemen. Their livelihood depends upon their business, and so long as they can get more business by depreciating the value of produce as the most likely means to ensure a sale and to secure a commission—they will do so, as most conducive to their interest, however it may go with the planters. *

To my second objection he replies:—"The general opinion in Colombo is that there are too many buyers." This will be news to most of us. From our point of view, upcountry, there cannot possibly be "too many;" but I can quite understand any individual tea buyer taking that view, even if there were only two.

In his next reply he has quite misapprehended my meaning, and lost my point, a most telling one. He says:—"No after-sales are at LOWER rates than offered in the room." I should think not: that would, indeed, be absurd! My objection is that, in consequence of there being too few buyers, or that buyers accommodate each other, so that *fair bidding does not take place in the room*, witness the everlasting after-bargains made on the lots withdrawn, the local market is to be distrusted! Is it not a fact that nearly all the lots withdrawn (for want of fair bidding?) are sold after the sale *at* HIGHER *rates than were bid in the room*? So keen, indeed, is the competition of these "too many buyers" that they all are in the habit of letting parcels he "bought in" under their value; so that one of their number may buy the lots after the sale at the planter's own HIGHER reserve, taking their chance in the room of there being no reserve. Next, "Tea Buyer" informs us that "small lots have a far better chance here than in Mincing Lane." We are glad to know this, though it must surely be a new state of things in the local sales, for not long ago we were assured, in the brokers' monthly reports and in the columns of the local papers, that too many small lots were sent, and that they were placed at the same disadvantage here as in London. This is a distinct improvement in the local market, and the planters should not fail to make a note of. Big lots, of course, give the "brokers" no more trouble, and take up no more of their time than small lots, while giving them much more profit. Was it not business-like on their part, to discourage small lots as much as possible? But your broker as well as your buyer is a very honorable man, and so are they all honorable men. The incessant application of the whip for big lots not having had the desired effect, we are not told that small lots and lots of 'em will do. Lastly, after all the care taken by every planter to solder down his tea hot from the fire, it is not nice to contemplate 75 per cent of the cases being ruthlessly opened again in Colombo, where we know tea will not keep good a day exposed to the south-west monsoon. We have "Tea Buyer"'s assurance that the operation is too rapid to injure the tea, but as practical men we know accidents will happen, and good theory does not always mean good practice, though we are thankful for good intentions. The fact remains that IF a chest of tea *is* left open, and its contents exposed to the south-west monsoon in Colombo a whole day before being shipped, the tea must suffer in condition very seriously.

Your correspondent "Tea Buyer" is, I believe, the largest local buyer, and, in discussing this matter in your columns, has added to the many other obligations he has placed so many of us planters under for valuable information and hints always so freely and kindly given whenever asked.

PLANTER.

* Oh! oh! "Planter" forgets that apart from the special care taken with tea valuations (for reputation's sake if for no other) there is a constant and speedy check in that infallible test, Mincing Lane. Planters as well as brokers eagerly watch what Ceylon teas fetch there and contrast results with local valuations and prices at local sales.—ED.

MR. PINEO'S SCHEME FOR PUSHING "CEYLON TEAS" IN AMERICA.

"The Hermitage," Kandy, 17th May 1888.

SIR,—Mr. Rutherford, I think, is under a wrong impression in supposing that Mr. Pineo's "scheme" for placing Ceylon tea before our American cousins needs *money* from the Planters' Association Tea Fund.

Mr. Pineo has come to the Ceylon planters with a very business-like proposal, from powerful friends in America, to push the sale of Ceylon tea, and we know how splendidly they can do these things in that go-ahead country. It would appear to me very shortsighted policy should Ceylon planters not now respond freely to such a chance of spreading our tea in front of the United States and its sixty million inhabitants. I maintain we can give to Mr. Pineo's fund not 6,000 lb., but twice that quantity without in the least encroaching upon the preserves of the Planters' Association Tea Fund Scheme Mr. Rutherford so ably started.

I am sorry Mr. Rutherford goes so far as to say he does not think it fair to give an extra donation to Mr. Pineo's scheme. Surely we have 300 tea gardens in Ceylon that might give away a 20 lb. packet, and smile at such a flea-bite! when they consider the enormous benefit gained, should we get the Americans to take our Ceylon tea.

I threw out the suggestion of circulating lists amongst the District Associations, not in any way intending it to clash with the existing Tea Fund scheme, but with a view of expediting matters, as I believe it is of importance that Mr. Pineo's friends in America be assured *as soon as possible* that his scheme will be backed up and carried through by the Planters' Association of Ceylon. If the Association will consent to receive contributions to Mr. Pineo's fund, the sooner it is publicly made known, the better, and I feel confident that 6,000 lb. of tea will very speedily be at their disposal.

Although Mr. Pineo has taken up other work here, I feel certain that it will in no wise interfere with the object of his visit, which is to spread Ceylon tea over America through powerful agencies, and in so doing to pile up dollars for himself his friends, and the Ceylon planters.—I am, sir, &c.,

SHELTON AGAR.

LOCAL AND LONDON SALES OF TEA.

Colombo, 17th May 1888.

DEAR SIR,—Any good that can result from the public discussion of any subject can only be realized when this is approached fairly on either side, and the sneering tone adopted by "Planter" in his Shakespearean paraphrase, in comparing the honor of Colombo brokers and buyers to that of Cassius, is hardly conducive to friendly discussion. I also object to the term "patronizing" as applied to the act of a planter using the Colombo sales as a means of converting his produce into rupees.

With regard to "Planter's" requirements in his ideal market, viz., one in "which competition is always keen enough to offer the full value of the tea in the sale-room," I would remind him that the value of produce as of everything else is what it will fetch, and that no buyer will continue to bid either when he can see (and how plainly it can be seen after a few years' experience in public sale-rooms) that the tea will not be sold, or that it is being "bolstered up" in the endeavour to reach the merchants' or planters' limit. And as regards after bargains, how frequently do we find tea withdrawn from sale here, figuring in London catalogues on account of the estate, and how curiously interesting is it to compare the price realized with that refused on this market. If your correspondent takes this trouble, he would certainly be interested, and if his own tea were in question, he might frequently do so with at any rate mixed feelings. I would also draw his attention to the amount of tea withdrawn from the sale in London, and ask him to compare the relative proportions.

As to what "Planter" calls his second objection of there being too few buyers, he must not take the number of individual bidders in the room as representing the number of buyers, most of the bidders probably representing several firms of London merchants and holding their credits, and the difficulty of satisfying each of these (who import largely from India and China) with the occasional shipment of a small invoice of Ceylon tea which frequently does not pay the commissions, and often does worse by holding out hopes of an ultimate extension of the market is very great.

As regards small lots, they are of course a nuisance, and cannot be expected to command the extreme value of proper sized breaks, say of 25 chests to 50 chests, but they *re* on a distinctly better footing here than in London where breaks of less than 12 chests or 18½ chests are not even seen by the bulk of the trade, and are sold at the end of the sale, when all the larger buyers have left the room, leaving only the smaller men and a few outsiders who have troubled to sample and taste the "small breaks" with the object of picking up bargains.

There is no friendship in business, and the idea of all the Colombo buyers entering into a conspiracy backed up by the brokers to transform the Colombo auctions into a "knock-out" is too absurd to discuss. I can only say that had Diogenes found his honest man, he could not have done better with him than to send him here where he could not fail to have realized a fortune, as he would be sure to receive the undivided support of "Planter" and his friends. Your correspondent should reflect a little before stalking through the Fort of Colombo as a ghost of the ancient philosopher.—GORDON FRAZER.

TEA MANUFACTURE: GREIG'S MACHINES.

Bambrakelly Tea Estate, Lindula, 17th May 1888.

MR. EDITOR,—I have the pleasure to inform you, and in the interest of the Ceylon tea industry, that Greig's Patent Combined Fresh Leaf Withering, Drying and Final Firing Machine (the X L-ALL) has proved a great success; it was erected under Mr. Greig's superintendence in this factory, and has been from the first start working steadily daily without a hitch for about three weeks, and has proved the correctness of its new principle and of his certificates in praise of his machines in Assam, Travancore, &c.

The leaf is withered in the early morning in batches of 70 and 80 lb. every 3, 5, and ten minutes according to the state of the leaf, more than keeping pace with three rolling machines, and gives a bright copper-colored infused leaf in the cup, and the tea produced has been judged by experts to be quite as good and even better for strength and flavour than the naturally withered on the tats; the samples tested were taken from the bins and not specially prepared.

When withering, the expenditure of firewood is merely nominal, as one charge to furnace will last 3 or 4 hours by its perfect damper arrangement. The withering temperature 200 deg. at the thermometer, as it is with the other temperatures used, is less on the leaf by the sudden expansion of the air, and acts on the leaf on every side as it constantly turns over, as a warm zephyr and is pure atmospheric oxygen air, and from the simple and ingenious construction of the stove (in which there is no iron to burn away) none of the products of combustion (carbonic acid gas) can mix with it. For final firing the temperature is raised in a second or two, by shutting a door, up to 400 deg.: even the finest dust tea is done at a great rate, and gives a fine cured flavor to the tea. For firing the roll, the temperature is raised by opening the stove draught door and at as high a temperature as can be got, say 500 to 600 deg., and it is hardly possible to burn the tea, as it is constantly changing and exposing fresh damp particles to the action of the hot blast, and by its action gives an extra twist and curl to the tea.

As an example of the general utility of this machine, after withering 20 fills in the morning and forenoon, then it finally fired 10 chests of pekoe, then finished off all the half-dried tea from one desiccator to the extent of 963 lb. made tea in one day. The machine is attended by one cooly who also stokes the fire, and is mere child's play; it is self-acting. The machine and stove stand on a floor space of about 8 feet square; it is remarkable for economy of fuel of any kind. The workmanship is the very best, and the machine costs for this the smaller size £97 sterling including all the stove fittings. During wet weather particularly this machine, as a perfect witherer alone, is invaluable, and should revolutionize tea manufacture.

I quite agree with this description of the machine as working in my factory. E. RICE WIGGIN.

18th May 1888.

AMERICA is still the country for practical inventions of all sorts, but especially for labour-saving appliances. One huge harvesting machine, lately invented, is not only a reaper and binder, but thrashes out the corn from the straw, finally placing the grain in sacks, so that the whole harvesting process is completed while the machine is being drawn through the field by the eighteen or twenty-four horses harnessed to it.—*Mark Lane Mail.*

NOTICE.—This is a slight decrease on our stock at the beginning of the year. The island of Banka (one of the Malacca group, north-east of Java) was visited by storms of great violence on January 1 and 10. The island is the source of the nutmeg production, and large numbers of trees have been uprooted, while from others the unripe fruits have fallen. For the next six months not even a moderate crop can therefore be looked for.—*Chemist and Druggist.*

CEYLON UPCOUNTRY PLANTING REPORT.

TEA AND LABOUR IN THE KELANI VALLEY—THE 'NATIVE BOY' PLENTIFUL—'CEYLON' A NAME TO CONJURE WITH—DEMAND FOR TEA-PLANTS—NUTMEG CULTIVATION.

The rush of FLUSH which followed the rains, was checked too soon in some districts for the planter's liking. The rain that had fallen did not supply moisture enough, and the first effort which the trees made to reclothe themselves, and which gladdened and wakened us up, seemed to have fully exhausted all the virtue the rain had brought. We were back again at a standstill. Now, however, we are in for it again, for showers have been scudding about, and a fresh renewal of life is visible everywhere. With a see-saw like this going on, we are interested in learning the different conditions which obtain in other districts, and what we hear of KELANI makes us perhaps a little envious. There the tea has flushed with a squalid prodigality. You get invitations to come on with coolies, and you will get as much leaf as you like to pluck *for nothing*, and be able to sell it at the highest market rate.

One man guaranteed two thousand pounds a day, and would be glad to see you take it away, just that the trees might be kept in order; the labour force being unable to get over the ground in anything like time, so that fields had to be abandoned *pro tem.* I don't know if anyone has responded to the invitations to come down and enjoy the fruit of other men's labours, but the liberality displayed is somewhat unique. It points, however, to the weakness of Kelani labour. I fancy there will be very few, if indeed any district in Ceylon with a record like the above, and it is well that it should be so. The labour question in the Kelani Valley is every day becoming more and more serious. R1,000 advanced for about thirty men, and the planter ready to do it again, is a pretty high tide so very early. You can't get the same work out of the cooly as they used to do there, and as for holing and draining, Ramasami has a most decided objection to tackling hard work of that kind in such hot climates, especially when hands for plucking are at a premium, and rival kanganies bidding all round. How in all the world the land advertised for sale is ever to be opened, with things as they are at present, is a problem which wants looking into, and may be commended to the prayerful consideration of intending buyers. Many experienced men on the spot, who have clearings on hand now, find opening work very arduous indeed, even with a fair labour force to fall back upon, and don't come much speed even with that.

The "NATIVE BOY" for the home tea shop seems to be very plentiful in the island, seeing that as many as two hundred applied to a late advertisement, all anxious and willing to try their luck in the West. It was not that the wages offered were very excessive, for they were not that: rather I should say, the spirit of enterprize and a wish to see about them. It is to be hoped that at home they will be a success as an importation, and that the tea house will flourish.

CEYLON is now evidently a name to conjure with, and all kinds of wares, from CROCKERY to braces, seem to take better with the public, if the magic word has been spread as a protection over the articles in question. We have all known of this as being existent for some time now at home. But the circle widens, and I hear from a correspondent in Melbourne that they are selling there a "Ceylon dinner set," which is described as "a horribly ugly affair of the old willow style; a dark-blue pattern on a white ground. It is certainly no credit to the colony it is named after." It is rather humbling to have the name of our little island thus degraded.

The inquiries for tea plants have begun, and it would seem as if there was to be a good demand, more perhaps than there are nurseries to supply. Prices are as usual various, but those who have really good plants to sell ready for the S. W. don't think R9 and more a thousand too much to ask. During the drought there was an appearance of a considerable number of tea trees on most estates having succumbed, but although there have been losses all over, still they have not been at all so severe as was at first conjectured, the rains having brought round very many that looked all but dead. There are few estates, however, which have not more or less supplying to do, and I would conclude that the demand for plants will be a brisk one.

Among other things which have suffered from the dry season, is the NUTMEG. The drought has been harder on it even than wind could be, and although the trees are somewhat pulling themselves together now, they have a good deal to make up, and have still a shabby appearance. As for fruit, so much fell during the warm weather in an immature condition, that now, when the best months of the year have come, there is little to be got. Nutmeg planting still goes on in a quiet way, but the slow growth of the tree is apt to discourage the grower, especially the European one, who wants quick returns if by any means possible.

PEPPERCORN.

NOTES ON PRODUCE AND FINANCE.

The columns of the *Grocer* contain several letters on the subject of blended tea, the main idea being whether the grocer himself should blend his tea to suit the requirements of his trade or purchase it after it has been blended. The answer to this question, one would say, entirely depends upon the amount of experience of tea possessed by the grocer. If the retailer knew something about tea, he would be in a position to blend; if his knowledge of the grocery trade did not include an education in tea, his blends might be after the style of the mixtures about which the juryman chemist in Pickwick was apprehensive when he left his boy all alone in the shop. As a correspondent of the *Grocer* points out, "It is much more satisfactory to buy teas and mix them to suit your own trade, than to trust a stranger who knows or cares little of the taste of your customers. In order, however, to enable retailers to blend teas properly, it is necessary that they should know how to do it. Is this knowledge attainable by the average grocer? Assuredly it is. There are some men of vitiated taste to whom any amount of training is altogether useless; but by one possessed of an ordinary palate, the art may be acquired if he takes for his motto—Buy with caution, blend with care. There are three causes, at least, which have helped to divert the tea trade from its proper channel, and these are ignorance, prejudice, and carelessness. I have often wondered at the small stock of knowledge which a number of both wholesale dealers and retailers have regarding an article which they are handling daily and hourly. A partner in a London tea firm called on me lately, when I inquired for a sample of Saryune Kaisow. He gave me a sample, and on returning to know the result of competition I told him his tea was not a Saryune at all. "Oh, yes," he said, "it is a Ching Wo Saryune." The same ignorance prevails, to a great extent in the commercial community. There are a few who have a knowledge of tea, but the larger number know little, if anything, respecting the characters of the various districts of India and China, or of the kinds suitable for blending. The retail trade, as far I could ever learn, are affected in the same way. The majority buy so much Assam, Moning, and Kaisow, without ascertaining anything as to how they will

assimilate, and these, with perhaps a little caper or Lapseng Souchong, go to form their standard blends."

The rapid increase in the importance of the Indian tea has developed the tendency to combine under one proprietorship independent tea gardens with a view to economy in working. This is illustrated by the fact that though the number of gardens declined from 941 in 1885-6 to 883 last year, the area meanwhile was increased by 18,288 acres, the total area being 934,134 acres. Improved methods of cultivation also are resulting in an increase in the average yield per acre. The increase has been very extraordinary in Sylhet and Kachar.—*H. & C. Mail*, April 20th.

GOLD IN CEYLON: REPORT ON THE DEWURANGALA GOLD-FIELDS.

In addition to the several special letters in our columns this time, we give the following report which Mr. G. Armitage has written for the local "Times":—

Having visited, and to some extent prospected, the Dewurangala Gold Fields, I now send you a few notes which may be of interest.

The fields are situated about one mile from the road between Galle and Morawaka. The path leading from the main road is on the left of the Atwela bridge going to Morawaka and about 35¾ miles from Galle. The fields over which gold has been found extend on both sides of a stream. Some of the land is dry, but other parts are decidedly swampy. So far, the area acknowledged to be auriferous is not more than about 10 or 12 acres, but, from the large size of the nuggets found, there can be little doubt that the country round for miles is more or less auriferous. Color has been found in a neighboring valley to prospect which a license has been obtained. I am also informed that gold has been found higher up the stream. I dug several pits, going down in one over 19 feet, and am satisfied that the bed-rock is that immediately below the drift known to the natives by the name of *Illan*, and which contains garnets, catseyes, &c. The bed-rock is called "Malawa" by the natives, irrespective of the nature of the rock. It is not the same on all parts of the field, being a granulite in some parts, and in others a talcose schist. The former is very much disintegrated, the feldspar having been converted into kaolin. The latter for some inches is in an equally—if not more—disintegrated state, but below this the rock is harder than those composed of granulite. I was told that gold is found where the bed-rock is of a granulite formation, and precious stones *only* where it is schistose, but this (as might be expected) I found was not the case. The gold having been drifted on to the bed-rock, it naturally matters little of what it is composed. Had either of these rocks been the matrix, and the gold discovered through its decomposition, it would have been quite another matter, and deserved consideration. It is, however, quite possible that the gold deposited on the schistose rock sank as the latter disintegrated, and the parts being less cohesive than in the stiff argillaceous granulite, the diggers would have to seek lower in it. This, they never do, as they only work to get out the *Illan*. From the fact that all the gold found in these fields has been found in the *Illan*, and that deeper digging gives no sign of further drift, and above all that the bed on which the *Illan* has been deposited is to all appearances a bed-rock and not a detrital deposit, it may be inferred that the "Malawa" of the natives is the bed rock of the gold deposit. In Ceylon we need never expect to have to go down very far before reaching our alluvial deposits as they have none of them been covered over by or had the protection of, large sheets of Basaltic lava, such as is seen in Australia and California.

A writer to the *Observer* lays great stress on the peculiar appearance of the gold, and this he might well do, had it been washed down as gold along with the drift. Under the latter circumstances it could never have retained its present appearance, but, as it has evidently come down (in my opinion) as auriferous pyrites, and the sulphide of iron has been decomposed and washed off *in situ*, the gold has retained its hackly appearance. This decomposition probably took place before the drift was covered by the detritus now overlying it, and the large amount of undecomposed, or only partly decomposed, pyrites to be found in the drift has been protected by this covering. I have in my possession a specimen of auriferous quartz from Australia (showing the color of the oxidized iron) with gold in the hackly condition in which it is found at Darangalla. It must not, however, be supposed that all the gold found there has this appearance; some of it has evidently travelled a little.

I herewith send you tracings of some nuggets which I placed on my pocket-book and run my pencil round. These will give you some idea of the sizes of the larger ones. They were taken off a portion of an acre of ground. The owner, or rather the holder, of the license to dig (Constable Arachchi) showed me probably some 50 or 60 more, but I did not count them. In all, they weighed about half a pound. The gold seemed to be more or less of the same quality as those you gave me, but I did not try any on the touchstone. As I wrote to you before, I make out roughly that there is about 80 per cent of gold, or say 19 carats.

I went about half way up the Dewurangala Hill, and found the rocks to be chiefly granulite of a more or less schistose character.

The only nuggets I found were the two small ones I showed you; but my time was too limited, and I could not rest satisfied till I had seen the results of deeper digging, which took up much of my time.

The country round should be well prospected, the quartz and pyrites being tested as the work proceeds. The rough testing could be all done in camp, but, for anything more elaborate, samples would have to be sent to Colombo. There is very little encouragement for prospectors in this country, as they have to bear the expense, and got no concession from Government.

THE NORTH BORNEO PEARL OYSTER.

From the interesting letter which has been placed at our disposal, we are led to suspect that the pearl oyster of Borneo is essentially different from the so-called "oyster" of the Ceylon pearl banks. The Borneo mollusk seems to be a true oyster, existing on mud or sand banks at the mouths of rivers and in comparatively shallow water,—3 to 10 feet against 5 to 10 fathoms in the case of the Ceylon pearl-bearing mussel. In shape our pearl shell is an oyster, but the byssus, by which it clings to masses of coral or other rock, separates it from the edible oyster, which, bred in mud and lying on mud, needs no such appendage. Our only doubt as to the classification of the Borneo shells with the oysters instead of the mussels, arises from the statement that the Borneo mollusks are found in masses two feet thick. Something in the nature of a byssus would seem to be necessary to enable them thus to adhere? On the other hand, the North Borneo oysters bred on the mud or sand of estuaries are not only edible, but superior in quality to the common rock oyster. If, too native testimony can be relied on, they come to maturity in less than half the time allotted to our Ceylon shell, even if we adopt four instead of the old period of seven years for the full age of the latter. From their liability to destruction by fresh-water floods, the Borneo oysters are likely to be quite as precarious a source of revenue as are our own bivalves, while in the quality of the pearl yielded there is no comparison. The Ceylon pearls are amongst the finest, if not the finest in the world, some attaining a large size while perfect in lustre and shape. The pearls yielded by the North Borneo oysters are, on the other hand, described as never larger than small rice grains and

as irregular in shape, few assuming the spherical form. Those "seed pearls," therefore, must derive their main value from the fancy of native chiefs and rajahs that the carbonate of lime yielded by the combustion of such pearls is specially desirable as "chunam" to be used with betel-leaf, arekanut, tobacco, and other ingredients of the favourite oriental masticatory? Of course, the principles on which the only fishery possible since the North Borneo Government was organized has been conducted, contrast as strongly with the Ceylon system of careful conservation and working on Government account as do the qualities of the respective shells. In Ceylon, Government as proprietor and conservator of the pearl banks claims two-thirds of the oysters fished, while in Borneo, the Government takes 15 per cent of the proceeds of the fishery and a poll-tax of one dollar from each man engaged in the work of collecting the shells. The mode in which the value of the Borneo fishery was ascertained does not appear. Some rough and ready, approximate method was no doubt adopted, sufficiently accurate for the purpose. Fishing in from 3 to 10 feet water is far less toilsome and risky than diving in an average of 7 fathoms, so that the Borneo fishermen must have been well rewarded in comparison, that is, if the small irregular pearls fetched appreciable prices. The North Borneo oysters which grow on sand or mud banks at the mouths of rivers might, perhaps, be advantageously introduced into Ceylon and cultivated for their edible qualities, the small pearls coming in as a by-product; while, if careful marine surveying proves the existence off the shores of North Borneo of coral-strewed and algæ-growing banks with an average depth of seven fathoms of water over them, the Government of the New Ceylon might well consider the advisability of making experiments with the true pearl oyster (*Avicula* [*meleagrina*] FUCATA *), the shells being obtained either from Ceylon or Western Australia, and conveyed in large tanks filled with sea-water. When Capt. Donnan has seen and examined the North Borneo shells, we shall doubtless be able to speak more confidently of their conchological position.

