One illustration given by the author, to show that liquids penetrate into plants through their roots, we do not think very happy. He notes an observation made by himself, that Indian corn made to sprout in a flower-pot and watered with milk had white leaves; and he suggests that the minute particles of solid matter in the milk must have entered the plant and caused the whiteness. He admits, however, that the whiteness may have been due to chemical action. In noticing the growth of plants in artificial light, he hardly gives sufficient credit to the observations of Siemens and of Dehérain on growth in the light of the electric arc, both uncovered and variously shaded. Mr. Storer has scarcely that respect for earthworms with which Darwin has imbued us, for on the only occasion he mentions them, he styles them pernicious, on the ground that harm is done to plants in pots by their casts, which become slimy mud when watered, and thus clog the pores of the earth and the roots of the plants.

In vol. i. p. 295, a serious mistake occurs, though doubtless by oversight: it is stated that nitrate of soda used as a top-dressing for mowing-fields that contain true grasses "favours the growth of clover rather than of grass." The reverse of this is the truth. There is a good chapter on irrigation, in which it is pointed out that, "in spite of all that has been done of late years in California and the adjacent regions, it is still probably true that no other subject relating to agriculture so much needs to be attended to by the American people as this matter of watering the land." The questions of the disposal of excreta and of sewage are dealt with in their chemical aspects. Perhaps, hardly due credit is given to the latest improvements in some precipitation processes for clarifying sewage, but we are glad to see that the author fully realizes that the sewage subject is essentially a sanitary and not an agricultural question. He also exposes some economic fallacies as to the value of sewage by citing various instances in which valuable matters are found at our doors so diluted as not to be worth the cost of collecting or saving. One illustration is the presence of gold in the clay of Philadelphia—1 of gold in about 1½ million of clay. If the gold from the bricks of the houses could be brought to the surface in the form of gold-leaf, on each brick would be a golden surface of 2 square inches. In the clay beneath the portion of the city already built over is 120 million dollars' worth of gold, yet no one dreams of extracting it. So, except under very favourable conditions for the sewage, valuable manures may be obtained more cheaply than from sewage.

The necessity for the selection of ripe, as well as pure, seeds for sowing, and especially on poor soils, is insisted on and illustrated by records of experiments. The great importance, whether for good or evil, of micro-organisms to the farmer, is often pointed out; and the writer discusses the question of the sources of nitrogen available to plants, and the very important question as to the fixation of free nitrogen from the air by humus or by clay soils. The conclusions of Berthelot, Armsby, Dehérain, and others are stated, and the author regards it as proven in the light of existing knowledge that some nitrogen from the air is really fixed as an incident to certain fermentations which occur in the soil. This much debated and debatable point, which is of the utmost economic importance, still requires further elucidation; and we may hope that some further light will be thrown on it by the researches of Sydney Vines on the nutrition of the common bean.—*Nature.*

BUTTER-MAKING.

Butter-making as a science is utterly unknown in this country, but to those who may be engaged in this industry on any considerable scale, the following instructions for butter-making, which are observed at the Ontario Agricultural College Farm, Canada, will perhaps commend themselves as worthy of consideration:—

1. Good ventilation for the milk-house, milk-cellar, or diary-room is most essential, and may be provided for by leading an air-drain under ground for, say, 200 feet. Through it a supply of pure, fresh, cool air may be admitted. The foul or warm air may be allowed to escape through ventilators or windows in or near the ceiling.

2. Cream should invariably be removed from the milk, before the milk is sour.

3. The cream of each churning should be gathered into and kept in one vessel.

4. The whole of the cream should be well stirred every time fresh cream is added.

5. In summer, cream should not be left longer than three days before churning.

6. The best churning temperatures are between 57 and 60 degs. during summer, and between 60 and 64 degs. during the winter.

7. Butter can be more thoroughly washed free from butter-milk, while in the granular condition than after it is gathered or pressed into a roll.

8. Only the best pure salt of medium and uniform fineness of grain should be used, and from three quarters to one ounce of salt per pound of butter will be found satisfactory for the summer.

9. The utmost cleanliness in milking, in vessels, in utensils and in all surroundings must be observed to preserve the flavour and body of milk, cream, butter and cheese from contamination.

The same authority uses the following general rules:—

1. Milk from healthy cows only should be used, and not until at least four days after calving.

2. Any harsh treatment that excites the cow lessens the quantity and injures the quality of her yield.

3. Cows should be allowed an abundant supply of wholesome, suitable food, and as much pure water as they will drink.

4. A supply of salt should be placed where the cows could have access to it every day.

5. Cows should not be permitted to drink stagnant, impure water, nor to eat cleanings from horse stables, leeks, turnip tops, nor anything that would give the milk an offensive taint.

6. All milk vessels should be thoroughly cleansed, first being well washed, then scalded with boiling water and afterwards sufficiently aired to keep them perfectly sweet.

7. Cows should be milked with dry hands and only after the udders have been washed or well brushed.

8. Milking should be done and milk should be kept only where the surrounding air is pure and free from all objectionable and tainting odours. Milking in a tainted stable or yard, imparts to milk an impure taint. Sour whey should never be fed, nor should hogs be kept in a milking yard, or near a milk stand.

9 Tin pails only should be used.

10 All milk should be properly strained immediately after milking, and for that purpose a detached strainer is preferable to a strainer pail.—*Indian Agriculturist.*

AGRICULTURE ON THE CONTINENT OF EUROPE.

(Special Letter.)

PARIS, 24th December 1887.

Nearly one-third of the vineyards of France have been destroyed by the phylloxera whose ravages have received as yet no wholesale check. Farmers who have thus suffered, turned whenever practicable the land into meadow, or cropped it with grain and roots. After some years had elapsed under this system of changed culture, the soil when dosed with spcial industrial manures seems to have recovered, and to present a new departure for successful vine culture as well as ameliorating those vines which are not a prey to either a parasite or a fungus.

Farmyard manure is the usual fertilizer applied to the vine. As the latter grows often in sloping situations, and difficult of cart-access, that manure is thus expensive and out of proportion to its value. Hence the plan of employing chemical fertilizers judiciously as phosphates, potash, and nitrogenous matters, which present many advantages. On the first appearance of the phylloxera, Liebig laid down that the high feeding of the vines was one powerful means for combating the scourge; they could resist the insect better than a vine badly nourished. Becchi, the director of the agronomic station of Florence, attested by his experiments in 1866-68, that the application of potash salts to the soil enables the vines to resist the oidium, better than those receiving farmyard manure. The Swiss attribute the relative exemption of their vines from the attacks of the phylloxera to the use of chemical manures—another illustration of Liebig's assertion, that a sickly and famished plant falls the earliest victim of disease. The animal world also affords apt illustrations of this truth.

Messrs. Boussingault and Grandeau have analysed the soils of vineyards in Alsace and the Champagne districts, as well as vine cuttings, the vine produced and the residuum or pulp of the press. Assuming 18,000 vines to the acre and 880 gallons as the average yield of vine, a vintage would remove from an acre of land about 14 lb. of potash and 8 lb. of phosphoric acid. Now, wheat abstracts from the soil nearly four times the amount of phosphoric acid and the quantity of potash is nearly the same; while potatoes remove four times the quantity of potash and double the amount of phosphoric acid as the vine. In the Champagne districts the soil famous for producing the most renowned branch, only approach in point of richness to ordinary arable lands. Here farmyard manure would suit vineyards. In the Champagne regions, and less so in those of Burgundy, the soil is calcareous. Quite the contrary is the case in the Bordeaux or Claret regions where the soil is markedly silicious, poor in potash and lime, but notably rich in magnesia; at least such is the out-come of the analyses of the soils of such producing claret-brands as Châteaux Laffitte, Yquem, and Margaux.

It will thus be seen that the vine has no greater mineral exigencies, but rather the contrary than other cultivated plants; that the composition of the soils in Champagne, Burgundy and Bordeaux, differs in poorness in potash and phosphoric acid; yet all can be ameliorated by suitably selected fertilizers just as ordinary soils, whilst the latter have everywhere produced by their slower action the best results. Now for the vine, as for other shrubs, the application of farmyard manure has a tendency to promote the development of wood. Nitrate of soda and sulphate of ammonia by the rapidity of their action induce the undue growth of branches and leaves at the expense of the fruit. Woollen rags, torrefied leather refuse, dried blood, oil-cake &c, if cheap, are excellent vine manures as they decompose slowly and thus magazine their nitrogenous or stimulating influence. Natural phosphates dephosphorized scoria or slag, kainite, &c., are also excellent fertilizers. Chemically a manure sufficient for the demands of the vine during ten years, excluding the leaves which naturally fall and remain, ought to contain in pounds weight 132 of nitrogen, 220 potash, and 176 of phosphoric acid per acre, representing a market cost of 170fr. or about 17fr. per annum, for ten years Ten gallons of wine yearly, out of the augmented annual yield of one-fifth would pay for the outlay.

There are many farmers on the Continent who have never accepted the substitution either in whole or in part of maize for oats in horse-feeding. Indeed some go the length of asserting, if maize dominated over oats the best breed of horses in the land would ultimately die out. Maize, it is alleged, runs the horse into flesh and fat; the animal becoming spiritless instead of hard muscle, an energetic and vigorous character. Feeding entire horses on maize reduces them to the vitality of castrated animals. Further maize diminishes the vigor of mares in the rearing of their foals, developing indolence instead of energy. However, no one wholly excluded oats from the ration, but reduced that aliment next to an algebraic x. There is in oats a special principle or stimulus that no other grain possesses—independent of the question of relative richness—and peculiarly adapted for the development of vigor while enabling the animal to recruit rapidly its exhausted strength.

The poultry yard of late is receiving more attention as a source of revenue. It is now no longer left to the side attentions of the farmer's wife. Poultry fatting in a word is becoming a profitable business. Like the fattening of live stock the object is to impart a superior quality to the flesh by rendering it more tender, more savory, more easy of digestion. To effect this successfully and with profit, the animal must be fed abundantly from its birth—so as to aid the development of muscle—by an alimentation rich in nitrogen substantial and of small volume. By degrees the ration is augmented with substances rich in sugar fecula or fat. If the chickens belong to a good and precocious breed, and received ordinary care and feeding, they will in three or four months be able to be sold off to the fattener.

The fatting process must not commence till the animal has almost completed its development. If earlier the high feeding will produce muscle and bone, not fat If the adult age be exceeded it will rarely pay to fatten such birds. Pullets of the Crèvecœur race can commence to be fattened at four months; the Houdan and Dorking at five, Flèche at six, and the Bresse at seven or eight. The season most favourable to fattening is the close of autumn or winter. If hatched in March or June, the chickens would thus be ready for fattening operations at the foregoing epochs. The castration of the birds of both sexes dates from antiquity, and takes place when they are about three months old. In some countries the operation is dispensed with. To supply fat-forming food is not the be-all of fattening; care must be taken that the fat when produced be not eliminated from the system. Hence, keep the muscles inactive; in other words coop the birds in pigeon-holes just capacious enough to allow them standing room; above all let the place where they are kept be dark, as light is an exciting agent, and so consumes muscle. This explains why formerly poultry to be fattened had their eyes extracted.

The simplest manner to fatten is to place a small trough in front of the crib filled with a paste of average thickness consisting of barley, buck-wheat, or maize flour, wetted with skim milk or cheese-whey. Add a little salt, prepare the paste the eve before using it to allow fermentation, and thus facilitate digestion. Pending the first five days, feed twice a day, afterwards give the paste three times daily. Some fatteners commence by giving crushed buck-wheat and maize the first three and unbruised oats during the last two days. Three weeks suffice for the whole process; some pullets demand more time. Ordinarily, out of 100 birds, three successive selections are made for the market. Fattening mechanically consists in forcing small balls of the paste by means of a machine, down the throat of

the bird. Pliny says, they were the inhabitants of the Isle of Delos, in the Grecian Archipelago who first fattened poultry; this was over 2,000 years ago. The Romans, 160 years B. C., fattened young cocks on flour and milk; moderns proceed on the same lines.

In localities where farmers are not yet grouped into co-operative associations, for the purchase of seeds, manures, implements &c., nor the purchases subject to the control of an agronomic station, the following plan is adopted respecting beet-seed. Buy the latter a long time in advance of the period sowing. Select a fair sample of the seed, and test its germinative power according to the following standards of Sempotowski and Petermann. The germinative power of the capsules is 75 to 80 per cent and 65 to 60 per thirtieth part of an ounce (one gramme) of the naked seed. The purchaser ought to insist on the merchant guaranteeing a certain number of germs, for a fixed weight of seed, and to decline accepting his purchase, if the seed does not attain the determined minimum of germs according to the venders' guarantee; a toleration reduction of five per cent below the germ-standard, may be allowed.

Carrots are taking more and more a greater extension in the feeding of horses. Bulk for bulk, an acre of carrots would seem to supply more nutriment, than an acre of oats. The following is the average of a series of analyses of the respective nutritive constituents of both crops.

	Oats.	Carrots.
Water	14·3.	85·0.
Nitrogenous principles ...	12·0.	1·4.
Fatty matters	4·8.	0·2.
Carbonaceous matters ...	41·8.	11·0.

The difference is very great; but the carrot is aqueous while oats are dry. The former contains eight times more carbonaceous than nitrogenous (or albuminous) matters; hence, ought to be excellent for mixing with other rations, such as beans &c. Taking the yield of oats per acre at one ton, and of carrots at 20 tons, the difference would be in favor of the latter, since oats have not a nourishing value twenty times superior to that of the carrot.

The question is being discussed, whether it is better to harrow meadows—to free them of moss and permit of the aeration of the soil—at the commencement of spring or in autumn. For grass land in elevated situations, where the soil remains humid for a longer time in spring, perhaps autumn would be the more propitious time to give a stroke of the harrow, the more so, as in spring the transition of the soil from a moist to a dry condition is often sudden. After the harrowing, apply the top dressing, which will work into the openings effected by the teeth of the implement. When spring arrives and the land has become dry, the passage of the roller will bind, refresh, and vivify the soil.

The rearing of calves is a matter of serious importance in Germany, and it is therefore not surprising to encounter much diversity as to the best methods for tiding them over their first year. The bases of the rations mostly consists of oats, oat-meal, linseed cake, good clover or prime meadow, hays. To this régime is added in winter a small quantity of crushed carrots. Some give a little beet, but the grand majority of rearers are against that practice. The new meat-powder produces excellent results. It is essential that the calves should have full liberty of movement, abundance of fresh air, and that the byre should not be too cold. Great regularity ought to be observed in their feeding, and a little salt given two or three times a week will be an excellent promoter of good health. The bedding must be kept scrupulously clean, and the troughs scoured in summer, weekly, and in winter, fortnightly. Acidity in the mangers is often the fruitful cause of scour. A good indicator of the progress and the condition of the calves is to weigh them once a month. Nothing more common in Paris than to keep a record of the weekly weight of babies. A pair of nursery scales is as essential as a cradle.

CINCHONA (AND COFFEE AND TOBACCO) IN JAVA.

We call attention to interesting information respecting these products on page 520. We shall shortly have somewhat to say of the pre-eminently prosperous position of late held by tobacco—almost the only 'product' with a rising tendency in price for some years back. As regards coffee, our Java brethren are beginning to be quite cheery, imagining the leaf-disease is finally disappearing while no other pest is anticipated. But it is in cinchona that Ceylon planters have most practical interest at present, and it is worth noting that on the authority of an apparently reliable report, the number of private plantations in Java are put down as, at least, "sixty," that these are from 5 to 8 or 9 years old, and that the bark of these gardens is expected mainly to come into the European market during 1889-90. Let us suppose that on the 60 private cinchona gardens there is an average of 200 acres planted, or with growing trees—which is surely a liberal allowance considering what an acre of cinchona trees means,—and we get 12,000 acres under the product in private hands in Java. But such figures would, after all, convey only an inadequate idea of what effect the Java enterprise may have on the world's market; for, apart from the fact that the area planted may represent 15 to 25 millions of fully grown trees, each ready to yield 3 lb. of bark 12 to 18 months after this time, there is the astonishing richness of the Java bark to face. The results obtained from the hybrid ledgeriana in the report we refer to are truly amazing, and we may therefore calculate that by 1889-90, Java will be ready to supply 45 to 75 million lb. of bark three to four times as rich as the average of Ceylon barks, or in other words that she will have for export the equivalent of 180 million lb. of bark of the same grade as that sent from this island during the past twelvemonth. Taking the world's demand for this quality at from 30 to 40 million lb. per annum, we have to face the probability of Java having about six years' full supply. We leave our cinchona planter readers to draw their own inferences from these figures, or rather to examine and criticize the information and calculation on which they are founded

In this connection we shall later on call attention to some very valuable statistics in reference to the Ceylon cinchona bark exports furnished by Messrs. C. & M. Woodhouse. The all-important question with home brokers and merchants still is, what has Ceylon to send into the home market during the current and following seasons? We have given our estimate at ten million lb., for 1887-8, although we believe a larger export could be compassed if the market became specially encouraging or if the threat of Java swamping Ceylon barks altogether "next year" were considered likely; but our estimate is based chiefly on the fact that most planters with cinchona, outside of Uva, have now to face tea plucking and preparation as well as cultivation, and we cannot help thinking that there will be far less labour to spare for bark stripping and harvesting than in the past few years. At the same time we are bound to say that the testimony of keen observers like Mr. T. C. Owen is to the effect that there is a marvellously less show of cinchona throughout the country than was the case two years, or even one year, ago. The same gentleman has just been reminding us that the alleged deterioration of bark in store is not borne out by the many experiments recorded in the Blue Books in the early days of cinchona cultivation in India. Very careful tests were applied as to this very point and the result

went to show that bark carefully stored and not exposed to the sun showed no falling-off in quality.

CINCHONA IN THE DUTCH MARKET.

AMSTERDAM, Dec. 14th.

CINCHONA.—Yesterday I received the analysis of eight samples of Java bark which were sent to a renowned German analyst for the purpose of ascertaining whether the trees, of which the samples were cut, would suitably be used for multiplying. The result is stated as follows:—

1st sample, Ledgeriana	...	9·80 per cent	quin. sul.
„ Hybrids	...	9·35	„ „
„ „	...	10·97	„ „
„ „	...	10·50	„ „
„ „	...	8·98	„ „
„ „	...	11·26	„ „
„ „	...	9·50	„ „
„ „	...	9·50	„ „
	Total...	79·89 per cent. or an average of 10 per cent.	

The planters will receive orders to raise at least 300,000 plants from these rich trees, which have been selected from a large number of the same kind in a private plantation existing since 1881. The fact here stated must cause reflections with regard to the future of cinchona bark and its alkaloids, which may prove to be of some interest to bark planters and shippers and buyers of the alkaloids.

There are in Java at least sixty private plantations of cinchona bark, besides the extensive Government plantations. Most of the former have been established in the year 1879 to 1882. Seeds and plants were furnished by the director of the Government plantations, the existence of which may be dated back before 1860.

It is a curious fact that private planters obtained in many instances richer bark than the Government, whose barks seldom surpassed 7 per cent. sulphate of quinine, whilst many a parcel was forwarded by private planters having 9 to 10 per cent. of this alkaloid.

It is generally suggested that the heavy quantities of Ceylon bark shipped lately pressed down the value to figures at which the net receipt did not even cover the expenses for harvesting, and freight and selling, if the bark did not contain more than 2 per cent of sulphate of quinine. Since a few weeks, circumstances have altered in favour of owners of bark, but it may be supposed that this improvement will induce many a Ceylon owner, who did not ship his bark for the aforesaid reason, now to send over as much as possible to Europe, and that in consequence a drooping tendency will again prevail ere long. But it is not so much my purpose to point out that probably low rates of bark and quinine will predominate shortly, as to direct the thoughts of persons interested to the period when Java with the produce of its private plantations will fall into the market; this will be in 1889-1890, when a great number of trees will have attained the age of seven to ten years, every tree yielding, say, 3 lb. of bark of 6 to 10 per cent of quinine, every bale of 130 lb. bark representing 8 lb. to 13 lb. of sulphate of quinine.

If the consumption of quinine has not increased on an enormous scale every cinchona tree, the bark of which does not contain at least 4 per cent of quinine, will then have lost its *raison d'être*, and every plantation which produces lower bark may be looked upon as a dead loss.

All these remarks regard manufacturer's bark only. The cinchona known by the general name of "Druggist's Bark" has not been, and will probably not be, cultivated on any large scale, and its future value will, therefore, not be so gravely prejudiced by the coming Java deluge.

QUININE.—On December 6th a Government contract tender took place of 750 to 900 kilos. (=26,250 to 31,500 oz.), buyers' option delivery in 1888. The lowest offer came from Bohringer's (Mannheim) agent—35f. 61c. per kilo. (=1s 8d per oz.), the next following from Auerbach's agent (36f. 50c.), the third from a Hague house at 45f. The Government can order the parcel at any time in 1888. Judging from former experience, it may, however, be supposed that 450 kilos. will be ordered in February. During the recent rise only a small business has been done in this country, owing to the inability of manufacturers to deliver promptly. The last price paid was 40f. per kilo. and at this figure small sales for consumption have taken place. Some weeks ago a clergyman died, eighty-two years old. This venerable gentleman began his career about sixty years ago as an apothecary's apprentice. In his diary a note was found, dated from 1828, in which he states that he was seriously ill, and that he owed his recovery to the kindness of his principal, who gave him sulphate of quinine, although its price was 1 guilder (1s 8d) the grain. This is 21*l* 12*s* per oz. against 2s 1d now! *Tempora mutantur*!

COCOA BUTTER.—The market is very firm. Prices 8 per cent above last auction. Messrs. van Houten & Son inform their customers that owing to the partial rebuilding of their factory their production of cocoa butter during the month of December will be smaller than usual, and that, consequently, their usual January sale will be a comparatively small one.—*Chemist and Druggist.*

DRUG SALE SPECIMENS.—There is scarcely a fortnightly drug sale in London at which some new or interesting drug or drug-substitute is not to be found, and if a small syndicate of young pharmacists, ardent regarding research, were ready at hand, they would find ample material to work upon. Few of those who frequent the sale-rooms have the ability to report upon the specimens which come under their notice, and those who have the ability are busy commercial men who have only the time to avoid what is spurious and doubtful, far less examine them systematically. Amongst the articles which we have recently observed are the false calabar beans which were referred to in our last report of the drug sales. These do not come on our market for the first time, although a year ago they received, under the name of cali beans, some attention as a probable source of physostigmine. The seeds are lenticular or obscurely reniform in shape, and about 1 in. in diameter, the thickness varying from $\frac{3}{8}$ to about $\frac{1}{2}$ an inch. In colour of testa they also vary, some being of an orange-red colour with coffee-brown streaks, others of the brown and black colour of calabar beans, and all having a black hilum extending round four-fifths of the circumference. The seeds are obtained from one or more species of *Mucuna*, a genus of plants closely allied to the physostigmas. So far we have obtained no evidence whatever that they are related chemically to the calabar bean, for we cannot find physostigmine in them. There has just been imported *viâ* New York for private sale a gluey-like substance of the consistence an appearance of honey. It has a faint fishy odour, and this has led to the belief that it is fish-glue. The substance, however, is resinous in character, and on examination we find that it presents all the characters of an elemi, but differing from the true elemi in some particulars. It yields, however, a resinous acid resembling elemic acid, but time has not allowed us to carry our examination further. A correspondent has sent us a pretty sample of "saffron" which would pass muster with anyone devoid of the sense of smell, for it has no odour of saffron. It presents the appearance of bright-orange filaments, without the characteristic stigma of saffron, nor does it contain any crocin (or polychroit), the colouring matter which makes saffron such a valuable dye. It contains very little colouring matter, and that of a nature which leads us to suppose that the "saffron" is simply a fibre which has been dyed with an azo-orange. As this article has been offered for sale in the ordinary course of wholesale dealing, chemists should be on their guard. It is easily recognised by rubbing a few of the fibres with a dozen minims of water, and adding a drop of hydrochloric acid. The colour becomes pink-like, but the colour of true saffron in these circumstances does not change.—*Chemist and Druggist.*

SOAP A SUCCESSFUL REMEDY FOR BORERS.

To the Editor of the "Australasian."

Sir,—Since reading in your valuable paper, some two years ago, that common soap was a remedy for the borer in young orchards among the fruit-trees, I have used it in, say, 20 cases or more, and found it quite successful. I always took care to force the soap well into the hole the borer had made, after which the grub gave no further trouble.—Yours, &c.,

J. L. BEALE.

MULBERRIES.

The foliage of the green-fruited and black-fruited Mulberry tree is very variable, but the outline of the tree is depressingly monotonous. This tree imparts to all the Central Asiatic cultivated districts on this side of the mountains of the border range of Sungaria their luxuriant appearance. The Mulberry tree in Kashgaria, or in the country of the Sarts, is used for silk culture—a quiet occupation for women; while the tasteless Mulberries are shaken from the tree by the children. They are considered the most valuable nourishment from the regions of Garafshan, eastward to the Amu-Daria. Dried Mulberries furnish a sweet food in the countries where corn is scarce, and in every household, large piles are stored for winter use. In Shugnan, a dishful of dried Mulberries is used as the unit of measure, and the help of the physician, as well as the skill of the singer, is valued at so many dishes of Mulberries. All through the Paendsh district the dried berries are ground. A bagful of Mulberry meal forms the provision for pedestrians and hunters. In the region of Vaendsh a heavy bread is baked out of Mulberry meal, which replaces the corn bread during hard times. On the upper Darvas and in Shugnan, the Mulberry juice is thickened into a tough syrup of peculiar flavour. The Shugnanites enjoy distilling Mulberry brandy. The wood of the Mulberry tree furnishes to the Tadshik of the upper Amu-Daria his winter shoes and sandals, his whips and guitars, and to the boy of Roshan his hobby-horse. The ripening of the Mulberry announces the beginning of summer. The last Shah of Shugnan had set up opposite his residence, on a high hill, an indicator, set in the direction of the point in which the sun rose over the hills at the time of the ripening of the Mulberry.—A. REGEL, cited in the "*Report of the Montreal Horticultural Society*, 1886—87."

COTTONSEED HULL ASHES AS A FERTILIZER.

The following experiment is reported by the Georgia Department of Agriculture:

Considerable quantities of ashes are obtained at cottonseed oil mills, from burning the hulls of the seed for fuel. Although rich in potash, it has been held by some that these ashes should not be mixed with acid phosphates, because of their reducing effect upon the soluble phosphate present. Chemically it is true that carbonate of potash (the form present in ashes) added to a soluble phosphate does precipitate a double phosphate insoluble in water. Analysis, however, shows this to be soluble in a solution of ammonic citrate, (the reagent used to extract "reverted" phosphate from manure,) and this experiment was instituted to determine if the precipitation destroyed the availability of the phosphate in the soil.

Light colored cottonseed hull ashes were used. Analysis showed them to contain, potash, 20.15 per cent; phosphoric acid 6.10 per cent.

The following mixture was made

	Pounds.
Acid phosphate	200
Nitrogen mixture	41
Ashes	45
	286

(45 pounds ashes contained as much potash as 75 pounds kainit.)

66

The acid phosphate contained—

	Per cent.
Soluble phosphoric acid	11.50
Reverted phosphoric acid	2.50
Insoluble phosphoric acid	1.50

The nitrogen mixture contained in the 41 pounds 5.8 pounds of ammonia (actual and potential.)

If no chemical change took place, the mixture should have analyzed—

	Per cent.
Soluble phosphoric acid	8.04
Reverted phosphoric acid	2.70
Insoluble phosphoric acid	1.07
Potash	3.13
Ammonia	2.03

As a matter of fact, after standing one week, the mixture was found to weigh 275 pounds (having lost 11 pounds of carbonic acid gas, water etc.,) and a sample analyzed yielded—

Soluble phosphoric acid	7.65
Reverted phosphoric acid	3.55
Insoluble phosphoric acid	1.10
Potash	3.30
Ammonia	2.09

27.5 pounds of the mixture were applied to a section (1-20 acre) of the plot on which Experiment 3 was conducted. It yielded as follows:

	Seed Cotton, per acre.
Basal mixture and cottonseed hull ashes	936 lbs.

This combination of potash, therefore, made a better yield than either the kainit or muriate.

I have no hesitation in recommending the mixing of cottonseed hull ashes with acid phosphate.—*Oil, Paint and Drug Reporter.*

EXPERIMENTING WITH FERTILIZERS.

We have received the following results of an experiment made by the Georgia Department of Agriculture, to test the results of fertilizing with cheap composts compared with equal quantities of high-priced commercial fertilizers, and to test the relative values of cottonseed and cottonseed meal in composts.

The sections of the plot contained one-half acre each, separated from each other by blank rows unmanured and unplanted. Two mixtures were made, as follows:

1.	Lbs.
Acid phosphate	93 75
Cottonseed meal	37 50
Kainit	18 75
	150 00

2.	Lbs.
Acid phosphate	93 75
Cottonseed (scalded) 3 bush.	90 00
Kainit	18 75
	205 50

This is equivalent to the application of 300 pounds per acre of a mixture made as follows, per ton, and in No. 2 substituting cottonseed for cottonseed meal at the rate of 2½ of seed for one of meal:

	Lbs.
Acid phosphate	1,250
*Cottonseed meal	500
Kainit	250
	2,000

*Or cottonseed 10 bushels.

No. of section, 6; No. of rows to each section, 11; length of rows, 550 feet; distance apart, 3½ feet; area of each section, one-half acre; area of plot, 3½ acres.

MANNER OF FERTILIZATION.

No. of Section.	Manure.	Per Section. Lbs.
1	Commercial fertilizer A	150
2	Commercial fertilizer B	150
3	Mixture No. 1	150

4.....Commercial Fertilizer C.....	150
5.....Mixture No. 2.....	205½
6.....No manure	0

RESULTS IN SEED COTTON—POUNDS AND FRACTIONS.

No. of Section.	Total per Section.	Total per Acre.
1	387	774
3	400	800
3	475	950
4	458½	917
5	460	920
6	274	548

No. of Section.	Cost per tion of manure cash in Athens.	Cost per acre.	Value of crop per acre.	Profit per Acre
1	$30 00	$4 50	$30 96	$4 54
2	30 00	4 50	32 00	5 58
3	20 00	3 00	38 00	13 08
4	30 00	4 50	36 68	10 26
5	16 50	3 30	36 80	11 58
6	0	0	21 92	...

CONCLUSIONS.

1. The mixture containing the cottonseed meal made the highest yield. That containing cottonseed made the next highest. Both exceeded the yield from the commercial fertilizers used in competition. 2. Financially the cottonseed meal mixture paid best, the seed mixture next best. The commercial fertilizers in this case all paid very well for their use. —*Oil, Paint and Drug Reporter.*

WINE FROM ORANGES.

The wonderful crop of oranges which has been produced in California has led to the manufacture of a new and non-alcoholic wine from that fruit. A gentleman who has travelled extensively in California, in conversation with a reporter, thus describes the process:—"In San Gabriel, Los Angelos Co., Cal., where the sweet naval or seedless orange grows to great perfection and in large quantities, the Mexican residents made from it a wine, not unlike the May wine of the Germans. This wine, of course, has to be consumed at once, or it would spoil. But the idea was suggested by this practice that good wine could be made from sweet oranges, and the question was how to make the wine so that it could become a marketable and profitable commodity. As soon as the souring was overcome, more money had to be invested. This was accomplished after considerable money had been lost. The sweetest oranges are selected, those of the naval or seedless kind: but not until they are fully ripe. Oranges when shipped to market for eating are generally packed green, and ripen on the way. Not so with those used for wine. When gathered, a machine removes the peel, leaving only the juicy pulp. The pulp is placed in a large vat, with layers of the angelica grape sugar. The pulp and sugar are allowed to remain together about three weeks, when, by the aid of a jackscrew press worked by machinery, the whole of the juice is squeezed out. This is run off into casks and purified every month for about two or three years. It is kept from souring by the addition of distilled glycerine preservatives; and at the end of that time is considered fit for general use. It is drawn off into casks of a commercial capacity, and is ready for shipment.

"As transportation, especially to a distance, would cause the wine to muddle, it is again refined at the end of the journey and the dregs precipitated before it is put into bottles, in which condition it is sold to the general public. The wine has already been exported to England and many parts of Europe."

"Is not the wine fermented in some way?"

"Not at all. It is purely the juice of the orange, a simple fruit wine and contains no alcoholic spirits whatever. People eat oranges after meals as a digestive; now they can partake of the pure juice alone for the same reason. I think it will soon outrival any of the mild drinks of the present day."

"Then it is simply a still wine without any intoxicating qualities?"

"Yes, in its original form. But it can be made into a sparkling wine by the introduction of carbonic gas. By diluting the orange juice one-half and adding the gas, a beverage equal to champagne can be produced, without any of its intoxicating or enervating effects. This has been done, and temperance drinkers have been delighted with it. As a summer drink it is far better, according to medical men, than lime or lemon juice, as it does not leave such bad results as sometimes follow the drinking of lemonade."

"Is it expensive to the consumer?"

"If it were not for the time required to bring it to perfection, it would be very cheap. In this city and in Europe the cost of transportation has to be added, yet with this it could be sold by retail with a profit at, say about $7 per case for 12 quart bottles, or $8 per case for 24 pint bottles. Singly, I suppose it would depend upon the profit desired by the retailer. In California it is very cheap and it is now being extensively used, even where fermented wines are to be had at a low price."—*Oil, Paint and Drug Reporter.*

HISTORY OF QUININE.

When the Jesuits went first to Peru, the aboriginies knew nothing of the cinchona tree's medicinal value, using the bark only for its coloring matter to dye their various fabrics.

Peru was discovered in 1513, and no mention is made of Jesuits' bark or Peruvian bark, as it was afterwards called, until 1600.

There is a story that some of the Jesuits who suffered severely from ague and the results of malaria, drank out of a pool in the Peruvian forest into which had fallen one of the trees. Having the hot stage upon them they drank heartily, and the following day failed to have their regular fever and chills, and looking for a cause the bark was discovered. This may or may not be true.

Another story is that an Indian cacaque cured a Jesuit missionary who was attacked with intermittent fever, and that Peruvian bark was what was used.

The bark and its praises reached the court, and the Countess of Chinchon, wife of the Viceroy of Peru, was herself cured of intermittent fever. She carried the bark to England, and being benevolently inclined, dispensed it to the poor. It was called on this account chichona bark, one letter being left out of the name through an error of spelling, and it is so called to this day.

The Peruvian bark began to be sent in 1640 to Spain to their brethren by Jesuits in Peru, and through them was spread all over Europe, being called at that time Jesuits' bark, but this name was superseded by that of Lady Chinchona. For a long time it was very costly because of the labor entailed in obtaining it and getting it out of the country.

The chinchona tree grows upon the sides of mountains, rather high, and flourishes best where the temperature is warm and equal all the year round. Moist atmosphere is also necessary, and such a condition is also favorable to the luxuriant growth of climbing and twining plants, which so firmly clutch and bind the trees that even when the trunk is cut through, the tree will not fall until these vines are also cut loose. Then the bark ispeeled off and arranged into bundles, which are packed out of the forests on the backs of the poor natives.

These cascarilleros or bark-peelers endure great hardships. They cannot understand the value of the bark, as they only regard it as a dye stuff, and think that there are better stuffs nearer at hand.

The system of cutting the trees down threatened to exterminate them, and the method of peeling the bark of only a quarter of the way round was tried with success. After these quarterings were removed, the denuded surface is covered with moss, and by the time the rest of the bark is removed—that is,

four years—new bark has formed under the moss, which gives as good yield of quinine as the original bark.

The tree became so scarce that the Dutch Government had a number of trees transplanted to Java, where the conditions were favorable for the development of the bark. When these trees grew up, analysis of the bark showed that very inferior trees had been planted. However, better trees were planted and did well. About the same time the English Government took trees to the south of India, and they now have several millions of trees yielding good bark, and there are there many private plantations.

It has been found that they thrive finely under cultivation, and by "mossing" the trunks and using certain fertilizers, the yield of quinine from the bark is greater than in wild trees. Its cultivation is not yet tried in the United States, but it is quite likely that suitable locations will be found where the tree may be raised. Then we will get cheaper quinine. —*Alta*

PEPPER GROWING IN EAST SUMATRA.

The starting of a company to cultivate pepper in the district of Langkat, noticed by us recently, betokens a change of front in planting enterprise, upon which depends the permanence of European settlement there. So long as tobacco continues to be the only export crop under cultivation in that quarter, there is little prospect of the productive resources of the country being fully turned to advantage. Hitherto, failure has dogged every effort to grow other products than tobacco, which bears the repute of exhausting the soil too freely, no matter however hard individual planters may have tried to go in for variety in cultivation. The company above mentioned is the outcome of a fresh endeavour to meet this acknowledged danger, by taking in hand the growing not only of pepper but also of cubebs, the attap palm, and gutta percha. The lines on which the novel venture will be run, bear the mark of effectiveness. The promoters of the undertaking turn out to be Mr. Eckels, owner of the Mabar estate in Deli, and the Baron De Lapeyrie, a French civil engineer, who has spent years in this quarter of the world as agent for Decauville's portable railway. The Baron has gained a thorough knowledge of business planting prospects in Langkat by personal experience. These advantages at the start do not however count materially, unless the Government aids the advancement of private enterprise in this direction, by relieving planting industry on the East Coast of Sumatra of a handicap in the shape of heavy export duties, which have been kept on in spite of remonstrance on behalf of the aggrieved interest. The duties per 100 kilogrammes come to 80 guilders cents on white pepper, and 2 guilders on black pepper. Every produce article happens to be taxed on export. Gutta percha comes off burdened with a duty of 8 guilders on every 100 kilogrammes. It is evident that in framing the export tariff in force on the East Coast of Sumatra the immediate interests of the Treasury have been steadily kept in view. The consequences of this selfish line of policy have not failed to manifest themselves. Long ago, it was pointed out that the high export duty on nutmegs and mace would stop the further starting of nutmeg plantations in Deli. Despite of every warning, wrongheadness had its way. The export duty is still on the statute book, with the result that nutmeg growing in Deli has become for good a thing of the past. The remunerative prices for pepper now ruling may after all render the export duty on that article endurable. The injustice of laying it on at all, nevertheless, comes out strikingly, when account is taken of the circumstance that, in the neighbouring pepper producing countries such as the Lampong districts, Riau, and the Straits Settlements, the export of pepper takes place free of duty. Planters on the East coast are not only handicapped by this load, but also by difficulties in securing cheap labour. The advantages sure to result to Deli from the success of Messrs. Eckels and De Lapeyrie's enterprising venture, need not be further enlarged upon. The successful cultivation of other articles will spur on the planters to more energetic exertions in improving existing methods. Pepper growing by Europeans under judicious management and unfettered by official restrictions, will co-operate materially in energising the industrial life of the colony. At present, there is no sign of anything of the kind, owing to planters feeling the ground insecure under their feet. Nowadays there is no security against any cultivation once started being crippled by heavy taxation, so long as the Government takes it into its head to look upon export duties as fair means of raising revenue on the East Coast of Sumatra. The Home authorities assert that they set developing the resources of the Netherlands East Indies far above revenue considerations, and declare their anxiety to further planting enterprise in every way. They have now a fine opportunity for shewing that by these assurances, business is meant, by doing away altogether with the exceptional tariff of export duties levied on the East Coast of Sumatra. Starting peppes cultivation at all under such discouraging circumstances speaks volumes for the self-confidence and determination of the promoters of the company, who we hope will find their enterprise rewarded with a liberal measure of success.—*Straits Times.*

UBIQUITOUS RUBBER.

There are two things connected with the manufacture of India-rubber, says the *Hatter's Gazette*, which cannot fail to produce reflection in the minds of the people who have given the business a thought; the one is the extraordinary number of requirements which our growing civilisation has produced of late years, and the other is the manner in which the India-rubber trade has supplied the new wants of the age! It is not a little interesting to observe how readily the India-rubber business has adapted itself to the requirements of men in the learned professions. For instance, I have before me a catalogue in which are tabulated a large number of surgical instruments, amongst which are four "ophthalmoscopes," four "laryngoscopes," eight "spray producers," over twenty "abdominal belts," five "throat syringes," seven "hypodermic syringes," thirty-seven "ear trumpets," &c., &c., and over and above these duplicated articles there are a large number of single instruments for various uses in the profession. I have before me another catalogue, which embraces a much wider range of articles, both in the soft and hard goods manufacture than the above. The goods in this are specified under no less than twenty-five classifications, many of which contain a large number of articles for different uses.

Nos. 1 and 2 embrace piece goods, garments, and various articles of dress, both for men and women. Nos. 3 and 4 describe articles for "travelling, fishing, and sportsmen." In Nos. 5 and 6 we have airproof articles, ranging from air pillows to "lifeboats"; No. 7, "domestic appliances," a numerous family; No. 10, "playing balls" for various games; No. 11 "Tobacconists' articles," a large group; No. 8, "hospital and surgical articles." The number of appliances in this classification is both large and exceedingly varied in character. No. 12 comprehends a vast assortment of elastic bands; No. 9, gives a large and varied list of military and naval appliances, among which are a number of articles for the amelioration of human suffering; Nos. 13 and 14 embrace "fine India-rubber sheeting" and card cloth fabrics; No. 15 contains "printers' blankets" and various articles therewith connected; Nos. 16 and 17 contain a very large number of mechanical and railway appliances. In No. 18, we have any quantity of hose pipe and tubing. No. 19 embraces "hat pressing bags" and "blocks." No. 20 contains a large assortment of chemical and hard articles in rubber, moulded, and numerous ornamental articles; No. 22, in this we have "ventilated tents" and other appliances; No. 25 comprehends India-rubber mats, in great variety. I may here

mention a little historical fact, that among all the surgical instruments now in use, with the exception of those required for dissecting purposes, the little stethoscope is the oldest, and yet, though this is the case, I remember the time when a medical man required to sound a patient's chest, it was done by the old method of tapping with his hand, and applying his ear to the part. It is little, if at all, over sixty years since the stethoscope superseded the old clumsy method of knocking at the chest doors of their patient by the medical man, in order to learn if the heart and lungs were doing their duty in a proper manner.

The following list of things is taken from the catalogue of a house in which only small articles are enumerated, and from which we omit surgical appliances:—The articles under the head of domestic, stationary, and sanitary articles, embrace a number of draught tubes, "tubular rubber door springs," "squeegees," "foot warmers," "muff warmers," "Panstrepton bath brushes," bathing caps, "spring bags," India-rubber teats, teething pads, baby jumpers, gum rings, gum brushes, teeth brushes, feeding bottles, India-rubber copying brushes, India-rubber marking pens, "Claude rubbers," "watch preservers," and "stud guards."

We have next articles for mechanical and railway purposes. Amongst these are "buffer bearing springs," "conical shape buffers" and "bar springs." "Pump ball valves," "hydrant ball valves," "closet cones," "gauge glass washers," "hat blocks," "gas bags" for various purposes, Indiarubber washers, amongst which is the "man-hole washer." Then there are wheel tires, aerated water bottling machines, washer tubes, pump rings, and pump valves.

The above are only a few out of a great number of small articles contained in the catalogue, and they have been noticed simply for the purpose of showing the almost endless uses to which India-rubber, both in its natural and vulcanised state, can be applied.

The hospitals and infirmaries have had many articles made of rubber which have been of much service in alleviating the sufferings of their patients. But I do not think there is any profession that has been so greatly benefited by the use of articles made of India-rubber than the surgeons; many of their useful instruments are made of the gum, and some of the most important tools could not be made of any other material.

From what has been said, the reader will have observed that there is an adaptation in this material to many of the business affairs of life which few other things in nature possess.—*Indiarubber and Guttapercha Journal.*

DRUGS: MATERIA MEDICA NOTES.

COMMERCIAL COCAINE.—Some time ago Dr. E. R Squibb called attention in *Ephemeris* to the curious manner in which the cocaine hydrochlorate of the same maker varies in quality, in so far as the United States are concerned. It has also been frequently pointed out in this country that commercial cocaine hydrochlorate is not always of the high degree of purity which such an important remedial agent should be. We pointed out (THE CHEMIST AND DRUGGIST, vol. xxx. page 297) that a most useful test whereby any one may prove the purity of the salt is that which was devised by Mr. Henry MacLagan, an American pharmacist. That test, according to its deviser, consits in adding one or two drops of solution of ammonia to a solution of 1 grain of cocaine hydrochlorate in about 2 oz. of water. If the hydrochlorate is pure, that is free from amorphous alkaloid, there is, on stirring, an immediate precipitate, which in a few seconds separates into flocks of crystals, and these subside leaving the supernatant solution clear. We showed that it is better to use 1 oz. of water to 1 grain of cocaine, and that a sample of crude cocaine gave no precipitate whatever. The test is now recognised as a most delicate one, and is generally adopted. There recently came under our notice a case in which a chemist had reported to a manufacturer that the cocaine hydrochlorate made by the latter was impure. The manufacturer averred, however, that the hydrochlorate conformed to MacLagan's test, giving a perfectly clear solution with ammonia, and this he took as a proof that the salt was free from amorphous alkaloid. Our attention was called to the matter, and we find that another manufacturer in Germany has reproduced the test in the following form:—

"To 0·1 gramme hydrochlorate of cocaine, diluted in 100 grammes of distilled water, 5 drops of liquor ammoniæ Ph. B. are added. The solution should remain perfectly bright. (McLagan's test.)"

There is no mention here, it will be seen, of the separation of cocaine hydrate on the addition of ammonia, and it is rather a strange fact that on testing the product of this manufacturer, we find it not to conform with his own test, but to the original one. We have tested other samples, and find that two of German origin quite responded to the modified test above quoted, affording no precipitate, one of them only giving a faint milkiness. Three other specimens gave immediate precipitates with ammonia, which in a few seconds became crystalline, and on subsiding left the supernatant solution clear. These were, therefore, pure; the first two were not; but we may add that when in the latter case the volume of water was considerably decreased, a precipitate of an amorphous character was afforded. It is perfectly obvious that some manufacturers are working up to what they consider a standard of purity, which is really one of impurity. The result is that they produce a cocaine hydrochlorate which is very bulky, is in the form of micaceous scaly crystals, and dissolves readily in water. The pure hydrochlorates are much heavier and dissolve more slowly.

BETEL-LEAF OIL.—Several months ago we stated that a Dutch-Indian pharmacist of Samarang, in Java, had succeeded in extracting an essential oil from the leaves of the betel pepper (*Chavica Betle* and *C. Sirèbua*). These leaves are extensively used by the natives of the Indian Archipelago and other Eastern countries as a wrapping for the betel-nut and gambier, which every man, woman, and child there uses as a masticatory. The leaves and fruit of the betel pepper are also used, like those of other chavicas, as medicinal remedies, but they had not been the subject of a pharmaceutical investigation until recently. We have received a specimen of the essential oil, and, on examination, find that it possesses the peculiar odour of the betel pepper leaf, which closely resembles that of long-pepper fruit. It is of a deep amber colour, and has a specific gravity of 0·943. It is soluble in less than its own volume of rectified spirit, and the solution is not disturbed by the addition of spirit up to ten volumes. With sulphuric acid the oil gives a coffee-brown colour, but perfect charring only occurs on the addition of a little nitric acid to the mixture. Nitric acid alone darkens the oil at first, it rapidly becomes—from reddish-brown-a dark-brown colour, and resinifies, the acid also being coloured brown. Hydrochloric acid alone has no effect upon the oil; but if a trace of nitric acid is added to the mixture the oil assumes a lilac colour. Dr L. Rossbach, of Jena, in Germany, has tried the oil as a remedy for headache, colic, liver disorder, catarrhal affections of the mouth and throat, ulcers, and especially in cough. It has also been recommended in consumption. These are the disorders for which the leaf is prescribed in India; but according to the Dutch *Pharmaceutische Weekblad* it has been found impracticable to employ the leaves in Europe, as they cannot be dried without losing their aromatic and stimulant properties. It is stated that essential oil of betel will ere long be included in the *Pharmacopœia Neerlandica.*

CUBEBS.—The last number of the *Kew Bulletin* brings the series for the year to a close, and looking over the list of twenty-eight monographs which comprise the series, there is every evidence that the issue has been successful—so far, at least, as the value of the contents are concerned. There might be greater variety of subjects and more notes in each number. The present one contains eight notes. It

would be very desirable to keep this number as the standard. The first note in the number is on cubebs, which have lately become of considerable importance owing to the high price which the drug has attained. It is pointed out incidentally that the figure in Bentley and Trimen's "Medicinal Plants," which is given as from the Royal Gardens, Kew, has been proved to be *Piper Chaba*, Hunter (*Chavica officinarum* Miquel), belonging to the long pepper family. To the note is added a correct drawing of the plant (male and female), taken from a Java *Piper Cubeba* and one of Miquel's types in the Kew herbarium. A description of the plant is given, and it is stated that it is found wild only in Java, Sumatra and Borneo. According to Descourlitz cubebs were at one time cultivated as an introduction by the French in the West Indies, but at present they are unknown there. The produce of other species of pepper are sometimes called cubebs, such as the fruit of *Piper borbonense*, which yields the native cubebs of Mauritius (*cubèbe du pays*); and, as pharmacists very well know, the recent high prices of the drug have brought into the market all sorts and conditions of things which have passed as cubebs.—*Chemist and Druggist.*

GUM TREES.

The rapid growth and the value as timber and fuel of many of the Australian Gum trees (Eucalyptus), have induced planters in this country to attempt their cultivation, but the experiments have proved beyond question that none of the species is sufficiently hardy to bear the winters of the eastern and central parts of this kingdom. In some localities they escape injurious effects during a cycle of comparatively mild winters, giving rise to hopes that they are permanently established, but a colder winter, or a cold, wet autumn, followed by an ordinary winter, kills or irremediably injures the young trees. Of the many species tried at Kew, for instance, only one, Eucalyptus Gunnii (fig. 150, p. 781), has lived through many years without some kind of protection, and the young shoots of this have often been destroyed. A tree of Eucalyptus Gunnii, which for many years bore the incorrect name of Eucalyptus Polyanthema, stood, some thirty years ago, near the old Mesembryanthemum-house, near or on the site of the present Orchid-house, and many will remember it as the first Australian tree they had seen growing in the open air in England. It was then perhaps about 20 feet high, and, so far as we remember, it was not materially injured by the intense frost of the winter of 1860-61, when large specimens of Cupressus macrocarpa and Pinus insignis were killed outright. That season the thermometer fell, on two or three occasions, below zero at Kew, where, if we remember rightly, it has never since been so low.

Some years later, when the new range of houses was built, the alterations necessitated the removal of this tree, and it was transferred to the western slope of the mound on which the Temple of Æolus stands, near to No. 2 Museum, and the result was that it died to the ground, or nearly so, but, what was surprising, it threw up new stems, and is still flourishing. It is a native of Tasmania, where it is called "Cider tree," growing abundantly in marshy places at elevations of 3,000 to 4,000 feet, and forming a tree 20 to 30 feet high. The same species inhabits South-eastern Australia, ascending in the alpine regions, according to Von Mueller, the historian of the genus, up to 5500 feet, where it is quite dwarf. But, according to the same authority, it is also found in the lowlands, from Guichen Bay and Lake Bonney, eastwards to Gippsland, and under the most favourable conditions it attains a height of 250 feet. Whether this lowland form be hardy in the neighbourhood of London is questionable, at all events, it would be safer to procure the Tasmanian or alpine form. There is a coloured plate of it in Hooker's *Flora Tasmaniæ*.

In the hills of Arran this species thrives well, and even on the eastern side of Scotland it withstands, in certain localities, all except the severest winters. In an interesting account of Australian and New Zealand forests in Arran (*Gardeners' Chronicle*, November 27, 1886, p. 680), the Rev. P. Landsborough states that there is, or rather was last year, a tree of Eucalyptus Gunnii at Whittinghame, East Lothian, which was planted in 1845, and which though cut down to the ground by the frost in 1860, is now more than 60 feet high, and matures seed, from which a stock of young plants has been raised. The foregoing evidence amply proves the hardiness of this species.

Another species which is apparently hardy in the south-western and western counties, is Eucalyptus coccifera, a native of Tasmania, exclusively growing on the tops of all the mountains, where it forms a bush or small tree 5 to 15 feet high. In England, at Powderham Castle, Devonshire, for instance, it has attained a height of 60 feet, with a girth of stem of 7 feet, and it flowers freely. In 1879 this tree withstood 23° without injury (see *Gardeners' Chronicle*, n. s., xii., p. 113, with a figure of the tree, and xiii., p. 325, with a figure of the flowers and fruit here reproduced). One noteworthy circumstance is that it has apparently changed its flowering season, for it produced its flowers in December and January at Powderham Castle in 1880, whereas in 1883 we find it notified (*Gardeners' Chronicle*, n. s., xix., p. 730) that it was in full flower in the middle of June. Fuller particulars will be found in the places cited, and there is a coloured plate in the *Botanical Magazine*, 4637, prepared in 1852 from a tree growing in the nursery of Messrs. Veitch at Exeter. This species also flourishes in perfection in the Isle of Arran and other parts of Great Britain and Ireland. The flowers of Eucalyptus coccifera have been described as purple, but they are represented as yellow with a purplish tinge towards the base.

Eucalyptus alpina is a bushy species, known in a wild state only on the summit of Mount William in the Australian Grampians; and seedlings of it raised in the Melbourne Botanic Garden attained a height of no more than 10 feet in a quarter of a century. In Western Scotland it seems to have found a more congenial climate, having grown as much as 2 feet in one season.

One of the varieties of Eucalyptus amygdalina supposed to be the giant variety, trees of which have been measured exceeding 450 feet in height, has proved hardy in Arran since 1871, and that last year it flowered for the first time, in the month of August.

Eucalyptus resinifera, a native of New South Wales and Queensland, is recorded among the plants uninjured at Ventnor during the winter of 1879-80;* but its preservation was probably due to accidental shelter rather than hardiness, because its home is a warm country.

Eucalyptus [illegible], a tree [illegible] in Tasmania, Victoria, and New South Wales, was reported as uninjured at Colwyn in North Wales during the winter of 1879-80, though it had suffered somewhat the previous winter.

The singularly striking Blue Gum, Eucalyptus globulus, of which we give a photographic illustration in the present issue, which is now familiar, in the small state at least, to most gardeners, but is certainly much less hardy than E. Gunnii and E. coccifera. It was, however, uninjured in 1879-80 at Penzance, and at Garron Tower, Larne, Antrim, where it had attained a height of 50 feet. The winter of 1880-81 killed all the Blue Gum trees in Arran, except one at Lamlash, which last year was 40 feet high, though it had been polled to the extent of 8 feet. But although it may survive many years in the most favourable localities, and attain large dimensions, it is perhaps not absolutely hardy in any part of the United Kingdom, that is to say, in the sense that it would be prudent to attempt planting it extensively with the idea of deriving profit therefrom. The extremely rapid growth and long growing period render this species particularly susceptible to frost, as the shoots are rarely sufficiently matured. Baron Von Mueller's interesting history of this species in the *Gardeners' Chronicle*, July 31, 1880, is so complete, that there is nothing we can add to it. But we may

* Rev. H. Ewbank, in the *Journal of the Royal Horticultural Society* (Frost Report), viii., p. 10.

repeat a statement concerning the truly marvellous rate of growth of the Blue Gum in Guatemala, Central America, where in twelve years it has been known to attain a height of 120 feet, and a circumference 9 feet in the trunk. Assuming this rate of growth to be maintained for twenty-five years, the result would be a height of 250 feet, and a foot less than half that yearly rate of growth for another twenty-five years, we should have 350 feet—about the greatest height it is known to grow. But allowing a hundred years as the full period of growth, it is very short in comparison with the life of an English Oak or Beech.

Although this species offers no claim to be regarded in this country as a timber tree, yet its colour and rapid growth render it very desirable as an ornamental shrub for summer bedding or for the so called sub-tropical garden. Young plants are easily raised and kept in a moderate temperature in the winter season (a cool green-house suffices), so that they are available for the summer decoration of the garden, where their singular habit and beautiful colour render them very attractive. In the South of France these trees flower early, and their blossoms may occassionally be seen in the markets at Christmas time or soon afteawards. The great vlaue attributable to this tree when planted in marshy localities is due, not entirely to the rapid growth of the tree but also to the drainage operations necessarily connected with its planting. Nevertheless, some of the benefit arising from its planting on a large scale may not unfairly be attributable to the balsamic odours it emits, and which are now known to be more or less antagonistic to the development of bacterial or miasmatic germs.

The magnificent blocks of Jarrah timber exhibited at the Colonial Exhibition will be familiar to most who visited that interesting display. Few or no timbers excel the Jarrah in hardness and durability. It is the produce of E. rostrata, a species native to Western Australia. To Mr. Bosisto, of Melbourne, great credit is due for the production of oils, tannin, and other useful materials, which these species, or some of them, supply in abundance.

It is impossible to speak of these Eucalypts without calling to mind the services of Baron Von Mueller, not only in making known, but in distributing seeds and plants of these most valuable trees. Their discrimination is by no means easy, but it is to be hoped that the cultural experiments of M. Naudin at Antibes will be of great service, not only botanically, but also economically, as showing which species are available for growth in warm, temperate, and subtropical districts in Algeria, India, and elsewhere. In purely tropical countries none of the species seems to thrive, but on some of the Indian hills, and in many of our Colonies, these trees are destined to be of great value. —*Gardeners' Chronicle.*

UNDER the old doctrine that nothing but liquid could pass through cell walls, and by the endosmotic process, it was difficult to conceive how there could be any ground for the popular belief that hybrids occasionally spring from grafting. Yet the fact that new varieties can originate from grafting has been proved true by the experience of careful experimenters in recent years. The new discovery that the substance called protoplasm is continuous, and passes from cell to cell, as well as plant liquids, makes the explanation of graft hybrids now clear.—*American Cultivator.*

NATIVE AGRICULTURISTS AND BONEDUST.—The unwearying efforts of the Agricultural Department of Government to induce cultivators to make use of manure are bound to bear fruit eventually, although the change comes slowly about. The latest incident reported as a sign of gradual improvement in native agriculture is that a hundred maunds of bone-meal were sold last year to certain villagers of Bengal, who had previously received small quantities of the manure gratuitously on trial. There can be little doubt that the cultivators in Bengal would have been forced long ago to take to the use of manure had nature not been so lavish of her favours. As is well-known, the rivers of Lower Bengal slowly build themselves up into highlevel canals, which every autumn break through or overflow their margins, leaving a rich deposit of silt upon the adjacent flats. Every year some thousands of square miles thus receive, as has been aptly said, a top-dressing of virgin soil, brought free of expense from the Himalayas—a system of natural manuring which in some places defies the utmost power of overcropping to exhaust its fertility. It is something, however, to know that the absurd prejudice against the use of bone manure is beginning to give way. We can only hope that it will vanish altogether before it has time to affect permanently the position of Hindu cultivators in their rivalry with the peasantry of other countries.—*Englishman*, Dec. 22nd.

THE CHINESE QUINCE.—From Mr. Van Volxem, of Brussels, we lately received fruits of this species, remarkable for their delicate perfume. As, however, the flesh is hard and leathery, we cannot recommend it for culinary purposes. The Chinese Quince, Cydonia sinensis, was originally described by Thouin, in the *Annalis du Muséum*, p. 144, t. 89, and was introduced about 1802. It was figured in the *Botanical Register*, t. 905 (1825), from a specimen in the nursery of Whitley & Co. (afterwards Osborn's). The flowers are large and pinkish in colour, and the fruits are not often produced out-of-doors, though Thouin figures one from the Paris garden. The tree, moreover, is apt to be injured by spring frost. Bentham and Hooker refer the genus Cydonia to Pyrus, but for garden purposes it is inconvenient to call Pears and Quince by the same name, hence for gardens the epithet Cydonia sinensis seems preferable, the more so as there is also a true Pear which bears the name Pyrus sinensis. To meet this difficulty, Mr. Hemsley, in his *Index Flora Sinensis*, calls our present plant Pyrus (Cydonia) Cathayensis. Dr. Shearer, who gathered the specimen at Kiu Kiang, says, in a note in the Kew Herbarium, that "it is called by the Chinese, Wooden Cucumber, from its solidity and shape. . . . . The large and fragrant fruit is said to be used for scenting Tea and flavouring wine. The bark is olive-green with bald patches, and the trunk thick and contorted. Growing in tubs it is indeed a very handsome shrub."—*Gardeners' Chronicle.*

OBSERVATIONS ON THE CULTIVATION OF ARROWROOT.—The cultivation of arrowroot is grounded upon one only principle, whatever may be the nature of the soil and the variety of manure applied. It consists in tilling well the land before planting, and weeding during the growing season. If this principle is fully acted upon, a good crop is always certain, whatever may besides be the circumstances of the soil or of the manure. It is from the result of this principle, that we see the arrowroot succeed better in a well-tilled and weeded soil, without manure than in a ground well-tilled and unweeded but with manure. It should here be remembered to have the ground weeded for arrowroot is more important than to apply manure. There is a common principle in theoretical agriculture which has very few exceptions:—"That anything sowed or planted succeeds better when made by lines or rows than when it is executed at random; but from that principle is derived a general and exclusive maxim in agriculture." The greater the distance between the rows of arrowroot, the greater will be the produce and the finer the tubers; daily experience proves that to be a fact. The thickness of the plant does not increase the produce of the crop; on the contrary, the produce is rather less, notwithstanding a double quantity of tubers has been used in vain. Beside the greater produce and the economy of the tubers, planting at a good distance has other advantages. Arrowroot exhausts the soil a great deal, but when planted at a distance, the soil is a great deal less exhausted, and what exhaustion it suffers is partially restored, as well by the air and the light that the breadth of the lines permits it to enjoy amply, as by the effects of the frequent tillages which keep it always in a proper state of becoming impregnated with meteorical substances caused by the repeated contract of all its parts with the gaseous atmospherical matters —true source of fertility and soul of vegetation.—*Cor.*

THE LANKA PLANTATIONS COMPANY, LIMITED.

Directors :—R. P. Harding, Esq., Chairman, George Allen, Esq., James Thos. White, Esq., Sir Herbert Bruce Sandford, Horace George Hayes, Esq.

Resident Manager.—Mr. Edward Gonne Harding.

Agents in Colombo.—Messrs. J. M. Robertson & Co.

Secretary.—Mr. William Bois.

Authorised capital, £200,000 in 15,000 ordinary shares of £10 each and 5,000 preference shares of £10 each.

REPORT.

To be presented at the Seventh Ordinary General Meeting of the Lanka Plantations Company Limited, to be held at the Offices of the Company, on the 29th December, 1887, at 12 o'clock at noon.

1. The Directors submit their report for the twelve months ending 30th June last, together with the balance sheet and accounts of the Company made up to that date.

2. The quantity of coffee shipped home was 3,126 cwt. against an estimate of 3,568 cwt. and the amount realised therefrom was £14,796 12s 2d. The crop of 1885-6 was 2,416 cwt. only. The prices of coffee during the past year have been much better than in 1885-6, the average being 85s 1d per cwt. against 66s 8d per cwt.

3. The Cinchona Bark harvested has been about 106,560 lb. (of which 9,907 lb. were sold in Ceylon), the greater part has been realised, and the whole is expected to produce £1,583 18s 8d. The depression in this market has been very great, and at present there seems but little prospect of improvement, as the price of Quinine continues to rule very low.

4. In consequence of continued prevalence of insect pests the Cocoa, estimated at 400 cwt, only produced 352 cwt., realising £1,111 18s 11d, but the latest advice is to the effect that the shade trees having now grown up, this pest has almost disappeared. The cocoa trees are looking well and strong, and there is every prospect of a better crop for the current year.

5. The cardamoms promised well, but did not produce the estimated quantity, the growth having been retarded by drought. The quantity received has been 3,700 lb. only, which realised £298 18s 2d.

6. The tea on the Fordyce and Fruit Hill Estates has been less productive than was expected, also in consequence of the drought. The estimate of made tea from these Estates for the season was 104,000 lb., but the shipments received, together with the sales in Ceylon, were only 81,790 lb., which includes tea made from leaf purchased from other Estates, the total make realised £3,696 13s 3d, and the net price averaged was 10¾d per lb., a price which it is expected will be considerably increased as the trees become older. The estimate for the year 1887-8 of made tea from the Company's Estates is 115,000 lb., and from purchased leaf about 40,000 lb. Under the advice of the Agents and Manager, the erection of a Tea Factory on the Fruit Hill Estate was approved in March last, and was commenced in August. The work is progressing rapidly, and it is hoped that it will be completed by the end of March next year, when the facilities for manufacture will be greatly increased. The land under cultivation for Tea is as follows :—

Estates.	Under 1 year.	1 to 2 years.	2 to 3 years.	3 to 4 years.	Total. Acres.
Ampittiakande ..	—	50	70	—	120
Arnhall ..	50	—	—	—	50
Fruit Hill ..	—	90	—	130	220
Fordyce and Garbawn ..	—	21	118	161	300
Gonagalla and Paramatta ..	—	77	58	—	135
Rupperhannock ..	—	40	10	—	50
Rillamulle ..	30	70	—	—	100
Yattawatte ..	—	60	—	—	60
	80	408	256	291	1,035

7. Of the proposed issue of 2,000 six per cent £10 preference shares, 85 more have been applied for and allotted at par, leaving 585 shares still available for applicants.

8. The dividends on the preference shares issued prior to the 30th June last, have been duly paid, the profits shown by the accounts fully justifying their payment.

9. It was with great pleasure that the Directors declared an interim dividend of 2 per cent on the ordinary shares, and such dividend was paid on the 7th July last. Although the profit and loss account does not enable them to declare any further dividend, they have the strongest grounds for believing that a more prosperous time has commenced for the Company. The new products are rapidly coming into full bearing. Ceylon coffee has attained a remunerative price, and Ceylon tea has taken a strong hold of the market. These two last named products now occupy the first places in their respective markets, and with a return of normal seasons, normal crops may be expected. The Tea planted in 1883 should soon yield from 300 to 400 lb. of made Tea per acre, and from year to year henceforth the quality should improve and the shipments increase.

10. The Coffee in cultivation at present promises well, and the Directors quote with pleasure the opinion of the Company's Agent in Colombo on the present condition of the Company's Coffee and Tea crops. In a letter, dated the 24th October last, they write :—"Reports from upcountry are far more reassuring now than they have been for some time as regards green bug. The cold wet weather that has set in with the North-East monsoon has, we are told by latest advices, in some instances killed off the pest in great numbers, and in most others has put a stop to its depredations for the time being. We trust therefore, all strong Coffee will thus be able to ripen the crop now on it before another drought can bring another onslaught of the bug. Tea is flushing well after the long drought, and a great deal of what has been lately pruned is beginning to bear."

The two Directors who on this occasion retire are Mr. Robert Palmer Harding and Captain Horace George Hayes, and they both being eligible, offer themselves for re-election. Mr. John Smith (a Shareholder) the Auditor also retires and offers himself for re-election. The Directors append a Statement showing the names, acreage, and state of cultivation of the Company's Estates.

LARGE ORANGES IN FLORIDA.—I visited the packing house of a neighbour yesterday and saw some very large Navel oranges. We measured and weighed several that were from thirteen and one-half to fourteen inches in circumference and that weighed from one pound to one pound and two ounces. The largest one that we found in the lot was fourteen and one-half inches around it and weighed a pound and a quarter. He had four boxes spread out on a table and was sorting them, sixty-eight of the largest filled a box. He told me that a few days ago he picked four boxes of oranges from one tree of the Arcadia variety. When sorted, sixty-five of the *smallest* filled a box, while it took only fifty-four of the largest to fill a box. I thought these were large enough to report to the Dispatch, but today I was shown an orange from another grove which I measured and weighed. It was almost perfectly globular, and was *sixteen* inches in circumference, measured around the stem and blossom ends, and *seventeen and one-half inches* around the other way, and it weighed *one pound eleven and one-fourth ounces.* The one who grew this orange reports filling a box with forty oranges and a barrel with ninety. Who can beat St. Johns' river oranges for size?.—W. C. STEELE.—*Florida Dispatch.*

CEYLON UPCOUNTRY PLANTING REPORT:

THE TEA MARKET—CACAO CROPS—WITHERING TEA.