After writing so far, we referred to an extract from the *North Borneo Herald*, embodied in our compilation "All About Gold, Gems and Pearls." The article is descriptive of "Seed-pearl Shelling at Batu Batu Bay." In quoting this article originally into the *Observer*, we remarked that "the pearl shell alluded to is the species found in Tambalagam Bay, near Trincomalee, the large thin shells of which are said to be used by the Chinese as substitutes for window glass, and which are put to artistic use, small pictures being painted on them, having all the effect of transparencies." The article quoted distinctly states that the "seed-pearl shells" (and it is of these that Mr. Cook writes) are of the species *Placuna placenta*, called by the natives "selessip." (*chippei* or *sippei* is the Tamil for shell.) Only the old shells were fished, and although there is no statement that the animal was eaten in a fresh state, we are told that besides the value of the seed pearls and the shells, the oyster (that is the flesh of the animals inhabiting the shells) dried in the sun, but not salted, sold for from $4 to $6 per picul in Labuan. The oysters, therefore, are edible; they bear only seed pearls, and they breed on mud-banks in shallow water, for the article quoted states:—"The scene on the sand or mud banks in the bay is lively,—men, women, and children, up to their knees in water, gathering the shells that are imbedded." The shells sell for $1.80 to $2 in Singapore, and regarding the "seed pearls," we are told that they "are sold in Labuan at one Mayam $1.80; one Bastinga, 10 Mayams $80. A great many of the seed pearls are disposed of in the village at Batu Batu. When the fisherman buys his few necessaries at the Chinaman's shop, he pulls out his little bundle of seed pearls and pays in that currency, the Chinaman making a good thing out of this transaction. These seed pearls are not much valued in Europe, but in China they are used as ornaments or *pounded into medicine*, and the shells being, thin and transparent, are also a substitute for window glass."

Then we have the statement that the fishermen themselves had suggested the poll-tax of $1 per person employed in fishing. It thus seems highly probable that the oysters written about by Mr. Cook are of the inferior species (for pearl yielding) *Placuna placenta*. The distinction between this and the true pearl oyster was indicated in the pearl fishery papers sent from Ceylon, but Mr. Cook may not have had time to read them fully. It is curious, however, that he did not describe the shell as large, flat and thin, these being remarkable characteristics of *Placuna placenta*. Of this oyster as found in Ceylon we have never heard that it was edible? In Ceylon as in North Borneo these shells delight in brackish water, and on more than one occasion, an excess of either salt water or fresh has proved fatal to great numbers of them. This statement by Tennent renders it still more likely that the "seed pearl oyster" referred to by Mr. Cook is *Placuna placenta*. Tennent states that the minute pearls from this shell "are exported to the coast of India to be calcined for lime, which the luxurious affect to chew with their betel. These pearls are also burned in the mouths of the dead." When the shells from North Borneo reach Capt. Donnan, we suspect he will decide that we have guessed correctly, and that there is no occasion for us in Ceylon to import pearl or edible oysters from Borneo, however the question may be decided of Borneo indenting on Ceylon for a supply of the true pearl oyster, *Avicula* [*meleagrina*] *fucata*.

* Mr. H. S. Thomas of Madras is supported by the British Museum authorities in insisting on this change, *Avicula* [*meeagrina*] MARGARITIFERA being properly the name of the large Australian mother-o'-pearl shell which attains dimensions of 12 inches against three for the true pearl oyster.

(*Letter referred to.*)

The Treasury, Sandakan, 11th April 1888.

W. D. Gibbon, Esq., Agent for the Government of British North Borneo, Kandy, Ceylon.

Sir,—I have the honour to acknowledge the receipt of your letter of the 5th ultimo on the subject of pearl oyster fisheries, and I am directed to thank you for the valuable information furnished, and to ask you to be good enough to convey the thanks of this Government to your Colonial Secretary and Messrs. A. M. & J. Ferguson for the kind and courteous manner in which they have supplied the papers and reports on the subject.

The book on "Gold, Gems, and Pearls" is particularly useful as a permanent source of information.

On reading Captain Donnan's report on the Ceylon fisheries, I tried to associate your Ceylon oysters with that of North Borneo, but hardly think I have succeeded.

Yours is found on coral or rocky banks in about 7 or 8 fathoms. The size of the shell is said to be about 3 inches; the oyster is not edible, at least it is not readily eaten by the natives; while mud passing over the banks is thought to be one of the causes of destruction.

Per book post I am sending you a sample of our Linkabo oysters: these are found on the *mud* and sandbanks formed at the mouth of the Labok river in from 3 to 10 ft. of water. A matured bank may be from 100 to 600 yards long, perhaps more; half this in breadth.

The oysters are edible and are used daily by the natives who prefer them to the common rock oyster. I have tried both and quite agree with them. The pearls are all under the size of rice grains of very irregular shape, few being spherical.

Fresh water floods from the Labok is said to be cause of the destruction of the Linkabo oyster banks, and this would seem to be borne out by the fact that during the rainy season of 1887, Nov.-Dec., there were no heavy floods or freshets; consequently pearl oyster banks have been forming and one has been worked during the last three months. This bed is two feet thick of oysters built or massed together in small places and one man may detach a piece containing 30 or 40 oysters and throw it into his boat. From the bank the oysters are taken home to the village where the women and children are waiting on a rickety platform in front of their hut: the boat comes alongside, then a basket is lowered and the oysters are hoisted aloft. Each shell is opened with a knife, the oyster is turned over and examined for seed pearls which are extracted. The oyster and shell then pass through the floor, beneath which may be seen a putrid mass of decomposing oyster and shell. The natives seem to thrive on the smell as they are said to do in Ceylon. We also have our "charmer," but he is evidently a superior being to your man of sharks. Sherif Abdul Cader is one of the direct descendants of the Prophet. The Sherif does the praying (in which the Bajows believe) and Government manage the rest.

The Government share amounts to 15 per cent and $1 a head, for each adult who works at pearling. This is the first year during many that there has been a crop.

I am inclined to think that our oyster is different to yours, and that it does not take so long to reach maturity; natives say about 18 months or two years, but we have little information on the subject, and are only just beginning to gather all we can. If you can help in this assisted by your friends in Ceylon, you will render this country a great service.—I have the honor to be, your obedient servant,

ALEX. COOK, Treasurer.

CAPT. DONNAN'S OPINION on the above:—"The oysters referred to are evidently of a different species to the Arippu oyster, and are not governed by the same conditions; and I fancy no comparison can be made between them. I should like to see a specimen of the shell. I send you herewith a few of the Cheval Par oysters of the recent fishery, which you may send on to Borneo if you like."

AFRICAN TEAKWOOD.

The interesting fact is stated that so indestructible by wear or decay is African teakwood that vessels built of it have lasted for 100 years, to be then only broken up because of their poor sailing qualities from faulty models. The wood, in fact, is one of the most remarkable known, on account of its very great weight, hardness, and durability, its weight varying from 42 to 52 lb. per cubic foot. It works easily, but on account of the large quantity of silex contained in it the tools employed are quickly worn away. It also contains an oil which prevents spikes and other iron work with which it is in contact from rusting.—*Madras Mail.*

COFFEE PROSPECTS.

Sir,—I read with a doleful face the letter from your London correspondent, in your issue of the 30th ultimo, headed "The Outlook for Coffee." The Planters of Coorg pride themselves on living in a snug little coffee-producing province, and some of them, especially among our Native Planters, are vain enough to think that a large or small crop from Coorg is likely to effect the Europe market. Let us look at what the following figures tell us. The present Brazil crop is estimated at 8,000,000 bags, which put into tons would represent 600,000. Now the average crop from Coorg for the past eleven years is 4,300 tons, and the bumper crop within that period, 1879-80, was 6,324 tons, so that it would take 139 average crops, and nearly 100 *bumper* crops from Coorg to produce as much as the present estimated crop from Brazil. No wonder the coffee market is depressed. For our own sake let us hope that the estimate of the Brazil crop is, as estimates generally are, *doubtful very.*—COORG PLANTER.—*Madras Mail.*

THE LEMON.

WHAT VARIETIES IS IT BEST TO PLANT?

I have read with great interest the letter from Italy on lemon culture and your comments thereon, wherein you say it seems that "those who are planting lemons will reap a golden harvest."

Now, can you tell a new-comer what variety of lemon is the best to plant? What are the relative merits of Sicily, Villa Franca, Belair Premium, Eureka, or others, as to quality, early ripening, shipping, hardiness to frost, etc., etc. Is the earliest bearing lemon necessarily the most profitable? What months in the year are best for us here to try to hit the New York market? What months in the year does the foreign fruit most abound in New York? When are best prices attained? Above all, though some variety may from some cause bring a higher price, which is the best market variety for solid business purposes? Will those who claim that their favorite variety of lemon ripens particularly early, give some evidence in the way of written acknowledgement of receipt in the market of actual shipments of marketable quantities, not specimen fruits?

What do lemons bring per box, on the average? Is the lemon box the same size as the orange box? How many lemons to a box of the different varieties—should lemons be wrapped? Is it true that they are picked for shipping as soon as they are large enough and then artificially colored? What size lemon takes best in the market? Would it be good policy to plant lemon trees between orange rows, where the orange trees are too far apart? If not, why?

"NEW COMER."

San Antonio, Pasco Co. Fla., Dec. 27, 1887.

[If the *Dispatch* had a dozen correspondents in each department of rural industry with such a faculty for asking pointed questions as "New Comer," our capacity as a cyclopædia of current information on rural affairs would be severely taxed. But we like this sort of thing, it brings out the facts. Fortunately for us, our correspondents are numerous and "clever," few queries are too hard for them and they are always glad to share their knowledge with "inquiring friends."

Villa Franca, Belair Premium, and Sicily are first-class varieties. We believe the same is true of Eureka and Genoa, though we know less of the two latter. We could never see much difference in time of ripening, hardiness, or prolificness. So far as our knowledge extends, we have no early lemon, comparatively speaking. The earlier the fruit can be got in into market, the better the price. Florida lemons usually go forward in August and September. The bulk of foreign lemons is received later. Average price for first class Florida lemons is about $2 50 per box, net. Lemons are shipped in same sized boxes as oranges. They will run from 2 50 to 300 per box. The fruit should be wrapped. Some gather green and ripen by process, others do not; the admissibility of doing this is a mooted question. Small lemons sell best

We are not "up" in lemons as well as we might be, and our answers are probably too general to suit our correspondent. Will Messrs. Phelps, Kedney, Ayer and other lemon growers come to our relief in this matter? We should also like to hear from E. Bean and Messrs. Sgobel and Day on maketing lemons.—ED. *Florida Despatch.*]

ON THE USE OF NITROGENOUS MANURES.

From a series of investigations by Professor Paul Wagner, Director of the Agricultural Research Station at Darmstadt,* endeavours have been made to assist in the solution of those questions on manuring which relate to the nutrition of cultivated plants with nitrogen.

1. *Does the Application of Nitrogenous Manure Produce an Increased Yield of all Crops?*—Different plants were manured with varying proportions of nitrogen per acre. The yields of cereal crops, Carrots, Potatoes, Turnips, Flax, Rape, and grass showed a considerable increase, and the gains were exactly proportional to the increase of manure, while on similar soils no extra yields of Peas, red Clover, Lupines, Vetches, and Lucerne were obtained; proving that leguminous plants obtain their nitrogen from sources inaccessible to the cereals, Potatoes and Turnips, &c.; and these supplies are so copious that under normal conditions of cultivation the plants do not need manuring with nitrogenous salts.

Should the soil, however, be poor, it is recommended to apply, even to leguminous plants, a small quantity of nitrogen in the form of nitrate soda or ammonium salts, to help them over a critical period of their growth, and to assist them in arriving as quickly as possible at that stage of development in which they possess the capacity of obtaining nitrogen from the air and subsoil.

2. *In what way does an increased yield result from the manuring with nitrogenous salts?*—The main object consists in endeavouring, by the supply of ample and easily absorbed nourishment, to bring the young plant as rapidly as possible to that condition in which it can offer successful resistance to all injurious influences, and then to carry it on to perfect maturation.

If the necessary quality of soluble nourishment is wanting in the soil, manuring with even a small amount of nitrogen considerably increases the yield of crop. At the same time it must be remembered that a plant does not live on insolated nourishing materials, but on a "food" composed of nourishing materials. A plant can form no leaves, no stems, flowers, or fruit from nitrogen, phosphoric acid, potash, or lime alone; the different nourishing ingredients must co-operate, and each must be present in proper quantity.

3. *Quantity of Nitrogen to be used.*—Plants require more than mere nutriment; they require water, warmth, and light. If there is a want of water or of light, or of warmth sufficient to produce a growth proportional to the nitrogenous manure given, the excess of nourishing materials is of no use. Manuring with nitrogen can only take full effect so far as not only the other nourishing ingredients but also water, warmth, and light are present in sufficient amount. All other elements the cultivator gives in excess, but nitrogen should be measured out to the plants; with nitrogen he, so to speak, feeds his plants, regulates their activity of production, and puts them in a position to take full advantage of the favourable conditions of growth presented to them, permanently or at intervals—favourable characters of the soil, the climate, and the weather.

The pamphlet will repay a careful persual.—JOHN J. WILLIS, Harpenden—*Gardeners' Chronicle.*

* Translated by George G. Henderson, M.A., B. Sc., and published by Messrs. Whittaker & Co., London.

ARBORICULTURE IN THE PUNJAB.

The Lieutenant-Governor of the Punjab has exercised a wise discretion in arranging for the submission of reports on arboriculture triennially, instead of annually as heretofore. This arrangement was introduced partly with a view to reduce the amount of reporting work demanded of District Officers, and partly because progress can be better judged when the operations of three years are comprehensively reviewed than when the work of only twelve months is considered. This is a step in the right direction, for in all parts of India reporting is often a weariness of the official flesh, and a waste of Governmental time. A special Committee on Arboriculture was lately appointed in the Punjab, in view to the drawing of systematic attention to the subject of tree-planting throughout the province. The Committee recommended that arboricultural reports should be submitted quinquennially, but the Lieutenant-Governor prefers the triennial arrangement. A Manual of Arboriculture for the use of District Officers, Committees, and Boards, containing directions for arboriculture, rules relating to concessions in connection therewith, and standing orders, is being drawn up by the Conservator of Forests, the Financial Commissioner, and the Government Secretariat. In the period 1884 to 1887, the length of district roads planted with trees in the Punjab was 1,343 miles; 4,925 acres were planted as groves; and 223 acres were planted as nurseries. The average annual expenditure in the two years 1882-83 and 1881-84 was Rs. 119,692; and the income was Rs. 41,904; shewing a net cost of Rs. 77,788; and in the three following years the average expenditure was Rs. 151 912, income Rs. 70,986, and net cost Rs. 80,926. The increase of income from an annual average of Rs. 41,904 to one of Rs. 70,986 was "decidedly encouraging." In six districts the income exceeded the expenduture. The devolopment of arboriculture by private persons is particularly satisfactory. In one District there are now small plantations in no less than 320 villages, 91 of which have been made without pecuniary aid, and the rest at the expense of Government. "In many cases," says the Conservator, "these plantations are most promising, and, though small, will soon become valuable." The species of trees that are being planted in the Punjab include the orange, apple, pear, peach, rose, mango, apricot, pomegranate, fig, date, pipul, lemon, banyan, mulberry, plantain, deodar, willow, eucalyptus, loquat, neem, olive, shisham, siris, ghaz, chel, ber, tut, jaman, aru, kikar, farash jand, boher, etc. Fodder-producing trees are in special favour in some Districts, but elsewhere fruit trees are more often planted as these localities "already abound with trees which in time of necessity can be used for the purpose of fodder, and consequently no special attempts in this direction have been made." At Simla, for example, the demand is chiefly for fruit trees, and 5,800 trees were planted in "permanent places" in the year ending 31st March 1887. These included apple, pear, peach, apricot, plum, cherry, fig, and other small fruit. The blue gum, which gives so funereal an aspect to parts of Ootacamund, has been planted near the Secretariat Office at Simla, but suffers somewhat from the snow. The other trees and shrubs lately planted about Simla include the deodar, horse chestnut, poplar, willow, broom, furze, &c. There are about 8,000 miles of district roads in the Province unplanted with trees, and if peace on the frontier is not disturbed, the work should, at the present rate of planting, be completed in seventeen years.—*Madras Mail.*

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

PARIS, April 14.

As marked interest is now being devoted to Scientific Agriculture, and meat and milk farming being the industries not only of present and future, but of great

est moment, it is necessary to bear in mind the valuable and exhaustive analytic experiments of Messrs Lawes and Gilbert, on farm stock, viz., that 32½ lbs. of animal fatty matters, are equal in nutritive value, to 65 lbs. of cereal starch. A meat has the advantage over a bread diet, in presenting the elements of nutrition in a more concentrated form. However, health is best kept up by a judicious mixture of both ration. Man consumes per 100 parts of the nitrogenous matters, in the flesh of the ox, sheep, and pig, 60, 50, and 78, respectively; and of fatty matters in the flesh of the same animals, 80, 75 and 90. Thus of the flesh of all these animals, pork is the most economical. In 1882, France—whose population is nearly 38 millions—consumed meat to the money, retail value, of 1,964 fr. millions; of this total, 138½ fr. millions represented imported meat.

Bran cake, the new cattle food introduced to the German market, is making way. It is now being employed for the feeding of calves and hogs. The cakes are 6 inches long, 3 broad and ¾ inch. thick, with bevelled corners. The interior of the cake is hard, requires a fair blow to be cracked, when it splits, not into crumbs, but into flakes. Dr. Schulze, of Breslau, has given a fresh analysis of the cake, and found its composition to be: water 12·51; nitrogenous matters, 17·79; fatty 4·42; cabonaceous, 55; woody fibre, 6·11; ash, 4·17. Microscopic examination showed that the cake was made from wheat bran, strongly compressed. There is no gelatine in the composition, as might be expected to bind the bran; nor is there any foreign matter to account for the high percentage of nitrogen. It is said the company divides 15 per cent on capital, a hint for milling interests to consider.

Since Dairy Schools are the order of the day, that of Paeselez-Meinersen, near Luneburg, in Germany, merits notice. It was opened in 1881 and accomodates only seven girls. M. Hasselmann is the director. The pupils follow four sections of work: the dairy, school, household management, and the kitchen and flower gardens. The schooling is confined to the three Rs. reading, writing, and arithmetic, the latter with special reference to keeping simple accounts; the flower and kitchen garden, in the light work of which they take part, is limited to cottage and farming wants; the housekeeping is in greater part restricted to that "heart of the house"—the kitchen. For the dairy, the girls have to assist in all the processes of butter and cheese making; to keep a register of the yield of each cow, and to test samples of the milk. The director gives every theoretical explanation required.

The school manipulates 66 gallons of milk daily; some is purchased by contract from farmers. The Laval hand separator is in use. From time to time, the Swartz and Holstein butter systems are tried. Since the adoption of the hand separator, more butter, and of a superior quality, has been obtained, as compared with other methods. The experience of M. Hasselmann respecting the utilization of the skim milk is important. He considers it is very suitable for making into cheese, but is above all excellent for feeding calves. He shows by his books, that when skim milk is made into cheese, or employed for hog-fatting, it is not so remunerative as when given to calves. His plan is to give calves unercamed milk daily, fresh and pure; on their being able to consume their five quarts, he supplies them with as much unskimmed milk as they can take. In the course of eight or ten weeks, they are fattened, not very fat exactly, but "fleshy," which ought to be the aim of intelligent fattening. He does not believe in the theory, that to obtain whiteness of flesh, feeding on whole milk is essential. He maintains that the aptitude for whiteness is inherited by the calf from its mother—is dependent on race and the kind of food given to the cow. M. Hasselmann has tried every variety of substitute to milk in the rearing and fattening of calves, and considers substitutes are of little utility, but often quite the contrary, as they can prove a danger.

To prevent stakes, employed to sustain young fruit trees from rotting, prepare a mixture of two parts of coal ashes, and one of quicklime; place some in the hole for the stake, and ram more round the latter when in position. To protect young plantations from being injured by game, as deer, etc., add to one part of coal-tar—to correct corrosiveness—two of cow dung and one of wine. Apply the mixture carefully in the middle of October.

ECONOMY IN WORKING TEA ESTATES.

Economical working of tea estates is now securing the best attention of all parties who are in any way interested in tea, and year by year more clearly goes to prove that it is only a survival of the fittest man, *viz.*, the cheapest worker. Some ten or twelve years ago anyone who had failed for every other profession in life was considered quite good enough for tea. Things are vastly changed now, in a few years' time, and though interest is yet strong enough to procure men billets in tea, it is, generally speaking, in subordinate positions such as assistantships; and it only requires time to do away with this also. Men all the world over can afford to be generous as long as their purse-strings are not brought into play; but when that takes place, it is wonderful how soon the sense of their own rights makes itself apparent.

What is required of a man to make a good manager is, in the first place, a liberal education; and, in the second place, sufficient good sense in his composition to apply his knowledge. The *Madras Times*, I notice, advises a Planter's College being started for young men to undergo a course of agricultural training. This may seem to recommend itself to some people, but I am inclined to look at the suggestion as a purely theoretical one, and unsuitable to practical working, for a few of the following reasons:—First, an education of two years in an agricultural college in this country would require that each student should have a certain amount of means to pay for his fees and maintenance; and this in itself would be a difficulty to at least nine-tenths of young intending planters. Second, taking it for granted that a young man has passed his examinations and got his diploma, would any proprietor or agent be prepared to give him the management of an estate, or would he be required to serve an apprenticeship? If the latter, would he be of any use on an estate? Or, would he not be rather a hindrance? Would it not be a case of "A little knowledge is a dangerous thing?" If my opinion be worth anything, I should say it would pay a manager far better to make such an intending assistant an allowance to keep off the estate. When a youngster comes out, it is far and away the kindest thing to keep him to his work and teach him all work in the estate, even to the keeping of accounts, and by so educating him make him a useful man, who, when his agreement is up, will be in a position to take charge of an estate. When work is slack, encourage him to take leave and thoroughly enjoy himself, and you will by so doing make a good man of nine out of every ten young fellows coming out, and the youngster will think the boss not such a bad chap after all, "though, by Jove, how he does make you work when there is work going!"