9th Jan. 1888.

The fall in the price of *tea* in London is having its usual effect here in our make being locally depreciated. It is, perhaps, not a bad thing at the commencement of a new enterprize to have tea-tasters who incline to be hypercritical, and have a keen eye to note defects, but we would value their opinion a great deal more if it were less influenced by the fluctuations of the trade. As soon as the London market, for causes altogether outside of the question of quality, becomes animated, then we are told that our teas have improved, and the reading of our local tea circulars is a pleasant pastime. But when the prices rattle down, and stand as they do at present at 1s average, let the tea be what it may, and the make what it may, there is then discoverable a manifest falling-off, a marked deterioration or some other mysterious thing equally unpleasant to account for the decline. Why a man's palate should be affected by the state of the stocks of tea or the slacking of demand is a question worth looking into, and might be made the subject of an interesting paper for some of our scientific Societies. One thing is sure,—that this periodical disparagement has become monotonous and argues a poverty of imagination on the part of our tea-tasting authorities, which is humbling to contemplate. They may surely now rest satisfied, having harped long enough on that string, and try something else. It is of course presumption on my part to offer any hint for the future, but might it not be suggested that at some distant time we may see it recorded, that "prices were easier all round, and spite of the teas being quite up to the high standard commonly sold here their values could not be realized." It is rather hard, when you know that the teas you may have sent down for the local market are as good as your best, not only to have to put up with a low price, but a low opinion besides, for the one is an injury, and the other an insult. I fancy the former is easier to bear.

Cacao crop is coming in freely, and the new blossom is in part also putting in its appearance. The wet weather we had, although beneficial on the whole, has not been without its drawbacks. You hear a great deal more of damaged pods than usual, where the husk has been penetrated by a worm the holes made by which allow the rain to soak in, until the nibs inside have germinated and begun to grow. Where a careful watch has been kept on the insect enemies of the cacao, and the edict of extermination steadily and unsparingly carried out, the good effect is especially noticeable this year. Cacao dearly wants an ever-watchful eye, and is a plant that will repay any attention bestowed on it. It is as sensitive to care as to neglect.

The tales you hear of the difficulty of *withering leaf* during the last wet weather would seem to point to a good thing ready for the man who can invent a suitable and economically-worked machine which would effect that purpose. To have all your withering space three feet deep with leaf or to require to keep it for nearly ten days, and then find a lot of it go bad, are examples of how men were tried. Dodges, such as beating the leaf with thin sticks, or giving it a slight twist in the roller to make it wither, are samples of the make-shifts which some men were driven to; but it is clear that Ceylon will not be worthy of its past, if in time we are not possessed of some simple mechanical means of helping forward this important part of the process in the science of tea manufacture.

PEPPERCORN.

COFFEE AND SLAVERY IN BRAZIL: NO. 1.

We owe an apology to our old correspondent, Mr. A. Scott-Blacklaw, for so long delaying to commence the publication of some interesting letters he is sending us from Brazil, in continuation of his previous contributions. We would ask him to send any information he may have, or come across, in reference to other products besides coffee—say cacao, rubber and even coca and cinchona—in South America. The following, though a little out of date, is still of interest, and Mr. Blacklaw dates from Rio de Janeiro a few months ago:—

I intended to have followed up my letters of last year with a few more, but my occupations partook much of the nomadic order, and my notes on various subjects got mixed up, and I fear this will be somewhat of a wandering epistle.

COFFEE.—Some of your readers have, no doubt, felt the juggling movements of the coffee markets for some months, for I do not think that the ups and downs in prices, and the gains and losses on the shipments have been confined to Brazilian coffee only.

The causes of these movements are difficult to find out. Buyers in Rio and Santos were, no doubt, influenced by the expected small crop, and they were justified to a certain extent in believing there would be much less than last year, from the barren state of the coffee plantations seen alongside the railway lines, and the pessimist accounts from those residing on coffee estates. The small deliveries from the interior, for a few months before the picking season of the current crop commenced, served to confirm the expected shortness.

In these circumstances speculation ran wild for some time. Coffee was selling at a higher price in Rio and in Santos, than the same article was quoted in New York, Havre, or any of the shipping ports in the consuming countries. Coffee certainly did rise in price, but it did not follow the continued upward tendency of the Brazilian market. On the contrary, after getting up to a higher price than the article has sold for during the present generation of coffee planters, there was a sudden and unexpected fall. For some time there was hope that the lost ground would be gained again, and no doubt it will be, but the tightness of the money market in Rio, added to the extra caution now exercised by the banks, has allowed the market to drift into a stagnant state, from which even the further reports from the interior of the confirmed shortness of the crop which is now being gathered, do not seem to rouse it. As regards the future of coffee, there is not much to say, and the little that can be said cannot be relied much on.

True, the crop now being picked is small, and the *Journal do Commercio*—the safest authority—has reduced its estimate for the current season to 2,000,000 sacks of 60 kilos. This will, perhaps, apply to the districts which supply the Rio market, and it is confirmed to a certain extent by letters which appear occasionally in the same paper since the planters have begun picking. But there is a factor which cannot be overlooked, the extensive young coffee districts tapped by the admirable railway system in the far interior of São Paulo, and whose shipping port and whose market is Santos. There have been very few letters published from these districts, and scarcely any of them speak of an extraordinary shortness of crop; on the other hand the planters in some of these young districts, being afraid that the credit of their occupation should suffer, have written describing the heavy crops they are now picking—the yield ranging from 10 cwt. an acre in Araraquara to 30 cwt. an acre in Jahu. We will allow the latter to be exaggerated or confined to some exceptional

fields. We all know that young plantations bear well in seasons that are not suitable for old coffee trees.

Much has been written about the long spell of dry weather during July and August of this year having destroyed the expectations of a good show of flower in September or October,—the latter being the principal blossoming month. But you Ceylon coffee planters are glad of a dry January and February to secure you good blossoms in March and April.

Rain has however fallen all over the coffee districts during the early days of September, and there is no doubt the coffee crop for season 1888-9 will be, if not above an average, at least equal to former years.

Much cry has been heard of disease amongst the old coffee districts. As I mentioned to you before, this has run itself out, and the coffee along with it, in the lower parts of the province of Rio. It has now got a hold in the upper parts. It is difficult to get a good description of its characteristics: some say it is a fungus, others an insect which attacks the leaves, while many hold that it is at the roots the attack is made. One fact, however, is notable, that this blight, of whatever nature it may be, seems to visit old districts only. This seems to suggest that there is some ingredient in the soil necessary to the healthy growth of coffee which becomes exhausted. Through time, owing to this the coffee plant gets weakened, and becomes an easy prey to disease. Healthy trees get affected also in the same way that we find in everyday life healthy subjects attacked by diseases which have been generated in a community, from causes in which the want of proper food or neglect or ignorance of sanitary laws is among the number.

There is an unlimited field for coffee in Brazil—there are enormous tracts of forest lands only waiting for means of communication with the sea ports. The coffee tree flourishes as well in Ceará at a latitude of 3 degrees south, as it does at 24 degrees south in São Paulo, and between these lies an inland zone many hundred miles in width, with a large part covered with virgin forest, in a salubrious climate, being for the most part an undulating plateau from 2,000 to 3,000 feet above sea-level. As long as the railway extension propaganda continues to spread, just so long will Brazil continue increasing her exports of coffee. Old coffee estates will continue to die out, from want of weeding, from growing corn and beans amongst it wherever there is the least projection of light, and the want of manure. This any plant would be expected to do. What does it matter? It has given good returns to the owner, and the latter contentedly buys a piece of land near where the next projected railway extension is being surveyed and moves his *living property* thither. Many of the old people remain in old districts—owing to old associations, and plant corn, beans, mandioca, and cane. None of these products gives much profit, for the three first have to compete with the provinces of the south, where European colonization has taken a firm hold, and the last mentioned can only be grown to pay where there may be a central factory near. Cane, however, is the only crop which can be made to pay in these old districts, and every new sugar factory which is opened shows the adaptability of these old coffee fields for cane growing. How rich the soil must have been is shown in its having produced crops of coffee, corn, beans and mandioca for ever so many years without a particle of manure, and now in giving luxuriant crops of a plant which has been found in the British colonies to be so exhausting. The word *manure* is not met with in the Brazilian vocabulary. Who would spend money in manure when we have so much land to fall back on? In the flatter lands along the coast, if the cane crop appears smaller in a field where five or six cuttings have been taken from the same plant (or as they would say in the colonies after five or six ratoonings), it is left to rest for a year or two, for weeds and undergrowth to take charge of it, and to supply its place they clean, burn, and plant some other piece.

But I have digressed from the subject of coffee; and I find I have also filled my sheet, so I must leave what more I had to say for a future opportunity.

A. SCOTT-BLACKLAW.

COFFEE, SUGAR, AND TOBACCO IN NETHERLANDS INDIA.

(Translated for the *Straits Times.*)

Dr. Burck, the acting manager of the Government Botanical garden at Buitenzorg has made public, full particulars regarding the specific against coffee leaf disease. Assuredly, there will be no want of experimenting with it, now that the discoverer who, however, does not yet feel quite certain of success, has shown that no one need be deterred from trying it on the score of expense. It seems however to be a sure fact that, in some parts of Java, the planters have got the better of the disease. Hence, there is every prospect of a bumper coffee crop next year.

Sugar bears every appearance of yielding handsome profits should present prices keep on. Badly managed estates fetch a mere trifle when thrown on the market, but, recently, an estate which happened to stand under good management, realised a high price. Wherever the cost of production has been lessened sufficiently to admit of work being conducted remuneratively, the future looks hopeful enough. Estate owners have now every chance of easing themselves of the burden of debt they labour under. Meanwhile the banks which have advanced them capital have incurred serious risks.

The most flourishing branch of planting enterprise at present turns out to be tobacco growing, especially on the East Coast of Sumatra. That residency is now in through telegraphic communication with Java since the line between Medan in Deli and the Padang Highlands has been completed. The line was opened to traffic on the 16th December. The treasures to be unearthed there, draw thither from all sides, crowds of young men in such numbers that the labour market has been glutted for a long time now. The evil has taken such wide dimensions as to call for serious warnings against such people coming there at a vesture, trusting to good luck befriending them in the battle of life. When a situation is secured by some stroke of good fortune, the prospect is far from encouraging. Often years elapse before the pursuit of the silver Mexicans becomes rewarded with success. During that time, these young fellows have to manage the best way they can on small salaries amid the scum of the Chinese nation. The days have gone by when the country was so little known, that the Deli Company could only with difficulty get young men even by offering liberal conditions. Now, like other companies, they indent on Europe for employees where any number of them is obtainable.

The mission of Professor Pekelharing to inquire into the causes and phenomena of beri-beri, has had one permanent result already. The laboratory he himself started at Batavia will be kept up for the study of bacteria. Meanwhile beri-beri continues to rage in Acheen, notwithstanding every precautionary measure against it.

TROPICAL PRODUCTS.

THE AMSTERDAM CINCHONA AUCTIONS.—The dates of the ten periodical public sales of cinchona bark to be held at Amsterdam during the year 1888 have been fixed as follows:—January 19th, February 23rd, March 22nd, May 3rd, June 7th, July 12th, August 30th, October 4th, November 8th, December 13th. An astonishing uncertainty prevailed in London in many quarters

as regards the result of the Amsterdam cinchona sales until long after they were finished. It has been, generally asserted, both in the press and in private reports, that "extreme prices" were paid, and that the unit fully maintained the advance of the recent London sales. There is no doubt that nothing of the kind happened, and that our telegram of the result of the auctions, giving the unit as slightly below that of the last London sales, was entirely correct. The action of the principal quinine operators, who since the Amsterdam sales have shown much more disposition to yield to the market, is in itself a sufficient proof of the correctness of our report.

QUININE.—It is stated that Mr. Alexander Böhringer, at the request of the board of directors of the New York Quinine and Chemical Works (Limited) has resigned his position as manager of that company's factory at Brooklyn.

ANNATTO.—Seed is in rather large supply. Several parcels Ceylon were bought in, 3½d being the price for good bright. Fair to good, slightly damp, sold at 2¾d to 3¼d per lb.; dark and mouldy. 2d to 2½d per lb. Fifteen baskets Pará roll, good bright, which have been frequently offered, came up again for sale. They were bought in at 1s 9d per lb., but 1s 4d was suggested as the price.

BAEL FRUIT remains neglected. Even good fruit appears almost invaluable, and the two lots of common discoloured fragments offered today had to be withdrawn, no offer being forthcoming; 1½d per lb. was solicited.—*Chemist and Druggist*, Dec. 15th.

QUININE IN HEROIC DOSES.

Anything that is likely to induce a large consumption of quinine is sure to benefit a cultivation which it was at one time hoped would go far towards making up to our planters for the decadence of coffee. We all know how very unfortunately it has chanced that the bright hopes of large returns from cinchona cultivation have been frustrated. The supply of bark from the plantations formed in India and Ceylon has not only proved sufficient to counterbalance, as was all along expected, the falling-off in the natural supply from the forests of South America, but has created such a surplus as has proved to be largely in excess of the demand for the esteemed febrifuge. The result has been to lower the price of cinchona bark in the European markets to such an extent as to nullify to a great extent the value of the tree as an adjunct to other planting enterprises.

But now, it appears as if there is likely to be a change in the practice of the administration of quinine. When we read—as we did in our London letter the other day—of such foremost men in the drug trade as Messrs. Howard and Mr. Thomas Christy interesting themselves in the subject, we may be tolerably certain that they regard the subject as one of importance, not to themselves alone as manufacturers and dealers respectively in the drug, but also to the medical profession and to the general public. We have recently noticed and republished the contribution made to the English press, towards stimulating the freer use of quinine as a prophylactic likely to stay to a great extent the baneful use of opium. Much may be hoped from the wide diffusion of our letter to the Anti Opium Society on the subject; but much more, perhaps, may result should the Messrs. Howard and Mr. Christy associate themselves in an endeavour to spread widely a knowledge which has gradually grown up in tropical countries of the superior value of quinine as a medicine when taken in what we have termed in the heading to this article "heroic" does. The usual dose prescribed in Ceylon in old days, as given in our medical hints for planters, is as much of the sulphate as would cover a threepenny piece. More recently, a similarly popular but increased dose was permitted, the direction going as far as the quantity which could be heaped upon a sixpenny piece. Now we hear of some doctors who recognize the fact that even the last limitation effects but little good, and who have taken to prescribing the sulphate in quantities such as a teaspoonful or more! Perhaps it might be thought that the great reduction which has taken place in the price of quinine may have brought about this change in medical practice, but our London correspondent tells us that he himself had such doses given to him by a doctor resident in Ceylon as far back as 1872, when Howard's sulphate was only purchasable in the colony at some 25s the ounce, and we are aware of more than one Ceylon planter who has been treated up to 20 or even 30 grains at a time. The fall in price cannot, therefore, be held to account to any appreciable extent for the changed practice.

Writing on the subject separately, our London correspondent says:—"There are few residents in the tropics, I fancy, but have had sufficiently wide experience in the use of quinine to have commenced to realize for themselves, how almost useless the Lilliputian doses of earlier practice proved to be. That these doses eventually effected the object for which they were given cannot be disputed; but it was only after long continued taking of them that they did so. The administration of larger doses was dreaded because there are few people who could take them without experiencing very unpleasant results, such as nausea and headache, a still worse one certainly being the production of a state of sleeplessness. But, if all that I hear be correct, such doses may be used without unpleasant results if taken on an empty stomach and before rising in the morning. I believe it has been discovered now that other drugs in the pharmacopœia, the use of which has been restricted for the same results above described as following the use of heavy doses of quinine, may be safely administered with the same precaution observed as to the time and circumstances of doing so. If this fact become widely recognized among home medical practitioners you may soon hear of a far more popular use of quinine in European countries than has yet been known. There are many people who would hesitate to wait for a cure during the long time required to effect it by the use of small doses of the medicine, but who would willingly submit to its employment if the beneficial results could be attained to in a few days only. Whether in the long run more quinine would be consumed under such an innovation on former custom or not, I can hardly say; but if the rapidity of cure can be established, there is no doubt it would be far more frequently prescribed than at present. Not alone is ancient custom likely now to be largely departed from in the direction referred to, but it is now fully established that the stimulant in which quinine has always more or less been given is not valuable alone as a solvent for the drug, but is absolutely necessary to stimulate the circulation so as to carry it rapidly throughout the system before it becomes absorbed into the food and so to a great extent lost. To be effective, it is now realized that quinine must pass with rapidity throughout the veinous system. If absorbed by solid matter its effect is nearly wholly lost."

We thought it best to refer our information on this head for a local medical opinion, and we have been favoured in reply with the following interesting remarks :—

"I think the general tendency in the practice of the present day is to give larger doses of quinine both for its tonic and its antipyretic effects than prevailed say 10 or 20 years ago, but except in Germany where Liebermeister for instance recommends 20 to 45 grains and even more in the treatment of typhoid fever, *heroic* doses are not favoured by the profession. But large doses, *i.e.*, 10 to 20 grains, are commonly prescribed in the treatment of the malignant forms of malarial fever, remittent, &c.

"I don't believe the pathologial effects, head symptoms, deafness, temporary blindness, rash and very rarely *abortion* and convulsions, can be obviated by the use of the drug in the early morning or an empty stomach, even if it could be always restricted to such times. But its solution in *Hydrobromic Acid* prevents these effects to a considerable extent if not entirely.

"Mr. J. Ferguson's paper on the value of quinine in checking the opium habit is very interesting, and I shall make a note of it as a subject for discussion in the Ceylon Branch of the British Medical Association."

PLANTING IN LOWCOUNTRY: SIYANE KORALE.

WEATHER—COCONUTS—DIGGING AND MANURES.

11th January 1888.

After an almost continuously wet December, January has dawned fine, a little too fine some would say. This weather is but a foretaste of what we will have to go through for two or three months more. I do not think the period of drought has a more visibly disastrous effect on any other product of tropical agriculture than on coconuts. During a season of even comparative rainlessness a coconut estate presents a doleful aspect with fallen and drooping branches and the ground dotted with immature nuts. This is not however the general appearance of every estate, but every estate more or less has patches answering to this description dependent on the lie of land, soil, or the nuts which formed the original nursery. The last crop of coconuts has been exceedingly small, but the generally compensating advantage of high prices, is this season absent. If petroleum be used exclusively in its crude form as fuel for steam machinery, and the recent command of the Emperor of China against the use of kerosine oil as an illuminant to avoid fires be made general all the world over, happy days are in store for the coconut planter, otherwise with the coming into bearing of the vast tracts which the Colonial Secretary told the Legislative Council recently are being opened in the North-Western Province, not to speak of the new plantations springing into existence in other parts of the world, coconut planters will be forced to ask the aid of the Government to advertize their product in all parts of the world, as successfully I hope as a similar request was made by tea planters.

Exactly a month ago your correspondent "W. B. L." promised to astonish me with some scientific theories. He has kept his word and has also returned to the charge on a subject which you had decreed as closed when withholding a communication of mine in answer to an onslaught that was then made on me. Fair play demands that I should be permitted a reply. I challenge "W. B. L." to point out in any of my writings reference to an "agricultural rule" against digging coconut land "periodically." Why not give up this vague word for one more definite? It is hardly any use carrying on a discussion with a man who will not boldly meet you and either support a dictum that has been more than once definitely challenged or honestly acknowledge that it was hastily and thoughtlessly made. Combatants are not likely to meet when moving in a circle and in the same direction. I took and take exception to the dictum "I approve of annual ploughing or digging, because, in general, it cannot be done oftener." I say it is opposed to reason to disturb the feeding roots when they are most active, for "W. B. L." himself bears witness to the fact that it takes at least 18 months for the coconut tree to respond to cultivation. The response of course is in the form of increased fruit bearing. When all the energies of the tree I say are necessary to meet the increased demand made on it to bring to maturity a large crop, to re-maim the roots by digging or ploughing amounts to little less than an act of madness. At this time of day it is a mere waste of time to quote authorities however high in support of what is well known to everyone having the least pretensions to a knowledge of agriculture, that the spread of roots is dependant on the mechanical condition of the soil, and that a free soil is more absorbent than a stiff one.

I lay not the slightest claim to any knowledge in Agricultural Chemistry, except what is naturally acquired by anyone engaged in practical agriculture, nor have I access to a library stocked with standard works on this subject as "W. B. L." evidently has; but I humbly venture to suggest that "agricultural chemists of today value manure by the measure of nitrogen they contain" is not universally true. The value placed on the constituents of any manure is solely dependant on the crop for which it is to be used. *I* never cited a Welsh gentleman to support my practice of applying manure where it is soonest available, round the stem of a tree. I practise it because I apply bulky manures, and bulky manures cannot be efficiently worked into a soil that is not sandy, except at a prohibitory cost. If I were applying artificial manures, and if the weather were favourable to the operation, I should certainly dig or plough it in by preference. That the *annual* stirring of the soil is never carried out even by its great advocate is proved by his avowal that only 12 acres of land were dug up during the past rainy season.

"W. B. L." recently attempted to sneer at me, when I said that as the action of bones was stimulating, they must be used with caution, especially on young plantations which have a tendency to overbear. By immediately after admitting that if bones be used "the tree needs to be kept in vigorous growth by other manures," he unconsciously supported the position I took and cut the ground from under his feet. That bones is not a manure that can be continuously used by itself has been proved by Lawes in experiments extending over twenty years, particulars of which appear in the *Tropical Agriculturist* for Dec. "W. B. L." has been a great advocate of the use of bones and has gone into figures to prove that by the application of one ton of bones to coconuts a profit of R180 can be calculated on. He even advises its application to young trees not in bearing to induce precocity. No mention was ever made by him to its being used with any other manure till I sounded a note of warning against its too general or exclusive use. Bones and bones only has been the burden of his song as a manure for coconut, and yet in his latest deliverance he says:—"I have generally found that if I have a good stout stem and a heavy head of leaf, I have a heavy bearing tree; therefore I manure for wood and leaf, and leave the fruit crop to shift for itself." In a foot-note he says:—"This is a rather off-hand way of treating the matter, but when one has to deal with nonsense, why be particular?" Of course it is "nonsense" for "W. B. L." to speak of bones, the use of which he so strongly advocates, as "a manure for wood and leaf."

As far as I am concerned this is my last contribution to the discussion on the advisability of constantly stirring the soil of coconut estates and of using bones exclusively in its cultivation, a discussion which I regret to admit was not soberly carried on by either party, and which has been unnecessarily prolonged by the point at issue being systematically evaded. I shall touch on a more useful subject in my next.

PLANTING AND INDUSTRY IN FIJI.

A parcel of beche-de-mer was recently sold by our local auctioneer Mr. D. Paul, and good prices were realised. Teat fish brought £70 per ton and black fish £51 10s. The figures make our mouths water these hard times, and the question is continually asked when are the present absurd regulations to be abolished. I know not what amount of reliability may be placed on the assertion, but it is continually stated by many that the shore reefs are very prolific in this slug.

Much anxiety is at present occasioned as to what industry in the way of planting is to be next tried in Fiji by way of helping to lift the country out of its present slough of despond. Sugar at the ruling market rate, barely pays, and is only suited to men of large capital. Copra is not to be thought of for new men to commence fresh plantations on their own account, although the present cocoanut properties are not to be despised, and may profitably, be enlarged by their present holders. For cattle there is no consumption, and present stock owners are anything but fortunate in their possessions. Coffee does not pay, so it is asserted. All cannot go into the fruit trade, so land owners are at their wits end for a profitable article to cultivate. Tea is looked upon with favor, but the present rate of labor is considerably in advance of Ceylon, where it is alleged labor can be procured at 6d. per diem, against our 1s. to 1s. 6d., according to the kind of labor employed. It is generally thought there is ample Fijian labor available if it were only directed by the Government into proper channels. However, whatever efforts are to be made to create a new industry, they will have, in a considerable measure, to be fostered by the Legislature of the country. The Government will have to evince in practice that it is desirous of assisting, in place, as heretofore, of retarding the planting interests of the country. It is only the initiation of some such policy that will put new hearts into the few remaining settlers, and so retain their interest and hard-earned experience to the country. Otherwise, Walker will soon be the name of the last small planter in Fiji. In Ceylon, tea planting has lifted the planters from deep distress to competence if not wealth. And why not in Fiji? Last year Ceylon had some 120,000 acres of tea planted and is increasing the area at the rate of tens of thousands of acres yearly. Fiji is spoken of as being particularly adapted for tea planting, and it is reported, that at Mr. Mason's tea plantation at Taviuni, the estimated outturn of the crop for the year was exceeded by 5000 lbs. in the first half of the year. Surely this is promising enough for others to give the industry a trial. —*Fiji Times.*

THE PRESENT AND FUTURE PROSPECTS OF THE CANE SUGAR AND OTHER AGRICULTURAL INDUSTRIES IN TRINIDAD,

BY

JAMES L. O'CONNOR,
Chairman of the District Agricultural Board of the Naparima Ward Union.

The great struggle which for many years past has been going on between the Beet and Cane Sugar Industries, and which has recently not only reduced to an alarming extent the Public Revenue, but now even threatens to sweep away an Industry to which the Colony owes the high position it has attained among the British possessions in this part of the world, is my excuse for submitting this paper to your consideration. But I must in the first place crave the indulgence of the planting body if my criticisms should appear to them to be rather severe. No one can doubt the fact that if their position has become so critical, it is due neither to a want of intelligence nor energy on their part, but in a great measure to circumstances beyond their control, which, however, may be so altered as to operate favourably in restoring their prosperity.

It is hardly necessary to enter here into the various causes which have brought about the great depression in the sugar market, but I shall endeavour to show how it should be met, and what chances there are of competing successfully with an adversary which can hardly become more formidable than it is at present, owing to the fact that the great intellects engaged in promoting its success appear to have almost reached the limits of scientific researches bearing on its production, and it is indeed fortunate that such is not the case with the cane sugar industry, otherwise there would be no alternative than its entire abandonment.

In glancing over the history of the past, what do we find?—that although the producers of beet sugar have been progressing with gigantic strides towards the attainment of a rapid decrease in the cost of production, we have been moving onward it is true towards the same end, but only at what may not be inaptly termed a snail's pace.

The following figures will, I think, fully bear out my statement, and show at the same time the extraordinary results brought about by the introduction in the Beet industry of the Diffusion system, which it cannot be doubted will produce still greater results when adopted in connection with the manufacture of Cane Sugar.

Germany.	Tons Beet per Acre.	Production Sugar Tons.	Percentage using diffusion.	Ton Sugar per Cwt. Beet.	Ton Beet required for 1 Ton Sugar.	Ton Sugar per Acre.	Remarks.
	R. c.		R. c.	R. c.	R. c.	R. c.

Austria 1886, Diffusion 212 usines: equal to 95 per cent. Other process 11 usines.
France 1886, about 75 per cent. of all usine work with diffusion.

The difficulties by which the cane sugar producers are hampered, and which threaten them with ruin, do not appear to be insurmountable, neither are the measures to be adopted in order to revive the industry on a more solid basis impracticable, but the difficulty to be apprehended will probably be found in the hesitation and unreasonable objections that may be raised by the timorous as to the remedial agencies to be adopted.

In the first place the subject of a proper supply of labour is of paramount importance, and the sacrifices to be made to render such labour remunerative must not be overlooked.

In bygone years, during a long period of great depression, caused by the low prices of sugar and

the scarcity of labour, the expediency of encouraging by every reasonable means a resident peasantry on the sugar estates was attended with very satisfactory results, and was seldom overlooked. Many inducements were held out to the labourer to reside on the estate on which his services were required. He was generally provided with suitable house accommodation, and sometimes free medical attendance, and some land was allotted to him to cultivate provisions. He was even allowed, when found to be very steady and industrious, to rear stock. It can readily be imagined that such privileges were a great inducement to many to establish themselves and their families permanently on the estates, and cost the proprietors very little. Time has shown whether the gradual withdrawal of those privileges was a wise measure. They were no doubt discontinued in order to extend cultivation, which it would have been more prudent to restrict, and increase by superior tillage the return from the land. Some of the labourers became settlers on Crown Lands, while the greater number removed to the neighbouring villages where inducements to lead an intemperate and idle life led to an increase of pauperism and crime. As the price of food increased by the discontinuance to cultivate ground provisions, and owing probably to the improved state of the sugar market, the labourer's pretensions to higher wages naturally increased, and the practice of paying higher wages to non-resident labourers became general, but has recently and very properly been discontinued as being most impolitic.

Whatever sacrifices it may be deemed necessary to make, with the view of encouraging a large resident peasantry on the sugar estates, it cannot be doubted that the benefit which would arise from such sacrifices would amply compensate the planter, and there is reason to believe that while some of our creole labourers might be induced to become resident labourers, thousands of labourers now in the neighbouring islands, where the distress among them seems to be increasing daily, would be glad to avail themselves of an offer to settle here if a liberal scheme were devised, satisfying the immigrants that their condition would be improved by making Trinidad their home.

The introduction also of a system of tenant farmers, wherever practicable, would help very much towards improving the condition of the labouring classes, while it would prove equally beneficial to the proprietor of sugar estates. But in order to insure success such schemes as suggested must be well matured, for it is no easy matter to conciliate interests, which, although apparently conflicting, are nevertheless identical; and when it is considered that the welfare of two classes, the employers and the employed are involved, a policy which will tend to produce mutual concessions and inspire mutual confidence cannot be too strongly advocated.

In considering the question of remunerative labour, it is very important not to loose sight of the fact that it cannot be obtained with the prevailing low prices of sugar in the absence of cheap food for the people, and it can hardly be doubted that the suggestions just made if carried out will tend much towards reducing the price of food.

A good supply of labour alone, however, will not suffice to restore the prosperity of the sugar cane planter, although it will help him on considerably. The sharp competition that now prevails necessitates through reforms in the modes of culture, while the manufacturing appliances must comprise the latest improvements, and it is to be hoped that the present depression will be viewed with a keen appreciation of what has been done in older countries towards reducing the cost of production.

The agricultural resources of the colony are great, yet comparatively little indeed is done towards improving them. It is a fact that while the best British soils now bear four times the crop they bore a few centuries ago—and this is due to improved tillage—our soils have been considerably deteriorated by defective tillage, but not exhausted as supposed by some planters. In referring to this subject, Messrs. Wall and Sawkins, in their very able report on the geology of Trinidad, page 117, state that—"The term exhausted has been employed as usual in the colony, but it is highly objectionable, as soils which have been worked fifty years may be more productive and more remunerative if properly operated than others which are only just brought under cultivation."

It is also a fact that manures are imported yearly from different countries at no small expense, and applied to our cane fields, while no attention is paid to their preparation on a large scale from local resources, which are allowed to waste, and here again let me quote from the same report the following observations and advice which will bear out my statement, and, it is to be hoped, prove interesting to those who may read this paper:—

"It has been customary to attempt to ward off exhaustion by the application of expensive imported manures. The following suggestions for supplying the essential substances more cheaply, and equally perhaps more efficiently, may be useful, especially since the deposits of guano are described as diminishing in consequence of the enormous quantities which are annually carried away. Phosphoric Acid and Phosphate of Lime by the introduction of crushed bones, or if collected in the Colony to be crushed before application, mixed with Sulphuric Acid and allowed to digest some time, this latter process frees the former acid and renders it available for the plant. Carbonate of Potash and Sulphate of Ammonia in small quantities would afford the necessary alkalies. These substances with the application of lime, already referred to, would supply the mineral matter of the cane.

"The principle of extending the area under canes to the utmost limits and producing the last hogshead possible, seems to be far too exclusively pursued, and the question of reduced cost of production to be effected by superior systems of cultivation and manufacture almost entirely neglected, and yet the latter is not only the most promising course of procedure to secure the Colony from disaster in the case of further competition with cheaper grown produce, but it may be predicted would initiate an entirely new era in its industrial history."

Although Messrs. Wall and Sawkins wrote the above extracts 26 years ago, they are still applicable to the present state of agriculture in the Colony, and although more attention is now paid to improved modes of culture, and some improvements have been effected in manufacturing appliances, yet the results as to the cost of production show that much remains to be done. The importance of a cheap supply of fuel, a heavy item of expenditure in the manufacture of sugar, and one which will be considerably increased by the adoption of the diffusion system, appears as a rule to be disregarded, so far at least as the procuring of it from local resources is involved. Large shipments of coals and patent fuel come across the ocean yearly—a distance of 4,000 miles, while it is well-known that important carbonaceous deposits exist in different parts of the Island, and one not further than a mile from this town on the "Vista Bella" Estate, at about half a mile from the Government Railway. No serious action has ever been taken towards developing the resources of such valuable mineral fuels. On the other hand, thousands of uncultivated acres that could be made to produce at an inconsiderable outlay an abundant supply of bamboos for fuel are neglected.

There are other products necessary to the maintenance of the cane sugar industry, which it is the practice to import from other countries, such as oats and oil meal, and which might very well be substituted by Indian corn and corn meal, products which by the exercise of a little extra trouble could be supplied by the planter himself at a comparatively small expenditure. But as there are sometimes certain interests at par with those of the planter which unfortunately have to be satisfied to his detriment, this circumstance has probably operated towards the neglect of the minor industries in connection with the cane cultivation.

The production of a crop of about 1300 tons of sugar means an expenditure for oats and oil meal alone for the stock, of some $10,000, and although a moderate outlay would suffice to produce from the estate lands the necessary amount of grain and meal, leaving a large profit to the proprietor, yet the experiment has not been made, and we are satisfied to continue in the old groove and fear to free ourselves from old prejudices.

The heavy losses hitherto sustained by the use of antiquated and defective machinery and appliances can no longer be tolerated, if those interested in the cane sugar industry expect to compete successfully with the producers of Beet Sugar. The age in which we live does not admit of any hesitation, which, under present circumstances, would be fatal to the former industry. The return of Beet per acre in Germany is about 12 tons, which yield about 1⅛ tons of sugar of a quality very inferior to our vacuum pans, and the total cost varies from £8 to £11 per ton.

With the best machinery here now in use (the average number of tons of canes per acre being about 20), the yield of vacuum pan sugar per acre may be computed at about 1¾ tons. But by improving the modes of culture, and thereby increasing the yield from 20 to 26 tons of canes per acre, and even over, and by substituting the Diffusion process with all the recent improvements for our mills and copper walls, an increase to 3 tons of superior vacuum pan sugar per acre may fairly be anticipated, with the result of a diminution in the actual cost of production of at least 25 per cent. while effecting a considerable improvement in quality. And let me ask, under such circumstances can any one now doubt that a new era of prosperity is opening for the cane sugar producer, if he can only manage to secure the necessary capital to take advantage of the great scientific improvements in machinery and manufacturing appliances of recent years, which prove beyond a doubt that no plant can yield sugar at as great a profit as the sugar cane; for the Diffusion system is now an accomplished fact. The defects which at one time existed, have vanished before the scientific researches of those, who, from the very beginning, predicted for it a bright future. The cane slicing machines have now been brought to great perfection, and everything else connected with the process.

Referring to this subject, the following extract from an article by Mr. Edmond Riffard, an eminent authority on such matters, will bear out my statement as to the relative value of the cane and beet. "*En présence de ces faits la sucrerie indigène betteravière a le droit d'ouvrir l'industrie coloniale. Nous n'approuvons pas d'avantage les récriminations de ces derniers, car ils sont les maîtres de la situation si tant est que leur volonté de suivre le progrès soit bien arrêté.*"

As a native of the colony and as one who has always taken the liveliest interests in its prosperity, I cannot refrain from referring here to the recent formation by His Excellency Sir William Robinson of District Agricultural Boards. The great interest which His Excellency continues to take in their success, is a pledge of his earnestness to develop every branch of our agricultural resources and secure for the country that measure of prosperity, which it is beginning to lack, and which, as a rule, is enjoyed in agricultural communities with similar institutions.

The liberal policy of the present Government towards agricultural industries in general, is such as to justify the belief in the revival on a sound and permanent basis of the cane sugar industry, while products which are now included among Minor Industries will in a few years hence form no insignificant part of our exports.

The policy of the Mother Country is so much opposed to protection, that it is unreasonable to expect any relief which would involve the necessity for a change of that policy. But adversity, which is a severe is also at times a useful teacher, and if I may be allowed to predict the future from the past history of the country, it is not unreasonable to expect that the great sugar crisis, by which all classes of the community are more or less affected, will in due time give way to a more prosperous state of things which will be brought about by a more general observance of the relations of science to agriculture, and by the prompt and decisive action of those capitalists who have already such large investments in the Colony: for if results based on scientific principles are to be depended upon, no one can any longer doubt, that to use the words of Mr. Edmond Riffard, quoted above, the cane sugar producers are now masters of the situation.

So far as we are concerned, the question seems to resolve itself to this, that considering the special advantages, situation, climate, fertility of soil, etc., possessed by Trinidad, if the necessary capital to permit of the introduction of more scientific methods of culture, and at the same time the most approved modern appliances be brought to bear on the cane sugar as has been the case with the beet sugar industry, the result must be a complete victory for the former. And under present circumstances it may be asked, what are the agricultural industries that offer to capitalists a safer investment than that of the cane sugar in this Colony and in some of the neighbouring Colonies enjoying the same advantages of climate, stability of the Government, and absence from popular commotions.

Possibly the struggle that has been going on between the two great industries for many years on very unequal terms, may have somewhat, in certain localities, reduced the chances in favour of carrying on the cane sugar industry successfully by private enterprise. But the remedy in such cases seems to be a simple one, viz., the formation of joint stock companies. The immunity from losses so far as human foresight can be relied upon, and the large dividends such companies would enjoy, cannot, I think, be doubted, in the presence of such facts as have been, I trust, satisfactorily proved in this paper. —*San Fernando Gazette.*

COD-LIVER OIL AS A CATTLE FOOD.

The suggestion of Cod-Liver Oil as a cattle food perhaps savours of the incredible; but it is nevertheless a fact that the experiment has been tried with success in England. In a country like India, where from want of proper food, and the wasting diseases which are so common to the cattle in this country, as often to make them resemble 'Pharaoh's lean kine,' this discovery of the properties of Cod-Liver Oil for fattening cattle is worthy of attention. Cod-Liver Oil has hitherto been associated in our minds with the nourishment of the human system, but when it is understood that this oil differs in its nature from castor and other aperient oils, and is distinctly nutritive, it will be easily understood how it can be used for fattening cattle, as well as the rearing of sickly and inferior stock. Animals, like human beings, require a certain amount of fat or oil to supply them with the requisite amount of caloric. The fact is recognised in many forms both for man and beast. In the case of such animals as horses, sheep and horned cattle, the fat has usually been supplied to them in the form of linseed or cotton cake, and the substitution of a more nutritive oil is therefore a question of comparative expense. This would, therefore, appear to be solved by the use of cod-liver oil. Any pasturage from roots and twigs, deficient in nutrition, may be made the vehicle for the transmission into the stomach of the commisariat camel and mule of a small quantity of a cod-liver oil, which will sustain and keep in condition transport animals on the line of march. The pasturage of our troops, so inferior in seasons of drought, and so liable to engender colic in wet whether, can now be safeguarded. Mr. Alfred Bonwick, the managing director of Messrs. Jensen & Co., we learn, himself greatly interested in agricultural pursuits, conceived the idea of trying the experiment of feeding cod-liver oil on a commercial scale. It would be a long history to relate the means by which the perfecting and cheapening of the supplies have been effected. They involved the outlay of much capital. In carrying them

out, a little town has been created at the head-quarters of the new industry, situated at Brettesnoes, in the Lofoden Isles, the very heart of the best Norwegian cod-fisheries. There, in the midst of perhaps the most lovely scenery in Norway, has gradually risen a huge commercial undertaking, affording, in this branch, employment for over 500 fishermen and working people.

It is claimed for Jensen's Norwegian Cod-Liver Oil, that it protects the chest and lungs of horses and cattle exposed to wet and cold, being a nourishing food, a stimulant, and a valuable curative agent and safeguard against pneumonia and influenza. It increases the yield of milk and the richness of cream, and whether with goats, calves, lambs, pigs, or puppies, the results have been found most efficacious. Writing on this subject the *Livestock Journal* says:—

The cod livers are now obtainable perfectly fresh, a vitally important matter in the preparation of the cod-liver oil. The bodies of the cod and the herrings produce an oil (trade oil) used for many purposes, principally for dressing leather, to render it soft and supple. The bones and flesh, formerly a waste product, now, when dried and ground up, form the base of what is known as fish potash manure. By dint of thus increasing and multiplying the uses of the fishing harvest in the Norwegian waters, the original cost of all has been brought to a minimum, and cattle oil—that is cod-liver oil—intended for feeding animals, is now manufactured and sold by the company at rates rendering it available for any stock-keeper in the country, whether a breeder of horses or sheep, cattle or pigs, or oxen or fancy dogs, or fancy fowls. Sir C. A. Cameron, M. D., President of the Royal College of Surgeons, Ireland, writes of this cattle oil:—"It is an excellent idea to give this oil to cattle. A few ounces added daily to their food, would be most beneficial to their health, and would help materially to fatten them." So it has proved in practice! With young stock—calves, fowls and lambs especially—brought into the world in the midst of the most inclement weather, as it is often their unfortunate lot, the cattle oil is said to be the means of saving hundreds of valuable young lives. It provides them with warmth, the first necessity of young life. A full-grown horse or cow is given a wine glass full of the cattle oil night and morning. It costs almost exactly 1*d.* per day. A ton of cake, costing about £9 10s., contains 112 lbs. of oil. A barrel of cattle oil, costing from £4 10s. to £5, contains 220 lbs. pure cod-liver oil, the highest form of nutriment, and the most efficient to a perfect digestion known. The most important points claimed, therefore, for Jensen's cattle oil for farmers' use, are its (1) powers of saving young life, especially lambs and calves, and (2) its highly fattening properties, both for young and full-grown stock. One of the greatest companies in the world as owners of horses, is giving it an exhaustive trial. If it will keep their horses free from influenza alone, it will pay them well. If it will put up the average of the working days of a horse six to nine months, as results already achieved make very probable, shareholders can congratulate themselves on an increase of dividend from the use of the cattle oil.

We learn that in order to introduce Messrs. Jensen's cod-liver oil for cattle to the notice of the authorities in India, Messrs. Hertz and Collingwood, the London agents, are sending out a trial consignment, so that we may at an early date be able to say something definite on the subject, so far as India is concerned.—*Indian Agriculturist.*

THE GIBBS AND BARRY TEA DRYING MACHINE.

Our readers will be interested in the information furnished in the following letter by Mr. Gibbs, showing that the drier can be supplied at moderate prices and of such sizes as may suit varying circumstances:—

To the Editor of the "Ceylon Observer."

3rd December 1887.

DEAR SIR,—With reference to your admirable report on the Gibbs and Barry Tea Dryer, will you allow me to explain to your readers that, the estimate of R4,000 applied only to the old type machines. They are now made with very many improvements at fully 25 per cent less price. They are made also in any sizes to suit any garden, the smaller ones being easily worked by hand. Your planter friends therefore have only to instruct our Agents as to the quantity of leaf they wish to dry per diem and the power they have to spare, to obtain exactly what they require. I have the pleasure to forward by book-post a descriptive *brochure* by which you will see that I have applied this system of different sizes and capacities to the purposes of wheat drying, sugar drying and other products with complete success, the range being from 9 feet by 2 feet, up to 48 feet by 3 feet 6 inches. Since Mr. Barry left England I have perfected a very simple and economical stove in which wood and coal can be used for these dryers.

—Yours very faithfully, WM. A. GIBBS.

THEINE AND OTHER CONSTITUENTS OF TEA AS FACTORS IN ITS QUALITY.

We commented on the figures for theine obtained by Dr. Paul and Mr. Cownley without having carefully read the accompanying remarks. A perusal of the paper, pencil in hand, shows the correctness of our inference that neither the flavour, strength, nor general quality of tea can be taken to depend on the amount of theine which may be yielded to the analytical chemist. The eminent chemists who conducted the experiments trace flavour to the essential oil (with reference to which, therefore, analyses should be conducted); and strength they are inclined, naturally enough, to refer to "the substance resembling tannin" which so largely exists in tea, but only a portion of which is ever extracted in a really good infusion. That neither strength nor general quality depends on the proportion of theine present in tea, is proved by the moderate percentage in the specially fine Strathellie tea operated on, and the slight difference, for theine, between "weak and strong" Indian teas. We are glad to observe that further examinations are to be made, and we trust that the proportion and influence of the essential oil will be specially noted. Some local chemist ought to go to a tea factory and analyse tea at every stage of green leaf, withered, rolled, fermented, and partially and fully roasted. It is surely curious that the chemists, though they give elevations at which teas were grown, say not one word about what was to us so obvious, the influence of altitude on the proportion of theine in tea. We suspect the substance we have been accustomed to call tannin will be found to follow the same rule of diminishing with altitude, while the amount of flavour-imparting essential oil increases.

THE FALL IN QUININE to 2⅝ per unit reported from London yesterday may be accounted for by large holders of bark at home, tired of waiting so long, coming on the market with a rush at the first signs of recovery. There is certainly nothing in the Ceylon statistics or prospects to justify the fall. On the contrary, the latest railway return shews a weekly transport of 40¼ tons of bark against 136½ tons in the same period of 1887. Should it be a case of clearing off bark stocks in London, of course good will result. We cannot altogether forget that some of the good friends who preach to us 'keep down exports from Ceylon' are not quite disinterested, having stocks of bark of their own lying in London stores waiting for a better market. The large dealings recently reported in quinine must give an impetus to manufacturing which cannot fail again to re-act favourably erelong on the Bark market.

PROPORTION OF THEINE IN TEAS

OF DIFFERENT QUALITIES AND GROWN AT AT DIFFRENT ELEVATIONS.

From the figures obtained by Dr. Paul, which we published on page 501 (January number), it is quite evident that in drawing inferences, we must qualify our conclusions by allowing for difference of age in teas, different grades and difference of circumstance under which teas may have been prepared—weather specially—as well as for the varying elevations at which they are grown. Such qualifications made, it seems evident that on the whole the distinctive alkaloid, theine, which is supposed to give tea its chief characteristic preponderates in teas grown at low elevations. High-grown teas seem to have less theine as well as less tannin (the latter the element on which strength and probably colour chiefly depend), but there is, doubtless, truth in Mr. John Hughes' suggestion that a volatile oil and not theine is the origin of the aroma of tea, which is peculiarly delicate in that grown at high elevations. Such high-grown teas may not be so valuable for blending or mixing purposes, but they have a value of their own for those who like to drink genuine teas unmixed, —for those who are connaisseurs in teas, just as some are in wines. It is a fact that as a rule Kangra Valley and Darjiling teas are prized for their delicate flavour, as doubtless are the high altitude teas of Ceylon. Remarking that the general inference is justified that the proportion of theine in fully manufactured tea is higher than in the green leaves (such we take "original tea" to mean), and that on the whole Indian and Ceylon teas seem to rank much alike in theine (allowance being made for our younger Ceylon plantations), we now proceed to place plantations and figures for dry tea in comparative order. First the high altitude teas, all grown above 4,000 feet:

Estates.	Elevation in ft.	Percentage of theine.
Calsay	5,000	3·13
Radella	4,800	4·30
St. Leys	4,600	3·66
Venture	4,300	3·95, 3·57, 1·26, 3·68 } 3·87
Woodstock	4,200	3·57
St. Clair	4,200	4·09

The anomalies which disturb the scale of decreasing theine according to increase in altitude from 4,200 feet to 5,000, seem to receive their explanation in the grades of teas experimented on. Radella at only 200 feet lower than Calsay shows nearly 1 per cent more theine, but then the Radella tea analyzed was broken pekoe against the pekoe souchong of the higher estate. The higher quality of the tea makes all the difference, and it seems a great pity Dr. Paul did not secure for his experiments teas of the same grade for each estate. St. Leys with pekoe dust seems in its proper place in the scale of altitude, and so does Venture with its specially complete average of four kinds. The different results for Woodstock and St. Clair at precisely the same altitude are, of course, accounted for by the difference in the grade of the teas, pekoe souchong in the case of Woodstock and broken orange pekoe in that of St. Clair. On the whole we seem justified in temporarily assuming an *average* of 4 per cent of theine for teas grown at 4,000 feet, the average going down gradually to 3½ per cent at 5,000. That, if the proportion were observed, might mean 3 per cent at 6,000 and 2½ per cent at 7,000. But further analyses of teas of uniform grade are desiderated to establish absolutely certain results. Qualities of soil may modify the effects of high altitude climate.

When we come to teas grown below 4,000 (and the figures in the table leave, unfortunately, a hiatus between 4,200 and 3,500), the anomalies are greater and more violent than in the figures we have been considering. We take the only figures available, thus:—

Estates.	Elevation in feet.	Percentage of theine.
Hardenhuish	3,500	4·24
Penrhos	2,500	4·89 & 4·96=4·92
Strathellie	2,000	4·33
Morton	400	4·15
Nahalma	300	4·80 & 4·29=4·55

Here the lowest figure is shown opposite the estate of highest altitude, but with a drop of 1,000 feet to Penrhos, all gradation is disturbed by the very high average of 4·92. This and especially the 4·96 (close on 5 per cent) for Penrhos broken pekoe beats the record, not only in the case of Ceylon but of India, the highest figure opposite an Indian tea (orange pekoe) being 4·89. Penrhos in rainy Ambagamuwa at 2,500 feet elevation excels in theine even the famous low-country estate Nahalma, at only 300 feet above sea-level. But the Nahalma tea is, we suppose, half-a-dozen years younger than that on Penrhos. Strathellie at 2,000 differs only a little from Morton at 400, although the first-named estate had orange pekoe against pekoe. Taking Nahalma as a type of low-country estates, we suppose that, as the tea grows older, we may count on 5 per cent at sea-level and on to 2,500, going down to 4½ between 2,500 and 4,000. Then 4 per cent going down ½ per cent for every 1,000 feet additional altitude. But further experiments are demanded before we can adopt any definite scale.

We should like to see similar analyses for tannin, and, if such a thing is possible, for the essential oil on which flavour is supposed really to depend, just as is the case with cinnamon bark.

CINCHONA BARK:

PROBABLE CEYLON AND JAVA EXPORTS.

We call attention to the interesting figures and remarks forwarded by Mr. James Sinclair on page 547.. Without endorsing his calculations, it is rather curious that his estimate for the current season's shipments should work out so near to the press figures, our own estimate being 10 million lb., Mr. Sinclair's 9,835,000.

From Europe, we have important news respecting Java bark showing that the total exports from private plantations to Amsterdam, may be put down as follows:—

1885		632,250 lb.
1886		847,800 ,,
1887		1,200,000 ,,
1888	(estimate)	2,250,000 ,,
1889	(do)	3,750,000 ,,

From the letter on page 543, the authority for these estimates will be seen. Besides the above, the Government plantations give from 800,000 to a million lb. a year. Here then we seem to have the probable increase of fine bark from Java which has to be faced for the next two years, a very much less formidable quantity than was to be anticipated from the figures of Mr. Mundt and other authorities. We have been reminded, however, with reference to the Amsterdam report we published a few days ago, that although special consignments of Java bark analyse up to 7 and 10 per cent sulphate of quinine, yet the average of all the sales work out to not much more than 3 per cent. The average will certainly be higher as the older barks increase

in the exports; but perhaps it would be enough to say that the Java exports may analyse double (in place of three or four times) the value of Ceylon barks. In that case, the estimated increase in the Java export for 1888 would be equal to about 2 million lb. of Ceylon bark, and if we do not ship more from Colombo than 9 or 10 millions for this calendar year, we may count on a comparative decrease in the available quantity from the two countries equal to 2 million lb. of Ceylon average quality. For the succeeding year 1889, the anticipated increase from Java (equal to 3 million lb. of our bark) will also probably be nearly met by another falling-off in shipments from Ceylon. But if not, there is the growing consumption of quinine sufficient to make the demand equal to any difference. The prospects of cinchona bark owners are therefore not at all so gloomy as we feared from the previous Java report.

STATISTICS OF CINCHONA BARK AND PRICES OF QUININE FROM 1880 TO 1887.

The figures compiled by Messrs. C. M. and C. Woodhouse (which will be found following after this) are very interesting, and to the cinchona grower, while painful in some respects, are yet in others hopefully suggestive. The total imports of bark into the United Kingdom in 1880 were under 9 millions of pounds, the exact figures being 8,917,776, of which Ceylon supplied only 1,140,000, or about 13 per cent. Our contribution in 1881 was remarkably smaller, only 834,624 lb. in a total of no less than 14 millions. The percentage of Ceylon bark in 1881, therefore, was only 6 per cent, so that no wonder, if the world was taken by surprise and the market disorganized by our subsequent performances—performances which beat even the cheap cuprea bark of South America out of the market. The great rise to 14 millions of pounds imported into Britain in 1881 against less than 9 millions in 1880 must have been very largely due to increased supplies of cuprea bark, which, though it possessed the qualities of that from cinchona trees, was really not a cinchona bark. The demoralization of the market which cuprea bark initiated was speedily brought to a culminating point by a perfect flood of Ceylon cinchona bark, so much of it branch and twig stuff of poor quality that we see Messrs. Woodhouse reckon the proportion of quinine (apart from the other alkaloids) at only 1 per cent average for the whole. The disorganizing process has its history in such figures as the following:—In 1882 the bark imported in Britain was 15,600,000 lb., of which the Ceylon quota was 2,561,000, or 16 per cent. In 1883 Ceylon made a leap to 5,360,000 lb. out of a total of a little over 13 millions. Our proportion in that year was, therefore, 40 per cent of the whole. In 1884 Ceylon gave 8,742,000 lb. to a total import of 11,848,000, our percentage rising to 75 per cent. In 1885 Ceylon alone gave more than the total of 1884, the proportions being:—

From Ceylon ..	11,914,000
,, other countries	2,433,000

So that the Ceylon percentage suddenly sprung to 82 per cent, perplexing dealers and dismaying speculators. In 1886 Ceylon increased its supply and other countries followed suit, the result being a total import of 16,281,000 lb (nearly twice the figure for 1880), of which Ceylon contributed no less than 12,872,000, or 80 per cent. For 1887 there are estimates of lower quantities from Ceylon and what have now become minor sources of supply. We need scarcely remind our readers that the highest figures given for Ceylon bark in any one year, nearly 13 millions of pounds, are short by some millions of pounds of the total exports from Ceylon. Of course some of our bark went to America and other markets, and it looks as if in counting by bales, Ceylon gets credit for less bark than she really sent to England. Suffice it that we swamped the markets of the world, conferring simultaneously untold benefits on humanity by compelling a reduction in the price of Howard's quinine of more than 75 per cent, or from 12s per ounce in 1880 to under 3s, quotations having been so low, indeed, recently as 2s 3d. Simultaneously we have reduced the value of the unit of quinine in bark against ourselves and all other producers from 2s in 1880 to 3d. now and even less!

The encouraging figures for planters who still have bark to harvest and sell are those which represent the decrease in branch and the increase in root bark: the latter especially as showing the large proportion of trees which are neither shaved nor coppiced but finally taken out of the ground. The figures for a special property are particularly striking: the proportion of root bark being over 50 per cent of all harvested in two separate years, and 40 and 46 in two other years. The process is increasing and will increase more and more as tea attains the bearing age. Ceylon, which is going so fast ahead of Java in tea growing, will, probably, a few years hence, cease seriously to compete with the Dutch Colony as a producer of cinchona bark. Meantime we must say we cannot pretend fully to understand a second set of figures which the Messrs. Woodhouse give for Ceylon cinchona, and which tend to show that far more (in 1886 and 1887 nearly twice as much) Ceylon bark was brought to auction than was imported, thus:—1886: imported 12,872,000 lb.; brought to auction 21,299,000. We suppose the meaning of the problem is, that the different qualities are reduced to 1 lb. for every unit of quinine, that alkaloid varying in Ceylon bark from ½ per cent in branch to 1½ in root and stem and 3 per cent in renewed. If what is reported from "Netherlands India" be true, as to the richness in *quinine* of even the hybrid cinchonas, we fancy the average for Java-grown bark will henceforward be at least 4 per cent. We do not forget the quotations of 8 to 12 per cent, but Mr. Moens found such qualities rare. But even an AVERAGE of 4 per cent ought to enable Java to take first place in the world as a source of cinchona bark. In Ceylon we have grown some good officinalis and a limited quantity of rich ledger as at Yarrow. But in Java the conditions of *soil*, and perhaps climate, seem as superior for ledgeriana and its hybrids as the conditions here, labour included, are for fine tea. So let each colony go ahead with what suits it best. If the best tea in the world is conceded to Ceylon, she can well afford to let Java have the credit and the profit of the best bark.

CINCHONA BARK STATISTICS.

(*By Messrs. C. M. & C. Woodhouse of London.*)

Total imports into U. K.: in 1880, 8,917,776 lb.; 1881, 14,040,096 lb.; 1882, 15,599,920 lb.; 1883, 13,095,152 lb.; 1884, 11,848,592 lb.; 1885, 14,347,648 lb.; 1886, 16,281,104 lb.; 1887 (9 months), 12,729,024 lb. Of which from Ceylon: in 1880, 1,140,048 lb.; 1881, 834,624 lb.; 1882, 2,561,216 lb.; 1883, 5,360,320 lb; 1884, 8,742,160 lb.; 1885, 11,914,000 lb.; 1886, 12,872,384 lb.; 1887 (9 months), estimated, 10,416,750 lb. Value of unit of Quinine: in 1880, 1s 10d to 2s 2d; 1881, 1s 2d to 1s 9d; 1882, 9d to 1s 2d; 1883, 4½d to 9d; 1884, 5d to 9d; 1885, 4d to 7½d; 1886, 3d to 5¾d; 1887 (9 months), 1¾d to 4d. Manufacturer's quotations for Quinine.—Howard's in oz. bottles: in 1880, 11s to 12s 8d; 1881, 8s to 12s 6d; 1882, 8s 6d to 10s; 1883, 7s 6d to 8s; 1884, 4s 3d to 8s; 1885, 3s 4d to 4s 8d; 1886, 2s 6d to 3s 4d; 1887 (9 months), 2s 3d to 2s 8d.

C. M. & O. WOODHOUSE.

THE HANKOW TEA GUILD.

"Mercury" writes to the London *Standard* :—Reverting to the telegrams on this subject from your correspondent in China, as set forth in your issue of May 18th and 19th, also to my letter to the *Standard* of July 4th last, corroborating your representative's messages—at that time credited by a very small portion of the Tea trade in this country—it is now evident that your informant was far ahead of his neighbours in his grasp of the situation and prospects of the commodity so carefully "protected" by the above Guild,

for the special benefit of their fellow-countrymen. After a most unsatisfactory and desultory season to the Teamen supplies in the North have ceased; the remainder of the "Shuntams"—which rubbish, owing to the fall in silver of late years, has so disastrously swelled the export—is being broken up the natives and sold as dust to the Russians for brick Tea, Teamen thereby avoiding payment of half the heavy duty. Accordingly there will be a deficiency to London of between fifteen and twenty million pounds from the North of China alone this season—much more than the equivalent of an entire second crop, as your informant predicted so far back as last May: moreover, the determination of foreign buyers not to purchase the residue of the crop has extended to Foochow, from which port likewise supplies are at present ten million pounds short of last year's, the Teamen there asserting they will keep their unsold stock until next season, and then mix it with new leaf.

The all-powerful guilds, therefore, seem to have been beaten hopelessly upon their own territory, and it is not surprising to learn that Chinese officials have become alarmed at the greatly diminished revenue from Tea. This concern on their part, it is to be hoped, may result in a better article being prepared for export than of late years, which is all that is required to regain for China tea the supremacy which undoubtedly now is held by Indian and Ceylon growths. Ample supplies of these latter have prevented the market for China tea in London from advancing materially in price as yet; still, such a decrement as thirty million pounds of low-priced tea in a single season must before long be felt acutely by retailers here, and cannot but tend to the distribution of a vastly more healthy, if somewhat more costly, article than has existed since the public demanded cheap tea, unconcerned as to how nasty and unwholesome such might prove.—*L. & C. Express*, Dec. 30th.

PLANTING IN NETHERLANDS INDIA.

(Translated for the *Straits Times*.)

The steady spread of planting enterprise in Palembang, and the increasing inflow of coolies have resulted in the passing of a Labourer's Ordinance by the Netherlands India Government, specially applicable to that Residency. Besides the usual provisions, it prescribes that no coolie shall work more than ten hours a day inclusive of the time he is engaged on extra duties. Contracts with coolies must also make it compulsory on the employer to supply the coolies with rice and salt only. It must also explicitly be set forth in contracts when the employer agrees to supply the coolies with rations and clothes how these supplies will be furnished. The Ordinance expressly provides that the quartering and medical treatment of the coolies shall be provided for by the employer free of charge. Medical treatment is also made compulsory in case of wounds received even when not in service.

The Surabaya *Courant* reports the receipt of advices from London announcing a rapid advance in the price of cinchona. Recent sales of bark at Amsterdam show a marked rise in quotations. The rise will prove highly welcome to cinchona planters in Java from its rendering lighter the burden of taxation on them.

COCONUT OR COCOANUT.—Professor Balfour directs the attention of botanists (*Ann. Bot.*, p. 185) to the fact that cocoanut should correctly be written coco, and that now that coca is becoming an important therapeutic agent, it is all the more necessary that a correct orthography should be followed, so that less confusion may arise than at present appears to exist, he having known people who were content in the belief that the coconut palm was the source of both cocoa and coca. Dr. Balfour appears, however, to have overlooked the fact that the name coco is commonly applied to the root of *Colocasia antiquorum.*—*Pharmaceutical Journal.*

COFFEE IN COORG.—During the year 1886-87, Coorg coffee rose from Rs. 24 per cent. to Rs. 45. This remarkable rebound after several years of low prices, caused the greatest activity in the market, but coming at a season when the out-turn was as a whole unusally small, the planters did not benefit as they might have done otherwise. On the other hand, the commonest native coffee, as well as the most inferior kinds of plantation coffee, were in great demand, being purchased chiefly by French and German firms on the west coast, and obtained frequently at high prices as the superior kinds. Most of the coffee from Coorg, estimated at three-fourths of the whole, was despatched to the sea port on the west coast, the remainder being sent to the curing establishments at Eunsur and Bangalore. The quantity of coffee exported in 1886-87 amounted to 3,631 tons. The total area assessed for coffee, during this period, was 80,570 acres, while about 15,000 acres, situated in the steep ghat slopes and other uncongenial localities, are not under cultivation.—*Madras Times.*

SUGARED MORTAR.—Deputy Surgeon-General Short, F. L. S., writes to the *Madras Mail* from Yercaud:—"How true is the saying, 'There is nothing new under the sun,' as relates to the question of sugared mortar. To my personal knowledge it has been in use for the last 40 years, and, as pointed out by Surgeon-General Cornish, Mr. Baldrey, and others, the difficulty of breaking old walls is a proof of its tenacity. As a small experiment, perhaps the following may prove interesting. I purchased some years ago at an auction sale a Burmese image of Buddha, or one of his satellites, in white marble, which some mischief-maker had damaged by knocking off its nose, and as there is no deformity equivalent to a noseless person or image, the features of this human form divine were completely disfigured. After a time I thought I might perform what doctors call a valiacotian operation, and thus remedy the disfigurement by giving it a new nose. With this view I set to work and got some slaked lime (chunam), prepared from the common limestone, or kunkur, finely powered, sifted, and softened with a saturated solution of sugar and water, and after freely washing the wound with the solution, I put on an artificial nose, which to my delight succeeded beautifully. It is some five years now since this was done, and the image has, under a tree in the compound, been exposed to all weathers. There is the nose as good and firm as the marble of which the image itself is made. In another instance, a china garden seat got broken. This I caused to be filled with chunam (lime) and restored to its original form and size. The seat was rebroken through the carelessness of a horsekeeper and the seat itself injured; this also the bricklayer managed to repair with the usual chunam. Then came accident number three. A stout lump of a gardener must needs get on it to reach something on the tree under which it was placed, and the top of the seat came down and was smashed to pieces. This time the bricklayer failed completely to mend it, and so at last I took it in hand, and got some well-sifted powdered chunam, and had it ground in a millstone, with a saturated solution of jaggery got for the purpose, and to the mass I added the whites of two eggs; and then with this substance I brought all the broken pieces together and kept the seat upside down for a couple of days to allow the mortar to settle; when taken up, the seat was found perfect and the broken pieces quite firm, and there it has stood under the same tree with the Burmese image for the last three months, during which time I have frequently had occasion to use it. Side by side they prove the tenacity of sugared mortar, or chunam in one instance, and the addition of the white of an egg in the other. In the first I used white crystallized sugar; but in the second the common jaggery from the bazaar." Might not plaster of Paris, which is often used as a cement in pharmacies, bind much firmer if made into a paste with syr. simpl. instead of water?—*Planters' Gazette.*

JOHN BULL'S VINEYARD.*

Under the above title an Australian landholder has written about the wine-producing capabilities of the land of his adoption; with regard to which wines it may be noted as somewhat remarkable that they have never established any perceptible hold on the palates of Anglo-Indians.

Mr. De Castella's own estate, according to the *Saturday Review*, of which he gives an enchanting picture, is situated in a valley enclosed by the Plenty and Dandenong ranges and watered—the expression can rarely be used of any Australian valley—by the Yarra Yarra. Here are grown the wines which have been honored with the German Emperor's prize—the Sauvignons, Carbinets, Hermitages, Rieslings, which under the general name of St. Hubert are esteemed in Victoria itself as the best among the native growths. Our author speaks with a becoming modesty of his own products. His book is commendably free from all taint of self-seeking, and is conspicuous for nothing so much as its note of patriotic enthusiasm. He is a champion rather of the wine-growing capacity of the Australian soil than of the quality of the Australian wines. He is sensible of the defects and shortcomings of the local wine-growers. A principal source of failure is in the very ease with which the grape can be grown and the wine made in most parts of temperate Australia. The temptation to everybody who has a few acres of land to make wine is irresistible, and the opportunities are unparalleled. The plant is one of the simplest cultivation, the labor pleasant and not excessive, the yield enormous. Nothing imported thrives so well as the vine in Australia, not even the rabbit or the sparrow. The cuttings are stuck into holes made with a crowbar from six to ten feet apart, according to the soil. In three years they begin to produce grapes fit for wine-making. When in full bearing an acre will yield from 300 to 500 gallons. There are no accidents to fear, no enemies to encounter, no frost to blight the young shoots, no rain to damage the ripe berries. The phylloxera, it is true, made its appearance a few years ago in the Geelong district; but the wines attacked were promptly rooted up, and the pestiferous intruder has ceased to exist. To make wine is almost easier than to grow grapes, and it is the fatal facility with which it is made, not to speak of the idyllic nature of the industry, which tempts the fortunate freeholder into multiplying the number of vintages, to the confusion of the tasters and the discredit of the colony. To the complaint of European experts that Victorian growers, "in contempt of all truth, take the names of the great wines of Europe to adorn their products," Mr. De Castella's answer is easy. It is not the growers, but the merchants, who give the names of claret, hock, Madeira, and port to the wines—those appellations being only generic—to indicate the kinds of wine offered to the consumer. As the grapes are all of European origin, it is natural that the growers should attach their names to the wines made from them. But Hermitage, Riesling, Burgundy, Tokay attached to Victorian wines, only indicate that they are made of the Hermitage, Riesling, Burgundy, or Tokay grapes; the produce of which in Australia is sometimes very different in character from what it is in Europe.