This way of educating young men coming out has been the exception. Had it been otherwise, there would not have been so many failures when young fellows got the management of a garden. The old style of manager, the typical jolly good fellow, who used to be off his garden just as often as he very well liked, left the garden to his Native establishment to work, and provided he had a smart English writer, he did positively nothing but sign his name to accounts as rendered by his factotum the Baboo, and with such men as it is to be wondered at, that when prices came down, gardens, instead of being in the position to proclaim a dividend, had a call for assessment? How were these matters represented to proprietors? Sometimes short rainfall, mosquito bight, and bad seed blamed; and when this began not to go down with proprietors,

agents recommended a change of management, the chances being that the incoming manager was quite as big a duffer as the man he relieved. As likely as not, they exchanged billets.

A Native establishment is most essential to a garden, but a manager must be wide awake, and not allow himself to be swindled; and to do so, he requires to know the Native character well, and to study and also to know the value of money, and how and where to spend money. A few examples of different styles of working may better show how one man works expensively and another man economically. One planter finds he requires a number of new lines, as well as to do a lot of repairs to buildings in the cold season. He has a good labour force. Well, he picks out 10, 20, or 30 good coolies for this work, and puts a sirdar over them, and from time to time supervises all their works, and allows of no scamping. Or again, perhaps he is short-handed: he then gets in Bengali contractors to do the work, arranges rates, and if he be a man of any experience, he will know what the different kinds of work should cost, and not allow his Baboo to pocket "feesh" in the barefaced manner a garden Baboo is accustomed to do; and then sees all the work measured up, as well as seeing that work done is good, and not allow the contractor to build and repair so that his services will be required the following reason. Another planter calls up his factotum the Baboo: "Well, Baboo, any building or repairs necessary?" With the usual result that it is all left to the Baboo, who, from past experience of his manager, knows to a nicety to what extent he can bleed him. In consequence, the estate pays the piper. Baboo shuts his eyes to all bad and scamped work the contractor does, divides the spoil, and arranges for a similar campaign the coming season. This sort of thing goes on year after year on the second man's garden, whilst the other, with a little personal supervision, saves all this.

How is it to be accounted for that one garden locally manufactures for 4 annas and the neighbouring garden requires 5 annas? I will explain it. There is a very prevalent idea ruling amongst managers and agents, that a large yield can be manipulated cheaper than a very small one. This is all very good and well, but there is no earthly reason why a little more saving and care should not be exercised on a poor estate, and this is where the shoe pinches. A manager who has always had an assistant is inclined to think he cannot do without one, and if agents deprive him of his assistant, he increases his Native establishment, though by what right he does so I do not very well see. Locally, with care, teas cannot, and ought not, no matter how small the yield, to cost more than 3 annas 6 pie; and given that as the maximum cost per pound, good estates should be able, if deemed necessary, to work under it. I mean a good estate, where it is allowable to have a fairly large establishment. A poor, worn-out estate cannot be expected to claim this as a right. The fact that some managers object to do their accounts and writing is surely no concern of the estate, as long as the English writer employed is paid by the manager; but on a poor estate, on which large sums of money have been expended, proprietors have a right to dictate what is allowable and what is not; and when this is more generally acknowledged enconomical working will be the order of the day, and not the exception. Local expenditures have been now brought down considerably, and what we want to see is Calcutta expenditure also brought down. One anna a pound, or five rupees a maund, should be the limit of Calcutta expenditure. That matters are tending this way there can be no doubt. Competition for agencies is strong enough now-a-days to insure economy.—*Indian Planters' Gazette.*

AGRICULTURE IN BENGAL.

The Second Annual Report of the Agricultural Department of Bengal though dealing with a period of only eight months, records progress in many useful experiments which, if carried on long enough must prove of great value to the country. Warned, however, by the want of continuity in agricultural experiments in Madras it is not easy to feel convinced that any series of experiments not leading to immediate results will long be allowed to continue. An important part of the work of the Director is the organization and maintenance of village records, including the supervision of surveys, and the preparation of records of right. The cadastral survey is similar to that carried on in Madras by the Revenue Survey, but the greater part of the work was stopped by order of the Secretary of State and, for the present, the survey and record are to be confined to estates which are the property of Government, or on which those interested offer to pay for the advantages of a settlement. As things now stand it was found that in the great majority of villages in the Mozufferpore district much uncertainty prevailed as to the existing rent, and the ryots appreciated the work of settlement in spite of attempts made to deceive them by interested parties. The survey actually enhanced the value of the ryots' holdings as has been shown in some sales that have taken place in settled villages, so when the survey was stopped the ryots in some cases even offered to pay for the continuance of the work. The cost of the cadastral survey is reported to have been only about 6½ annas per acre. The amount of survey actually completed was not very great, still the results obtained would probably not differ greatly for the rest of Behar. If this be so there is certainly not much room for the expansion of agricultural operations in that district, though there may be ample room for improvement. From the statistics of the 235 villages of which the final record has been published it appears that 78 per cent. of the whole area is under cultivation. Of the remaining 22 per cent., which is returned as uncultivated, 3 per cent. is rent-paying land under thatching grass, 5·3 per cent. is under orchards, and 7 per cent. is unfit for cultivation, so that only 6·7 per cent. of the whole area included in these villages is left for pasture land, and most of this is of an inferior quality. The average rental per acre is a little over Rs. 3. This Mr. Finucane believes to be higher than for any other province in India, when account is taken of the fact that this is the average for the whole rent-paying area "which, as all culturable land has been brought under cultivation, includes land of the most inferior descriptions, while the average of other provinces is struck on only the comparatively small percentage of the entire area brought under cultivation, in which land of the most inferior qualities is not included."

The subject of the reclamation of lands impregnated with saline substances does not concern Bengal so much as some other provinces, still there are considerable areas in Behar which are rendered unfit for cultivation by excess of salts. Experiments on these are now being made in accordance with a plan found to be very successful by Mr. Maries, the Superintendent of the Maharajah of Durbhunga's Gardens. He dug up the soil to a depth of two feet, and then planted it thickly with trees which had been thoroughly established in pots before planting out. The trees which he found most successful were *Inga Saman* (rain tree), and *Albizzia Procera*. In three years the ground was completely filled with roots, and the salt was to all appearance gone. It is probable that salt lands on a large scale are best treated by drainage, but it is not always possible to apply that cure, while the planting of suitable trees is a comparatively easy matter.

The interest caused by Dr. Bonavia's book "The Date-palm in India" led to attempts being made to introduce the cultivation of the tree in the Patna, Burdwan, Orissa, and Bhagulpore, but the results were everywhere unsatisfactory. Probably the climate of Bengal is too damp for this plant of the desert. The experiments made in Madras have been much more satisfactory, for in the review of

last year's forest report the Government observed that "the successful cultivation of this valuable palm in this Presidency is now placed beyond the region of experiment, and extended operations may be undertaken without further delay." A subject of much interest in Bengal is the eradication of the disease amongst silk-worms. Various causes have led to the decline of the Bengal silk industry, but the most potent one is the spread amongst the worms of a disease known to the rearers at *Kata*, and pronounced to be identical with *pébrine*, the disease which has done so much injury in the south of Europe in recent years. Mr. Wood-Mason and Baboo Nitya Gopal Mookerjee, a distinguished Cirencester graduate, were deputed to investigate the question, and decided to introduce the Pasteur system of micro-copically examining the moths intended for seed, and rejecting the eggs of those that were diseased; and the introduction of healthy conditions in the rearing of cocoons—that is, fresh air, cleanliness, plenty of space, and exercise, all of which are ignored by the rearers in the existing system. Mr. Mookerjee has brought up three experimental crops in accordance with this system, and believes that he has eradicated the disease from his stock of silk worms. The native rearers show a preference for the seed raised by him, and incurred the expense of buying at his advice untainted mulberry leaves at a high price so as to avoid using the tainted leaves in their own possession. It is now intended to send Mr. Mookerjee to Paris to study the disease under M. Pasteur.

The more strictly agricultural experiments made in Bengal are of comparitively little practical interest here. A large series of experiments were made on manures with very varying results. The great effect of bone dust on certain corps especially on potatoes was clearly shown, and by nothing more strongly than by the anxiety of the ryots, among whom it had been distributed gratis last year, to obtain a supply. The attempt to introduce improved agricultural implements into Bengal have not been very successful. An iron plough costing even so little as Rs. 6 is found to be too expensive, and attempts are being made to introduce a very cheap form, which looks very much like an ordinary ryot's plough but has a good wrought iron share. Ploughs which invert the soil are not found to be satisfactory, since the ordinary bullocks are not strong enough to draw them, and they cannot be used in paddy cultivation. Special attention is called to the subject of improving the breed of cattle by inducing the Zemindars to take an interest in the matter and import some good bulls. Even isolated efforts can do much good in this direction, as is shown by the fact that the improvement effected about Patna by Mr. Taylor when Commissioner there, by introducing one or two good English bulls, is still strongly marked in that district.—*Madras Mail*.

THE LIME.

Its Culture in the West Indies.

[By H. A. Alford Nicholls, M. D., F. L. S. for Antigua Churchman.]

The lime tree is not a native of the West Indies. It is believed to have come originally from the south of India, and to be closely allied to, if not descended from the citron. The tree was introduced into this part of the New World by the Spaniards about the beginning of the seventeenth century, and it quickly became naturalized in the West Indian Islands. Atwood, in history of Dominica, published in 1771, mentions that limes were exported from Dominica to the neighbouring islands as well as to Europe and this fact is deserving of special notice, inasmuch as it is the earliest recorded instance of a fruit trade between the West Indies and the Mother Country.

The lime fruit is now, however, principally grown for the sake of its juice which is exported from Dominica and Montserrat in a concentrated form, and from these two islands—as well as from Jamaica and Trinidad—it is sent to Europe and the United States in its natural or "raw" state. The concentrated juice is the source of a considerable portion of the citric acid used in medicine and the arts, and the natural fruit juice is bottled up and sold in Europe and America as a refreshing and wholesome beverage. It is also used as an antiscorbutic—*i. e.* to prevent the outbreak of scurvey on board ships—and all English vessels leaving Great Britain for long voyages are bound to have a good supply of lime juice on board. The spread of temperate habits among many of the nations of the world is calculated to increase the demand for the juice of the lime, for it makes a most grateful and perfectly innocuous drink in hot weather, and indeed at any time. A sip of lemonade made from pure lime juice, allays better perhaps than anything else the raging thirst of fever, and many distinguished medical men recommend a decoction of the lime as a very efficient febrifuge.

The cultivation of the tree is very simple, and the plants are raised without difficulty from seed, and they are usually of a very hardy nature. They are planted at distances of from twelve to twenty feet from each other, but, of course, the fertility of the soil has a great deal to do with the distances. In poor and dry lands, and on steep hill-sides where the trees do not grow very large, the proper distances would be from twelve to fifteen feet, but in rich flat lands twenty feet may be even too close.

In very windy places it is advisable to plant shelter belts of trees at distances of about two hundred feet. Pois doux (*Inglaurima*), Bois immortelle (*Erythrina velutina*) and Galba (*Calophyllum Calaba*) are about the best kinds of trees for these shelter belts, but fast-growing indigenous trees may be and are used, care being taked to select those not liable to be broken by strong gusts of wind.

In poor soil it is necessary to hole the land; that is, holes two feet square and two feet deep should be dug at the proper distances, and left open for a few weeks in order that the soil may be thoroughly oxygenated. In filling up, none of the soil taken out is to be put back, for the holes should be refilled with weeds and surface earth from the vicinity, and some manure may be put in with advantage. The earth should be raised in a mound where the hole was; for no matter how well the filling process may have been done there will always be a subsidence of the soil, and the young lime plant will then be left growing in a hole—which is a thing to be carefully avoided.

When planted in good land and kept free from weeds, the lime trees will commence to bear in about three years from the time of planting; and as the plants are generally about a year old before they are put out into the field, this gives four years from the planting of the seed to the first bearing. Full crops cannot, however, be expected before the plants are seven or eight years old; and in poor soil, it will take a long time for the planter to get anything like a return out of the estate. In some parts of Dominica the lime trees grow so luxuriantly and so quickly that a good crop may be expected in about five years from the time of planting or even earlier—but this is of course exceptional and only occurs in places where forest land has been opened up, or where the system of holing has been properly carried out.

The yield per tree of course varies considerably, according to soil, rainfall and climate; but with careful cultivation, a fair average soil, and a rainfall of about 60 inches per annum, from three hundred a barrel of lime can be reckoned on from each tree planted at the wider distances.

In Dominica the flowering usually begins in March, and the crop commences in June or July, and continues to December.

But a few limes may be gathered all the year round, except at the end of the dry season during which time the trees are practically at rest.

The limes ought not to be picked off the trees. They should be allowed to fall to the ground and in this way one can only be sure of getting the fruit when it is in the best condition for obtaining the juice. The work of gathering the limes is usually done by women and children who are paid from three pence to four pence

per barrel during crop time, and they receive higher rates when the limes on the ground are few and far between. The juice is extracted in various ways, but the process of squeezing underlies them all. Cider presses are used in some places, and the small sugar mills have been utilized in others. The best form of mill is perhaps one made with heavy horizontal wooden rollers covered with sheets of copper roughly perforated so as to catch the limes. With a good press or mill, from seven to eight gallons of juice can be obtained from every barrel of limes.

When the juice is exported in its raw state it is necessary to take particular precaution to exclude all dirt, fruit-pulp and seeds. If the limes be gathered in rainy weather, the mud must be washed off them before they are pressed in the mill, and it is as well to strain the juice through several copper sieves with meshes of decreasing size. Another good plan is to allow the juice to remain in puncheons or casks with a tap put in about ten inches from the bottom. The juice will then "settle," the seeds and the heavier part of the pulp falling to the bottom, the oil and other impurities rising to the top. The juice can be drawn off in three or four days, and it is allowed to run as long as it is clear. The casks in which the juice is exported must be completely filled to exclude the air, and they should be bunged up as soon as possible. If the system be adopted, the juice will remain in good condition for some months. When it is necessary to keep it for a long time, half an ounce of salicylic acid can be added to every fifty gallons of juice, the acid preventing the fermentation and consequent destruction of the product. It may be remarked that the salicylic acid will not interfere in any way with the wholesomeness of the juice.

Concentrated lime juice is prepared very simply by evaporation in open copper pans until the required density is obtained. In Dominica the juice is usually boiled down from 10 or 12 to 1—the resulting product being a very acid stuff, about the color and consistency of molasses. The concentrated juice is sold in London or the United States, and is usually shipped in beer hogsheads, averaging about fifty-two gallons in capacity. The price varies very much, a hogshead of juice at the higher concentration sometimes selling for about £13 and sometimes—but far less frequently—for nearly double that some. The demand for citric acid is increasing, but so is cultivation of the lime, and it is feared by many planters that before long there will be an over-production, and a consequent heavy decline in the value of the juice. It is to be hoped, however, that this will not take place, for Dominica and Montserrat would suffer very seriously if lime cultivation became unremunerative.—*Florida Dispatch.*

MADRAS AGRI-HORTICULTURAL SOCIETY.

ANNUAL MEETING.

ECONOMIC PLANTS.—The grievous depression amongst the planting community of Southern India mentioned last year unhappily still continues and paralyses private enterprise in the direction of new introductions. The stock of such plants is, however, still kept up in the Society's Nurseries in hopes of better times reviving the demand. Numbers of Maragogipe Coffee, Erythroxylon, Coca, Lance-wood, Mahogany, Landolphia, Trincomalee-wood, Edible Prickly-Pear, and other useful plants are still available.

CHOCOLATE.—The large tree of Theobroma Cacao of which mention has more than once been made in the Committee's Annual Report as flourishing and bearing fruit under the shade of the Cocoanut Palms, succumbed to the drought, but another plant a year or two younger growing near it not only survived, but seemed not to suffer. The old plant was isolated in the grass, so had no protection but the shade overhead, and got only such water as was given to it directly by hand; while the survivor is in the new border closely surrounded, sheltered, and shaded by the Cocoanut Palms and the young trees and shrubs in the border, and got the full benefit of the periodical floodings of the border. The Honorary Secretary is still of opinion that the cultivation of Cocoa might very possibly be successful in Madras if the cultivators would take the same trouble as the growers of the Betel-leaf do in Bengal, to shade, shelter, and irrigate their crop.

RUBBER PLANTS.—The *Landolphia* plant mentioned in last report successfully ripened its crop of fruit, and from the seeds Mr. Gleeson raised about 80 plants which were in due course placed at the disposal of Government for future experiments. Orders have been issued to various officers to take over the plants and try them in climates and situations which are expected to be favourable to their growth and development. The Castilloa elastica plants mentioned in last report still thrive.

BREAD-FRUIT.—A batch of root-cuttings of the tree which bears the seedless bread-fruit was obtained through the kind offices of Mr. Logan, the collector of Malabar, and the Superintendent hopes to raise from them a few good plants. A large, rooted plant was also obtained by Mr. Robinson, the Chief Engineer of the Madras Railway, from the Western Coast, presented to the Society, and planted at once in the cocoanut tope where it is showing great promise. Two other fine plants are thriving, planted out in the gardens, one having been presented by Mr. Lovery, and one being the survivor of a number received from Dr. Trimen, Ceylon. The Committee is informed that Mr. Lovery has interested several of the wealthy Brahmins living in and about Malapore in the subject; the produce of the tree being specially suited to the needs of their community. The Society is of course willing, and anxious, to do its best to obtain plants from Ceylon or the Western Coast, for every one who is prepared to pay the cost which should not come to more for each plant than that of a young, grafted mango.

TREE TOMATO.—The Committee still hears frequently from the hills of the great success of its introduction, thanks to Mr. Morris of Jamaica, of Cyphomandra betacea. Unfortunately the plant will not grow on the plains, but in the cooler climates of Southern India, it is an unqualified success, and its popularity continues to increase. Happily its fecundity is so great that the Society has no difficulty in complying with demands for seed by applying to some of its correspondents in more favoured localities.

PRICKLY-PEAR.—A few enquires have been made during the year for plants of the Edible Opuntias introduced from Cyprus and Malta, but no report has yet been received of their success. In the Society's Gardens, plants of both are well established and growing freely, but have not yet fruited or even produced perfect flowers by which they could be identified. The Society's collection of *Cactaceæ* has been greatly enlarged by gifts from Poona, Calcutta, and elsewhere during the year, and it is hoped that progress may shortly be made in naming them all correctly; but, with the exception of the naturalised species, and two or three others, plants of this order do not appear to flower freely in the climate of Madras. Interesting information is now being collected on the subject of the local distribution of naturalised species.

CARLUDOVICA PALMATA.—In August, 1887, three plants of this palm were received in a Wardian case from Dr. Henry Trimen, Director, Royal Botanic Gardens, Ceylon. Two of them unfortunately died, but the third promises to grow well, and is now five or six times as large as they were when they arrived.

PARITIUM ELATUM.—(The Mountain Mahoe) seeds of this plant were received from Kew, on the 19th July, 1884 from which a few plants have been raised. Two of them have been planted in the new border in the coconut tope where one of them is very promising, being now about 23 feet, 9 inches high, and 9 inches in girth, and 3 feet from the ground. It is stated in the Treasury of Botany, 2nd Edition (page 847), that this plant "affords the beautiful lace-like inner bark called Cuba bast, at one time only known as a material used for tying round bundles of genuine Havannah Cigars, but afterwards imported, particularly during the Russian War, as a substitute for the Russia bast used by gardeners for tying up

plants; it is now largely substituted by other materials. The tree, which is found only in Cuba and Jamaica, grows fifty or sixty feet high, and yields a peculiar greenish blue timber, highly valued by the Jamaica cabinet makers."

MORINGA.—A species of this tree M. Pterygosperma Gaertn., is well known to Anglo-Indians as the producer of the "horse radish" used on the plains, and less generally as the supplier of the main constituent of "Drumstick curry." There is another representative of the family with finer and more beautiful foliage in the Gardens, where it has stood, a solitary specimen, for many years, without flowering. Interest was excited in the subject by "The Kew Bulletin" which, in its first number mentioned another species which produced a tuberous root, reported to grow, and be valued as food by the Arabs, in the Desert. The Honorary Secretary wrote to the Director of the Royal Gardens, Kew, on the subject, who kindly sent the Society, in May last three roots which he described as "in the resting stage." One of these roots was destroyed by insects and the other two sent out feeble shoots; the first to shoot dried up altogether, and the third is again dormant. From the account given of this plant it would probably be a very valuable introduction.

FRUIT TREES.—As in most years the Society has complied with considerable orders for grafted mango plants, but has recently set on foot enquiries as to the possibility of obtaining by selection and grafting, or from seed, ripe mango fruits, all the year round. So far as the information received goes, this most desirable state of things seems to be not only possible, but even easily attainable, by any one who can expend the necessary capital and spare the time to await results. The introduction and establishing of the Date of Commerce as grown in Tunis, Arabia, Persia, and elsewhere, has been warmly taken up by Government and large quantities of seeds and off-sets imported. The subject of the growing of oranges and lemons and their present distribution in India, has been again under consideration during the past year, though there was never any doubt of the feasibility and desirability of the proposals made. Several species of the Order Aurantiaceæ are indigenous in the jungles of Southern India, and probably climate and soil suitable to every member of the family could readily be found within the limits of the Presidency if the inhabitants possessed the energy and capital required to grow and carry them to market.

LANCEWOOD.—No information has been received from the Forest Department or the Government Botanist as to their success, or otherwise with the 74 young plants of Oxandra virgata handed over to Government, of which mention was made in last report, but four remaining in the Gardens look well.

DENDE.—One of the specimens of this tree seeds of which were received from Kew, on 19th July 1881, planted out in the new border in the coconut tope and mentioned in last year's report is like many of its neighbours of other species growing splendidly. It is over 24 feet high, and girths twelve inches and a half at three feet from the ground. It is a very handsome and umbrageous tree in leaf and habit not unlike a Scotch Elm, and promises to be a very valuable introduction being the Fustic Dyewood (Chlorophora tinctoria) of the West Indies.

AVENUE TREES.—As usual, the Society raised and distributed large numbers of shade-giving trees for avenues, and to replace the destroyed Forests of the Coffee Districts. The Kigelia, the Rain Tree, and the Cluteria continue to be the favourites, but a large supply of Albizzia stipulata was on special application got through the Conservator of Forests for a firm of coffee planters on the Western Coast. What the Rain tree (Pithecolobium or Inga Saman) is capable of doing in the way of growth, requires to be seen to be believed. Some careful measurements of the great tree in the gardens are recorded in the Proceedings of 4th May, last, from which it appears, though it shrunk a little in the dry weather, to have increased in girth during the later months of the year 1884, about half an inch a month, and in December, after the rains, a full inch. On 30th July, 1881, it measured 6 feet, 3 inches, at 3 feet high, and 5 feet, 9 inches at 5 feet, with a spread of 85 feet from North to South, and an height of 46 feet. On 21st April last, it measured 8 feet, 8 inches, at 3 feet from the ground, and 8 feet, 1 inch, at 5 feet, with a spread of 88 feet from North to South, and 97 feet from East to West, and a height of about 58 feet. It is now 23rd March, 1888 at 3 feet high, 8 feet, 11½ inches, at 5 feet, 8 feet, 3 inches, with a spread from North to South of 92 feet and East to West of 191 feet, and a height of about 60 feet. In August 1878 when the tree was said to be under six years old, it measured 4 feet, 1 inch, at 3 feet from the ground, so that in ten years, a tree now only 16 years old, has much more than doubled its girth; the increase at the ground being from 5 feet 5 inches in 1868, to 12 feet on 21st April, 1887. That the growth of this tree is not abnormal, is proved by an inspection of the survivors of a complete avenue of Rain Trees planted by Mr. Burrows, in the end of 1878, when he was President of the Madras Municipal Commission, along Nungumbaukum High Road; though it is sad to think what an avenue Madras would now have if the officers in charge had done their duty and protected the young tree from the wheels of carts and the horns of cattle. From the North of India, we here that the planting of the Rain Tree has been tried with success on barren land poisoned by salt and alkaline efflorescence. The following is an extract from the "Tropical Agriculturist" of December 1st, 1887, page 406:—"The Guango or Rain Tree (Pithecolobium Saman) is a native of Brazil and Venezuela. It is fast growing and ornamental, and very suitable for open spaces. It is so much desired in India that in 1880, the Jamaica Botanical Department sent 30 lb. weight of seed. Dr. King, the Government Botanist, in Calcutta, says of it:—"This wonderful tree grows faster than any hitherto introduced into Bengal with the single exception of Casuarina. It gives a beautiful shade and yields a pod with a sweet pulp which a greedily eaten by cattle. For avenues, contonments, squares, and situations where dense shade is wanted, no tree is more suitable than this." The Society has applications for large quantities of seed of the Rain Tree for the current season, including one of 20 lb. from Bengal. At the suggestion of Colonel Cox and by the kindness of Mr. Peake the Forest Officer, stationed in South Canara, the Society obtained a quantity of seed of Vateria Indica said to form in that part of India avenues unequalled anywhere, from which a fine batch of young plants has been raised. This tree is at present exciting much interest as the alleged producer of "Piney Tallow," but as the name of Callophyllum inophyllum which is extensively planted in Tanjore, and used in Travancore, to produce lamp oil, is to any ordinary ear exactly the same in Tamil as that of Vateria Indica in Malyalum, there is room for confusion and error.

INGA DULCIS.—As usual the Society has sent on application to Ceylon, Penang, and all parts of India, particularly the North, large quantities of this invaluable and most versatile tree. It is probably, the most universally cultivated tree in Madras, being as general for hedging, and nearly as good, as the Hawthorn in England. It bears any amount of clipping and chopping, or worse, nibbling by sheep and goats and gnawing by horses and cattle. If attended to, it forms an impassible fence; if neglected, grows into a noble "Bullfinch." It sows itself and grows on all waste land, and that even with its roots in salt or brackish water. Single or surviving [illegible] grow into grand timber trees. The timber is used by the [illegible] man for cart building [illegible] created by the bite [illegible] furnish a never [illegible] stricken feeder of [illegible] scramble for the [illegible] and in the hot weather [illegible] be eatable, the hungry cattle eagerly devour the tough outer pods.

SEEDS FOR THE BANKS OF THE SUEZ CANAL.—On the introduction and recommendation of Mr. Gregg, the Society supplied to Captain Symons of the P. & O.

Steamship "Pekin," two large collections of seeds specially sellected as likely to grow in sandy soil without the very best and sweetest of water. Lists of the seeds supplied will be found in the Monthly Proceedings.

CASUARINA MURICATA, ROXB.—Experiments and enquiries are now on foot to ascertain and bring to notice the value of this tree as a producer of timber useful for building purposes, pavement, and other economic uses, as it seems positively wicked to chop up trees a hundred feet high, straight as a dart, and girthing at breast height five or six feet, for fuel, which is practically the sole use to which they are now put. Mr. Chisholm, the late Consulting Architect to Government, has spoken very highly of the timber for building purposes; and Mr. Thorowgood, the Engineer of the Madras harbour works is now making experiments with it for the pavement of level-crosssings over the Beach Railway. Mr. Thorowgood's experiments are yet in their infancy, but it is believed that the traffic will prevent the white-ants, the bane of woodwork in the tropics, from doing much mischief, and that the cement in which the blocks are set will prevent warping, to which this wood, being immature, is specially liable. Should the trial be a success, it may be expected to revolutionize the dusty thorough fares of Madras.

From a paper entitled "A description of wood and Asphalt, as used for the pavement of streets in Cities and Towns" read on 7th April, 1886, before the Institution of Civil Engineers of Ireland, at Dublin, by Mr. Parke Neville, and published in "The Universal Engineer" of 24th April, 1886, we learn that about two dozen different wood pavements have been tried in the City of London, and that the average life of the pavement in streets carrying the heaviest traffic was 9 years, at a cost of two shillings and seven pence half-penny per square yard. On 29th April, 1879, papers were read before the Institute of Civil Engineers, which, amongst other facts, demonstrated that hard, tough wood should be selected to creasote, creasoted beech pavement on Sunderland Bridge having worn less in fourteen years than granite sets in four years; that it is an absolute necessity for wood pavement that it should have a thoroughly good concrete foundation; and that the cost of maintaining wood pavement to get seven years life from it is one-eighth and of scavenging one-sixth of Macadam. With such facts before us, there can be no doubt of the advantages of wood pavement generally, and there appears to be every probability that Casuarina timber will, on fair trial, be ascertained to be specially well suited for the purpose. The planting of the tree on a large scale has been practiced for so short a time, and the wood has been so much used in an unmatured state for fuel, that comparatively little mature timber has been handled; but in hardness, toughness, density, and specific gravity, it is almost unrivalled. Hard wood is scarce and costly in Europe, and if it should appear on experience that Casuarina wood is equal to or better than other woods in use, Madras has in her hands, a source of almost incalculable wealth. Another reason why experiments which may lead to the retention of growing trees till they reach something like mature age should be pressed and encouraged, is that the price of Casuarina wood for fuel has fallen during the last fifteen months nearly thirty per cent.; large plantations in the market can find no purchasers, and petty owners are grubbing up their young tree to realise before the price falls still lower, without any intention of replanting. Should large clearances be made followed by the abandonment of the fuel planting enterprize, the result may be disastrous. The indigenous and established sand-binding plants have been smothered by the Casuarina trees, and the consequence of the removal of the latter can only be the transformation of, at a moderate estimate, fifty miles of Coast line North and South of Madras, metamorphosed in the last twenty years into fine forest, into a chain of bare and blowing sand-dunes, the inland edges overlaping and hopelessly destroying the cultivated land, while those on the seaside contribute a liberal quota to the already surcharged streams which threaten to choke the new harbour. The fall in the price of firewood was the immediate result of a glut in the market caused by the Cyclone of 9th November, 1886, intensified by the bringing in of vast numbers of trees killed by the drought in the early part of 1887, but it is not unlikely to continue from the expected introduction of cheap coal from the Singareni coal fields.

UPPER BURMA.—In addition to the usual flower and vegetable seeds furnished on indent to the military authorities for the use of our troops, a large quantity of seed potatoes was applied for and sent to Upper Burma. From accounts received privately, large areas of the country are likely to prove suitable for the growth of potatoes and other English vegetables.

NATAL.—The Society's interchange of plants with Natal has been much restricted by the rigid enforcement of the rules of the Emigration Department, the commanders of ships not being allowed to take up the space on deck with plant cases. Captain Reeves, however, continues to persevere in his good work of distributing useful plants, carrying a few each voyage in his private cabin. He has now been forced however to turn his attention more to seeds, and during the past year carried to Natal a quantity of Black Pepper seed obtained on his application from Travancore and the Western Coast.

JAPAN CLOVER.—This plant, Lespedeza striata, so strongly recommended by, and received by the Society from Dr. Schomburgk, the distinguished Botanist in charge of the gardens at Adelaide, has not succeeded. The plant is said to furnish a very valuable bite for stock in the hot season on the Californian plains, and may be worthy of further trial, especially as the seed is observed to be quoted at a not unreasonable price in the catalogue of one of the leading firms of Seedsmen in England.

TEFF.—A quantity of seed of Eragrostis abyssinica, an African cereal, was received from Kew, sown in the gardens, and distributed. The plant grew well both in Madras and on the hills, and certainly flowered, but the ears did not seem to fill, in Madras at least. The grain is very small, and though the value of the plant for both grain and forage is undoubted, it is not likely to claim a share in the attention of the native cultivator who is too poor to grow anything for forage, or to risk any doubtful experiment, and already possesses Cholum, Raggy, and Paddy, which, in good seasons, grow and produce a thousand fold with little more labour and attention than that required to plough the land and sow the seed.

ENSILAGE OF MEADOW GRASS.—M. Emile Mer has just completed a careful study of all the methods employed for preserving forage. The following are the conclusions he has published.—1. The grass ensiled fresh cannot be consumed sufficiently rapidly to make good forage, because it is already sour after the first fermentation. 2. When it is ensiled half faded, the process of turning sour is sufficiently slow to admit of waiting some months; but in order to utilize it when it is still partly in the state of sweet ensilage, it should still be eaten as quickly as possible, that is, when the mass has cooled and the settling down ceased.—3 Forage ensiled fresh cannot be preserved from one year to another and probably it would be the same with grass ensiled after being dried.—4. Putting into the silo should be proceeded with very carefully when the forage is partially withered because it more easily moulds, either because the settlement being more difficult, the air has more access or because it contains more air from having commenced to wither. For these reasons the cover should be thicker.—5. The consumption of sour ensilage is very bad for cattle even when given in small quantities and with other food. Sweet ensilage mixed with hay, in equal parts, has not this defect. The author adds: It is undoubtedly preferable to be able to ensile freshly cut forage even if cut after rain as was latterly believed possible, but as the advantages of the system of ensilage are far from being so brillant as has been supposed, it is doubtful whether it can ever be of any service.—*Universal Press Association.*

COFFEE CROPS AND PLANTING IN COORG, S. INDIA.

(From our Correspondent.)

MERCARA, 10th May.—I promised to let you know about crops in Coorg. Both the plantation and native crop has turned out equal to estimate, being somewhat above the average. The total plantation is about .. .. .. Tons 4,500
Native .. .. .. ,, 2,000

Altogether .. .. ,, 6,500

Few planters took advantage of the high prices ruling in September and October to sell for forward delivery; so then crops, which are now arriving in the London market, are selling at some 20 per cent below the figures then obtainable. The rates now ruling, however, will pay very well, seeing the crop was good and the working of estates is carried on more economically nowadays; shade also, with which almost every estate is now covered, has secured them against any serious injury from leaf disease or borer. The prospects for next crop are anything but satisfactory, the blossom showers having fallen very irregularly. Only in a few localities has there been sufficient. Over a large area it has not been enough for a fair blossom, and where it has been its effect has been impaired by the intervals between the showers. Good rains within the next week might improve matters, but the minds of most are made up for a poor crop.

The recent high prices combined with successful cultivation over the district generally has led to the opening of new land, and it is said that as much as 3,000 acres will be planted up this monsoon.

GOLD IN THE SOUTHERN PROVINCE.

(From a Correspondent.)

I understand the arachchi who found the gold in the Morawak Korale came in to Galle on Monday, bringing his finds, and showed them to the Government Agent and others. He had about 4 lb. in weight of gold, the biggest piece weighing about 5 sovereigns, or say 12½ pagodas, worth about R50 intrinsically. The Government Agent has, I hear, secured this for the Museum. The arachchi declares that very little has been found, besides what he has in his possession, and he has sold *none*. He adds that for many years they have, when gemming, come on what he now finds is gold, but threw it away, under the impression it was *diyaratran* (literally water-gold—? pyrites). The arachchi states that he dug his all out of a gemming allotment of half an acre, but that it will *not* pay to look for gold alone; the gems pay the expenses of working and the gold is profit, but you cannot rely on finding it. He states that Mr. Armitage found little or nothing, nor has Mr. Dominico.

It is reported here, that Mr. Armitage was of opinion that it would not pay to work the alluvial deposit on which the arachchi states he found his gold, but that he thought the neighbourhood should be thoroughly prospected, as more has been found here than in any other part of Ceylon.

THE DEBATE ON THE TEA DUTIES

embodied so much that is interesting, including Mr. Goschen's expressed hope to be able to reduce the rate, that we give the detailed report from the London *Times*:

On Clause 2, which imposes a duty of 6d per lb on tea,

Mr. PICTON moved to leave out the clause. He pointed out that whenever a reduction of the duty had been made it had always been followed by an increased consumption of tea. A wise commercial policy had converted tea from an article of luxury into a necessary of life, and his main objection to the continuance of the duty was that it was burdensome to the poor. Many people had to be content if they could get during the day a few pieces of bread and butter and a cup or two of tea, and when they had to live on so little it became a positive cruelty to take 6d for every pound of tea that they consumed. (Hear, hear.) It was estimated that from one-half to two-thirds of the tea used in this country was used by the labouring classes, and this showed how much the tax on tea was a tax on a necessary of life, and therefore a tax which must tend to depress the standard of comfort among the labouring classes. The tax on tea was to a considerable extent a hindrance to the progress of temperance. People could not yet get a cup of good tea as cheaply and as easily as they ought to do, and in many parts of the country it was still far more easy to get alcoholic drinks than it was to get a cup of tea. The continuance of the tea duty was a hindrance to the expansion of our commerce, and particularly with India, which was now competing with China in the export of tea to Europe. We had compelled India to give up duties on British manufactures; and it was only right that we should show a little one reciprocity by giving up the sixpenny duty on tea. (Hear, hear.) The continuance of the duty was absolutely inconsistent with all sound principles of taxation; it was bleeding industry just when it needed strength. While reality and realized personalty did not bear as much as it ought to do of the burden of taxation, we were not justified in imposing such burdens upon labour in times of peace. For times of war there were such things as war taxes which people paid readily to satiate their savage passions. (Hear, hear.) It would be a good thing to show them that labour escaped certain taxes in time of peace. It was the business of the Chancellor of the Exchequer to find a substitute for the tea duty if it were given up; but money might be found by retrenchment and also by the rectification of the death duties, the reform of which would greatly strengthen our resources. He moved the omission of the clause.

Mr. H. VINCENT said that, as he had explained on a former occasion, he objected to the renewal of the tea duty, as it was a duty on a non-competing import, which had become almost a necessity to the great mass of the population. He did not, however, propose to move an amendment upon the subject now, because it was not a favourable moment. He trusted that in the coming year the encouragement which the Chancellor of the Exchequer had given to one branch of British industry would be extended to other branches. He congratulated the hon. member for Leicester upon his conversion in respect of one principle at least of the fair traders. An hon. member who proposed that the Chancellor of the Exchequer should abolish the tax upon tea, coffee, and cocoa was bound to suggest how the £5,000,000 at present obtained from that source might be made good. In the hon. member's opinion land could be further taxed, a view which he certainly could not share. But the Chancellor of the Exchequer could easily find other sources from which to obtain the revenue which the duty on tea at present supplied. Let him turn his attention to the absolute necessity of giving British labour the fair play which was given to labour in every other country. By adopting the principle involved in that advice the right hon. gentleman would not only obtain funds which would enable him to free tea, and probably tobacco and other articles, from duty, but he would give a much needed stimulus to trade and employment in every part of the United Kingdom.

Sir G. CAMPBELL argued that the taxes upon property ought to be greater, having regard to the heavy taxes upon labour. In particular he advised the abolition of the tax upon carriages and racers.

Mr. GRAY hoped that the time would come when the poor man's breakfast would be cheaper than it was now, and when the duty upon tea would be removed. He could not, however, agree that the financial void

which the reduction of the duty would cause ought to be filled by increased contributions from the land.

Mr. ILLINGWORTH thought that the amount contributed to the Imperial revenue by the working classes was too large. The taxes they paid upon beer, spirits, tea, and tobacco were almost oppressive. In the past several taxes of this kind had been reduced and Parliament had for many years set its face firmly against anything in the direction of socalled fair trade. The Chancellor of the Exchequer would no doubt ask those who proposed to abolish the tea duty how they would suggest that the deficit should be made up? Let the reduction in the income-tax be postponed and, if necessary, let the penny taken off last year be replaced. (Hear.) This tax fell upon the income-drawing and propertied classes and their claim should be subordinated to the more pressing claims of the working classes. (Hear, hear.) The Chancellor of the Exchequer had stated that he thought the income-tax ought to be reserved to meet war expenses, but since, in time of war, the greatest sufferers would be the working classes, the income-tax in time of peace could not be put to better use than in removing the burdens on the necesaries of life. (Hear.) Tea was a necessary of life among the working classes, and it would be an act of equity and of true wisdom to abolish or at any rate reduce the excessively high tax now placed upon it. To do so would also bring the right hon. gentleman as much popularity as he could secure by reducing the income-tax. The payers of income-tax, however, were much more in touch with Chancellors of the Exchequer than the working classes, and hence the claims of the latter did not receive that attention to which they were entitled.

The CHANCELLOR OF THE EXCHEQUER said that income-taxpayers brought no preasure to bear on the Chancellor of the Exchequer and were the most long-suffering of all taxpayers. It ought always to be borne in mind, however, that the income-tax had been successively raised for the purpose of meeting an emergency, and it seemed only to be just, quite apart from any question of popularity to which the hon. member had referred, that if it was raised to meet an emergency it ought to be lowered when the emergency had passed away. (Hear, hear.) He quite agreed with the hon. member that it would be a most popular thing to reduce the tax on tea, and this showed that in the course Her Majesty's Government had taken in not reducing the tea duty but in reducing the income-tax they had been influenced by a regard for what was best in the interests of finance and not by any considerations as to popularity. (Hear, hear.) The hon. member for Leicester alluded with regret to the fact that the consumption of tea had not shown as much increase as might be desired. Such increase was "fairly satisfactory but not very satisfactory," as he had occasion once before to remark. But it ought to be borne in mind that this was in some degree due to the importation of Indian teas displacing the Chinese teas and to the fact that Indian teas were much stronger. (Hear.) He was informed that a pound of Indian tea produced more cups of tea than a pound of Chinese tea would produce, and this naturally had some effect in diminishing the quantity of tea used. He did not desire to depreciate the suggestion made by the hon. member. On the contrary, he thought it would be extremely desirable that the tax should not be totally abolished but reduced. (Hear, hear.) He would not like to abolish altogether a tax like this, because the machinery for its collection being thus terminated it was the more difficult to re-impose it. (Hear.) If he had the necessary number of millions to spare he would much prefer to reduce both the tea duty and the tobacco duty than to abolish entirely the tea duty. (Hear, hear.) He was sure every member would be glad to see the time come when progress would be made in the reduction of duty on consumable articles. The hon. member for Kirkcaldy spoke as if there were a growing tendency to throw taxation on the working and to relieve the wealthy classes, and the hon. member for Bradford spoke rather in the same direction; but he would place some figures before the Committee—not in a controversial spirit, but in order that the facts might be known. The total of the taxes on consumable articles had fallen from about £43,000,000 in 1876-7 to about £41,000,000 in 1887-8 or about £2,000,000. The taxation per head on consumable articles had fallen from £1 6s to £1 2s 3d. He rejoiced in that fact, but the same time he would call the attention of the Committee to the fact that the taxation on property and the earnings of the professional classes—he meant the death duties, stamps on transfers, house-tax, and income-tax had increased £12,000,000, or 71 per cent. That was after the reductions had been made on the sugar duties. At the same time there had been an increase in rates, which fell to a great extent on the wealthy classes, and which, therefore, swelled the increase of taxation upon them. From that expenditure on rates the working classes had derived a very considerable advantage. For instance, in the matter of education the whole increase of taxation went to the advantage of the working class. (Hear, hear.) They had only so far to a slight extent been relieving the wealthier classes of some of the additional burdens imposed during the last few years. He made a proposal this year to relieve the income-tax payers of a million and a half, a large proportion of which would go to the benefit of persons with small incomes, but a portion would go to relieve the wealthy classes. He proposed also the duties on wines and on foreign securities and other transactions amounting to £500,000, which would fall exclusively on the well-to-do classes. He thought, therefore, he might fairly contend they had not been drawn in the direction of relieving the well-to-do at the expense of the working classes, which would be entirely contrary to the financial principles they professed. (Hear, hear.) He had used an argument to which he adhered, which was that the income-tax was a valuable reserve in times of emergency, and there he thought he had the support of his right hon. friend the member for Mid Lothan. There was the great difference between the two sorts of taxes, that the income-tax could be put on at a moment's notice, whereas in the case of putting any additional duties on consumable articles, it was generally some time before full effect could be given to them. There existed the greatest difference of opinion as to the manner in which the gap left by taking off the taxes on consumable articles should be met. One hon. member had suggested retrenchment. The Government were only too anxious to economize, so far as the efficient administration of the affairs of the State would allow, and would resist as much as any member of that Committee any extravagance beyond that point; but he did not think that by any possible retrenchment the gap could be filled up. Hard cases had been put where persons spent a large proportion of their earnings on tea, but such cases occurred under almost every duty. Nor could he admit the force of another argument—viz., that in proportion as the price of the article had fallen the duty should be decreased; for if the consumer had to pay less for his tea he was not entitled to look upon it as a grievance that the duty had remained the same as before. (Hear, hear.) He was brought nearer to the cheap breakfast table which was desired. An hon. member had said that tea could be bought for 4½d per lb., but he was afraid that very few poor persons had the benefit of that price, and that the advantage of that cheap price went into the pockets of the middleman. (Hear, hear.) It would be satisfactory to him if it should happen that during his tenure of the office he now held he could make a reduction in the taxes referred to. (Cheers.)

Sir W. HARCOURT thought his hon. friend the member for Leicester was quite entitled to give emphasis to that subject. It was an unfortunate thing that there should be a proposal of which the relief went almost exclusively to the propertied classes. (Ministerial cries of "No, no.") The Chancellor of the Exchequer had pointed out why he thought there ought to be this relief, and no one could deny the fact. Unquestionably it was a circumstance in which this Budget was distinguished from former Budgets. The right hon. gentleman had referred to the increase of contribution of what might be called the

wealthier classes of late years, and the diminution of contribution on the part of the consuming classes. Some years ago the injustice between the contribution of the two classes was monstrous. Something had been done to redress that inequality. He believed no greater social advantage had ever been conferred on the community than the arrangement of the tea duties by the right hon. member for Mid Lothian. He should be glad to see that work completed. He entirely sympathized with the principle mentioned by the hon. member for Leicester. They could not, however vote the refusal or the reduction of this duty without making other arrangements, but it was necessary all the same to enter their protest against the principle of the Budget in which a reduction of taxation appeared not to be divided in the proportions adhered to by former financial arrangements.

The CHANCELLOR OF THE EXCHEQUER pointed out that the relief was given, not only to the income-tax payers, but to the ratepayers, whom he considered to be a general and wide class of the community. The reason of the exception was that the income-taxpayer alone had been hit by the late increase of duty, and because of the extraordinary position they were in of having to deal with the whole of local finance.

Mr. DIXON-HARTLAND asked what became of the tea which entered the country in a broken state and was found to be unfit for consumption. In Germany a large trade was carried on in making caffeine out of bad tea, and manufacturers in this country could make a good deal of money if this bad tea could be obtained without paying the 6d. duty.