Mr. De Castella complains that John Bull has hitherto been neglectful of his vineyard, that Australian wines are less esteemed than they deserve, because "fashion rules the drinking of most of the Britons." Wine grown in the Colonies is not a fashionable beverage, and therefore it must be cheap. But if we insist upon cheapness, we cannot have quality. Should John Bull retort that he must have quality before he gives the price, the rejoinder from the Australian side is, that the national palate has become so dulled and depraved by indulgence in the brandied and artificial wines of Europe as to be incapable of appreciating the natural flavour of a pure wine. On this side there must be an education as well as on the other. Such a book as Mr. De Castella's is calculated to lead to a better understanding of the estate we possess in Australia—an estate, to the due cultivation of which we are impelled by a double interest. Without doubt we have within our own Empire a region capable of supplying us with all we desire in the article of wine, better and cheaper than we can get it elsewhere. All that is wanted to develop this beautiful and wholesome industry is to multiply the number of happy landholders in that Eden which Mr. De Castella so picturesquely describes. This is an operation which carries a triple blessing. It blesses those that stay and those that go, as well as the land which receives them; and the greater the number of wine-growers in Australia, the more numerous will be England's best customers and the richer her colony.—*Pioneer.*

BRITISH AND FOREIGN CONSULS' REPORTS.

STRAITS SETTLEMENTS.

Gum Copal. The copal shipped from Singapore is found in deposits or layers near the surface of the earth on many of the islands of the Malayan Archipelago, prominently in Celebes, Timor, and the Moluccas (much of it comes from Ternate, Amboyna, and Macassar); also from Borneo, Java, Sumatra, and the Malay peninsula. Gum copal arrives at Singapore raw, just as it is dug up by the natives, with earth and ground adhering to it, and has to be cleaned and "chipped" before being exported. The "chips" and dust are occasionally also exported, as they contain a fair percentage of pure gum. It is curious to note in the colonial trade statistics what effect this "cleaning process" has on the weight and value of the article between imports and exports, as follows:—

	Imported.		Exported.	
1884	Pic. 23,037	$145,708	Pic. 23,917	$159,745
1885	19,864	153,600	19,779	168,927

These are certainly very strange figures, even if some old stock from 1883 was exported in 1884, or quantities were received from native prahns without being reported at the import bureau, since it cannot well be accepted that at the end of 1885 any stock was held for exportation in 1886, and one wonders how the "dust and chips" are accounted for, considering that, as per statistics, 795 piculs were exported in excess of receipts. The excess of the export values, though very large, is easier explained, *i. e.*, in charges of receiving, shipping, weighing, cleaning, packing, shipping, insurance commissions, &c. The statistical figures show that the average import price was $6.97¾, and the average export price was $7·52 1/5 per picul. This is probably owing to the fact that the gum sometimes arrives here so full of foreign adhesions as to command only from $4 to $5 per picul, the price of the best being at present about $11. The margin is thus very great, and the room for imposing and cheating in exports also. Copal importers can therefore not exercise too much care in their purchases, and it is probably best to buy it on commission in the uncleaned state from first-class firms only, and to have it cleaned at home.

Gum Benjamin.—This gum is received principally from Sumatra and Siam Proper with a little from the Coromandel and the Philippine Islands. Its vapour being very aromatic, it is used in places of worship by Christians, Islamites, and Pagans alike as incense, and many natives of Asia, who can afford it, burn it to give fragrance in their dwelling-houses. The imports and exports were as follows:—

	Imported.		Exported.	
1884	Pic. 7,512	$233,900	Pic. 7,112	$235,638
1885	7,428	206 788	7,283	217,066

The exports go to nearly all the countries in Europe, the United Kingdom receiving by far the most. They were:

Year	Exported from	Quantity	Value
1884	Singapore	Pic. 1,687	$110,921 00
1884	Penang	436	19,173 00
1885	Singapore	2,307	116,514 00
1885	Penang	1,228	55,905 00

Preparations of Dragon's Blood.—Dragon's blood is the product of the province of Djambi, in Sumatra, and, to a slight extent, of parts of the west coast of the Malay peninsula, north of Province of Wellesley. The article comes into the market prepared and put up in two different ways, viz., in cakes or lumps about 1½ in. thick, or in small tablets or sticks about 8 to 9 in. long, both tablets and sticks being well packed into palm leaves, to prevent it from running by the action of heat. It varies in price from $20 to $50 per picul, all depending on the purity of the article, since adulteration is resorted to, such as mixing brick dust or other foreign matter with the extract while still warm, before being poured into moulds. I have before me four samples, $20, $25, $40 and $50 per picul, respectively. The first is cake, and nearly as heavy as its volume in brick. By scraping it, it feels gritty, and the scrapings, when mixed with water and daubed over paper, give an uncertain dirty crimson colour, while it should be a good crimson, with a light subtint of purple. No. 2, looking like a thin plug of tobacco (about 1½ by 7 in.), and wrapped into palm leaf, is purer, more solid, but not free from adulteration. No. 3 looks like a thin, long stick of liquorice, and has a palm-leaf wrapper over all, with both ends closely tied and thread wrapped over all the entire length. It is very solid and said to be a special preparation by grinding up the extract with a little oil, which, it would seem, preparation would seem to me almost impossible, tends to give solidity when dry. Alteration in this since by breaking a stick in two and holding a broken end to the light, any admixture of any substance in the least rough and not exactly the same colour as the true extract would show itself. No. 4 (at $50) is in cake and looks different from all the rest. It comes from the Malay peninsula. In colour when broken it looks like dry blood, with a purplish subtint. In rubbing it it feels as smooth as wax, and its volume is much lighter than No. 1, at $20; it is no doubt pure and genuine.

Dragon's blood is not always abundant in this market. The imports and exports at Singapore were as follows:—

	Imported		Exported	
1884	Pic. 340	$9,370	Pic. 280	$9,567
1885	1,054	2,1090	375	15,727

Gambier Cultivation.—The cultivation of gambier here is entirely in the hands of the Chinese, and goes hand in hand, to a great extent, with pepper planting, as the decocted leaves of the gambier plant serve as fertiliser to the pepper vines. The demand for gambier has been on the increase for various reasons, chief among which, next to speculation, is that gambier exhausts the soil in a short time, needing frequent changing.

Gambier Adulteration.—Adulteration is carried on to a large extent in the preparation of the article, and great frauds also committed by the Chinese middle traders, who supply the exporter with the marketable article already packed in matting, in square pressed bales or cubes. These frauds, which commenced a few years ago, have now assumed alarming proportions, and become the cause of much vexation and trouble to the European exporters, and discussions have taken place in the local Chamber of Commerce as to the best means to overcome the difficulty. But the merchants here appear to be powerless. The "Kougkek," or Chinese gambier syndicates, simply say, "You must take it as we have it or you won't get any." No Europeans are engaged in gambier planting, and the exporter is forced to take it at the stipulated market prices, pay goodly commissions to his middle trader, and to ship it to his customers in Europe or the United States, knowing that the complaints of the latter will be well founded, and of course "the brunt of the fraud" falls upon them, and those that use it in manufacture. The bales of gambier brought to market in most instances contain admixtures of pieces of sticks, stones, clay, and lumps of pressed out gambier leaves.

TURKEY IN ASIA.

The Sponge Fisheries.—Sponge fishing extends all along the coast of Batroon, Tripoli, Latakia, and the island of Ruad, north of Tripoli. It is not confined only to native fishermen, for many Greeks come over from Kalimno, Stanchio, Rhodes, and Samos, in their little crafts, to share this traffic with the Syrians. The catch commences in June and extends to October, this season being the most suitable owing to the calmness of the sea. The diver generally remains at the bottom of the sea from sixty to eighty seconds, unlike the Australian pearlshell fishers, who often remain under water for hours at a time. This is due to the fact that the native Syrian diver has simply an open net around his unprotected body and uses no instrument of any kind in collecting his sponges; he cannot be induced, like the Turks, to adopt the diving dress, or "Skafander." The depth to which Syrian divers descend is from 25 to 175 feet; below these depths no good sponges are said to be found. Three kinds of sponges are known here—prime, seconds and the red ones, taken near Batroon. The latter are by far the best. They have to be cleaned and freed from sand and then pressed. The best qualities are exported from Beirut to Paris direct, the others go almost exclusively to Trieste, while the Greeks send their share of the catch to different markets in Europe. The average annual catch is estimated at about $150,000 in value. The local authorities exact a tax of 10 p.c. from those engaged in the business. —*Chemist and Druggist.*

A NEW VEGETABLE.

It rarely falls to our lot to have to chronicle the introduction of an absolutely new vegetable. New Peas—literally as like Peas from the same pod—new Potatoes, new Cabbages, Tomatos, Onions—these there are by the score. Only a few of them, however, stand the trial of the test at Chiswick, where the synonyms imposed by gardeners and seedsmen are as ruthlessly cut down and referred to their proper places as are the like double names by the systematic botanist in preparing a monograph.

But now we have really a novelty to lay before our readers, and it is one which we venture to think is far from unpromising. The tubers were exhibited at the meeting of the Royal Horticultural Society, on December 13 last, by Mr. Haskings, gardener to Sir H. Thompson, Hurstside, West Moulsey, and were obligingly communicated to us for the purpose of illustration.

The plant producing these tubers is a Labiate, and is said to be a species of Stachys, allied to the Woundwort of our hedges, but without the disagreeable odour; but as we have not seen flowers or seed-vessels, we do not know whether this is correct or not. At any rate, the plant goes for the present under the name of Stachys tuberifera, our excellent correspondent, M. Naudin, having bestowed this name upon it, to replace that of Stachys affinis, which is quite a different plant.

Our first knowledge of this vegetable was derived from a notice in the *Revue Horticole* 1885, p. 236. According to this, the plant was introduced from China to the Société d' Acclimatation of Paris by Dr. Bretschneider, Physician to the Russian Embassy at Pekin. M. Naudin, however, in his recently published *Manuel de l' Acclimateur* (1887), p. 507, speaks of it as coming from Japan, and probably also from China. Possibly it may be the same as Stachys Sieboldi, which we learn is cultivated in Japan under the name of "Chorogi," but of this we have no means of judging. Its culture in France is due to M. Paillieux, who now grows it on a large scale for this Paris market, where it is known under the name of Crosnes, from the locality in which it is cultivated.

As will be seen from our illustration, the tubers are borne at the ends of underground branches, or stolons, exactly as in the Potato. The tuber in this case is, in fact, the thickened extremity of an underground branch, and it is marked by buds, or eyes, at the nodes, as in the Potato. Those who

know the Fir-apple, or Asparagus-Potato, will recognise the similarity between that variety and the new-comer. These tubers are produced in great profusion, though at present of small size, are doubtless capable of enlargement at the hands of the gardener, especially if seedling varieties can be obtained. Unlike the Potato, these tubers have a bud at the end of the tuber (terminal), and this curves upward to form the new shoot; hence the propagation of the plant is easily effected, and as each tuber consists of several internodes—that is, has several buds or eyes—we have no doubt whatever that they may be propagated by sets or cut tubers, as in the Potato.

The plant is alleged to be perfectly hardy and of the easiest possible culture. It will grow anywhere, on any ordinary soil, but like other plants it will no doubt repay a little attention in the way of trenching and manuring. Its defects at present are its small size, and the fact that the tubers do not keep well when lifted; but both these defects can be overcome or evaded. In point of flavour we have heard it compared to Salsafy, Jerusalem Artichokes, and to boiled Chestnuts. Our own taste would lead us to consider it as most nearly allied in point of flavour to the latter. M. Carrière publishes the following analysis, which shows that the plant is a valuable food agent:—

Starch	17·80
Albumen: (including 0·69 N.)	4·31
Fatty matters	0·55
Woody matters and cellulose	1·31
Mineral matters: (including 0·28 phosphoric acid) ...	1·81
Water	74·19
	100·00

M. Carrière, while admitting that the difficulty of preserving the tubers militates against them as a market-garden crop, points out that it is well suited for the domestic kitchen garden, where the tubers can be lifted in late autumn or winter and eaten in fresh state, either boiled, fried like Salsafy, made into sauce, or cooked in a dozen other ways that any cook—especially a French one—will devise.

The microscopic examination that we have been able to make, does not reveal so large a proportion of solid starch as the chemical analysis would lead us to expect. Probably the amylaceous element exists in some other form than starch, as is the case in the Jerusalem Artichoke. The mass of the tuber consists of polygonal cells, with thickened corners, minute granules perhaps of inulin, a few oil globules, large granular nuclei, and very bright nucleoli. Pitted vessels, sieve-tubes, and other elements of a modified stem-structure, are clearly apparent.

We believe that this new vegetable will make its way, not perhaps as a staple article of food—its tubers are too small for that—but as a very acceptable change on the tables of the connoisseur.

Its complete hardiness and easy cultivation will, we should also expect, cause it to be considered a luxury by the poor.—*Gardeners' Chronicle.*

THE EXPORT PROSPECTS OF JAVA CINCHONA BARK:

AMSTERDAM AS A CINCHONA MARKET.

Sir,—Your issue of December 17th contained an article about Java cinchona bark. It was shown therein that Java will probably come forward with considerable quantities of bark after 1889, and it may therefore, perhaps, be of some interest to your readers to judge whether the Dutch market is equal to find an outlet for these quantities or not.

On examining the catalogues of the public sales here since 1882, I find that the imports of bark from private plantations in Java amounted to:—

382 packages of about 150 lb. each in		1882
844	,, ,,	1883
1,746	,, ,,	1884
4,215	,, ,,	1885
5,652	,, ,,	1886
8,000	,, ,,	1887

On January 19th, 1888, 668 packages Government, and 1,434 packages private bark will be sold, whilst the following nine auctions next year will doubtless offer as much, or rather more. The total importation of private bark for 1888 may therefore be estimated at 15,000 packages, that of 1889 at 25,000 packages, to which must be added the Government crop of 5,000 to 6,000 packages a year.

Before the beginning of this year (1887) our market could not be said to have been equal, in every respect, to the requirements of a large importation of bark. The chief importers, the Netherlands Trading Company, acting as the Government's agent, followed their own way, selling their 2,000 to 3,000 packages a year in one or two auctions here, whilst the private parcels were sold, as occasion arose, at auctions too small to attract the attention of many buyers.

The Netherlands Trading Company disposed of excellent warehouses, and the greatest care was taken in bringing the bark under the buyers' eyes; they also introduced the custom (since followed by all private importers) of publishing the analysis of every parcel before the auction, and permitting buyers to take samples themselves. The private importers, on the other hand, were in anything but an enviable position. With no warehouses of their own, they wholly depended upon the goodwill of the "Veemen" (warehouse corporations), who, in many cases, set apart rooms for the storage of bark quite unfit for the proper exhibition and sampling of cinchona bark, and insufficiently lighted—rooms, in fact, which they could not use for any other purposes. This, however, was not surprising, as the cases and bales containing cinchona bark had to be put down opened, arranged side by side with gangways between, and to remain in this state for weeks, thus yielding less profitable warehouse charges than other articles, such as coffee, rice, spices, &c., which, being piled up, completely filled a room, the floor of which would scarcely be covered if stored with cinchona bark. Another inconvenience for buyers was that, every importer employing his own "Veem," the different parcels were stored in different places, often far distant from each other.

Such was the state of things until April 1886. Since then all has been changed for the better, and Amsterdam may now boast of a well-organised market, second to none in the world.

In April 1886 the "Kina-Establishment" opened its warehouses to importers of cinchona bark, under the direction of a warehouseman who had handled the article from the very beginning of its appearance in this market. Their show-rooms, just as those of the Netherlands Trading Company, are splendidly lighted through skylights, and spacious enough to allow 8,000 packages and more to stand open, side by side, with passages for the samplers, during some weeks before every auction.

The "Kina-Establishment" not being established with a view to make money out of it, but merely for the benefit of the market, the tariff for storing, &c., could be fixed at very low rates, whilst, on the other hand, everything is done with the utmost care to promote the importers', and consequently planters' interest, and to make buyers feel comfortable.

The "Kina-Establishment" and our cinchona market are greatly indebted for their quick and perfect success and development to the director of the bonded docks, who put at its disposal the finest warehouses in the docks; and to the Netherlands Trading Company, who energetically supported a proposal addressed to the Government and readily accepted by them, to sell their barks in eight (next year in ten) periodical auctions, thus offering to private importers a centre for the sale of their bark, and securing to the auctions a greater interest by the inclusion of the splendid old "druggists' bark," which none but the old Government plantations can offer.—I am, sir, yours truly, GUSTAV BRIEGLEB.

Amsterdam, Dec. 28th.

—*Chemist and Druggist*, Dec. 31st.

FRUIT DIRECT FROM THE FLORIDA GROVES.

A new undertaking in the fruit line, says an American contemporary, is the shipment of Florida oranges to Europe. The first lots were sent over on fast steamers last week, and others are being sent on every sailing day. During the months of November and December, the markets throughout England and Scotland have no supply of oranges except immature and consequently very sour fruit from Spain and Italy. Florida oranges ripen early, and will have practically no competition in foreign markets for two months. The transportation costs about fifty cents a box, which is less than the advance of English prices over our own. Orange tree planting has been carried to such an extreme in Florida that nearly all of the suitable land has been utilized, and groves have been planted even where the soil is not of a proper nature for this fruit. —*P. M. Budget.*

THE CULTIVATION of cinchona as a private enterprise is rapidly extending in the Darjeeling district. There are now four private plantations there possessing between them 2,098,580 plants, or nearly half as many as the Government plantation. The gross yield of the former in 1886-87 was 30,000 lb. of bark against only 1,760 lb. in the preceding year.—*Indian Engineer.*

THE CHO-CHO creeper introduced by Mr. Nock of the Hakgala gardens about four or five years ago at about the same time as the tree tomato has become so common now that they sell for about 12c. per dozen in the Kandy market. The original creeper at the Hakgala gardens is said to have cleared over R300 by the sale of its fruits. It was doubted whether the creeper would fruit in Colombo, but I am glad to say it does. I have just seen two fruits on a somewhat neglected creeper in the railway avenue, Maradana. —*Cor.*

MR. E. E. GREEN'S REPORT ON COFFEE BUG.—Our "coffee" planters will be pleased to learn that at our instance the Government have sanctioned the issue of some twelve copies of Mr. Green's able Report with coloured plates, to be sent to various scientific authorities in England and elsewhere who are likely to be interested and, in return, to give an opinion on the same, which may be of some use.

THE USES OF PLASTER are, we believe, very little understood in this country; at any rate we do not remember seeing it ever tried as a manure or as a disinfectant. The following note from an esteemed exchange ought to convince all sceptics as to the value of common plaster:—"There seems to be an opinion prevalent with many that as plaster or sulphate of lime does not enter largely into the composition of plants, it can be but little use as a fertilizer. They do not consider that there are subtances which, while they do not contribute directly to the growth of plants, have chemical or mechanical properties that play a very important part in vegetation. Plaster has both of these properties. As a disinfectant and deodorizer it is one of the best, as well as cheapest substances at our command. Any one who has kept stock of any kind stabled during the warm summer months, knows what a hard task it is to keep their apartments clean and odourless. Now, if they will keep a barrel of fresh-ground plaster in a convenient corner, and every day, on sweeping the floor clean, sprinkle it freely with the plaster, it will absorb all disagreeable, noxious odours, rendering the air sweet and pure, while the value of the manure will be greatly enhanced by the retention of the ammonia. Poultry-house should also be swept clean at least twice a week in summer, and once a week in winter, and the doors sprinkled with plaster; it will add greatly to the value of the manure, and the satisfaction of having clean, sweet, odourless coops and healthy flocks, will abundantly pay expenses. Try it and be convinced."—*Indian Agriculturist.*

FORMATION OF STARCH BY PLANTS.—Experiments have recently been conducted at the school of Agriculture, Canterbury, New Zealand, by Professors W. E. Ivey and G. Gray, with a view to determine the formation of starch by plants. It has long been known that starch is formed either in chlorophyll granules or in starch-forming corpuscles, which ultimately become converted into chlorophyll granules, but up to the present, little has been done towards ascertaining the rate of formation and dispersion. Accordingly a series of experiments were made to determine the rate at which starch is formed in the leaves of Peas, Beans, and Wheat, and up to date the following results have been obtained:—Starch is least plentiful in leaves collected in early morning, more plentiful in those collected late in the afternoon, but before evening. The degree of sunshine has a direct effect on the rate of starch—formation; in continuous cloudy weather starch is formed by plants but very slowly. This result was brought out in a striking manner. During some very cloudy weather, plant leaves collected before 9 o'clock a.m. exhibited but small quantities of starch, except on two occasions, when they had been under the action of direct sunshine; in those instances starch was proved to exist in large quantities. Determinations have not yet been made in leaves collected during absolute darkness.—*Gardeners' Chronicle.*

A VERY IMPORTANT PRINCIPLE IN CULTURE BY IRRIGATION is thus stated in the "Science Gossip" of the Melbourne *Leader*:—In some experimental researches on drainage carried on at Meudon by M. Berthelot it was ascertained that the drainage of rainwater carries off a much larger quantity of nitrogen than that supplied to the soil by the atmosphere. The obvious conclusion to be arrived at in respect to a locality wherein the rainfall is less than the evaporation is that the whole of the water which flows from the soil should be returned to it, so that no nitrogen may be lost. In a climate where the rainfall is in excess some of the water must, of course, be allowed to flow away. The *beau idéal* of irrigation should, therefore, be to provide every field with a reservoir sufficient to store its own rainfall, and to return the water to the upper end of the field by pumping. This is what it will come to, although it may not at present be considered practicable.

THE BANANA TRADE, TRINIDAD.—Mr. Hart, Superintendent of the Royal Botanic Gardens, Trinidad, has published a pamphlet advocating the culture of Bananas in that island for the New York market. Mr. Hart shows that the scheme is quite feasible, and that the variety to be grown is that known as Gros Michel. Jamaica in 1885 exported Bananas to the amount of £130,000, an amount still increasing; and there is no reason, according to Mr. Hart, why Trinidad should not share in the spoil. Mr. Hart looks to the United States to take as many Bananas as can be grown, and reads his fellow-countrymen a lesson in the following terms:—"Throughout the American continent we find a readiness to adopt to certain uses whatever comes to hand, which we do not find in older countries with more lengthy traditions. The Englishman, whether he calls himself Conservative, Liberal, Radical, or even Home-Ruler, is, and cannot help being, when at home, in most of his actions nothing else but a Conservative, and hence his general unwillingness to adopt new ideas and take up food-sources as quickly as the American. For these reasons it is doubtful, even if the difficulty of transit were overcome, whether the trade would prosper to the same extent and with the same rapidity as it has done in America." While in the main we agree with Mr. Hart, nevertheless we believe, that, if the Trinidad planters could supply our markets with some of the finest flavoured varieties in place of the mawkish things we get now, there would spring up a demand even in conservative Britain. Many people also are unaware how greatly even ordinary Bananas are improved by stewing with syrup.—*Gardeners' Chronicle.*

Correspondence.

COFFEE AND THE AFRICAN LAKES COMPANY, LIMITED.

Mandala, East Africa, *via* Quilimane, 16th Nov. 1887.

DEAR SIR,—Some little time ago Messrs. Buchanan Brothers, planters, Zemba, pointed out to me the paragraph on page 658 of your *Agriculturist* of April last.

The Messrs. Buchanan have a larger plantation than our Company, and the greater part of the coffee referred to was their produce, but shipped by our Company. The first plant was brought from the Edinburgh Botanical Gardens in 1878 by the Blantyre Mission, and from them we bought our first plants.

We have as yet no leaf disease, but have suffered from borers, both grubs and matured beetles, especially at Zemba. I attribute our comparative immunity here to a flock of turkeys, which I brought up, for the express purpose of keeping down insect life among the coffee. Our plants are at present in magnificent bloom, and promise a very heavy crop. Irrigation seems necessary, at least for young plants; labour is cheap, but difficult to obtain regularly; carriage to the coast, though of course a consideration, is becoming cheaper and better for produce. Still I fear you are right, and it will be long ere we seriously affect the world's markets.

We read your valuable journal with much interest.—I am, yours very truly,

JOHN W. MOIR, *p.* Manager African Lakes Company (Limited), of Glasgow.

PLANTATION AND NATIVE COFFEE: WHICH IS THE MORE PROFITABLE TO CULTIVATE.

28th Dec. 1887.

SIR,—There is a question I should like to submit to your experience regarding the economical production of coffee, and that is whether it is on the whole more profitable to grow native or plantation coffee.

The question should, I think, be considered under the following heads:—

a. The cost of growing and cultivating the two kinds.

b. The cost of picking and preparing the crop for the market.

c. The difference in prices between the two kinds and the scope of the markets to take them up.

d. The cost of upkeeping the two kinds of estate, with consideration of their lasting and productiveness.

e. As to whether disease affects each to an equal extent.

The collapse of the coffee industry in Ceylon and South India during the last decade was in my opinion due to the great charges of opening and upkeep which had become stereotyped into a fashion, so that when crops failed and prices fell, the shock was sustained entirely out of the profits of the estate and to an only small degree out of the charges. The standard works on coffee present a regular budget of charges, felling, lining, pitting, filling in, walking up a row, walking down a row, picking a leaf, pruning—all manners of devices for spending money, which I am quite certain are never thought of by the native cultivator. Look again at the enormous expenses of the pulping machines, storehouses, barbacues, cement, tar, piping and so forth, while Mr. Ramaswamy Chetty hires half-a-dozen women and pulps his coffee in the family rice-mill. Small properties, again, though suited to the native, are in my opinion entirely hostile to large profits, for the expenses of management are so enormous. The owner entertains a superintendent, pay R300 a month with a fine bungalow, a pony, carriage, and a piano for his wife, nice drive up to his house, rose bushes and claret, if not orchids and champagne. I wonder if any emigrant in Manitoba raising horses, or in South America raising cattle, or in New Zealand growing wool, indulges in a superintendent and such luxuries! I believe that a large property say of 1,000 acres plantation coffee ought to be opened and brought into cultivation for one lakh of rupees including 10 per cent for interest, and that if operations and accounts date, say from October 1888, a crop of 2½ cwt. an acre ought to be gathered in December, January '91-'92, and that at present prices, £90 for plantation coffee per ton, this should yield £11,250, or R1½ lakh. Native coffee would cost less and fetch less. The question I submit for an answer and for which I should be excessively obliged is whether these views are right, and which sort of planting it is best to go in for, native or plantation.—Your obedient servant, S.

P.S.—I have omitted charges for land, for that is an undeterminable factor. At what distances apart should native coffee be planted?

[See our answer and discussion on this subject, page 553.—ED.]

To the Editor of the "Ceylon Observer."

CINCHONA.

London, 22nd Dec. 1887.

DEAR SIR,—The interest I take in cinchona must be my excuse for again troubling you on this subject.

The enclosed two letters which I have cut out of the *Financial News* you may consider of sufficient importance to publish. I can bear out Mr. Hicks's statement of "bear talk" regarding quinine, as a broker offered me a few days ago 30,000 ounces German make, to be delivered 10,000 oz. a month for January, February and March at 1/10; I at once accepted the offer, when he raised the plea he must consult his clients, which, I need hardly say, was the last I heard of the matter.

The cinchona auction held on 20th went off flatly, as 8,700 packages were catalogued; out of this 4,577 was Ceylon; this was the largest quantity of Ceylon ever offered with one exception. The result of forcing the market in this way, especially at this time of the year, was to bring the unit down again all round to 2½d.

This large quantity represented about one-twelfth of the entire London Stock, and was far too much for the trade to swallow; as only 2,000 bales Ceylon, 230 South American, 210 Indian, 200 Java found buyers.

I remarked to two of the largest buyers and manufacturers of quinine, at the auction: "I hope you will never have to grow cinchona for a living, to sell at the prices you are buying at." The reply was very true: "How can you expect better prices when you force the stuff on us in this way? Keep it back and we will be able to give you better prices." I therefore repeat to exporters, keep your supplies back; those that hold the longest will reap the greatest benefit. Yours truly, E. F. DELMEGE.

THE QUININE MARKET.

(*Pharmaceutical Journal*)

Active movements are understood to be on foot among both the domestic and foreign manufacturers of quinine to form an association or combination for the purpose of removing the present severe competition and relieving the market from the overproduction which at present prevails, and which has forced prices down to a very low point. Lower prices and

serious loss to the manufactures are promised by the present situation, unless the manufactures adopted some drastic measures. Quinine is lower at present than it has ever been before. The prices now rule at from 40 to 45 cents per oz. for German, and American from 39 to 46 cents per oz. A good idea of the course of the market may be obtained from the prices per oz. for the last five years which follow :—

American per Ounce. December 1st.		German per Ounce. December 1st.	
1883 ..	$1·75 to $1·80	1883 ..	$1·60 to $1·80
1884 ..	0·83 to 0·90	1884 ..	0·75 to 0·85
1885 ..	0 88 to 0·95	1885 ..	0·82 to 0·92
1886 ..	0 54 to 0·65	1886 ..	0·52 to 0·54
1887 ..	0·39 to 0·46	1887 ..	0·40 to 0·45

The decline which is shown by these figures has been due to two causes. The first is the largely increased yield of bark, owing to the great development of the Ceylon and Java plantations, which no doubt produce much more bark than the cinchona trees of South America. Not only has the increase come from the extension of the plantations, but also owing to the fact that the trees when stripped of their bark now are swathed in moss and enabled to grow new bark, which can be stripped from the trees. Thus the productive power of the trees has been quadrupled.

The second reason for this great decline in prices has been the strong competition among manufacturers both foreign and domestic.

It is believed by some members of the trade that the foreign manufacturers were the first to bring forth the idea of a combination, and that they have been carefully developing the plan, and that the American manufacturers are favourably disposed towards it. Unless this combination is formed, it is probable that the pressure of the great stocks on the market will force prices down further. It is claimed that quinine can be profitably produced as low as twenty-five cents per ounce, but satisfactory figures showing this result have not yet been shown.

Thus, while bark has been bought lately at Amsterdam at 1s 0½d per unit, equal to about 18c. per oz., and while the cost of manufacturing in Germany has been decreased lately, say from 14 to about 10 c. per oz., making the total cost to manufacture 28¾ c. per oz., yet such a price for bark would not pay the planter. In fact, nothing less than 2d per oz. would afford any margin to the planter and that price represents about the average price which manufacturers are paying. This would make the cost of the bark 25 c. per oz., and the cost to produce 35 c.

There is estimated to be a surplus stock of about 700,000 oz. of quiuine on the American market, and a surplus of 1,000,000 oz. abroad. This would naturally depress prices further. Yet, on the contrary, the market is showing a firmer tone, and has advanced sharply during the present week, the stronger feeling being upon the belief that the combination is being successfully formed. If it is, even higher prices may be expected in the near future.

QUININE.

TO THE EDITOR OF THE "FINANCIAL NEWS."

Sir,—In your issue of today you print an extract from the *Boston Commercial Bulletin* on the quinine market in which it is sought to show that at the recent low prices of bark, quinine could be profitably manufactured in America at 25 cents or 1s ½d per oz. As this idea is most misleading, I hope you will allow me to put before your readers the facts of the case.

The lowest quoted price for bark in London or Amsterdam was 1½d the unit., meaning that a pound of bark containing 1 per cent of quinine could be bought for 1½d, so that 100 lb of such bark could be bought for 150 pence. Such 100 lb of bark would contain 1 lb of quinine, so that 16 oz. of quinine would cost 150d or 9½d per oz. in the bark. Before buying, commissions, freight and manufacturing expenses had been incurred, to say nothing of a manufacturer's profit. According to the *Boston Commercial*, the cost of manufacturing in Germany "has been decreased lately, say from 14 to about 10 cents per oz." If you add these 10 cents, or 5d., to the cost of the quinine in the bark you get the lowest price at which sales were attempted, and as a matter of fact some manufacturers have been obliged to close their factories, and some to buy quinine themselves to sell to their customers, because they thus avoided the manufacturer's loss, and got a dealer's profit.

With regard to the bark portion of the extract, the following are facts :—

At 1½d. per unit the calculation for growers was not whether it paid to grow bark, but whether, after counting all money spent in planting and cultivating as so much lost capital, it were possible to get enough money for the bark to pay the mere labour for cutting, the drying, freight and selling expenses, and judged by this low standard it was found not to be worth while taking the bark, and cutting was stopped, and estimates came home of 9,000,000 for the year ; or even less, as against 14,000,000 and 15,000,000 in the two previous years.

The large speculators who have so cleverly and farsightedly taken up quinine with an evident knowledge of the inner workings of the trade so complete and accurate that few in the trade are as well informed probably know all this and that, at least for some months to come, they need not fear large supplies of bark.

Further facts with regard to the quinine market : At the recent large Amsterdam bark sale, on the 8th instant, a certain large German quinine manufacturing concern was the largest buyer.

Ever since that sale the London representative of that firm has been the most persistent bear talker of quinine. Other manufacturers have followed on the same lines, and we have had the strange spectacle of manufacturers discouraging buyers of quinine.

As soon as a buyer of large quantities of quinine at 2s. appeared the said bear talker tackled him, and talked the article down, and even invited offers for large quantities at 1s 11d. Within the last day or two buyers screwed up their courage to offering 1s 11d for large quantities, and were met with refusals to sell on the plea, amongst others, that they were speculators, and that manufacturers would only sell to consumers.

Next Tuesday, 20th inst., some 8,000 packages bark will be offered for sale, and when they shall have been sold it is difficult to imagine (according to latest Ceylon telegraphic advices of small bark shipments) where further large supplies of bark will be found—that is to say, quantities of bark anything like in proportion to recent large sales of quinine.

With the foregoing facts in their possession, I will leave your readers to form their own opinion as to why German quinine is not 2s 6d now, and to draw their own conclusion as to its probable price after Tuesday's auction.—I am, sir, yours, &c., RIVERS HICKS.

5, Savage-gardens, Trinity-square, London,
December 17th, 1887.

THE COCA PLANT IN SOUTH AMERICA AND ITS CULTIVATION IN CEYLON.

January 16th, 1888.

DEAR SIR,—Having visited the coca districts on the tablelands of Peru and Bolivia, I take leave to endorse what is said by your correspondent in this month's number of your *Tropical Agriculturit* especially as regards the profit yielded. In Bolivian coca growing yielding nearly 50 per cent profit, and the plant raised in Bolivia being far superior to the Peruvian one. The coca industry is now more confined to the Southern republic, so much so that an Austrian naturalist lately remarked about South America : "The Chili saltpetre comes from Peru and is not saltpetre, but nitrate of soda, and the *Peruvian* 'Erythroxylon Koka' comes from *Bolivia*." To export this valuable tonic, it should be in the form of an essence, as coca loses its aroma in transit. The South American Indians that I have had to supply the dried leaves to in railway camps in Peru near the coast, could hardly be made to

draw their supplies from our commissariat on the coast, because they found the article devoid of aroma as compared with the new coca they got on the plateaux. Still the bicycle-clubs in England and France believe they strengthen the physique of their members by a decoction of old coca leaves. The Swedish army tried this plant for strengthening the troops on experimental marches, especially with a view to save water, but the benefit derived would have been much greater had I sent the Government the *essence* from La Paz instead of a serroon of leaves that I bought at Arica before I had much experience of this plant and its Indian devotees.—Yours &c.,

E. S. THOMASSEN, C.E., F.R.G.S., M.S.A.

CINCHONA BARK CARRIED BY THE CEYLON RAILWAY FOR A NUMBER OF YEARS:

A GREAT FALLING-OFF EXPECTED BY MR. JAMES SINCLAIR.

Bearwell, 20th Jan. 1888.

DEAR SIR,—By the courtesy of the General Manager of the Ceylon Government Railway, I have been furnished with a complete statement of the loadings of cinchona bark at every station on the line from 1883 down to December 31st, 1887, and as it is desirable that those who still have plantations should know all that it is possible with reference to the available quantity for harvesting during the next few years, I venture to send you the statement referred to for publication. The bark carried by the railway during last year, notwithstanding an increase of 162 tons from Nanuoya, shews a decrease of about 1,000 tons as against the previous year, indicating that the beginning of the end of cinchona is not far off in the districts served by all stations below Nanuoya.

On examination it will be seen that the great falling-off is at the stations below Hatton. Those acquainted with the districts referred to, and who can recall the immense areas under cinchona some few years ago, which are now almost denuded, will have no necessity to refer to the figures supplied by the railway for a verification of the prediction that we are on the eve of a very considerable falling-off in shipments. But let those who know little of such districts as Maskeliya, Ambagamuwa, Dolosbage, Pusselawa, and those round about to the east of Kandy, glance at the figures of the loadings for four years past at the stations serving them, and it becomes at once apparent that if these loadings cease, and Dimbula-Dikoya and Uva cannot maintain and increase their yield very materially, there will occur presently a collapse in shipments, coming upon us in the same unexpected manner as the heavy yields of recent years.

Hitherto it has been impossible to frame any reliable estimate of out-put; but with the foregoing facts before us, and the help of Mr. Pearce's figures, there is material for a fairly accurate forecast, provided no violent fluctuations in the price of the article takes place.

The railway carried 5,852 tons in 1886 against 1,875 tons last year, a falling-off of 1,000 tons, chiefly from the deficiency at stations below Hatton. This, in connection with the published weekly rail traffic, has enabled me to make an estimate for the current year, which will, I think, be found near the mark.

You will see by the statement sent you, that I put the total to be carried by rail at 2,820 tons. Owing to the commercial year ending 30th September and that of the railway on the 31st December, it may not be strictly accurate to take all the bark as coming from Uva, which is not accounted for by the railway; but assuming it to be near enough for the purpose, the total shipments for 1886 were 15,364,912 lb., as against carried by rail 13,108,480 lb., leaving to the credit of Uva 2,256,432 lb.

During 1887 total shipments 14,389,184 lb., as against carried by rail 10,920,000 lb., leaving for Uva 3,469,184 lb.

On arriving at the estimate for the current year, I credit Uva—that is Madulsima, Badulla, Haputale—with the same as last year, namely 3,500,000 lb., and to the railway as per my estimate 6,334,720 lb., or a total of 9,834,720 lb.

I think I ought to draw your attention to the fact that the falling-off at Talawakele for 1887 would have been much more pronounced, but that a lot of bark from Dimbula and Dikoya must have found its way by road to Nawalapitiya during the slip, and that the increase of 160 tons at Nanuoya is due more to the Udapussellawa bark finding its way by road to Nawalapitiya and Gampola during that time than any increase from that district, still further emphasizing the fact that the districts below Hatton are now all but exhausted.

I have no doubt, with your faculty for drawing correct conclusions from statistics, you will be able to give the public some interesting information regarding the position of this product of Ceylon at the moment.—Yours truly,

JAMES SINCLAIR.

HEROIC DOSES OF QUININE.

Colombo, 18th Jan. 1888.

DEAR SIR,—In connection with your article *re* large doses of quinine, it may interest you to learn that a fellow-passenger on board the N. L. Lloyd's S. S. "Braunschweig" who complained of headache and lassitude was recommended to try a small dose of quinine, but as he had never taken any, he consulted the doctor, who gave him two grammes or about 31 (thirty one) grains, one dose. When informed by Mr. —— that the doctor had given him as much as would cover two two-shilling pieces, I replied that it could not have been quinine of the same quality as Howard's or even German quinine,

if quinine at all; that such a dose would probably make him as deaf as a post or "lift the crown of his head" if it did not actually kill him. But the result actually was that this large dose had not the slightest bad effect, and I heard nothing more of the feverish headache which had previously troubled him. The doctor kindly showed me in one of his German medical works that from two to three grammes was now the recognized dose of quinine, that is in Germany, I suppose,—Yours truly.

JAMES WESTLAND.

ESSENTIAL OIL IN TEA.

Colombo, 21st Jan. 1888.

DEAR SIR,—As I see you are interested in the subject of the essential oil in tea, you are free to make use of the following remarks by Dr. Hassall, the well-known food analyst:—"The volatile oil is not present in fresh tea; but is developed in the course of drying and roasting. It is of a lemon colour, readily solidifies, and becomes resinous on exposure to the air. It is to it that the aroma is mainly due. The amount present in tea is stated to be about 1 per cent, a statement we consider to be open to much doubt. For the estimation of the volatile oil, a considerable quantity of tea must be operated upon. This must be distilled with water, and the distillate received into a cool receiver. The oil should be found floating upon the water. We may state, however, that, in certain attempts we have made, we have failed to obtain any weighable amount of the oil. The distillate had the odour of tea, but no oil drops were visible."

I might add, that, according to Mulder's frequently quoted analysis, green tea contains ·79 per cent, and black tea ·60 per cent of essential oil.—Yours very ruly,

M. COCHRAN.

COFFEE IN THE HULL.—Our blessed "Centro de Lavoura e Commercio" on the 18th ultimo writes a powerful despatch to the minister of agriculture anent the export of coffee in the hull. It will ruin those interested in coffee cleaning; it will serve as a substitute, these coffee hulls, for the bean and altogether the export of coffee in the hull had better to shut down on.—*Rio News.*

COFFEE IN SOUTHERN INDIA.—Mr. Jas. Macfarlane of Maskeliya left today for Tuticorin on a trip through Southern India as far as the Nilgiris and Mysore, his main object being to see the fine coffee plantations at Coonoor and Coorg, which are still yielding their 8 to 10 cwt. per acre. In one case of a Coonoor property, the absent proprietor gets some £5,000 profit annually, through crops at the rate we mention, neither leaf disease nor bug affecting his trees; and he attributes all to cultivation—that is to a plentiful supply to the soil of "old bones"! We trust Mr. Macfarlane will have a pleasant and interesting trip.

COFFEE REVIVING.—It is cheering to hear pleasant accounts of poor old coffee coming to the front again in several directions. Those who still hold some acreage in the cisalpine districts are getting encouraging pickings and good prices—for instance 2,500 bushels from a Maskeliya property and a sale at 13 rupees all round—must be satisfactory, while the appearance of the bushes is all that could be desired. Old hands think it hard if—with tea, and some of them cinchona, as well,—the three strings should fail them, even although there may be a chance of tea coming down to 8d. a lb. until the people of the American States and European Continent wake up to the advantage of drinking good tea and plenty of it.

THE ACTION OF SULPHUROUS VAPOURS ON PLANTS.

The following conclusions were arrived at as the result of the elaborate series of experiments performed by the late Professor E. Morren, and published in the *Belgique Horticole* after the death of the author:—

Leaves are more sensitive to the action of sulphurous acid than flowers. A proportion of sulphurous acid gas, sufficient to affect the leaves, has no appreciable effect on the flowers. A proportion of 1-80,000 to 1-90,000 part of sulphurous acid gas is sufficient to cause great pathological alterations on the leaves of fruit trees; 1-80,000 of sulphurous acid in the air will effect the Apple; but one part of gas in 10,000 of air produces no result. The changes produced by sulphurous acid gas on leaves seems to spread after the gas has directly ceased to act. The prejudicial effect of sulphurous acid gas on the leaves is shown by the appearance of yellowish-brown and irregular specks. These are particularly noticeable at the tips and edges of the leaves, and extend over the cellular part of the leaf. The nerves are least affected, and usually remain green. Adult leaves are usually more sensitive to the action of sulphurous acid than are young leaves that have not attained their complete development. The alteration begins by the formation of dull greenish-white spots, situated between the nerves and on the edge of leaves; these pots, which spread a little, turn green, then rusty-brown. At length the dead tissues are destroyed, and the leaves are perforated and torn. The action of sulphurous acid gas (a proportion of 1-80,000) is evident in a very short time, usually in three to five hours.

Sulphurous acid gas dissolved in water, and placed on either of the surfaces of the leaf, is almost without effect on the upper; while on the lower surface, each little drop causes the formation of a spot of greenish-brown discoloration visible on both surfaces. It is proved from experiments concerning the comparative effect of sulphuric acid and sulphurous acid dissolved in water, that this gas by its contact with the vapour of water and the oxygen of the air is not changed, at least not rapidly into sulphuric acid. Each of these two acids has a distinctly different effect. The action of sulphurous acid, as a solution or in a gaseous state, is as potent by night as by day. All the sources of sulphurous acid—and these are numerous—affect the vegetation in the neighbourhood. Near certain industrial establishments which use sulphur, or which consume pyretic fuel, the vapours spread death around them. The action is unvarying: wherever a furnace is used and a chimney is raised, this result is noticeable. We speak of Belgium, where coal of more or less pyretic character is usually burnt. The smallest chimney isolated in the country, influences the foliage near it, and with a little experience we can easily pick the leaves showing the effects of sulphurous acid.—*La Belgique Horticole*, p. 324.

COCONUT BEETLES.

The Acting Principal Civil Medical Officer of the Straits Settlements has just sent in to Government a Report on the beetles which have wrought such fearful havoc among coconut trees here. The Report is well worth the attention of coconut growers who will find in it information and suggestions, both valuable and practical. Investigations brought to bear upon the subject have resulted in demonstrating the fact, that these destructive insects belong to two species known respectively by the name of *Oryctes nasicornis* and *Calandra Palmarum*. The former turns out to be the so called elephant or rhinoceros beetle; large in size, black or dark brown in colour, with a long curved horn on its head. Beetles of this kind do most mischief to cocoanut trees when full grown, by feeding upon the soft woody fibre in the crown of the trees. Beginning operations under the sheath of one of the leaves, the beetle in question bores a hole into the head of the tree. Within four or five days, it generally succeeds in reaching the centre

of the heart. When once there, it goes no further but sets to work eating its fill until the time comes for departure. The trees may stand several attacks of this kind, but in the end fall off, and die slowly. Evidence of beetles having been at work soon becomes manifest by the disfigurement of the heads of the stricken trees, in consequence of the insects eating through the young folded leaves in their progress to the centre of the tree. The centre shoot of the tree falls off when once cut through. Leaves that have suffered in the same way grow short of the full length and present a deformed appearance. When fruit stalks happen to be cut through, the tree becomes impaired in its bearing powers. These beetles are said to begin boring operations at night. In boring their way into the tree, they cast out behind them a moist brown fibre, which betrays their presence by accumulating in a lump at the entrance of the hole in which they are burrowing. These signs, easily visible in short or young trees, are not readily detected in tall ones. Should the beetles be carefully destroyed at once on the discovery of these tell-tale lumps, the trees will be but little the worse for the mishap. When the signs have been unnoticed, the mischief wrought by the insects only becomes evident by the centre shoot of the affected tree dropping off. This particular kind of beetle displays most activity in October and November, and even somewhat earlier in the year. Its eggs are laid and hatched chiefly in decaying stumps of coconut trees. The precise hatching time seems to be somewhat uncertain.

The *Calandra palmarum* is a different sort of beetle altogether, and belongs to the weevil species. It is further distinguished by being of a black colour, with an orange-hued spot on its back. Sometimes its colour is wholly dark orange. It does not bore into the trees, but lays its eggs on them. On the eggs hatching, the grubs, by boring, make their way into the tree, and subsist there. Growing in size, they bore away in the wood through and through. Should they happen to run tunnels through a vital part of the tree, the death of the latter follows. On reaching full size, the grub stops boring somewhere near the outer surface at the head of the tree. When the transformation is complete, the grub now become a beetle, readily makes its way out into the world. The grubs can only be detected in trees by hearing them at their boring operations. The death of the trees without any assignable cause may safely be put to their account. Information as to the ways and habits of both kinds of beetles are still deficient, as regards the seasons of activity and breeding of the one, and the egg-laying peculiarities of the other. Dr. Simon considers that for the prevention of the destruction of coconut trees by these insects, care should in the first place be taken to destroy all the beetles as soon as they are found. Were the Government to offer a reward for their destruction, it would stimulate search for these pests. Dead coconut trees or stumps should be cleared away at once on or near estates where these palms are cultivated, and trees damaged by beetles beyond recovery should be felled and burned. Dr. Simon goes further and deems that it should be made penal to allow rotten coconut trees or dead stumps to remain near living trees. The only way to ensure the detection and destruction of the Oryctes beetle lies in the daily inspection of the trees. Prohibition against allowing in the neighbourhood of coconut plantations, of any materials favouring the propagation of the Oryctes, will doubtless prove of avail in remedying the evil, as well as the immediate destruction of trees infested by the Calandra so as to [illegible] grubs. It is to be hoped that coconut cultivators in the Colony will profit by Dr. Simon's suggestive Report.—*Straits Times.*

NOTES ON GAMBIER.

The shrub *[illegible]* was first described by Rumphius, but attention to its practical application originated with Dr. Campbell, one of the earliest medical officers stationed at Bencoolen. This gentleman made a study of the useful plants of his district, and was very anxious that a trial of the tanning powers of gambier should be made. After mentioning that gambier was chewed by the Malays with *pinang* and *siren*, Dr. Campbell thus describes the method of preparing it for consumption. "The young shoots and leaves are shred and bruised in water for some hours until a feculum is deposited, this is inspissated in the sun to the consistence of a paste, is thrown into moulds of a circular form, and, it is in this state that the gambier is brought to market." Substitute boiling in an iron pan for inspissation in the sun, and there is not any really great difference between the primitive principle described by Dr. Campbell and that of today, by means of which, gambier has turned out thousands tons for shipment to Europe and America.

Before going into the question of manufacture, however, a few lines should be devoted to the growth and cultivation of gambier. The main points in gambier planting which are so attractive to Chinamen, are the great rapidity with which they get a crop out of the ground, and the small original outlay which is required. The history of the majority of these plantations will show that pepper has been planted out of gambier profits; of course pepper is a great hit when all goes well, but it wants a considerable capital to start with, and it takes some years before it gets into anything like full bearing. It is altogether a plant of slower growth and longer life than gambier as it is now cropped. The leaf of the young gambier plant is thick and fleshy, and yields a large quantity of extract, but as the shrub ages, the leaves become thinner and more fibrous in texture and lose their characteristic fleshiness. In a little over ten years, a plantation is almost valueless, and, as a general rule, is abandoned within fifteen years. This result is certainly due to the savage treatment to which the shrub is subjected; the Chinaman commences cropping his gambier about eighteen months after he has put it into the ground, after which he will go on cropping it two, three, or even four times a year, being guided more by financial considerations or market rates than by the fitness of his plantation for the cropping. The shrubs are cut down with no sparing hand: leaves, shoots, and twigs are all lopped off by the Chinaman's knife, and the plant is well nigh reduced to the condition of a mopstick and left with barely sufficient leafage to enable it to carry on its existence: no attempt is made to manure the plantation. The soil, deprived of its natural shade, is left either to be burned into the consistency of a brick, or else the whole place is overrun with *lalang*. The only wonder is, that a gambier plantation is not used up sooner. It is quite an error to suppose that the plant exhausts the soil like indigo: with similar treatment gambier would last as long as pepper. The spent leaves from the gambier pans are said to be very good for pepper, these leaves are quite exhausted by the time they leave the *[illegible]*, and cannot possibly stimulate or nourish the vines, but they form a useful shade for the roots, and they are very serviceable in keeping off both white and red ants, the bitter principle of the spent leaves repels these destructive insects which are otherwise attracted to the vines when they blossom.

The manufacture of gambier is as barbarous as its cultivation. The green leaves and shoots are roughly chopped with a *Parang* and thrown into a *qualli* which is then filled up with water, the furnace below the iron pan is of the roughest possible [illegible] and [illegible] an immense quantity of [illegible]. [illegible] *qualli* is then ladled into small and shallow wooden

tubs, the leaves in the trough are once more swept into the pan and reboiled, after which they are taken out and thrown outside to be afterwards carried off to the pepper garden. The liquor left in the *qualli* from the second boiling is too weak to be converted into gambier, but is an excellent extract in which to boil up the next lot of green leaves.

As soon as the extract in the small wooden tubs already spoken of is sufficiently cool to allow of the hand being placed in it, a very curious process of agitation is adopted by the Chinese which it is difficult to clearly describe. The coolie squats before the tub, and plunges his half closed hand into its semi-fluid contents, and in the hollow thus formed by his hand he incessantly works up and down a piece of light wood shaped like an elongated dicebox, the immediate effect of this treatment is to cause the gambier extract to thicken, in fact it sets up a process of crystallisation, the extract assumes a concrete form and becomes *gambier*. When it is quite cool it is turned out from the tub as from a mould and cubed with a knife, which, as a rule, is made out of the iron hooping of a Manchester bale. The cubes are then put on coarse bamboo trays with wide meshes, the trays are placed in rudely constructed racks over the *dapur* and should be left there for four or five days to get smoke-dried. The cubes at the end of this time will have thrown off an immense percentage of water, and have become greatly reduced in size. It is then packed in mats and sent off to one of the gambier houses fronting Boat Quay, one and all of which possess a capacious well of moderately dirty water.

It is easy to distinguish good gambier. If sound ripe leaves are boiled for a sufficient number of hours, and if the cubes are made not too large and are properly smoke-dried, then the gambier will be delivered into the godown in a hard compact mass weighing as near fifty catties as possible. There is some difficulty in stripping off the mat, the cubes are distinct and are of a good brownish black colour externally, and when broken will exhibit a deep mahogany red with an occasional streak of dark yellow; there is a total absence of steaminess about such gambier, and when it has been put through the press, the pools of water near the bed plate and pump will not be covered next morning with a milky white surface.

In the ordinary run of gambier which merchants are now content to receive, there are no traces of cubing, and when cubes are to be discerned, they are of an extraordinary size, the colour is of an unclean white to a dirty pale yellow, and the mass frequently steams. There is a farce gone through at the press of "rejecting" bad stuff which is worse than useless, because it costs money, the "rejections" are all worked over again with mat scrapings and are rushed though the godown with unfailing success. Any one who will take the trouble to walk along Boat Quay, between Elgin Bridge and Coleman Bridge, will see "rejections" being worked over by the ton, not a catty of this beastly stuff is lost by the Chinese. "Rejections," of which our shipments are now so largely composed, are simply nothing much more than masses of putrescent boiled vegetable matter; it frequently shows large patches of a black or dirty blue colour, it cannot hold together but drops to pieces when handled, and often has a sour fetid smell. The fact is that the Chinamen, finding that anything will be accepted, boil down leaves which may be either too old or too young mixed up with useless shoots and twigs, the *bangsal* proprietors save as much fire-wood as they possibly can, it being one of their principal items of expenditure, the extract is not sufficiently boiled and the crude stuff will not crystallise properly. It is doubtful whether it can stand a few days smoke drying, but it is not put to this test however, for after a very brief course of *asap*, it is bundled up in mats and delivered in all haste to the merchant, who accepts it with results which must be best known to himself.

A few words as to the general chemistry of gambier may be interesting. Roughly speaking, good gambier may be said to contain between 40 p. c. and 50 p. c. of tannic acid, the other chief ingredient of gambier being a soluble gum; its action upon hides is to precipitate all their fatty and fleshy matter, leaving nothing but the imputrescible substance, that is to say, leather. Notwithstanding this precipitation, the hides take up so much gambier as to gain in weight by the process.

There is no space in this rapid sketch for any details about the working of the "Hongkek" or of adulteration of gambier with foreign matter, but the overloading of gambier with water, combined with what can only be called the fraudulent method of its preparation, constitute adulteration of the worst and most destructive type.— *Straits Times.*

THE DYES AND COLOURING MATERIALS OF THE ARGENTINE REPUBLIC.

When Brazil, with its immense forests bordering upon tide-water, was first opened to foreign commerce, the demand for its dyes and dye-stuffs was so great that no inconsiderable part of the revenues of the King of Portugal was derived from the royalties he exacted from the trade.

In the case of the countries of the River Plate, their mineral regions and forests were so remote from the sea-board, and the navigation of the Parana river was then so uncertain and so limited, that but little was known of their resources in dyes and dye-stuffs; and subsequently the facilities with which all these articles of prime importance in the textile arts have been procured from the Brazils and the countries of Central America have been so great, that but little scientific attention has thus far been paid to the classification of such articles in these lines as this country affords. It is only in countries where textile manufactures are most flourishing that the art of dyeing is studied and applied in its full significance, and in the absence of cotton and woollen mills in the Argentine Republic, the materials for producing colours have received but little application. There has been no demand for them either at home or abroad.

MATERIALS USED FOR COLOURING.

Under these conditions, and with such limited opportunities for the use of colouring-matters in the textile arts, it is not strange that the Argentine Republic is almost an unexplored country in the matter of dyes and dye-stuffs. The full extent of its resources and possibilities in these respects can only yet be conjectured; but lately public attention has been somewhat directed to the subject, and Professor Max Siewart, the well known German scientist and chemist, now of the University of Cordoba, has devoted considerable attention to this department of chemistry. M. de Moussy, in his work in French, has also made extensive reference to the subject. Their researches and investigations, and especially some of the experiments of the former, seem to be of so much interest, not only to those who are engaged in textile manufactures, but also to those who are especially occupied with the chemistry of dyes and dye-stuffs, that Mr. Baker, the United States Consul at Buenos Ayres, has translated them, and we summarise his paper.

DYES: *Cochineal.*—This insect grows in the greatest abundance upon the opuntia of this country (the Argentine Republic). If the people of the interior possessed more enterprise, the cochineal could be made to produce a splendid return and a most profitable business. In all parts of the country the tunas or prickly pears are used for hedges or to protect vegetable gardens, but less in view of the production of cochineal than to harvest the fruit which is eaten fresh or under the form of a thick syrup or preserve, made by cooking it in copper vessels. In the province of Tucuman and other places, where the cochineal is gathered, it is crushed in wooden mortars, and afterwards, the paste is formed into little cakes, which, when dried, are sold under the name of "grana" (scarlet).

VEGETABLE SUBSTANCES.

It is difficult to give a clear explanation of the vegetable dye-stuffs which are in use in the different

provinces, for the reason that the natives call the same plants or trees by different names, and in some instances use the same name to designate very different plants. Were the trees or plants sufficiently determined, it would make no difference in regard to the confusion which exists as to their common names; but in the absence of their botanical designations, the former in some cases have to be used.

ENTIRE PLANTS.

Indigo.—This is the *Indigo anilifera*, a papilionaceous plant. There are two species: the one cultivated, which being treated in the same manner as the Chinese plant, produces an identical colouring matter, making a blue deposit by the action of concentrated sulphuric acid; the other, which grows wild, called "añilcillo," or "añildo," from which a blue matter is also prepared, but somewhat different from the first, because with sulphuric acid it only forms a white insoluble paste. This white mass in water again gives a blue dye without being decomposed.

Saffron.—The first watery decoction of this plant contains a yellow colour; the second a red one; but it is evident, owing to the crude appliances, that the separation of the two colours by this method is very imperfect.

Wild Chamomile.—A number of very different plants are comprehended under this name, though none of them have any similarity to the camomila. The dry plant is boiled in water charged with alum, and by dipping the wool into this boiling liquid, it is dyed a very clear yellow.

Sweet Chilca.—This plant, which is found on the shores of the rivers in nearly all the provinces, is a resinous and very aromatic little bush belonging to the family of the Compositæ. It produces a fragrant and a somewhat sweet-tasting fruit, whence its name. The dry bush, together with its fruit, is generally used to dye yellow, though the juice extracted from the green plant produces the same colour.

Palala.—This name is given to a plant very little known, which produces a fiery orange colour.

Valda, a plant or vegetable, the extract of which without being previously impregnated by any mordant, dyes wool to a very firm yellow. The wool dyed yellow by the valda is changed to green when passed through a solution of "añil." On the other hand, should these yellow threads be dipped into a hot bath of carbonate of soda, or lye from the jume, the yellow tint becomes orange.

Tajo, sometimes called "Santa Maria," is a bush which grows about 10 feet high and produces in the spring a very delicate yellow flower. A decoction of the plant produces a colour corresponding to that of the flower, which is unalterable by alkalies.

Jalo. This is an arbaret, which chiefly grows in the province of Salta, and is used for dyeing yellow.

Figue, a plant, also sometimes called "fije," which belongs to the family of the Cinchonaceæ. It contains a yellow tint, but not much is known as yet of its application.

LEAVES, FLOWERS, AND FRUITS.

Clavelina.—The flowers of this plant are used to produce a scarlet colour.

Malva.—This is the mallows, the dark violet flower of which serves with alum to produce tints from grey to violet blue, and with salts of tin the dark violet tints.

Molle.—This is the "molle à tenir," the young branches of which, with their leaves and fruit, are specially used for tanning purposes, because they contain 19·2 per cent of tannin, but with the use of copperas they also produce a grey tint, much employed in dyeing wool.

Tusca.—The fruit is rich in tannin, and therefore can be used with copperas to dye from grey to black.

Garabato.—The pod of the garabato is short and thick, containing four or five seeds. While the seeds themselves are lacking in tannin, the pods contain almost 22 per cent of this material in a perfectly pure state, which with copperas makes a blue grey to a black dye. Inasmuch as the garabato is a very abundant tree in the northern provinces, and produces [illegible] quantity of pods, it offers a material [illegible] most favourable attraction as an important article of export.

ROOTS.

Alcarello.—The barks of the roots and even a part of the trunks of these trees with a combination of alum, produces a yellow tint, which, with a combination of carbonate of soda, is transformed into dark crimson.

Raiz Punzo.—In English this is called red-root. With alum the watery extract produces a red colour, which, if afterwards treated with carbonate of soda or with ammonia, is transformed into a deep scarlet red.

Raiz del Cerro, also called "Soconto," the root of which contains a highly-esteemed colour, probably the alizarina, which has not been heretofore found, except in the *Rubia tinctorium*. The wool is dyed without any mordant from crimson to dark wine colour, and the tints are fast resisting the action of lye or the rays of the sun.

Raiz de Pata.—The pata is a low tree, and in the bark of the roots, in the bark of the trunk, and even in the wood itself, a colouring matter exists which has not been critically studied, but which with alum, produces a tint called "coffee colour."

Sacha-uva.—This is a Berberis, the roots of which, like the European plant, contain a yellow matter, which, without mordants, dyes wool a very fine yellow.

BARKS.

Cebil grows in the northern provinces of Tucuman, Salta, Jujuy, and in the Gran Chaco in great abundance. The bark is principally employed in the tanneries, because it contains about 15·5 per cent of tannin. In combination with copperas it can also be used in dyeing to produce tints from grey to black.

Sauce.—This is the willow *Salix Humboldtiana*. The extract of the willow produces the tints most esteemed by the people of the country. The natives have for some time been endeavouring to imitate successfully the natural tint of the vacuña wool, because the ponchos woven with this wool have the highest price and are of the best quality. As it is extremely difficult to separate the fibres of the vacuña wool in such wise that the different tints may be woven exactly equal, a substance which will dye any other white hair or wool the colour of the vacuña—coffee colour—in its shades, and be at the same time firm, and lustrous, must be of great value. Only the extracts of the barks of the sauce and the algorrobo serve efficaciously to this end. To produce the deepest tints of the brown colour, the cuticle of willow bark is employed, but the derma as preferred for the lighter tints. It is necessary, however, to saturate the threads with alum, as a mordant before attempting to dye with the sauce.

Vogal.—This is the wild walnut, which answers the same purpose as the sauce, but its colours are less firm and brilliant.

WOODS.

Quebracho Colorado.—By boiling the sawdust or shavings of the red quebracho, a dark-brown liquid is produced, which, being evaporated to dryness and cooled, produces an almost black resinous residuum, which is brittle and of a certain lustre, but with which as yet no scientific experiments have been made. For this reason neither its exact chemical composition, nor its physical properties are perfectly known, but from its appearance it is very similar to the matter which has long been known to commerce as "dragon's blood." The extract of quebracho is used alone to dye wool, as also with such mordants as alum and copperas, or sulphate of copper. In the first mode, the wool is dyed from bright to dark brown; in the second, from grey to black; in the third, to a violet red.

Algarrobo Blanco.—A brownish-black sap sometimes runs down in the bark of the very old trees when

impregnates it with a resinous and gummy substance that completely dissolves in hot water, thus forming a dark-brown tint very similar to the extract of quebracho colorado. By detruncating the trees of the very largest size, a black and extremely bitter sap exudes from the tree which gradually solidifies in the air. This has not as yet been scientifically analysed. The aqueous extracts made from boiling the wood and then evaporating to dryness do not solidify on being cooled so perfectly as those of the quebracho colorado, but form delicate viscous and somewhat tough superficial laminæ. The solution of the colouring matter of the algorrobo without recourse to any mordant, produces very fast colours, not only in wool and silk but also in cotton and linen goods as likewise in the fibre of the chagnan. The colour varies from the clearest to the blackest brown according to the application.

Corovillo.—It appears that both the bark and the wood of this plant contain the same colouring materiral which the natives call "tinta punzó"—deep scarlet red. The preparation and application however of this colouring matter is a secret in the hands of certain families in the interior, who refuse to give to the public any information on the subject.

Lapacho.—The chemical composition of the organic material of this tree is very complicated. From experiments thus far made, it appears that its bark and wood afford about 7 per cent. of tannin and 7·5 per cent. of colouring matter, which crystallises well, and about 12·5 per cent. of another colouring matter of less value, since it does not crystallise; also about 5 per cent. of a substance similar to caoutchouc. As the latter, as well as the colouring matter, is insoluble in water, because of their resinous composition, it is not strange that the wood long resists decay. Indeed, it is stated that when the wood has remained some time in water, it becomes indurated to such an extent that it is impossible to cut it with steel axes.

Dr. Siewert, after a careful scientific study of the yellow colouring matter which exists in the wood, pronounces it a very important dye-stuff. After describing at length his method of preparing it for use, he says:—"Inasmuch as this colouring matter, hitherto unknown, easily eliminates the carbonic acid of the carbonate of soda and dissolves into a liquid the colour of blood, it is certain that it represents an organic acid. And for this reason, in accordance with its origin, it has been named 'lapachic acid.'"

The lapachic acid, its salts, and the products of its decomposition merit much attention from dyers, because, according to the mordants and the degree of concentration of the flux, they produce very diverse colours in wool and silk; that is to say, whether the goods impregnated by the mordants be at once passed through the flux of the colouring matter or the contrary, or whether they are dyed in cold or heat, the following colours are produced:—

1. *Rose Crimson.*—Use chloride of tin, alum, or acetate of lead for mordants; then dye in a flux of the lapachate of soda, and purify by soap.

2. *Yellow.*—Saturate the cloth with the bichloride of tin, then pass it through the hot flux of lapachate of soda, dry it, and purify it in a hot bath of lapachonic acid.

3. *Clear Brown.*—According to the strength of the mordant of sulphate, or, better, of acetate of copper and of the flux of lapachate of soda, each one of the tints of brown will be produced. The goods are afterwards cleansed by soap.

4. *Dark Brown.*—The goods impregnated with chloride of iron, are dyed in heat in the flux of lapachate of soda, and afterwards cleansed by soap.

Nothing has ever been done in the matter of making the dyes and dye-stuffs of the country articles of foreign commerce. In spite of the fact, that all parts of the Republic are so rich in these materials, there has scarcely been a movement towards their utilisation, beyond the meagre demands of a few spindles and hand-looms in the interior provinces, the people importing quite all the threads, yarns, and woven goods used in the country. That there is a field here for the building up of a large trade in colouring materials, scarcely admits of a question. In regard to most of the articles above enumerated, they are found or grow spontaneously in the country, and are immediately accessible along the shores of the Upper Paraná and the Paraguay. The lepacho, the quebracho, the algorobo, and nearly all the other trees mentioned, grow in great quantities and wonderful luxuriance all along those rivers; while as to the rest, there are railways leading through the provinces where they are found.