Mr. CHILDERS drew the attention of the Chancellor of the Exchequer to the fact that the proposal of the Government in 1885 was that the income-tax should be increased, and the duty on articles of consumption increased also.

The CHANCELLOR OF THE EXCHEQUER reminded the right hon. gentleman that the only way in which it was possible for him or his friends to propose a tax on consumable articles was to put themselves in alliance with the temperance party and propose an increase of the beer duty. As to the bad tea, he stated that he would inquire into the matter. But it seemed to be a proposal which would not be attractive to tea drinkers generally. (Laughter.)

Mr. PROVAND argued that the working classes of the country paid an undue proportion of the national taxation.

Mr. FENWICK complained that the Chancellor of the Exchequer had not given any relief to the working classes.

Major RASCH protested against the suggestion that the tax should be taken off tea and an additional tax placed upon land. As an agricultural member, representing not so much the squires as the tenant farmers, he should certainly vote against the amendment.

Mr. GLADSTONE said that, although he agreed with the view of the hon. member for Leicester, it would be impossible for him to go into the lobby in support of the amendment. He could not think that it would be useful or desirable to take a division on the question before the Committee, which was to provide for the expenditure of the country. The Chancellor of the Exchequer was bringing forward the resolution not with the view of having changes made, but to preserve the prerogative of the House. He had never given a vote which would reduce the income of the country below its expenditure, and he never would. A great number of persons would gladly join the hon. member in a division if only they were able to see that the country would have the means which were absolutely necessary. (Hear, hear.)

Mr. ILLINGWORTH remarked that if the Committee determined to impute the tax by the gap which would be made if the income could be filled up in the present Budget by arresting the reduction of the income tax.

Mr. PICTON said that he could not reconcile it with his duty to withdraw the amendment.

Mr. GLADSTONE observed that if the proposal of the hon. gentleman had been to reduce the [illegible] from 6d to 4d his objection would have been removed, as he believed that the reduction of the tea duty was entitled to preference over the reduction of the income-tax.

The CHANCELLOR OF THE EXCHEQUER said he should now like to add this to his argument. When the right hon. member for Derby spoke of the injustice of the tea duty he should like to know whether that view could have been anticipated as the general view of those who had been responsible for the finances of the country for so long a period. After the income-tax had been raised two years ago to 8d, he was now called upon to reduce the tea duty rather than to reduce the income-tax to 6d. The right hon. member for Mid Lothian once proposed to abolish the income-tax altogether. (Mr. Gladstone.—"In 1874.") But in the interval the party opposite when in office had not touched the income-tax. Why they should now be called upon to decide on a question of this kind he could not understand. It was meting out to him somewhat hard measure, as the right hon. gentleman had never yet proposed the reduction of the tea duty.

Mr. GLADSTONE said he had reduced the tea duty to 6d, and he did not make it lower because he had not the necessary surplus; but the Chancellor of the Exchequer had a surplus and the question was how it was to be disposed of.

The CHANCELLOR OF THE EXCHEQUER said the right hon. gentleman had to raise the income-tax in order to lower the tea duty, and but for that the disparity would not have been so great as it was with the income-tax at 7d.

Mr. PICTON said he wished if it was practicable to adopt the suggestion of the leader of the Opposition and to move the reduction of tea duty from 6d to 4d instead of moving the rejection of the clause.

The CHAIRMAN said there was no such motion, as the clause could be opposed without it on being put from the Chair, and it was now too late to move an amendment in the clause.

The Committee divided on the question that the clause stand part of the Bill, and the numbers were:—

Ayes..	...	...	259
Noes...	...	...	98
Majority...	...	...	— 161

The clause was therefore added to the Bill..

The *Times* had the following editorial remarks:—

Then the House went into Committee on the Customs and Inland Revenue Bill, Mr. Picton produce one of the familiar demagogic motions insisting on the abolition of the tea duty. Though Mr. Gladstone discountenanced a division, the leaders of the Opposition went out of their way to support the view that the working classes were defrauded of relief in the Budget now before the House, because the abatement of the income-tax was not accompanied by any corresponding reduction in the imposts on consumable commodities. The Radical view of the matter is that to levy any taxes from the working classes is, as Mr. Picton puts it, "cruelty." The working classes are now politically supreme in this country; a very large proportion of the aggregate national income falls to their share, and to free them from all taxation whatever—that is, from the necessity of contributing in any degree to the maintenance of the State which assures them protection and of which they practically control the government—would be, from every point of view, unjust and mischievous. The tea duty is now the only important source of revenue with the exception of luxuries, such as tobacco, spirits, and malt liquors, which a large and, perhaps, increasing proportion of the population do not consume at all, to which the working classes contribute, and to abolish it would be to render the existing unequal incidence of taxation still more unjust. Mr. Picton and his friends would redress the imperial balance by laying new taxes on land, which, of all interests in the country, has suffered most grievously in recent years. The charge against the Chancellor of the Exchequer of having postponed the interests of the working classes to those of the propertied classes in reducing the income-tax without any corresponding reduction in the duties on consumption is very easily answered. As Mr Gladstone

showed, there has been a steady diminution in the taxation on consumable articles during the past half-century, and at the same time a vast increase in the taxation of the professional and the land-owning classes. More especially within the present decade the increase of expenditure has been almost entirely borne by the classes who are liable to the income-tax, and augmentations of that burdensome impost, professedly intended to meet some temporary exigency, have been allowed to become, in a measure, permanent. The Chancellor of the Exchequer, therefore, was entirely justified, when he had the oppotunity, in reducing the income-tax, though even now it stands at double the rate at which it stood a few years ago. He could not have satisfied the demand which was pressed upon him by Mr. Picton without surrendering one of the few sources of revenue which render it possible to maintain our fiscal system in working order and at the same time to avoid an iniquitous distribution of the national charge. The division which was taken, in spite of Mr. Gladstone's advice, showed a majority for the Government of 259 against 98.

COTTON CULTIVATION IN CEYLON:

DISTRIBUTION OF SEED.

We learn that the Hon. W. W. Mitchell having provided a supply of Tinnevelly cotton seed, the Government have distributed it to each of the Government Agents to be planted and to note the results. The Director of Public Instruction has also distributed a quantity amongst his agricultural instructors. Dr. Trimen is having some seed, also Mr. Price, for the gardens under his charge. Mr. Mitchell hopes to get some Egyptian seed shortly and to try it also. There is some more Tinnevelly seed available, and Mr. Mitchell will be happy to let anyone have some, who will really try to raise a crop. A native "gin" has been sent over from Southern India and can be seen as a pattern at the offices of Messrs. Darley, Butler & Co. Altogether a good start in cotton growing will be made.

UVA BEATING JAVA IN RICH CINCHONA BARK.

Java must look to its laurels, for there is every chance of the old cinchona clearings in many parts of Uva yielding as rich bark as any got from Java. If care is taken in shaving and stripping, we feel sure that "renewed" bark in Uva will yet raise the Ceylon average very considerably. The latest lot from the well-known Cannaverella field of about 7,000 lb. renewed officinalis has analysed in Colombo 5·94 per cent sulphate of quinine, a result which ought to wake up our Java friends when they are told that a very great deal more has to come from the same quarter. In fact, Uva has the great reserve of bark in Ceylon now.

MORE TEA MACHINERY:

ANOTHER SUCCESSFUL WITHERING AND DRYING MACHINE.

We can do no less than call attention to the report given in the *Tropical Agriculturist* on the authority of Mr. E. Rice Wiggin of the successful working of "Greig's XLall (excel-all!) Machine." We have maintained hitherto to Mr. Greig, that, if he has a really good thing for the tea-planting community, at a cheap price, he and his agents have been hiding its light under a bushel, so little has been heard of it. Here is, perhaps, an answer to our protest, and by an advertisement, it will be seen, further information can be got on application. We had heard that Mr. Greig was putting up a set of his machinery on Kandapolla estate. Has this been finished and given satisfaction? Nowhere are planters keener than in Ceylon to scent out a good thing, and, therefore, if the Bambrakelle machine continues to do the good work reported of it, we and Mr. Greig too are sure to hear a good deal more about it.

CHINA FINE TEA TO BE SCARCE.

All accounts received from Hankow, Foochow, and the Southern China tea markets indicate that there will be a marked change during the coming season in the trade. The Indian export will exceed 100,000,000 of pounds, and from Ceylon from 12,000,000 to 15,000,000 pounds will be shipped to London. The Indian and Ceylon teas are now in high favour. The leaf is strong, of fine flavour, and, being properly cured, keeps sound for a long time, whereas China tea has, during the last ten or twelve years especially, deteriorated steadily; teas of fine flavour and good strength are scarce, and the leaf is no longer of good keeping quality. The teas of Ceylon and India are cured and prepared for export by machinery. There is no manipulation of the leaf by dirty and perspiring coolies, a detail that should commend itself to people who are reasonably fastidious. This year fine China teas will be very scarce, and it is not likely that much third and fourth crop tea will be packed in excessive quantities as heretofore, as the prices in London are now so low. It appears as if China, which is no longer the pre-eminent tea producing country, is in some danger of losing the trade altogether. The Indian yield will ere long be 150,000,000 pounds, and it is said in two more years Ceylon may be able to export 50,000,000 pounds.—*Chinese Times*, April 28th.

NOTES ON INDIAN TEA.

Our first tea auction sales will be held on the 10th instant, and not on the 17th instant as anticipated. About 5,000 packages will probably come under hammer, most of the invoices are from Dooars and Terai estates, and the quality will likely be found preferable to teas on the first sale last year.—*Calcutta Cor.*

GAUHATI, April 30th.—From October to 23rd April we have only had 3·40 inches of rain. This drought severely tried the young cultivation, and the first flushes were late in coming out. During the last week we have had some good rain, 4·78 inches or as much as fell in the last six months. This rain has wonderfully improved the gardens which before were looking dry and parched.

SOUTH NOWGONG, April 29th.—Weather very curious. Hot winds worst on record these last five years. Tea literally made on bushes. Glass showing from 104 to 79. Rainfall only 3·94 against 5·15, but as I write rain is falling. Spider blight, too, is very bad, but thank goodness no sickness amongst coolies or local villagers. Drought has been so bad that even villagers are going two and three miles to fetch water, their own wells having dried. All gardens behind last year on this side of district.

DARJEELING, May 8th.—We have had a very heavy fall of rain, which has done much good throughout the district. The *chota bursat* in fact, and certainly not before it was wanted for tea and crops of all kinds. There was a good deal of hail mixed up with the nor-wester in some parts of the district, and a great deal of damage has been done to tea on those places where it fell at all heavily.

SOUTH SYLHET, May 8th.—If friend Jupiter Pluvius was scanty in his favours last year and the beginning

of this, he is now doing his best to make up for lost time, and last week's record would be hard to beat if it goes on as it is doing! The storms of this year, although not quite up to Dacca tornado form, have been quite bad enough; and many gardens will remember the hail for many a long day to come. One garden especially being so badly cut as to quite make the difference between a good profit and paying working expenses. Monoomookh, the principal steamer station on the Kushiara river, had something like a tornado; all the buildings nearly have disappeared, and of the saw-mills all that remains is bare poles. The corrugated iron sheets of the roof were blown clean across the Munnoo river; twisted and torn into shreds; large numbers of empty boxes were smashed by the lumps of ice which fell; and in one case one lump went clean through the iron roof of a factory! To call this hail would be a misnomer. Pigs, deer and other wild animals were killed outright, and had the storm occurred during the day, there is no knowing what mortality there might have been amongst the coolies. On one garden in the afternoon a coolie woman, who was plucking, was killed by lightning, and several others in the vicinity were injured. On all sides nothing is heard but lamentation over coolies' lines, and leaf-houses that were.—*Indian Planters' Gazette.*

DRUGS AND BARK TRADE REPORT.

(From the *Chemist and Druggist*, April 21st.)

ANNATTO.—The demand is extremely slack. Ceylon seed in good upply, but barely saleable at the last figures—2½d to 3d per lb., according to quality. Brazilian roll without inquiry; a rather dry and dark parcel was brought in at 1s 2d per lb.

ARECA NUTS.—At today's auctions 70 bags from Colombo sold at 10s per cwt. for the entire parcel.

CALUMBA.—Although our stock is a very heavy one, inferior qualities being especially well represented, holders do not seem willing to submit to further reductions. An offer of 40s was declined for a parcel of good yellow washed root, which was bought in at 45s per cwt. Some fair mixed root, all sizes, partly wormy, sold at 22s, the remainder of the parcel being bought in at 25s per cwt. Forty-eight bales very dark wormy root found a buyer at 4s per cwt.

CINCHONA.—Large shipments arrived from Ceylon at the end of last week, and the exports from the island seem again to be somewhat on the increase. At today's auctions nearly the whole of the cinchonas offered were of South American origin, and the bulk belonged to the varieties for which fancy prices, quite out of proportion to alkaloidal value, are paid. A newly-arrived parcel of flat yellow *Calisaya* bark sold at 2s 2d per lb. for fine bright and partly very bold but somewhat papery bark, rougher and softer lots realising 1s 10d, and damages from 1s 3d to 1s 9d per lb. Twelve bales cultivated Bolivian Calisaya, in flat but thin and rather unsightly pieces, were bought in at 2s 2d per lb. Another parcel, which did not look like genuine Calisaya, is said to be held at 1s 9d to 2s per lb. Six bales *Maracaibo* (imported *via* Hâvre) sold at 7d to 9d per lb. for sound, and 5d to 6d per lb. for damaged bark. Small dull quilly damaged red bark (imported *via* Hamburg) sold at 9d per lb.; *Loxa*, according to quality, at 1s 0d to 2s 1d; and *Huanoco* in quill at 11d to 1s 4d per lb.

COCA LEAVES.—Several parcels were offered, but only 11 bales of the *Trujillo* character sold at 3d to 6 per lb. for broken and ordinary quality. A single bale bright green but broken leaf is held at 1s 6d per lb. nominally. Fair *Huanoco* leaves were bought in at 1s 1d per lb. nominally, while for a very common lot, though offered "without reserve," no bid at all could be obtained. The parcel of ordinary *Java* leaves offered at a recent auction was again bought in.

CUBEBS.—A better demand exists, and the last quotations are well maintained. Three bags genuine, but very small berries, said to contain 20 per cent of stalk, are priced at 20s per cwt. Another lot of the same kind, but mainly the stalks, sold at the rate of 23s 6d per cwt., the stalks alone subsequently bringing 60s per cwt. Two bags rather bold brown berries (imported *via* New York) also sold, at 17s 10s per cwt.

OILS (ESSENTIAL).—*Cinnamon* oil steady at 1s 3d to 1s 9d for fair to good oil. *Citronella* dull at 15-16thd per oz. for native brands. *Cajaput* not in much demand. A parcel was bought in today at 3s 6d per bottle. *Lemongrass* steady at 1¾d per oz.; today 1¾d was refused for 27 cases from Cochin. *Nutmeg* oil bought in at 3½d per oz. *Peppermint* firmer for H.G.H., which is not obtainable under 10s 6d per lb. on the spot. Cocking's Japanese oil is quoted at 5s 3d per lb. *Menthol crystals* are quoted at 7s per lb. for Cocking's, other brands offering below that figure. *Otto of rose* is exceedingly firm at the last quotations. Of *Ylang-ylang*, 6 bottles, 11¾ oz. each, "Sartorius" brand, sold today without reserve at 5s to 5s 9d per oz., which, if the quality is genuine, is probably the lowest price on record for this brand; another lot of ordinary ylang sold at from 2s 3d to 2s 6d per oz.

VANILLA.—A report is current that a considerable shipment has been lost in a steamer between Marseilles and London, and it is also said that the coming crop will be a very small one. Nevertheless, prices remain very low, although some slight improvement was apparent today. The 97 tins offered today were nearly all sold at 19s 6d for good 7½ to 8½ inch, 14s to 17s for fair 7 to 8 inch, and from 4s to 10s for foxy to good beans of various lengths.

PATCHOULY LEAVES.—No less than 130 bales, mostly of recent import, were offered for sale. There was not a single bale among the parcel of really fine quality, and, with the exception of 8 bales dusty, discoloured and stalky leaves, which sold at 3d for sound and 1¾d to 2½d per lb. for damaged, the whole was bought in at nominal rates. Many lots were very stalky and sandy or mixed with spurious leaves.

THE DUTCH MARKET.

AMSTERDAM, April 18th.

CINCHONA.—The next auctions here will be held on May 3rd and will consist of 449 cases and 1,276 bales Java bark, and 8 bales Ceylon bark, subdivided as follows:—*Succirubra*: Quills, 249 cases; broken quills and chips, 16 cases 132 bales; root, 5 cases 55 bales. *C. Schuhkraft*: Quills, 11 cases; broken quills and chips, 48 bales; root, 30 bales. *Ledgeriana*: Quills, 12 cases 14 bales; broken quills and chips, 87 cases 702 bales; root, 196 bales. *Officinalis*: Broken quills and chips, 93 bales *Hybrid*: Quills, 69 cases; broken quills and chips, 6 bales. Ceylon, broken quills and chips, 8 bales, weighing together about 130 tons, of which about 76½ tons are manufacturers' bark, containing the equivalent of about 5,900 lb., or about 3¾ per cent sulphate of quinine, and about 53½ tons druggists' bark.—*Chemist and Druggist*, April 21st.

NETHERLANDS INDIA NEWS.

(Translated for the *Straits Times*.)

The inflow of planters and capital from Java to British North Borneo, under the attraction of the liberal land regulations in force there, has alarmed the Netherlands India Government. Hitherto, in the Netherlands provinces in Borneo, obstructive legislation has worked against European settlement on the wide stretches of waste land in that quarter. So matters stood until the 27th March. On that day, all of a sudden, the Java Government *Gazette* made public an Ordinance to regulate the leasing of waste land in S. E. Borneo. The measure, a half one at the best, is not likely to lessen materially the "rush" to British North Borneo. There land may be had on a [illegible] years lease at a low price, and a nominal quit rent. Government liberality in [illegible] Dutch Borneo stops short of such progressive [illegible]. The N. I. regulations will only bear of 75 years [illegible] at quit rent of one guilder per one [illegible] Other taxation will follow as a matter of course and at the expiration of the lease the Government resumes possession. Under these circumstances, to [illegible] an estate in Dutch Borneo, 750 acres in area would take 15,000 guilders to open against only 2,000 in British North Borneo, so far as regards price and quit rent.

Before an applicant can secure the land he wants in Dutch Borneo, the Circumlocution Office has to be reckoned with. His application must go, first, to the Governor-General, who sends it to the local authorities. They consult the native headmen. The matter is then referred to a mixed commission of natives and Europeans. They have to draw up a report. The latter, accompanied by explanatory documents, passes from one department to another, until it finally reaches the hands of the Governor-General. His Excellency then, should no difficulties arise, may grant the applicant's prayer. The applicant has, however, to go through other formalities before he can take possession. In British North Borneo, on the contrary, land may be had on terms which are simplicity itself, compared with these obstructive provisions. The Batavia *Nieuwsblad* accounts for the obstructiveness, by pointing out that liberal measures taken by the Netherlands Indian Goverment have always failed to take effect, owing to the paralysing influence of the bureaucratic spirit. The one in question lies under the same disadvantage. It is certain not to work in favour of settlement and planting enterprise. Under such an obstructive policy there is no probability of Netherlands Borneo proving to be a field for investment at all comparable with British North Borneo.

Sugar growers in Java have decided upon holding a grand congress at Samarang, towards the end of this month. The object is to devise the best means of counteracting a disease called sereh which is spreading and working dire havoc among the standing crops of cane. Not only the indigenous but also the imported articles are stricken. Its prevalence means the loss of millions of guilders to the planting community.

The *Locomotief* brings under notice the success achieved in East Java with an artificial manure from Glasgow, styled osammonite. "It has been found highly suitable for sugar cane. On no less than sixty estates, it gave the best of results. This manure commands attention more than ever now. The price comes to ten guilders per picul. These low figures and the satisfactory results attending its use will no doubt push on its sale considerably.*

A Batavia paper points out a detrimental peculiarity of teak timber grown in Java. The standing trees are apt to get hollow in the stem. In that island, within whole reserves, trees which grow luxuriantly and look sound, have become hollow inside, and can supply at the utmost, only a few thick planks. A timber dealer at Batavia has found out a remedy to check the evil, which seems effective enough when applied to newly cut beams, immediate after they come to hand. Rubbing oil dregs well into the beams, and afterwards keeping them above ground on supports, has been found to be the best mode of procedure.

GOLD IN THE SOUTHERN PROVINCE OF CEYLON.

THE DEWURANGALA GOLD FIELD:

PRACTICAL INFORMATION.

(By a Special Correspondent—an Australian Gold-digger.)

22nd May.

In your issue of 17th instant a correspondent, writing under the head of "Gold in the Southern Province," states that the arachchi who found the gold in Morawak Korale brought his finds, about 4 lb., to Galle, and showed them to the Government Agent, the quantity named having been dug out of his gemming allotment of half an acre, but the gold alone would not pay, the gems pay expenses, the gold being profit. According to former reports the depth is only eight feet. 4 lb.=48 oz. gold at say £3 15s sterling per oz, which is much under the value of virgin gold, comes to £180 sterling. Why that would not pay is a problem which would amuse an Australian miner, when told the depth was only eight feet. But let us look at it a little closer. If 48 oz. was found in nuggets, what about the fine gold? It is contrary to all experience to find gold in pieces, such as we hear of the arachchi having found, and not to find considerably more in fine gold. For every oz. in pieces over 1½ dwt. or 2 dwts., I would expect to find at least 3 oz. in fine gold. But let us be very moderate, and say one oz. of fine gold for every oz. in pieces, this would give us 96 oz., which at £3 15s = £360 sterling. The fine gold if not taken out must be there still. Another question comes up: how much of the half acre had been worked out at the time the whole of the 4 lb. was realized? I suspect not more than the half of it. And yet it would not pay! The arachchi may be right however; if a man does not know how to take it out, it won't pay though it be there in sufficient quantity. Your correspondent goes on to say:—"He adds that for many years they have, when gemming, come on what he now finds is gold, but threw it away under the impression that it was diyaratran." It requires an effort to believe that they threw away gold, but suppose there is no mistake in this statement, it would be interesting and important to know *where* they were working all these years: they could not have been digging much of that time in that half acre. Evidently the arachchi has found out another gold field elsewhere. The whole thing gets very interesting; surely the Government Agent will see to it forthwith.

* Can any reader tell us what the manure really is? If it can be laid down in Java for ten guilders per picul of 133 lb. it can be sold in Ceylon for the same number of rupees and might pay as an application to tea?—ED.

TEA MANUFACTURE: SIMPLEX PATENT TABLE.

We ought to have called attention to the circular-advertisement issued with the *Observer* regarding Messrs. Law & Davidson's "Simplex Patent." The table of their rolling machine, to judge by the testimonials, seems to be specially approved, and, we believe, the patentees have a brisk and growing demand for permission to use it with other rollers. The improvement resulting from the application of the Simplex table to some of Jackson's Rollers is very marked, both in the character of the roll, and the less time and less power required.

NETHERLANDS INDIA NEWS.

(Translated for the *Straits Times*.)

The *Locomotief* points out the rapid increase in the value of estate property in Deli. An estate called Tuntungan has just changed hands for 750,000 guilders. The value of the standing crop is not included in this amount. Only a tenth part of the estate lies waste. The acreage of land not yet brought under tillage shrinks rapidly in Deli. In Serdang all the available land upcountry, has been taken up. On the sea coast, selectors can still pick and choose, provided they go to work with sound judgment. Last year, no less than 37 new estate concessions were granted in Serdang.

The Government in Java have lent a hand to help the sugar planters. The latter are at their wits' end how to counteract a disease which under the name of "Sereh" has wrought dire havoc among the growing sugar cane crops there. The disease is spreading rapidly, and seems to be proof against remedies. The planters, too, have a hard battle to fight against falling prices. The Government aids them in the struggle for existence, by allowing the free carriage of sugar canes and plant cane on the State railways.

DRUG MARKET REPORTS.

ANNATTO remains neglected. For 10 baskets good soft bright Brazilian *roll* 1s 6d is wanted, while 10d par lb. was refused for a much inferior lot, which is held at 11d per lb. One case rather bright powder (*via* Amsterdam) sold, without reserve, at 1d per lb.

CINCHONA.—Several odd lots were offered at today's auctions, but they did not include anything calling for remark, the bulk being old secondhand parcels. One case Ceylon quill, thin rusty succirubra, sold at 6d per lb. without reserve; 30 bales Maracaibo, common, dusty, and damaged, at 1d to 1½d; a few bales of fair broken mossy Lima quill, at 2½d; thin rusty Guayaquil, at 6d per lb. The shipments from Java have been rather heavy lately, and the total exported since the commencement of the season is nearly double that of the corresponding period of 1886-7. The exact figures are:—

		Private plnts.	Govt. plnts.	Total.
July to	Feb.			
1st 1887	29th 1888 ½ kilos.	2,00,1711	490,653	2,491,824
,, 1886	28th 1887 ,,	1,125,310	480,777	1,606,087
,, 1885	28th 1886 ,,	677,627	330,242	1,007,869
,, 1884	28th 1885 ,,	627,352	278,431	905,783
,, 1883	29th 1884 ,,	467,154	410,275	877,429

The shipments for the present season thus being already equal to 2,763,207 lb.

OILS (ESSENTIAL).—Star anise cheaper, three cases just arrived selling today at 5s 11d per lb. Cajaput oil is without demad. The price of 3s 4d is named for ten cases at 24 bottles. Cinnamon unaltered. A case of fine pale oil is limited at 3s per oz. Citronella. quiet at 15-16th d. per oz. For a lot of 22 cases good Cochin lemongrass 1¾d per oz. was refused, and the whole bought in at 2¼d nominally. An offer of 3s 1d for good Dominica oil of limes was also refused. Oil of patchouly quiet; 2s per oz. suggested. Peppermint firm for American; there are no sellers of H. G. H. oil under 10s 6d although 10s 3d could be obstained. Two cases H. G. H. spearmint bought in at 14s per lb. Of 6 bottles fair ylang-ylang imported *via* Hamburg (V. Javega brand), two sold at the low price of 4s 6d per oz.

QUININE.—The downward movement still continues, and a rather considerable trade (some 77,000 oz. since our last report) has been done at falling prices, mostly by some of the German manufacturers themselves, who are apparently doing their utmost to depress the market—a seemingly anomalous way of procedure, for which various reasons are assigned, one being that the Amsterdam auctions take place today, and that they want to bring down the unit value at those sales. The manufacturers working for the fall are the Mannheim, Brunswick, and Auerbach factories, the firstnamed having accepted 1s 1d for delivery, the second 1s [illegible] for delivery, and 1s [illegible] on the spot, and the last-named 1s 1½d and, subsequently 1s 3½d per oz. The English, French, and Italian makers, as well as the Frankfort and Stuttgart factories, are, it seems, adopting a passive attitude. Yesterday second-hand lots sold at 1s 3d. per oz. for cosh and today there was some further business done at that figure.

QUININE AND IRON CITRATE.—Fourteen cases of this preparation (each holding 4 60 oz. bottles) were offered for sale. The clause "without reserve," printed in the catalogue, was declared not to apply when tho lot was reached. The make (the cases only bore the mark L.S.) was not stated, but an analysis was said to have proved tho presence of 15 per cent. quinine, equal to the B. P. strength. The lot was bought in at 9d per oz., 8½d being suggested in vain. No offers were forthcoming.—*Chemist and Druggist*, May 5th.

THE DUTCH CINCHONA AUCTIONS.

AMSTERDAM, May 3rd.

At the cinchona auctions held today, 1,646 packages bark were sold of a total of 1,[illegible] offered. The unit averaged 9½ to 10 cents per half-kilo. (=1 7-10d to 1 4-5thd per lb.), being thus rather below that obtained at last week's auctions in London, though quite as high in proportion to the value of quinine then and now prevailing. Druggists' bark chips and quills realised, according to quality, from 10 to 78 cents per half kilo. (=1¾d. to 1s 2d per lb.), and ditto root from 15 to 26 cents (=2½d to 4¾d per lb.) Manufacturers' bark, in chips and quills, sold at 8 to 98 cents per half-kilo. (=1½d to 1s 5¾d per lb.) and ditto root at 14 to 70 cents (=2½d to 1s 0½d per lb). The principal buyers were the Amsterdam Quinine Works, the Brunswick factory, and Messrs. Zimmer & Co.

QUININE.—The disastrous consequences of the speculative movement of December last became apparent only too quickly. It became evident that the consum, ption did not possess sufficient power of assimilation- and all attempts to further screw up the price of quinine failed because of the superabundant production. At present no trace of the recent excitment is left in the market, and the prospects for the future of the article are again as dark as they were before. To an experienced judge of the market there cannot be any doubt that for the present all bases for a legitimate improvement in the quinine trade are wanting. The steadily recurring unfavourable reports speaking of diseases in the cinchona plantations do not merit any credence, and it is known that even the smallest lasting improvement in the price of the alkaloid must cause a rapid increase in the production of cinchona. The continued appearance of new febrifuges also opens up an unfavourable perspective, the importance of which is not underestimated in competent quarters. The consumption of quinine in Germany has been very considerably reduced by the new febrifuges. America, it is true, is a large consumer of quinine, and it is still dependent upon the European production for a large proportion of its requirements, but is should be be borne in mind that the supply of the American markets cannot be considered an irrevocable privilege of the European makers.—*Chemist and Druggist*, May 5th.

COMMERCE PROCURES DRUGS for us. The nomady tribes dig for rhubarb on the bleak steppes of Tartayt for a livelihood; the sailor braves the storm, and we all here at home work hard simply to get food, for a livelihood; but from all this commercial work, the sick man in London recovers health, and lives. It is true we are dependent on the lowest class of shepherds, Hottentots, and Indians in South America, and therefore the quality of some drugs suffers from bad collection; but this is improving, and the cultivation of cinchonas in Java, cardamoms in Ceylon, senna in Tinnivelly, is giving us drugs of first-rate excellence.—*Chemist and Druggist*, April 28th.

Supplement to the Tropical Agriculturist, May, 1888.

ROYAL BOTANIC GARDENS.

REPORT OF THE DIRECTOR FOR 1887.

1.—*Péradeniya Gardens.*

Roads and Paths.—Work on the carriage roads is almost constant in these extensive grounds, and it is becoming increasingly difficult to keep them in good condition. There is very much more carriage traffic than was the case formerly, and the large overhanging trees, of which the shade is so much appreciated, cause much damage in wet weather from their heavy drip. Moreover, the beds of river gravel, which have supplied binding material since the foundation of the Garden, are now almost worked out, and for the future we shall have to look for a supply outside the Garden. During the past year, several roads were remade, including the drive to the Store and Plant houses. All the footpaths in the old arboretum were taken in hand and entirely remade, turfed, and drained. A new footpath was constructed from that under the Java Almond trees to the Cabbage Palm avenue, and another is half finished, leading from the large Circle through a part of the arboretum hitherto inaccessible to visitors, and containing some fine and picturesque trees. The grass-verges on both sides of the Main Drive have been renewed, and it is intended in future to pay more attention to them than has hitherto been possible. The excessive rainfall at the end of the year has left all our roads in bad condition, and much work is required on them.

New Conservatory.—In accordance with the intention expressed in last year's report, I have now nearly completed the construction of a new house, which I expect will prove more suitable for the culture of Orchids, Ferns, and other ornamental plants than the structures at present existing here. The framework of the new house is entirely of iron, save a low brick wall, and I have to express my thanks to Government for supplying me, free of cost, with sufficient old railway rails for the main supports; the lesser ones are formed of iron rod, and the whole covered in with galvanised wire-netting. The form of this building is a cross with wide unequal arms and a shallow dome at the intersection. The length of the cross is 51 ft. in one direction and 42 ft. in the other, and the width of the arms and diameter of the dome 21 ft. The stages for the plants are built wholly of stone, and the paths are cemented. No woodwork being employed in any part, the ravages of white ants and dry rot need not be feared. It is intended to cover the wire-netting at the sides with leafy climbing and twining plants, whilst that over the roof will support a light covering of bamboo-tats, coir-netting, or grass, as may prove most suitable. I confidently expect this will form a valuable addition to our resources, and by enabling us to have on view a finer collection of beautiful plants will prove also an additional attraction of the Garden. It is an expensive work, but the cost is being spread over two years, and, by the exercise of economy in other directions, will be met out of our ordinary votes.

Cultivation, &c.—During the wet weather of June, the Cockchafer larvæ were again busy at the roots of the grass on the Circular lawn. But the damage done was much less than in 1885, and again the crows were our best friends, searching for and devouring incessantly the grubs so long as any were to be obtained.

The two well-known and picturesque groves of palms at the entrance and in the centre of the large Circle have received some attention this year. Most of the palms in them have now attained a great height and considerable age, and the ground beneath them has become bare and unsightly. Several times we have endeavoured to plant this with young specimens which should take the place of the older ones as these died off, but so deteriorated is the soil and so completely filled with a network of roots that nothing could be grown. During the very wet weather of the end of the year, however, we have succeeded in establishing 40 young palms—mostly of additional species—under the old ones, by planting them in tubs sunk in the ground; by the time these have rotted away the young plants will have thoroughly got hold of the soil.

An avenue of Palmyra Palms has been initiated on the site of the old kitchen garden. The seeds were planted *in situ*, and have germinated well.

One of the Talipot Palms (*Corypha umbraculifera*) in the Garden has flowered during the year, and has been an object of much interest to visitors. The event is of more importance than usual, as the age of the tree being pretty accurately known, a question often discussed is set at rest. The specimen is remembered well to have been a seedling of two or three years old when Mr. Gardner became Superintendent of the Gardens in 1843; it is therefore 46 or 47 years old. I believe, from inquiries I have made in other cases, that this is about the usual age for this Palm to reach maturity and flower. The great inflorescence was first observed to be pushing itself up in August, and by the middle of October it was in advanced bud and feathery in appearance; the flowers opened about November 25, and still remained in perfection at the close of the year.

Visitors.—The number of signatures, nearly all of travellers and tourists, entered in the visitors' book at the Lodge during the year is 1,302. This, of course, is but a small proportion of the number of persons who visited the Gardens.

The suggestion I ventured to make in my last report as to the desirability in the interests of the public of removing the Pérádeniya railway station from its present out-of-the-way position to the crossing of the Deltoṭa road has not at present had any practical result. It has, however, met with almost universal approval, and is especially strongly supported by the residents near Pérádeniya. I am therefore emboldened to again press it on the notice of Government, and to do so in the interests of the Gardens themselves. We should save much time, labour, and expense in our constant communication with Colombo and Kandy if we had the railway station at an easy distance, and without the intervention of a heavy toll on our carts.

Weather.—The rainfall of 1887 was somewhat unusually distributed through the year. We suffered a good deal from drought in March, but this was followed by the wettest April on record. May was very much drier than usual, the S.W. monsoon rains setting in late. At the end of August and beginning of September we had unusually heavy rains, which were followed by a month of very dry weather. October and November gave a rainfall well up to the average, whilst December was here, as over the whole Island, excessively wet, more than double the usual amount falling.

We experienced some very cold mornings at the end of January; a thermometer in my verandah registered at 7 A.M. on January 30 the very low temperature of 58° F.

The following is Mr. Clark's record of the rainfall for the year. The heaviest fall in any twenty-four hours registered was 3·02 in. on December 14–15.

The average monthly rainfall for the last 4–5 years is also added.

Rainfall at Pérádeniya.

	1887.		Average.		
	Rainfall.	Rainy Days.	Rainfall.	Rainy Days.	
January ...	1·26	3	1·69	4	for 4 years

2.—*Hakgala Garden.*

No additional works of any importance have been undertaken during the past year, though many small improvements have been made. All we can attempt to do is to keep up the Garden at as high a degree of cultivation and efficiency as our votes will permit. The Superintendent much complains of the want of a stock of good gardening tools, but this want (which is felt in all the Gardens under my care) cannot be fully relieved with the scanty means for such purposes at my disposal.

The Public Works Department have done some further repairs to the Superintendent's bungalow, which has also been repainted and whitewashed.

Some damage has been caused by the very heavy rains at the end of the year to the roads, paths, and flower beds; and it will take time and labour to repair and restore them to their former condition.

From Mr. Nock's full report for the year I extract the following details:—

Carriage Drive and Paths.—The carriage drive and the various paths in the garden were maintained in good order until towards the end of the year. For the last six weeks of the year very heavy rain fell—33·77 inches falling in December—and this has greatly damaged the drive and paths in every part. On many of the steep places, and under large trees, the continual downpour and drip fretted out all the gravel and small stones, and the rush of water has ploughed up the paths to a great depth.

A great drawback to the formation and maintenance of roads in this garden is the want of good gravel. There is no gravel nearer than Sitá-eliya, one mile on the one side, and Alakolagala, two and a half miles on the other; and even at these places it is very poor: at Sitá-eliya being no more than rough sand brought down by the heavy rain, and limited in quantity.

The old portion of the carriage drive now wants metalling, and an endeavour will be made to do it during the coming year.

Several times after heavy rain the drive was well beaten with heavy stamps. This work, when done by hand takes a good bit of labour, and the want of a handy roller has been much felt.

Rough sand was carted in from the stream at Sitá-eliya at intervals of two or three months, and spread over the paths in the fernery and other parts of the garden, to give them a neat and fresh appearance.

Two new paths have been made during the year—one to connect the main drive with the shrubbery path by the large triangular bed above the herbaceous garden, and the other from the south-east end of the propagating house across the gully by carpenters' quarters, and leading into the new part of the nursery garden. Two retaining walls, each 10 ft. long and 7 ft. deep, were built in this gully to support a rough wooden bridge, which has been laid down by the carpenter, and a retaining wall, 20 ft. long, with an average depth of two ft., was built on the lower side of the new path near the gully.

Another retaining wall, 88 ft. long, with an average depth of 3 ft., has also been built at the south-east end of

the flower garden, and the hollow filled in with the soil taken from just above, where it is intended to build a shed for the cart bullocks.

In November, the curve of the main drive, which was very unsightly just below the flower garden, was altered, by cutting away the bank for a distance of 50 ft. and varying in breadth from 8 ft. to a few inches. New drains were made here, turf verges laid down, and the road repaired and metalled.

Turf verges, 12 in. wide, were laid along sides of drive and new paths for a total length of 424 running yards, and 106 square yards of turf were laid down on the side banks in the flower and herbaceous gardens.

Fernery.—In January, 1,020 plants of mixed ferns, begonias, violets, and primulas were planted out under the trees in the new part of the fernery opened out at the end of last year. A large number of similar plants have also been planted in shady spots in other parts of the fernery and rock beds. Several of the beds have been entirely replanted, the old soil with the jungle roots being removed and replaced with surface soil from the jungle. The fernery being formed under the native jungle trees, it must be expected that the roots of these trees will always give trouble. They grow with such rapidity into the new soil placed there for the benefit of the ferns, that in many of the beds there is now nothing but one mat of roots; and unless the soil is constantly stirred and renewed the ferns suffer very much. The heavy rains in December having washed away large quantities of the surface soil, the true state of things is quite visible, and a large amount of work, in the way of replanting and manuring, requires to be done at once.

Many of the tree ferns have grown rapidly during the year, and some of the specimens of our native tree ferns (*Alsophila crinita*) are really very fine, and are much admired. One specimen in the centre of the fernery is now 15 ft. high, and carries a head of 22 fronds, the spread of these being 17 ft. 8 in. An average frond on this specimen spread out measures 9 ft. long and 4 ft. broad.

Plant Sheds and Nurseries.—The main work, as usual, in the sheds and nurseries has been the raising and keeping up of a good stock of plants for the use of the garden and for distribution.

About 100 scions of the large plum have been grafted on the small-fruited, but strong-growing, cooking plum. They have nearly all taken, and are doing well.

A large piece of new land was added to the nursery at the beginning of the year, and a strong post and rail fence was placed round it. The fence is 220 yards long.

Borders and Shrubberies.—A good deal of attention was given to the borders and shrubberies in opening out new borders, laying down turf verges, digging, manuring, staking, pruning, and keeping them tidy. 52,703 garden plants and shrubs were set out during the year.

Roots and stones were removed from the bit of land between the herbaceous garden and lower summer arbour. On the side next the drive, for a distance of 78 ft., a border was made and planted with showy plants, ribbon-border fashion. The other part was planted with foreign shrubs, and the spaces between filled in with mixed chrysanthemums.

A few shrubs were also planted at the back of the summer arbour, and clumps of red and yellow cannas were planted alternately along each side of the path from the main drive to the arbour.

The rock beds in the bend of the drive above the new pond were entirely remade and replanted with ferns, begonias, and shade-loving plants. As this is a very sheltered spot, several cartloads of specially-prepared soil was placed in the centre, and in it a plant of Abyssinian banana (*Musa Ensete*) was planted, in the middle of August. It was then only about 6 in. high; it is now 5 ft., and is expected to become a very fine plant.

A rock bed was prepared under the eugenia tree just below the rose garden, and 60 of the different *Cactaceæ*, which we had in pots, have been planted out in it.

The *Duranta* hedge planted along the boundary, near the entrance gates, last year did not come on at all well. It has been therefore supplanted by the native *Ligustrum*, in the hope that this will grow and form a neat fence, as it is a very hardy plant. This part of the garden is very much out of order, and the jagged irregular bank along the roadside is very unsightly; it is hoped that during the coming year something will be done for its improvement.

Upper Ornamental Pond.—The largest piece of work undertaken during the year was the excavation of the mud and silt from this pond.

In some places the mud was 4 ft. deep, and the average must have been very nearly 3 ft. About 100 cartloads of this were used to fill up borders, the hollow place below the herbaceous garden, and for mixing with manure for the roses and other plants. The rest was laid in heaps in the nearest vacant spots. Piles were driven in to strengthen the bank along the path on the north-east side, the bank filled up level with the path, and a verge laid along it. Two retaining walls were built up on each side of the path where the old outlet was, and the space between filled in with clay, well rammed, and on the top of this the outlet drain was laid. The water in the pond, which used to be very muddy, is now quite clear.

In April, limestone was blasted from rocks in the bit of jungle between the patanas just below the garden. The stones were broken up small and carted to, and burnt in, the lime kiln near the entrance gates. They produced 100 bushels of lime, which has been of great value for mixing with the silt from the pond, and for general garden purposes. The lime kiln belongs to Mr. W. I. Cotton, who very kindly allowed us the use of it at a small cost.

Flower Garden.—The main improvement in the flower garden has been doing away with the small terraced bank in front of the bungalow, which was not only unsightly, but required a good deal of labour to keep tidy. It has now been made into one slope at an angle of 45 yards, which carries turf well. The borders and beds were manured and replanted, and a fair show of flowers was kept up till November, when the whole was rearranged, and plants set out for flowering from January on through the Nuwara Eliya season. But the excessively heavy rains which fell in December (33·78 inches) has completely spoiled this design, the majority of the plants being killed right out. Nearly all the beds and borders will have to be replanted. This will of course throw them much later in flowering, and different kinds of plants will have to be put in to fill up. The rain was so heavy and continuous, and the soil of such a nature, that many of the beds for several hours each day, for a month, were under water.

As it is hopeless to get verbenas to thrive anywhere in the body of the garden, on account of the hares, the beds in front of the propagating house were raised with old soil from the potting shed, and formed into eight triangles, the plant used for the divisions being *Dianthus plumarius*, which I find here makes a very good edging plant. Each of the divisions is planted with a different colour, and I trust that, as this bed is continually under observation, we shall succeed this year in growing verbenas successfully.

The rock beds on each side of the steps leading up to the office were considerably raised, and planted with sweet-scented stocks, which did remarkably well, and lasted in flower for a very long time.

Rose Garden.—As it was found that the roots from the privet which formed the hedge round the rose garden were doing much damage to the plants, it was removed in November. The rose plants were thoroughly pruned and manured, and a liberal dressing of lime pointed in. Portulacas and pansies were again planted over the surface of the beds between the plants, and gladiolus bulbs along the centre of the beds.

Although the rose plants flowered very well, especially in June, they made but little growth, and at the close of the year, after the rains, they do not look at all flourishing. However, I trust that when the fine weather comes they will feel the benefit of the treatment given them in November, and make better growth the next season.

Herbaceous Garden.—This garden has been thoroughly set in order, the paths have all been metalled and gravelled, and the turfing of the banks and verges completed. An additional bed for Liliaceous plants has been made. At various times during the year some 560 plants of different sorts were set out in their places in the Orders to which they belong.

A quantity of large labels, 18 in. long, 2¼ in. broad, and ⅞ in. thick, made of seasoned *Eucalyptus globulus* wood, were prepared for naming the Natural Orders. The upper 9 in. of the label received three coats of white paint, and the remaining part was twice dipped in a mixture of boiling linseed oil and powdered coal. We prepared labels in this way three years ago for the rose garden, and up to the present time there is no sign of decay. The names are painted black on the white ground, and are easily read from any of the paths. Seventy-six of these were painted and set out to mark the natural orders represented; 625 of a smaller size were painted and set out to mark the names of the species and varieties.

Rats and Porcupines.—A perfect swarm of rats visited the garden at the beginning of the year. They did considerable damage to seeds and young seedlings. We destroyed large numbers by poison, and by catching them in traps. I caught in one particular spot no less than 55, 30 of these in one month.

The porcupines destroyed nearly the whole of the Dahlia bulbs planted out in the shrubbery, and also a large number of other plants with tuberous roots. None were caught, and they only remained about the garden for a short time.

Visitors.—The number of visitors during the year was 1,170, showing an increase of 159 over that of last year. April again showed the largest number, 215, and June the smallest, 32.

The total rainfall for the year was 101·91 inches, which fell on 224 days, as shown in the following table:—

1887.	Rainfall.	No. of Days.	1887.	Rainfall.	No. of Days.
January ...	4·89 ...	16	August ...	3·32 ...	15
February ...	3·67 ...	11	September ...	6·43 ...	20
March ...	1·21 ...	7	October ...	10·04 ...	24
April ...	7·48 ...	19	November ...	13·40 ...	23
May ...	8·20 ...	17	December ...	33·77 ...	29
June ...	4·45 ...	27			
July ...	5·05 ...	16	Total ...	101·91	224

Weather.—The greatest fall in any twenty-four hours was 3·90, from December 17 to 18, against 3·92 from August 7 to 8 last year.