Mr. Baker proceeds to give some interesting information about such plants, shrubs &c., as require attention for their proper cultivation and development. The saffron might profitably be cultivated. Indigo plantations are worthy of attention, and the conditions are peculiarly favourable for the culture of cochineal. Mr. Brown says:—If the indolence and indifference to progress of the lower classes of the Argentine people were not known, it would be difficult to explain how such an industry as the production of cochineal, at once so simple and so easy, is permitted to be so negelected, since in the interior provinces the aridity of the soil and the dryness of the climate indicate them as admirably suited for the business, and I do not think that it could possibly fail to pay large profits on a very moderate capital. All through the level interior, and especially in the provinces of San Louis, Rioja, Catamarca, Santiago del Estero, and certain portions of Cordoba and Tucuman, the plant is found in the greatest abundance, and the insect is reproduced spontaneously. It is an industry which can be prosecuted by any person who has enterprise and a few hundred dollars capital. That which is obtained now without care and without cultivation, will give some idea of what such an industry would yield if properly conducted. It is probable, however, unless foreign enterprise comes in and takes advantage of the openings which the Argentine Republic offers in the several industries for the production of dyeing materials which I have mentioned, that they will remain undeveloped for as many centuries in the future as they have in the past.—*British Trade Journal.*

A NEW COFFEE PLANT.—Coffee-planting has been carried on with more or less—generally—less success in Natal for yours past, and an enterprising Albany farmer has succeeded in bringing the plants to maturity, though it is more than doubtful whether the experiment could be developed into a commercial success. A new coffee plant has, however, it is stated, lately been discovered in West Afrcia, the berry of which is said to resemble that of Arabia in appearance and flavor. It grows not on a shrub, but on a tree nearly seven feet high, which develops rapidly and yields an abundant crop. Arrangements are already being made for introducing its cultivation in favourable localities. It might be worth while to try the new coffee plant in South Africa.—*American Grocer.*

GROWING ORANGES.—I notice in the *Gardeners' Chronicle* of December 17, p. 755, a correspondent writing about an Orange tree bearing twenty-three full-sized fruits. I send you a fruit gathered from a tree bearing fifty-six fruits, nearly all ripe and of the size of the fruit sent. I think it a great pity Orange growing is so neglected in private gardens. In fact when you do meet with them they are generally found in a very sickly condition. What can be more pleasing, ornamental, and useful at this season of the year than a good house full of such cultivated Oranges? Their management is very simple. Insects are their greatest enemies—green-fly and scale; the former is easily kept down by fumigation, the latter by a dressing of Gishurst Compound once a year.—G. BLOXHAM, the Gardens, Brickhill Manor, Bletchley, Bucks.—*Gardeners' Chronicle.*

COFFEE CULTURE: 'NATIVE' AND 'PLANTATION' FASHION.

We call attention to the letter of "S."* (written by a gentleman of considerable influence in India), with the questions which he raises. Some of these "S," will find answered on page 566 by our planting correspondent, "Peppercorn," and, having made reference to other quarters, we have the opinions of two more practical men to give as follows:—

"If leaf disease and green bug are about, then coffee can hardly be too well cultivated, though high cultivation must not be confounded with extravagant cultivation. If leaf disease and green bug are present, I do not believe any cutting down of cost will make coffee a permanent paying investment. My advice in this last case would be 'Don't go in for coffee on any system of cultivation. If unfortunately you have already done so, then sell if you can, and if you can't then take all the crop that will come, and do as little as possible in return—make money while your coffee lasts.'"

And again:—

"I really don't know what answer to give you for 'S.' I have almost forgotten all about coffee! An Uva man tells me that native coffee is n't affected to nearly the same extent as plantation with bug or leaf disease†. Native coffee after two to three years is allowed to take care of itself, an occasional weeding is generally all it gets, so that cultivation costs very little. No doubt there will always be plenty demand for native coffee, and if it is pulped and cured same as plantation I don't see that the value of the two would vary to any extent. 'S' will be a plucky man if he goes in for either."

The only native gardens in Ceylon that gave continuous crops at all approaching those ever yielded by regularly cultivated plantations, were gardens along the roadsides getting the full benefit of manure and road-washings. Our old calculation in the palmy days of coffee in Ceylon used to be an average of 5 to 6 cwt. per acre for plantations and of 2 to 3 cwt. for native gardens. But certainly the garden owner's expenditure was much less—only the more care he did give, as a rule, the better return he got. Plantation coffee generally sells at from 25 to 40 per cent better than native; but when prices run high, inferior coffee much more closely approximates to superior in the market. The chief peculiarity in native gardens is the absence of any topping, pruning or weeding. One thing is certain,—that when leaf-disease became epidemic in Ceylon it ran through and snuffed out our native gardens in one-half the time which was required to bring down our plantation coffee-trees. We are not so strong as our planting friend quoted above in saying "Don't plant coffee at all." If the land be virgin and the soil really good, we would advise "S." to follow the example of the Coorg and Mysore planters who plant under shade and in some cases treat their trees a little more in the native fashion than was the custom in Ceylon, allowing them grow up. The Mysore planters have thereby (through the shade chiefly) kept off leaf-disease and continue to get good crops. From Mr. F. H. Price, of the local Civil Service, who has just visited Java, "S." will be interested to learn, we have a similarly favorable report of coffee in Java grown under shade, great big trees loaded with berries (12 to 20 cwt. per acre was the estimate), and Mr. Price was told by Government officials that they had a rule now forbidding the cutting down of their big forest trees in clearing land, only allowing lopping; while everywhere on open coffee land which had suffered from leaf-disease, the dadap tree was being cultivated as fast as possible to secure shade. As regards the expense of preparing coffee, we think the cost of barbacue and pulper will be speedily covered by the difference in price obtained, provided good crops are gathered, and "S." need not be told that when a hardworking resident proprietor looks after his own work, there should be no room for the extravagance he refers to. Fifty rupees an acre per annum used to be considered the very minimum for the cultivation of an established coffee estate in Ceylon; but hard times and short crops brought it down to 30, 20 or even 10 rupees in accordance with steadily diminishing returns, before tea took the place of our old staple.

* See page 545.

† That must be a recent experience; for at the outset leaf-disease did enormous damage to native coffee.—ED.

WYNAAD NOTES, Jan. 5th.—Our hopes regarding crops, have, by no means, been fully realized; and those estates are exceptional which have at all exceeded their estimate. However, *bad* crops are also exceptional; so that with a generally fair "medium," and much improving prices we have good reason to be content. The reports which reach us from different realiable quarters regarding the probable continued rise in both coffee and cinchona markets, are especially encouraging. There is an extraordinary demand for coffee amongst the natives about here. The local Moplahs, are offering prices (cash down) for tails, cherry, and in fact mere sweepings—exceeding that which is offered for parchment, in the regular market. There is some mystery about this, and it is generally supposed that our rubbish is being purchased for the Arab Market, to represent Mocha the real article being almost unobtainable. One Moplah last week offered R2,000 for "tails and cherry" and a brisk trade is going on all over the district. Coffee is sold in the bazaar, for ordinary drinking purposes at one rupee the seer; which in the land of coffee, is very high indeed. Unfortunately there is another side to the question. The increased value of coffee, has invited our old friends the coffee thieves to a great exhibition of energy, and hardly an estate has escaped their depredations. The police have not hitherto been very successful in convicting the real culprits. But their researches have brought to light sundry "dodges" which are certainly ingenious. That, for instance, of preparing cherry coffee—with a rapidity to defy detection. It is well know that stripping, (*i.e.* mixed green, half ripe, and ripe)—which is the thieves' mode of gathering, can only be dried, and must take at least ten days or a fortnight, to become one uniform color, so that the chances of detection are considerable. If however, they can produce the appearance of dried cherry, in a short time there is no saying how long it may have been in their possession. And this appearance is caused, by *steaming* the newly picked coffee, and then drying it as soon as possible. This can be done very rapidly,—and only an experienced person could discover (by a slight stickiness in the beans) that there was any deception in the method of curing. Naturally it does not improve the color, but this matters little when one considers the uncritical market in which it will probably be disposed of. We had begun to despair about cinchona, which grew and flourished in proportion to its decadence in value. We spoke of it as "an estate weed," and many were more than half inclined to root it up, and replace it with the hitherto despised coffee. But if we are to believe our prophets, good times are coming even for cinchona. Certainly a more cheerful spirit expresses itself regarding cinchona prospects, and after our many reverses we, planters, are not given to be over sanguine.—*Madras Times*, January 6th.

INDIAN AND CEYLON TEA LONDON MARKET REVIEW FOR 1887.

[STENNING, INSKIPP & Co.]

INDIAN.

THE COURSE OF THE MARKET.—The low prices at the close of 1886 and the increasing deliveries caused a steady tone at the opening of business for the year, and values hardened until about the middle of February, when slackness set in, but only for a short time, being succeeded by a good demand, especially for the better qualities, which marked an advance. The commoner grades were in rather large supply, and soon became dull at easier rates, especially for low and common broken teas. This position was maintained until the arrival of the new crop in June, but the teas being poor met with no support, and were difficult to sell, even at low values; later on, arrivals showed better liquors, and were well bid for at high prices, especially good-flavored Darjeelings; inferior teas continued very slow of sale. Towards the end of August large actions caused dulness, and all Teas sold cheaper except choice flavory parcels; about a month later rather more enquiry set in, especially for common and medium kinds, which after fluctuating in demand, ultimately received more attention; the poor quality of China, no doubt, contributing to the enquiry. The year closed with a continuance of the demand for Teas for price, and with a somewhat duller tone for the higher grades.

PRESENT PRICES.—With the exception of Broken Teas, Fannings and Dusts, which are 1d. to 2d lower, values are on a par with those ruling at this period of 1887.

THE SEASON.—With the extended use of machinery, and the quickening and cheapening of transport from the great majority of estates, the Teas have been, as a rule, produced at a less cost than hitherto, and although, for a time here, values went to an exceedingly low point, we think, so far as the present season has gone, that results to well managed properties have been very satisfactory; on some estates heavy plucking has been attended with very low and possibly losing averages. These varying results would indicate what has been so often urged that a moderately fine system of pluking will prove the most remunerative in the long run. If coarse plucking during the next season be anywhere contemplated, we would warn planters that they will have not only to contend with common China, but also, and more adversely, with larger supplies of Ceylon teas. This latter growth is having more and more effect, not only on the course of the Indian market, but on that of the China as well.

FIGURES.—The remarkable falling-off in the demand for China tea in recent years has further increased during the twelve months just expired, so much so that for some time the total home consumption was hardly equal to that of Indian and Ceylon together, and for four months indeed was actually less; moreover, this has taken place at a time when the bulk of China tea is selling at lower prices than ever before known, and goes to prove that the taste of consumers is becoming more and more established in favour of tea grown in our own dependencies. As to the future of China tea it is difficult to believe it can regain the estimation it once held amongst consumers, unless producers so entirely alter their mode of cultivation and manufacture as to enable them to export teas as good as those of 15 or 20 years ago. But even such a radical change as this could hardly have any effect on the progress of Indian and Ceylon tea for many years to come, and during the interval the production from these latter countries will have attained such dimensions as to quite subordinate the produce of China.

In drawing any comparison between the consumption of Indian and Ceylon with China, it must not be forgotten that the decrease in the use of China is even greater than appears at first sight as both Indian and Ceylon teas go so much further in the tea-pot.

The quantity shipped on Garden Account again shews a slight increase, this is mainly due to the low exchange and, for a portion of the season, a low average selling price in Calcutta, together with the yearly increasing attention paid by buyers in London to successive complete Garden Invoices.

The quantities compare as follows:—

	July to Dec. 1887.	1886.
	pkgs.	pkgs.
On Garden Account.....	311,186	271,374
On Purchase Account.....	210,812	198,953
	or 60 per cent. on G. Acct.	or 57½ per cent.
	1885.	1884.
	pkgs.	pkgs.
On Garden Account.....	226,972	192,183
On Purchase Account.....	170,260	212,566
	or 57 per cent.	or 47½ per cent.

QUANTITY FROM THE DIFFERENT DISTRICTS.

ASSAM.—An increasing amount of sttention during the past few years has been given to manufacture, resulting generally, so far as the current season is concerned, in an improved style of tea. The good prices made here for useful liquoring parcels should be an incentive to further efforts; there has been, however, too large a proportion of light coloured liquors without pungent flavour, and these have only sold with difficulty at rather low rates, compared with the prices paid in 1886.

CACHAR.—We have again to report no improvement on the produce of last season, the teas with few exceptions have been weak and wanting in flavour; in some instances it seems as if quantity had been preferred to quality. We also note that fewer marks even than last season have shown desirable character.

SYLHET.—Until lately supplies were only of moderate quality, we are glad to note that recent arrivals contain some fair teas, but still below the standard of what this district is capable of producing and has produced occasionally in past seasons.

DARJEELING & TERAI.—The quantity of true flavoury tea, although still small has been greater than last season, it seems to us that the good prices to be obtained for desirable liquoring teas are causing greater attention to be paid to their production. Dull and flavourless parcels have again been difficult to sell.

DOOARS.—The produce of this district, although improved, still disappoints the expectations raised a few years ago; we hear, however, that the weather this season has been more conducive to a large yield than to a good cup. The fact remains that more than one of the marks, which have hitherto been noted for turning out good liquors, have fallen off.

CHITTAGONG.—The bulk of the manufacture has not been nearly equal to that of last season, when the teas were excellent, and realized handsome prices. We would remind planters that tea from this district when arriving regularly, of good quality, attracts much attention from buyers.

KANGRA VALLEY & KUMAON.—Last season we reported that the produce was disappointing, this feature has unfortunately again been prominent, and fewer desirable teas than ever before have appeared here.

DEHRA DOON.—Only small quantities have arrived, and these fully maintain the improvement noted a years ago.

NEILGHERRY.—The flavoury teas usually received from a few gardens in this district have been but sparsely represented this season.

TRAVANCORE.—Larger quantities are yearly being produced here, and care seems to be given to manufacture; when the liquors were good the teas realized full rates.

JAVA.—The low prices ruling generally have affected this variety, and transactions have been much smaller both of direct and indirect shipments. The quality has been rather over the average. 38,954 packages have been offered during the 12 months, as compared with 46,552 in 1886, Holland taking a larger proportion than last year.

SORTING.—As a rule four, or at most five, breaks in an invoice are all that are really needed, viz.: Orange Pekoe or Broken Orange Pekoe, Pekoe, Broken Pekoe, Broken Tea and Pekoe Souchong, with an occasional lot of Fannings and Dust. Such an assortment should be practicable if the leaf be plucked moderately fine Dusty teas are much objected to by buyers, and fre

quently realize comparatively low prices. When a garden is producing but a small quantity there should be as few different kinds as possible, with a view to avoiding small or non-sampling breaks.

BULKING IN INDIA.—As we long ago pointed out, this should not be undertaken unless it can be so thoroughly done as to insure perfect uniformity of quality; an equal quantity of tea moreover must be given with each chest, nor would it be worth while to risk loss of quality through binning prior to bulking. The chief advantages of bulking in India are as follows:—

1.—Saving of time in bringing tea to market.

2.—Saving of Warehouse Charges to the extent of about 1s. a chest.

3.—Prevention of risk of damage to leaf through bulking here.

4.—Less liability to loss in weight, test packages only being weighed.

5.—The superior condition in which the packages reach the buyer.

WEIGHING NET.—This system has made fair progress, but there is still a want of accuracy in some quarters, the variations often much exceeding the limit of 2 lb. either way, *i. e.*, above or below.

WEIGHING INDIAN TEA.—The following are the amended regulations which came into force November, 1885:—

The weight of Indian tea for duty may, if desired by the importers, be ascertained under the following regulations:—

1.—The packages on arrival to be weighed to ascertain the gross weight of each package.

2.—The importers to give with each entry a statement that the teas in each break have been bulked in India, and that the chests of each break contain even net weights.

3.—In order to test the accuracy of this statement, 10 per cent of each break to be turned out and weighed net, but in no case are less than 3 chests to be turned out.

4.—If the variation in weight of the test packages from each other be found to exceed 2 lb., the whole parcel is to be tared. For instance, if the test packages weigh net 79, 80 and 81 lb. respectively, the variations would not exceed two pounds, but, if one package be found to weigh 79 lb. and any other 82 lb. or more, then the whole break to be tared; unless the importer and surveyor consider that an average tare can equitably be given, in which case the tares must not vary more than two pounds, as in the case of net weights.

5.—Duty is to be charged on the average weight of the packages weighed net, provided that when the average of the packages weighed net amounts to so many pounds and a half or more, the half or more will be charged as a full pound; when the fraction is less than a half it may be disregarded.

6.—All Indian teas bulked in this country are to be weighed gross, and each chest tared.

MARKS OF CHESTS.—Nothing is wanted, or is of any service here beyond (1) garden mark, (2) description of tea, (3) garden numbers, and (4) bulked if such be the case. Gross, tare or net, are not of the least use, and should be discontinued.

SMALL BREAKS.—An alteration was made in September for these, when the limit was fixed at 12 chests, 18 half-chests and 30 boxes; breaks below these quantities are sold at the close of the daily auctions.

SIZE OF BREAKS.—Some progress has been made during the current season in turning out good sized breaks, and much relief has in consequence been afforded to all concerned; the system advocated in our Annual Review of 1886, of putting together in one break similar teas, has been adopted to some extent with Calcutta bought parcels to the satisfaction of all concerned; we trust no relaxation in the efforts to produce large breaks will be allowed by owners of gardens as the increasing quantities of teas at auction will call for further exertions to place attractive invoices before buyers.

We regret to note that splitting up of lots is still carried on in Calcutta, involving unnecessary work to all concerned, and causing much annoyance to buyers.

LOSS IN WEIGHT.—Much dissatisfaction has arisen from time to time on this point. The gross weight of the package should always be a few ounces—say four or five,—over an even number of pounds. The empty package complete, with lead, nails, bands, &c., should be, on the contrary, just below an even number of pounds—say by about 4 ounces; in weighing here the gross weight is *reduced* to the even number of pounds, whilst the tare is *increased* to an even number of pounds. This method applies to teas not bulked at the garden, and also to Calcutta-bought teas.

With regard to garden-bulked teas to pass the test for weighing nett, as before remarked, it is imperatively necessary to put an equal quantity into each package of the break, and this quantity should be an ounce or two over the desired weight of contents—viz., if the packages are invoiced, to contain 100 lb. tea each, not less than 100 lb. 2 ozs. should be weighed in; test packages proving here a fraction under 100 lb. will be reckoned as 99 lb. only, or a loss of 1 lb. on each chest of the break. We fear, when great pressure prevails at the London warehouses, some laxity as to weighing takes place, but the loss thereby incurred can be but small compared with what may be caused by neglect of the foregoing precautions at the garden in weighing and filling the packages.

WEIGHT OF PACKAGES.—When a gross weight of 129 lb. is exceeded, there is an additional charge of 5d per chest up to 159 lb.: the following scale of charges fully explains this and deserves attention:—

Management rate, per package, subject to discounts at present varying from 15 up to 60 per cent:—

Gross ...	160 to 199 lb.	130 to 159 lb.	90 to 129 lb.
	2s 9d	2s 3d	1s 10d
Gross ...	80 to 89 lb.	60 to 79 lb.	45 to 59 lb.
	1s 8d	1s 5d	1s 2d
Gross ...	35 to 44 lb.	17 to 34 lb.	Under 16 lb.
	1s 0d	7d	4d

HOME CONSUMPTION OF INDIAN, CEYLON AND CHINA.

	Indian & Ceylon.	China.	Total.	Percentage. of Indian & Ceylon.
1887 ...	93,054,000	87,553,000	180,607,000	51½
1886 ...	74,665,000	100,000,000	174,665,000	42¾
1885 ...	68,894,000	106,309,000	175,203,000	39½
1884 ...	63,038,000	106,918,000	169,956,000	37
1883 ...	59,097,000	114,953,000	174,050,000	34
1882 ...	50,497,000	115,569,000	166,066,000	30½
1881 ...	48,836,000	112,156,000	160,992,000	30½
1880 ...	43,807,000	111,307,000	155,114,000	28¼
1879 ...	35,243,000	125,576,000	160,819,000	22
1878 ...	36,776,000	120,192,000	156,968,000	23½
1877 ...	28,013,000	123,012,000	151,025,000	18⅝

Compared with 1882 (6 years ago), the consumption of China Tea has decreased 24¼ per cent., whereas that of Indian and Ceylon has *increased* 81¼ per cent.

The Total quantity of Tea, Indian and Ceylon, offered at auction was, during 1887 1,153,262 chests 1886 948,320; 1885, 823,848; 1884, 769,342; 1883 730,574; 1882, 619,479.

SEASON 12 MONTHS: 1ST JUNE TO 31ST MAY.

* These Totals include Ceylon.

CEYLON.

The year opened with a good enquiry at full rates; this position was well maintained until March, when larger supplies of less satisfactory quality caused lower values; soon after, a recovery took place which lasted until June, when good liquoring Teas commanded same advance; afterwards arrivals decreased, and the quality again being hardly so good, values ruled weaker and irregularly, but towards October better demand sprung up and full rates were realized for all grades

In the following month dulness took place, and at the close of business for the year a decline of 1d to 2d per lb. had occurred, chiefly on the better grades.

The quality has been on the whole satisfactory, but seems to be subject to sudden variations, due probably to climate. The Teas continue to be largely taken both for mixing with other growths and for use by themselves, for which they are so well adapted. A demand for export has prevailed throughout the year, and as time goes on when larger breaks can be sent home we look for a great increase in the consumption on the Continent.

Buyers have paid much attention to teas possessing a deep rich colour. Such have throughout been very saleable, whilst pale liquoring parcels were difficult to sell. We would urge planters to be very particular on this point, taking care to avoid dulness in taste.

Considering the low prices that have ruled generally, it is satisfactory to find that the average price of Ceylon tea has been only a fraction less than that of the preceding twelve months. The quantities offered and the average price throughout the year, have been as follows:—

1887 ...	182,955 Pkgs.,	aver. 1s 0⅞d	per lb.
1886 ...	101,145 „	„ 1s 1d	„
1885 ...	58,921 „	„ 1s 3⅛d	„
1884 ...	15,701 „	„ 1s 2⅞d	„ (1st August to 31st Dec. only.)

We would direct special attention to the remarks on the first and second pages of this review under the heads of Sorting, Bulking, Weighing, Marks, Size of Breaks, and loss in weight.

SMALL BREAKS.—On and after 1st January, 1888, the limit for these will be the same as for Indian teas, viz., 12 chests, or 18 half-chests, or 30 boxes, and breaks below these quantities will not be sold until after the close of the daily auctions.

JANUARY.—A good demand at full rates prevailed throughout, the quality being very satisfactory.

Public sales contained 9,372 packages, against 4,472 in 1886.

FEBRUARY.—The enquiry was well maintained for the desirable liquoring teas, at the close of the month teas at all wanting in quality sold rather lower.

Public sales contained 11,310 packages, against 5,361 in 1886.

MARCH.—Heavy arrivals, and the quality not being so satisfactory, caused dullness accompanied by lower values; a few fine teas alone maintained former rates.

Public sales contained 11,283 packages, against 7,789 in 1886.

APRIL.—An improved demand took place and a portion of the fall of the previous month was regained; especial attention being given to liquors having a deep color.

Public sales contained 12,474 packages, against 4,667 in 1886.

MAY.—The demand continued good, throughout, notwithstanding the large arrivals which, however, were of good quality.

Public sales contained 10,275 packages, against 12,329 in 1886.

JUNE.—Arrivals this month were heavy, but as the quality was disappointing values declined, a few invoices with good liquor alone maintaining former rates.

Public sales contained 20,258 packages against 11,264 in 1886.

JULY.—The supply continued ample, common and medium sold slowly, especially Broken sorts; fine and finest with good appearance were readily taken at an advance.

Public sales contained 25,359 packages, against 11,743 in 1886.

AUGUST.—Arrivals were not so heavy, and, the quality of a great portion being poor, prices were rather weaker and irregular. Fine and finest sold well at good values.

Public sales contained 25,878 packages, against 15,884 in 1886.

SEPTEMBER.—Supplies continued to decrease, but as a fair quantity proved of desirable character, a good enquiry prevailed throughout, and an advance took place towards the end of the month.

Public sales contained 16,065 packages, against 10,529 in 1886.

OCTOBER.—Good competition ruled throughout, and high rates of the previous month were well maintained.

Public sales contained 13,047 packages, against 6,615 in 1886.

NOVEMBER.—No change occurred until about the middle of the month, when less animation was shown, particularly for the commoner grades, which went more in favour of buyers.

Public sales contained 13,297 packages, against 8,689 in 1886.

DECEMBER.—Supplies continuing ample, and the quality being not quite satisfactory, a decline of 1d to 2d per lb., especially on the better grades. Commoner kinds in sympathy with Indian attracted attention at the decline.

Public sales contained 12,950 packages, against 6,077 in 1886.

CHINA TEA MARKET REVIEW FOR 1887.

(From *Stenning, Inskipp & Co.'s Report.*)

LONDON: 9, GREAT TOWER ST., Jan. 1888.

The year under review will be a memorable one for the revolution in favor of Indian and Ceylon teas, and to the consequent displacement of China growths. The large deficiency in the China export (viz., 38,000,000 lb.) coupled with the decrease of 21,700,000 in the delivery of China Congous is about balanced by the larger deliveries of Indian, 14,691,000 lb., and Ceylon teas, 3,098 000 lb.

The quality of the Northern teas of China of the present season has proved most disappointing, the proportion of fine teas being most unusually small; later on in the season when the trade realized the position, a demand sprung up for fine teas, and numerous contracts were made at a substantial advance on the original cost; present rates shew very dear as compared with Indian teas.

The quality of the early arrivals of the Southern teas showed a marked improvement on the past two or three seasons, and the teas sold readily; later on, however, large quantities of very low undesirable teas arrived; these met with a very poor reception, prices at one time being down to 3½d and 4d per lb. (about the lowest on record.) At the close of the year fair medium Congous shew relatively very good value whilst finest grades remain exceptionally dearer.

The strong hold on the Home Trade which Indian and Ceylon teas have now taken should be a warning to the Chinese growers to do their utmost to improve their quality.

In Common Congous the fluctuations have been from 5½d to 4d per lb.

Public auctions still continue in favour for common teas, and most kinds of fancy teas.

The China export shews 144,800,000 lb., against 143,000,000 lb. last year, and 147,000,000 lb. in 1885. The stock of congou in London shews 49,000,000 lb. against 51,000,000 lb. last year, and 53,000,000 lb. in 1885.

Public sales contained 99,791 packages, against 65,822 packages in 1886.

REVIEW OF COFFEE FOR 1887.

(From *I. A. Rucker & Bencraft's Price Current.*)

January 4th, 1888.

Has consumption decreased? To form a sound opinion, as broad a range as possible should be glanced at and the following figures compiled by us some little time ago at the request of one of our friends, are, we believe worthy of study. Each period comprises twelve months, either January-December or July-June, and the deliveries during December 1887, are of course estimated, a fact which can have no influence on the tenor of the figures.

July-Dec. Deliveries—	July-June 1887. tons		1887-88. tons	1887. tons
United States	77,767		at	176,000
Europe	155,020		the rate	363,000
	232,787	=	of 466,000	539,000

Deliveries—	1886-87. tons	1886. tons	1885-86. tons	1885. tons
United States	212,562	231,254	226,931	230,048
Europe	433,120	440,200	423,430	424,810
	645,682	671,454	650,361	654,858

The average price of each period works out as follows as applied to good average Santos in Havre:—

103 = 103 96 75 53 46.75 48.50 francs.

In the twelve months of 1886 deliveries were 671,454 tons, or 5,000 tons heavier than the largest record up to that period, viz., 666,290 tons in the twelve months 1884-85. In the twelve months 1886-87 deliveries were only 645,682 tons, and this in face of the popular assertion that during that period the trade was stocking itself heavily. As a matter of fact the figure 645,682 tons is far too large, and is very misleading, because it is an undisputed fact, that during the period 1886-87 large quantities of Coffee went in and out of stock in one port only to appear in another port, owing to the abnormal state of trade then current. Great authorities have computed this abnormal in and out movement of stock at 500,000 bags, or 30,000 tons. If we wish to be well within the mark let us calculate it at only 20,000 tons, and then in the light of it the figures of the twelve months 1887 become easier to understand, and the probable figures of the twelve months 1887-88 on a basis of 103 francs follow as a natural sequence. Thus—

1886 deliveries on a basis of	53	francs	671,454	tons	
1886-87	„	„	75	„	625,682 „
1887	„	„	96	„	539,000 „
1887-88	„	„	103	„	466,000 „ say 500,000 tons

These figures appear to us to prove that the rise in price has checked the consumption of coffee, and that every advance from 53 francs upwards has had a direct influence on the requirements of consumers. The foregoing may be treated as direct evidence, all indirect evidence tends, we think, to corroborate the above. At an average price, therefore, of 96 francs, deliveries should be in Europe and America about 45,000 tons per month. Increase the price, and deliveries would become further curtailed.

What do our supplies appear likely to total for the next twelve months? The following little table shows the absolute past and the probable future of Brazil figures. The calculation is formed on the assumption that the current Brazil crops will give receipts of 3,000,000 bags, that the 1888-89 crops will give receipts of 6,250,000 bags. At the present moment up to date receipts in Rio and Santos total 1,549,000 bags. We are told that Rio will give another 900,000 bags, and Santos we presume at least another 600,000 bags. It is far easier to imagine the total above than below 3,000,000 bags. As regards the 1888-89 crops at the present moment we believe the best information points to crops above the figure given. Directly the large houses publish their official estimates, the following little table can be adjusted.

SHIPMENTS TO EUROPE AND THE STATES.

January 1st.

	Jan. to June.	July. to Dec.	bags	tons
1885.	6,208—3,394=2,814	+ 2,986=5,800,000	=348,000	
1886.	5,096—2,986=2,110	+ 3,275=5,385,000	=323,100	
1887.	5,691—3,275=2,416	+ 1,350=3,766,000	=225,960	
1888.	3,000—1,250=1,650	+ 3,350=5,000,000	=300,000	

Say 300,000 tons of Brazil Coffee available for 1888.

Below we give the importations of coffee during the last three years, and deduct from them the Brazil shipments, thus geting at the importations of coffee from countries outside the Brazils.

	1887. tons	1886. tons	1885. tons
Imports United States	181,000	220,119	226,124
„ Europe	355,000	373,350	431,110
	536,000	593,469	657,234
Deduct Brazil shipments	225,960	323,100	348,000
Coffee from other countries	310,040	270,369	309,234

After deducting 20,000 tons, abnormal movement in 1886 and 1887 already referred to, we find that during the last three years coffee producing countries outside Rio and Santos have given us a yearly average of 290,000 tons. During 1887 they gave us say 300,000 tons, and our readers can form their own opinions as to whether the out-turn during 1888 is likely to be above or below the average. As far as we are concerned we shall estimate the weight as likely to be available at the average of 290,000 tons.

With current Brazil crops estimated at 3,000,000 bags. They must count the bag as 1 cwt. The "sack" used to be 1½ cwt.

With 1888-89 Brazil crops estimated at 6,250,000 bags.

It appears likely that we shall have available during 1888—

about 300,000 tons Brazil Coffee
„ 290,000 „ Coffee from other Countries

about 590,000 tons + the visible supply now current.

If values are to rule on a basis of 96 francs for good average Santos, and if our deduction be fairly correct that on that basis the trade will take delivery during 1888 of decidedly under 550,000 tons of coffee, it is evident that additions during the second half of 1888 will be made to stocks.

The following quotations show roughly the result of the year's work:—

	Jan. 1st 1888.	Jan. 1st 1887.
Fine middling Plantation Ceylon	93s to 95s	85s to 88s
Middling „ „	90s to 91s	77s to 81s
„ Costa Rica	88s	71s
„ Guatemala	87s 6d	70s
Good ordinary foxy Guatemala	83s	63s
„ Channel Rio, c. & f.	81s	67s
„ Avr. Santos in Havre	100 francs	78 francs
„ Avr. Java in Holland	51 cents	40 cents
	Jan. 1st 1886.	Jan. 1st 1885.
Fine middling Plantation Ceylon	74s to 80s	76s to 82s
Middling „ „	62s to 66s	65s 6d to 70s
„ Costa Rica	54s	53s
„ Guatemala	54s	54s
Good ordinary foxy Guatemala	40s	48s
„ Channel Rio, c. & f.	37s	41s 9d
„ Avr. Santos in Havre	45¾ francs	52 francs
„ Avr. Java in Holland	25½ cents	28 cents

As regards our yearly anticipations of supplies, we give our usual tables:—

	Java. Government.	Private.	Sumatra.
1880-81	1,047,000	325,000	132,000
1881-82	1,007,600	283,800	118,900
1882-83	1,025,000	341,000	121,500
1883-84	1,072,000	328,000	141,000
1884-85	1,019,000	297,000	129,200
1885-86	500,000	219,000	87,600
1886-87	817,000	326,000	83,200
1887-88	257,000	125,000	83,000

1888-89 crops are said to promise better results.

	Menado.	Macassar, &c.	Total.
1880-81...	10,700	87,600	1,602,300 bags
1881-82...	10,900	133,100	1,554,300 „

Santos „ ...	1,871,000	2,096,000	1,664,000	2,620,000
Total bags...	5.057,000	6,211,000	5,532,000	6,129,000

1887-88	
Rio estimate	1,750,000
Santos estimate	1,250,000
Total ...	3,000,000 bags

As regards the 1888-89 crops, the prospects are reported as favourable, market gossip estimates

Rio	from 3,750,000 to 4,500,000 bags
Santos	from 2,500,000 to 3,000,000 „
	6,250,000 7,500,000 bags

We shall publish no figures officially until the great houses speak.

The following estimates and figures are interesting, but we believe of little commercial value, except as a rough guide as to whether the out-turns are likely to be above or below the average of the last two or three years.

All those who are interested in statistics must have often noticed that if any past year be taken, and a sum total compiled from all the assessed out-turns, the figure never equals by many thousands of tons the quantity of Coffee which really arrives.

It is, we believe, for this reason that statistical tables, published with great care, comparing the quantity of Coffee likely to be required by the trade with the quantity of Coffee likely to be available according to the estimates year after year, prove to be misleading. In all these tables, without exception, year after year, the sum total of the Coffee estimated to be available from countries outside the Brazils and Java is under assessed.

The only safe plan is to try and decide whether the Coffee likely to be available promises to be more or less than the quantity proved to have been available in previous years, by deducting Brazil shipments from the total arrivals returned by Messrs. Duuring & Zoon in Europe, and by Messrs. Moring & Co. in the States.

	1887-88	1886-87	1885-86	1884-85	1883-84

Guatemala & Salvador	400-440,000	515,000	502,000	510,000	425,000
Nicaragua & Honduras	80,000	80,000	75,000	80,000	80,000
Haïti	500,000	400,000	500,000	630,000	—
Porto Rico	400,000	230,000	260,000	420,000	314,000

TUESDAY EVENING.—As we go to press, the news reaches us that Messrs. Johnston & Co. estimate the 1888-89 Brazil crops at 8,500,000 bags, viz., Rio 5,500,000 bags, Santos 3,000,000 bags.

I. A. RUCKER & BENCRAFT, 37, Mincing Lane.

ANNUAL REVIEWS OF TEA AND COFFEE MARKETS.

Referring to the details in the annual Market Reviews, (page 554 *et seq.*) we will proceed to notice the

PROGRESS OF CONSUMPTION OF INDIAN AND CEYLON TEA IN BRITAIN.

More than half of the tea delivered for home consumption in Britain now is of British origin, that is grown in British possessions. This position was reached towards the end of last year, but even for the 5 months between 1st June and 30th Nov., the proportions delivered were:—

Indian 40,875,000 † Ceylon 6,117,000 lb.=total British 46,992,000, or say 47 millions against

China 60,858,000 † Java 1,653,000 lb.=total non-British 62,511,000.

Deliveries for 5 months of Java had gone down as above from 2 millions in 3 years, and China from 71½ millions, while India rose from 27½ millions, and Ceylon from 2 millions and 83,000 pounds. The monthly deliveries of Indian tea had gone up from 5,598,000 lb. in June to 8,294,000 in October. The monthly deliveries of Ceylon tea had increased from 780,570 lb. in June to 1,341,790 in August. The latter is the highest monthly figure for Ceylon tea as yet. The progress of our tea is shown by the following figures for deliveries:—

	(1st June to 31st May)	Monthly average
1884-85	2,046,000 lb.	170,000 lb.
1885-86	3,933,000 „	328,000 „
1886 87	7,744,000 „	645,000 „
1887-88 (5 mths)	6,117,000 „	1,223,500 „

For the 5 months the monthly deliveries had averaged 1,223,000 lb., and as deliveries preserve a fair proportion to imports, we may anticipate a rise to close on 2 millions *per mensem* of Ceylon tea before 1888 closes.

The proportions of *monthly* deliveries by the beginning of 1889 will probably be :—

Indian	.. ..	10,000,000
Ceylon	.. ..	2,000,000
China, &c.	.. ..	8,000,000
Java	.. ..	300,000
Monthly total	..	20,300,000
		12
Annual total	..	243,600,000

The monthly and annual totals might be increased so as to raise the latter to 250 millions, but for the now well-established fact that one pound of Indian or Ceylon tea goes nearly as far in household use as 2 lb. of China. This is the chief reason why the British rate of progress in consumption *seems* to have been arrested. The disturbed state of Ireland, too, must be taken into account in looking at the figures for Indian tea. All this considered, we believe our figures will be about those we have calculated for deliveries in Jan. 1889.

So far we had written with reference to the figures given by Messrs. Gow, Wilson & Stanton for 11 months of 1887. We have now the figures for the 12 months, and Messrs. Wm. James & Henry Thompson explain that the falling-off in total deliveries in 1887 was not due to a decrease in deliveries for home consumption. These increased by nearly 3¾ millions (of which nearly one-half was strong Indian and Ceylon kinds, 1 lb. equal to almost 2 lb. China). The decrease of 5½ millions in total deliveries in 1887 as compared with 1886, was due entirely to 9 millions less exported, and this decrease is explained by the fact that Russia took a larger proportion than usual direct from China, large quantities of inferior leaf and dust being taken for conversion into brick tea. The good quality and comparatively cheap prices of Indian and Ceylon are rapidly giving them a foremost position in home consumption. The decrease last year in the home consumption of China was 14¼ millions of pounds, apart from the 9 millions less exported. Against the decrease in home consumption of 14¼ millions pounds of China, we had increases in India and Ceylon, thus shown in figures :—

Indian	.. ..	14¾	millions pounds
Ceylon	.. ..	3¾	" "
Total	.. ..	18½	" "

This process will go on in proportion as Indian and Ceylon planters are able, while continuing to produce tea of fine quality, to effect such economies as will enable them to sell their product at moderate prices. High prices are very pleasant, but they at once lower consumption, as has been strikingly shown in the case of coffee in the United States last year. We must, therefore, be prepared for an average under instead of over one shilling per pound.

To return to the figures for 1887 : The total deliveries of both kinds, for export as well as for Home consumption, were :—

		lb.	
Indian	.. ..	83½	millions
Ceylon	.. ..	10	"
Total	..	93½	"

Of teas of foreign origin, the total deliveries were :—

		lb.	
China	.. ..	119¼	millions
Java, Japan, &c.	..	3	"
Total	..	122¼	"

The excess of foreign over British (the latter scarcely known in the market 50 years ago, and of but small consequence 10 years ago, or even 30 years back) was only the difference between 122¼ millions and 93½ equal to 29 millions of pounds.

With the process of substitution now so rapidly proceeding, so that Indian and Ceylon teas are running China and other foreign teas "neck and neck," we cannot doubt that 1889 will see the British contingent far ahead. We see no reason why our vaticinations for 1889 should not be fulfilled, thus :—

	Monthly deliveries.	For the year.
Indian ..	10 millions, equal to	120 millions
Ceylon ..	2 " "	24 "
Total British ..		144

	Monthly deliveries.	For the year.
China ..	8 millions, equal to	96 millions
Java, &c. ..	291,666 "	3½ "
Total foreign ..		99½ "

Or, say, at least 140 millions of pounds British against 100 millions foreign. Allowing 40 millions for exports, of which 30 millions China to 10 millions British, the Home consumption will probably be :—

Indian ...	...	80 million pounds	
Ceylon ...	...	20 "	"
Total British ...		100 "	"
China ...	...	70 "	"
Java, &c.	...	2½ "	"
Total foreign ...		72½ "	"

From the very elaborate and comprehensive "Tea Market Review for 1887," of Messrs. Stenning Inskipp & Co., we quote on page 554 figures and remarks which will enable our readers to judge for themselves as to the present position and future prospects of the article which has so rapidly and so successfully succeeded coffee as the staple product of Ceylon.

H. A. HERTZ & CO.'S REVIEW OF THE TEA MARKET FOR 1887

is a very convenient broadsheet to paste up for reference, being printed only on one side. For each month of the past year, it gives full details clearly arranged of the position of Indian, Ceylon, and Java teas and the leading kinds of China. The tone of the market for each kind of tea in each month is noted, the public sales of each kind and the lowest quotations for China black leaf and red. These ranged from 8d (only once attained) down to 3¾d in November. This we suppose is the lowest price at which tea fit for use was ever sold, and it could scarcely do more than cover the export duties and "squeezes" to which tea is liable in China. The ruling prices for the year were 4d to 6d, the miserable average for the two kinds named being about 4½d. No wonder though exports from China, once the only source of supply should fall off so largely. In tea specially "the old order changeth, giving place to the new." The rise of Indian tea in 50 years has been great : that of Ceylon tea in a fifth of the period has been marvellous. So that "better fifty years of Europe than a cycle of Cathay," in the tea enterprise as in other matters. We quote the information referring to Ceylon teas :—

1887 :

January : Ceylon Teas.—Teas of good quality, especially Pekoe Souchongs, in active demand at full to advancing rates; indifferent quality neglected and irregular ; public sales Ceylon, 9,291, import [illegible], delivery [illegible], stock 1,763,470.

February :—Ceylon Teas.—Easier tone generally during latter part of month, decline of about ½d to 1½d for Souchongs, Pekoe Souchongs, and Pekoes, and more for all Broken Teas, partly caused by inferiority of quality ; public sales Ceylon, 9,142, import [illegible], delivery [illegible], stock 1,[illegible].

March.—After a further decided decline for all Common and

low medium grades, prices commence to recover. Fine sorts in all limited supply, and very firm ; public sales Ceylon, 11,423, import 746,280, delivery 616,230, stock 2,054,290.

April :—Ceylon Teas.—Prices shew a firmer to improving tendency, most marked for all quality grades of Pekoes and Broken Pekoes (rise of about 1d to 2d per lb.) ; public sales Ceylon, 13,017, import 679,000, delivery 657,420, stock 2,075,870.

May :—Ceylon Teas.—Prices are further advancing for Pekoe Souchongs, Souchongs, Good Medium, Broken Pekoes, Dust and Broken Teas- and Choicest grades, but are weak and irregular for Good Medium to Fine Medium Pekoes and Fine Medium to Fine Broken Pekoes ; public sales Ceylon, 10,444, import 886,780, delivery 779,130, stock 2,183,520.

June :—Ceylon Teas.—Depressed, and marking a decline of 1d to 2d per lb., owing to increased arrivals and inferiority of quality ; public sales Ceylon, 21,541, import 1,230,240, delivery 780,570, stock 2,736,830

July:—Ceylon Teas.—Improve for all teas of character, but remain weak and depressed for indifferent teas ; public sales Ceylon 21,714, imports 1,650,270, delivery 998,590, stock 3,388,510.

August:—Ceylon Teas.—Quality shows decided improvement and prices a further rise ; public sales Ceylon, 25,795, import 1,178,610, delivery 1,341,790, stock 3,225,610.

September:—Ceylon Teas.—Are in strong demand at briskly advancing rates ; public sales Ceylon, 15,274, imports 781,570, delivery 1,197,220, stock 2,809,960.

October:—Ceylon Teas.—Continue in active competition at fully prics maintained ; public sales Ceylon, 13,387, import 815,110, delivery 1,008,950, stock 2,615,980.

November:—Ceylon Teas.—Evince symptoms of weakness during latter part of month, most noticeably in Medium to fine grades of Broken Pekoes and Pekoes ; public sales Ceylon, 13,702, import 872,330, delivery 790,010, stock 2,698,300.

December:—Ceylon Teas.—Have suffered a sharp decline in value, about 2d to 3d per lb. for Fair to Fine Broken Pekoes, fully 2d per lb. for the same grades of Pekoes and Pekoe Souchongs, and 1d to 1½d lb for Souchongs ; public sales Ceylon, 13,089, import 1,193,030, delivery 741,900 stck 3,149,430.

THE COFFEE MARKET.

We give (on page 557) an interesting review by Mrsess. Rucker & Bencraft. In round numbers now, the world's production of coffee for export may be taken at 600,000 tons, or 12,000,000 cwt, of which Brazil yields one half, all other countries supplying the other half. Another 130,000 tons may be added for consumption in producing countries, of which 40,000 may be put against Brazil and 90,000 against other countries growing coffee, chiefly Arabia and North-east Africa. Our calculation in last "Handbook and Directory" was 654,000 for export ; 135,000 for home consumption : total production 789,000 tons. But the yield has since fallen off. The fall from a total of 1,664,000 piculs in 1883-84 to 614,000 in 1887-88 shows how disastrous the results of leaf disease have been in Java as well as in Ceylon. It remains to be seen if with rich soil and compulsory planting, Java will recover her position as a great coffee producer. Poor Ceylon has retired from serious competition. The figures in the Report under review show that leaf-disease has reduced Ceylon coffee crops by one-half in five years, while in the same period the Indian crop has shown scarcely any falling-off.

PLANTING IN MANILA.

(*Translated for the Straits Times.*)

Cocoa trees flourish in the Philippines and have taken kindly to the novel environment, so different from the tropical parts of America, their original home. They thrive remarkably in the Philippine soil, notwithstanding the careless way the trees are cultivated and looked after by the natives. The cocoa grown in the province of Albay bears a high reputation in the produce market, and is deemed to be quite equal to the Venezuelan article. The climate in many portions of the Philippines does not favour its luxuriant growth. With greater care in cultivation and more attention to turning out the product in a marketable condition, this Philippine export article would command wider appreciation and greater range of custom. In the Philippines themselves, the native grown cocoa fetches a high price, and holds its own against the imported article.

EVERLASTING SUMMER IN SAMOA.

We are permitted to publish the following interesting latter, written by a young business man in Samoa to a relative in Southland :—

Apia, Samoa, January 18th, 1887.

MY DEAR ——,—My ——— informs me that you desire to know something about the new land I have chosen to venture my business career upon. It is with very great pleasure that I give you what information I am possessed of. There is a good future for Samoa, but with regard to us, Englishmen, it mainly depends upon what steps are taken for the good government of the Island. At present it is very risky venturing much, but in a few months it is hoped matters will be decided. With regard to timber,—I took ample observations when travelling through the group last year. There is plenty of timber of a very durable nature, and which would be very valuable, but the difficulty of obtaining it is very great. The country is very hilly, and the trees suitable for sawing are not in any large quantites together. They are much scattered. I do not think it will pay just yet. *Re* trade, I found on my return from the Colonies this is at a stand-still. All merchants are just waiting to see how things go. The Samoans themselves are not working, and as the greater part of the business is done with them, you will perceive how it is nothing much is doing. What we want to send the place ahead is settlement. Settlement of a class of people who do not mind roughing it and who have a little capital. There is much wealth in the land. The soil is very rich and all tropical products grow luxuriantly. We have at our disposal some 250,000 acres of this land, and we desire to make some use of it as soon as possible. To encourage persons to try their luck, we are forming several settlements. Settlers are required to have a capital of from £500 to £1000, and at the end of 5 years, providing they fulfil the stipulated conditions, a conveyance of 200 acres (the amount to be allotted), will be made over to them free of cost, except the cost of deeds. In each settlement there will be 10 of these allotments, the rest of the land surrounding will be let under the perpetual leasehold system. I am certain anyone coming will do well. We will arrange for a suitable outlet for all produce. One thing, anyone intending to come must make up his mind for an *everlasting summer*. We have no cold weather although plenty of rain, especially at this time of the year. I do not feel the heat oppressive, nor would anyone in good health. I rather enjoy it. The chief products, which command good markets, are coconuts, coffee, cotton, bananas, pineapples, vanilla, tobacco, oranges, lemons and limes. These are very simply cultivated ; commonsense being the only requisite necessary. I am sorry I cannot offer much inducement for you to come, as I am afraid the heat and roughing would not now agree with you. There is decidedly better openings here for young men than in New Zealand—the only drawback that may occur is what I mentioned before, viz., 'the future administration of the place.' In our business we have every prospect of doing well, but nothing much is done at present. We are forming a sure foundation but slowly. One drawback in our line is the bad money in circulation, and we have a great difficulty in effecting exchanges with the Colonies. This we are endeavouring to overcome. It is expected that the U. S. S. Co. of New Zealand will shortly run one of their boats to this place. This will give a start and help to run the Germans off. The Germans are trying hard to get this place, but the Samoans proper do not look upon them with favour. Enclosed find a photo of my house and place of business. The men are hands we have to employ. You will notice that I have plenty of oranges and coconuts about me. If we had any means of exporting, I would willingly send you some ; they are delicious. We get plenty of fruit, and that is our chief article of diet. The Samoan people are a friendly lot and are very partial to Englishmen—I get along with them splendidly. They are not savages and have no recollection of ever being cannibals, so we are in no danger of ever being pickled.—Believe me, &c.,—*New Zealand Paper.*

THE PLANTING ENTERPRISE IN TRAVANCORE, SOUTHERN INDIA.

[We greatly regret that by an unfortunate oversight the following letter, containing information which we highly value, should have been delayed so long.—ED.]

Olivers, Nagercoil, 4th Oct. 1887.

(*To the Editor of the "Tropical Agriculturist."*)

DEAR SIR,—Unexpected delay has occurred in sending you the statistics of plantation work in Travancore, but I have now the pleasure of presenting them to you for publication. I hope these will become world-widely known, and therefore write some explanatory remarks, which may be useful to those who may be not well acquainted with this part of the globe on which we move.

These statistics do not contain all the plantations in Travancore: those being omitted, on which, owing to the failure in coffee, no work is now carried on.

The estates now reported are divided into four Districts. The *Assamboo* or *Southern* District begins very near the south end of the mountains, about 20 miles from Cape Comorin, and extends for some 25 miles northward. Then a space occurs until about due east from Trevandrum, where the *Central District* begins, and extends to and beyond the pass in the hills, through which the high road from Quilon to Thencottal runs. Then another long space intervenes, and the *Peermade District* is reached. After that, far away in the extreme north and east of this country, is the *Kannan Devan District* on mountains of higher elevation.

ELEVATION.—The Assamboo and Central Districts are nearly the same. Peermade higher. Kannan Devan much higher still.

RAINFALL increases as you go from the south to Peermade; but again is much less on K. D: this being farther from the sea to the east.

CULTIVATION.—In this, the Kannan Devan is newest, and it contains thousands of acres yet untouched. It has very little coffee, and the tea there is but new. The chief cultivation is cinchona. A letter from this district states, that the tea is of too recent a date to have an opinion as to its value, and that the cinchona bark has for young trees shown a good analysis, and that if prices in the market are encouraging, they are prepared to export a considerable quantity of good bark. Until this year, this district had great difficulty in modes of access: but the present Government has sanctioned a liberal grant for roads in reply to an application by our Association.

As to the other three districts, COFFEE was begun in the south by the Grants and Frasers, and others more than 20 years ago, and many entered with hope into this enterprise in all these districts. As in Ceylon and other places, so here, coffee has suffered very much from leaf disease and wind: but it still holds on in some places; and even fair crops have been lately obtained. I do not think that our Travancore planters are so down-hearted as to agree with a cry which I see in your *T. A.* for September, "*Farewell to Coffee.*" We have men still to be found, on the contrary, who face even the difficulties of coffee with the hope, that, by taking due care, this despised article with the revived prices will reward their diligence.

CINCHONA has not been very extensively planted, but it has grown well. I saw a letter lately from a planter in the southern district who has a large acreage of cinchona. He gives decided preference to a good hybrid between *C. Succirubra* and *C. Ledgeriana*, and has been successful in propagating this variety by grafting on succirubra stocks. In this, following the plan of Mr. W. Smith of Mattakellie, he finds that not only tender ends are suitable but even mature wood from smaller branches: any faults in the growth being corrected by pruning. The export of bark has here begun too recently to speak of results, but as to future prospects for cinchona in Travancore, he thinks that the climate and the very tree soil (so very important) unite in giving ground for the hope, that Travancore as an exporter of rich barks has a bright and prosperous future before it.

OTHER PRODUCTS.—I have very little to say of these. Cacao and Pepper are likely to succeed at low elevations, and on suitable soil. The latter has been long known as an export from this country, and was formerly a profitable Government monopoly.

TEA.—Like our brother planters in Ceylon, we have substituted tea for coffee on many estates; and this process is still going on with increasing speed, and well it may with the encouragement already received. The planting of tea here has not yet attained to age and extent enough to enable me to give statistics of yield per acre, but I have full authority to show that the *quality* is really superior, and is already accorded a high place in comparison with the teas of Assam and Ceylon, witness the extract which I gave in my former letter from Messrs. Wilson, Smithett & Co. I have also corroborating testimony from Messrs. Gow, Wilson & Stanton's Market prices. Thus we have in the Central District *Ponmudi* (not Conmudi as misprinted) at 1s. 4d. and in the Southern District *Seafield* at 1s. 7d. prices realized. From *Belford* estate, which adjoins Seafield, samples of tea were sent to Messrs. Arbuthnot Latham & Co., London; and I quote from the reports of two experts who examined the samples:—"These teas are considered the finest that have yet been received from Travancore. The quality is perfect, and they have a most distinctive liquor with bright golden infused leaf, and, as there is nothing to approach them in the market, they would no doubt meet with strong and spirited competition. Valuation:—*Orange Pekoe* 3s. to 3s. 2d. *Pekoe Tea* 2s. 3d. to 2s. 4d." This was of course from fine plucking. From the *Peermade* District, tea has been sold in the London market for the last two years, and the prices have ranged up to 2s. 2½d. A glance through the market prices lists in London shows that the shipments from Travancore sale after sale have fetched prices that compare favorably with the prices realized for all other teas, either Indian or Ceylon.

I cannot but emphasize this fact, and the more so, because this enterprise in Travancore is scarcely out of its infancy.

As to soil, your footnote to my letter in *T.A.* of August indicates the opinion, that the soil in Travancore is superior to that in Ceylon, and there is a freeness in the soil here which is very favorable. As to climate, that of Travancore is well known to be humid: the continuous line of mountains running parallel with the sea-coast and so near to it, confines the vapours, and causes them to charge the air with moisture. And this is very favorable to the growth of tea.

We have a great advantage also in cheap labor, and easy access to ports for shipping, and again we have abundance of wood for firewood and making chests.

From the whole of the above, I can exultingly carry you with me to the conclusion, that, in this enterprise, we can fearlessly compete with the world, and, with the *blessing* of Providence on our work, we can with confidence anticipate a future of prosperity.—Yours sincerely,

JOHN COX,

Chairman, Travancore Planters' Association.

TAPIOCA.

Our food supplies are derived from many widely different orders of plants, bulbs and roots. Among the plants which supply food for man, the manioc, mandioc or manchot, also called the cassava, is a native of the warm regions of America, and was cultivated by the inhabitants of Brazil and Mexico. It has also been introduced into India, and is grown about Calcutta and Madras. It flourishes better on the borders of the sea and on islands than in the interior of the continent. On the coast of Coromandel the roots are more fibrous, and, therefore, inferior to those raised in Malabar. It is extensively grown in Guiana, the West Indies, Straits Settlements, and various parts of Africa.

It belongs to an order remarkable for the prevalence of acrid and poisonous juices, and is nearly allied to the physic nut of Jamaica, noted for the fierce acridity of its seeds. Nor does the mandioc

differ in this respect from its allies, and the juice even of its tubers is very acrid and poisonous. Yet, from the amylaceous stores of these tubers, after the poisonous juice has been removed, is prepared the nutritious and wholesome cassava bread, much used as an article of food in the various places it is cultivated, and also the tapioca, well known throughout the world, and one of the most esteemed varieties of starch.

The root of the mandioc is branched and woody. Its lateral branchlets swell into tubers, which are black externally, knotty and somewhat tapering, and of a great size, sometimes weighing fifty pounds. The rind being removed, the tubers are reduced to a pulp by rasping, or by holding them against a wheel or grindstone the pulp is washed with water, pressed and baked upon iron plates, and now becomes cassava bread; while the starch which floats off in the water, is sometimes imported into Europe under the name of Brazilian arrowroot, but is more generally subject to a process of granulation, by which it becomes flake and pearl tapioca: this is the wet process. The dry process is carried on as follows:—The mandioc is rasped by hand, water added and then put to be pressed; afterwards dried, sifted and subsequently baked. In making the starch, the deposit in the water is left for some time to allow the starch to settle; it is then washed three times, dried in the sun, and is then fit for sale.

Singapore, Penang and Malabar tapioca is put into bags weighing about 110 pounds each for exportation.

No less than thirty varieties of the mandioc are grown in Brazil. There are two principal species (for most of the others seem to be but mere varieties), the bitter or poisonous species, and the sweet species. The root of the latter is reddish and harmless, and can be used, unlike the bitter species, without any further preparation than boiling as a culinary esculent, its starch being also available for tapioca. Rio tapioca is prepared from the fine, creamy starch, by sifting the puba manioc in water, after which it is strained and pressed in a sieve and made into small flakes: the dietetic nature of which is excellent, containing more gluten, one pound being equal to two pounds of the kinds grown in other countries. Rio tapioca is put up for exportation in barrels weighing 120 pounds each, and commands double the price of all other grades.

The poisonous substance of the tubers, which is supposed to be hydrocyanic acid, is completely removed either by washing or by heat. It is very volatile, and although cattle are poisoned by eating the fresh root, yet, if it is cut in small pieces and exposed to the sun, they eat it without injury. It is said that the expressed juice of the mandioc root is one of the substances used by the Indians for poisoning their arrows. A gentleman who has been a resident in Jamaica for many years, gave the writer the following information respecting the Obeah Man: (Webster's definition of Obeah means a species of witchcraft practiced among the West India negroes.)

Some of the Obeah men are very expert in preparing poisons. They have several kinds to be used according to circumstances: one of the worst of them is made from the root of cassava. They express the juice from the rind, and allow it to ferment. Quantities of small worms are soon seen in the liquid, one of which taken into the stomach is almost certain to cause death. One of the worms is concealed under the thumb nail, which is allowed to grow long for the purpose and the operator in handing his victim a cup of coffee or some dish of food, manages to drop the worm into it.

The juice of the bitter cassava mixed with molasses and fermented, forms an intoxicating liquid, much relished by the negroes and Indians. The concentrated juice, known as cassareep, is highly antiseptic.

The mandioc is a woody plant, with slender stalks, and grows to the height of about eight feet. The leaves are smooth, palm shaped. It has small green flowers, which grow in clusters, and it is generally propagated by cuttings. In about eight months after it is planted, the tubers may be gathered.

On a single Chinese plantation near Kwala Lumpor, Malacca, there are over two thousand acres of tapioca under cultivation, and the enterprising Chinaman who owns it has imported European steam machinery for converting the cassava roots into tapioca, which is sent to Singapore for shipment to the different markets of the world. In the appendix to "Coffee from Plantation to Cup," by Mr. F. B. Thurber, page 307, there is a very interesting account of a visit made by him to a pearl tapioca manufactory in Singapore.

An intelligent Floridian told the writer that the cassava raised in Florida as food for live stock is more in quantity than can be produced in hay on the best land in any Northern State, that it contains more nutriment than either timothy or clover. Its roots are used by natives for puddings, it is adapted to the poorest soil, and is always welcome as food for cattle.

A man who has tried cassava raising, says:—"Enough can be raised on five acres to fatten from 75 to 100 head of cattle for the market, and they will be as finely flavored as any Ohio cornfed stock. Hogs like it, and fatten on it rapidly, and it seems to be admirably suited to table uses, as a substitute for the white potato. A factory to manufacture starch from the cassava was started, but was not a success, not having suitable machinery, and the cost of freight being so great as to prevent it being sold as cheap as the starch made from corn."

Its method of cultivation is not difficult. It should be planted in hills four feet apart, so as to be worked byharrow both ways. Deep cultivation will not answer, as it interferes with the lateral roots, which are a foot or more in length. It should be planted in February or March, having been cut in lengths—the tops only—of two or three inches, and covered about four inches below the surface of the ground. There will be about 3,000 hills to the acre, and, as each hill will yield probably fifteen pounds, the product would be 45,000 pounds—over twenty tons. This will fatten three sets of 1,000 cattle each, during a single year: the net profit on which would reach about $10,000. In the West Indies it is dried and ground into flour, and is the staple article of food for the whole population.

The large amount of gluten that is in the starch made from the cassava root has not escaped the attention of manufacturers of floor oil-cloth, who use it very extensively as a filling.

Tapioca is recommended to the convalescent as being easy of digestion. It may be used in soup or broth, or mixed with milk or water or butter. It is excellent food for either the healthy or sick, for the reason, that it is quickly digested without fatigue to the stomach.

HOW TO MAKE A TAPIOCA PUDDING.

Ingredients—Four ounces tapioca, one quart milk, two ounces butter, four ounces sugar, four eggs, flavoring of vanilla, lemon or bitter almond. Mode of making:—Wash the tapioca, and let it strew gently in the milk by the side of the fire for fifteen minutes, occasionally stirring it; then let it cool a little, mix with it the butter, sugar and eggs, which should be well beaten, and flavor with either of the above ingredients, putting in about twelve drops of the essence of almond, vanilla or lemon, whichever is preferred. Butter a pie dish, and line the edges with a puff paste; put in the pudding, bake in moderate oven for one hour. If the pudding is boiled, add a little more tapioca, and boil it in a buttered bowl an hour and a half. If the botanists have classed the tapioca of commerce under different names, the merchants in New York City have not been slow to follow their example. We know of four differnt firms who put up their packages as ground tapioca, mandioc, cassava, glutena and manioca.—*American Grocer.*

IRRIGATION IN AUSTRALIA AND THE MESSRS. CHAFFEY.

(AN INTERVIEW.)

Said Bishop Barry to me a few days ago, "I can conceive of no nobler act of philanthropy on the part

of men of wealth in the colony than the establishment of small and permanent communities in the back country." The Messrs. Chaffey are about to establish just such a community as the bishop indicated, though not, it is scarcely necessary to say, out of motives of pure philanthropy.

Everybody has heard of the Messrs. Chaffey by this time, and, instructed by local experiences, have pictured to themselves magnates or millionaires, ostentatious and gorgeous in appearance and retinue, as broad in projects and promises. It is all a mistake. The two Canadians are distinguished only by the assurance of reserved power and the dignity of quiet knowledge. They appear to be hard-working, simple-minded men, with a single eye to their own business. Having completed their arrangements, they are perfectly willing to talk to a friend, or through a friend to the] public of what they intend to do, and how they propose to set about it, and even to go back so far as how they began to think about it.

"I find that our International Exhibition was the first attractive power?" "Yes," says the elder of the brothers, "we read about your exhitition, and then we began to think about your country and our partner, Mr. Cureton, came over to have a look at it. He spent two years, chiefly in the saddle, rode a good deal, and remembered most he saw, and told us so much that we came out. We looked about too; did not go into anything blindfolded."

"You had a fair knowledge of all the colonies then?"

"Yes; we had looked into most of them, and we liked Victoria best, and Mildura the best in Victoria."

"If one should ask why?"

"The style of the people suited us, and the Mildura land seemed about the best we had seen—the best for us. Most people, I daresay, take all mallee country to be alike. We think—of course we may be wrong—that Mildura is just a little the best of it, and the water supply is grand. They would be proud to see such a river as the Murray in California."

"The people vexed you some, though?"

"Some of the people, yes. It was not all square work, but that is all over now. The whole affair is figured out and signed, and we are ready for work."

"You start at once?"

"We do."

"Without any visits to America or Europe."

"Without any visits to any place outside Australia. We shall start for the country in a week or two. We shall expect to have 200 men at work within a few weeks. We have already arranged for bricks to be burned in kilns of 500,000 each. We are getting estimates for pipes and conduits. We shall very shortly import two traction engines of 16 horse power each. They will follow the mullenising of the mallee; stump grubbers something like your steam ploughs will work on cables between the engines, tearing up everything; the stumps we shall gather together for fuel, and the land will be clean, tilled, and deep broken before anything is put into it. A wheat or corn crop may go in first. The land is always better for planting fruit trees after one crop."

"What kinds of fruits and other crops will you chiefly depend on?"

We shall mix them carefully. Grapes for raisins and currants will be a first mainstay. You import a good many raisins and currants, and pay a good deal of money for them; we want some of that money. Then, in tinned fruit, £55,000 these colonies paid for tinned fruit only last year; £55,000 will pay for a lot of labour and machinery. And the three-quarters of a million sterling which all the colonies pay for all kinds of fruit may all be earned here by men who know their business, and the value of land and water and a perfect climate."

"The climate down the Murray is good?"

"For fruit-growing it could not be better. I think it is better than the climate of Southern California. There are not the same abrupt changes in every 24 hours. The fruit should mature better."

"Then you begin to a certain extent with ordinary cereals—wheat, oats, maize; you go on to fruits—grapes, peaches, apricots, and tinning fruits chiefly. Do you propose to cultivate any other products?"

"Yes, many others; sorghums of various sorts, Egyptian corn, tobacco to some extent, cotton by way of experiment, fibre plants, too, of all sorts. We have promised to set off and maintain a 10-acre block for Mr. Guilfoyle for experiment in that way."

"And do you expect to do any trade in fodder, with squatters in the north?"

"We shall expect to do a good deal. We shall be prepared to supply food for stock cheaper than it has ever been grown in Australia before, and it should pay them to buy it."

"As to the class of labour and the manner of settlement you propose to establish, what can you do with a new arrival, say a man with a wife and a couple of children, and about a £10-note in his pocket, and what will he do for himself by-and-by?"

This question led to a lengthy explanation. Mr. Chaffey said they would always, in selecting labour, give preference to a man who would be likely to become a settler. He might take a 10-acre block at once and spread his payments over 10 years. He could begin to work on it in his spare time. If, after a year, he felt able to stand on his own legs, they would lease or sell him more ground, supply him with water for a first corn or hay or wheat crop, take the rent out in produce, provide storage and transit for the balance, and make an advance till it suited him to sell. He would not make anything from his fruit for three years; after that, profit would come in fast.

"How fast, and what might he ultimately expect?"

"In the tenth year on our last estate our tenants sold raisin-making grapes on the vines for 215 dollars an acre."

"That is, to say, 2,150 dollars, or £430 a year from 10 acres of irrigated vines?"

"Yes. But there is another class we shall try to accommodate. There are lots of people doing pretty well in town who would like to have an interest in the country. We will sell them land on terms, will engage to clear, plant, and irrigate it for them, and hand it over at any time with 95 per cent. of the trees growing. We shall expect to do business with a lot of people on these lines."

"And as to the bulk of your country, the great balance of your 250,000 acres?"

"We will sell it or lease it to any men, or companies of men, who will engage to fulfil the conditions we have made with the Government, and we will supply them with water as they require it."

"And, now, Mr. Chaffey, to get a clear idea, or rather to give the general public a clear idea of what they may expect from this venture of yours, will you try to realise what sort of conditions should be in existence on your Mildura station five years hence?"

"Mr. Chaffey's habit is rather to plan for than to picture the future, but judging of the future by the past, he would expect to see at Mildura in five years' time, a compact settlement of at least 500 souls, well provided with all the necessaries and most of the luxuries of civilisation,—church, school, and agricultural college should be in working order. Ten thousand acres should be in fruit trees and general crops by that time, and how many more communities round our own will depend, of course, on the measure of our success, and the capacity developed amongst Australians for imitation."

"You feel sure of success?"

"We are putting our money and time and experience into the thing; we are going to settle down there right away, and, besides that, we have tested, weighed, figured everything right out. We have had analyses made of the soil, compared them with the results of analyses made of soil from successfully irrigated colonies in America. We know there is more than enough water, and fuel near by, that will lift it for us at a rate that is scarcely to be taken into account, a climate that cannot be beaten, and as to the market?"

"Aye, the market?"

"That is the last thing to trouble any man, who has gone deep into the matter. I have told you (your own Customs returns told me), that you import now £750,000 worth of various fruits in

With the natural increase of population, and the education of taste, afforded by good and cheap commodities, you will double that quantity within 10 years, though I can hardly hope, that we alone shall be able to supply you with such an amount in 10 or 100 years. A million and a half a year is a bigger contract than we ever reckoned on. But take others into the reckoning. Suppose you go in as big as California, is not the world open to you? There are a million and a half acres of vineyards and fruit gardens in California now, and fruit is a better price than when the first acre was watered. I expect to see a million and a half acres tilled on the Murray before I die, and have not the slightest doubt about the market. There may be a glut—a glut almost always precedes the opening of the best market for any produce—but there is no doubt whatever about the sufficient opening being found, when it is properly sought. Do you know anything, about preserved apricots now? Do you know that an apricot properly dried, not boiled or made into jam at all, undergoes such a chemical change, that all the mawkish sweetness of the ripe fruit is changed into a pleasant acid? The fruit properly treated, will keep for years, and cook as well as on the day it was gathered. It is the most pleasant and one of the most powerful anti-scorbutics, known. Bring that fact home to the navies of the world, and you can keep on with the the planting of apricots. But really there is no fear or doubt about the market. Your market is the world, and when the world is glutted you may stop your taps and hoes but not before."

"Then you really believe that irrigation colonies may go ahead on as solid a basis and with as fair a promise in Australia as in California?"

"I do. I am going out to Mildura now with my family to make myself comfortable, and to work; to spend money and to make money; and before I die I shall expect to see the present population of Victoria doubled by work done in and in connection with irrigation colonies alone. The mallee country is all good. The limit of cultivation will be the limit of cheap and adequate water supply. I have no doubt that a million and a half acres might be tilled and watered on the Murray alone: the average of labourers required for such work being one to ten acres. That would be 150,000 men; how many do you keep now, and how many women and children do they keep company with?"

And as to our other rivers, "you must remember that you have but one Murray, but there are opportunities enough on all your rivers, you have done a little work on them already, not much, because you did not know much about it, but still it seems to have paid. And on the Murrumbidgee, Lachlan, and Darling, there are opportunities, but the expenses would be heavier. There is but one Murray."—*Australasian.*

INDIGO.

The Editor, *Dyer and Calico Printer*, has received from Mr. Olpherts a few notes on his process of manufacturing indigo, which are as follows:—

First.—The plant will be put into the vats free from the sand and clay which adhere to the lower part of the stems.

Second.—The plant will be steeped in as fresh a state as it can be. We are told by the best authorities:—"When the plant is beginning to blossom, it is fit for cutting; when cut, great care should be taken to bring it to the steeper without pressing or shaking it, as a great part of the beauty of the indigo depends on the fine farena which adheres to the leaves of the plant."

Third.—The "subsequent treatment" to which Professor Church alludes is the washing or scalding of the exhausted plant in the cases, to obtain any colouring matter that may remain in the plant.

The water in which the plant has been thus washed, &c., will form a natural yeast when put into the water in which other plants will be steeped. A yeast which has been long wanted to create rapid fermentation is thus provided with the double economy described.

Fourth.—It will be convenient to be able to carry the plant short distances in these cases by coolies, and over places where it is difficult to transport it, and in moving the plant from boats on to carts and the reverse, which generally occasions a great loss of leaf.

Fifth.—A vat of 25ft. × 16ft. will require about fifty cases measuring 3ft. × 2ft. 6in. × 2ft., made of strong galvanished wire, their end to be of cord netting, the mesh to be ½in.; such a case will weigh about 8lb. including ventilators, &c. The weight of the cases for a vat of the size named will be about 400lb.; their cost will vary from 2*s.* to 5*s.* each. It takes some twenty-two country cart-loads of plant to fill a vat of the size named; the load is supposed to weigh from 5 to 7 maunds, or 4 to 5 cwt. The difference between the weight of the stems of the plant left in the fields from which the colour-producing parts of it have been cut, and the weight (400lb.) of the cases, must be a very variable measure, and can only be judged of at the factory.

Sixth.—Objections are taken to my plan. Some say that if they were to work my plan, they would not fill their vats, as at times (owing chiefly to the difficulty of getting carts and coolies to cut the plant, a work the coolies hate) they find it hard enough to do so at present. The answer to this appears to be—So much the better for the proprietors, as then the expense of carting, loading, watering, unloading, beating, heating, &c., will in a great measure be avoided. What is the use of incurring this unnecessary expense, except to show in the manufacturing reports that the vats were all filled, and that no more could be done, the produce being wretched? Then why fill and waste so many vats of your plant, which, by my plan, can in a great measure be avoided, as shown in Professor Church's report? Nevertheless, they will have had the power of manufacturing far more of their crop by adopting some such change as I propose.

On the subject of manufacturing charges I said *they* could be reduced to 50 per cent. I have referred to the estimates for the year 1884, approved of by the Agents for the Begum Serai and Khan Mirzapore Concerns, in which I was interested, and find the items R14,312 entered as manufacturing charges for the Begum Sirai factory, and R11,163 for Khan Mirzapore. These items are made up of the cost of the different processes I have named, and the cutting of the plant and press-house expenses; 50 per cent saved on these amounts represents a large sum.

Real objections can be raised to my plan, where men do not grow the indigo they manufacture themselves, but buy it from the natives who grow it for the factories. There will be difficulty at first in getting the native cultivators to cut *their* crop different from the way their fathers cut it; but when the advantages of my plan are known, these difficulties will disappear, when it is seen that it will *pay* all concerned in the industry to adopt them, particularly where second cuttings are unknown—for instance, in the N. W. Provinces, where the indigo manufacture commences about the end of July, and ends about the 1st of October. If they try my plans, as some intend, they will find they can manufacture their indigo in about the third of the time (when assisted by women and children, the crop will be run over very quickly, at present men only are used for this purpose; the stalk can be cut down when from rain or other causes men can be spared) it, now takes, which will give the indigo time to sprout and give second cuttings. By heating judiciously, the manufacture can be carried on while there is plant to cut.

In many places this late manufacture will not interfere with the preparing of the lands. In proof of the advantage of being able to heat the water with ease, and which will be still more easy when the quantity is so reduced by my plan, Mr. E. M. Macnaghten, then the Manager of the Regum Serai Concern, wrote to me on the 29th September 1875. "Produce to-day: heated, 4 vats; produce, 1¾ presses; unheated, 2 vats; produce, 2 dongas; about 500 per cent. of the heating process."

The indigo ought to be steeped in water, at least the temperature of the plant when it arrives at the vat. This prevents it being chilled, which checks fermentation.

The only change necessary to effect the advantage of being able to heat in the same vat we steep in, is fitting the steeping vat with a vent similar to the vent in the beating vat, so that the steeping vat can be used as the beating vat for the liquor. When the cases containing the plant which has been steeped in it have been removed, the cost will be that of the vent and the setting of it in the wall. The beating vat does not require any change.

My estimate of £20 per vat for this and the cases described will leave a margin that will pay for the charges I propose, namely, that of the *mal* boilers and table, or nearly so.

Steeping the plant in the cases I employ for so many purposes in addition to those named, is that the *ceete* can be sent without removal or loss in the return carts to the fields, so that the nuisance of the *ceete* heap at the vat is avoided. The plant cannot be equally steeped without the cases. If the plant is over-steeped, the colour is injured, and if not sufficiently steeped there will be a loss of colouring matter; in either case one or other is inevitable and inflicts a loss to the factory which under the present system is unavoidable.

Another advantage in my plan is that at least the same quantity of the colour-producing parts of the plant can be steeped in about one-third the depth of water required by the present system. This great reduction in the depth of the liquor to be beaten ensures its being better oxidised than when a greater body of liquor has to be acted upon; and when the prejudice to the use of chemicals ceases, it will be an enormous saving of such chemicals, whether used in the steeping or beating vats.

The boiling of indigo is the preserving of it, as is the boiling of fruit, &c., and if the invariable rules for cookery, *i.e.*, to skim off the scum or foreign matter which is thrown to the surface by the action of heat is not observed, the colour and purity of the substance so neglected must be deteriorated. There is no loss of colouring matter attending the skimming, as the stuff thus removed can be put in the *mila* or elsewhere.

The system of the boiling of indigo is thus described by the late Mr. Cosserat, of the Burhogah Factory:—"The scum is thrown back into the body of the stuff, by the application of cold water on to the boiling liquid, when the process is supposed to have been finished!! In fact, after taking the trouble to separate the dirt from the *mal* by boiling and bringing it to the surface, we take the further trouble to mix it up again by precipitation, after boiling, instead of removing it whilst we can by skimming."

I have a small sample of cloth dyed by Messrs. Wilkinson & Co., indigo refiners, &c., of Church, near Accrington, from the stuff I took from the waste water from the table. It is a fine sorrel green and much admired. It is a fast colour, having been dyed in 1882. Having my boilers and table, there will not be any trouble or expense in recovering this stuff in considerable quantities from the table or *mal* boilers, it having been boiled.

Mr. Wilkinson wrote to me on the 16th of October 1882:—

"I have made a trial of the stuff you sent to me in a small bottle. I find it is composed of the very materials which spoil the pure colour of indigo, &c. I venture to say if you can take out this scum, you will, to a certainty, produce a far purer indigo blue," &c.

And, later on, Mr. Wilkinson wrote:—

"I see no reason why the result you are aiming at should not meet with complete success. If it does, we shall then get far purer indigo, which would be a saving to the consumer twofold—first in carriage; second, in having to separate and taking it out afterwards," &c.

The late Mr. Cosserat, writing to me on the subject, said:—"The dirt you found on the *mal* table water can only be separated from the mass by boiling long kept up, &c. If such be the case, the thing is to arrest this dirt whilst it is floating about in the water, before it has time to settle on the fecula on the table. The question is how this can best be effected," &c.

My plan for pressing indigo without sheets, except at top and bottom strainers, which I practised at Khan Mirzapore throughout the season of 1881, without failure or trouble (except from the bad workmanship and material of the presses), the security against the breaking of the blocks, and being able to know by the trial plug set in the side of the frame or cylinder is thoroughly pressed throughout to the centre without having to take the pressure off, and the enconomy of labour (by the introduction of my antifriction conical rollers) in the actual pressing—as any two coolies can complete this part of the press-house work, which at present takes eight or ten at a small factory—the saving of the cost of sheeting and the loss of indigo in various ways connected with sheets, &c., must be considerable.

I had three pressings in a day of twelve hours from one press (an hydraulic press), which was constantly getting out of order. Were it not for this, and their cost, they would answer. When presses are made such as I have described, in which the pressing can be completed with ease in five hours, at from £50 each, according to size, which they should be made for, if ordered in numbers of not less than six, their cost may not be prohibitory.

Mr. Cosserat was so pleased with one of my antifriction roller presses, that he had another made at Messrs. S. Owens & Co., Whitefriars Street, in 1882, when I sent one of an improved make to Khan Mirzapore, where I hear it is highly approved of.

Mr. Cosserat wrote to me respecting these presses, which have now vastly improved:—

"I will, however, briefly mention two good points—1st, the facility with which a block of indigo can be cut into cakes without the terrible amount of breakage, which all practical planters in the district of Tirhoot, Sarun, and Chumparun complain of; 2nd the saving of the loss of dye caused in various ways through using sheets as at present," &c. When the arrangement of fitting the steeping vat for the double purpose of steeping and beating is made, the indigo recovered from the waste water must be freer from impurities than that made by the ordinary process. The indigo made by Mr. Filgate at Shapur Mircha, from the waste water chiefly, I believe, on the last day of his manufacture—was made under extreme difficulties, hence the remark made by Professor Church in the seventh paragraph of his report. I am sorry I had not any of the stuff I made from the waste water and from the table and *mal* boilers to give to the Professor. This subject is of such magnitude and importance to all concerned in the industry, and to the dyeing and colour business of the world, that it deserves the attention that will be given to it. My plans apply to the system of obtaining colouring matter from the plant by decoction, as well as by the fermenting process, or whether the heat necessary for the manufacture be had by the direct or combined action of fire, steam, or solar heat, of which latter we may expect to learn more. No skilled labour beyond that employed at indigo factories in general is required to work the changes I propose. I have only given a few short extracts from the many letters I have in my possesson from practical planters, and have no authority for giving them.—*Indian Planters' Gazette.*

PLANTING IN UVA, CEYLON.

COFFEE—TEA—STONE FRUIT.

20th Jan. 1888.

The weather now in this district is delightfully bracing, air fresh and keen in the mornings and evenings, and moderately warm and bright throughout the day, a great contrast to last month, which was one continuous drizzle. Green bug is still bad, but I think there is less of it since the rain ceased. Opinions

differ however on this point. Have you ever examined this pest under a microscope? If not, do so; it is worth while. The prospects of crop are fairly good. I do not think, however, that many estates will do quite so well this year as last in the matter of coffee crops. Coffee stripping, for some reason or another, appears to be much less prevalent throughout the district than last year, perhaps because there is less of it to strip. The acreage of tea has been largely increased recently, and this product gives every promise of being a success financially (as a rule), and it will be still more remunerative when the railway reaches the Pass. I do not suppose there is a single "featherless biped" as Carlyle would say (black or white) in Haputale who does not approve of the broad-gauge scheme. I at least never heard of him. I expect that we shall have an enormous crop of stone fruit here this year. Plum and peach trees are covered with blossom, the plum trees especially are a sheet of white bloom. Last year an estate in the district produced excellent pears, literally by the hundred-weight*. Fruit culture is no doubt at present very much neglected in Uva, but with a little attention and some attempts at cultivation, I am confident that nearly all the English fruits would flourish here and would pay handsomely in the event of the railway coming. Someone should introduce cherry trees: they would, I am sure, do well. Are English fruit trees to be obtained at Hakgala? If not they should be obtainable there.

CEYLON UPCOUNTRY PLANTING REPORT:

EFFECT OF DRY WEATHER ON TEA—"ABNORMAL ACTIVITY UNDERGROUND"—UBIQUITY OF LEAF DISEASE ON COFFEE—AN INQUISITIVE CORRESPONDENT—HOW TO GROW COFFEE: 'NATIVE' OR 'PLANTATION' FASHION—THE WAY TO MAKE ESTATES PAY—A GOOD YIELD FROM A YOUNG TEA ESTATE—A WONDERFUL TEA MAKER.

23rd Jan. 1888.

It will soon become as nice a question as our future firewood supply what we are going to do with our labour, if the present dry weather continues very much longer. Short work can tide us over a little, but the intervals between every round have to be longer each time, and even with that the average pluckings are getting less and less, and point clearly to ceasing altogether. A shoot that is willing to grow gets checked at once by the cold wind, and "bangy" is all you get from it. While we sit and wait for the renewal of fresh life and the rush of flush, we may get some comfort by concluding that during these early weeks of our "tropical winter" the plant is being strengthened in its roots. Anyhow, that was how I saw it put in a V. A.'s report on a tea estate. He was evidently anxious to be as cheerful as adverse circumstances would allow. There had been little visible improvement during the past six months, he said, but this was to be accounted for by an abnormal activity underground! The report was intended for a home proprietor, who, it is to be hoped, looked on the backward condition of his property and the steady increasing expenditure, in the light of the philosophy of the immortal Micawber, that of going back as it were for a little so as to get a better spring.

Whatever the weather is doing for tea, there can be no doubt that it is suiting leaf disease all round. Our scientific authorities have been assuring us of late that we might look for our coffee being attacked by leaf disease in a milder form, and until this present outbreak it certainly seemed as if their forecast were to come true. But the attack that is on now is as bad as the worst I ever saw, and is all but ubiquitous. Even a struggling sucker on an old coffee stump has germs enough to inoculate a continent. In these degenerate days the coffee on this side has certainly not much to boast of in the way of wealth of foliage, and the shabby mantle of green that there is is fast being lost, and in a short time the trees will be leafless: our hopes for "next year" in regard to crop are therefore rather cloudy, and fall very far short of wishes.

While on coffee I am reminded of your correspondent "S." who seeks through the *Tropical Agriculturist* some information on the question as to whether it would be more profitable now-a-days to grow coffee in native or plantation fashion.* He wants the subject considered under the following heads:—

a. The cost of growing and cultivating the two.
b. The cost of picking and preparing the crop on kinds. the market.
c. The difference in prices between the two kinds, and the scope of the markets to take them up.
d. The cost of upkeeping the two kinds of estate, with consideration of their lasting and productiveness.
e. As to whether disease affects each to an equaly extent.

That 's a pretty big order, and would want a treatise rather than a portion of a letter to answer it. It has a strong likeness too in its comprehensive nature to the inquiry put by a young lady to her partner in the pauses of a quadrille "What is your opinion," she earnestly queried, "on the education question of England, Scotland, and Ireland?" To attempt to answer "S." in any kind of fulness is not to be thought of, but since you, Mr. Editor, ask me what answer would I give, it is in short this: If your correspondent can get coffee *to grow well*, either native or plantation style will reward him handsomely. During the palmy days of coffee I never heard of a European growing the plant except in the approved plantation fashion. What the native style would have done, had the ground been kept clean, could only be conjectured by patches here and there, too stony to hole, and in which "monkey-sown" plants came up of themselves. Such patches I can remember on several estates, and they certainly did well, but were less regular in their bearing than the highly cultivated portions.

The several standard works on Coffee-planting will give your correspondent all the exact information he is in search of, and very much better than I could. Today, the coffee owned by Europeans, —native patches having all but died out—has reverted pretty much to a state of nature, except that weeds are kept down. Bullied and worried by the twin plagues of bug and leaf disease, he is a brave spirit who would expend money in ought else than gathering. By-and-bye, if coffee lasts, we will get to some kind of idea how a *laissez-faire* policy remunerates. I know of one man who, after much painful experience in the varied fields of tropical agriculture, has come to the conclusion that the only way to make estates pay is not to spend money on them! There is a good deal of hidden wisdom in that policy, but it wants a smart man to successfully carry it out.

The Hantane side is looking up as a tea district. What do you think of 252 lb. an acre from young tea from 2½ to 3½ years old? This has been got from one of the new clearings on the "Hantane" estate. [Capital!—ED.]

What the proper qualifications of a tea-maker should be evidently wants some clearing up. One man who applied lately for a vacant post offered as a testimonial a certificate of his efficiency as a volunteer, signed by the gallant Major who commands the Kandy Company! Another, who said he had had considerable experience in several factories, was asked what sort of prices had been

* Why not supply the Colombo market.—ED.

* This letter and some further information on its subject will be found on page 545, and see also page 553—ED.

realized for the teas he had made. He paused ere he replied, then beginning with dust he quoted R1·75 as his figure! He was engaged at once as a very likely man, and out of mercy for his immortal soul. Think of the sublimity of lying he would have attained to had he been encouraged to quote for every grade! PEPPERCORN.

[This is better than the Dimbula man who gave "81" as his average (as a batsman), on which an Ambagamuwa visitor supposing the only talk of planters was *tea*, remarked "and a very good average I call it!"—ED.]

COFFEE AND SLAVERY IN BRAZIL:—No. II.

SLAVE MANUMISSION LAWS AND THEIR WORKING—PLANTERS VOLUNTARILY ARRANGING TO FREE SLAVES AFTER 1890—THE "POOR WHITES," "THE FREE NATIVES," AND IMMIGRANT COLONISTS IN BRAZIL.

In my last I mentioned that there was little likelihood that the production of coffee would be lessened by the want of land to fall back upon, or through the old districts being worn out from exhaustion, or from attacks of disease, either at the leaves or roots of the coffee trees.

What may in time affect it is the *labour market*. We have all of us for years expected that the collapse of this was to be the great calamity from which all agriculture in this country was to suffer. The vitality of the institution of slavery has been strong beyond the expectation of the slave-holders themselves, but it cannot now survive for long. I fear it will go before they have had time to think of how the forced labour is to be substituted.

In 1871 a law was passed, by which the children of slave mothers were to be free if born after the date of that law, 28th September 1871. This is called the "Rio Branco" law after the minister who carried it through the Houses of Parliament. *Born free* was understood to mean that they were to be slaves to the master of the mothers until they were 21 years. The mother could be freed by buying her own freedom, but the children could not without paying the master for the estimated value of their services up to the age of twenty-one years. An Emancipation Fund was to be started which was to be supplied with funds from the proceeds of taxes relating to the holding and transferring of slave property. It was thought that through the action of these two fundamental conditions of this Rio Branco law slavery would rapidly decrease. Somehow or other, little difference was observed, the Emancipation Fund did not do a great deal owing to the high price fixed for those who were chosen to be freed and to the small amount available to effect the purchases. After this had worked for some years, it was seen that unless a law were passed fixing the time when there would be no more slaves, the old system was to continue a blot on the national escutcheon for a longer time than was consistent with an advanced civilization.

In 1885 a new law was passed, the fundamental principles of which are that slaves were all to be registered, their age stated counting at the date of the passing of the law, 28th Sept. 1885, and a fixed value put on each according to age. The values are £100 for under 30 years, £90 for under 40, and £80 under 50; those above 60 were declared free on condition they work for three years for their master; those above 65 were declared free unconditionally, but the District Judge was to decide if these were able to work for their living. If they were not their master was bound to keep them, allowing them only such work as they were able to perform.

An end was to be put to slavery altogether by deducting so much from the registered value each year, until in thirteen years from 28th Sept. 1885 the slave would have no value whatever. The law, however, does not say that there shall be no more slaves in Brazil after that date, and although the Government were pressed to put in a clause to this effect, the question was shirked by stating that the Emperor could issue a decree declaring all free at that date. No doubt this will be the case.

I may state that for females 25 per cent of the above value is deducted. It was also stipulated by this new law that the Emancipation Fund was to be assisted by an extra 5 per cent on all taxes at present collected. One-third of the produce of this tax, however, was to go towards introducing European immigrants.

The valuations of those freed by the Emancipation Fund were to be taken from the registered table of value according to age. Slaves who had not been registered before the 31st March 1887 are declared free. The action of this latter clause shows that there must have been a great many not registered, for, although the returns are not received from all the districts of this widely-spread Empire, those which have been sent in show that there are some 40 per cent fewer slaves than the former registrations under the Rio Branco law warrant, that is to say, instead of 1,000,000 slaves in Brazil there are about 600,000. The reasons for this difference some account to deaths not having all been registered, to voluntary emancipations not having been notified to the authorities, and to some masters having intentionally left slaves out of the new register to let them have the benefit of the omission for freedom's sake.

The question, however, is not to be left here. The enlightened planters of the Province of Sao Paulo are taking the lead, and are voluntarily freeing their slaves on the condition of working until the 31st December 1890, associations are being formed amongst the planters having this for their object. These benevolent ideas are spreading into other Provinces, so that supposing there may be no alteration in the law these voluntary efforts will have such an effect on public opinion that the *escravocral* will be by 1891 a non-existent individual. This long digression on the subject of slavery was necessary before I could enter into the labour question or the future supply of labour.

The transformation from slave to free labour is undoubtedly a most important subject for Brazil. It seems to be admitted that the freed slave will not work much for his former master. One however would expect that those slaves who are now being freed voluntarily by their masters on condition of three years' work will not be so ready to leave the old estate as those who will ultimately be freed by force of law.

I find that those masters who are exercising their benevolence in this way are also doing their best to prepare the slave for freedom by giving him a piece of land to cultivate, and seeing that he does cultivate it. Perhaps the slave works five days a week for his master, the sixth day he works for himself, the produce goes towards buying clothes or any extra expense beyond food, which his master supplies him with and they are encouraged to *save* the rest. Some go so far as to allow them to marry and settle down in a small house which they build themselves. If all owners of slaves were to do the same as these, many of the slaves would settle down on the old plantation.

It is not expected that the "poor white," as one may call the present free labourer, will do more to assist the large farmer than he does now, which is practically next to nothing.

The free native of the country will only work as much as keeps him from starving; if he do consent to work for a farmer, he will submit to no rules as to the regular carrying on of the work, and he will work only the days or parts of days which may suit his fancy. If told even quietly of a fault, he will leave regardless of being paid for the time he has worked. The law will protect him in demanding his wages, supposing he leave in the manner I describe. The wages of these men, if for a less [illegible] is 1$ to 2$ per day and their food. There are exceptions amongst those who work by the month. Some are engaged by the month [illegible] per month to work every day except Sundays and saints' days, others per contract month [illegible] —this is really service by the day, so much for every

30 days or according to the number of days worked same as your coolies, but there is no law to protect the employer. The labourer can leave when he likes, and can demand his wages up to the time he has worked. The wages run from 30s to 40s per month and food for the former and 40s to 50s for the latter; 20s to 25s more will be given to those who buy their own food. An able-bodied negro will do as much as two of these.

We may calculate that the wages of a labourer will not be less after slave emancipation than it is at present—that will be equal to from £2 10s to £3 10s per month for men—at present free women do not work, and I do not expect they will be trained to do so in the future.

It is from subjects like these and from the freed negro that the much talked of "transformação de trabalho" transformation of labour, is to be effected—a task which agriculture on a large scale—*roura grande*—will find very difficult indeed.

The newspapers are filled with schemes for calling native labour to work. There is no doubt a large element of free native labourers spread all over the country, and could wise legislation induce it to leave its patch of corn, beans, mandioca, and pumpkin with a bamboo and grass covered hut in the middle of it, the agriculture of the country could be saved. It is not, however, to these two classes, the freed slave and the Portuguese—Indian desendant—that the advanced intellect of the country is for the most part directed, but to the European colonist. In the Province of São Paulo for the last few years considerable sums have been spent by private individuals in introducing families from various countries of Europe and setting them on large coffee plantations. The pioneers in the schemes lost money owing to the inferior class of people whom the emigrant agents sent out. Many fazendeiros persevered, however, and got a better and more orderly set of people, and every encouragement was given to families already settled to bring out their relations. A great many of these have come from Portugal, Italy, the Azores, Madeiras, and Cape de Verde islands. There procured from districts where agricultural labour is poorly paid, many of them are simple in their habits and in time they settle down contentedly to work. Those who have been settled on the large plantations have had their passage money advanced to them, and a house to live in on their arrival. They do not work as day labourers, but have so many thousand coffee trees allowed to them to give so many, generally five, weedings a year and to pick the crop. They are paid for this by the thousand trees if the coffee is not giving a regular crop, and by the bushel of cherry coffee picked, if in good bearing coffee. Some planters give them half the coffee from the trees which they treat, that is to say half the value of it, the planter taking the other half. In addition to this the colonist receives a piece of land in which he can grow whatever he likes, which are generally corn, beans, rice, mandioca, potatoes of various kinds, cabbages and all sorts of kitchen garden produce. These he sells after supplynig his house and domestic animals with food.

It is a trying time to the colonist for the first six months until he can have a crop from his own small farm. We has to receive advances from the planter, and the latter is unwilling to give much owing to many going away leaving debts unpaid. To the steady-going family, advances may be given to buy a cow, the climate being mild, the stock of clothes he brings from Europe serve for some time. His difficulties may be said to appear after the first year, by degrees he repays all his advances, and then lives a comfortable life. That these colonists do better here than they would have done in the country they came from does not admit of doubt. That coffee planting will pay at the rates paid, or proportion of produce allowed, to the colonist at the prices the bean has been selling it during the last few years, there can be no question, for this system of improving the labour market has been adopted not only by private planters but by Associations. The Provincial Governments are now assisting by giving bonuses to planters for introducing them.

The new slave law, as I have mentioned above, takes the system into consideration by allowing a third of the extra 5 per cent on all taxes to be given towards it. The Government have not as yet paid any money on colonization account from this fund, but regulations are issued for realizing the payment, and copies of these have been sent to consuls and representatives of Brazil abroad, and full publicity have been given to them here.

These include the payment of passage of the immigrant from his home to the estate where he intends to work, but the payment only to be made after the family is settled down to work on some estate or industrial establishment. The subject of European Colonization for Brazil, I must leave to a future letter.

At present I mention these particulars as showing on what agriculture in the hands of large farmers may have to contend with in the near future, and as bearing on the subject of coffee, with which I commenced this epistle.

Your interests are now so much bound up in tea, my remarks on the labour question here as affecting the coffee market will not be so interesting to you as formerly.

A. SCOTT-BLACKLAW.

CINCHONA BARK IN CEYLON.—If all proprietors or managers of estates gave us such specific information as a leading Dimbula resident proprietor in sending his Directory returns, we should very quickly be able to say how Ceylon stands in respect of total supply of cinchona bark:—"Total bark that will be sent from this estate when all growing is harvested say between now and Jan. 1890, 200,000 lb. of average 3 per cent bark."

PADDY CULTIVATION IN CEYLON: ANALYSES OF SOILS.—We draw attention to the valuable letter on this subject given on page 569, and hope Mr. Cochran will be able to supplement this interesting information with a comparative analysis of fertile paddy soil. The barrenness of large portions of our patana soils has been, and we suppose correctly, attributed to an excess of protoxide of iron, and there can be little doubt that a good deal of such soil could be rendered fertile by being turned up and exposed to the air, some lime being also applied.

INDIAN TOBACCO AT HOME.—Indian cigars and tobacco were brought prominently under the attention of visitors to the Colonial and Indian Exhibition, and of the former some 366,000 were disposed of by sale. "This considerable sale," write the official agents, "served to introduce Indian cigars to numbers of people who had never before tried them, and we have reason to believe that, as a result, tobacconists throughout the country are dealing much more largely in Indian cigars".—*Pioneer.*

MR. JAMES GIBSON OF YATIYANTOTA writes to us from Goruckpore, N. W. P., India, a private letter from which we extract the following:—

"I feel strong and well already away north here, where it is jolly cold and fine and fresh. For miles and miles all over I see nothing but wheat, peas, and flax growing; the crops, I am told are bad, and this has been a season of drought, and certainly the whole plains seem awfully dry. The Himalaya mountains stand out close in the north all clad in white, and look very beautiful, but in fact the whole country does so; wherever I drive, it is through long avenues of sissoo, and blue gums, not short avenues but some of them four or five miles long. Does your mouth not water at apples, pears, walnuts, grapes, for fruit; large groves here and there, of big mangoes; and cauliflower, peas, turnips, leeks, and onions, kail, &c., &c., for vegetables; and acres of roses, carnations, wall-flowers and all old home sorts for flowers?"

Correspondence.

To the Editor of the "Ceylon Observer."

PADDY CULTIVATION IN CEYLON: ANALYSES OF SOILS.

20th January 1888.

SIR,—A good deal has appeared of late in the *Observer* on the subject of paddy cultivation, but no analyses, so far as I am aware, of fertile paddy soils of Ceylon have been published; so, in the absence of exact information as to the composition of such soils, the next best thing to know is the composition of soils on which paddy cultivation has failed. With the consent of the Assistant Government Agent, Nuwara Eliya, I give below an analysis and report I made for him on in Dec. of 1886:—

"Analysis of a sample of soil from the Walaganwala paddy fields, on which paddy grows, but does not mature its seed, received from the Principal Civil Medical Officer, Colombo.

Moisture	2·500
* Organic matter	6·460
Soluble in standard hydrochloric acid:	
Silica	·590
Iron peroxide	3·526
Iron protoxide	·836
Alumina	5·640
Lime	·126
Magnesia	·115
Potash	·077
Soda	·028
Phosphoric acid	·034
Sulphuric acid	·056
Chlorine	·012
** Insoluble Silicates	80·000
	100·000
* Containing Nitrogen... ..	·129
Equal to Ammonia	·157
** Containing Silica	72·000

"The soil was dried in air and passed through a sieve of 10 meshes to the lineal inch, which kept back 3·1 per cent of gravel, nearly pure quartz, and ·654 per cent of organic matter as roots, seeds, &c. The soil which passed through the sieve of 10 meshes was powdered till it all passed through a sieve of 40 meshes to the lineal inch, and it was this prepared sample which was subjected to chemical analysis, with the foregoing results.

"The soil was of a free, sandy nature, containing a very large proportion of insoluble silicates. The element of plant food in which the soil appears to me to be specially deficient is phosphoric acid. I made two determinations of the phosphoric acid in the hydrochloric acid solution, with closely concordant results, obtaining only ·034 per cent. In a nitric acid solution of the soil, I obtained ·045 per cent. The deficiency of phosphoric acid would account for the paddy not yielding seed, as that is by far the most abundant of the mineral constituents of rice grain, as the following analyses from standard works of the ash of rice grain show:—

Phosphoric acid	62·23	53·36
Potash ...	20·21	18·48
Soda ...	2·49	10·67
Lime ..	7·18	1·27
Magnesia ...	4·26	11·69
Oxide of iron	2·12	·45
Chlorine ...	Not determined	·27
Silica ...	1·37	3·35
	99·86	99·54

On the other hand the whole amount of mineral matter in rice grain is so very small, ·9 per cent in dried rice, ·3 in naked rice, compared with other cereals, *e.g.*, wheat 1·7, oat 2·7, pea 2·4, beans 3·1, that I think it would be advisable in the absence of any analyses of soil from fertile paddy-fields (I have seen no such analyses) to have a few soils from fields known to produce good crops of paddy analysed for comparison. The soil contained ·836 per cent of protoxide of iron, which is generally regarded as injurious to vegetation. I do not think that any of the Ceylon soils are quite free from this ingredient, so that whether or not this constituent be present in deleterious proportion would also have to be determined by comparison with the composition of fertile soils. Protoxide of iron is converted into the harmless or beneficial peroxide by aerating the soil by mechanical working or by liming.

"I understand * that sometimes, when paddy-fields become sterile, the Sinhalese simply remove a layer of the surface soil altogether, and, by planting upon the underlying soil, get good crops. An examination of the sub-soil might indicate whether or not such a course would be advisable? As the result, however, of the foregoing analysis, I would recommend the application of bone-dust to the soil with the view more especially of increasing the amount of phosphoric acid present. I have potted the balance of the soil in four pots and shall try the effect of different manures. In the event of my getting definite results, I shall give due notice of the same." M. COCHRAN, F. C. S.,

Analyst.

It is a pity that as yet the investigation into the cause of the sterility of the paddy grown on the Walaganwala fields has not been supplemented by manuring experiments on the spot, as, when attempting these on the small scale in flower-pots, the experiments are necessarily carried on under abnormal conditions. In the present case, I divided the soil not required for the analysis into four equal parts, which allowed somewhat less than 2 lb. of soil to each pot. One of these was left unmanured, one was manured with sufficient bone-dust to add ·111 per cent of phosphoric acid to the soil, another with sufficient slaked lime to add ·260 per cent of lime to the soil. The fourth was manured with a little dry cowdung. Four seeds were planted in each pot on the 19th of January 1887. The four pots were placed in the back verandah, watered regularly and left to take their chance. They only received a little of the sun's oblique rays in the afternoon. I could not venture to put them out into the open, lest the blades should be cropped by birds or quadrupeds. No doubt, had the plants got more sun, better results would have been obtained.

The average time taken for the first three seeds to germinate and appear above ground was, in the soil manured with lime, 9 days; in the unmanured soil, 12 days; in the soil manured with bone-dust, 15 days. In the soil manured with cowdung, the first two seeds took 14 and 27 days respectively.

On the 26th of May, I measured the growth from the ground to the tips of the blades. The results, together with some other data, are tabulated below:—

	Manured with bone-dust.	Unmanured.	Manured with cowdung.	Manured with lime.
	ft. in.	ft. in.	ft. in.	ft. in.
Greatest length	3 0½	2 9½	3 7½	2 0
Mean length	2 9	2 7½	3 2½	1 6½
Date when in ear	June 1	May 28	May 26	
Number of ears	2	2	1	
Seeds in each ear	14	12	7	
Length of straw from ground to lowest seed ...	11 in.	10 7 in.	11 0½ in.	

* Information received from the Rev. S. Coles

None of the seeds were very well filled, and some were mere leaves, and what surprised me was, that, although the paddy manured with bonedust had the greatest number of seeds, these were not quite equal in quality to those grown in the unmanured soil, and in the soil manured with cowdung. The sickliest plants were those grown in the soil manured with lime, although these were the first to germinate. These came to nothing. The blades were short, of a very light green, very deficient in chlorophyll.

The blades of the paddy manured with bonedust were of a rich dark green, and those of the unmanured paddy were but little inferior. It is evident that, as grown in the shade, the paddy was but little, if at all, benefited by the phosphoric acid of the bonedust; but had profited somewhat by the nitrogen of the same. M. COCHRAN.

LUXURIANT GROWTH OF TEA.

Dolosbage, 25th January 1888.

DEAR SIR,—What do you think of 2 months (from pruning) flush I send you under separate cover? yours faithfully. TEA.

[The growth is marvellous, over a foot of luxuriant shoots and leafage. The jât is fine, but the growth must be due to rich soil and a specially forcing climate. The rocks of Dolosbage contain a good deal of gold which will probably be yet extracted by deep mining. Meantime such tea grown on the surface soil means a good deal of silver.—ED.]

HOW TO CLEAN SILICATED CARBON FILTERS.

28th January 1888.

DEAR SIR,—In reply to "Housewife" asking for a recipe to clean silicated carbon filters, I can refer her to "Goodeve's Hints on Children in India." I have tried the recipe there and found it answer, and so have saved the cost of another new one.—Yours truly, ANOTHER HOUSEWIFE.

OUTTURN OF TEA FROM WET LEAF.

Central Province, 27th Jan. 1888.

SIR,—A question has arisen between a friend and myself: does it necessarily follow that the deduction of *on'y 10 per cent* from all tea leaf brought into a factory (be it ever so wet) would give a correct outturn of made tea, *i.e.* a pound of made tea to every four lb. of *wet* leaf? Kindly let us know through the medium of your columns, and oblige, A. S. H.

[Ten per cent seems certainly liberal; for, many allow no deduction, but in districts where 40 to 80 inches of rain fall in a month and also where coolies are said to dip their baskets in the stream (!) 10 per cent may not be enough!—ED.]

THE CHINA TEA TRADE: ITS POSITION AND ITS POSSIBLE FUTURE.

Colombo, 30th Jan.

DEAR SIR,—The *North-China Herald* of the 6th inst. contains a letter (see below) from the Sub-Committee of the Shanghai Chamber of Commerce to the Commissioner of Imperial Maritime Customs at Shanghai, on the deterioration of the China tea trade.

After comparing the deliveries in London of the tea from the various producing countries, the Sub-Committee, referring to the great decrease in the deliveries of China tea, and consequent increases in those of other countries, point out what proper care in cultivation and preparation will do when skilfully applied. They instance the case of Java teas, which a few years ago were weak, and poor in quality, but which have made rapid strides in make and strength and consequently in flavour. They also point out that India and Ceylon enjoy advantages of absolute freedom from taxation, a large number of flushes of leaf per year, and consequent greater yield per acre than China tea, and comparative nearness to the consuming markets. They then say they have confidence in making the following suggestions for the improvement of China tea. To those acquainted with the Indian and Ceylon system of tea cultivation and manufacture, these suggestions will be highly amusing.

Having some knowledge of the modern method of cultivating and manufacturing tea, which the Sub-Committee evidently have not, I will venture to criticize their suggestions with the view of enlightening them on the subject, and also of showing them how impracticable their suggestions are unless the method of cultivating and making tea in China is entirely changed, and the Indian and Ceylon method substituted for it.

The idea of revolutionizing the China tea industry, which has existed perhaps for a thousand or two years, is a very grand one indeed, but is it not chimerical?

As you will probably publish the Sub-Committee's letter, I will save your space by numbering each suggestion, and remarking upon them seriatim without repeating their words:—

1. Is it not more probable that the Chinese now make their tea in the same way as they have always done; but that the great decline in the value of tea of late years has induced them to retain for their own consumption the good descriptions, and sell to foreigners their inferior sorts? There can be no doubt that the modes of cultivation or curing in vogue in India and Ceylon would be highly beneficial if adopted in China, but how is this to be done?

The Chinese cultivator could, if it suited him, pluck his leaf differently to what he now does, he could take off only the flush which will make good tea, leaving the bangy and hard leaves on the trees, but he cannot carry his green leaf to the factory to be spread out to wither to the point modern manufacturers think necessary to insure of good tea being made out of it, because there is not a factory near every tea garden. There is not the least necessity for the Chinese Government to send a number of intelligent and practical China men to India and Ceylon on a wild goose chase, to acquire the knowledge of the modern methods of tea cultivation and manufacture.

They can be acquired by a careful study of the *Tropical Agriculturist* and the various handbooks which have been published in India and Ceylon on the subject.

2. The Chinese require no instruction in the proper methods of firing and sorting tea, nor do they require factories or machinery for the purpose of making good tea. Large factories are only wanted for withering green leaf. Tea can be fired on Chinese choolas, and hand-rolled better than by the use of expensive machinery, though not so economically. It is, therefore, unnecessary for the Government to introduce these, and work them under strong protection. Where labour is so cheap as it is said to be in China, its saving is a secondary consideration.

3. That the Chinese method of making tea is very primitive admits of no doubt, but not altogether in the sense the Sub-Committee use the word. We may be quite sure that the cultivator does all he can to turn his green leaf to the best advantage; if he could make good tea fifty years ago,

he can make it now if it suited him to make quality instead of quantity.

The accounts published by those travellers who have visited the tea districts, and have reported upon the process of manufacture, differ so much, that it is impossible for outsiders to make out how the cultivator plucks his leaf, and then treats it, and the Sub-Committee appear to be equally ignorant.* Some authorities say, he sun-dries it until he has a sufficient quantity to sell to the tea-men who are located in every town in the tea districts; others say, he keeps his green leaf until he has collected a few piculs, which he carries to the nearest town for sale; others again say, that he rolls his leaf, half-fires it, and then sells it to the tea-men to complete the manufacture.

Anyway, under either of these methods, the tea-men cannot receive the leaf in a state to be converted into the best tea. In the first case it would be too much dried to roll, and would have to be moistened to admit of the process; in the second case, the leaf would be fermented before being rolled; in the third, the leaves would not be withered and fermented to that nicety which India and Ceylon planters consider necessary to make the best tea.

The Sub-Committee say, under the influence of rain or any untoward circumstance, the process breaks down entirely, but they do not describe the process. Are we to infer that there is an uniform one all over China?

4. The points which require the greatest change are not only fermentation and firing, but plucking, withering, and fermentation. The Chinese understand the method of firing properly, and where sirrocos are not used, we have adopted their choolas.

5. For the reasons given in my paragraph No. 1, I doubt if there has been any falling-off in the way China tea is prepared. Is it not more probable that owing to the enormous decline in prices, the cultivator, to make up his returns, increases his quantity by plucking bangy or hard leaves? If he does, the deterioration is easly accounted for.

6. If the revival of the China tea trade depends upon the export of flavoury teas alone, then it is likely to be a distant event—present English prices do not appear to tempt holders of the best teas to part with them.

7. Indian and Ceylon planters will perfectly appreciate the difficulty in making large chops of 50,000 to 150,000 lb. of even quality, if the leaf from which it is made has to be kept a week or ten days after it has been picked from the tree, as the Sub-Committee say it has. With regard to their remark on Indian tea chops, I will only point out that it would require a big estate to pick, prepare, and pack in one day 5,000 to 7,500 lb. of one description of tea.† Fancy how many Chinese native tea gardens it would require to make up chops of 50,000 to 150,000 lb. of uniform quality!

8. In our experience, the difference in skilfully made tea between that grown at higher and lower elevations is in flavour. The teas of the higher elevations are more flavoury than those of the lower, but the latter are stronger. The great deterioration complained of can scarcely be attributed to difference between the different districts where tea is grown.

If the quality of our teas is to deteriorate greatly unless we replant every ten years as Mr. Fortune wrote is necessary, to maintain good quality,

* In Williams' "Middle Kingdom," it is stated that the twigs are roughly stripped.—ED.

† But who ever heard of even a small break of tea being plucked and finally packed on the same day?—ED.

there is a poor lookout for Ceylon planters, who have been consoling themselves in the midst of their misfortunes with the idea that they had at length found a long lived plant. Modern authorities led us to believe, that the tea tree lived in China for one or two hundred years. Fortunately we know from our own limited experience, that ten years old tea trees do not show the least symptoms of dying in what we consider their youth.*

The remainder of the Sub-Committee's memorandum only calls for criticism on one or two points?

The first is, that as the Chinese Government only interested itself in the question, in defence of its falling export duty, is it likely they will sweep away all taxation on tea simply to benefit the foreign shippers and consumers? If it was not for the revenue derived from the export duty, what would the Chinese Government care, whether there was a pound of tea exported or not? The cultivator cannot care very much, whether he converts his bangy and hard leaves into tea, for the use of foreigners, because at 4d to 6d per lb. in London, he gets very little remuneration for his trouble.

The Sub-Committee remark further that the enormous English duty does not affect adversely the value of China tea! They do not appear to perceive, that a uniform duty of sixpence per pound is a direct protection in favour of these countries which produce good teas.

The duty on the chief portion of China tea made from coarse leaf is more than 100 per cent., whereas on teas made from young flushes it is only 50 per cent.—Yours truly, A TEA PLANTER.

P.S.—Common China congou is terribly handicapped. There is the English duty of 3d per pound, the China lekin and export duty 2d per pound; difference in strength between India and Ceylon and China teas say 2d per pound; moreover Indian teas only turn out 8 per cent of inferior, such as broken mixed, fannings and dust, against the Chinese 25 per cent. Can the shipment of low class China tea be continued long? is a question of great importance to Ceylon.

THE CHINA TEA TRADE:
REPORT BY EXPERTS.

The following report has been addressed to Mr. H. Elgar Hobson, Commissioner of Imperial Maritime Customs, Shanghai:—

Shanghai, 17th December 1887.

SIR,—In replying to your request for information about the tea trade, we think it would be of some interest to prelude our remarks by giving a very few figures showing how the taste in England has changed during the past few years.

Let us compare the deliveries in London for the twelve months from 1st June to 31st May 1880-81 and 1886-87:—

Tea	1880-81	1886-87	Decrease	Increase
China	158,036,000	131,256,000	26,800,000	...
Japan	149,000	65,000	84,000	...
Indian	48,285,000	75,425,000	...	27,150,000
Ceylon	...	7,744,000	...	7,744,000
Java	1,779,000	3,671,000	...	1,892,000
African	...	4,000	...	4,000
Total deliveries	208,250,000	221,144,000	...	...

This year promises to give even more striking result than these, the last published figures. These figures are very instructive, as they not only show the decrease in China tea and the gains of other countries, but they also prove what proper care in cultivation and preparation will do when skilfully applied. We refer particularly to Java teas, which a few years ago were weak and poor in quality, but which have

* At high elevations tea bushes are really only at the full bearing stage at ten years old, and Mr. Arnold-Bemrose describes the plant as practically everlasting.—ED.

made rapid strides in make and strength, and consequently in favour. This improvement has been brought about by greater care in cultivation and preparation. The reduction of taxation to a minimum has proved a great stimulus to the energy of the planters.* Japan teas, being unsuited to the English taste, have never taken any hold on the public, and are not likely to do so. India and Ceylon enjoy the advantages of absolute freedom from taxation, a large number of flushes of leaf in the year and consequent greater yield per acre than China tea, and the comparative nearness to the consuming markets.

We have confidence in making the following suggestions for the improvement of China teas.

We know that the tea we want was once procurable in China, but as it is no longer brought to market we conclude it is not made, and we are therefore strongly of opinion that the modes of cultivation or curing in vogue in Ceylon and India would be highly beneficial if adopted in this country. We should recommend that a number of intelligent and practical Chinamen should be sent to those countries to learn the process themselves so as to become teachers to their fellow countrymen on their return. It would be an advantage if factories were established in one or two of the principal tea districts under official protection, using all the modern machinery. The introduction of machinery will require strong Government protection, or it may possibly cause disturbance amongst the workers that it will replace. We know for a fact that a tea-rolling machine was imported from Ceylon some two years ago, but it has not yet been used, as no men were found with courage enough to face a possible riot amongst the coolies.

The Chinese method of preparation is so very primitive that tea can only be properly cured under the most favourable climatic conditions. Under the influence of rain or any other untoward circumstance the process breaks down entirely, and hence the irregular quality of one season's produce compared with another. This irregularity might be obviated to a great extent by the better housing of the raw leaf.

The points that want the greatest change are fermentation and firing.

Ever since the opening of the Suez Canal there has been a yearly deterioration in the way tea has been prepared for the Foreign markets, and teamen lay the blame on the buyers in Hankow. The fact is that teamen have studied first the cost of making, and second the palates of the Hankow buyers, and they have found that a tea half fermented and slightly fired arrives at the market in the most attractive form to buyers. The result is that we now get a pale-liquoring, brisk tea, which has lost half its strength and nearly all its keeping qualities, becoming vapid and flavourless in a few mouths. Fermentation should be allowed to go on until every leaf is red, and firing should be done slowly as in olden days. Without proper fermentation you cannot get a strong, rich liquor, and it is on strength and make alone that the Indian teas rely for their reputation. No one ever heard of Indian or Ceylon teas being recommended as being of superior flavour to China tea. It is in the matter of flavour we look for the revival of the China Tea Trade. What we want is a strong tea, full of aroma, and so perfectly cured that it will retain the qualities for a long time. The Canton teas of this season have shown a great improvement on those of many previous seasons, and have met with a good reception in London. What can be done in Canton can be done in other parts of the kingdom.

The present system of attempting to make large chops of 1,000 ½-chests to 3,000 ½-chests, purporting to be of even quality throughout, is one of the main causes of the deterioration of the article. To make this quantity in one chop necessitates the delay of many days in purchasing the requisite quantity of leaf, often extending for a week to ten days after the leaf has been picked from the tree, during which time the leaf is rapidly deteriorating. In India, tea is always made in small chops rarely exceeding 100 to 150 chests, all being the pickings made in a single day; and by preparing and packing the tea the day after it is picked,* the best qualities of the leaf are retained.

Another source of deterioration is the mixture of leaf from inferior districts with that grown in the better districts. This mixture is often difficult to detect shortly after the tea is made, and as often deceives the foreign buyers in Hankow; but the voyage to England brings out the coarse flavour of the inferior mixture, and is a great cause of disappointment and loss.

Mr. Robert Fortune, in his "Two Journeys in the Tea Districts," written about 1848, describes the processes of making tea. We specially mention Mr. Fortune as an authority, as not only did he visit all the tea districts in China, but he was the first to introduce China tea into India, and engaged several Chinese experts to superintend the making of tea in India.

We would also call attention to Mr. Fortune's remarks on the replanting of tea shrubs every ten years, a necessity which we are given to understand has been lamentably neglected, and to which perhaps may be traced a good deal of the deterioration of which we now complain.

Our previous remarks mostly refer to Black Tea, and we would now wish to add a few about Green Tea. Everyone is aware that this is an article depending for its value on the care displayed in its making and colouring. From the same basket of leaf a small portion may be found, which, if carefully selected and prepared, will be worth Tls. 70 a picul, duty paid, whilst the lowest grade may not be worth more than Tls. 7 or 8 duty paid. The bulk of it, however, consists of an ordinary twisted leaf, called Young Hyson, and on the value of this depends the proportion value of the chop. The enlightened policy of the Japanese Government in charging only $1 a picul on Exported tea has enabled the Japanese to produce an article similar in most respects to Young Hyson, which has so successfully competed with it that it has reduced the values of China Green Tea below the cost of production. China tea is still saleable in the United States and Canada on about a par with Japan tea, but for several years China Green Tea has been a very unprofitable business both for the maker and the shipper.

The following figures will show the decrease in the production of China Green Tea and the remakable advance made in the Export of Japan teas.

GREEN TEAS.

	1872-73	1886-87
Export to the United States and Canada	2,934,510	15,967,764
Export to Great Britain	10,623,600	7,405,797
Export to Bombay	806,080	2,092,267
	34,364,190	25,465,828
	...	34,364,190
Decrease	...	8,898,362

JAPAN TEAS.

	1872-73	1886-87
Export to the United States and Canada	12,003,026	44,948,646
Export to Great Britain	nil	37,318
	12,003,026	44,985,964
	...	12,003,026
Increase	...	32,982,931

The make of Moyunes, Teenkais, and Fychows has fallen off considerably of late years, but we still get sound, pure teas from these districts. There is one point, however, to which we would wish to draw the Government's attention, and that is, the stuff which is manufactured in the neighbourhood of Ningpo under the name of Pingsueys. Some of the dealers adhere honourably to making pure tea, but the majority are only too apt to mix spurious rubbish with their teas which is carefully coloured to look like the true article but which is slowly and surely undermining their business. The least harmful form is tea powder mixed

*But the Java planters still complain grievously of heavy taxation. See paragraph quoted the ohter day.—ED.

* We do not suppose that tea was ever packed the day after it was picked.—ED.

with congee and rolled into pillules to sell as Gunpowder. In many other cases all sorts of foreign substances are introduced, and many instances of seizure by the United States Customs have taken place of late years. This is a distinct case where Government interference would be valuable to the trade.

Duty.—It is an unchallengeable axiom that a trade gravitates to the country that can produce the cheapest article, and in the instance of tea we find it going to countries which are most lightly taxed. The black tea trade is going to India, Ceylon and Java; the green tea to Japan. We will ask attention to the black tea business in Shanghai this season, to show how onerous these duties are. The average price of Shanghai Oongou this season, has been about Tls. 14½, duty paid, and the present stock of 70,000 ½ chests is worth roughly Tls. 9, duty paid. Duty and Lekin amount to Tls. 4.10 to Tls. 5.10 according to districts, or quite 50 per cent of the value of this stock. How can China compete with Free Trade countries as long as these killing duties are imposed? The present prices of Oongou in Shanghai are 25 to 30 per cent below cost of production, although the export to Great Britain from all China is 30,000,000 lb. short of last season, and rates of freight and exchange are exceptionally low. The duty in England is enormous, but as it falls on all alike it does not act to the detriment of any one producing country in particular, and that it does not affect the value of China tea adversely is proved by the fact of equal price being obtainable in heavily-taxed London and duty-free New York. It may affect consumption, but not prices.

If the Chinese Government are really desirous of improving the production of tea, the best of all plans would be for them to throw the country open to foreigners, so that they may establish tea-curing hongs with modern machinery in the tea districts, and, if necessary, may acquire land for the better cultivation of the plant, and last but not least, abolish all duties on the article, so that it may compete on fairly equal terms with India and Ceylon. The capital requisite for the purchase of machinery and plant would then easily be found, and cultivation on scientific principles would make the most of the industry. Tea would then be treated in its preparation as an article of human food, every process would be as clean as human care and invention could make it, and we should avoid what Mr. Alabaster calls the 'perspiration saturated' stuff which is now brought to market.

One point more calls for serious attention, and that is the almost universal custom of Tea Honga knowingly issuing false musters of teas in Hankow. It is an abuse easily remedied, and if once remedied it would do away with one half of the troubles to which foreign buyers are now subject. A fine of $500 or so on any Hong guilty of this malpractice would have a most salutary effect.

We have omitted to say that we hear, on very reliable authority, that Ceylon is producing tea at a cost of about 5d, per lb. f. o. b. Tls. 8.50 to Tls. 9. —We have the honour to be, Sir, your obedient servants,

(Signed) Joseph Welch, J. Findlay, A. J. H. Carlill, Charles Cole, E. H. Kenney, F. J. Green.

THE ASSAM TRADE.—The river trade of Assam is important and miscellaneous. More than forty millions of oranges, valued at nearly two lakhs of rupees, were last year sent down the Surma river, and 527,000 bamboos followed the same route. Potatoes, which are grown almost entirely in the Khasi Hills, were sent out of the province to the value of nearly three lakhs of rupees. The export of coal from Assam continues to increase, and more than doubled on the amount of the previous year. This is entirely due to the increased output of the Makum mines, near Dibrugarh, which, besides furnishing a large export, supply nearly all the coal used in the Valley. Nevertheless there continues to be a large import of coal into Assam from Calcutta.—*Pioneer*, Jan. 23rd.

SUB-TROPICAL NEW ZEALAND.

Written for the *Otago Witness* by G. E. Alderton (late N. Z. Government Commissioner *re* fruit culture).

THE FAR NORTH: ITS TOPOGRAPHY AND CLIMATE, FRUIT GROWING V. FARMING. A PEEP AT KAWAU AND SIR GEORGE GREY.

It is a popular belief in California that the climate changes every six miles. Up here in the far North it is very similar. In Auckland a fortnight ago, everything was burnt up for want of rain, while at Whangarei, 80 miles to the north, the grass and all vegetation were as green and as fresh as in spring time. Down in Otago you only get 32 in. of rain in the year; at Auckland, 46 in. fall, and farther north as much as 58 in. These figures of themselves indicate three distinct climates. Auckland is as far north as it is safe to grow wheat and potatoes, and even there heavy rains in December and January sometimes destroy wholly or partially these crops. Farther north, cropping with wheat or potatoes is very risky, and never attempted on a large scale, as too often the rain destroys the wheat crop and rots the potatoes in the ground. Farmers, as a rule, content themselves with growing just enough of these for home consumption, and the public have to rely on the South for supplies. What then do they grow in the Far North? Well, they can grow grass all the year round, and support cattle and sheep without root food, while fruit and vegetables grow with a luxuriance not surpassed by any country in the world. It is not, however, so suitable for grazing as your Southern lands, as the best land is usually heavily timbered and costs money to get into grass. After the timber has been burnt off, it takes years before the stumps rot and the land becomes ploughable. During all this time, the farmer can do nothing but graze his farm, but as soon as the land will permit, he lays down a small orchard as an aid to farming. By-and-by they will do here as the farmers in California have done before them, namely, throw up farming altogether and go in for fruit. Any kind of fruit culture is more profitable than any kind of farming. Such is the accepted rule in California, and I am firmly of opinion that it applies to this part of the colony with equal truth. Take wheat, for instance. A fair average crop would be 30 bushels to the acre, but assuming 50 bushels, and selling at 5s, the gross return would be £12 10s. Take an acre of apples, at 10 years of age, you will get not less than five tons of fruit, which at only ½d a lb, or say £4 10s a ton, would gross to £22 10s. Place the cost of gathering the crop against the cost of seed, wheat, harvesting, &c., and the balance will still be in the favour of the apples. But the retort is made, "You have to wait ten years for the result!" Nothing of the kind. The land in between the trees should be cultivated all along, and the better the soil is worked (as long as it is compensated for what is taken out) the sooner the trees will bear, and the larger will be the crop. Some apples, such as the Irish peach, begin to bear when three years old. Another objection is urged, "that there may be no market for fruit." That also is a fallacy, for fruit if it cannot be sold fresh, may be made imperishable by drying or evaporating. Five tons of apples evaporated would yield about 1200 lb. of fruit, which at 7d a lb would be worth £35: the cost of evaporating being about £1 a ton. Apples, however, are the least profitable of all fruits to grow, and I merely named them as being the "poorest" to compare with wheat. I visited some farmers the other day, the Messrs. Hutchinson Bros. (who, by-the-bye, have for a neighbour, Lady Douglas, relict of the late popular Sir Robert Douglas, at one time a member of the house), who pointed to one Earl Rivers plum tree, from which they had this season taken 2 cwt. of fruit, and sold it at 6d a lb, say £5 for the tree. 75 such trees go to the acre. The Messrs. Hutchinson Bros. have not an acre of such trees, but they intend putting down ten acres next planting season. They have lemon trees from

which they have sold in a year £6, £7, and £8 worth of fruit. I mention these gentlemen particularly because they are thorough farmers and understand what they are about. They have one of the best farms in the North, beautiful rich volcanic land that can be worked any day in the year, and although they had a good market for their butter and beef, they have decided to go into culture on an extensive scale. While referring to this farm, I may mention that a week ago (the beginning of Februrary), the grass here was as fresh and green as in the best spring weather. The topography of this part of the colony seems to favour a bountiful and regular rainfall. On the East Coast, at the entrance of the Hauraki Gulf, are numerous lofty islands, such as the Great and Little Barriers, with peaks over 3000 ft. high. Straight inshore a mountain chain begins at Whangarei Heads and runs across the mainland to the west coast, with every here and there small peaks 3000 ft. or 4000 ft. high. As the weather steadies down south, the N E. trades press in upon the north, and just that part described above, comes within the influence of the trades, the high peaks catching the clouds and draining them of their moisture. Auckland and the gulf inside the islands do not get any of this rain. Kawau, the island home of Sir George Grey, situate just midway between Auckland and Whangarei, and inside the gulf proper, had none of the rainy weather experienced further north, though the day I was there, a slight drizzle fell, while to the north, there was every appearance of heavy rain. Kawau, the home residence of the most remarkable man in New Zealand history, is one of the most charming places I have ever seen. It is surrounded with scenery that is simply indiscribably grand, and there is no wonder that Froude went into such heroics over the place. I have been twice around the world and have seen most places known to globe trotters, but I cannot recall a view so grand and inspiring, as that obtained from the heights of Kawau. All around is the sea, placid and calm, as it usually is here, with just the slightest shimmer on it in the track of the sun; over the mainland, but a stone's throw away to the eye, a narrow white fringe of surf is lazily lapping up against the rocks or slowly rolling up a sandy beach; to the right is the North Harbour, a broad sheet of ultramarine water, looking for all the world like a loch in the Highlands of Bonnie Scotland. The great cliffs on the other side are covered right down to the water's edge with the noble pohutukawa, here and there throwing out a blaze of red from their Christmas flowers. At the head of the bay, is a yacht at anchor, its sails unfurled and flapping up against the mast; while lower down two figures may be seen in a boat enjoying the *dolce far niente* just as they are wont to do it in the Bay of Naples. Forget for the moment your identity, and let your imagination carry you away into dreamland, and you may look out upon the classic coast of Greece and see great bays and inlets, and perpendicular cliffs that the white gulls never weary of passing and repassing. Islands everywhere—there a low one with its pretty white lighthouse; others larger and grander towering heavenward, with great fantastic rocks standing out against the blue of a cloudless sky like castles in the air. It was Lady Bowen, herself a native of Greece, who so loved to compare these coast scenes to her own classic shores. In years gone by, Kawau was noted for its beautiful gardens and orchards, but now the place shows signs of neglect. The rare plants which Sir George loved to collect from every corner of the globe have either disappeared or are grown over with other vegetation. His orange and lemon trees, once quite a sight, have become a prey to the borers, and are decaying away. The grounds around the house also show the air of neglect, but to many, and particularly to city folk, this is preferable to the rigid order observable in well-kept town residences. Our steamer, the well-known coaster of other days, the S. S. Wellington, warned us to embark, and presently the picture was as animated as pretty. Bon Accord harbour, in which the Wellington lay, is a charming little deepwater bay opposite the house, surrounded by a low range of hills which circle around and nearly meet. The land is densely wooded right down to the water's edge, mostly with pohutukawa, but higher up are acres of pines planted by Sir George. When all are aboard, the shore seems quite lonely, with only a few of Sir George's servitors on the beach, and himself standing on the end of the little stone jetty, a child in his arms, waving a handkerchief in farewell to the departing steamer. Just than three cheers go up for Sir George, followed by the band playing "For he's a jolly good fellow. The old man dances and jiggles the child to the music, and one cannot help remarking upon the contrast of the fiery old Sir George in Parliament, and the venerable old gentleman frolicking on shore with a child.

THE MADRAS BOTANICAL DEPARTMENTS.

Report for 1886-87 by M. A. LAWSON, Esq., Government Botanist; Director of Cinchona Plantations.

Season and Rainfall.—As I have remarked in my report on the cinchona plantations, the weather, during the past year, may be considered to have been somewhat abnormal in its character. The early months in the year having a more than usually high rainfall, while the later months, owing to the failure of the north-east monsoon, were exceptionally dry. The tota amount of rain registered during the year was 54·38 inches, spread over 146 days. Last year the rainfall * was 52·48 inches, spread over 142 days. The frosts, which were very severe during December and January, did a considerable amount of damage to the younger trees and plants; even such commonly hardy species, as the Willow and the Acacia Melanoxylon, being cut right down to the ground. The prolonged drought too proved fatal to many of the trees and shrubs which had been planted out during the past two, three, and even four years.

General condition of the Gardens and Parks and improvements which have been made in them during the year—1 *Ootacamund*—(*a*) *Government Gardens.*—These gardens, taken altogether, have continued to improve during the past year. The lawns and walks are for the most part in a satisfactory condition; especially those in the lower part of the gardens. The shrubs, which were planted near the entrance, have grown well, and I hope, that in another year, they will render the general appearance of this part of the gardens more agreeable than it has been hitherto. The ravine above the Doctor's house, which last year I reported upon as having been cleared of brambles and brushwoods, was planted up with selected shola and other trees, and these are doing well. This part is, however, still in an untidy condition, on account of a number of struggling blue gum coppiced shoots, which are still standing. These have been purposely left for the sake of sheltering the newly-planted trees, as the ground lies very much exposed to the south-west monsoon, but they will be cut down in another year or two, as these trees increase in size, and are more able to protect themselves from being blown down. A number of clumps of ornamental shrubs were planted in various parts of the gardens, chiefly upon the grass slopes. As yet they make little show, on account of their growth having been checked by the drought; they were most of them, however, kept alive by constant watering, and I have no doubt during the coming season will grow vigorously. The greatest nuisances which have been experienced during the past year have been the rats and the grubs of the common cockchafer. I have tried traps and poison for the former, but without any great success; and for the latter, I have discovered no remedy at all; and I believe that the only way of maintaining the lawns in good condition will be by constant top-dressing. The fountain, which I alluded to in my last year's report, has not been

* At Ootacamund, of course; little more than half the rainfall of Nuwara Eliya.—ED.

started, owing to the difficulty there has been found in obtaining a sufficiency of water free from silt, and because I doubt if a jet of a yellow flood would be attractive.

Coonoor—*Sim's Park.*—The general condition of this park is good. All the exotic trees have made rapid growth and a little thinning will be necessary during the coming year. The coppiced shola, which lies between the pond and Wellington, and which was so heavily thinned out two years ago, exhibits much improvement. The bridle road, which was made through this shola, is much used, not only by pedestrians and equestrians, but also by people driving in carriages.

Barliyar—(*g*) *Experimental Garden.*—All the trees in this garden are doing well. The mangosteens produced a very large crop of fruit during the year, most of which was sold in Ootacamund and Coonoor. The place is very unhealthy; the laborers are constantly being knocked down with fever; and I regret to have to report that Sarathy, the overseer, died of fever last March. The garden is rough and untidy, owing to the large amount of undergrowth, but it would cost a considerable sum to keep it neater, and as the undergrowth helps to keep the soil cool during the hot season, and therefore is of advantage to the young trees, I do not propose spending more money for the sake of merely improving its general appearance.

Kalhatti—(*h*) *Experimental Gardens.*—This garden is to be sold, so soon as some plants growing there can be removed to Coonoor, and this will be about July of the present year.

Proposed New Gardens.—The new garden at Gúdalúr has been sanctioned—*vide* G. O., No. 1060, of 3rd December 1886, Revenue. It will consist of 7½ acres belonging to the Tirumalpad of Nilambur, from whom it will be leased for ninety-nine years at the rate of two rupees per acre per annum, together with a renewal fee for every twelfth year of two rupees per acre. Besides this Garden at Gúdalúr, Government have sanctioned the taking up of a quarter of an acre, or whatever may be found necessary in the Nilambur teak plantations for the purpose of growing *ipecacuanha*, which plant has not yet been successfully grown in any of the Government gardens elsewhere.