The average rainfall for the four years 1884-87 is 86·68: the average number of days on which rain fell during the last six years is 217·8; and the average monthly rainfall for four and half years a fraction over 7·29 inches.

The wind was pretty steady from the S.E. until April 25, and was light or moderate in force. It then went round to the N.W. and continued, with few exceptions, in that quarter until September 21. From then till October 5 it blew from S.E. It then blew for nine days from the N.W., and back again to the S.E. until the 28th. From then till the 5th of next month the direction was from N.W., when it settled down to S.E., and continued to blow from that quarter till the end of the year.

It commenced to blow strong on April 28, and was moderate or strong until May 21, when it became very strong until the 26th, and only moderate for the last few days of that month. All through June and July the force was very strong. From then until September 9 it was variable, when it became very strong again for a few days, and then light or moderate till the beginning of November, when it settled down to light, and, with few exceptions, continued to blow lightly until the end of the year.

The greatest pressure per square foot during any twenty-four hours was 5,248 lb., equal to 32·40 miles an hour, on July 4, against 8,333 lb., equal to 40·80 miles an hour, on June 16 last year.

The mean daily horizontal movement of the air for the year was 206·95 miles.

The windiest month was July, with a mean daily horizontal movement of 404·40 miles.

The calmest month was February, with a mean of 106·57 miles.

The barometic pressure and temperature of the air for the year was as follows:—

Barometic Pressure. (5,581 ft. elevation.)

1887.	Mean.	Range.
January ...	24·509 ...	·177
February ...	24·554 ...	·274

November ...	61·3 ...	22·0
December ...	59·3 ...	14·0
The 12 months ...	62·7 ...	32·5
Maximum temperature of air, 77·5, on March 29.		
Minimum temperature of air, 45·0, on Jan. 11 and 25 and February 6.		

The highest temperature in the sun's rays during the year was 145·0, on March 22, and the lowest on grass was 37·0 on January 11, and March 13.

The mean amount of cloud for the year was 6·4. The cloudiest month was December, with a mean of 9·3, and the brightest was March, with a mean of 3·0.

3.—*Henaratgoḍa Garden.*

This Garden has been maintained in good condition during the year, and the plants under cultivation are mostly doing well. Notices of several will be found under their names in section 8 of this report. The Garden suffered somewhat from dry weather in the early part of the year and in September, and generally from want of manure.

Over 3,000 pods of Cacao were sent out gratis to Government officials for distribution to the native villagers. A good many pods, when young, were devoured by squirrels and wild cats, and 179 of the former and 3 of the latter were shot by the conductor.

The road of approach to the Garden has been altered and improved by the clearance of a good deal of scrubby jungle. The wooden bridge at the commencement of the road is undergoing repair by the Public Works Department, and brick pillars have been set up at the entrance, where it is intended to put up gates.

Several new flower beds have been laid out, and a number of new Palms and ornamental trees planted. *Tabernæmontana crassa*, introduced here in 1881 as a rubber-yielding plant, has now formed a very ornamental flowering tree with large sweet-scented blossoms. It is 22 ft. high, but has not as yet produced seed.

4.—*Anurádhapura Garden.*

The past year has exhibited the climate of the North-Central Province at its worst, and the Garden has suffered severely from the extremes of drought and flood. Though the total rainfall for the year, 67·03 in., is 12·47 more than the average annual fall, yet from the middle of April till the end of September scarcely a drop of rain fell : the small pond in the Garden quickly dried up, the water in Tissawewa became at length completely exhausted, and for the latter part of the period no water at all could be obtained. I regret to have to report that a large number of the plants reared with so much care during the past few years died during this time, including Tea, Coca, Pepper, Croton-oil, Cinnamon, Cassia Bark, Sapan, Teak, Panama Rubber, China Bamboo, Grevillea robusta, Rambutan, Nam-nam, and Avocado Pear, besides a great number of ornamental species. Among the plants that were able to live through the drought were, Cocoanut, Jak, Breadfruit, Papaw, Mango, Soursop, Wampi, all the Orange kind, Plantain, Arecanut, Annatto, Surinam Quassia, Cotton, Ceara Rubber, and Rain-tree ; the Liberian Coffee bushes suffered a good deal, but have mostly survived. This severe drought was followed by very heavy and continuous rain, which in December, amounted to a deluge, no less than 26·55 in. falling in that month, and over 6 in. on one day, the 21st. Parts of the garden were now submerged, and a number of young plants sent from Péradeniya to supply the losses caused by the drought were killed. A great effort, however, has been made to renew the Garden, and much fresh planting has been done. It may be confidently hoped that such a complete failure of water in Tissa tank will not occur again, now that the Yóda-ela channel from Kalawewa is in working order.

During this disastrous season the native Conductor has worked well, though he has suffered from fever, and is naturally somewhat disheartened at the failure of so much of his cultivation. He deserves full credit for his perseverance under these trying circumstances. Our small force of labour is almost wholly occupied in watering, and is not sufficient to allow of proper cultivation. We have had, however, as usual, the help of a small Provincial vote, without which it would have been impossible to carry on the ordinary upkeep.

Somewhat more inclination is being shown by the people to cultivate food plants, and there has been a better demand for Jak, Plantain, Arecanut, Mango, Lime, and Orange plants. But objection is raised even to the trifling prices charged, and a free gift seems to be expected.

5.—*Badulla Garden.*

Progress here is necessarily slow, but I think as much has been made as unfavourable circumstances allow. It has not been found possible this year to afford us prison labour to any extent, and our few coolies can do little more than keep up the small portion of the Garden under cultivation. The ridges of the old paddy fields are, however, now almost wholly effaced, and several new paths have been made or planned out, but the multitude of weeds and coarse grasses on the land will give much trouble for some years to come. A low bank has been thrown up round the whole circumference of the ground, and a hedge of Madras thorn planted on the top as a protection against the incursions of the cattle which graze on the neighbouring race-course.

At the request of the Government Agent I have taken over as a portion of the Garden a narrow strip of land adjoining its western boundary. On an inspection of the ground I find it will be difficult to actually include this in the Garden fence, but it can be kept up as an approach to the entrance and planted with shade-giving trees. It is intended to set up gates at either end of the carriage drive during the year.

The Garden is much exposed, and soon begins to suffer in dry weather. Our water-supply is obtained from an irrigation channel supplying paddy fields above, and in time of drought the cultivators are inclined to stop our supply. It has, however, now I believe been made distinctly understood by the parties concerned, that, as was arranged when the site was fixed upon, the Government Garden has a claim to a share of the water from this source at all times.

Large quantities of plants, cuttings, and seeds have been forwarded by cart, coolies, and post from Péradeniya towards stocking the Garden, but much more in this way has to be done before much show can be made. White ants are very abundant, and have worked destruction in the nurseries and devoured nearly all the stock of bamboo pots. But most of the plants put out are

doing well, and many young trees have made very good growth, especially *Cedrela odorata*, *Albizzia moluccana*, *Prosopis glandulosa*, Divi-divi, Loquat, &c. *Erythroxyon Coca* is fruiting freely.

Several varieties of Tobacco have been grown for seed—Brazilian, Virginian, Havana, Sumatra, and Manila, and a large crop of each sort, except of Manila, was produced and carefully collected. The Havana variety appeared to suit the locality best. There has been some demand for seed, and over 60 oz. have been disposed of to planters and others.

The rainfall for the year was 93·89 in., being 15·58 in. more than the average ; but of this no less than 41·67 in. fell in December.

6.—*Interchange of Plants and Seeds.*

Though our relations with other botanical establishments are maintained, I find it increasingly difficult to obtain seeds and plants of interest additional to those we already possess. Many of those I am most desirous to acquire are liable to lose vitality or to succumb to adverse influences during transit, and arrive dead. Disappointments of this kind during the past year have been unusually large. The recent publication of a Catalogue of the contents of the Gardens will, it is expected, by showing clearly what we possess, result in the acquisition from other countries of many of our desiderata.

The customary *gratis* supply of useful and ornamental plants to public places and persons in the Colony has been made on application as follows :—To the Government Agents and their Assistants at Galle, Badulla, Kalutara, Mátalé, Kégalla, Hambantoṭa, and Haldummulla ; the Public Works Department, Colombo ; the Colombo Municipality ; the Colombo Museum ; the Pavilion, Kandy ; the Nuwara Eliya Local Board ; the Superintendents of Police, Colombo and Galle; the Engineers' Quarters, Kandy ; the Medical Officers, Lunugala and Deltoṭa; the resthouse grounds at Wilson's Bungalow, Horton Plains, and Anurádhapura; the Stationmasters of Mátalé, Rambukkana, Hatton, and Koṭagala ; and the Rev. J. Langdon's Industrial School at Haputalé.

I have to express my obligations to the Agents of the great Steamship Companies, the P. & O. and the British India, for their continued assistance in carrying free of freight to or from Colombo Wardian cases passing between Pérádeniya and the other Botanical establishments of the Empire.

8.—*Notes on Economic Plants and Products.*

Tea.—The cultivation and manufacture of tea have now fairly attained the position of the leading planting industry of this Colony. It is estimated that little under 180,000 acres are now occupied with this culture, and the exports during the last financial year reached a total of over twelve million pounds (12,013,686 lb.), the average price realised being close upon 1*s.* 1*d.* per lb. The planting of tea still goes on in all parts and at all elevations of the Colony where the rainfall is sufficient ; and even in the Uva districts considerable areas are now cropped with this hardy shrub.

In connection with this industry the question of fuel must shortly become one of pressing importance in several districts. I made a few remarks on this subject in my report for 1883 (see page 10), and am not able to add much to them. For the higher elevations the Australian Wattle-acacias are unrivalled. As an example of their remarkably rapid growth, that of the silver-wattle (*A. dealbata*) at Hakgala may be noticed. Trees of this, six years from seed, are 51 ft. in height, with stems over 4 ft. in circumference at the base. The tendency of this species to send up numerous suckers is of course much in its favour as a fuel-producer, but necessitates a plantation apart from other cultivations. Of trees of a more valuable character we have endeavoured to meet a very large demand for seed of *Cedrela Toona*, *Grevillea robusta*, and the native *Albizzia stipulata*, and have been able to supply many hundred ounces from the trees in Pérádeniya. The *Grevillea* seems the most generally suitable. Toon, with its beautiful wood probably unrivalled for tea-boxes, is really too good to grow for fuel. At medium elevations a very common weedy little tree (*Trema orientalis*), the "Gẹdumba" of the natives and the "Charcoal Tree" of the English, may be recommended, as it will grow vigorously on the very worst and most stony land.

It is with unalloyed satisfaction that all who wish well to the Siṇhalese must see that a real beginning has been made in inducing them to work as daily labourers on the tea-estates. Managers are gladly employing this Siṇhalese labour where they can obtain it, and in some cases are paying something above the usual rate of cooly wages as an inducement; the work is light, easy, and constant throughout the year. In the general interest of the country it is greatly to be hoped that everything will be done by those who have authority over, and influence with, the impoverished villagers to help them to overcome their prejudices and accept this regular work now offered to them.

The success of tea-growing in Ceylon is leading many other countries to attempt its cultivation, and we have lately sent a supply of seed to New Zealand, where the experiment is being conducted by the Chief Conservator of Forests, on both the east and west coasts of the Northern Island. The plant is doubtless capable of culture under a very wide range of climatic conditions, but the success of tea-cultivation anywhere as a commercial speculation depends entirely on the cost of production, and mainly on the rate of wages for labour.

Coffee.—With an export which has dwindled down to 180,429 cwt. in the past year, it would really appear as though this cultivation, so long associated with Ceylon, were destined to become one of quite secondary importance to the Colony. This further great decrease is due to continued diminution of area, and this has gone on in spite of the high prices for coffee ruling in the market.

But in addition to other trials coffee has suffered severely during the last two or three years

from the attacks of a scale-insect or "bug," which has in some places occurred in such vast quantities as to have actually killed out the bushes, probably already deteriorated by long-continued attacks of leaf-disease and by imperfect cultivation. The presence of this pest has no doubt largely helped forward the abandonment of coffee-cultivation in favour of tea.

It seems the general opinion of practical planters that this insect is different from either of the "bugs" familiar to them hitherto as foes to coffee—*Lecanium Coffeæ*, the ordinary brown coffee bug, and *L. nigrum*, the black bug. It is, however, undoubtedly very nearly allied to the latter. The distinctions between the three kinds have been well pointed out by Mr. E. E. Green, of Pundalu-oya, in a paper illustrated with coloured figures, which has been printed by Government. He names the new pest—which is generally known as "green-bug"—*Lecanium viride*, and thinks it a distinct species. I may add that it is by no means confined to coffee, and that I have for several years noticed it in the Botanic Gardens, where it occurs commonly along with other kinds of *Coccidæ* on a great variety of plants with persistent leaves. It is accompanied, like the other species, by a black fungus; and as in their case, no efficacious remedy has been found for its ravages.

In spite of all drawbacks, I am still of opinion that coffee, at all events as a native cultivation, is still worth encouragement. Liberian is the best sort for growing in small gardens; and sold locally at present prices gives a good return to the cultivator. A large stock of this kind is always available at Henaratgoḍa Garden.

Cinchona.—It is astonishing to find that an enormous export of bark has been still kept up in spite of the very low prices obtained. Considerably over fourteen million pounds (14,389,184 lb.) have been shipped from Ceylon in the past year, yet the unit of quinine has been even as low as 1½*d*. at one time, and much of the bark sold could barely have paid expenses. This quantity is however less by nearly a million pounds than that sent home in 1886, and it may be confidently expected that the export from Ceylon will now rapidly fall. The history of this industry in Ceylon, however unsatisfactory, has been most instructive, and has fully shown the truth of what was so strongly insisted upon from the first by those who looked ahead, that quality and not quantity was the object to be aimed at by the grower. This more far-seeing policy has been followed in Java, and we may now soon expect to see large supplies of rich bark coming from that country.

Some seed of *Remijia pedunculata*, one of the "Cuprea" barks, was received from Kew in April, but I regret to say none of it germinated.

Cacao.—A very moderate extension only of this cultivation is now going on, and the export of the past financial year shows an advance of only 3,000 cwt. (16,638 cwt.) over the year before.

We are still endeavouring to spread this cultivation among the villagers, and a large distribution of seed was made, especially in Mátalé and Kégalla districts. Consignments of seed, of both Forastero and Criollo varieties were also made to Bombay (for Goa) and to Zanzibar, where efforts in Cacao cultivation are being made.

Indian-rubber Trees: Hevea brasiliensis.—Since the plantation of this tree at Henaratgoḍa was thinned out and the poorer and stunted specimens removed, the remainder have thriven remarkably. There are now 457 fine trees, the largest with a stem 53½ in. in circumference at a yard from the ground. A very large crop of seed was produced in June and July, and a case containing 2,000 was sent to Kew for transmission to Jamaica, as well as smaller quantities to Madras, Rangoon, Penang, and Buitenzorg. A request for seed in quantity from the Straits was received too late, but will be complied with next season.

Hevea Spruceana.—As recorded in my reports for 1884, 1885, all of a previous consignment of this rubber died. I have this year received from Kew six more plants, but I regret to have to report that only one has survived.

Castilloa elastica.—The trees of this rubber now grow very slowly; the largest tree at Henaratgoḍa has scarcely increased an inch in circumference during the year, being now 39 in. Some further information as to the method of extracting Caoutchouc from this tree followed in British Honduras will be found in the Kew "Bulletin" for December last. Young plants of this as well as of the climbing Rubbers, *Landolphia Kirkii* and *Urceola esculenta*, are on sale at Henaratgoḍa.

Sapium biglandulosum.—Seeds of this rubber-producing plant, the "Touckpong" of British Guiana, were received from Mr. Jenman in May and germinated well. He reports of this tree: "It is quite hardy, of rapid growth, yields abundant milk, and the rubber is of high-class quality." Samples of the rubber were shown at the Colonial and Indian Exhibition of 1886, and very favourably reported on.

Gutta-percha Trees.—All the sorts we have are doing well, but the plants of this family are all of very slow growth. The "Gutta Sundek" trees (*Payena Leerii*) at Henaratgoḍa are now 18 ft. in height.

Cubebs.—The high price at which this drug has been lately selling in the home market has led to several inquiries as to the possibility of its cultivation in Ceylon and the means to obtain plants. A few remarks may be therefore offered on the subject.

Piper Cubeba is a pepper, and, like the majority of its congeners, is a climbing plant. It is considered to be native in Java, Sumatra, and Borneo, but can scarcely be said to be known wild.*

* The plant lately recorded as Cubebs in one of the local newspapers as found in the south of Ceylon was doubtless one of our wild peppers, of which we possess a dozen species.

The cultivation of Cubebs as a commercial pursuit appears to be carried on only in certain parts of Java and Sumatra, and the business to be almost entirely in the hands of the natives. The dried fruits, which form the Cubebs of commerce, come into trade through Singapore. No details are known of the mode of cultivation, which, however, appears to be merely that of ordinary pepper, the stems being allowed to climb over the trunks of trees, and the fruits plucked before they are quite ripe, and carefully dried. There is no reason to doubt that it could be easily carried on in the moist low-country of Ceylon, and it is perhaps remarkable that it has not been practised by our native population who grow other kinds of pepper so largely. It is, however, by no means easy to obtain the true *P. Cubeba*, which is a plant very little known, and indeed imperfectly understood even by botanists. Several other species approach it very closely, and even at Kew the cultivated plant, hitherto believed to be *P. Cubeba*, and figured by me under that name in 1877 ("Medicinal Plants" III., t. 243), has since been determined to be another species; and there is nothing now there to represent the Cubebs plant.* The botany of the subject is still greatly involved, and in trade also numerous spurious and false Cubebs are met with, the fruits of allied species.

One of the difficulties in the way of commencing the cultivation of Cubebs is due to the plant being dicœcious, with the male and female flowers borne on different plants. On several occasions I have succeeded in getting plants for the Gardens, and at present I have some fifteen young plants at Henaratgoḍa, obtained by propagating from a single one from Singapore. Unhappily, on flowering this proved to be a male, as has been the case with each of the other plants I have been able at different times to obtain. Either sex is, of course, useless alone, and I am now attempting to get ripe seed from Java. But it appears to be difficult to obtain this from the natives. The crop is said to be a somewhat uncertain one, and this may account for the irregular supply of the market and the great fluctuations in price.

Ipecacuanha.—This very valuable drug has been in cultivation here for many years. The Gardens first received it in 1848† from Kew, and additional consignments from the same source were obtained in 1866 and 1871, whilst in 1874 a hundred plants arrived from Calcutta in good order. Many remarks on its cultivation will be found in Dr. Thwaites' reports from 1872 to 1878. So long as it was grown at Pérádeniya very little satisfactory growth could be obtained, and the plants remained very small, but at Henaratgoḍa the results have been somewhat better. Still, as I remarked in my report for 1880, not much progress, so far as the production of the roots themselves went, could be reported. During the past year, however, as a result of more care in the preparation of the soil and choice of situation for the beds, some roots of much finer growth have been produced, and I do not dispair of yet producing a good sample of this important medicine. The plant is propagated with extreme facility by division of its roots, but from its small size and very slow growth it must always be the subject rather of garden than estate cultivation. Mr. Cantley, in his last report on the Singapore Botanic Garden, notes that in Johore he saw thousands of plants in excellent health grown in rich vegetable soil with wood ashes, and well protected from the sun and wind by palm-leaves. I may note that a commercial sample has been imported to London from Singapore (probably from this very plantation) and has formed the subject of analysis, showing a proportion of 1·7 per cent. emetine, which is well up to the average of the Brazilian drug.‡ By order of the Madras Government a plantation is about to be formed in the teak plantation at Nilambur on the Malabar coast.

Coca.—Our numerous old bushes at Pérádeniya bearing this year a large crop of seed, I advertised it for sale and disposed of some 25,000 seeds to over 100 purchasers. As this seems to show some renewal of interest in the plant, a few further notes upon it may be here given. As stated in my report for 1884, we received the plant originally in 1870 from Kew, and I believe that all the plants now in the Colony have been derived from the Pérádeniya stock.§ This matter of origin is important, as more than one variety is in cultivation. Mr. Thiselton Dyer informs me that there is some doubt as to the source of the Kew plant, but it is thought likely that it may have been obtained from M. Triana, the well-known South American Botanist, in which case it was collected in New Grenada and not in Peru or Bolivia. His specimens in the Kew Herbarium, collected on the Rio Magdalena, are precisely like the cultivated plant at Kew. So long back as 1876, when I described and figured the Kew Garden plant ("Medicinal Plants," i. t. 40) it was obvious to me that it differed somewhat in the form of its leaves from the typical *E. Coca*, and I added a figure of the usual pointed form of leaf for comparison. It is probable that several forms are cultivated in South America, and perhaps some may be richer in alkaloid than others. I am informed by Dr. Burck, of Buitenzorg, that two varieties are now being grown in Java, and that one of them has yielded on analysis a percentage of 87 per cent. of Cocaine, which is considerably higher than that of the sample sent home by me from Pérádeniya, as recorded in my report for 1885. I am now sending home for analysis some other more carefully prepared samples of our variety. The existence of different varieties of this species may probably explain the fact, noted in my report for 1884, that though a

---

* See Kew "Bulletin" for December, 1887, where will be found a figure, taken from a dried specimen from Java, of the true plant. A more complete illustration is given in two folio plates in Miquel's treatise "De vera Pipere Cubeba" (1839), of which there is a copy in the Pérádeniya Library.

† This is eighteen years earlier than the date usually given for the introduction of the plant into the East. I regret I have nothing beyond the bare record, in Mr. Gardner's report of these Gardens for 1847-48, of its receipt here.

‡ Pharmac. Journ., November 12, 1887, pp. 400 and 406.

§ Mr. T. Christy of London, is believed to have sent some seeds and plants to Ceylon, but I am unable to trace them.

mountain plant in the Andes, it is not found to grow in our higher elevations. Experience in Ceylon shows that it does well only at levels below about 2,500 ft., and that as a rule some shade is necessary.

Pepper (Piper nigrum).—The plants received from Singapore two years ago are now making good growth, and appear to be of a more vigorous and better variety than any of the native ones so much grown for local sale. It is remarkable that the cultivation of this product on a large scale for export has never been seriously taken up in Ceylon.

Gambier.—This is another great cultivation at Singapore, and, like pepper, is mainly in the hands of the Chinese. Between 25,000 and 30,000 tons of this tanning material are annually exported thence, much of it of a very inferior quality. I have found it most difficult to obtain living specimens of the plant (*Uncaria Gambier*) from which this extract is prepared. Seed appears very difficult to get, as the climbing stems are all cut before flowering, but in March I received over 200 cuttings in Wardian cases. Of these, one sickly specimen only survives.

Tobacco.—It seems probable that a serious attempt at this cultivation as a planting product is about to be made in Ceylon. This is the result of the successful sale in Europe of a trial shipment of leaf grown in the Dumbara valley, east of Kandy, and of the visit to Ceylon of a tobacco grower of experience from Sumatra. So favourably impressed was he with the prospects of this cultivation here, that it is understood that considerable purchases of land have been made for the purpose; and tobacco culture for the home market is at last likely to have a fair trial. It is expected that Ceylon leaf will prove to be specially suited for the wrappers or covers of cigars.

A good quantity of seed of four varieties of tobacco—Brazil, Havana, Virginia, and Sumatra—was carefully harvested at the Badulla garden and disposed of to numerous purchasers.

Report on Colonial Fruit.—In compliance with a request from the Secretary of State, I wrote and sent in to Government in May last a report giving such information as I could obtain on the fruits grown in Ceylon. The object of the inquiry, which extended to all the Colonies of the Empire, has been to ascertain whether the trade in fresh and preserved fruit between the Colonies and the home or other suitable markets could not be extended and improved. However important in relation to some Colonies this question may be, it has little or no practical interest for Ceylon; we are too distant from home to allow of our sending thither fresh fruit as a commercial speculation. Australia can grow for itself all it requires, and we have no other market within reach for our tropical productions. There is, however, one direction in which an improved trade in fresh fruit is possible, and I may quote here a paragraph from my report on the subject:—"In the neighbourhood of the ports of Colombo and Galle there has taken place a considerably increased production of such fruit as can be sold to the dubashes and bumboat men who supply the ships. It appears that this trade has become one of considerable magnitude, but no records of its amount are obtainable. It is certain that the quality is usually very inferior, and the prices paid to the native growers extremely low. The trade needs encouragement and regulation, and its details are well worthy the careful attention of the agents of the great Mail Steamer Companies at Colombo."

As regards *preserved* fruit, I made the following remarks:—"I cannot but think that an export trade might be set on foot in preserved plantains and pine-apples. These can be readily and very cheaply grown in any quantity and of fine quality. Plantains simply sliced and dried in the sun like dates are very tasty and nutritious, and would, if cheap, be likely to sell well at home. A trade in preserved pine-apples has sprung up at Singapore, and might well also be attempted here in Ceylon." It should however be added that in such a business success very greatly depends on the style in which the fruit is put up; unless it look attractive and pleasant, there is no chance of a sale in Europe.

Cherimoyer (Anona Cherimolia).—This delicious fruit has been produced, I suppose for the first time in Ceylon, on trees sent out from Hakgala in 1882, and Mr. Nock reports that Mr. J. Sinclair, of Talawakelé, Dimbula, has kindly sent him a few seeds from them. The Hakgala trees themselves have not yet flowered, though doing well. The best elevation for this fruit is from 3,000 ft. to 5,000 ft., and it is hoped it will soon now become frequent within that zone.

American Blackberry.—I obtained seeds of a strain of this fruit, "Wilson Junior," which has been highly recommended, and they were sown at Hakgala, but I regret to say that none germinated. Several cuttings of English wild Blackberries from Kew have however been successfully started at Hakgala.

Brazil Nut (Bertholletia excelsa).—Of this handsome South American tree, which affords the hard-shelled oily seeds (nuts) so well known in England, we received three plants from Kew in November, 1880. They have not grown very fast, the largest at Henaratgoda being now 20½ ft. high with a girth of 11 in. at a yard from the ground. The only tree at Péradeniya is much smaller, but has twice had the misfortune of being eaten off down to the ground by cattle.

Mangosteen.—Mr. Cantley, of Singapore, when on a visit here in March brought with him some young plants of this favourite fruit tree. Fifteen were planted at Péradeniya and thirteen added to the plantation at Henaratgoda, and all are doing well.

Tuberous-rooted Vine (Vitis (Ampelocissus) Martini).—This is a native of Cochin-China, and was first brought into notice some years ago by Mr. Martin, of the Saigon Botanic Garden. We received seeds of it in 1883 (see report for that year) from the Hongkong Botanic Gardens under the name of *V. Martinellii*, and there are now two healthy plants at Henaratgoda. Mr. Ford, of Hongkong, informs me that it requires a rich soil and then produces very large tubers; the stout stems, which die down every year, require the support of a wire trellis. The grapes, which under liberal cultivation

are produced in about four years, are said to be large and of a good flavour. Such a fruit ought to be a great acquisition to a tropical country—and I hope we shall succeed in the culture of this interesting plant.

Tuberous-rooted Bean (Pachyrrhizus).—Under the name of "*Dolichos tuberosus*" we received from Kew in June last seeds of a pulse which appears to be a useful addition to the vegetable garden. The young plants put out in August grew vigorously over the ordinary bamboo supports, and in November produced a crop of large pods which, sliced and served like French beans, were very sweet and tender. But besides the pods the plant also afforded large, elongated, arrowroot-like tubers on the roots, which, though without much taste, are palatable when well cooked, and somewhat like a very firm-fleshed turnip. I have not been able to trace the name under which the seeds were received, but the plant appears to be a variety of *Pachyrrhizus angulatus*, Rich. (*Dolichos bulbosus*, L.) which, though said to be widely grown as a tropical vegetable, seems hitherto quite unknown in Ceylon.*

Cho-cho.—Mr. Nock writes :—

It is interesting to note that the old plant, the parent of all in Ceylon, is in a very flourishing condition, and since the vines were cut back and the roots manured, it has produced a fine lot of handsome fruit, several of them weighing 3½ lb. each. I may also mention that the yam which the plant produces is much relished by the natives. It makes, to their taste, a first-rate curry, and is preferred by many of them to the "English" potato. To test the weight of yams one plant would produce I had one lifted, in October, and found it yielded 22 lb. of edible roots. This plant was about eighteen months old.

Ullucus tuberosus.—Mr. Nock reports further on this plant :—

It does very well in this climate and crops freely. On one root which I lifted I counted 263 tubers, varying in size from one inch in diameter to the size of small peas. The largest tuber in the whole crop weighed only ¾ oz.; but want of size is made up for by number, and the produce of one root would be enough for at least one good dish of curry. Its cultivation is exceedingly simple, and it will, I think, prove to be a valuable addition to the native vegetables. If the tubers are planted in good soil, about 18 in. apart, it matures its crop in from four to six months. All the cultivation it requires is to be kept free from weeds by hand, and watered occasionally in dry weather. The stems trail along the ground and produce roots at almost every joint, and these also produce tubers so that the soil about them must not be disturbed. As soon as the tops die down the tubers should be lifted, and are then ready for use. Like potatoes, those that are required for "seed" should be stored in a dry place until they begin to sprout, and they are then fit for planting. This would be about the month of April.

Teff (Eragrostis Abyssinica).—At the beginning of April I received from the Royal Gardens, Kew, a small quantity of seeds of this cereal of Abyssinia. Some were sent to Hakgala, and Mr. Nock reports :—

It was sown on the 5th, began to germinate on the 10th, and grew very fast. By the end of May it was 18 in. high. It began to flower on the 15th of May. It was harvested in July, and yielded a crop of 41 ounces of grain. The yield would have been much larger but for the destruction by hares, which eat a considerable quantity of the young plants. The grain is very small, but well-tasted, and I have no doubt will make a good flour for cakes.

I also sowed a bed at Pérádeniya, which is at too low an elevation for this mountain grass. It was in flower by April 20, and seeded sparingly in June. In Abyssinia this small grain is much appreciated by all classes; it is cultivated there at elevations of from 6,000 ft. to 7,000 ft. A full account will be found in the Kew "Bulletin" for January, 1887.

Barley.—For some years this cereal has been grown by the Badagas on the Nilgiri hills for the use of the local brewery at Ootacamund, and on the initiation of Mr. J. W. Howard, manager of the branch of the same Company at Nuwara Eliya, an effort has been made to promote its cultivation in our hill country. This gentleman has supplied those willing to try it with seed from N. India, free, and agreed to purchase the crops at Rs. 2 per bushel. He has, at my request, kindly given me the results so far, and he thinks them promising; I fear, however, that our climate will in most years prove either too hot or too wet, or both, to allow of a crop ripening. The greatest success as yet has been met with at Welimada, on the slopes of Wilson's Bungalow, Uva, where in the season 1886–7 a crop of 30 bushels an acre (33-fold) was reaped in February, the seed having been sown in November. But in the present dry season (1887–8) the yield has been only 13-fold. The only other place where barley has been successfully grown is at Hanguranketa, where in 1886–7 100 bushels were harvested; but this season the crop has entirely failed there. Unsuccessful attempts have also been made at Uda Pussellawa, Mátalé, and Kégalla. Some 200 bushels have been brought to the brewery, but the grain was not fit for malting owing to the growers having harvested it before it was fully ripe.†

Eucalyptus Plantation, Hakgala.—Mr. Nock writes :—

The trees suffered very much during the high winds in June, July, and August, and the whole plantation looks very scrubby, as the tops of many of the best trees have been broken off and the branches torn about in all directions. It is evident that in exposed situations this class of trees should be planted very close together in order to support one another in rough weather. I find, too, that, like all other trees, to really thrive and make good timber they want good soil. They can, however, be grown for firewood on comparatively poor land.

---

* Since the above was written, I am imformed by Mr. Thiselton Dyer that the seeds were received at Kew from Trinidad, and that the plant is the "Yam Bean" of the West Indies.

† I have the opportunity of adding to the above the encouraging results of the present season (1887–8) in the Welimada fields. The grain was reaped in March, and several samples competed for the prizes offered by Mr. Howard at the Show held at Nuwara Eliya at the beginning of April. All were of remarkably good quality: the grain hard, dry, and well filled; the best weighed as much as 56 lb. per bushel. The exceptionally dry season appears to have been very favourable to the complete ripening of the grain.

The following table shows the height and girth of the fifteen selected trees, and may be compared with the table of growth for the years from 1884 given in the last report. The soil they are growing in is very poor, so that they might be expected to do as well as this in almost any soil. They are nearly six years old from seed.

Names.	1888. Height. ft.	Girth. in.	Names.	1888. Height. ft.	Girth. in.

English Oak.—About 4,000 acorns were received at Hakgala from Kew. On December 8 Mr. Nock reports that they are germinating freely, and that in a few months' time he hopes to have a good stock for distribution in the hill country.

Conifers at Hakgala.—Several of these have now attained a very respectable size. The following are Mr. Nock's notes on those which are doing the best :—

Cupressus torulosa, the Himalayan Cypress. The largest specimen of this ornamental pyramidal tree is 62 ft. high with a girth of 6 ft. 4 in. This species does equally well at Pérâdeniya.

Cupressus macrocarpa is now 56 ft. high with a girth at base of 6 ft. 9 in. and a spread of branches of 40 ft. It is a very handsome tree and produces excellent timber.

Cupressus, species, with small fruit. This, of which we have several large specimens, is one of the best trees in the garden, and is growing very rapidly now. The largest is 58 ft. high, 8 ft. 4 in. round the base, and the spread of branches measures 38 ft.

Pinus longifolia, which is one of the most valuable timber trees of the Himalayan regions, continues to thrive well, and the largest specimen, by the office, is now 41 ft. 6 in. high and 6 ft. 6 in. round the trunk at base, and through the branches 25 ft. This is so far the best *Pinus* yet tried here ; it really grows well, and being very ornamental is very useful for planting round bungalows at high elevations. The only other *Pinus* that is doing well is *P. sinensis*, but these are all young yet, and look rather weak in the stems.

Cryptomeria japonica.—A few of these plants are now growing rapidly and are exceedingly handsome trees. The tallest is 42 ft. high with a girth of 6 ft., well shaped and clothed to the ground with branches.

Thuja gigantea is now 31 ft. high and 4 ft. round the stem close to the ground.

Ebony.—In response to an application from the Department of Agriculture of the United States, a supply of seed of this valuable cabinetwood has been sent for trial in South Florida. It is scarcely to be expected that this thoroughly tropical forest-tree can succeed there ; but experiments in the same direction are being largely tried in the State with other equatorial species, and the cocoanut is already successfully grown in some places. Seed was at the same time, in November, despatched to Jamaica, Perak, and Fiji.

Ceylon Oils.—At the Colonial and Indian Exhibition of 1886 there were exhibited a few small samples of some of our native oils from the Northern and Central Provinces.

These were submitted to a well-known expert, Mr. L. Field, and in his report he has remarked on the very great suitability of some of them for soap-making. Punnai, Illupai, and Kękuna oils were all new to him, and of each he speaks very highly in this respect, and expresses the opinion that a very large demand for them would arise if they could be supplied at a cheap rate. It would appear that there may be here an opening for a large business in the native districts.

Punnai nuts, the seeds of *Calophyllum Inophyllum*, can be obtained in quantity on our coasts ; the Illupai, or Mi tree, *Bassia longifolia*, is abundant throughout the drier districts ; whilst the Kękuna, *Aleurites triloba*, though not native, is to be found in every village in the moister regions of the Island.

9.—*Herbarium, Museum, and Library.*

Herbarium.—I made two botanical collecting tours during the year, one to Héwessa and neighbouring parts of the Pasdun kóralé, and the other to the very little known mountain, Ritigala, in the North-Central Province. In these expeditions I was successful in adding a few plants to the Ceylon flora. The Ceylon Herbarium is now all in very good order, and additional specimens are readily intercalated in their places as they are obtained. I have devoted some spare time to sorting and arranging our duplicate specimens, but have very little leisure for this kind of work.

The late Mr. W. Ferguson, shortly before his lamented death on July 31, permitted me to go over his valuable collection of Ceylon *Algæ* (seaweeds, &c.), to select from it a series for Péradeniya where this class of plants was poorly represented. A list of the Ceylon species has been published during the year by Mr. G. Murray of the British Museum, and I have now arranged our collection in accordance with it.

The whole of Dr. Thwaites' accurate analytic drawings of dissections of Ceylon plants have been laid into their places in the collection of coloured drawings.

The *General Herbarium* has been enriched during the year by the following donations :—

From the Royal Herbarium, Kew :—Collections from Malacca and other parts of the Malay Peninsula, collected by Hervey, Curtis, and others, and from the Seychelle Islands collected by Neville.

From Dr. King, F.R.S., Calcutta :—Four bundles of Indian plants from the Calcutta Herbarium
From C. Curtis, F.L.S. :—186 species of plants from Penang.

My principal employment during the past year has been the compilation, with the aid of the Library and Herbarium, of a Catalogue of the contents of the Gardens. This has long been felt as a pressing want both by the Garden staff and the general public, and especially by our correspondents in other countries ; but it is a work which cannot be done hurriedly. The list as now completed is brought down to the end of 1886 and contains about 3,000 species, mostly trees and shrubs. The Government Printer has done his share of the work with accuracy and despatch, and the little book, "Hortus Zeylanicus," of 130 pages was printed within the year and published in January, 1888. It is now on sale at the price of Re. 1, at the Garden gate. A Herbarium of cultivated garden plants, named in correspondence with the Catalogue, has also been in course of formation at the same time ; it has made considerable progress, and will be constantly kept up.

Museum.—At last I am able to report the commencement of the long projected Museum of economic botany. The hand specimens of Ceylon timbers mentioned in my last report have been all cleaned, poisoned with corrosive sublimate, and labelled with printed tickets giving their botanical, Siṉhalese, and Tamil names. Stands have been made to accommodate them, and the whole series, 335 in number, occupies two rooms of the Museum building. There are several duplicates of the same wood from different parts of the Island, but a good many of our timbers are still unrepresented.

At the close of the Colonial and India Exhibition in London, in 1886, I made an application to Dr. Watt, the officer in charge of the Indian Economic Court, for a set of any drugs, food products, or other vegetable substances of which duplicates might be available. In April last three cases of such specimens were duly received at Pérádeniya, and though a good many were considerably damaged by sea-water, I have been able to select over a hundred specimens of grains, fibres, drugs, resins, &c., which will be very useful for reference.

We have also received a valuable donation from the Museum of the Pharmaceutical Society in London, an institution to which it has been occasionally within my power to contribute specimens. This consists of 150 fine samples of the drugs in ordinary use. I have not as yet unpacked these—they arrived in November—as I have no proper receptacles to contain them. Until I am able to provide a supply of air-tight glass-stoppered jars, nothing can be done in the way of the exhibition of specimens of this kind.

10.—*Receipts from Sales.*

There is a substantial increase in the sales at Pérádeniya during the year. This is mainly due to the large sale of seed of timber-trees for planting on tea estates. The sales of Wardian cases were 16, and of boxes of Orchids, 20.

WILSON, SMITHETT & CO.'S

CEYLON TEA MEMORANDA FOR 1887.

LONDON, FEBRUARY 10TH, 1888.

The amount of Ceylon Tea brought to auction between January 1st to December 31st, 1887, was nearly double that sold in the previous twelvemonth and realized an average price of close upon 1s. 1d. per lb. against 1s 1½d in 1886. Considerable irregularity has characterised the market throughout the year, the operations of dealers generally being carried out in a thorough hand to mouth way; this may, we think, be attributed chiefly to two causes: firstly to the uncertainty in the minds of dealers as to the probable supply, and, secondly, to their experience of the early deterioration of CEYLON Tea. The first hindrance to a more regular market will be removed, of course, when the present acreage in Tea has come into full bearing, and the increase in the annual yield is no longer one of arithmetical progression; the second drawback is one to which we invite the earnest attention of planters. We look forward to seeing the fine delicate highgrown Teas of CEYLON come more and more into favor in those quarters where the finest descriptions of CHINA Tea have hitherto held the supremacy, and where, by reason of the growing scarceness or inferiority of the latter, a large field lies open to the competition of a formidable rival. A very marked feature of fine CHINA Tea has always been its keeping power; it not only keeps well but actually improves up to a certain time, and it is an everyday lament amongst connoisseurs of CHINA Tea that since the days of the clippers, the arrivals of New Season's Teas have shewn no really fine quality, which means the London Market has seen them too soon. It is noticeable too that the early arrivals of New Season's DARJEELINGS also improve; when they are first put on the Market they taste green and raw, but nevertheless realise very full prices, and it is evident, from the competition they arouse, that they eventually ripen into full and flavoury Tea. We are of opinion, that over-withering and fermenting and too quick firing are chiefly responsible for the early deterioration of CEYLON Teas; the fine CHINAS, we have alluded to, always have a somewhat greenish out-turn and feel "spongy" when grasped and appear to have been literally "dried," whereas a great many CEYLONS seem to be thoroughly "toasted;" the leaf is parched, and after the first brisk burnt aroma has passed off, the Tea is dead and flat; the use of machinery seems to have brought with it the temptation to fire the greatest amount of leaf in the fewest number of minutes possible; we fear that the climate of Ceylon presents a great bar to keeping reserve samples of manufacture for any length of time in good condition, but we commend to producers the great desirability of making experiments with a view to discover the way to make their Teas keep better.

Our list of gardens, with estimated yield and average price per lb. realised, numbers this year 270, whose out-put in Mincing lane has amounted to not less than 5,000 lbs.; we may observe that in cases where the produce has sometimes been sold in Colombo a very correct estimate has not been always attainable, for the reason that a large number of these Colombo purchases have been bulked together and shipped under fancy marks. On the whole, however, we believe our statement, which has been carefully compiled from a daily register of the public sales, will be found to give a very correct idea of the results obtained on the several estates and in the several districts. It is noticeable that by dint of continued fine plucking the same three estates that headed the list last year occupy the same prominent position this year with only this difference, that BLACKSTONE and AGARSLAND have reversed their respective relations. It must be left to the experience of planters to decide whether such fine plucking as obtains on these estates is in the long run hurtful to the bushes; with the career of the famous LOOLCONDERA estate before our eyes it would be hasty to condemn fine plucking on this account; with temporary exceptions at the time of drought early last year this Tea garden has shewn as fine quality as ever during the past year, and has averaged fully 1d. per lb. more than in 1886; but with regard to the question whether it is not after all more remunerative to pluck in a freer manner, we must remind producers that CEYLON Tea depends for its continued popularity upon a maintained reputation for distinctive character and quality, and upon the continuance of that popularity depends the very life of the industry. Adherents of the system of liberal plucking will no doubt point to the splendid results again achieved by MARIAWATTE, viz., an average price of 1s 2¼d per lb. with a yield of something like 1,100 lbs. an acre, but the fact that this estate is very highly cultivated must not be lost sight of; CEYLON Teas, excepting perhaps some of the lowest grown, have none of the inherent robustness of INDIAN and we fear that if, in their eagerness to rival the output of INDIA, planters resort to a system of comparatively coarse plucking, the bulk of CEYLON Tea will be reduced to a low level of pointless mediocrity, in which case prices would unquestionably fall to a range below that now ruling for ordinary liquoring INDIAN.

The figures immediately below speak for themselves and are highly encouraging to planters in INDIA and CEYLON; 10 years ago the proportion of INDIAN Tea drunk in the United Kingdom and Ireland was 18¾ per cent. of the total consumption; five years later the percentage had risen to 30½, and last year more than half of the total consumed was INDIAN AND CEYLON.

Home consumption of China and East Indian growths in 1877, 1882 and 1887.

	CHINA.	INDIAN and CEYLON.
1877	123,012,000 lb.	28,013,000 lb. or 18¾ per cent. of the total.
1882	115,589,000	50,497,000 or 30½ " "
1887	90,600,000	93,054,000 or 51 " "

MALTINESS.—This attribute should, in our opinion, be confined to the robuster but less flavory low grown teas, and especially to the lower grades. Where fine flavor is not a marked feature of the tea a brisk malty aroma is undoubtedly of great value, but it almost annihilates that delicious delicate flavor characteristic of well-manipulated high-grown tea, which constitutes its especial value.

BROKEN PEKOES should not be too small nor contain any large proportion of minute flaky leaf; such teas do not blend well. Unless of exceptional strength, Ceylon Broken Pekoes do not compete with Indian. The best style of manufacture for the highest grade is that of a semi-broken Orange-Pekoe with plenty of tip and a well-made leaf.

PACKAGES.—Souchongs and Pekoes may be packed with equal advantage in chests or half-chests; there is a demand for both sizes. Broken Pekoes as a rule sell best in half-chests; it is a mistake to pack them in boxes. Breaks of good whole-leaf tea (Pekoe Souchong, Pekoe, or Unassorted) in 20 lb. boxes are very desirable and as a rule realise about 2d per lb. above the market value of the tea. Such packages have a ready retail sale and are the means of making the public acquainted with the peculiar merits of Ceylon tea in a much more satisfactory way than through the medium of the packet trade.

SMALL BREAKS.—Lots numbering less than 18 half-chests 12 chests or 30 boxes are reckoned "small breaks," and are reserved to the end of the auction, when they are disposed of to the very limited competition of the small buyers.

Wilson, Smithett & Co.'s Ceylon Tea Memoranda for 1887.

Summary of CEYLON TEA sold at Public Auction in London between January 1st and December 31st, 1887.

☞ **NOTE.—A Qualities are very Strong Blanks, highly finished.**
B „ are Strong Blanks, well finished.

The MICHOACAN SILVER is the nearest approach to real Silver yet produced. It is, both in colour and finish, equal to Silver. Wears the same colour throughout. Resists acids, and does not tarnish.

It is particularly adapted to Hotels, Restaurants, &c., and for this purpose we recommend the "Old English" pattern.

SAMPLES SENT ON APPLICATION TO RESPONSIBLE PARTIES, OR ON RECEIPT OF STAMPS TO THE AMOUNT, AS PER LIST.

SHIPPERS AND THE TRADE ALLOWED AN EXTRA DISCOUNT.

ADVERTISEMENTS.

[For acknowledgement of Subscriptions paid and for list of *T. A.* agents, see top of 6th advertising page. 2nd column, farther on.]