Herbarium.—Extensive additions have been made to the collections contained in the herbarium during the past year.

The work of re-arranging the plants in the Madras Herbarium was commenced during the beginning of this year, but owing to my time having been much occupied by other things, I have not been able to make that progress which I could have desired; but later on in the year, I hope to recommence the work and carry it on without further stoppage to a completion. Till this very necessary re-arrangement has been made, it is impossible to say how complete the collections belonging to this presidency may be. I am constantly being referred to for the purpose of naming plants; and the herbarium is now sufficiently extensive to enable my doing this without much trouble.

Library.—A sum of Rs. 516-3-5 was spent during the year on the purchase of botanical works.

Notes on some of the more interesting Plants which have been introduced or grown in the Gardens during the year.

Broussonetia.—Cuttings of this plant were sent by Mr. Robertson, the Principal of the Agricultural College Saidapet. They have all struck root and are doing well, and will be planted out both at Ootacamund and at Coonoor, in both of which places I think they ought to thrive.

2. *Grewia asiatica.*—The plants sent by the Agri-Horticultural Society, Madras, are healthy and growing, but are not yet sufficiently advanced to render it desirable that they should be put out at once.

3. *Grewia* ——.—Although I got 200 plants of this species, nearly allied to *Grewia asiatica*, from seed which was sent from Kew two years ago, none of them have done as well as I could wish. They have been planted out on the Naduvatam, Hooker and Wood estates, and at Barliyar, but in none of these places are they growing well. I think the situation in every instance is too high and cold or too dry.

4. *Teff Eragrostis Abyssinica.*—The seed of this valuable fodder, which was received from Kew, has been sown both at Ootacamund and at Coonoor. The crop growing at Ootacamund has been sadly injured by the grub of the cockchafer, while at Coonoor the plant has suffered from want of rain. Another year, if I can harvest good seed from the present crop, I shall sow later in the season.

5. *Ullucus tuberosus.*—This did very well during the past year in Ootacamund. The plants yielded a large number of fine tubers, and may become a welcome addition to our present vegetables, but it is never likely to equal in value the potato.

6. *Hop.*—I am sorry to have to report that the results connected with the cultivation of the hop have been anything but satisfactory. I am afraid that neither the soil nor the climate of the Nilgiris suit it.

7. *Arracacia Esculenta.*—This plant has done well both at Ootacamund and at Barliyár, showing that it is capable of thriving under great variations of temperature. The tubers are fairly agreeable to the taste.

8. *Cochin China tuberous-rooted vine.*—I have nothing further to report on this, the plants at Barliyár have flowered again but have not set any fruit.

9. *Medicinal Rhubarb.*—I have tried growing this plant under many different circumstances, but have only succeeded in growing it satisfactorily when it has been provided with an abundance of lime, and from this I argue, that it is not likely either to prove a profitable crop on these hills, which are almost entirely destitute of that mineral. Should it be able to withstand the heat of the plains, there is no reason why it should not successfully be grown in the neighbourhood of Coimbatore.

10. *Ipecacuanha.*—The stock of this most important medicinal plant, has, during the past year, been increased from about two hundred to over seven hundred plants, and the greater number of these, as Government have sanctioned the proposal, will be put out in the Government teak forest at Nilambúr. As mentioned in my last year's report, the few that had been planted three years ago in this forest are growing vigorously, and I have little doubt but that the soil and climate of Nilambúr will suit them far better than those of Barliyár. Last autumn, it was reported that the stock of ipecacuanha in the European market was almost exhausted, and that there were faint prospects of this stock being much increased by fresh imports from abroad, and it was further reported, that the price of the drug had risen from half a crown to ten shillings a pound. Whether this sudden failure in the supply of the ipecacuanha drug is due to the plant having been uprooted in its natural habitat, or whether it is due to some commercial ring having been formed, I am not able to state, but it is certainly very desirable that the plant which produces the best known cure for dysentery, a complaint so common in India, should, if possible, be grown in the country.

11. *Naregamia alata.*—This is a low growing plant, belonging to the order Meliaceæ, and is found in great abundance on the West Coast from Bombay to Cochin, and probably farther south still. It has been called the "Goanese Ipecacuanha," and is said to be used largely by the natives in cases of rheumatism and fever. Surgeon-General Bidie is having the drug tried in Madras, with the view of finding out if it resembles the true ipecacuanha in its action in cases of dysentery, and as an emetic. Mr. Hooper has made a chemical examination of *Naregamia* and has found an alkaloid, which he proposes to call "*Naregamine*."

12. *Gymnema Sylvestre.*—This, and many other species of the same genus, have the property of paralysing the palate, so that it is impossible to be conscious of the agreeable taste experienced after eating substances, which are either bitter or sweet. Mr. Hooper, as will be seen from his report, has made a careful analysis of the leaves of *Gymnema sylvestre*.

and finds, that this peculiarity resides in an organ acid, which he has extracted from them, and called gymnemic acid.

13. *Cyphomandra battacea.*—This grows well at Coonoor, and bears a very agreeably flavored fruit, about the size of a hen's egg. It belongs to the order *Solanaceæ*, is a native of south America, and sometimes goes under the name of the "tree tomato."

14. *Castilloa Elastica.*—This India rubber-producing tree, flowered for the first time last year. The seeds were sown, germinated freely, so that there can be no doubt about our being able to establish this tree permanently in India.

GOVERNMENT ORDER.—The management of the various gardens appears to have been satisfactory. Mr. Lawson may address the Government separately on the subjects of widening the road through Sim's Park, and improving the position of the Overseer in charge. It seems probable that an experimental garden at Yercaud on the Shevaroy Hills would serve no useful purpose, but the Government desire to have a report on the suitability of Courtallam and Rámandrug as soon practicable. 2. It is to be regretted that the work of rearranging the plants in the Madras Herbarium has not yet been completed, but the Government notice with satisfaction that Mr. Lawson recognises the importance of this work. Acknowledgments of his Excellency the Governor in Council are due to those ladies and gentlemen who were good enough to assist the department with presents of plants and specimens.

3. The notes on plants, contained in section VI of the report, are interesting and should prove useful. Attempts might be made to cultivate the medicinal rhubarb plant at Gùdalùr. Colonel Cox would no doubt be willing to assist in conducting the proposed experiments at Coimbatore. Trials might be made in the Jail garden, if the Superintendent sees no objection. The result of the experiments with *Naregamia alata*, which are being carried out under the orders of the Surgeon-General, should be reported to Government. The report is silent on the subject of the cultivation of the Jalap plant, which was ordered in G. O., 7th July 1886, No. 566, Revenue. The Government desire to know what progress has been made.

MURREE BREWERY COMPANY, LIMITED.

THE CEYLON BREWERY PAYING 11 PER CENT.

We read in the *Pioneer*:—

This Company, taking advantage of the presence at home of Mr. Harry Whymper, the Managing Brewer, held its last meeting at Morley's Hotel, London, General H. C. Johnstone, C.B., in the chair: some of its largest and most influential shareholders appearing to be retired Anglo-Indians. The shareholders in this country can hardly complain of their interests suffering in consequence, for what with the Report sent home by General S. Black, one of the Directors resident in the Punjab, the Report and explanations of Mr. Whymper and the discussion which followed, the information obtained concerning the Company's progress and present position was as various and complete as could be desired. The result of the Company's working for the year ending 31st August 1887 was the declaration of a dividend of 12 per cent, a bonus of R10,000 being divided between the more deserving of the Company's servants: among these the Brewers are honourably mentioned, and Mr. J. Brown, the Secretary, upon whom has fallen the brunt of a very large and difficult business during Mr. Whymper's absence, was singled out for special praise. Towards the dividend earned, the Quetta Brewery gave a return of 8½ per cent, and that at Ceylon about 11 per cent, which, for new concerns, is good. The Ootacamund Brewery earned only 2½ per cent, a relative failure explained by the fact that Madras and Bangalore, which are comparatively close to Ootacamund, drew but few supplies, whilst Kamptee and Secunderabad, which are distant, drew largely. At and near some of the seaport towns, the Scotch Brewers contrive to compete with a liquor which is sold even below the Government contract rate. It does not appear that there is any remedy for this state of things. General Black reports that the valuations of Buildings and Machinery at Quetta and Ootacamund have been reduced by R82,000 in all, and that the Company's stocks have been taken at low rates throughout. The Brewery at Murree, which was originally designed for an outturn of 5,000 barrels, and will, during the current season, require to produce 30,000, is, as can easily be imagined, all too small for its work. The difficulty must, Mr. Whymper states, be met either by building a new brewery, or entirely reconstructing the old one. If carriage between the hills and plains is one of the standing obstacles of breweries in the hills, and beer can be brewed equally well at both elevations, Rawalpindi rather than Murree would seem the spot for a fresh start. There was some difference of opinion about the amount of the dividend, whether it should be 12 or 15 per cent; but the lower rate was, as Mr. Whymper pointed out, a high average to maintain, and the meeting had not much hesitation in determining that the profits of a year of exceptionally cheap material did not justify a lavish disposal of a sum the residue of which might come in usefully were the current year less fortunate. A proposal put forward by General Sir R. J. Meade, that the Company should raise from three to five lakhs by 7 per cent debentures, the proceeds to take the place of a portion of their Bank credit, was lost in favour of an amendment, introduced by Colonel H. Lane, that the existing arrangement should continue. Such a concern as the Murree Company ought to be able to borrow for all its needs at 7 per cent., whilst a Bank Cash Credit is a much more manageable fund than a Debenture Bond. A shareholder wanted to have all dividends payable in England remitted home at a fixed exchange of 1s 10d in the rupee—a monstrous proposal which was promptly sat upon, as it deserved. Mr. Whymper referred to the contract which the combined brewers of India had entered into with the Government, for a term of ten years, at reduced rates—an arrangement, by the way, which applies only to Bengal and Bombay, Madras and Burma being excluded. The contract is a good one for both sides, and Mr. Whymper is mainly to be credited with its conclusion. The Company is to be very truly congratulated upon having agreed to retain his services to the end of the contract. It commenced operations in 1860, and in eight years had lost nearly half its capital. It took nearly as many years more to entirely recover its losses. For these many years Mr. Whymper has been the good angel of the concern, and it would be difficult to exaggerate either the services he has done to the Murree Company, or the share he has had in establishing a very important industry in this country.

THE CINCHONA BARK AND QUININE TRADE.

Writing with reference to Mr. J. Ferguson's letters from London on Quinine and Cinchona Bark, Capt. W. T. Hody Cox says on January 3rd :—

"I today received the *T. A.* for December, and have read your letter. With reference to the portion of it at page 414 where my name appears, I found out some months ago that the shipments of *twig* or rather *small branch* bark had very much decreased. If however you examine the sale lists you will find that there is still an enormous quantity of *inferior* bark sold. Anything analysing under 1½ per cent of sulph. of quinine I call inferior. I have, for some months past, arrived at the conclusion that it would not be advisable to work up the inferior qualities of bark in the East in the form of 'quinetum' for several reasons, some of which are as follows:—

"1. The cost of transporting the chemicals to the East would be as much as that of getting the bark to England.

"2. Cinchonidine is a better form of alkaloid than quinetum, and can be purchased in England at an almost nominal price.

"The scheme, which I have been working at for the last two months, is precisely what you mention in the latter part of your letter, and as I communicated it to the same London firm, it is probable you heard it from them. The great difficulty I have had to contend with is the fact that Companies are prevented by their articles of association from joining in such undertakings, and a large amount of the capital invested in cinchona in Ceylon is represented by Companies. I shall be happy to sent you my details for a scheme to distribute quinine among the masses."

As regards the first reason offered, the difficulty would be removed if the Colombo Sulphuric Acid Manufactory were established, as we hope erelong will be the case; and if bark were even roughly treated here, and the results sent home, much saving in freight, charges &c. ought to be experienced. Capt. Hody Cox will be interested in our recent notices of cinchona prospects in Ceylon and Java, and we should like to have his opinion with reference to his experience with South India barks, of the information given in this month's *Tropical Agriculturist*. He will find it mentioned that the cost to the Dutch Government of the fine bark which they got from their large old trees in the Java Government Gardens was in 1886 equal to 4½d per lb., apart from freight and sale expenses which increased it to 5¾d per lb.; while the profit—counting the bark as averaging 5 per cent sulphate of quinine—is given at only ½d per lb. In the case of South American and Cuprea Bark, 5d to 6d per lb. is also given as the minimum profitable price; while in respect of Ceylon bark,—full calculations being offered, derived doubtless from Colombo mercantile authorities*—the actual cost, from the harvesting of the bark to its disposal in London, is under 2½d per lb. Indeed any sale of Ceylon bark below an average of 2 1-10thd per lb. means a downright loss in the actual outlay in labour and cash, apart from the bark itself. With an average percentage of quinine in the bark under 1½ per cent. the cost of manufacturing sulphate of quinine is put at less than 2d per lb. of bark, and the minimum rate to cover outlay of planter and manufacturer apart from intrinsic value of the bark) is 1s 3½d per ounce of quinine. All this enables us to see exactly where we stand and to show the planter how he is doing no good to himself or to anybody else, but rather harm, when he harvests and ships inferior bark to sell for less than the limits given above. Finally, we call attention to a rather sanguine view of the immediate future of quinine taken from the *Chemist and Druggist* on page 578.

* The cost of collecting Ceylon bark is given by Ma. J. D. Riedel of Berlin at 1d per lb. of dry bark, apart from carriage. "Logie Elphinstone's" calculation to us as embodied in our Handbook was that anything over *five cents* (less than a penny) per lb. in Colombo clears the expense of collecting and forwarding twig and branch bark, where estates are near to a railway station; but this reckoning soils very close to the wind, and a penny per lb. for collection apart from transport is safer.—ED. C. O.

FUEL FOR TEA.

What "J. L. A." writes (page 586) about the rapid growth of Australian gums,—meaning we presume *Eucalyptus globulus*,—the rapid growth of these trees, their suitability for fuel in tea factories even at five years old, and the fact that they yield a second growth when coppiced, is worthy of attention from tea planters. We mentioned in a recent issue that having consulted Dr. Trimen on the subject, he agreed with us that at high elevations nothing better could be cultivated for firewood than the Australian wattles: *Acacia dealbata*, *A. melanoxylon*, &c. All these trees, in varying degrees, have a strong tendency to throw up shoots from their spreading roots which grow close to the surface. They should never, therefore, be grown amongst or close to tea. Gums are bad enough grown amongst coffee or tea, but the wattles are deadly. Trees for fuel or timber had better be always grown on separate suitable pieces of ground. We speak from experience. For low elevations Dr. Trimen enumerated suitable trees in his Report for 1883, page 10, from which we quote as follows:—

In some of the coffee districts where tea is being largely planted, some difficulty is felt as to the supply of fuel necessary for its manufacture. The reckless and ill-judged clearance of the whole of the jungle, as yet regretted principally as shelter from wind, will now be felt from another cause. As it is quite useless to attempt to bring back the old native trees to their much changed habitations, it will probably be necessary to plant and keep up fuel reserves. For this in the higher elevations nothing can be better than the quick-growing wattles, blackwood and eucalypts of Australia. In the lower districts (2,000-4,000 feet) there are many quick-growing native trees that would be found suitable; for example, "Malaboda" (Myristica laurifolia), which is recommended also for tea boxes, "Milla" (Vitex altissima), "Badula" (Semecarpus Gardneri, &c.), "Gedumba" (Trema orientalis), "Gúranda" (Celtis cinnamomea), "Nuga" (Ficus laccifera, &c.), "Kalaha" (F. Wightiana), "Walgona" (F. callosa), "Dawul kurundu" (Litsæa zeylanica), "Etamba" (Mangifera zeylanica), "Wá" (Cassia siamea) is an excellent tree for fuel at elevations below 2,000 feet. Several of these woods would also do for tea boxes, and "Helamba" (Anthocephalus Cadamba), a common low-country tree, is also well spoken of for that purpose. It is of great importance to use only perfectly seasoned wood for boxes; if used green the juices may act on the lead lining, as happened in a case which has recently given rise to litigation.

PLANTING AND COOLIES IN DELI.

(Translated for the Straits Times.)

One of the crying wants of Deli, namely, the scarcity and dearness of Chinese coolies, bids fair to be erelong supplied. Efforts to secure direct emigration of coolies from the Celestial Empire to the neighbouring Dutch Settlement have hitherto been unattainable, owing to Chinese official obstructiveness. The endeavours made to gain this desirable end of so much importance to the plant-

ing community, were not given up for all that. By last advices the prospects of success have become somewhat brighter, owing to the higher Chinese authorities no longer raising any difficulties on the subject. To the planters, these particulars will prove tidings of great joy indeed. Deliverance from the extortion and exaction of the Straits cooly brokers, comes now within measurable distance.

In London, a Sumatra land syndicate has been floated to take over a concession of land in Siak, granted to Mr. Dates by the Sultan of that State.

On the Ludwigsburg estate a riot arising the other day out of tobacco sorting, resulted in twenty coolies finding their way to jail.

Coolies for Deli are medically inspected beforehand at Penang to find out whether they are fit for estate work. The brokers, at present, owing to the high price of these fellows, try to pass unsuitable labourers. Their efforts have been too often crowned with success, notwithstanding every care.

THE PROFITS ON CINCHONA.

In a recent issue of the *India Mercury*, Mr. Van Gorkom, formerly director of the cinchona plantations of the Dutch Indian Government, further discusses the profits to be made in cinchona growing. The conclusion he arrives at is that the law of the survival of the fittest is about to be put into operation in the Java cinchona industry. The weaker and least scientifically conducted plantations, he opines, will go to the wall within measurable time; the stronger will contrive to tide over the difficulty. This theory is neither original nor startling, and the essential part of Mr. Van Gorkom's article lies less in the promulgation of this view than in the figures cited by him in its support. In 1884 the total expenditure on the Government cinchona gardens, including freight of the bark and all sale expenses, was 148,384f (12,365*l*). During that year 207,170 kilos. (459,917 lb.) Government bark were sold by auction at Amsterdam. Assuming this bark to have averaged 5 per cent quinine sulphate and to have realized an average unit of 7 cents per half kilo., the proceeds would have been 145,019f. (12,085*l*) and have given a small balance on the wrong side. But, as a matter of fact the net amount realised was 378,572f. (31,548*l*), leaving a profit of about 155 per cent. This satisfactory result was caused partly by the fact that the unit value averaged very much above 7 cents per ½ kilo., but principally by the circumstance that the Government plantations have hitherto been able to harvest the bulk of their produce from old trees, yielding heavy bark of splendid appearance, such as is not yet obtainable from any private concerns. The latter is a factor which should not be lost sight of, since it is easier and cheaper to take 10 lb. of bark from one full-grown tree than 1 lb. each from ten young trees. During the year 1884 the average cost to the Dutch Indian Government of cinchona from their plantations, delivered at Batavia, was 55·8 cents per kilo. (=5d per lb.) In 1885 the cost was 52·4 cents (4 7-10d per lb.), and in 1886 it fell to 46·3 cents (=4⅛d per lb.) Add to this an average of 18 cents (3·5d per lb.) for freight and sale expenses, the total cost for 1886 may be placed at 64 cents, or 5¾d per lb. During 1886 the Government bark, if sold at an average of 14 cents per kilo., on an average of 5 per cent. sulphate of quinine, returned 70 cents per kilo., on which the profit was 6 cents per kilo., or say ½d per lb. To a private planter this gain would have been more than balanced by his outlay on interest of capital, taxes, &c., items which do not weigh on the Government produce.—*Chemist and Druggist.*

DOES CINCHONA-GROWING PAY?

A well-known Berlin wholesale druggist, Mr. J. D. Riedel, in a recent number of the *Pharmaceutische Zeitung*, offers his view of the question at what lowest sale-price of bark cinchona-growing can be made to pay. Mr. Riedel asserts that from 1880 to 1882 cinchona exporters in Columbia did not find it profitable to ship any bark for which less than 5d per lb. was paid at the London auctions. It should be noted, however, that at that time the London charges and allowances on cinchona were very much heavier than they are at present, deductions for difference in weight alone amounting to about 10 per cent. During the same period the cost of production of a carga (equal to 250 lb.) dry cuprea bark in the forests of Santander, where that variety had just then been discovered in immense quantities, was 2½d per lb., taking into account the loss on the Spanish exchange and the fact that nearly 6 lb. of green bark were required to yield 1 lb. of the dry article. Carriage of the bark through the woods and by the Magdalena River to Savanilla, the port of shipment, amounted, in 1880, to about 2d per lb., but afterwards, when the rates were increased, to as much as 6d per lb. As soon as the London price for this variety averaged below 6d per lb. the export of cuprea bark must, therefore, have ceased to be profitable. With the decline in the value of cinchona the exportation of bark from South America to New York and Paris receded to a minimum, and the shipments to London were mostly limited to old stock on hand. The increase of East Indian bark supplies, collaterally with the diminution in the South American shipments, is, in Mr. Riedel's opinion, evidence that cinchona can be produced much more economically in the British and Dutch colonies than in its original habitat. Labour being cheaper in Ceylon than in South America, the cost of collecting bark in the former country may be estimated at 1d per lb. of dry bark, or per 100 lb. 8s 4d; carriage to railway station, per 100 lb. 6d; railway freight and cartage to the mills in Colombo, 1s; repacking, pressing, export duty, and other charges at Colombo, and freight to London, 3s 6d; cartage, sampling storeage, and sale expenses in London, 1s 9d; insurance (on 40s per cwt.), broker's commission, interests on money advanced, &c., 5 to 5½ per cent. of 40s, 2s 5d; total costs and charges per 100 lb. 17s 5d or 2 1-10d per lb. It follows that if the average price at the London auctions is less than 2 1-10d per lb. the planter loses money absolutely, and it will pay him better to leave his trees alone or to burn them down, as the cheapest way of destroying them, than to harvest the bark. The cost of turning cinchona bark into sulphate of quinine, Mr. Riedel estimates (for London) at 1¾d to 1 9-10d per lb. of bark and the average proportion of quinine in the bark at 1¼ to 1½ per cent. Calculating on this basis, he arrives at the conclusion that if the planter is to receive back the mere cost of collecting and shipping bark, not allowing for any profit, the producing price per oz. of quinine is 1s 3⅗d.—*Chemist and Druggist.*

A SANGUINE VIEW OF QUININE.

The total sales and resales of quinine on the three last days of the year just brought to a close amount to about a quarter of a million ounces, a turnover which required probably a larger amount of capital than has been engaged in quinine in any three consecutive days during the year, though the quantity of the product represented falls perhaps a little short of what was sold in the first three days of the revival that occurred in November. There is little doubt that nearly half of these transactions were made on behalf of firms who were compelled to deliver quinine previously sold by them, and the operations must have cost them between 2,000*l* and 3,000*l*. Such an operation could probably not have been carried through successfully but for the strategic movement of depressing the last bark sales, thereby creating an artificial weakness and causing certain holders to realise without further delay. Of course such an operation will scarcely be attempted in the same way again, nor will there probably be any occasion for it until the lots sold for January-February delivery fall due.

Now, although 1s 11d to 2s 0½d are the only figures publicly reported, three seems little doubt that more than 2s 0½d was paid for large lots. It is rumoured that some weeks ago speculators have been trying to invest 20,000*l* to 30,000*l* in quinine, and would

even have been willing to pay 2d per oz. above the current quotations to effect the purchase. At that time the price of quinine was nominally 1s 3½d to 1s 4d per oz. with a very weak market, and after the article had risen to 1s 8d the intending speculators again considered the advisability of buying with 1s 8d as the basis, and 2d extra as the inducement to secure a large quantity. Finally they did buy, though not to the extent previously intended, and it is believed that they paid as much as 2s 2d per oz. for some of their acquirements. Besids these speculators it is said that there is a powerful syndicate now operating on a similar basis.

It is thought that the first lots bought in this manner were sold, not by speculative holders, but by the manufacturers themselves. This inference is drawn by the fact that, except 50,000 oz. sold at auction at 1s 3½d to 1s 4d, no transactions worth recording were entered into, while the quotations remained at the lowest range of rates. A little was bought at 1s 7d to 1s 8d after the drop from 1s 11d, at which latter figure the last extensive business was done, and as the buyers in this particular case declare that they have not yet resold an ounce, there was practically nothing in speculators' hands that would not on resale leave a great loss and it is scarcely likely that holders of stock would begin to sell at the moment of an upward movement, especially after they had seen all weak holders cleared out. On the other hand, it seems but reasonable to suppose that the slightest upward movement would be the signal for them to recommence buying, and this they probably did. The syndicate, carefully watching the clearance of the weak ones, seized the opportunity to get manufacturers to freely offer firm in a flat market, and commenced operations forthwith. No doubt manufacturers had accumulated large stocks, and were desirous of clearing these. They therefore sold freely, not only what they had ready made but also their future turnout, for forward delivery. The move to flatten the bark market enabled them to lessen their losses in the repurchase of quinine, but it prevented their getting the bark cheaper, as the large proportion was bought in by the importers. There is an impression that most of the quinine manufacturers must have lost a good deal of money in their struggle against low and constantly declining prices, combined with fierce competition and strenuous efforts to keep their works going, and that they will require all their strength to stand against the forces now arrayed against them.—*Chemist and Druggist*, Jan. 7th.

COCOS ISLAND

was first visited in the year 1826 by a Captain Ross, who, on going back home, brought out some people to settle here, being struck by the natural advantages of the place. When he got back, however on his return voyage with a party of colonists from his native Highlands, he found that the island had been taken possession of by a man called Hare who, whether of the Mormon faith or not, so far agreed with the tenets of the creed as to have sixty wives. Ross managed to make it warm for him, so after a time Hare left, and the original discoverer then brought over some Javanese and founded a colony. The work on the island was carried on by Ross's eldest son, who married a native; and their descendants, five sons, who have all been to Scotland to be educated, now manage the business which their grandfather, in the first instance, started. The eldest brother, the "Governor" as he is called, is a very clever and hard working man, to whom it was quite a pleasure for us to talk. He seemed to be conversant with everything that was going on in the outside world, and said he had been to England last year on a visit to his sisters. His particular study when at home for his education had been the engineering profession, another brother learn' doctoring, each having his special department in the interest of the community at large. They are grand boat-builders on the island, and built a 200 ton schooner classed A1 at Lloyd's for eighteen years, which took Mr. G. Ross home on his last visit. They have also a brigantine that they purchased commanded by a Norwegian named Flack, which carries the products to Batavia for sale. Besides the Ross family an American merchant skipper, Bonsley by name, has also settled on the island, and, like the others, is married to a Javanese lady. There is a splendid lagoon between the reef and the island, which affords safe sailing for boats, as, although there is always half a gale of wind blowing, there is hardly any sea inside the lagoon on account of the shelter which the island affords, making it almost land locked. The elder Mr. Ross, the Governor, teaches the natives everything, and all the varied products of the soil are utilised. The island abounds with coconut trees, from which is made copra, a well-known article of merchandise largely imported into England from Fiji and elsewhere, consisting of the kernel of the nuts crushed up and dried in the sun. It is said that it is used largely in Europe for adulterating butter, and making a large proportion of the codliver oil of commerce.* Here the natives, by pressing the nut, make their own sugar, vinegar, oil, soap, and a species of "toddy" as they call it, a raw spirit very strong and almost more deleterious than arrack.† There are no animals on the island for food except fowls, although at Horsburgh, the "capital," there are some deer. The main food of the inhabitants is rice, fish and coconut, the first-named article being imported. There is no money in the island, men being paid for their labour in sheepskin mats, which they exchange at the store for anything they want. Wages are good, and they are given half Saturday and all Sunday on which to fish and gather nuts on the adjacent islands for their own use. The place is very healthy and cool, the average temperature being about 75 degrees, and the height of the barometer between 29 and 30 inches. The population is divided into the regular Cocos-born natives and Malays from the adjacent peninsula. These keep quite distinct, the Cocosians numbering 95 men and 100 women, with nearly an equal number of each sex to represent the rising generation; while the Malays muster 57 men, 17 women, 19 boys, and 40 girls. The Cocosians are by far the finest race of the two.—*Visit of H. M. S. "Rattler."*

* Coconut oil has been recommended as a substitute for codliver oil, but the odour is a fatal bar to its employment as an adulterant of butter.—Ed.

† Toddy is the sap running out of the flower spathe, into vessels when fermented, but distillation is necessary to convert it into a spirit.—Ed.

"HORTUS ZEYLANICUS."

We have to acknowledge the receipt of a copy of this very useful compilation, the full title of which is: "A Classified List of Plants, both Native and Exotic, Growing in the Royal Botanic Gardens, Peradeniya, Ceylon; Compiled by Henry Trimen, M.B. F.L.S., Director. Price One Rupee. Colombo: George J. A. Skeen, Government Printer, Ceylon. 1888." The classified list extends over 120 pages, while a very handy alphabetical index of 8 pages is added. From Dr. Trimen's "Introductory Note" we quote as follows:—

With the exception of a "List of Plants suitable for Distribution," issued eight or nine years ago, and containing between 1,300 and 1,400 names arranged according to their uses, the present is the first attempt to give a Catalogue of the contents of the Peradeniya Botanic Gardens. I should, therefore, wish it to be considered as provisional only, and am fully conscious of its imperfection as a complete record of this rich collection. A considerable number of species, which still remain to be determined, cannot be entered: these are mostly trees and shrubs of other climates which have never flowered here, and of which the history and origin are lost. The correct identification of a good many others remains in doubt, and the list generally suffers from the unavoidable drawback of want of access to a large Botanical and Horticultural Library, sufficient to aright decision on matters of nomenclature. It will

however, probably be conceded that to wait until all doubts could be settled, and so delay indefinitely a work so much needed as the present, would be a less desirable course in the public interest than to print it forthwith in a somewhat incomplete condition.

The following Catalogue, then, which is brought up to the end of 1886, contains the names and native countries of all the Flowering Plants and Ferns, &c., growing in the Royal Botanic Gardens, Peradeniya, so far as I have been able to ascertain them. There are also included the few additional ones to be found in the Experimental Gardens at Henaratgoda and Anuradhapura, or planted in and about Colombo and Kandy. It thus comprehends all foreign plants in cultivation in Ceylon up to the elevation of about 2,000 ft., but not those cultivated only in the Botanic Garden at Hakgala or elsewhere in the hills.

I have also included in their places, distinguished from the exotic species by the prefix of an asterisk, all the native indigenous plants of Ceylon, even the commonest, growing in the Gardens of Peradeniya. Most of these have been conveyed to the Gardens from other parts of Ceylon, but some are wild (not cultivated) here. These last are very generally weeds; and under the same category must be classed also a good many introduced foreign species. With regard to the more ornamental of our native plants of small size, such as Orchids, Ferns, &c., it is not possible to have the list constantly accurate, as the stock of these is continually varying.*

A good many plants have had to be included as growing in the Gardens which cannot be said to flourish here—indeed some of them barely exist: such are mostly species from dry warm-temperate or sub-tropical countries, to which our constantly damp hot climate is quite unsuited. Many of the favourite garden and greenhouse flowers of England are of this character, and do not repay cultivation here, though some succeed well in the hill districts.

The dates within brackets appended to many of the exotic species are those of the first ascertained introduction of the plant into Ceylon. I regret that these indications are not more generally given, but the Garden records have afforded but little information on this interesting subject. All acquisitions since 1880, however, are dated. Of early introductions I have been able to obtain but scanty notices, the most important being records which exist for 1678, 1802, 1824, and 1846, of some of the foreign plants growing in the Island at those periods.

"Coffea Arabica," native of tropical Africa, is entered as introduced into Ceylon about 1690—a final settlement of a long-disputed point.

* A complete list of the native flora of Ceylon will be found in my "Systematic Catalogue," published by the Royal Asiatic Society of Ceylon in 1885. The names employed in the present Catalogue are almost invariably those there adopted.

THE CARDAMOM PLANT.

The Cardamom of Commerce, *Elettaria Cardamomum*, a member of the natural order Zingeberaceæ, is indigenous to the forests of Malabar, where it is found growing wild at altitudes ranging from 1,800 to 3,500 feet above sea level. A moderate degree of shade and any amount of moisture are the climatal conditions most favourable for the plant's luxuriant growth.

If the shade be too profound, the stalks which spring from the rhizome will be but few in number, but if sunlight be moderately admitted, they will increase amazingly, often exceeding 70 in number, but if exposed to sunshine for more than an hour or two daily, the plant languishes and eventually dies out. Each stalk throws out a scape, or peduncle, varying in length from 1½ to 2½ feet, on which the fruit is produced in the form of capsules, arranged in an alternate manner on each side of the shaft, at a distance of about 2½ inches from each other. From the description of the plant above given, a large crop might be expected, but the result does not fulfil the expectation to the anticipated extent, as owing to the large amount of moisture contained in the vegetable tissues of the cases which cover the grains, one pound of the green fruit reduces down to one quarter, or sometimes one-fifth of a pound when fully dried.

In its natural climate and soil, a sandy loam devoid of clay, the plant begins to bear in the 2nd and yields a full crop in the 4th year. My experience does not enable me to state precisely the yield of each tree. I think that the planter may consider himself fortunate, if he succeeds in harvesting on the average one-quarter pound of dry cardamoms per tree in the total number of 60 trees which occupy an acre, in the fourth year, less a certain percentage of loss occasioned by rats, squirrels and snakes, all which species of vermin evince a partiality for the fruit and are ever on the watch to pounce upon it the moment it becomes ripe; and this entails the necessity of great watchfulness on the part of the planter to forestal these marauders, and be in the happy position of that early bird which proverbially "gets the worm." Each stalk as it completes its functions in bringing its scape to maturity, and becomes effete, is succeeded by another stalk, sprouting from the parent rhizome, which begins to bear in the course of a year; and in this order, the growth proceeds with successive renovations, until the plant attains its ultimate span of existence, in the lapse of time: the extent or duration of which is not accurately known to the writer.

Until Ceylon glutted the Home Markets, cardamoms sold well, but they hardly fetch remunerative prices now, as the quotations have fallen from 5s a lb. to 1s 4d and even less for the small kinds of which there is a considerable proportion in all lots and which sell for about 8d a pound. The spontaneous way in which the plant was for a long time supposed to be exclusively produced, viz.; from the concussion of the ground occasioned by the fall of a large tree felled over it, was, if not a purely fanciful idea, probably a cunning one suggested by the interested motives of those, who were the fortunate holders of the cardamom hills and habitats. Whether such an origin has any better foundation to rest upon than mere imagination, it would be idle here to discuss, as there is no question of the fact, that cardamoms can be reared from seed sown in shaded nurseries in the ordinary way, or from the division of the rhizome into parts containing young shoots or eyes fit for development into them. The former is undoubtedly the quickest way of forming a plantation; although it must be admitted, the seed is singularly slow in germinating, taking never less than three and often as many as five months, before the little spikes show themselves above ground. Within a year from this time, the plants will, with careful culture, have attained a sufficient size to be planted out into pits dug for their reception in the shade of the forest suitably prepared by trenching, and the thorough extirpation of root and branch, of the brush wood occupying the surface. The process cardamoms are put through called bleaching, is a tedious one, and if left to agents, particularly costly. It is done by exposing them to the fumes of sulphur in closed receptacles: a process which has the effect of transforming their dingy grey, into a delicate pale straw colour. This may be called one of the tricks of the trade, which, while perhaps it may not appreciably deteriorate, or detract from the quality or flavour of the grains, captivates the public eye, and secures a better price.—*South of India Observer.*

TEA-PLANTING FOR AUSTRALIA; AND CEYLON TEAS FOR ITS MARKETS.

From the following letter addressed to the Melbourne *Argus*, it will be seen that there has been an inquiry into tea cultivation in Victoria by a Royal Commission:—

TEA: ITS GROWTH AND MANUFACTURE.

TO THE EDITOR OF THE "ARGUS."

Sir,—In reading over the report of the Royal Commission on the above subject, the practical planter

cannot but enjoy a hearty laugh at the many absurd statements by witnesses giving evidence before the commission. One gentleman says of some plants grown in the colony that they are doing well, and are now some 12 ft. high. Any person acquainted with the cultivation of tea must know that for commercial purposes the leaves plucked from such would be utterly useless for manufacture, and of no market value. The plant should never be more than 2 ft. 6 in. to 3 ft. 6 in. in height, and trained to present a bushy appearance, and not having the resemblance of elongated pipe stems. The climate of the colony in parts, as also the properties of the soil, are well adapted for the growth of this invigorating beverage, and I believe it could be cultivated in Victoria and brought to pay larger dividends than most commercial undertakings. It would be a pleasure to me to afford gentlemen every aid and advice on the matter of starting this as a native industry in your colony. In fact, I am so perfectly satisfied with the suitability of the soil and climate of this colony for the successful growth of the tea plant that I would be willing to enter into an arrangement with any gentlemen desirous of embarking in this line.—Yours, &c., WM. WALLER.

Oak-lodge, Carlton-street, Carlton, Jan. 6th.

Mr. Waller, a former Indian tea planter, we suppose, writes, what is doubtless true enough, that even in portions of Victoria there is soil and also climate in which tea would flourish. The plant would do better in the wetter climate of New South Wales, and still better in the semi-tropical and strictly tropical portions of Queensland, the Northern Territory of the misnamed colony of Southern Australia, and (as so long advocated by Mr. Wm. Cochrane of Dunblane though he had never seen the Colony) in the northern portion of New Zealand. But the wages of European labour are far too high in all the colonies, and the colonists have set their faces against even the introduction of cooly labour to replace that from the South Sea Islands by which sugar culture in Queensland was rendered possible. That sugar cultivation with all the advantages in its favour can be made to pay with European labour, we doubt; but that tea would never pay with such labour, we feel certain.

In this connection we may call attention to the two letters we publish from Ceylon planters on the prospect of pushing our teas in the Australian markets. The valuable suggestions made by "B. J. W." and Mr. H. G. Mackenzie (see page 585) will no doubt receive the careful attention of our Tea Fund Committee.

THE CEYLON LAND AND PRODUCE COMPANY, LIMITED.

DIRECTORS.—James Wilson, Esq., Chairman; Thomas A. Shepherd, Esq., Thomas A[illegible].

Report of the Board of Directors to the Third Annual Meeting of Shareholders, to be held within the Offices of the Company, Ingram House, 165, Fenchurch Street, London, E. C., on the 29th day of December, 1887, at 2 p. m. The Directors have much pleasure in submitting to the Shareholders the Accounts and Balance Sheet for the year ending 30th June, 1887. After writing off all Preliminary Expenses, £100 off Debenture Charges and extinguishing the balance at debit of Profit and Loss Account at 30th June, 1886, a credit balance of £2,[illegible] 11s 5d remains to be dealt with. The Directors recommend that out of the Profits a dividend at the rate of 6 per cent be declared on the called Capital of the Company for year ending 30th June, 1887, payable on 15th proximo, which will absorb £2,2[illegible], leaving a balance of £[illegible] 11s [illegible]d to be carried forward. Extension of cultivation on the Company's properties continues to be made and the general working of them is satisfactory. The Colonial Manager's latest advices state that the season is favourable, and he indicates that the Coffee and Tea estimates made by him at the commencement of current year are likely to be considerably exceeded.

The Cocoa autumn crop, owing to unusual drought during the blossoming season, will be short of last year's one, but for the past two months ample rains have fallen, forcing out quantities of blossom, and as it is setting freely a large spring crop may reasonably be expected. The prices realised during the year for the Company's produce, excepting for Cinchona Bark, have been very satisfactory and still remain so. The Company however has a very limited acreage under Cinchona.

The Directors have pleasure in stating that they continue to have the fullest confidence in the success of the Company, and would ask the Shareholders to bear in mind that there is but a small percentage of the acreage as yet in full bearing, and year by year as this increase, with average seasons, the position and prospects of the Company ought to improve. In accordance with the Articles of Association, one of the Directors retires at this time, viz., James Wilson, Esq., and being eligible, offers himself for re-election. Mr. James B. Laurie, the Company's Auditor, retires as usual, but being eligible offers himself for re-election.—By order of the Board, THOS. J. LAWRANCE, Secretary.

Ingram House, 165, Fenchurch Street,
London, 19th December, 1887.

[Six per cent just when the Company's places are coming into bearing promises well: the Company has undoubtedly very fine properties.—ED.]

TEA: THE FOOCHOW CHAMBER OF COMMERCE ON THE TEA TRADE.

We reviewed not long since the answer of the Foochow Chamber of Commerce to Sir Robert Hart's request for advice as to the rehabilitation of the Tea Trade, and we have now before us the report on the same subject of the Committee of experts appointed by the Shanghai Chamber (see Feb. No., p. 571). As a matter of fact the recommendations made by this Committee are very much the same as those we made in our article published in October last, and we are pleased to find our suggestions backed up by the authority of the names appended to this report. The first paragraphs of the report are a re-statement of the fact that Indian and Ceylon teas are ousting China teas from the London market; this it was hardly necessary to re-state; as, unless it had occurred, this report would never have been asked for; but it was perhaps not superfluous to give the exact figures. The deliveries in London in 1880-81 were of China tea 158 millions, and of Indian, Ceylon and Java tea 50 millions; in 1886-87 they were of China tea 134 millions, and of Indian, Ceylon and Java tea 87 millions; so that in the six years China has gone back nearly 24 millions while her competitors have gained about 37 millions, and "this year," say the Committee, "promises to give even more striking results than these, the last published figures."

The necessity for action being thus proved up to the hilt, it is time to turn to the remedies recommended. The first are two of the points mentioned by us; the despatch of Chinamen to the Indian tea gardens to learn the processes by whose use they are being beaten and the introduction of machinery such as is used with such good results in India and Ceylon. Years ago a tea-sifting machine was imported by a prominent green tea buying firm here. The Moyune teamen to whom it was shewn looked at it with scorn and horror. "Put our beautiful leaf into a thing like that! Never." And so the primitive modes of preparation dear to the Chinese packer go on, with the result, in the words of the Committee, 'that tea can only be properly made under the most favourable climatic conditions [illegible] the [illegible] of rain, or any untoward circumstance [illegible] to all [illegible]," when [illegible] the [illegible] of Spring [illegible] China [illegible] the [illegible] own [illegible] the [illegible] of the season's produce [illegible]. The report goes on to confirm our remark that it is not so much the cheapening of the China product that i

required, as the improvement of the quality. "It is in the matter of flavour that we look for the revival of the China Tea Trade," says the report. "What we want is a strong tea, full of aroma, and so perfectly cured that it will retain the qualities for a long time." We described the process by which enough leaf is secured from the growers, with the concomitant delay, while in India the leaf is fired on the day that it is picked,* and we find the report drawing attention to this delay, "often extending for a week to ten days after the leaf has been picked from the tree, during which time the leaf is rapidly deteriorating." Where the report differs from us, and the difference is not serious, is in stating that the leaf in India is prepared and packed the day after it is picked. This makes no difference to the argument; what is certain is that the system in India results in the best qualities of the leaf being retained in the packing, while they are allowed to evaporate in the delay that takes place in China before sufficient leaf is collected from the small growers to make what the Chinese teaman considers a normal chop. Farther, we suggested that the most effective remedy for the present deterioration would be to allow foreigners to go freely into the interior, and introduce the modern methods of preparing the leaf for market. This point also is taken up by the committee of experts. They say:—"If the Chinese Government are really desirous of improving the production of tea, the best of all plans would be for them to throw the country open to foreigners, so that they may establish tea-curing hongs with modern machinery in the tea-districts, and, if necessary, may acquire land for the better cultivation of the plant." Unfortunately this suggestion—the best that can be made—is the least practicable, for advantageous as it would be to the people, there is very little chance of the Government's allowing it to be put in practice as long as extra-territoriality exists. It is true that foreigners are allowed to undertake work that is not strictly religious in the interior, on the occasion of a great public calamity such as a flood or a famine, and the only way would be to impress the Government with the conviction that the collapse of the China tea trade is a similar calamity, calling for the assistance of foreigners on the spot. It is for the authorities who have asked for this report to consider, whether they can take this view of the evil for which they are seeking remedies.

The remarks made by the report as to the minor evils connected with the trade at present, the mixture of leaf from inferior with that from better districts, the neglect of re-plantation in worn-out gardens, the mixture of actually injurious rubbish in the so-called Pingsuey teas, and the almost universal custom of issuing false musters in Hankow, are all very much to the point, and these are all abuses which the authorities, if they are in earnest, can easily remedy. The report confirms our remarks as to the killing duties now imposed in China; but it is very doubtful whether the Tsung-li Yamên is broad-minded enough to realise that by reducing these duties to a nominal sum it would gain in the end more than it would lose. If the duties are retained they will be lost, for the almost entire transference of the trade to India, Ceylon and Java is in that case only a question of a few years; if they are practically abolished they will also be lost, but the people—and we believe that the Government is inspired, as far as its lights go, with an honest desire for the welfare of the people—will still have a market for their products. The choice is now plainly before them.

On the whole there is not much that is new in the report, but the facts and opinions it reiterates are now formulated with the authority of six of our most practised experts who are personally strongly interested in the question, backed by that of the General Chamber of Commerce who delegated the enquiry to them; and we can only hope that the Tsung-li Yamên will lay to heart the recommendations it contains.—*N.-C. Herald*, Jan. 6th.

* It depends on the weather: sometimes in wet weather the withering process occupies three and even five days.—ED.

THE PRODUCTION OF CINCHONA AND CEYLON ESTIMATES OF BARK EXPORTS.

The London *Chemist and Druggist* had the following article in a recent issue:—

In our trade report we publish a letter from our Amsterdam correspondent on the impending increase in the cinchona supply from Java. Our correspondent is a gentleman who has been intimately connected with the Dutch cinchona market ever since the Java planters commenced to ship bark to the mother country, and his statements deserve attention as coming from one who has made cinchona a special study. Our correspondent anticipates that in the seasons 1889 and 1890 enormous quantities of exceptionally rich Java bark will be shipped to Europe. This bark is now growing in the private plantations of the island, of which there are more than sixty, and within eighteen months of the present time the trees planted between 1879 and 1882 will be ready for shipping. Each tree is expected to yield on an average 1½ kilo. of bark containing from 6 to 10 per cent quinine. In addition to these shipments for the near future, a more remote period is to be provided for by the raising of at least 300,000 *Ledgeriana* and *Hybrid* cinchonas from the seed of trees of which several parcels of bark, sold at the last public sales in Amsterdam, were found to contain an average of 10 per cent of quinine. It is, therefore, quite possible that within a couple of years Java will absolutely dominate the cinchona market; for, although her exports may not attain the fifteen million standard of recent Ceylon shipments, their lack in bulk will be made good, and more, by their alkaloidal richness. The harvesting and shipping expenses of this rich bark will not, of course, be higher than those of the poorest varieties. Ceylon planters will do well, therefore, to seriously ask themselves whether they have any prospect of holding their own against such competition as, according to our correspondent's letter, is looming near at hand?

The estimates which are now given of the exports of bark from Ceylon during the season 1887-88 will probably prove to be as wide of the result as those of previous years have been. The crop for 1884-85 was estimated at 8,500,000 lb, it yielded nearly 11,700,000 lb. That for the season following was fixed, by the most competent judges, at 9,000,000 lb; it gave nearly 15,4000,000 lb. Undeterred by these failures, the knowing ones asserted positively that in 1886-87 not more than 11,000,000 would leave the island. As a matter of fact, nearly 14,400,000 lb. were exported. For this reason the "straight tip" is 9,500,000 lb, but we shall not be surprised to find, eleven months hence, that the Ceylon wiseacres are no better prophets of their bark shipments than are sporting editors of the winning animals at horse races. The fact is that the Ceylon cinchona trees resemble the London unemployed, in that no proper census has ever been taken of their number. In the eyes of the confident "bear," they are numerous as the sand by the sea shore; while the knowing "bull" is equally full of mysterious rumours of wholesale uprootings, and triumphantly points to reports of the burning of trees in the field because it no longer pays to strip them. It is certainly remarkable that from October 1st the beginning of the season up to November 25th the bark exports from Ceylon only amounted to 1,232,000 lb. or little more than half of the shipments in the corresponding period of 1885-86; but since then the news of the advance of quinine in London has reached Colombo, and only if the reduction in shipments should be maintained in the face of the temptation caused by the higher London prices may we conclude that shipments are likely to remain permanently on the decline. But the odds are that the Ceylon shippers, as they have always done before under similar circumstances, will consider only the possibility of immediate gain and begin to ship in all haste in the hope of participating in the rise. The Colombo market, before the recent advance in London, was thoroughly demoralised. The usual public sales had not been held for many

weeks and the ordinary varieties of bark were absolutely unsalable. But, as a Ceylon contemporary very pertinently observes, cinchona is not so much a crop as a reserve, of which the planter produces much or little as he pleases, or as exigencies demand. Now is it not, we will not say likely, but at least possible, that the Ceylon planters, if they should once become thoroughly convinced that in a few years they must succumb to the Java competition, will prefer to harvest their barks while they still fetch any money at all, and flood our market with as much as they can possibly get away, turning their attention to other crops, the steady rise in the value of which promises a surer reward than the treacherous cinchona? Whatever may be the case, we confess that we cannot share the sanguine views entertained in many quarters of improved values of the cinchona alkaloids. A ring among the quinine-makers may, indeed, have the effect of artificially raising the value, but it seems reasonable to assume that the consumption of quinine is certainly not increasing in larger proportion than the production of the alkaloid in the bark, and of the latter, so far as we can see, enough will be forthcoming from different countries to keep prices at the lowest possible level consistent with a moderate profit to the grower.

To the above we reply :—

To the Editor of "The Chemist and Druggist."

Considering that you so often quote from the *Ceylon Observer* press publications, and more particularly the *Tropical Agriculturist*, it is surprising that you should do us so much less than justice in the editorial on "The Production of Cinchona" in your issue of December 17th. You scarify the "knowing ones," "the most competent judges," the Ceylon "wiseacres," on the wide discrepancy between their estimates of bark shipments at the beginning of each season and the result. Where you have got your figures for "estimates," we cannot say; but, considering that the only statistics of cinchona cultivation in Ceylon have been embodied in the *Observer*'s "Handbook and Directory" from time to time, we should suppose, that, to get the best and most reliable export estimates of bark, you would refer to the same authority. Fully acknowledging the wide discrepancy between estimates and results in the earlier years you refer to,—when all concerned were taken utterly by surprise,—we have to point out to you that our estimate for the Ceylon exports in season 1885-6 was *ten* and not nine millions of lb. as given by "the most competent judges" whom you quote; while we particularly draw your attention to the fact, that our estimate framed on October 9th, 1886, for season 1886-7 ran :—"Cinchona Bark from 11 to 11 million lb." while later on we said not less than 12 million lb. For the current season we have taken 10 millions as the probable export, for the reason chiefly, that with the increasing demand on our labour supply on account of extended tea cultivation, and the plucking and preparing of the leaf, there should be neither the coolies nor the time to secure as much bark as in previous years. A great difference, too, is shown in the available supply in our planting districts; nevertheless, if there were a return to really good prices, we should not be surprised once more to see our estimate exceeded. —EDS.

PLANTING PROGRESS IN TRAVANCORE.

In sending us full Statistics of the Plantations in Travancore for our "Handbook and Directory," Mr. Cox, Chairman of the local Planters' Association, also affords a very valuable Report on the present position of the Planting Enterprise under the variety of heads which distinguish it over the way, now-a-days even as in Ceylon. The products included in Mr. Cox's paper are :—Coffee, Tea, Cinchona, Cacao and Pepper, and we give the Report in full in February's *Tropical Agriculturist*. It is satisfactory to learn that coffee is by no means extinct in the outlying planting offspring of Ceylon (as Travancore has been called), while cinchona robusta flourishes —the grafting of ledgers on succirubra stocks being successfully carried out, of course, on a limited scale. No one need fear, however, that Travancore cinchona will ever interfere greatly with the Bark market. It is in tea rather that Travancore should assume a respectable position, for, equally in soil, climate, abundance of timber and cheap labour, the district has many advantages, and its teas have been very favourably reported on by London experts. Pepper (long a native export) and cacao ought to strengthen the Travancore enterprise. We lately heard of the sale of a fourth share in a Travancore Tea estate to a young planter trained in Ceylon, which shows that things are at least moving over the way, and a renewal of prosperity may shortly be anticipated.

COCONUT PLANTING IN THE LOWCOUNTRY OF CEYLON.

THE DROUGHT AND ITS EFFECTS ON COCONUTS—PADDY CULTIVATION—MR. COCHRAN'S EXPERIMENTS—PLOUGHING—AERATION OF THE SUBSOIL—EFFECT OF DROUGHT ON RICE CULTIVATION IN INDIA—WHAT IS CLAY ?—HOW TO IMPROVE POOR SOILS—'LIVE' AND 'DEAD' SOILS—ANALYSIS OF CLAY.

SIYANE KORALE, 30th January 1888.

No rain or signs of rain since the dawn of the New Year. If the drought be as severe as it threatens to be, the look-out for coconut planters is very gloomy. Prices are lower than they have been since I became interested in coconut cultivation. The general belief is, that with ever-increasing stocks of oil and the consequent low prices, mill-owners are not engaged in a business that takes to the full their resources or yields much profit: this is evidently a popular delusion, as witness the alleged mission of Mr. W. C. Leechman to Europe.

The thanks of all paddy growers are due to Mr. Cochran for his highly interesting communication which appears on page 569 of the February No. Unfortunately the vast majority of those engaged in this culture are ignorant natives who will in no way be benefited by the lessons his analysis and experiments teach. The deduction I draw from his experimens with the soil from Nuwara Eliya is that the vast majority of our paddy fields suffer by being kept perpetually under water, and that fertility will be restored to them if they be broken up and aerated during the dry weather, so that the different compounds of iron in it may be rendered insoluble in water, and consequently harmless. It will be seen from the results of the experiments as given in a tabulated form that the grains of paddy corn on the unmanured soils gave comparatively better results than those sown in the soils manured with bones, cattle manure or lime. Why? Because in a pot the soil had no chance of becoming sodden and was well aerated. I think this gives us the key to the wonderful results yielded by the experiments of the agricultural instructors, for be it remembered that Mr. Green insists on the fields being ploughed during the dry months at the beginning of the year with the iron plough, and cross-ploughed with the native plough after the soil is saturated with the S W. rains, so that the noxious iron compounds have been rendered innocuous in the interval. I do not agree with Mr. Green that it is necessary for the field to be perfectly dry before it is ploughed with the English plough, for if the soil be rather moist as it is now, the work is facilitated and is in my opinion more thorough. Exposed as it will be after the operation to the scorching sun of the next few months, it will have a longer time to be perfectly aerated and rendered sweet

The following has an intimate bearing on this important subject:—"Nearly all soils contain iron; it is this that gives them their red color. Iron has two oxides: one of them, containing the least amount of oxygen, is soluble in water, and is therefore taken into the roots of plants. Copperas or green vitriol is composed of this low or protoxide of iron and sulphuric acid. On exposure to the air for a time, this low oxide takes in more oxygen and forms sesquioxide of iron which is insoluble in water. The subsoil, which has never been stirred to admit the atmosphere freely, contains the low oxide, and when first turned up if sown or planted soon, the roots of the crops take in this soluble compound of iron and are much injured if not killed outright." The last sentence fully explains the perfect horror Professor Wallace and all competent authorities have of bringing to the surface the unaerated subsoil, more especially that of paddy fields which possibly contains most iron owing to the opportunities for aeration being so few. Turn up a little of such sub-soil at a time, an inch or two each year, let it be exposed to the air and frost for a few months, and it will become innocuous. The new elements of plant food in this new soil will even act as a useful fertilizer."

According to the usual native modes of paddy cultivation, ploughing is never resorted to except at the commencement of the rains, so that the fields may be submerged immediately after the ploughing so as to kill the weeds and grasses displaced by the plough. The operation is repeated more than once, the land being constantly submerged, so that aeration to render innocuous the poisonous iron compounds is never possible. When the fields lie fallow, water, as long as it is obtainable, is turned on the field, so that even partial aeration takes place only in a season of prolonged drought when no water is available. From the light of Mr. Cochran's experiments and the extract I have given, it is apparent that a revolution in the preparation of fields for paddy cultivation is necessary before we can expect better returns from our fields. (Can it be that the higher returns of rice fields in India are due to the more severe and more prolonged droughts that are common there, than to an intrinsic superiority of soil?) It becomes the duty of revenue officers to make widely known the results of Mr. Cochran's experiments and the absolute necessity for ploughing fields at the beginning of the dry season, so that they may be perfectly aerated. Surely Mr. Elliott, who has such a deep interest in paddy cultivation, will take the lead.

Mr. Cochran's request to have samples of fertile paddy soil to analyse should be complied with without much delay. Five fertile fields lie between the railway line at Mahara and the road leading to Mr. R. L. M. Brown's property, and in the Kandyan country between the railway line and road leading from Peradeniya to Gampola.

It has become almost an axiom in agriculture that a sandy soil is improved by the addition of clay and *vice versa*. But what *is* clay? That has sorely puzzled some people. What I understand by clay is what occurs at the surface as a surface soil and which when deprived of moisture cracks and hardens like a brick-soil that has been cultivated, and not the clay that has been brought to the surface from many feet below the surface. We must understand the object of claying a soil; it is not merely to give body to it,—very necessary in dry cultivation to prevent to rapid evaporation, but also to add to its fertility. A sandy soil is admittedly not a rich soil, therefore the addition to it of a substance which itself is not rich will not add to its fertility by giving body to the soil. I have heard it asserted that because manure without admixture will not support vegetation and pure clay too will not support vegetation, and as by the application of the former to the soil beneficial results follow, therefore it can fairly be expected that beneficial results will follow the application of the latter. It is not necessary to seriously refute what is so self-evidently fallacious. There are two grand determinations of soils, "live" and "dead." The former is supposed by the action of "ferments"—chemical agencies—to have been quickened into life and is able to support vegetation. The latter is beyond the reach of these agencies and is therefore dead, but cannot be quickened by mere exposure to air if it be wanting in the necessary constituents, whose presence alone induces "ferment." Nor can it be rendered fertile by the addition of the constituents of a fertile soil. An instance is recorded of a gentleman, evidently more versed in theoretical than in practical agriculture, analysing a "dead" soil dug up from some depth and adding to it the elements of fertility it was wanting in, and putting some seed in it to grow. His practical gardener shook his head and said he was sure to fail, as the soil was "dead." Events proved that the gardener was right.

I alighted by accident on an analysis of Indian clay, white with an admixture of red, which is the characteristic of our clays, and I append it:—

Sand...	41·67
Combined Silica	15·81
Alumina	26·27
Ferric Oxide	2·51
Magnesia and Alkalies ...	2·82
Water	11·00
	100·08

It will be seen from the above that pure clays are composed almost entirely of sand (probably silicious), silica and alumina, neither of which plays an important part in vegetable economy, and that therefore they are unfitted to support vegetation, besides "if you mix pure sand with pure clay, even though you pour into it abundantly solutions of ammonia and all necessary salts, the result will be simply an indescribable medley fit for no man's land—a muddle, which after a while will resolve itself back again into clay and sand." But it is said the compound will be rendered fertile by a large admixture of stable manure or leaf mould.

OIL FROM SILKWORM COCOONS.—Says the *Japan Mail*:—"A resident of Koshu, who has been experimenting with the insides of cocoons, which have hitherto been generally used for manure, has discovered that a fine oil can be expressed, from them at a price 20 to 30 per cent cheaper than rape oil, the residuum being a valuable fertilizer of the soil."

QUININE.—The movement started in America has kept the ball rolling on this market, and enormous quantities of quinine (nearly all German, in bulk, of the B. & S. and Brunswick brands) have changed hands since last week. It is said that altogether over 250,000 oz. have been done this week. The price for German in bulk, which stood at 1s 7d. at the close of our last report, is now 2s per oz., which was paid today. The principal operators on this market have been two houses (one bearing an English, the other a German name) connected with the American trade. The English makers are believed not to be lending their support to the movement, but it is generally thought that they will be drawn into it if it should spread. The position of the cinchona market and previous experiences of similar booms encourage the view that the speculation may very easily be overdone. *Howard's* brand is still quoted at 2s 3d per oz.; *Pelletier's* is now the same price (which has been paid), and *Whiffen's* has sold at 2s. According to a New York firm of dealers, the cost of producing sulphate of quinine from the bark in Germany was formerly estimated at 20 marks per kilo. (about 7d per oz.), but improvements in the process of manufacture have now brought down the cost, it is estimated, to 5d. per oz., including the commission for buying bark, shipping charges, and freight to factory (probably from London or Amsterdam), actual cost of manufacturing, packing, commission for selling the product, interest on the plant, and wear and tear of the factory.—*Chemist and Druggist*, Dec. 3rd.

Correspondence.

To the Editor of the "Ceylon Observer."

CEYLON TEA IN AUSTRALIA.

[We greatly regret the oversight which has delayed publication of this letter, but the information afforded is still interesting and valuable.—ED.]

15th Oct. 1887.

DEAR SIR,—Seeing in the paper a discussion going on as to Ceylon tea being represented at the Melbourne Exhibition, I may as well give my experience. While in Australia I made inquiries with a view to gain knowledge as to the prospects of Ceylon tea down there. The majority of people I found quite ignorant of such an article. Others who had tasted Indian tea did not care for the taste, it being so different to the China stuff they are accustomed to drink.

What strikes me is, that, if Ceylon tea is to be pushed in the Australian market, it must not be done in a half-hearted manner, but with energy; it must be well canvassed and advertised, and this can only be done properly by a man who would give his entire time and attention to it, as we have not only China tea to fight, but also prejudice. In Australia one sees many ingenious ways of advertising besides by the daily papers and bill postings.

In my travels I saw but one notice of Ceylon tea for sale, and that was in a shop window in Sydney Arcade, and the price asked was 3s per lb. Now many people would not care to give that figure when they can get a good China tea for about half the price. A few people who had tasted Ceylon tea liked it very much, but did not know where to procure more at a moderate figure.

In Melbourne I also found Ceylon tea almost unknown: what good had been done at the last Exhibition to bring our teas to the notice of the public had no doubt been lost owing to there being no place known at which they could procure it, and also at the time the quantity being then produced being insufficient to meet any demand. Not having any samples of Ceylon tea with me, I was at a great disadvantage, as the first thing one was asked on speaking to any broker was "Have you any samples?" They told me what was wanted was a good strong liquoring tea that they could sell at from 1s 6d to 2s per lb. Privately no doubt a small quantity of higher grades would sell well. But for the public sale our medium teas would be the thing. Several shops have been opened in Melbourne and other towns for the sale of Indian teas. There is one in Melbourne where Indian goods are sold, where the public are invited to come and taste the tea in cup free of charge. But even this is hardly advertised enough. In some shops I saw that sugar would be given away with the tea,—20 lb. of sugar to be given to every purchaser of 5 lb. of 2s 6d tea.

This shows that it will be a hard fight with other teas unless we can sell cheap and so cultivate the public tastes.

At one auction of China tea, I saw some of the teas sold for 5d and 6d per lb.,* and at that sale saw very few sell above 1s per lb. When I say, send down medium teas, I do not mean rubbish, as that would only mean ruination to the cause. What is meant is souchongs of good liquoring quality. It is a fight that cannot be maintained by any private individual, as at first there will most likely be a loss, and no private person would be prepared for this. As it is for the benefit of all tea producers in the island it ought to be aided by all interested. while in Australia I met and heard of many Ceylon men: some doing well, others having rather rough times. It was a pleasure to meet anyone from the island. One had to answer many questions as to old friends etc.

After being so much on the move and getting no news, it was a treat to get hold of an *Observer*, which, after I had perused, I forwarded to another Ceylon friend, who prized it almost much as the writer of this.—I am sir, yours faithfully,

B. J. W.

* Inferior Foochow stuff, subsequently blended with stronger tea.—ED.

CEYLON TEA IN AUSTRALIA AND THE MELBOURNE EXHIBITION: AN OLD PLANTER TO THE FRONT.

28, Flinders Lane West, Melbourne,
13th Jan. 1888.

SIR,—As I am a bad correspondent, many of my old friends will be thinking that on leaving the island I had turned my back upon all its interests. As this is not the case, I must let them know what I have been doing, especially about their tea, and perhaps from my experience hints may be gained to enable them to push their teas better. When I came down in 1886, it was mooted that you were to have a Tea Syndicate to push your teas here and elsewhere. I was mentioned for the representation of the same here; however, as it was long in coming I bought on your market a few thousands of pounds. I tried to get at the public in a quiet way here, but I was not in a position to give away a sufficient number of samples or to push it thoroughly by advertising and taking a shop. I soon found then that in the meantime I could not work a living out of Ceylon tea alone. I put most of first shipments on the market here. For first two lots the result was satisfactory, but the demand here being so limited, I would have lost on the subsequent shipments had I not induced the house (tea merchants) I had in the meantime joined to take them over at about cost price. I found my partners were indifferent about Ceylon teas even for our blends, and needless to say I could not get them to see the necessity for the wholesale distribution of Ceylon tea samples. However, in a quiet way a good many samples have been sent all over the country. But as yet we have not many customers for Ceylons only. A certain number of dealers take Ceylons from us steadily, but these we know are for blending. To begin with, I think the blend with Ceylon is just one of the ways to give the public a taste of and for it provided you can afford to put sufficient into your blend to leave the Ceylon flavour distinct. At present prices, this, the general dealer is not able to do. The teas I got down cost from 11¼d to 1s ¼d landed here, and so that the successive shipments might be of an even average quality, I had two or three estates' teas and qualities blended for me in Ceylon. What I get was a fair broken souchong which seems fairly cheap, and now we shall see how it works out for the seller. It costs the wholesale dealer say 1s, to this add duty 3d and bond charges say ¼d, in all 1s 3¼d, wholesale dealer will want say 1½d to 2d per lb. upon it, so it costs retailer 1s 4¾d to 1s 5¼d; on this market you cannot get more from the householder for this class of tea than 1s 9d. This does not give the retailer sufficient encouragement to try and push a new tea. Of course if you get direct at the householder, your position is improved a little, but for many years the quantity you got rid

of by retailing only would not be felt upon your increasing crops. So that, even if you start syndicates and shops, you will still find it necessary to push your teas on the market as it stands, and be content to take what you can get for a time. What you want to create is a taste or liking for your teas, and get your profits out of the steady market of the future where they will not care to do without them.

I am glad you have gone in for the Melbourne Exhibition, but you must follow it up and have supplies always before the public. I had a little to do with your Exhibition Committee at starting, as it was thought I was the *H. M.* proposed by the Association: as, however, there are no less than 3 H.M.'s in town, all late of Ceylon; it was easy to make a mistake. After a time we found I was not the man wanted, so I handed over to the other. You should do well with the three Ceylon men you have on your Committee, but why, oh why, go to the opposition house for the fourth? I think it right that you should know his ostensible interest is the sale of Indian teas and curios! He wants to sell Indian teas in the packet and you want to sell your Ceylons in the same way! There are one or two old Ceylon men in town who would, I think, be very workable members, notably Messrs. James Hardie, W. A. Robertson and Mr. De Bavay; they are all busy men, but might be induced to give a little attention to Ceylon affairs for the sake of old times.

The Exhibition Commissioners are not to allow *the sale* of your teas in packets nor in the cup, but you will get all this information from your Committee, and how they mean to get past the difficulty I doubt not. Ceylons are rather wanted just now, and the market is to be tried with a few lots next week.

I had a run to Tasmania during the holidays. That is the country for ex-planters with farming proclivities, their grain is protected and is all required for home consumption. It is a pretty country, but as all the sons and daughters make for the main land, a man had better take a flock with him or a few Ramasamis, so as to be independent of the independent few who take service there.—Yours truly, H. G. MACKENZIE.

THE VALUE OF TEA ESTATES IN CEYLON.

London, 13th Jan. 1888.

DEAR SIR,—We think it right to inform those in Ceylon wishing to sell their estates, that 4 or 5 year old tea is worth 10 years purchase providing the estates are situated in a favourable locality with good soil &c., having all buildings and machinery up. This is the opinion of tea brokers in the Lane who have been resident proprietors in India. THOMAS GRAY & Co.

WATER-WHEELS AND TURBINES.

22nd Jan. 1888.

DEAR SIRS,—Will some of your planting correspondents kindly inform me first, the relative cost of turbines versus a 16-foot wheel and both equal to four horse-power, and what is the least fall of water a turbine of four horse-power would require, and also for one of six horse or more to power? I am building a small tea factory, but have not much water, but can get a fall. What I want to know is fall required for a four or six horse-power turbine and approximate cost of same put up: also price of a turbine by itself. I have applied to a local firm, but they want just the information that I require myself, as it depends on how I carry the water to get the necessary fall; therefore I want to know least fall required, as on that depends a wheel or turbine.—Yours, R. B.

[Our correspondent propounds questions specially requiring professional answers; but possibly some of his brother-planters may answer. Still if "R. B." has got a "Planters' Note-book," he ought first, by the rules given there, to measure and describe his available stream or supply of water. We are told of certain new turbines which with a fall of 5 feet can develop 3-horse-power, and of 10 feet, 6-horse-power. The turbine would probably not cost more than the 16 feet wheel. We have lately heard a professional engineer condemn water-wheels tandem fashion, a rather favourite idea of recent times, as not at all likely to answer their purpose.—ED.]

FUEL SUPPLIES FOR TEA.

27th Jan. 1888.

SIR,—I observe that your correspondent "Peppercorn" is continually harping upon the subject of our fuel supply, and in one of his last letters he terms it the "interesting problem of the future." Now if he takes no steps in the matter, I venture to think that this will prove a very uninteresting problem for him at any rate. Why does he not plant gum trees, the wonderfully rapid growth of these would form an endless theme for his facile pen to describe? As regards their value, I myself have used nothing else for the manufacture of 70,000 lb. of tea, and for this quantity about 350 trees between 4 and 5 years old have been utilized. Gums from their rapid growth and facility to transport to the factory by coolies render them in every way a most useful tree to plant, and there are always places on estates where fuel trees can be planted with advantage. Gums again present another advantage as fuel, namely, that if carefully coppiced they grow up again.

J. L. A.

OUR TEA INDUSTRY.—Mr. J. L. Shand's paper read before the Royal Colonial Institute is republished *verbatim* with all Appendices on page 593 *et seq.*, and also a full report of the discussion thereon, to be taken from *Colonies and India*. We may notice here one mistake made by the Chairman in speaking of the minimum rainfall in Ceylon as 70 inches. The annual average fall in at least two large districts of the island —Hambantota and Mannar—is less than half this figure; but Sir John Coode would be right in saying that the minimum for any of our tea districts was not under 70 inches. As for Mr. Pye's prophecy that the Chinese were going to improve manufacture and adopt honest commercial practices, all we can say is that when China does this "the skies will fall!"

MR. JOHN HUGHES ON THE CONSTITUENTS OF TEA.—In a recent communication, Mr. Hughes wrote:—

I think it only reasonable that high grown Ceylon teas should command a higher value on account of their fine flavour, and if the manufacture be properly attended, I doubt not certain estate brands will attract special attention in the home markets. I have read Mr. C.'s analyses and notice that he has *not determined* the tannin which I believe indicates the relative strength of the tea more than anything else. Of course the analysis of young fresh leaves will certainly show more potash and phosphoric acid than that of older leaves in which the proportion of lime and fibre is proportionally larger. This is a fact very well known among agricultural chemists, but I believe the tannin depends on the character of the soil and the elevation. I have no doubt that analyses made at different elevations and on different qualities of tea grown in Ceylon will be found to show more variation in this respect, say from 6 to 16 per cent, which is far more than the variation in the theine.

NITRATES AND AGRICULTURE.

It has generally been supposed that the nitrite formed during nitrification, is produced by the reduction of nitrate previously formed. Some experiments of Dr. Munro's (*Chem. News*, 56, p. 62) have, however, conclusively disproved this, and show that nitrite is not formed by the action of the nitrifying organism on solutions of potassium nitrate, and that solutions of ammonium chloride when nitrified first form nitrite, which afterwards passes into nitrate.

The question as to whether nitrates are indispensable for the growth of field crops has been investigated by Pitsch (*Landw. Versuchs-Station.*, 34, p. 217), whose results seem to show conclusively that barley, oats, beans, and wheat can be grown in a soil absolutely free from nitrates and from all nitrifying organisms, but containing nitrogenous manures, such as ammonium sulphate.

The last number (259) of the *Proceedings* of the Royal Society, contains a most valuable review by Sir J. B. Lawes and Dr. Gilbert, of the present position of the question of the sources of the nitrogen of vegetation. Especial interest attaches to their views on the claims of Berthelot and others to have proved that plants assimilate free nitrogen (see *Athen.* No. 3102, p. 484). They consider the experiments brought forward to be so conflicting, "that it is impossible to accept the whole as they stand, and for the present it seems necessary to hold judgment on them in abeyance."—*Athenæum.*

PLANTING IN JOHORE.

A Ceylon planter, now in Johore, sends us the following on planting prospects in that part of the world. Looking at the uniform failure which has attended the efforts made to cultivate Liberian coffee successfully in Ceylon, we are somewhat sceptical of the profitable nature of this cultivation in Johore, where climatic conditions and soil approximate so closely to those of Ceylon. If Johore is successful with this product, it will form the brilliant exception to all other places in the East where it has been tried. Tea will be the staple product of the country, we feel sure, before long, for the amount of rainfall, its even distribution, and the character of the soil, all promise well for the future of that cultivation; and we also see no reason why pepper should not be successfully cultivated by Europeans. Our correspondent, who only left Ceylon a short while ago, writes as follows:—

JOHORE, 7th January, 1888.

I feel sure that this country has a great future before it. If the pioneer planters from Ceylon had put in Liberian coffee and tea, instead of Arabian coffee, there would have been now thousands of acres of land cultivated by Europeans. People readily took up blocks of land, as they had only to pay the survey fees. A few only opened up, the others waiting to see how things would turn out, and, finding that Arabian coffee would not pay, they gave up all idea of opening.

COFFEE.—Now Liberian coffee grows well, and from the third to the fourth year, yields about 3 cwts. per acre. After that the yield is from 5 to 6 cwts. and I know of one place that is well cultivated and manured, giving as much as 8 cwts. per acre. The coffee is prepared on the estate for the market. Johore coffee at present fetches 70/ to 80/ per cwt. in the London market.

TEA.—There is only one tea garden in Johore, and that I believe is paying, although the greater part of it is opened on all abandoned gambier land. Had it been opened on virgin soil, and had the labor supply been good when it was opened, I feel sure it would have been a great success. Johore Tea sells in London at about the Ceylon average. This garden is situated about sea-level, and I think that better results would be got in higher districts.

PEPPER.—This is the home of pepper. It has been cultivated here by Chinese for over twenty years. The price at present is excellent: black pepper is quoted in Singapore at $21·50 per picul (133⅓ lbs.) and it pays you well to cultivate it, if you only get $10 per picul; so there is at present a good margin for profit. It is only lately that the Europeans have taken to planting pepper, as an idea was prevalent that it could only be successfully grown by Chinese. Now a European's pepper sells for a dollar a picul higher than a Chinaman's.

GENERAL—The average rainfall for the last three years is 102·24 inches, and this is very evenly distributed. In 1887, the most rain that fell in one month was 12·96 inches, and the least 5·49 inches. Tamil labor can be procured in any quantity now. A protector of Immigrants and a Doctor see that they are properly treated, and get their agreements carried out. Now that the country is opened up, Europeans get no more fever than they get in the Ceylon low-country. I have been here for seven months and never had bad fever. What with land almost for nothing, and being able to grow at least three products that are known to pay, I think this country offers a grand field for planters with limited capital.—EASTWARD HO!—Local "Times."

MANGOES IN INDIA AND CEYLON

are thus noticed in the Proceedings of the Madras Agri-Horticultural Society:—

Read the following letter, dated 7th November, 1887, from the Honorary Secretary to Deputy Surgeon General John Shortt:—

"I received a few days ago a ripe mango fruit from Mr. Holmes, of the Madras Club, with a note, asking us to plant the nut, "as it may produce a tree with the same habits, and give us fruit at Xmas time." I think it very desirable and quite feasible to cultivate and encourage such excentric habits on the part of the mango. Can you give me any information on the subject for publication in our proceedings? I have myself eaten mangoes from Chittoor, ripe at Christmas, and have seen trees producing unseasonable crops more than once."

Read also the following letter in reply from Deputy Surgeon General John Shortt, dated Yercaud, 11th November, 1887:—

"In reply to your letter of the 7th instant, allow me to say, that very little care or attention has been given to the mango as a fruit producer. Some care is given to them during infancy; after that, they are left to nature; neither pruning, manuring, or irrigation is attended to. Notwithstanding, we do get some splendid fruits from some of them, but if they were attended to like other fruits, the results would be better. On the Bombay side and towards Goa, two crops are obtained from the mango, but on the Madras side, only one. The plants will have to be forced to get them to fruit out of season. Recent mango grafts will often push out flowers out of season; advantage should be taken of those to take grafts off them, and to see that the actual branch in flower is made the *'Scion.'* Grafts from tree that produce a second crop from the Bombay side should be secured, and care should be taken to see that grafts are put on when the tree is in flower with its second crop, and thus I think we might succeed in establishing a second mango crop. I have myself eaten mangoes from second crops which were taken from Bombay to Tuticorin, and sent up here from thence by my daughter. Second crop fruits are procurable along the Western Coast on these occasions. I don't know whether you are aware that an indication of the failure of a crop of mangoes becomes at once evident, when the tree bursts out with a mass of young leaves, which is a certain indication that no fruits will follow. It is only by resorting to selected grafts: the scion of which has been taken from a plant that produced fruit out of season, and when in flower or fruit. A second crop of fruit may be obtained by ringing the stem, and at the same time attending to the tree by manuring, watering, and pruning; it freely. This plan might be put into practice anywhere, that is, ringing the mango stem out of season, and when got to flower and fruit, take grafts from it at once. This is a subject that

requires care and attention, and success will be the result. I have some papers on the subject, on which I cannot lay my hands just now."

The Honorary Secretary doubts the likelihood of success, by either of the plans suggested by Dr. Shortt, but agrees with Mr. Gleeson, the Superintendent of the Gardens, that by patient enquiry and careful selection, trees may be found and propagated with the habit already established of fruiting not twice a year, but at unusual seasons, by which means fruits might possibly be obtained in nearly every month in the year.

Surgeon General Bidie remarks, that, when at Colombo last year, during the Christmas Holiday, a basket of mangoes was brought to him, and on enquiry, he was informed that that was the season for Jaffna mangoes; also that he has heard that the late Maharajah of Travancore succeeded in having mangoes every day of the year.

DATE CULTIVATION IN INDIA.

Dated London, the 4th July 1887.

From DR. E. BONAVIA, *Brigade-Surgeon, Indian Medical Department (on leave),*

To the Secretary to the Government, N. W. Provinces and Oudh.

SIR,—I have the honour to submit to the Government of the North-Western Provinces and Oudh, the following information regarding the date-palm.

2. Convinced as I am that this useful tree, if largly introduced in India, would eventually be of great benefit to the people, I have collected information about it from all the countries where it is extensively grown. This information I now beg to place at the disposal of the Government of India.

3. As there might still be some doubts in India whether *seedling* date-trees are of any value, I paid particular attention to this point in making inquiries. In a letter from Sir R. Lambert Playfair, Her Majesty's Consul-General for Algeria and Tunis, dated Algiers, the 11th January 1887, the following is stated:—"From what you say, I have no doubt that off-sets could be sent to India without much difficulty; but really there is very little necessity for making the experiment. Seeds are sure to germinate, and the experience of the Arabs here is, that the fruit of seedlings is quite as good as that of trees propagated by suckers. The only objection is, that there is the risk of obtaining an undue proportion of male trees." Then O. Regnier in his "Observations sur le Palmier Dattier, et sur sa culture en Egypt," says:—"Seedlings sometimes produce bastard varieties. More frequently they perpetuate well-known varieties, at other times *new* kinds are raised, which are afterwards propagated by off-sets."

4. The foregoing is good evidence of the value of seedling date-trees. We have, however, proof of it in India already. Before leaving India on leave, I sent to the Director of the Royal Gardens at Kew, a fine collection of dates, solely from seedling trees grown in Oudh and Multan. They are now in the Economic Museum at Kew. Moreover, what Sir Lambert Playfair considers as a slight objection to raising seedling trees, I would consider an advantage at first for India. Fertilization of the female flowers by the pollen of the males is not generally known yet in India. An excess of males among females would therefore ensure a crop, and would not disappoint the growers. In course of time India would possess fine varieties of date-trees, and then it could easily furnish its own off-sets of female trees, and fertilize them as they do in other countries. In addition, the great advantage of seed just now is, that they cost comparatively little to import, and can be made into fruit-trees with less trouble than off-sets, so that all the places in India where the date-tree can be grown with advantage may be rapidly furnished with this important tree at small cost.

5. The following interesting extract about the date-tree is from a recent book called "Tunis: the Land and its People," by Chev. de Hesse Wartegg. I give it in order to show what can be done with the date-tree. At chapter 13 page 278, he says:—"South Tunis—on both sides of the large salt marsh, Sebcha Pharaon, which latter reaches far into Algiers—is a beautiful country of palms, which is not surpassed by anything on the shores of the Nile. Thirty oases lie close together in a row, and divide the desert land of the ancient Numidia from the large salt lake, which is dry during nine months of the year. This palm region *par excellence*, is known in Africa under the name of 'Beled-el-Djerid,' and no fruit is valued higher than the sweet large and juicy 'Djerid' date, which also fetches the highest prices in the European markets." At page 279 he says:—"The slender stems of the palm trees, often reaching a height of 100 feet, display their transparent rustling canopy. The sun is a necessity to them, and while they rejoice in his burning rays, they keep the earth at their feet in cool shade, and thus aid the growth of the figs, oranges, lemons, almonds, olives, and pistachio trees. The latter grow between and under the palms: the damp ground beneath being covered by the most luxuriant growth of herbs and grass. It is, therefore, a threefold vegetation." At page 280 it is stated that "of these oases, Gaffa is the largest, and possesses a palm-forest of about 200,000 trees, and is inhabited by from 3,000 to 4,000 Arabs and Berbers. In the oases of 'El Gettar,' water is not nearly so plentiful, and camels raise it with difficulty from draw-wells; but the date palm is here so exclusively the source of livelihood of the few hundred inhabitants, that there is no choice left to them, and they must get water at any price. In 'El Gettar' a palm-forest extends over a tract of land three kilometers long, and the entire region north of the 'Sebcha Pharaon' possesses no less than a million and-a-half of palm trees, which has many olive, orange, and almond trees growing between." Then south of the Great Shott "is the extensive district of the oases of Nefzani, with palm-forests of more than 300,000 trees, and with from 18,000 to 20,000 inhabitants, living in 40 villages."

6. The foregoing information is of some importance. It shows (*a*) that the date-tree flourishes in saline soils. It would, perhaps, be more accurate to say that *some varieties* of date-tree do so, as there are hundreds of kinds. There does not appear to be any doubt, however, that the "Djerid" date of Tunis is a very fine kind, and fetches a good price in the European markets. (*b*) It gives some idea of the population that can live almost exclusively on the produce of these date forests, bartering any surplus fruit for other commodities. (*c*) It shows that not only where water is near the surface can the date palm be grown, but also where water is obtained with great labour. (*d*) It shows that where date trees can be grown, and where water is easily obtained, there also oranges, lemons, and other fruit trees can be readily grown on a large scale under the shade of these palms and between them.

7. In India, both in Rajputana and in Sindh, on both sides of the Indus, the conditions are such, that if Arabs and Berbers had possession of these tracts of country, they would probably, in less than 50 years, turn them into gardens.

8. In my investigations, nothing appears to be more clear than that there are *two distinct classes* of dates—(1) those that ripen on the tree, or soon after they are plucked, and are those which are met with in European fruit-shops; and (2) those which do *not* ripen like the above (a raisinified date), but remain hard and crisp, and are either eaten in that condition, or cured in various ways.

9. The following information, by Senor Don Maximo Laguna was courteously furnished by the Secretary to Her Majesty's Legation in Madrid:—"The few varieties distinguished in Elche (Spain) are based on the character of the fruit. That which is most esteemed is the one producing the date called '*Candix*.' This ripens and sweetens *on the tree*. The others are of a yellower colour, harder, and with a smooth skin. In order that the latter may be fit to eat, it is necessary to smear them with vinegar, and cover them up for two days. Then they become sweet and agreeable. They will keep in this state for five or six days, after that they spoil, so that only the quantity immediately needed is prepared. Although in Elche artifical fertiliza-

tion is practised by attaching male flowers to the female bunches, more frequently male trees are planted with females: one male to two or three females, and at a little distance from them."

10. There is a notion that the date-tree is unsuited to a damp climate, and that it can only ripen fruit when its roots get into sub-soil water and its head remains in a dry, heated atmosphere. This notion may have arisen in two ways—*first*, because the date-tree may have first been known only under such conditions, and being intimately associated with Arabs, who inhabited regions mostly under such conditions; *second*, because the *best* varieties of dates, the choice ones of European markets, are those probably grown under such conditions. But it does not at all follow that an edible and very nourishing and useful date cannot be grown under totally different conditions.

11. In passing recently through Egypt, I saw along the railway a number of date-trees with their fruit only lately gathered, with their roots and water still lying on the land from the recent inundation of the Nile. Moreover, in Egypt, the date-tree has been associated with man from a very remote period. In the book called "*Vid* Cornwall to Egypt," by C. F. Gordon Cumming, at page 137, I find the following:— "In the time of the Romans the Egyptians gave receipts for taxes on fragments of tiles: about 1,600 years ago. A number of them are receipts for payments of poll-tax, cattle tax, *palm-tree tax*, &c. One receipt for a poll-tax is dated A. D. 103-104," . . . "After the conquest of Assyria, 1,500 years before Christ, large quantities of bitumen were paid in tribute to the Pharoahs, and with this the mummies were thenceforth prepared. The bodies of the poor were merely saturated with natron or bitumen, baked in an oven, swathed in woollen rags, and then tied up in a rough mat of *palm leaves* or '*papyrus*.' Thus, they were laid in rows of thousand in the great sepulchres." In Egypt, therefore, we have not only the annual regular rising of the Nile, inundating more or less the whole country on both its banks, but also the date-palm known there for hundreds—perhaps thousands—of years before the Christian era. It is in Egypt, therefore, if anywhere, that we ought to find evidence of this useful tree having, in the course of ages, suited itself to almost two diametrically opposed conditions of life. In order to obtain some proof of this, I wrote to the Head of the Public Works Department of Egypt for information on the date-tree of Egypt. Major Ross, R.E., of the Indian Irrigation Department, very kindly issued a circular to a number of officials, who were in a position to afford information on this matter, giving the questions which I had sent. Colonel Moncrieff, with his letter dated 15th June, 1887, very courteously forwarded all the notes collected to me, and added a memorandum of his own on each, regarding the reliability, carefulness, and power of observation of the sender. The officials who collected this information are—

Mr. Biancardi, for many years Traffic Manager of the Railway, and a great horticulturist;

Bechara Takla Bey, a Syrian Editor of a well-known Arabic newspaper;

A man of the Domains, a very practical native;

Mr. E. W. P. Foster, of the Bengal Irrigation Department, a most careful and painstaking officer, whose statements are pretty sure to be the result of close inquiry;

Mr. Marshall Hewat, an engineer of a good many years' residence in Egypt.

Dr. Harvey, of the American Mission, an old resident in Egypt;

Wilson Bey, a shrewd Scotch Mechanical Engineer: he has had many years' experience of Egypt;

Captain R. M. Brown, R. E., of the Bengal Irrigation Department, a careful and accurate man; and

Mr. Arnold Perry, a young English Engineer.

12. Colonel Scott Moncrieff, R. E., Under Secretary of State, Public Works Department, Egypt, in forwarding the above notes, and in reply to a question of mine, states—"The Nile rises with wonderful regularity in July. In September it is over nearly all the country, attaining its maximum in Cairo about 15th October, after which it goes down very fast, and the inundation is over early in November." It should be noted that from July to November is exactly the period in which the dates swell, colour, and ripen, and all those date-trees which happen to be on inundated ground have not only their roots under water, but are surrounded by a damp atmosphere, from the immense sea of water which the Nile makes. I should say during that period, which is the hottest of the year, the atmosphere would be similar to that of the North-Western Provinces of India in the rains, if not generally more damp.

13. In order to avoid repetitions, I shall here give only a *résumé* of all the notes received. All say that the *best* dates are produced by trees on dry land, which is irrigable, and sometimes also on trees which are close to the desert; that some of the best kinds of dates are grown on sandy lands, which can be irrigated when required; that those on low lands, to which water has access, are not bad, but they are not so good as the foregoing, and that whether the air and soil are damp or dry makes little difference. In the latter case, they should be irrigated as often as necessary. The trees planted in Rosetta, Aboukir, Ramleh, and Gabbary are all in a damp atmosphere, and bear also good qualities of fruit. Mr. Foster says that "in Rosetta the best kinds are *Zaghloul* (red) and *Samani* (yellow), cultivated on high sandy hills. The roots are probably in moist soil, as the spring level is high after floods. These, as a rule, are never irrigated. There are, however, lots of dates grown on lower, though sandy soil, which have improved very much in quality since the opening of the Rosetta canal has rendered irrigation easy. The drier the soil with surface irrigation, it appears the better is the produce. In Gizeh, date-trees are on lands subject to flooding on the basin system. Water may remain over the roots of the tree for 70 days without injury (!); a longer period will damage the produce. It is better, however, to reduce the time of inundation. From 20 to 70 days' flooding is *ordinary*. Unless flooded, the outturn of fruit is small, and quality is inferior. Three kinds of dates are grown in Gizeh, the best of which is *Sewi*, a yellow variety; *Amhat*, a very moist kind, turning from yellow to dark brown, when ripe; and *Hayani*, a red variety. The best dates of Gizeh are grown in yellow clay; sandy soils and ordinary black Nile deposit do not produce so good a date." Mr. Biancardi says:—"I have seen plantations accidentally inundated, with their crop injured. Too much water is not required. We have solitary trees in the middle of the canals. They look healthy, but bear no fruit." He does not, however, mention whether these solitary trees happen to be males or females; or if the latter, whether the people take the trouble to fertilize them in the midst of the canal: solitary trees can be found under the most favourable conditions, and still remain fruitless. Dr. Harvey says:—"Date-trees are sometimes inundated for one to three months, and that the trees are not injured by excess of water; and that trees on inundated ground produce most and best. On this point, however, some say that there is little difference whether the trees are inundated or not, a dry soil and a dry atmosphere are not essential to the production of a crop of dates."

14. Without taking into consideration the fact that the date-trees in Oudh have undoubtedly produced very fine fruit, it appears to me evident from the replies sent from Egypt, that, although a dry climate and soil, even where irrigation is difficult, will perhaps produce the best dates, which will dry on the trees and become the most suited for long keeping and for exportation, a damp soil and atmosphere—nay, in excess of these conditions—will not only, as a rule, not injure the date-tree, but will produce an edible and valuable crop. There can hardly be any doubt that in the thousands of years during which the date-tree has been associated with man in Egypt, different kinds have come into existence, some of which are suited to a dry soil and atmosphere, and some to conditions which are exaggeratedly the reverse of the above. It

is not improbable that some of these Egyptian varieties might be found suited also to the damper climates of India, such as Bombay and Bengal.

15. All the replies say, that, usually, there is no such thing as a bunch of dates ripening *all at the same time*. On the driest land and on the borders of the desert, the dates are allowed to remain until the whole bunch is ripe; but in most places the dates of each bunch are gathered in several pickings, either by hand, or the bunch is shaken over a large, net slung under it. They are either eaten as they become ripe off the tree, or dried in the sun, and prepared in various ways. Often the bunches are cut off in their red or yellow stage, and sold in the bazaars. They are eaten by the people, although they are astringent and have no sweetness. When the individual dates on a bunch begin to ripen, the whole is often cut off and hung in the houses of both natives and Europeans. The dates are then picked off and eaten as they ripen. A kind of jam is made of the unripe fruit, or they are salted and eaten as condiment, and the shrivelled ones are removed from the bunch to give strength to the remainder.

16. The weight of dates from a full-grown tree is given from 50 to 500 lb. according to circumstances and the care given to the trees. The life of a date-tree is given from 80 to 100 years, and that it is certain that some trees now standing are between 100 and 200 years old. Their life generally comes to an end by being blown down in a storm. As long as they live, with proper care, they produce abundantly every year.

17. The cultivation of the date-tree is very extensive in Egypt, and the crop is immense. Most of the natives live for fully three months both on the unripe and on the dry dates. The dates are cheaper to them than common bread, and the poorer classes keep the date-stones, and use them as fuel. Many uses are made of the trunks, leaves, leaf-stalks, fruit stalks, and the fibre of date-trees. Vinegar and spirit are made from the fruit. The trees which are most cared for give the largest and best crops. Pigeon-dung is largely used for manuring date-trees, so are horse and other manures utilized. Dust from old villages is also used. I fancy this corresponds to the *nona* of Indian cultivators. It is probably a compound of *nitrate of potash*. Manure is mostly used in Lower Egypt. In Upper Egypt, the tilling of the soil between the date-trees is supposed to supply the necessary aliment. A hundred date-palms are said to require the labour of *one* man for three months a year. The lower decayed leaves are removed once a year.

18. The practical native, employed on the Domains, gives the following names of distinct kinds:—Hayani, Arabiate, Kababi, Bind Eysha Zanar, Sergni, Rawaked, Samuni, Zaghlaul, Chetieh, Om Nasreddin, Alayly, Amri, Chihayet, Akoula, Mokarba, Bemeri, Zokour, Boimakhal, Abrimi, Sokaut, Hafer-el-Gnedi, Bezelnaka, Sobazenab, Gandila, Khodrawny, El Siwy, El Wahy, and others. The best of these, however, are Zaghlaul, El Amri, El Sokaut, El Gandila, El Khodrawy, El Abrimi, and El Siwy. Mr. Biancardi says the best varieties are Ghazali, Hayani, Amri, Aklawi, Beyd-el-Gamal, Bint Eysha, and Eglani. While Wilson Bey, the Scotch Mechanical Engineer, says the best of all is the *Amhat*, a small brown date grown at Gizeh, on sandy soil, which is not inundated. Then comes the *Amri*, a fine large date, black when ripe. When ripe, it bears transport to the Levant, Greece, and other parts of Europe. It grows in Shirkieh, Fakoos, Salhieh, and Abu-Kebir. *Samuni*, a large yellow date when ripe. It grows in sandy soil about Rosetta, and is not inundated. *Zaghlaul*, a fine rich date, sometimes plucked and eaten in its red and unripe state. It is also grown on sandy soil near Rosetta. The following he gives as inferior dates, *viz.*, *Hayani*, a coarse date, often eaten unripe and red. It grows on clayey soil in the Calioubieh. It is sometimes inundated. *Bint Eysha*, a small date, known all over the lower country, and grown in artificially-irrigated districts. *Aglani*, grown on clayey soil and irrigated parts of the Shirkieh.

19. Mr. Biancardi, who is not only a practical man of business, but also a horticulturist, gives the following details in his notes, which may be of some value:—

The young trees should be obtained from Abuhammad, Oren, or Salhieh, detached from the parent tree. They generally stand from four o five feet high, and are about three years old. They are wrapped up in palm-tree fibre, and transplanted in January and February. They would stand the voyage to Bombay well. They would only require the envelope over their roots damped once a day. On arrival at destination they should be planted in deep holes, one for each, up to their bottom leaf. The tree is then to be wrapped up in old matting and watered every day for 40 consecutive days, and then on alternate days, till four months are over. The roots are then supposed to be long enough to feed themselves, and the trees are then treated like any other fruit-tree. Such a thing as a full-grown tree dying for want of water is not known. A *nakhal* or two (date-tree cultivators) should be engaged to go with them, and carry out the process. They would teach the Indians in two or three years how to deal with these trees. In about five years 20,000 Egyptian trees, treated as explained, would yield £10,000 a year (according to Egyptian reckoning). The cost of 20,000, at a shilling each, would be £1,000. Their total weight would be 1,000 tons. They could reach India and be planted for the amount of £3,000 all old. They would require 200 acres of waste and poor land, which might be purchased for a small sum. Taking into consideration the four or five years which will have to elapse before they fruit, and the interest on the capital engaged, the total amount expended before the first crop would probably reach £6,000. Admitting that half the trees would die, or be fruitless, the other 10,000, producing half crop only, would represent £5,000 revenue for the first year. The first crops of a date-tree are not large. Some give one and some two bunches the first year. The number of bunches continue to increase till the trees reach the age of 15 years, when they will give as many as 10 or 12 bunches."

Mr. Biancardi may have added that, with care, a date-tree will go on producing this amount *annually* for 100 years or more.

20. No one probably is going to try date-planting in India on this scale; but it is not improbable that some of the Rajputana Chiefs, or His Highness the Nizam of Hyderabad, might be inclined to try the experiment on a small scale, and engage a couple of Egyptians to accompany the young trees, and treat them as they do in Egypt. Sir R. Temple, in his "Journals of Hyderabad," says:—

"Below the Manjhera Valley, and between the Rivers Manjhera, Bhima, and Kristna, lies the most important part of the Nizam's Dekkan. This area comprises marked variations of contour, soil and climate, and is either studded with hills or else literally fluctuates with undulations. The eastern portion is dotted over with artificial lakes or reservoirs, constructed by the Hindu dynasties, and known as tanks. Indeed, it is the finest scene of tank irrigation in all India, and it is here that the Pakhal lake is situated, which is probably the largest sheet of water in the Peninsula."

He goes on to say:—

"Geologically speaking, it may be said in general terms, that in the north and west, blackish trap and dark heavy soils prevail; while in the remainder, that is the south-east portion, reddish granite and laterite rocks and lighter soil prevail. These geological divisions affect the agriculture and produce in the most marked manner, for in the black soils are raised cotton and wheat, while the red soil produce the spring and autumn harvests of rice, dependent entirely on 'tank,' irrigation. Hence it is that even in this land of 'tanks,' the light soil districts are *par excellence* those of the artificial lakes."

According to the above description, the Nizam's territories would appear to be cut out by nature for the successful growth of the Egyptian date-tree on a large scale. After the trees had taken root, the tank water infiltration would afford them the sub-soil mois-

ture they delight in; while growing, both cotton and wheat might be grown between the young date-trees, and when fully grown, oranges, lemons, and fig-trees, &c, might be grown under their shade, as is done in Tunis. From what I saw of the Nizam's territory, I believe that in that fertile soil where water would be available, many of the European fruit-trees might be successfully grown; and with regard to date-trees, not only those grown in Egypt on the higher land might succeed, but also those grown on lower lands, and would in time feed the people of the Dekkan for several months in the year.

21. In all my researches about the date-trees, I have endeavoured to combat and get rid of the exploded notion that, unlike many others, the date-tree is a fixed unchangeable organism, as fixed as the notion books and people have got of it. Actual facts, however, show that within certain limits it has adapted itself in course of time to its surroundings in Egypt and other places. From a tree luxuriating in a desert climate, it has suited itself to soils subject to inundation for several months to the vicinity of the sea, to saline soils, &c., in some localities producing the finest dates; in others, inferior ones; but *everywhere* feeding the people and their cattle. We need not go very far to search for a plant that has been far more yielding to circumstances than this. The rice-plant is admittedly a tropical plant largely grown in Burma, Ceylon, South India, and Bengal. Nevertheless, out of the hundred and more varieties of rice, some have adapted themselves to the climate of Northern India as far as Peshawar; to that of the valleys of the interior of the Himalayan mountains; to that of Afghanistan, Italy, America, and others; and no doubt, that among the hundred and more varieties of date-trees, some are suited to a dry, some to a moist climate; others to a sandy, a clayey, or a saline soil, &c.

22. The date crop in Egypt ripens in September, and in case the Government of India should think fit to import some Egyptian seeds of the best varieties, I beg to add the following information given also in Colonel Scott Moncrieff's letter:—"In order to have seeds sent out on really a large scale to India, I should think it would be best to act through Government. If Sir Evelyn Baring were asked officially, I should think he would place the matter in the hands of Mr. J. R. Gibson (formerly Bombay Revenue Survey), Commissioner of the State Domains, and Mr. Hamilton Lang, C.M.G., Controller of the Daira Sanieh. Either of these officers is in a position to get any quantity of date-seeds. There would be some little expenditure of course, or it might be done by the Government of India through some good merchant-house, like that of Messrs. Carver & Co., of Alexandria, well-known and highly-respected export merchants."

23. Besides the Oudh date-trees, fruiting palms are to be found in India in various places by ones and twos, originally introduced from Mecca and other places in Arabia. A few scattered trees here and there, however, are not sufficient to induce any one to set about cultivating the date-tree in a proper methodical manner. A few Egyptian and Persian date cultivators might do much towards teaching the natives of India how to set about this culture so well understood in those places. That it is possible to introduce this important tree in India on a large scale, and that it will be of great benefit to the people, I have no doubt. Moreover, Mr. Thiselton Dyer, the Director of the Royal Gardens, Kew, in a letter dated 15th November 1886, says — "I am sure this enterprise is a sound one." In conclusion, whatever may be the value of the date-produce in India in ordinary times, there is, I think, no question that in famine times, a crop of dates would be a certainty.

CINCHONA IN UVA. We learn that cinchona shaved in the Badulla district a few months ago at five to seven years old gave 700 lb. bark per acre and the trees now look as well as ever, fast renewing.

TEA CULTIVATION.

(Paper read by Mr. A. M. Gepp at the Dikoya Planters' Association, 2nd February, 1888.)

The CHAIRMAN then introduced M. A. M. GEPP to the meeting, who read the following paper on Tea:—

I have divided my paper into three subjects, viz., *Tea Tasting, Hints on Manufacture*, and the *Future of Tea* in respect of *Consumption* and *Prices*.

TEA TASTING.—Tea tasting may be described as the art of being able to discriminate not only between good and bad tea, but after a time to find out which are the kinds most suitable for the London market. I have no doubt, of course, that several of you gentlemen interchange samples, but say for instance that you have got a set of standard samples that you wish to copy, then comes the trouble when you have finished your day's make, how can you be sure that your teas are equal to the standards? After the teas are graded, it will not be difficult to have some idea as to whether your own teas are up to the samples as far as appearance goes, but unless you are able to taste tea, you will still be very much in the dark. Say that your standards are strong full flavory teas, how can you know that your day's make is the same? A knowledge of tea-tasting will enable you to test this. I honestly do not think that a tea taster can be self-taught. He requires someone to point out the different flavors most suitable for the trade. One tea may be malty, another pungent, another thin, but of an extremely delicate flavor, another strong and coarse. This latter characteristic does not certainly come under the heading of fine teas, but from a buyer's point of view it may be by no means a tea that should be avoided altogether. Undesirable teas are those which are thin with no flavor, sour or much burnt. A tea-taster ought to be able to say without tasting, after looking at the infusions and the liquors, whether the tea is good or not. A bright coppery colour and all the leaves of an even colour, together with a bright red liquor and yellowing towards the sides of the cup, is an almost certain indication of good tea, whereas a dull unattractive liquor with black or brown infusion almost invariably shows a common undesirable tea.

Perhaps it may be interesting to describe the entire process of tea-tasting for the benefit of those of my hearers, who, though they may have tasted tea in a neighbour's factory, have not commenced making tea themselves, and see no necessity for starting a tea-tasting room. The embryo tea taster having duly furnished himself with perhaps a dozen tasting pots and cups, scales, sandglass and spittoon, places his pots and cups in a row on his tasting table and proceeds to weigh up from his samples the same quantity of tea into each pot. During this time the kettle has been put on, soft not hard water should be used. In order to ensure a good tasting, great care should be taken that the kettle boils and not overboils. The sandglass should be turned to run 5 to 6 minutes before the teas are turned out into the cups. After letting them drain for a little while, the tea-taster should go down his rows of pots and taking off the lids carefully note the aroma in his own mind, or, better still, on paper, of each tea. Doubtless he will not be able to describe it, but he may recognize the same smell on another tea. Then let him reverse the lids showing the infused leaves. He had better then examine each sample of dry leaf and write down on a piece of paper the description of the tea, whether broken orange pekoe, broken pekoe, pekoe, pekoe souchong, souchong, congou, pekoe dust, or ordinary dust, with any peculiarity or characteristic he may detect, and in the same way with the liquors, carefully putting down what strikes him, whether the teas are burnt, sour, thin, strong, flavory, or pungent. So far as I have read at present this was the substance with a few corrections of my paper before the Dimbula Planters' Association, and looking carefully through it I do not think I can improve upon it, but there are one or two points which I have not touched upon in connection with that subject which may prove instructive. Say, for instance, the different kinds of flavor, such as malty, pungent, peaty flavor, and burnt. The first flavor, "malty," may be described as a full rich tea, such as teas from a good many of the districts close at hand possess; "pun-

gency" is the rasping, almost bitter taste, and peculiar to the lowcountry teas; pekoe flavor is thin, delicate, and sweet; and burnt almost any tyro can detect; but then on the other hand many are apt to say that a high-fired tea is burnt, whereas it is the taste of the fire just sufficient to retain the flavor of the tea which a beginner cannot detect until he has had some experience and some teaching.

HINTS ON MANUFACTURE.—The second part of my paper I approach with a certain amount of diffidence, as I know that the greater part of those present are efficient tea makers, yet some hints may, I trust, be taken in the kindly spirit with which they are meant. The various stages of manufacture, you have, so to speak, almost got by heart, and it is quite unnecessary for me to describe them. I conclude that everyone knows a good from a bad wither, but we will take it for granted that a good wither has been obtained and the leaf is being put into the roller. How long should the 1st roll be? My idea, from practical experience, is that it should be ¾ of an hour to an hour and then sift out the small leaf in the usual way, then well roll the large leaf for another half an hour or so, and again sift out, which slightly increases your percentage of pekoe tips, and then roll the balance of leaf for about 20 minutes. This will soften any hard coarse leaves you may meet with. The tendency of the modern tea maker is to under-ferment in order to give pungency, but surely leaf which has not gone through the full chemical process is not likely to keep. Proper fermentation gives strength and flavour combined, whereas you sacrifice your strength by underfermenting. As regards firing I would still advocate firing at a high temperature. Teas which have the taste of the fire in the liquor will keep better than the under or imperfectly fired tea. Of course care must be taken not to burn, scorch, or char your leaf, but in the case of the high fired tea the flavour develops during the voyage from Ceylon to England, whereas with an imperfectly fired tea the moisture which has not been dried out of the leaf, comes out and causes the leaf to be soft and spongy instead of crisp, and the liquor tastes thin and flavorless. The retailer at home who has to keep his teas some time is careful to avoid the teas of an estate which experience has shown him are imperfectly cured, however cheap they may be. Sorting is still as important as ever, and tea makers must not be tempted to make simply *unassorted* because for the moment broken pekoes and pekoes are fetching low prices at home, The principal retailer, viz., the grocer, likes to have his 3/, 2/6, 2/, and 1/8 canister, and will in my opinion continue to have them. I would keep to the three principal grades of broken or perhaps orange pekoe (the preference being now at home for leafy teas), pekoe and pekoe souchong. When hand sieving I would caution you not to use too fine sieves. The cooly in order to get as much tea as possible to pass through the sieve is apt to smash and bruise the leaf and it becomes grey; rather use the next largest sieve to what you ordinarily do and break up your rough leaves with a good cutter. In conclusion there seems to me little doubt that however good a tea maker you may be, you cannot make fine flavory tea, unless the leaf itself is good, but a bad tea-maker will at all events spoil the leaf however good it may be.

FUTURE OF TEA IN RESPECT OF CONSUMPTION AND PRICES.—My last subject is a somewhat difficult one. It deals with an unknown quantity as it were. The wise man prophesies after the event, and a man must be either a very clever fellow or a fool who prophesies before the event. I never laid claim to being the former, and I am afraid there is no middle course. I leave the inference to you, but in spite of being called bad names by our good friends the *Observer* and the "Times," I shall attempt to forecast the future:—

At one time I thought of dealing with figures. They are not only misleading, but apt to be dangerous. The *Observer* in a leading article in its issue of 28th January deals pretty exhaustively with the subject as to figures, so I propose to speak on general lines as it were.

There is no doubt whatever, that teas of Indian and Ceylon growth are slowly but gradually supplanting those of China and will continue to do so as long as they can show better value on the London market, but I think there is no question that if Indians or Ceylons ever show a marked falling-off, that the London buyer will again turn his attention to China teas. Can we afford to lay down our teas (including Pekoe Souchong and the lower grade) at the equivalent of 6d per lb. in London and show a profit to the grower; and yet the Chinese can. If common congou had been ruling at that price in London this year there would have been no falling off in the export from China for the season 1887-8.

Teas for price are what we must be prepared for when the export reaches large proportions, and our only safeguard as far as Ceylon teas are concerned, will be to keep up the quality and strength, so that relatively our common grades will be cheaper than the China growths, being stronger and better, a comparatively smaller quantity of leaf being required to make palatable drinking tea. A good proportion of the finer grades will still be required for the richer classes, but the proportion will be small and the demand will be for the 1/8 and 2/ (duty paid) canisters.

Though there have been fluctuations from time to time in the London wholesale market, yet there has been a gradual tendency towards lower prices for the consumer, and the retailer cannot afford to raise his prices. With the competition of stores and direct agencies, the retail price can hardly advance, as the retailer would prefer to sell at a loss rather than lose his customers. The retail price controls the wholesale one, as my experience of the tea trade for several years past has shown me, and we must be prepared for cheap prices.

Lastly, gentlemen, I can come to no other conclusion than that with the increasing export of Ceylon teas, we must look to "pastures new" and loyally and strongly back up the gentlemen who are trying by every means in their power to find fresh outlets for your teas.

THE PONDICHERRY GROUND NUT trade for the current year practically commenced from the beginning of last week. The prices were nominal but prohibitive. Opinions differ as to the probable crop available for export, but it is doubtful if the present year's shipments will exceed 750,000 bags. Now that Bombay has become a competitor for the trade, under conditions generally superior to those obtaining at Pondicherry, a disturbance of the only available trade left for the little capital of French India is apprehended.—*M. Mail*, Jan. 24th.

ADIANTUM FERGUSONI, MOORE.—Dr Trimen writes to us from Ceylon:—"The facts as to the discovery of this curious Fern in Ceylon, are not quite correctly given in your note at p. 470. People in the tropics do not keep their plants in "conservatories," but place the pots or tubs containing them in the verandahs of their bungalows. It was in the verandah of the house of a native gentleman at Negombo, a town on the coast, some 20 miles north of Colombo, that my late observant friend, Mr. W Ferguson, first noticed this Adiantum. It was not a seedling but a fine, fully grown plant. Unfortunately, no one was able to give any information about it, and its origin thus remains quite unknown. It has, however, now become a common Fern in Colombo gardens, being very easily grown from the spores, which are always copiously produced. The progeny has never been observed to differ in the slightest degree from the parent, and the plant has certainly more claim to a distinctive name than the majority of the Maidenhairs on which horticulturists have recently bestowed them. HENRY TRIMEN."—*Gardeners' Chronicle*, Dec. 3rd.

THE TEA INDUSTRY OF CEYLON.

Royal Colonial Institute.

(From the "Colonies and India.")

The third meeting of the present session was held at the Whitehall Rooms, Hôtel Métropole, on Tuesday, January 10th, when the following Paper on "The Tea Industry of Ceylon, with a brief Reference to Tea Culture in India and other British Possessions," was read by John Loudoun Shand, Esq., late a Member of the Legislative Council of Ceylon.

The chair was taken by Sir John Coode, K.C.M.G., a Member of Council.

Among those present were the following:—The Right Rev. Bishop Marsden, Sir Charles Clifford Bart, Sir Henry W. Peek, Bart, Captain J. S. Hay, C.M.G., Administrator of the Gambia; Sir Arthur Hodgson, K.C.M.G., Colonel Arbuthnot, Messrs. E. Noel Walker, C.M.G., Colonial Secretary, Ceylon; J. Dennistoun Wood, F. P. Labilliere, Frederick Young, Lieutenant-General R. W. Lowry, C.B., Captain Arthur Brooke, C. B., Deputy-Surgeon-General C. G. Irwin, Bermuda; Messrs. W. H. Treacher, British North Borneo; C. Washington Eves, C. S. Farquharson, M. L. C. Jamaica; D. Morris, M. A., Assistant Director Royal Gardens, Kew; Arthur Lyttelton Young, Francis Hogarth, Queensland; A. P. Hogarth, C. R. Woodward, Queensland; Randall Pye, China; John Coles, Ashplant, J. Duff Dawson, George S. Duff, Hamilton Rankin, Herbert Brooks, H. T. Brooks, W. H. Glen, Victoria; George Hughes, Barbados; Stephen Bourne, Henry Douglas, J. R. Mosse, Ceylon; Henry M. Paul, Arthur Folkard, Ceylon; J. Van Langenberg, Vandersmagt, G. Vane, C.M.G. Ceylon; Major Craigie, Messrs. D. W. Lindesay, J. W. Barsham, J. H. Alexander, James Menzies, C. J. Ash, Shillington, F. W. Fox, J. W. Evans, John Gray, Thomas Gray, L. J. Bell, W. Hall, H. Grant, A. Murray, H S. Saunders, W. S. Murray, Ceylon; W. W. W. Hume, J. H. D. Drake, W. L. Watson, A. G. Low, Murray Mumford, Leopold Ware, G. Seton, A. E. Stanton, R. C. Haldane, Alexander Brooke, W. M. Leake, Ceylon; W. R. M. Leake, Ceylon; Miss H. Hall, Messrs. W. H. Davis, Lindsey Hobson, W. B. Liddell, W. H. Anderson, R. Porter, Ceylon; D. Reid, W. H. Reid, Alfred E. Campbell, J. M. Greig, Dr. B. H. Paul, Messrs. J. Lascelles, Victoria; A. G. Archer, Crick, G. W. Gordon, Mr. and Mrs. W. Rollo, Ceylon; Messrs. E. A. Filby, W. Pears, P. White-White, W. Christian, Colonel Freeth, Miss Woodd, Mrs. O'Halloran, Mrs. Dominic D. Daly, Miss Coode, Mr. and Mrs. Wm. King, Ceylon; Messrs. C. Taylor, Mr. E. M. Rossiter, Mr. C. McEntee, E. B. McEntee, Harold Moore, Mr. and Mrs. Pemberton, Mrs. Randolph, Miss Garforth, Mr. J. S. O'Halloran, Secretary.

The Secretary announced that since the last meeting 14 Fellows had been elected—viz., 8 resident and 6 non-resident Fellows.

The Secretary read the following letters of regret from Sir Frederick Weld, G.C.M.G., late Governor of the Straits Settlements, and Mr. W. H. Ravenscroft, Auditor-General of Ceylon:—

Chideock Manor, Bridport, Jan. 9th, 1888.

My dear sir,—I am very sorry to find myself unable to go to London to attend the meeting tomorrow and to be present at the dinner.

I have this morning received the advance copy of Mr. J. Loudoun Shand's Paper on "The Tea Industry of Ceylon," and have read it with very great interest. Its wonderful development is, indeed, a remarkable instance of the pluck and facility of resource which characterises British Colonies, and, as Mr. Loudoun Shand well points out, leads to results not only of commercial importance, but which tend to weld the Empire together.

I have great hopes of the future of the Straits—especially of Perak, Selangor, and the peninsula generally—as tea-growing countries, the plant flourishes admirably there, and the produce seems to be of excellent quality. A wild native tea shrub has been found in the mountains, as well as several varieties of coffee.—Believe me yours very truly, (Signed) Fred. A. Weld.

The Secretary Royal Colonial Institute.

33 Eaton Place, Brighton, Jan. 8th, 1888.

Dear Sir,—I am extremely obliged to you for sending me the Paper on "The Tea Industry of Ceylon." It would give me great pleasure to be present on the 10th to hear Mr. Shand read his Paper on the subject, but I am compelled to deny myself this pleasure, as an important engagement that I cannot defer will detain me in Brighton on that day.

It would be difficult to find anyone more competent than Mr. Shand to deal with the question, and, while I greatly regret that I shall not have the advantage of hearing his views from his own lips, and of hearing the subsequent discussion, I especially regret that I shall lose an opportunity of renewing my acquaintance with Mr. Shand.—Yours faithfully,

(Signed) W. H. Ravenscroft.

The Secretary, Royal Colonial Institute.

The Chairman: It is always a source of pleasure to the Council of the Royal Colonial Institute to lay before you, and through you before the public, reliable and authentic information bearing on our Colonies, and never more so than when the subject is connected with the industrial products of any colony. The paper that will be read tonight is, you will agree with me, on a most important subject, and I will only now say that you may accept, Mr. Shand as an authority on the subject equalled by very few, if by any, and certainly surpassed by none.

Mr. Shand then read his Paper on the Tea Industry of Ceylon.

So great is the interest attaching to the sources of supply of one of our most important articles of food, and so much in the record of the Ceylon tea industry applies to the cultivation of the tea plant elsewhere, that I preface my remarks with a short reference to the origin of tea, so far as it can be ascertained, and its present position as an agricultural industry in India and elsewhere.

Though the tea plant is not indigenous in China, it was by the Chinese that the leaf was first used as an article of food, and it was among them a household beverage several centuries before it reached Europe.

Like much other raw material used in daily food, the green tea leaf shows no sign of the properties which the leaf when manufactured possesses, and how these qualities were discovered will ever remain a mystery. It is probable that some wandering Mongolian tribes found the tea tree in its native home far north in India, and made a decoction from its leaves, from which they derived real or imaginary comfort; but as the tea leaf as at present used has to go through five distinct processes before it is fit for market, each of which has to be carried out with mathematical precision, and the neglect of any one of which causes the liquor to lack the agreeable and stimulating properties which are developed by careful manufacture, there were doubtless long years of experiment before the present system of manufacture was discovered.

It was possibly this entire dissimilarity between the green and manufactured leaf which gave rise to the idea, long accepted and doubtless encouraged by the shrewd Chinese, that there were secrets connected with the manufacture of tea known only to themselves. At all events, until fifty years ago, they retained a monopoly of the cultivation and manufacture of tea. It was very early in the seventeenth century that tea first found its way to European markets, small quantities being brought over by the Dutch East India Company. It was an age when strong drinks were good and plentiful, and the enormous price of tea and the prejudice which it had to overcome for a long time, prohibited its general use. It, however, steadily gained ground, and towards the end of last century, when it had been known in Europe nearly two hundred years, the trade with China had assumed considerable proportions. Europe took 18,000,000 pounds, of which Britain took about two-thirds; the Anglo-Saxon thus early taking the lead as a tea consumer, which he has all along maintained, and the

consumption in the United Kingdom is now far larger than all the rest of Europe put together. Tea was naturally looked upon as a fair subject for taxation. John Bull was John Bull in those days, and a thin small drink produced by foreigners was not allowed with impunity to oust home-brewed ales. The duty varied from 5*s* per pound and an *ad valorem* duty, in which form an occasional squeeze was put on, to 2*s*. 2½*d*. in 1845, when, in spite of all opposition, tea had to a great extent taken the place of stronger drinks. In that year the importation of tea into the United Kingdom was 40,000,000 pounds, and a proposal for a further reduction of duty was met with the answer that "Parliament was informed on high official authority that the imports of tea having reached 40,000,000 pounds, it was probable that the limit of consumption had also been reached, and that further reduction could only be accompanied by loss of revenue." Reductions of duty, however, from time to time took place, each reduction being accompanied by a largely increased consumption, and the 40,000,000 pounds of 1845 grew into 180,000,000 pounds in 1886. It is hard to say whether the limit of consumption per head of population has been yet reached, but the increased strength of Indian and Ceylon teas, and the greater number of cups of tea obtained from a pound of these teas than from a found of China tea, as noticed by the Customs report of last year and by the Chancellor of the Exchequer in the House of Commons, has for the present caused consumption to stand apparently still.

In the annexed table (Appendix No. III.) it will be seen how far the consumption per head of population in England exceeds that of any other European country, and that the Briton when he goes to the Colonies carries his tea-drinking proclivities with him.

What the consumption per head of population is in China it is impossible to ascertain, but those who have had the opportunity of observation, estimate it to far exceed that of any other country, and it is remarkable that the British and Chinese nations, so dissimilar in habits and conditions of life, should stand out so prominently as the tea drinkers of the world.

About fifty years ago, after several years of report and discussion, the suitableness of large tracts of land in Assam and elsewhere in the Indian Empire to the cultivation of the tea plant was recognised. Experiments were made in different places with tea seed from China, though, strangely, a far more valuable variety of tea was growing wild in the forests near the scene of some of the experiments. Chinese labour was also imported, without which it was considered at the time impossible to make tea. But with labour as with seed, it was soon found that the native material was more suitable; and after the errors and difficulties inseparable from an enterprise so entirely new, about which it was impossible to obtain any reliable information, had been surmounted, the cultivation of tea began to advance slowly.

What those early pioneers of the great Indian tea industry went through: the courage and endurance they showed in the face of difficulties which must have often appeared overwhelming; the sad fate so often attendant on pioneers which overtook many of them, form a memorable chapter in the peaceful victories of history. But their struggles, though severe, were successful, and tea culture spread. The Assam Company was soon formed, and though its career was at first chequered, and at one time threatened with extinction, skilful management brought it through its infantile difficulties, and to its financial success may in great measure be attributed the extension of tea planting to Cachar, Sylhet, the Dooars, Darjeeling, Kumaon, the Nilgiris, Travancore, and eventually to Ceylon.

The success attendant upon the working of the Assam and some other early-formed companies which had planted with judgment and under favourable circumstances soon began to be noised abroad, and a crowd collected eager to become shareholders in tea gardens. The investment was naturally an attractive one; it supplied an article of daily food which was by enormous strides increasing in consumption. There are fewer vicissitudes attached to the ingathering of a leaf crop than a fruit crop. The harvest season was practically perennial; the yield per acre reported to be obtained was fabulous; the prices realised by sale of produce splendid. The investment had all the elements of temptation. It was an era of speculation. Tea-planting in India, coffee planting in Ceylon were the successors of the railway mania in England. Tea companies were rapidly formed, many of them unstable and ephemeral. To possess shares in a tea company or a tea garden was generally supposed to place the key to fortune in the hands of the lucky owner. Moths fluttered towards the candle, and the candle spluttered, and was well-nigh extinguished by the singed wings; but in spite of all, the enterprise grew. There were men engaged in it who could face difficulties and overcome them, and the table appended (Appendix II.), which shows how the consumption of Indian tea has been steadily increasing in the United Kingdom, is the plainest gauge of the extent and success of the enterprise.

It is in round numbers estimated that the tea industry of India represents an investment of 18,000,000*l*. sterling, and the present annual value of the harvest is computed to be 4,500,000*l*.

There are few plants so robust as the tea plant, and few, perhaps, which will grow under such altered conditions, or over such a large area of the globe. In India and Ceylon it grows with equal freedom at sea level and at 6,000 or 7,000 feet above the sea, so much so, that it is not yet an established fact whether hill cultivation or low cultivation is the more remunerative. It has been introduced into the Straits Settlements, the Fiji Islands, Jamaica, Natal and into several other tropical or sub-tropical possessions of the Empire. In the four Colonies named it is being cultivated with apparent success. The adaptation of soil and climate have been proved, and samples of manufactured tea have been tested with satisfactory results, and there seems no reason why these Colonies should not in time supply their own and partially their neighbours' requirements. But, apart from being able to grow and manufacture tea, cheap labour, cheap fuel, and cheap transport are three factors necessary to success; and though Fiji may have an outlet for all the tea it can produce in the Australasian markets, the West Indies in the American markets, and Natal in supplying the expanding South African markets, unless accompanied by a hitherto unheard-of yield, no country where the average wage is 1*s*. or upwards a day can be looked upon as a serious competitor in European markets. The enterprise is still too young in the Straits Settlements to form an estimate of probabilities, but it may in time enter for the tea race with China India, and Ceylon.

TEA CULTIVATION IN CEYLON.

Nearly thirty years ago Emerson Tennent wrote:—"There is no island in the world, Great Britain itself not excepted, that has attracted the attention of authors in so many distant ages and so many different countries as Ceylon. There is no nation in ancient or modern times possessed of a language and a literature the writers of which have not at some time made it their theme. Its aspect, its religion, its antiquities, and productions have been described as well by the classic Greeks as by those of the Lower Empire; by the Romans, by the writers of China, Burmah, India, and Kashmir, by the geographers of Arabia and Persia, by the mediæval voyagers of Italy and France, by the annalists of Portugal and Spain, by the merchants and adventurers of Holland, and by the travellers and topographers of Great Britain." And Emerson Tennent's own charming, though now for practical purposes somewhat obsolete, contribution to the literature of Ceylon has done much to attract towards the varied interests and resources of the island. Nor has literary efforts been since relaxed in portraying the beauties, the interests, and the capabilities of Ceylon; and the student, the sportsman, the intending investor, the casual traveller in search of novelty, have ample means, according to their varied inclinations, of

obtaining accurate information from recent and reliable sources.

But in these days of facile travelling, knowledge of a country is obtained rather by personal observation than from books, and apart from its special attractions, which bring many visitors annually to Ceylon, it is the centre towards which the great ocean highways from north, south, east, and west converge, and the grand tour of the nineteenth century is incomplete without a visit to Ceylon. But it is not from mere book reading nor from chance observation that Ceylon has become a household word in the Mother Country. The island offers no livelihood to the British emigrant in the common acceptation of the word, for under a tropical sun the Anglo-Saxon cannot compete in manual labour with the rice-fed native; but it has been for forty years a favourite field for the immigration of the younger sons of the upper and middle classes, and has afforded to many a solution (though from unavoidable causes, as will be shown afterwards, of late somewhat bitter) of the increasingly perplexing question, "What shall we do with our boys?" and there is not a town—nay, hardly a village nor a parish—in the United Kingdom which does not in some way claim affinity with Ceylon.

But apart from the accident of local and familiar connection, the subject of my remarks to-night conveys a wider and more general interest; it is a history how one of the most prosperous agricultural enterprises the world has ever seen, was at its zenith, smitten by a fatal and incurable pest; how from the ashes of this enterprise there has risen another, which promises to be equally prosperous and far larger, and how by force of circumstances a latent source of imperial wealth, resulting in a large reciprocal trade between Mother Country and Colony has thus been developed. It is a history of a brave struggle and a victorious result: a history conveying lessons of caution and lessons of hope, from which I venture to think the landowners and farmers of England might learn something.

During the 300 years' tenancy of Ceylon by the Portuguese and Dutch, nothing was done to develop what has since proved to be the real wealth of the island. Both Portuguese and Dutch Governments were trade monopolists; and though a system of barter was carried on with the Kandyans, neither nation ever gained a footing in the Kandyan provinces. The European was arbitrary and dictatorial, the Kandyan highlander sullen and suspicious; and it was not until after 25 years of British rule, that the Kandyan prejudice to the foreigner having been overcome, and a grand trunk road constructed from Colombo into the heart of the Kandyan country, attention could be drawn to the suitability of the hills of Ceylon as a field for the profitable investment of that surplus British energy and capital which even then had to find an outlet abroad. Coffee, which had been to some extent cultivated under the Dutch rule, attracted chiefly, because its cultivation could be carried out in the high lands, in a climate congenial to European life; and Sir Edward Barnes, the then Governor of Ceylon, himself formed a coffee plantation on the hills near Kandy in 1825. Sugar, cotton, nutmegs, cinnamon, tobacco, cocoanuts were all planted with varying success; but attention became gradually centred upon coffee, and though for 10 or 12 years, owing to the difficulties always attendant upon pioneering, the advance was slow, it was certain. Land was taken up in various parts of the island, and thus the most suitable localities were discovered. About this time, also, the abolition of slavery in the West Indies, where Coffee had been largely produced, and the consequent labour difficulties, accompanied by a large reduction in the import duty on coffee into the United Kingdom, gave a stimulus to cultivation in Ceylon and capital and energy were drawn from West to East. So signal was the success attendant upon the formation of some plantations, so marvellous—nay, almost fabulous—the reports of the profits, that a fever was produced. Soldiers, sailors, clergymen, civil servants plunged into coffee planting with every penny they had or could borrow, and accompanied, as all such fevers are, by injudicious selection and extravagant mismanagement, who could wonder that a heavy fall in the price of coffee in Europe, and a consequent cessation of credit to plant and cultivate estates, produced a crisis which checked and threatened to stifle the coffee enterprise of Ceylon; but as in the case of Indian tea, so from the coffee crisis in Ceylon there emerged a body of men poorer, perhaps, but wiser; and now, founded upon experience taught by misfortune, the enterprise steadily grew, though subject, of course, to all the vicissitudes incidental to tropical agriculture, and in 1870 and the two preceding years the average annual value of the coffee exported from Ceylon was roundly 4,000,000*l*.

What coffee planting did for Ceylon is best told in the words of Sir William Gregory, the Governor of Ceylon from 1872 to 1877, who says:—"What, I may ask, is the basis of the whole prosperity of Ceylon but the planting enterprise? What gave me the surplus revenues by which I was able to make roads and bridges all over the island, to make grants for education, and to promote the general industry and enterprise of the island from Jaffna to Gall, but the result of the capital and energy engaged in the cultivation of coffee." But when the prospects of the coffee enterprise seemed brightest, when the exports were largest, when capital and energy were freely flowing to Ceylon, when the waste lands offered for sale by Government were fetching prices but a few years ago unthought of, when the result of intelligent experience had developed a system of high cultivation which promised to add length of days to large returns, a fungus, known now as the *Hemileia vastatrix*, was noticed on an estate to be attacking the leaves of the coffee trees. Rapidly the pest spread, and before a year was over it was perceptible all over the coffee districts of the island. The minute spores of the fungus attached themselves to the underside of the leaf, and as it developed the leaf ceased to perform its functions, and died; and the energy of the tree, which hitherto had been available for fruit-bearing, was now devoted to the constant reproduction of leaf. The export tables of coffee from Ceylon from this date show more plainly than anything else the ravages of the disease. It first became perceptible in alternate short crops; but the short crop became gradually shorter, and in time became chronic, in spite of a large increase of coffee-producing land, for planting was being vigorously prosecuted at this time; and though every effort which practice, aided by science, can suggest has been and is being made, the exports of coffee have shrunk to a fifth of their former dimensions. Other pests, attacking trees with constitutions already weakened by leaf disease, have in many cases completed the ruin of coffee estates, but not in all, for there are still a few districts, in several districts estates, and on many estates fields, in which, owing to superior condition of soil and climate, coffee can still be cultivated remuneratively, and as the disease, which at first used to sweep unchecked over vast areas of coffee, is certainly mitigated by the varied cultivation now existent, there is reason to hope that coffee may for many years continue to figure as an export.

With the exception of a few English planters who —attracted in some instances by love of sport, which they had more abundant opportunity of gratifying, in others by a drier and, to some constitutions, a more healthful climate—preferred remaining in the low country, engaged in the cultivation of cocoanuts and cinnamon, the whole Anglo-Saxon energy, from 1837 to 1867, was concentrated on the cultivation of coffee; and though many other economic plants, such as tea, cocoa, cinchona, and tobacco, had been grown experimentally, but little effort had been made to make the cultivation of these plants remunerative. Tea is said to have been introduced into Ceylon by the Dutch Government, and sixty years ago the China variety of the plant was growing in the Botanic Gardens, Ceylon. About 1842 it seems to have been tried on a somewhat large scale, but without practical results, and Sir Emerson Tennent writes:—"The tea

plant has been raised with entire success, but the want of any skilful manipulation to collect and prepare the leaf renders it hopeless to attempt any experiment on a large scale until assistance can be secured from China to conduct the preparation." But as tea was, at the time Tennent wrote, being made in India, independent of Chinese aid, it is more probable that contentment with coffee hindered the development of tea.

About 1866 attention seems to have been directed by several large landholders in Ceylon to the desirableness of introducing new products, specially with the object of utilising the large tracts of forest land in private hands, which, from elevation and other causes, were unsuitable to coffee cultivation, and from this movement sprang the cultivation of cinchona, cocoa, &c., which now swell the export tables. Rumour also reached Ceylon of the golden dividends which were being reaped by some of the Indian tea companies, and an occasional Indian tea planter travelling in Ceylon expressed himself struck with the great natural advantages which Ceylon possessed for the cultivation of the plant, combined with its excellent labour force and its great facilities for transport. The seed from the tea trees in the Royal Botanic Gardens at Peredeniya was all taken up by one enterprising firm. The field of tea which was referred to by Sir Emerson Tennent, and which had now become the property of a company, was taken in hand, cultivated and extended; but all the tea seed which had been so far introduced into Ceylon was of the China variety, which has proved to be of lesser value than the Assam hybrid. About this time, a movement was made by the Planters' Association of Ceylon for the appointment of a Commissioner to visit and report upon the Indian tea districts, with a view to a systematic cultivation of the tea plant in Ceylon. The report was thorough, and, though made at the time of depression following the era of wild speculation in India, was so far encouraging that it produced immediate fruit. Indents for tea seed were sent up to India, and nurseries were prepared for its preparation.

Fortunately for Ceylon, one of the largest and earliest of these experiments, and the one to which the public most looked, was conducted upon the Loolcondura estate, under the management of one who brought more than ordinary care and intelligence to bear on his subject. He was successful in planting a tea field; and, though entirely self-taught in cultivation and manufacture, he in due season turned out tea which secured local appreciation and favourable comment in the London market.

Simultaneously other experiments were carried on, all with satisfactory results as to the article produced, and the local market which had hitherto been supplied from India and China, was soon supplied from its own gardens. Nor was opportunity lost in bringing the tea of Ceylon into comparison with the other teas of the world; and so favourable was the verdict, that the important fact of Ceylon being able to produce an article of superior quality, was at once established. The export tables of Ceylon show that the death knell of much of the coffee had already rung, but in 1873 the price of coffee rose to nearly double what it had been a few years before; and with every economy being exercised in management, accompanied by liberal and scientific cultivation, no wonder the planter clung tenaciously to his coffee trees, hoping for a mitigation or a disappearance of the pest. About this time, also, the first cinchona bark harvests were realised, with such splendid financial results, that, coupled as cinchona cultivation could be with coffee by interspersion of cinchona trees through the coffee fields, the cultivation of tea was for some time retarded.

About 1876 the adaptation of the low lands of Ceylon to tea cultivation was proved, and it was also proved that so different was the nature of the tea tree to that of the coffee tree—the former throwing down a long tap root, and drawing nourishment from sources hitherto untouched by the coffee tree, which is a surface-feeder—that much land which had been under coffee cultivation could be readily and profitably converted into tea-producing property The planting of tea now began in earnest, and from sea level to 6,000 feet above the sea, a large area was rapidly brought under cultivation.

Ceylon commenced its new era under many advantages. The mystery connected with the preparation of tea had been dispelled, and the tea planter of India, after years of careful study, had settled modes of culture and manufacture. The Island was opened up by roads and railways, an abundant supply of tea seed from India was procurable, Ceylon planters visited the Indian tea districts, Indian tea planters visited Ceylon, and some settled there, and then the advice and assistance of experienced men was readily obtainable.

The very gloomy financial position of the island, and the consequent scepticism of success, which prevented any rush of capital towards the industry, though at the time it appeared to many a great and almost fatal drawback, has turned out to have been a blessing in disguise. The enterprise has been divested entirely of the element of speculation, and not a tea estate has been sold, not a company for the cultivation of tea has been formed, which has not been submitted to the most jealous scrutiny of figures.

For several years the wirepullers of Ceylon finance had found that many coffee investments showed yearly-increasing debit balances, and that the substitution of cinchona, cocoa, and other products had failed to fulfil promise or to restore the balance. Every conceivable difficulty was raised—"The soil is not good enough;" "You may grow tea, but you will never make it in sufficient quantity to make it pay;" "You may get quantity, but you will never get quality;" "It may go on for a few years, but it won't last," were but a few of the expressions of doubt hurled freely and without foundation at tea-planting in Ceylon, but it has lived them down. The yield from many of the older gardens has far exceeded the most sanguine expectations; the average price obtained has exceeded that of other tea-producing countries; the older tea fields—and it must be remembered that they were formed on land not selected for its suitability for tea, but for its unsuitability for coffee—some of which are now twenty years old, are giving a steadily-increasing yield, maintaining quality, and showing no signs of exhaustion. The labour supply, which comes chiefly from the Malabar Coast, and which arrives upon the estates free of any premium or incidental charge, is practically unlimited: the average rate of pay being about 6*d.* per day. The transport advantages are unrivalled, railways running through a large part of the land now planted with tea, and the country being covered with a network of excellent roads. The many recent improvements in machinery have much lessened the fuel difficulty, and imported fuel can be distributed among the estates which have not an abundant natural supply at a price which will not seriously affect the cost of production. The Ceylon tea industry has already assumed large proportions. There are probably now 200,000 acres of tea planted in Ceylon, giving employment to 1,200 British managers and superintendents, and 300,000 British subjects from India and Ceylon. The probable export of tea from Ceylon in 1890 will be 40,000,000 lb., and as there is a very large tract of land suitable for cultivation, the limits of the enterprise will only be bounded by consumption, for Ceylon has proved that it can place tea of superior quality in the markets of the world at a price which will defy competition, and with the enumerated advantages, coupled with its salubrious climate, the enterpise is attractive, and promises to continue remunerative.

CULTIVATION AND MANUFACTURE.

A few words as to the cultivation and manufacture of tea may not be out of place.

When the land upon which the tea field is to be formed has been selected, the forest trees are cut down, and, after they have become sufficiently dry, the clearing is burnt off; the land is then carefully roaded and drained, and pits are dug at regular inter-

vals in rows, in which the young tea plants, which meanwhile have been growing in the nurseries, are planted when the weather admits. The trees are not allowed to grow up high, but are from time to time pruned down and reduced to bush form, and when they are two or three years old, according to the elevation at which they are planted, the operation of tea-making commences.

The tea is made from the tender shoots only: generally two leaves and the undeveloped bud are plucked: care being taken not to injure the eyes from which future buds may spring, or future flushes may be checked thereby. Each tea plucker is provided with a basket in which he places the leaf, which is collected twice a day, and laid out as soon as possible on trays in withering rooms. After sufficient moisture has been withdrawn from the leaf, which is sometimes done by exposing it to a blast of dry air driven in by machinery, the leaf is placed in heavy rolling machines, in which it is tossed about, all the cellular tissues broken, and rolled up tightly as if by the action of the hand. After this process is completed, the leaf is taken from the rollers and placed in small heaps on tables, where it undergoes a process of fermentation, the colour changing from green to a bright bronze. When sufficiently fermented, the leaf is passed through the firing machines, of which there are great variety, and when sufficiently roasted is actually tea, and simple operations of sorting and sizing it into different grades prepare it for market. It has been mentioned before, that each of these operations requires to be carried out with mathematical precision, or the value of the tea as an article of food becomes much lessened. If the leaf is allowed to remain on the trees a day too long, or plucked a day too soon, if it is not withered to the hour, if it is allowed to ferment too long, if it is rolled excessively or insufficiently, and if the critical operation of firing is not watched to a second, the liquor resulting may be nauseous, and lose much of its agreeable and stimulating properties. Each operation of manufacture is carried out by machinery which ensures purity and cleanliness, impossible in China teas, and improvements in machinery have so occupied the mind of the Ceylon planter, that nearly every week sees a new patent launched, conducing to superiority of and economy in manufacture.

That even before the consumption of tea became general, it was necessary to protect the consumer from the vile and often unwholesome mixtures brought into the country and sold as tea, is shown by the various Acts bearing on the subject which were from time to time passed. An Act of 1725 provides that no dealer should counterfeit or adulterate tea, or alter, fabricate, or manufacture with terra japonica, or with any drug or drugs whatsoever; and six years afterwards, this Act being apparently insufficient, another statute was passed prescribing a penalty for the offence, called sophisticating tea. It recites that several evil-disposed persons do mix, colour, stain, and dye tea with terra japonica, sugar, molasses, clay, longwood, and with other ingredients; and again in 1766-67, an Act became law, the preamble of which sets forth—"That great quantity of sloe leaves and leaves of ash elders and other trees, shrubs, and plants were manufactured in imitation of tea." And, with a gastronomic interest in His Majesty's lieges which is remarkably secondary, proceeds to say—"That such evil practices were increased to a very great degree, to the injury and destruction of great quantities of timber, woods, and underwoods, the prejudice of the health of His Majesty's subjects, the diminution of the revenue, the ruin of the fair trader, and to the encouragement of idleness."

Though a great deal of the China tea which is imported into London is of so low a quality as by itself to be unfit for human food, the vigilance of the trade and the Custom House is so great, that there is practically now no adulteration of teas imported into England, nor in the present day of low-priced tea need the dealer who inclines to dishonesty to mix sloe or other leaves with his tea; but there are trade malpractices of the day which "prejudice the health of Her Majesty's subjects," and tend to the "ruin of the tea grower and fair trader."

It will be seen from the annexed table (Appendix No. V.), and chemical analysis proves the fact, how much more valuable the average Ceylon and Indian teas are than those of China and Java, and, though some of the China tea is of undoubted excellence, a large quantity is imported into the United Kingdom every year, which, though not absolutely injurious to human health, is of so low a standard as to be deficient in all the properties which constitute a good commercial tea. This tea is so nauseous and unpalatable by itself as to be unfit for food, and the custom of the trade is to bring it into consumption by mixing it with Ceylon and Indian tea: a custom which could not be gainsaid provided the mixture was sold as a mixture; but with the rapidly-increasing appreciation of Ceylon and Indian teas has risen an increased demand, and a section of those engaged in the tea trade do not hesitate to meet the demand, and make it lucrative to themselves by mixing China rubbish with Indian and Ceylon tea, and selling the mixture as Ceylon or Indian tea, often accentuating the fraud by the adoption of a Ceylon or Indian native name upon their packets, and turning the lie into a satire by the affix of the word "pure."

The new Merchandise Marks Act seems framed to check frauds of this nature, so injurious to the British tea grower and consumer, and the fair trader—so advantageous to the Chinese tea grower and the dishonest dealer; but in such an article of food as tea, admixture will often be hard to prove, and the grower of British tea must look rather for relief to the gradual education of the people, and to the appreciation of that which is good and pure.

What planting industry has done for Ceylon has already been told in the words of Sir Wm. Gregory, and every preceding and each succeeding Governor has borne similar testimony how mere fishing villages and groups of mud-huts have been turned into busy centres of commercial life; how roads and railways have intersected a country where but a few years ago the only means of communication were ill-defined footpaths; how schools and churches have dotted the surface of the island, and how all this has gone hand-in-hand with a vastly ameliorated condition of the people, is a story too well told by others to be dwelt upon here, and what the sequel of the story is to be, what proportion the industry is to assume, what success is to attend it, is to be measured in a great degree by the will of the people of the United Kingdom.

The special advantages of climate, of labour, of transport which Ceylon offers for the cultivation of tea have been already enumerated. That the export will increase enormously, and probably reach 1,00,000,000 pounds by the end of the century, and the rock which looms ahead is where markets are to be found for this rapidly-increasing quantity. A table annexed (appendix No. III.) shows the consumption of tea per head of population in most of the European countries, and it is surprising how small it is in many. Though a natural increase may be looked for, it must be borne in mind how slow has been the growth of consumption during nearly three centuries in which tea has been known in Europe, and habit and circumstances having in most cases settled the national beverages of ordinary life, no rapid increase can be looked for: it is to the Mother Country and the vast sections of the globe peopled by the Anglo-Saxon race that Ceylon must look for the consumer of the future. The table referred to will also show that though the British Isles consume far more tea than any other European country, the quantity taken per head is far behind that of the Australasian Colonies, but as colonial society is more largely composed of adults, and less frugality is probably exercised in house-keeping than in the Mother Country, the consumption of tea in the United Kingdom will in all likelihood not increase much further, nor would it be much affected by a reduction of the present duty of sixpence per pound. Such reduction would

tell against the consumer by flooding the markets with cheap and innutritious China teas, upon which the duty of course falls proportionately more heavily than upon the more valuable Ceylon and Indian teas, and would have the effect of still further lowering the standard of the tea supply of the United Kingdom, accompained also by revenual loss.

It is rather, then, to the continued displacement of China tea in the English markets, and the substitution of Ceylon and Indian teas, that the British tea-grower must look for the disposal of the largely-increasing quantities which will be thrown upon the markets.

Chemistry and commerce have settled the superiority of Ceylon and Indian teas, but the customs of the trade in great measure prevent its domestic application. Since the day when a licence was required to deal in tea, the trade has opened out as probably no trade ever did before. All sorts and conditions of men and women throughout the United Kingdom are engaged in the sale of tea. And the exigencies of excessive competitions, the nature of the trade which offers facilities and temptations for admixture of inferior qualities, and the spirit of the age which demands a cheap article, have so vitiated the trade that very few of the poor in our large towns know yet what the blessings of good tea are. But national will may do much to achieve what legislation is powerless to cope with, and to institutions such as the Royal Colonial Institute, the tea-planter of India and the Colonies rightly looks to extend the knowledge of and stimulate an interest in his enterprise, for he knows that knowledge will be followed by appreciation.

And surely these tea planters of Ceylon have a right to demand the sympathy and support of their countrymen. They have, by their efforts, prevented one of the fairest islands in Her Majesty's possession from lapsing into a mere military or coaling station, and becoming a financial burden upon the British taxpayer; they have built up an enterprise which gives employment to hundreds of thousands of the inhabitants of Ceylon and of the natives of the famine-stricken districts of India. If they are successful in the race of life, they return to the Mother Country to spend the fruit of their labours, and they provide suitable occupations for many who come after them, enabling them to enjoy the rights and privileges of Britons living under the British flag, instead of becoming aliens, and investing their energy and capital in foreign countries. They thus help to solve that domestic problem of daily increasing difficulty, the emigration of the better classes, and to give the Mother Country control of the resources of one of its most important articles of food supply, and make it independent of foreigners.

The large reciprocal trade which ensues from the tea-planting industry of Ceylon in cotton goods, in machinery, lead, iron, and the many requirements for manufacturing tea, forms a steadily increasing item in the export table of the United Kingdom, and apart from the portion of the wages of the labourer and artisan which is spent on food grown in British India and Ceylon, the whole of the money expended on tea production comes into England; but in these days of intense competition, this trade is necessarily reciprocal, and if Ceylon has to find a market for its produce in America and elsewhere, there it will also purchase its requirements; and apart from the cost of production, the whole profit derived from tea growing in Ceylon returns to the Mother Country, either in the form of interest on debentures or loans, dividends declared by companies, or profits of individual growers. It is estimated that apart from the large annual draft upon England for cotton goods, machinery, &c., the coffee enterprise of Ceylon returned in actual income to England the sum of 12,000,000*l.*, derived from the profits of capital invested. The greater the success of the agricultural enterprise of the Colonies, the larger is the sum brought into circulation in the British Isles. These seem strong imperial, political, social, commercial, and domestic reasons, applicable not only to the tea industry of Ceylon, but to many other similar Colonial and Indian interest, why the consumer should, in conjunction with the producer combine to overcome trade difficulties, to expose trade malpractices, and to protect, as far as possible, British-grown produce, and stimulate its consumption, other things being equal, giving preference to the fruit grown in our own Imperial gardens; and I venture to think, that if those who regulate the supplies of our army and navy, our asylums, our hospitals, our clubs, our numerous public institutions, were to direct their attention into this practical groove, they would do much to promote that strength of mutual dependence, which, more effectually than any other chain, should bind in yet closer union the Mother Country and the Colonies.

APPENDIX No. I.

Annual Tea Bill of the United Kingdom.

(Approximate.)

Annual consumption 180,000,000 lb., retailed at 1*s.* 11*d*
£17,250,000

Average wholesale price, including freight and London charges:—

90,000,000 lb. China and Java, at 9*d.*	£3,375,000
90,000,000 lb. India and Ceylon, at 1*s.* 0½*d.*	4,500,000
Duty on 180,000,000 lb. at 6*d.*	4,500,000
Cost of distribution and gross profit to dealers	4,875,000
	£17,250,000

APPENDIX No. II.

Percentage of British-grown and China Teas Consumed in the United Kingdom.

	Percentage of British-grown	Percentage of Foreign-grown	Total
1867	6	94	100
1877	19	81	100
1887	50	50	100

APPENDIX No. III.

Average Consumption of Tea in English Pounds.

	During five Preceding years.	Per head of Population.	During 1885.	Approximate Duty in pence per English lb.
Australian Colonies	18,200,000	7·66	21,474,395	3*d.* to 6*d.*
New Zealand	3,902,000	7·23	4,442,867	4*d.*

APPENDIX No. VI.

Estimated Cost of Bringing into Bearing 200 Acres of Land Planted with Tea.

Cost of 300 acres forest at Rs. 50 per acre Rs. 15,000

First Year.

	Per Acre.		
Felling and Clearing 200 acres at Rs.	13·	Rs. 2,600	
Lining, Hoeing, Filling in, Planting and Supplying 4 ft. by 3½ ft.	22·	4,400	
Seed and Nurseries	30·	6,000	
Roads and Drains	13·	2,600	
Weeding, say 15 months at Rs. 1	15·	3,000	
Lines, temporary	3·50	700	
Contingencies, Tools, Survey, Medicines, &c., ...	5·00	1,000	
Superintendence	12·50	2,500	22,800
		Rs.	37,800

Second Year.

Superintendence	2,500	
Contingencies, Tools, Medicines, Taxes, Stationery, &c., ...	1,000	
Supplying	500	
Upkeep of Roads and Drains	500	
Weeding, Rs. 1 per acre	2 400	
Permanent Lines	1,500	
Superintendent's Bungalow and Furniture	2,500	
Topping at Rs. 2·50 per acre	500	11,400
	Rs.	49,200

Third Year.

Superintendence, Contingencies, General Charges &c., Rs. 22 per acre	4,400	
Cultivation and Tools, per acre Rs. 28 ...	5,600	
Tea Factory, permanent, 80 × 42 feet, with fittings, and with Machinery consisting of 1 Excelsior Roller, 1 Desiccator (or Venetian), 1 Sifter, 8 H. P. Engine and Boiler, Shafting, Pulleys, Belting, &c.	14,000	
Plucking, Manufacturing, and Placing f. o. b. 40,000 lb. Tea at 18 cts. per lb. (200 lb. per acre)	7,200	
	Rs.	31,200
By 40,000 lb. Tea netting 1s. in London Exchange at 1s. 6d.=56 cts. ...	22,400	
		8,800
Capital account without interest at end of third year Rs. 200 per cultivated acre	Rs.	58,000

Fourth Year.

Expenditure on 200 acres at Rs. 50 per acre	10,000	
Extra Allowance for Lines, Bungalows, Withering Sheds, &c.	3,000	
Plucking, Manufacturing, and Placing f. o. b. 70,000 lb. Tea at 17 cts. per lb. (350 lb. per acre)	11,000	
	Rs.	24,000
By 70,000 lb. Tea at 50 cts. ...	35,000	
Profit	—	10,100
Outstanding Capital	Rs.	47,900

Fifth Year.

Cost of Producing Crop of 500 lb. per acre 100,000 lb. at 28 cts.	
Netting in Colombo 50 cts.=22 cts.	
100,000 lb. at 22 cts.=Profit	22,000
	Rs. 25,900

Sixth Year.

Crop at 550 lb. per acre=110,000 lb. at 20 cts. per lb., Profit	22,000
Outstanding Capital end of sixth year ...	Rs. 3,900

Capital, say Rs. 300 per acre, giving a profit when in bearing of 20 cts. per lb. at 600 lb. per acre=Rs. 120 per acre profit on Capital Account without interest.

A full report of the discussion which followed the reading of the Paper will be published in our next.—*Colonies and India.*

THE TEA INDUSTRY OF CEYLON.

DISCUSSION ON MR. SHAND'S PAPER BEFORE THE ROYAL COLONIAL INSTITUTE.

The following is a Report of the Discussion which took place at the Whitehall Rooms, Hôtel Métropole, on Tuesday, January 10th, upon the Paper by John Loudoun Shand, Esq., late a Member of the Legislative Council of Ceylon, which appeared in our last issue, entitled

The CHAIRMAN (Sir John Coode, K.C.M.G.): Before the general discussion begins, I should like with your permission to add a few words by way of amplification of one or two points, not that I would wish to convey the Paper is not complete, for it is very complete, and very interesting the delivery of it has been. Mr. Shand referred to the climate but only in a word. Now I have paid three or four visits to Ceylon, and have therefore some little personal knowledge of the climate, and there are one or two interesting facts I may bring before you with reference to that climate as adapted to the growth of tea. First, as regards the rainfall. The rainfall of Great Britain varies from 22 to 23 inches per annum as a minimum to about 70 inches as a maximum. In Ceylon the minimum is 70 inches * and the maximum is fully 200 inches. Moreover, observations taken over the whole island for the shape of a dozen years show that the fall occurs on from 150 to 200 days per annum; and when you remember this, and that in the intervals between the heavy falls there is a marvellous amount of sunshine—the island being within seven degrees of the Equator—you will understand one of the reasons why the vegetation is so luxuriant and so remarkable. I have seen something of the Eastern Hemisphere, and I know no countries which can compare with Ceylon in luxuriance of vegetation, except they be the Straits Settlements and Java. Both of these have been mentioned as tea-growing countries, and they are no doubt pretty much under the same conditions as Ceylon, but on the whole, so far as my knowledge of the meteorological conditions goes, they are not, I think, quite so favourably situated in Ceylon. Another important matter to be considered as a gauge of quality is the relative prices of Ceylon tea as compared with other teas in the market. If you refer to Appendix No. V. of the Paper you will, I think, be struck with the fact that Ceylon commands in price about 50 per cent more than Java or China tea. This is in the London market, and you will admit that Mincing Lane is about as good a judge of the quality and character of tea as you could have. As regards quantity, I believe I am correct in stating that last year was the first year

* The minimum of the tea districts there are two native districts of the island where the rainfall is not much above 50 inches.—ED.

in the history of the tea trade when the supply from China was less than 50 per cent of the total imports into this country. Not many years ago the percentage of the supply from China was very large indeed. The increase which has taken place in the quantity of tea produced by Ceylon is really astonishing. It has, in round numbers, doubled itself every year for the last seven years, and Mr. Shand is well within the mark when he estimates that in 1890 the produce will be about 40,000,000 lb. If it increases at the present rate the amount will be fully 50,000,000 lb. I do not know, ladies and gentlemen—ladies particularly—whether you fully realise what a million is. I will try to bring home to you by a few figures what is the magnitude of the increase that has taken place in the production of Ceylon tea. Mr. Shand has not gone so far back as 1876, but I learn from an authentic source that the export of tea in that year was 282 lb. as compared with 13,500,000 lb. at the present time. Now, 282 lb. represents a pretty good load for a man. It is what a strong man can just manage to carry on his back. Within half-a-mile of where we are met, I know of a case where men are in the habit daily of taking on their backs sacks of corn, each of which weighs about 276 lb. and carrying them from a barge to a store across the road. The produce of tea in Ceylon was, as I have said, 282 lb. in 1876—that is, only 6 lb. more than the weight of one of these sacks, and one strong man might have carried the whole of it. It is now 13,500,000 lb. To carry this load, supposing they were all engaged at the same time, would require 47,870 men. If the quantity becomes 40,000,000 lb. in 1890—as is not unlikely—141,000 men would be required to carry it, and if the yield at the end of the century should be 100,000,000 lb.—and, according to the past rate of progress, that would be the amount—no fewer than 354,600 men would be required to carry it. I hope this illustration will give you a better idea of what has been the growth of the tea industry in Ceylon than the mere mention of so many millions of pounds. I now call on Mr. E. Noel Walker, Colonial Secretary of Ceylon.

Mr. E. NOEL WALKER, C.M.G. (Colonial Secretary, Ceylon): In accepting the invitation to offer a few remarks on this occasion, I did not think I could make any effective contribution to the subject under discussion. I came chiefly as a listener and for instruction, and I have certainly attained that object. The present audience contains many persons who, being connected with and having experience of Ceylon, are much more able to be of service in the consideration of this subject. The whole of my life has been spent in the West Indies, where, as yet, tea has not been cultivated on a commercial and extenisve scale. It is true that in Jamaica at least the cultivation has been experimentally established by Government, under the direction of my late fellow-worker, Mr. D. Morris, now the Assistant Director at Kew. Experts in this county have reported the tea which has been produced in the mountain lands of Jamaica to be of high quality and of good marketable value. In the past few months, I am happy to say, the prospects of all West Indians have materially improved by the rise in the price of their chief staple, as well as by the promise of the abolition of the foreign bounties on sugar and of changes in the fiscal system of the United States. I hope my friends in the West Indies will take example from the planters of Ceylon whose energy and success have been so well put before us by Mr. Shand, and who, in fact, seem to have outrivalled the "heathen Chinee" in his own speciality. The record is, I think, one of which the planting community of Ceylon may well be proud. In a few hours I shall myself start of the interesting scenes of the lecture of this evening, and I desired to be present to join in thanking Mr. Shand for the services I knew he would render the Colony by his Paper. I feel quite sure he is correct in asserting that acquaintance with Ceylon tea is certain to lead to its appreciation and general consumption, and the Royal Colonial Institute, in affording the opportunity of disseminating the information, has added another to the many good works it has done in the direction of uniting the Colonies and the Mother Country. Of Mr. Shand himself, I should like to say that even a limited acquaintance with him has induced me to entertain a feeling of regret that we have no longer his immediate assistance at the Council table in Ceylon, but I feel sure I may say that by his Paper this evening, and his labours elsewhere, he has only changed the useful position he occupied within the Colony for an equally useful one in the Mother Country. Among the pleasant associations of my last days in this country, permit me to say that I shall always cherish the recollection of this evening's meeting.

Mr. RANDALL PYE:—I may be said to represent the unfortunate tea trade of China, which according to the very able address we have just heard from Mr. Shand, is so soon to be wiped out by the overwhelming increase in the production of India and Ceylon. The China trade in tea is not dead yet, however, and while I should not wish to throw the slightest cloud over the happy prospect that lies before Ceylon, still I think both Ceylon and India, but most especially the former, will be wise not to underestimate the strength of so powerful a rival as China, and there are certain facts bearing on the cost of production which must be taken into account. I have been a tea planter in Formosa, where the cost of labour is slightly greater than on the mainland of China; in Johore, where the cost is now very much the same as in Ceylon; and, during a residence of nearly 22 years in China and the East, have had frequent occasion to inquire into the cost of labour in the large China tea districts; and, taking the present value of the China dollar as 3s 2d for the purpose of calculation, the cost in China—where, too, it must be remembered, the labour of women and children is largely utilised—averages about 5s per month per head, as against 6d per day named by Mr. Shand; or, counting only working days, say, about 12s per month. Then, again, there is the consideration of climate. In Ceylon, as far as I understand, the tea picking goes on nearly all the year round; the plants have no rest from a winter, and are not reinvigorated by frosts such as they encounter in China, nor have they the advantage even of such cold as prevails in the winter in Formosa or India. Now you cannot always go on drawing cheques on a bank without putting some money in it, and the loss which the plant suffers from constant deprivation of a portion of its leaves must be repaired, either by the use of fertilisers, or by giving the plant a rest and trusting to nature, or both. As regards fertilisers, so far as my experience goes I am not convinced that any such aid will really supply that which the picking takes away, and if they are used there is alway the risk that such use may prove the source of the same trouble that befel the coffee plantations, for many people are of opinion that the disease which attacked the coffee trees arose from the use of manures. In China the use of powerful manures has not been found necessary, and I have never known anything used beyond a small quantity of bean cake (an exceedingly cheap commodity), which is sometimes dug into the ground in the spring. In regard to the competition of other countries, I may remind you that in Formosa alone, which now produces 12 millions of pounds of tea, the area of the possible tea land could easily be increased many fold—possibly tenfold. Oriental countries are in the habit of moving along very placidly as a rule, and are hard to move out of the paths beaten by custom; but when an awakening does come they move rapidly enough, and I think it will be found that when China wakes up to the fact that she must tend her tea plantations more carefully, that she must adopt more scientific methods of manufacture; when she chooses to relieve her people of some of the heavy burden of taxation now pressing upon them, amounting to about 50 per cent on the value of low kinds of tea; when she sets her house in order, and as a rule makes her tea honestly—which she has not always done—she may be found even a more dangerous rival in the future than she has been in the past, and may make it very difficult to find a market even for the smaller quantity named of 40,000,000 lb. of Ceylon tea.

Mr. W. H. TREACHER (late Governor of British

North Borneo): I fear that my contribution to this evening's discussion will be rather of an indirect character, but we have heard so much of interest concerning Ceylon that I should like, with your permission, to draw your attention, for a few moments only, to another British possession, which some people have named the *New* Ceylon. As some of the members may be aware, a description of British North Borneo, under that title, has been published by Mr. Joseph Hatton, the well-known writer. But as affairs are now going in that country, perhaps the "New Sumatra" would be a fitter title, as both German and Dutch planters—having discovered by practical experience that Borneo will grow tobacco equally as good as the valuable kind produced in Sumatra, and far superior to that of Java—are taking up large acreages in the territory of the British Company, and I am informed that during the past year 200,000 acres have been applied for and taken up for tobacco culture alone. There are, however, many points of similarity between Ceylon and the New Ceylon, and I have little doubt but that a planting interest, perhaps including tea, such as that now existing in the older country, will, before many years are past, spring up in the younger territory. Among other points of resemblance, I may mention the following:—The area of Ceylon is about 25,000 square miles; that of British Borneo about 30,000. Ceylon is situated between N. latitudes 5° 53′ and 9° 51′; British North Borneo between N. lat 4° 05′ and 7° 25′. The mean temperature at Colombo is 81° F. that at Sandakan, the capital of British North Borneo, is also 81° F. The coolest months in Ceylon are December and January, and the hottest, March, April, and May; in British Borneo the lowest average temperature is during December and January, and the highest average temperature during April and May. The average rainfall at Sandakan for seven years has been 124 inches, *i.e.*, on the coast line. I am unable to give the rainfall of the interior. Sir John Coode has just told us the rainfall of Ceylon varies between 70 and 200 inches, and this it is probable will be found to be about the range in Borneo. There is one great difference between the two countries, and that is in the numbers of the population. The population of Ceylon is put at 2,825,000, while that of British Borneo is only 160,000. It is stated that the land under cultivation in Ceylon forms only one-fifth of the total area. You can, therefore, imagine how much land there must be available for European cultivation in Borneo, with its larger area and so much scantier population. That the soil of Borneo is good is proved practically by its growing the most valuable kind of tobacco, and that the temperature and rainfall make it a good planting country is shown by the figures I have given. As to elevation of land above sea level, that taken up by the tobacco planters is flat land on the coast; but as you advance into the interior the elevation increases, culminating in the mountain Kinabalu, 13,700 ft. high. I have scarcely alluded to tea, and for the simple reason that, with the exception of a small experiment made in the early days of the Colony in the Government experimental gardens, tea has not yet been tried, but I have endeavoured to show you in these remarks that in British Borneo you have plenty of suitable land and a suitable climate. As in all new countries, labour will be a difficulty at first, but Indian coolie immigration has already been sanctioned in the case of the States of the Malay Peninsula, and this sanction will doubtless soon be extended to British Borneo. There are two other sources near to British Borneo whence labour can be obtained, viz, Brunei, the Malay capital of Borneo, and Hongkong, whence the best of labour, probably, for tropical countries is to be obtained—that of the patient and laborious Chinese. Sandakan is only 1,200 miles from Hongkong, and the Government are now about to establish regular steam communication between the two ports, to supplement the present sailing communication, so that Chinese labour can be imported direct, and not through the labour brokers of the Straits settlements. I may mention here that there is one tribe of agricultural Chinese who seem to take kindly to North Borneo—the Hakkas. Many of them have embraced the Christian religion, and are in consequence somewhat looked down upon by their neighbours. Several have settled in Borneo, cultivating small plots in the vicinity of towns. They are a very steady, hard-working race—the women getting through as much hard, out-of-door work as the men. This is a possible source of cheap and good labour. I may add, as showing the general nature of the country, that neither among Liberian nor Arabian coffee has leaf disease appeared, and that both kinds seem to flourish in Borneo. Amongst other products under cultivation at present, and showing encouraging signs of success, are cocoa, sugar cane, pepper, nutmegs, Manila hemp, &c. Land, as I have said, is plentiful, and the price at present is only $1 an acre, without auction. The Government is essentially British, and anxious to attract settlers by all legitimate means. I trust the few remarks I have made justify me, in your opinion, in thinking that the *New* Ceylon is not altogether an inappropriate title for this latest addition to the Colonial Office list, and I also hope that British North Borneo will one day do its share in helping to solve the question to which Mr. Shand has alluded, and that is—"What are we to do with our boys?"

Mr. D. Morris (Assistant Director, Royal Gardens, Kew):—I think the Paper by Mr. Shand is one of the most able and eloquent we have had for a long time. He has been a tea planter in Ceylon for a considerable period, and has had the management of large tea estates; he has been the chairman of the Planters' Association, and has represented them in the Legislative Council. I think, therefore, Ceylon is most fortunate in having him here tonight to represent the large tea industry of that island. I was in Ceylon in 1877, 1878, and 1879. Tea at that time had not been taken up with the seriousness which afterwards characterised the planters. I remember such men as Mr. Taylor of Loolcondura, Mr. Armstrong of Rookwood, and Mr. Cameron, who ought to be borne in mind in any historical account of the tea industry of Ceylon. Mr. Taylor, in his plodding, careful way, worked out unaided, the details of tea manufacture, and certainly he deserves to be held in the highest estimation as a pioneer of the industry. The sudden transformation which took place in Ceylon in a few years from a large and flourishing coffee industry to the tea industry is one of the most wonderful instances of well-directed energy and perseverance that has ever been known in the history of any British colony. Having made a special study of colonial industries, I may say I do not know of another instance of such a transformation. The island was almost in a state of ruin after the collapse of the coffee industry, but the spirits of the Ceylon planters never sank. They have had difficulties that others have not had to contend with, but they have surmounted them all. The tea industry is a wonderful monument of their energy and capabilities, and all in this room, I am sure, will wish them "God speed." As a contribution to the subject matter of Mr. Shand's excellent paper this evening, I would add a few words as regards the botany of the tea plant which may be of interest to those not already acquainted with it. Although the tea plant has been so long and so successfully cultivated by the Chinese, we have no evidence at present that it is truly wild in any part of China. The plant has been found wild only in the forests in the mountainous parts of Assam and near the south-west frontiers of China. Botanically the tea plant is known as *Camellia theifera* (Griff.). The plant cultivated by the Chinese is probably the species altered by long periods of manipulation and climatic influences. These have operated to produce a stunted, hardy shrub, exactly suitable to its environments, but differing in many respects from the tea tree as found wild in Assam. The Assam tea plant may therefore be provisionally accepted as the original species, and the China tea plant is a distinct variety of it. Between these a hybrid has been produced which is well known in India and Ceylon, and found by planters to partake of the hardiness of the China plant, with the free growing habit and productiveness under tropical conditions of what tea planters call

the indigenous or "wild" Assam. As in all hybrids, however, there is a wide range of difference between plants raised from this hybrid seed. Some are free-growing, yielding large crops of leaves, amenable to cultural operations, and easily adapting themselves to local circumstances. Others, on the other hand are slow-growing, more apt to yield flowers and fruit than large crops of leaves, and easily checked by adverse circumstances. To such well-marked forms—or what gardeners would call "strains"—of the tea plants planters apply the term "jat"—an Indian word meaning class, race, or kind. It will be easily understood that there are possible to exist as many "jats" of tea as there are kinds, varieties of rice, or of mangoes, or, indeed, of any plants that are susceptible of change under cultural influence or the interference of men by hybridising or crossing. The Ceylon planters have been greatly assisted by the Botanical Gardens of the Colony, the directors of which have throughout consistently and usefully supported them, and brought within their reach, not only the cinchona and the early plants of Assam tea, but in many other ways have encouraged the planters in their efforts to promote the industries of the Colony. I may add here that one of the first samples of Ceylon tea which reached this country was sent to Kew in 1867, and was very favourably reported upon. I will not now go into questions connected with tea in China, Borneo or Jamaica. I may say, however, that I planted a small quantity of tea in Jamaica, which has done well. I received some samples by the last mail, from my successor Mr. Fawcett, which I submitted to Messrs. Gow, Wilson & Stanton. They reported to me the tea was very good, and worth about 1s 9d a pound. I am afraid, however, that Jamaica will not be able to compete with Ceylon, because of the numerous advantages which Ceylon possesses. That Colony has a race of planters with such wonderful energy—men with so much "go" in them—that it is almost impossible for other planters to overtake them, favoured as they are, moreover, with a magnificent climate, a favourable soil, and large labour resources. I desire, in conclusion, to express to Mr. Shand the great pleasure I have derived from hearing his eloquent Paper this evening. It reminds me of addresses I have heard from him in connection with the Planters' Association of Ceylon, and I am glad to say neither his eloquence nor his usefulness to his brother planters has by any means diminished. His Paper to-night shows how thorough an enthusiasm he can rouse, even in so domestic a subject as tea.

Mr. W. MARTIN LEAKE:—I am in an apparent difficulty. Mr. Shand, in the appendix to his Paper, takes as the first year of a really considerable export of tea from Ceylon the year 1880. You, sir, pushing back your researches to the more remote date of 1876, have told us that in that year the whole tea crop exported might have been carried an one man's back. Now, I left Ceylon in 1873. I am made to feel quite an antediluvian, and it is obvious that if in 1876 a man could carry the whole crop, there could not have been much doing in the years preceding 1873. How, then, can I have anything to say on the subject? The explanation lies in this. Up to that date there were only two of us producing tea—the Ceylon Company and ourselves, and we had no difficulty in selling all our crops in the island at rattling good prices. Mr. Shand has in his Paper given a sketch of the early history of tea culture in Ceylon—a very impersonal sketch, and one in which no names are mentioned. All that I propose to do this evening is to amplify this sketch and to insert in it a few names. I have no records, and speak only from memory. Mr. Shand correctly fixes 1866 as the date when a movement was made in the Planters' Association for the appointment of a commissioner to visit and report upon the tea plantations of India. I was at that time, and had been for several years Secretary of the Planters' Association, and it was mainly at my instigation that the commissioner was appointed. As far as I recollect, the association voted 1,000r. for the purpose, and the Government gave a like amount, Mr. Arthur Morice was the Commissioner. He was absent only a few months. He had a pleasant trip, and, as Mr. Shand has said, made a very good report, and, I had almost said, there was an end of the matter. But more truly it was the beginning of it. I meant rather to say that there was no excitement, no enthusiasm of any kind, no inkling of the great things to come. There is another part of Mr. Shand's sketch in which I am indirectly referred to. He states that one of the largest and earliest experiments in tea cultivation in Ceylon was on Loolcondura Estate. I was at the time, jointly with my partner, Mr. Harrison—a gentleman known to you, sir, in his earlier days—proprietor of Loolcondura, and it was by us that the experiment in question was undertaken. In naming 1866 as the date when the landed proprietors of Ceylon began to turn their attention to new products, Mr. Shand has not, I think, gone far enough back. I would rather fix 1861 or 1862 as the date. A few days ago, while talking over this subject, Mr. Shand asked me "How was it we came to make this experiment?" I was obliged to reply that I didn't know. "Was it mistrust of coffee?" he asked. At once I answered, "Certainly not." For those were the days, if any, when coffee was, in Mr. Shand's words, the most prosperous agricultural enterprise that the world had ever seen, and the zenith of which he speaks I should date in 1867, from which year, though *Hemileia vastatrix* was still unheard of, the decline was rapid. Casting my memory back during the last day or two, I am inclined now to think that the true origin of our successful experiments in cinchona and tea lies in the fact that, when first Mr. Harrison and I took part in the planting enterprise, we were associated with a gentleman—one of those who have been so enthusiastically described to you by Mr. Morris as having of all in the world the greatest amount of "go"—an old Ceylon planter—I refer to the late Mr. John Gavin. When we joined him in 1862 he had, I remember, a great scheme for planting cotton in the eastern lowlands of the island. He had arranged for a free grant of land from the Government. But talking of planting in the unpopulated lowlands and securing a grant of land was more easy work than carrying out such a scheme—as anyone who knows the country will tell you. Besides, about that time, the cinchona plant was introduced by the Government into their gardens, and our attention was at once turned to that cultivation, which has from the first been a complete agricultural success. Mr. Gavin left Ceylon in 1863, but we had imbibed from him the planting spirit, and about 1865 we were planting Chiua tea. Thus the experiment in the cultivation of the Assam tea plant was in truth only one in a series of experiments. In 1866, after Mr. Morice's visit to India, we imported the seed of that plant from Calcutta, and a beginning was made of that great enterprise of which we have had a full account tonight. We received great assistance throughout from the Government of Ceylon, and we were especially indebted for advice and help to my good old friend, the late Mr. G. H. K. Thwaites, of Peradeniya Gardens. I cannot conclude without a few words about one who, though spoken of by Mr. Shand, is not mentioned by name—I mean Mr. James Taylor, the Manager of Loolcondura estate. You have heard what Mr. Morris had to say about him. Speaking perhaps with more knowledge, as having been associated with him in his work for some twelve years, I can endorse all that has been said about him. Without James Taylor we could have done nothing. He is a man who, of all whom I have known, is the most entirely devoted to his work. Self-advancement has been, I believe, as nothing in his eyes. He has cared for his work, and for that only. Here lies the root of the wonderful success attained. I would add that though Loolcondura had been selected as the estate most suitable for cinchona cultivation, it was not so in the case of tea. Mr. Taylor had shown what he was capable of in the matter of the cinchona. And it was therefore without hesitation that we entrusted the tea experiment to his care. How fully that course has been justified you have heard tonight.

Mr. J. L. RIGDEN (Natal):—I must confess I am not a tea planter myself, though I have some acquaintance

with the subject, and my remarks shall be few. The tea plant is not indigenous to Natal, neither does it exist to my knowledge elsewhere in South Africa. It was first imported in 1850 from Kew Gardens, and from seeds other trees were raised down to about 1877. This tea was considered to be the Indian tea, which was then comparatively new and experts considered the produce better than that of the Assam hybrid or the indigenous Assam. The result of the experiment showing that the climate and soil were suitable for the growth of tea, planters thought a better seed should be introduced, and consequently some was imported direct from India, which proved successful to such an extent that the Planters' Association memorialised the Government to bring over in their chartered vessels, freight free, any further seeds, which the Government agreed to do. Several further boxes were imported, and divided in proportion to the guarantees given in 1877. From the first batch of seeds about 5,000 plants were raised, but during the first twelve months these were reduced by more than half. It was not till 1880 that the first real field was planted—a field of about 5 acres containing some 10,000 plants. In 1886 the total area under cultivation was about 600 acres, and the amount of tea raised was about 57,000 lb. It was expected last year that the amount raised would be 100,000 or 120,000 lb., showing that, as in Ceylon, the production so far doubled itself in the year. The belt of country in Natal in which tea can be grown is, however, very small. It is grown at present not more than 12 miles inland. Within that limit the country is practically free from frost. An experiment has, however, been made upon some land 40 or 50 miles inland, and so far the experiment has proved successful. The great drawback to tea growing in Natal is the labour difficulty. The population at present numbers about 370,000 natives, 30,000 whites, and 30,000 coolies from India. The Kaffirs are willing enough to work, but they do not care to do so for more than three to six months at a time, after which they go home for a while, and consequently the planters cannot rely upon them; but, could they do so, they would probably be cheaper than the Indians. The labour of coolies, who are indentured for a term of five years, is more or less expensive. Employers have to pay a sum of 4*l* per head annually to the Indian Immigration Board, besides other fees, the wages themselves being at the rate of from 10s to 14s a month, exclusively of rations. Still, tea can be imported into London at 1s 1d per lb. including duty, and the sample is said to be very good. These facts, I think, compare favourably with those relating to other Colonies. The tea is not consumed very largely in the Colony itself at present, the greater amount used being imported, but the local consumption is increasing. What was expected to be an obstacle to tea cultivation in Natal is the rainfall, which varies very considerably. In 1884-85 it was only 31·91 inches, and, in 1885-86 42·10 inches, showing a very much less fall than other tea-growing countries. In Natal, too, the rain all falls between about September and April, the other months generally being practically without any, and often subjected to very strong hot winds, which dry up vegetation to a great extent. Still, the industry is yet in its infancy, and, so far as it has gone, I think you will agree with me, it has been successful.

Deputy Surgeon General C. G. Irwin:—I shall be unable to give you the eloquent phraseology of our worthy lecturer, the profound statistics of our excellent chairman, or the personal reminiscences of the original planter. I am put up, I presume, in contrast to the gentleman who is about to embark for Ceylon, for I have just returned from the United States. I cannot tell you much about the production or cultivation, or the consumption of tea, but I can perhaps claim from you some degree of attention on the ground that I am one of the oldest tea drinkers in the room—one of the oldest Indian tea drinkers. I have been a drinker of Indian tea for twenty-five years. I happened to be in Bombay, where nobody drank anything but China tea, but, being up-country we had to fall back on the native article. We felt the change, or fancied we did; but, strange to say, on our return we could drink nothing but Indian tea. This shows how tastes are influenced by circumstances. With regard to Ceylon tea, I have no doubt I have drunk a great deal of it, but I refer more particularly to Indian tea, which, as I have said, I have drunk for the last 25 years, and, as I happen to have an interest in that tea, I try to push it wherever I can. I have had an opportunity of studying the tea-drinking habits of other nations than the British. I have been a good deal in the United States, and I may say that from the White House—where I have taken tea—to the fashionable hotels and private residences, the quality of tea used is vile. The Americans generally are not tea drinkers, and there is, I think, an enormous field for the introduction of a really good tea. The pure American is a very amenable creature; you can lead him almost anywhere. He is in an eminent degree an admirer of British institutions, and is becoming more so every day. I believe the American of the future—and of the not distant future—will become a confirmed tea drinker; and I have no doubt that a large portion of the tea you expect to export from Ceylon will find its way into the States.

The Chairman:—A most agreeable duty now devolves on me. It is on your behalf to convey to Mr. Shand a cordial vote of thanks for the eloquent and instructive paper with which he has favoured us this evening.

Mr. Shand:—If the duty which has devolved on Sir John Coode is agreeable, that which I have to perform is still more agreeable, and that is to ask you to join with me in passing a vote of thanks to him for presiding this evening. His connection with this Institute is so well known that it would be impertinent in me to refer to it; but, apart from that, he has a connection which, to me, is of very great interest, being, as it is, intimately associated with Ceylon. I claim for the Ceylon planters that they have built up a great enterprise, which is likely to be a lasting one. I have told you how the Governors of the island have referred to the roads, the bridges, and the railways which that enterprise has enabled them to scatter over the country, but there is an enterprise of even greater Imperial importance, and that is the breakwater at Colombo. We provided the thews and sinews which went to construct the work, and Sir John Coode provided the brains. It is a monument of our industry and of his skill; and I do not think that any New Zealander will ever sit under our trees and sketch its ruins. In regard to the discussion, Sir John Coode thought I had not laid sufficient stress on the suitability of the Ceylon climate to the cultivation of tea. I did mention the matter more than once, but I have rather a delicacy in referring to the Ceylon climate, because I have lived there for twenty-two years, and I felt, therefore, that any detailed remarks on the excellence of the climate might become personal. Sir John Coode, after the manner of an engineer, has put before you, in a practical form, the facts of the development of the Ceylon tea enterprise. He has made the matter clear even to those who cannot understand millions. To the remarks that have fallen from our friend who is associated with China—and who has had what to me is a most interesting experience in China and Formosa—I attach great importance. I do not wish him to think we want to wipe out any enterprise. We want to live and let live. We know that China consumes nine-tenths of the tea she produces, and our desire is that she shall so prosper that she will consume the extra tenth she now exports. He says China will wake up. If he has read the consular reports for the last twenty years he will see that they all point to the same facts—adulteration and the putting into the market of badly prepared tea. It will require some warnings before her for the last twenty years China has not roused herself. I wonder when she will. There is, however, another factor at work in the process of deterioration, which I have on very good authority namely, that the enormously expanding tea market of the world has occasioned such a rush on the part of owners to supply that

market that injudicious cultivation and excessive plucking has so seriously affected their trees that, until a new area comes under cultivation, China can never fill that place in the tea market she once did. The remarks of Mr. Morris on the botanical question are of great interest. That is a question I did not venture to touch upon, because I am not a scientific man, but I may say that those who were associated with him know the vigilance and the energy he brought to bear in all the cultivations in which we were engaged. I do not think I need follow the vagaries of our peripatetic friend who is such an admirable advertisement of the effects of Indian tea. I claim for Ceylon tea no peculiar protection. I want India, Ceylon, the Straits Settlements, Natal, and any British Colony who can produce tea, to go hand in hand in checking the mal-practices of the trade, and I ask consumers to help us in introducing an article that is good and pure. It is a great privilege to have had the opportunity of addressing this meeting. We all know that we are units in an Empire holding a position which no Empire has ever held before, and I may say that there is no institution in any other country that offers the same facilities for the exchange of ideas, and for imparting that knowledge which producers desire to convey to consumers as the Royal Colonial Institute. Here is a common platform, on which the consumer or the producer of Canada or the Australian Colonies may meet and discuss their requirements and their means of benefiting one another, and thus I have had an opportunity of conveying, however imperfectly, a slight knowledge of an enterprise which, I claim, requires to be thoroughly recognised by the tea drinkers of the United Kingdom.—*Colonies and India*, Jan. 20th.

THE TEA INDUSTRY OF CEYLON.

London, E.C., 20th Jan. 1888.

DEAR SIR,—I send you cuttings of letters that have appeared in the *Standard* in reference to Mr. Shand's interesting paper on Ceylon Tea, which has evidently attracted a good deal of attention outside Mincing Lane circles. The enterprize is really regarded almost as a *new industry* well worthy of full inquiry, and it is therefore most important that correct and authoritative details of the present acreage already in tea should be sent home and made public for the future guidance of those interested. I daresay your regular London correspondent will have supplied you with *other* letters and notices from the papers, and *The Colonies and India* contains a full account of the discussion which followed the reading of the paper, also some remarks of my own in support of Ceylon tea.

It is wonderful what rapid strides it has made of late years; go where you will, you see it advertised in the grocers' shops, in the provinces as well as in London. Indeed, I am afraid that poor Ceylon is made use of in passing off rubbish that has never come from the beautiful spicy island of the East. A note of warning also comes from Mincing Lane, where, I regret to hear, there are complaints that the quality of Ceylon tea is falling off in consequence of planters picking too *coarsely* in order to increase *the yield*. It is to be hoped that this complaint applies to only a few cases, and that more and more attention will be paid to the scientific manufacture of tea, so as to improve the quality year by year. I can assure you, Ceylon is more talked about now than I ever remember, and so many that I know are either already engaged in the tea industry or intend sending their sons out to try their hands as planters on your beautiful hills.—Believe me, yours faithfully,

JOHN HUGHES.

To the Editor of the "*Standard*."

Sir,—I have perused with interest the extract given in your edition of today of Mr. John Loudon Shand's paper on the Tea Industry of Ceylon. With all due deference to that gentleman, I cannot but think that he is overstepping the mark when he mentions forty million pounds as the probable export of tea from Ceylon in 1890. A close intimacy with the island, and a recent visit thereto, satisfies me that while a considerable acreage has been planted with tea only a certain proportion can be expected to give a fair yield. Tea, like most products, requires good soil and suitable climate; and these points have not, in my opinion, been sufficently adhered to with regard to the acreage already brought into cultivation. For this reason, I fear Mr. Shand's expectations in regard to exports of Ceylon teas in 1890 will not be fulfilled.—I am, sir, your obedient servant, J. M. MAITLAND-KIRWAN.

38, Mincing-lane, E. C., January 11th.

To the Editor of the *Standard*.

Sir,—I have noted with interest Mr. Maitland-Kirwan's remarks in your issue of the 13th inst. on Mr. John Loudoun Shand's paper respecting the probable export of tea from Ceylon in 1890; and as this question is of importance to the trade here, it would be of great benefit to know upon what basis Mr. Shand quotes forty million pounds as the probable out-turn of Ceylon for 1890.

It has been my privilege to visit Ceylon, after many years' experience as a planter in India, and although Ceylon may for a time increase in her export, we have the grave questions to ask:—

1. How long can this last if the bushes are plucked from January 1st to December 31st?
2. Can any very great increase continue from soil that has rendered good service to the coffee shrub years gone by?
3. Is not Ceylon just as liable to blight—*i. e.*, mosquito and red spider—as experienced in old gardens in India; and, if so, what allowance has been made?
4. How much virgin land can Ceylon planters open up that will guarantee the figures as stated by Mr. Shand?
5. The island having suffered so greatly from blight in the past does this not point in a great measure to poorness of soil from over work; and if so, are the probabilities in favour of any great increase of tea?

Having interests in one or two estates, and having spent many years amongst the tea districts, I should like to know if the above queries affect the production or not?—I am, Sir, your obedient servant,

INDIAN PLANTER.

16th January.

To the Editor of the *Standard*.

Sir,—I see with pleasure in your issue of today a letter signed "Indian Planter," bearing on the Tea Industry of Ceylon, and calling in question statements made by me before the Royal Colonial Institute. I claim for this industry that it possesses an interest far beyond the mere question of production, and the vast dimensions it is so rapidly assuming make it important to all concerned that the figures of the future, about which there is necessarily the element of doubt, should be framed and received with caution.

The estimate of an out-turn of 40,000,000 lb. of Tea from Ceylon in 1890 is based upon the following figures. A most careful census taken in 1886, after making the most liberal deduction for land only partially planted up, and full allowance for the numerous cases in which the wish of the agriculturist is father to the thought, showed that there were rather more than 150,000 acres fully planted with Tea in Ceylon.

I calculate that this area should yield fully 250 lb. of made Tea per acre in 1890, and that 30,000 acres planted in 1887-88 should give 150 lb. per acre, showing:—

150,000 acres	at 250 lb. per acre	= 37,500,000 lb.
30,000 acres	at 150 lb. per acre	= 4,500,000 lb.
In all..	..	42,000,000 lb.

In reply to the other queries, there is no compulsory reason why the Tea bushes should be plucked from 1st January to 31st December, but so far, with the exception of the periods of rest given to the trees by pruning, this system has been adopted with no ill results, and the older fields (several of them now nearly twenty years old) planted upon land selected, not for its suitability for Tea, but for its unsuitability for Coffee, are giving a steadily-increasing yield, maintaining quality, and show no signs of exhaustion.

Neither mosquito, red spider, nor any other blight, has, so far, had any appreciable effect in reducing the yield from the Tea trees. Ceylon cannot expect immunity from pestilence, but as my estimate of probable yield has been placed considerably lower than the average obtained from Indian gardens, which those cognisant of the circumstances of both countries consider unduly cautious, full allowance has been made for possible pests. The coffee-leaf disease, "a fungus" which "Indian Planter" doubtless refers to, in no way "pointed to the poorness of the soil from overwork." Nor is it possible for it to attack the Tea trees.

The figures attached to my paper read before the Royal Colonial Institute, showing the cost of opening and working a Tea estate in Ceylon, and the resulting yield, are no mere sketch figures, but are based upon actual results which have been obtained, and though disappointment may attend the conversion of some Coffee estates into Tea estates, much of the land which was under Coffee cultivation is already yielding abundant Tea harvests, and the area of land suitable for Tea cultivation in the hands of Government is at least three hundred thousand acres. "Indian Planter" must know well that so much of the cost of production of Tea is expended upon the actual operations of harvesting, that though the discrepancy between realised and anticipated profits may be great, land once planted with Tea does not readily pass out of cultivation, and he may rely upon it that the probabilities are in favour of a great increase of Ceylon Tea.—I am, sir, your obedient servant, J. L. Shand.

24, Rood-lane, E.C., January 17th.

To the Editor of the *Colonies and India*.

Sir,—In the discussion which followed the reading of Mr. Shand's Paper on the above much of the available time was taken up by gentlemen who gave full details of the tea enterprise in Natal and Borneo, and by others who admitted that they had never been in Ceylon at all.

I should like, however, to express briefly my views on the probable continued success of the tea industry of this island, and on the favourable opening which it is likely to offer to the educated European who is fond of a country life. In 1877, at the request of the Planters' Association, I made an extensive tour through the principal planting districts, which occupied nearly two months, and afterwards spent upwards of three months in Colombo, analysing samples of soil from different localities, and also the manures then so largely used on the coffee estates, the analytical results being included subsequently in my official report.

I would, therefore, venture to point out that, when we contrast the comparative failure of coffee with the present aspect of tea, we must remember that the coffee tree is essentially a surface feeder, and that, the estates being generally situated on the steep sides of hills, and the soil constantly loosened during the weeding operations, the effect of the heavy rainfall is most disastrous.

Too frequently the valuable surface soil, containing the accumulated fertility of ages of forest growth and decayed leaves, has been completely washed away, and the coffee-tree, deprived of its natural supplies of plant food, and left without the assistance of manure, either dies a natural death from poverty, or falls a ready prey to the attacks of some fungoid disease.

In the case of tea, however, there is a long tap root, which extends deep into the subsoil, so that, when the tree has been carefully planted, and the soil is sufficiently deep and free from slaty rock cropping up, the shrub can draw an abundant supply of the necessary mineral constituents as required, while it can also, by abstracting moisture over a large area, withstand for a much longer time the ill effects of drought. No doubt in time some manure will have to be used, but at present, on many estates, the tea tree, well planted in suitable soil and aided by a climate specially calculated to produce frequent flushes of leaf, will doubtless thrive without artificial help. Indeed, on many plantations, excessive pruning has to be resorted to in order to check the too rapid growth of wood and leaf.

At the present time the most improved machinery is being put up at the central factories, and the study of the chemistry of tea manufacture offers an interesting investigation for our young chemists, as the various operations have to be regulated according to the weather at the time of picking. The flavour and strength of Ceylon tea varies according to the soil, elevation, and climate of the estate, as well as the care and skill displayed in the manufacture. It is one thing to produce a fine quality of leaf, and quite another—and perhaps a more difficult—thing to convert such leaf into a high quality of tea. There is therefore plenty of opportunity for improving the mode of manufacture, though rapid strides have already been made since the first few pounds of tea were shipped home. Average Ceylon tea contains less of the astringent ingredient tannin than India tea, and is therefore more suitable for children and persons with weak digestion. The flavour is so superior that it is used for mixing with inferior China, which could not otherwise be sold. If, therefore, really pure Ceylon tea is required, the purchaser must pay a good price, otherwise he will only obtain a mixture, and not the genuine article.

It is a fact as strange as it is true that heads of families who pride themselves upon the quality of their wine are content to drink such wretched tea themselves, and expect their visitors (often Anglo-Indians accustomed to a very superior beverage) to put up with the same at afternoon tea parties.

Let us hope that we may soon see a better appreciation of really good tea on the part of the general public, and this improved taste at home will soon stimulate our energetic Ceylon and Indian planters to still greater perfection than they have yet attained.—I am, &c.,

John Hughes,
(Consulting Analyst to the Ceylon Planters' Association.)

Analytical Laboratory, 79 Mark Lane, London, E. C., January 14th.

TOBACCO—THE COMING PRODUCT IN CEYLON.

Now that our correspondent "Peppercorn" has opened out on the subject, we may say that there is an unusually good prospect of the scientific cultivation of high-class tobacco at length being added to the permanent planting industries of Ceylon. Dutch planters of tobacco in Sumatra with whom we recently travelled from Europe were very frank in their statement of the large profits which were accruing from their plantations. Notwithstanding that Deli exports had risen from 35,000 to 150,000 bales (of 80 kilos, 176 lb. each), yet the prices obtained had steadily risen and there was no prospect of the market for good leaf falling. Not only so, but the Ceylon tobacco which they had seen in London and Amsterdam was considered fairly good and well worth cultivating.

To Messrs. Ingleton and Vollar of Dumbara belongs the credit of the revival of this industry on a new and satisfactory footing. Dumbara cigars have long been in the local and home market through Mr. Ingleton's agency; but it was a shipment of leaf by Mr. Vollar, we believe, which most attracted the attention of experts at home and brought out to Ceylon about six weeks ago two German gentlemen, capitalists and ready to encourage and extend an industry which promised so satisfactory a result. It is to enter the service of this tobacco "firm," if we may so speak, a

the Kandy agent and manager, that Mr. Ingleton is retiring from the management of Rajawella. Already land suited to tobacco has been prospected for in Dumbara, Matale, and Kurunegala districts. Some purchases have, we believe, been made, and cultivation on a considerable scale will shortly be commenced. Our planting correspondent alludes to the prospect of a large block of some thousands of acres being taken up, and, that from small experiments already made, a profit equal to R600 per acre nett had been realized! This beats Mariawatte; but unfortunately to get further good crops of tobacco from the same land is a matter of very high cultivation indeed. We trust our visitors and their manager will give attention to the chance of improving native cultivation of tobacco in the Uva and Jaffna districts. The question of resuming operations on Kantalay tobacco lands has been discussed; but is said to be decided in the negative because of the detrimental influence which the north-east monsoon exercises on the quality of leaf in tobacco fields in Ceylon. There is however much to be learned of an industry which is quite in its infancy here; but meantime we may congratulate the colony on the advent of Continental capitalists to aid in developing the new product and the gentlemen concerned on securing so competent an Agent as Mr. Ingleton of Dumbara.

CEYLON UPCOUNTRY PLANTING REPORT.

TOBACCO—ANOTHER TEA-ROLLER—TEA—GOLD—PRECIOUS STONES.

6th Feb., 1888.

Among the many different products to which Ceylon planters look for profits, is *tobacco* to be trump?

It 's a fat thing anyhow, so they say, and just at present there is "a boom" in regard to land that is suitable to grow it. You hear of new clearings in Dumbara; land being bought near Ukuwala for the same purpose; and the big German Tobacco Company that proposes to go in for a block of from 5,000 to 10,000 acres—there is a nice indefiniteness about these figures—with a local man as manager. The gentleman named is no mean judge of tobacco, and has experience enough in the raw and manufactured article to have made his name known outside of our little island.

As to the profits from successful tobacco growing, if but half be true that we are told there are fortunes ahead, and in the near future too. Over R600 an acre nett! is the lowest quotation I like to mention; if I were to give the highest I have heard, it would read too like a joke. Of course in Ceylon things do grow marvellously, but the growth of a story, especially a story of a good thing, is not to be matched by even the most rapidly developing vegetable product. Anyhow whatever returns may be reasonably expected from the cultivation of tobacco, it would seem as if we were about to have the culture fairly tested in several districts, and on a pretty extensive scale. Let us hope that the venturers may have a fair measure of success.

Yet another Tea Roller in the field, of a new style, and brought out from home by Mr. John Brown. At present its work and capabilities are being tested, and by-and-bye we will hear more of what it can do.

I have to thank you for the copy of Mr. C. S. Armstrong's special paper on "Tea Cultivation," which was written at the request of the Dimbula Planters' Association, and now printed in pamphlet form. The two illustrations "plucking at above full leaves" and "plucking at shoulder" are valuable as enabling you to see at a glance the styles of plucking Mr. Armstrong recommends; as aids in rendering clear a somewhat obscure text, they are also very useful. I think it rather a pity that the author did not overhaul his paper before it was reprinted in the pamphlet form. A little alteration would have improved it a great deal. Such a sentence as the following from page 6 is somewhat trying to read, although, of course, it can be seen what meaning is intended to be conveyed:—"This is not an overdrawn picture, gentlemen, and much as supervision is necessary in the factory, it is equally as necessary with the pluckers, and walking over the tea fields to judge how to continue your round and when to 'lift' your pluckers—owing to various causes which it is unnecessary here to enter upon, it is sometimes necessary to 'lift' your pluckers over a field and give it a few days' longer law—again you may find you are getting too rapidly over the ground," &c. &c. The sentence runs on three and a half lines further. But after all the readers of Mr. Armstrong's paper will not be taking it up in search of "style," but rather for a more practical purpose. Perusing it with that view, passages which before were rather stumblingblocks, and, indeed, partook a good deal of the nature of a planter's puzzle, are by means of the illustrations rendered tolerably clear. The reader steps at once into possession of Mr. Armstrong's matured experience, and has his latest ideas on the best ways of cultivating the tea bush.

I notice that there has been of late an interest taken by the *Observer* in Gold in Ceylon. There is an estate which I know well, and which had for some time a reputation for possessing gold. The belief in this mineral wealth took years to grow. Its genesis was the expressed opinion of an Australian visitor, who was struck by the resemblance of the quartz scattered about with the gold-yielding reefs of Ballarat. A period of time elapsed, and another visitor was on the ground. He, too, had a good deal of experience in gold-mining, and, like the former man, was much impressed with the auriferous appearance of the stone. Had he been outward-bound instead of homeward, he would have asked to have taken a few hundredweights to Melbourne to have had it tested. In those days coffee was truly King, and it was easier to grow gold than mine it, so nothing was done. Another period of time elapsed and a real Australian digger was on the ground. He heard of the reputed wealth of the land around, and, with the feverish earnestness of his class, set about to wash for it. He was not easily disappointed; worked on with praiseworthy perseverance, washed every stream in the estate, and came back without even "a show." His spoil was a few very small stones which he called "ruby sparks," but as for gold his verdict was "There is n't a trace." Another period of time elapsed, and our island had a visit for a few days from a great mining expert. Like the present there was then also about a rumor of gold. The expert was a man of great energy, capable of seizing every opportunity that would lead to his advancement and profit, and it became known that for a short time only his services were at the disposal of the public. A proposal was made to the manager of the estate of which I write that the great expert was willing to visit the property and settle once for all the question of its value as a possible gold field. The fee asked was £50 sterling if the work could be done in a day, and £25 for every other day after! But the manager did n't see it. After he had got over the shock of the fee demanded, he declined the offer, feeling assured that although the great expert would certainly find gold if he came, it would only be in the form of minted coin, and drawn

from the pocket of the estate proprietor. The verdict of the miner who had worked for love was taken to have settled the matter once for all.

The weather we are having,—well, as I don't want to be either irreverent or rebellious, I'll say nothing about it. PEPPERCORN.

PLANTING REPORT FROM THE HILL COUNTRY OF CEYLON.

THE DROUGHT AND ITS EFFECT ON TEA—DRYING UP OF STREAMS—JUNGLE AND PATANA FIRES—THE CHERRY FOR HIGH ALTITUDES IN CEYLON.

NANUOYA, Feb. 9th.

There are no signs of the abatement of the drought. A blazing sun, shining through a cloudless atmosphere and a strong desiccating wind are rapidly depriving the surface soil and the more delicate forms of vegetation of their moisture. But the exceptional rainfall of the last quarter of the year so thoroughly soaked the subsoil into which the roots of the tea plant penetrate, that from the luxuriant expanse of Mariawatte upwards through the Gampola and Nawalapitiya valleys Ambagamuwa, Dikoya, Kotagaloya, and Dimbula, the plant looks fresh and flourishing. Of course flushing has been checked and in many of the lower places entirely stopped, as it will be everywhere if the drought continues. At this elevation, however, (between 5,000 and 6,000) it is wonderful how the tea draws on the reserve moisture in the soil. The effect of the dry weather as yet, on the estate whence I write, has not been to reduce the daily pluckings to any extent when compared with the exceptionally large gatherings in January. With the drought has again appeared on the tender leaves a minute black insect which simulates black bug, but is really not a scale insect, but, I believe, an aphis. We have ceased to regard this dry weather visitant as of any consequence. Much more annoying is the tendency of many of the tea bushes to run into blossom and seed, and if all hands were not required for plucking and other work, the children would be put on to strip the trees of the products which we do not want them to yield. Yesterday, as the mountains came successively in view, we looked anxiously for cloud, but there was scarcely a fleck on the clear sky. As we came opposite "the Peak" near Hatton, a few small clouds appeared, but they only showed that as more and more of such aggregations of moisture appear, we may expect rain. Last evening and again this morning, masses of haze lay over the region extending from Bogawantalawa to Dikoya, Maskeliya, and Ambagamuwa, but they were merely heat exhalations. In the train the heat of the blazing sun was modified by the strong breeze. By the time we reached Nanuoya at 4 p. m., however, the wind had abated and the heat during a couple of miles ride was intense, continuing, at an elevation of 5,800, up to half-past 5. The volume of the rivers has been much diminished, while small streams and pools have been almost or wholly dried up. Every feature of the hills and mountains was distinctly visible, and I never before realized the number of divisions existing in the enormous mass which dominates over Dimbula and which we call "Great Western." A large sheet of rock seems to have scaled off near its summit recently, leaving a conspicuous red surface exposed. Of course, a good deal of patana burning is going on in this weather. We noticed a good deal of blackened surface in Ambagamuwa, contrasting with the rich green of the tea which has so rapidly superseded worn out coffee in that district, and volumes of smoke show that the Elk Plains are on fire. And the word fire reminds me that a companion in the train with whom I discussed the tea fuel question said he had heard from a gentleman hailing from the southern portion of the United States that there, groves of the common peach are planted for firewood, the tree coppicing readily. And this again suggests that the cherry, which grows so readily from cuttings in this region, might, with the peach, receive a trial.

SNAKE-BITE.—An interesting paper, by Mr. Daniel Morris, on the use of certain plants as alexipharmics, or snake-bite antidotes, has just been issued. Mr. Morris explains that his enumeration of the plants reputed to possess alexipharmic properties is offered without any expression of opinion as to their value. It is intended chiefly as an attempt to bring together for the first time a summary of information about these plants, in order that inquiry may be made to confirm or refute the popular opinion respecting them. "Opportunities," says Mr. Morris, "to test the action of these plants on a person actually bitten by a well-known poisonous snake are seldom offered to a competent investigator. But as material is being brought together which can be carefully tested by chemical and therapeutical investigations, the most prominent of these plants, such as species of *Aristolochia* and *Mikania*, deserve very careful attention."—*Nature*, Jan. 12th.

COFFEE is still holding out well on the Tinnevelly side of the Travancore range, to judge by Mr. James Clark's experience. This gentleman has just gathered a crop of 3,250 bushels from 210 acres—some of the coffee being 40 years old—and he had also the felicity to sell beforehand for R15 per bushel, delivery being taken of all but 800 bushels that came in after the date fixed; for the latter Mr. Clark is offered on the coast R13¼, but prefers shipping home. The sample is very good. Two years ago, Mr. Clark's coffee suffered much from leaf disease; he allowed the weeds grow up over the coffee, then sickled down, thatching the soil, and his reward is in the present crop. The fungus is still visible in patches, and shade is being grown. Liberian coffee is also doing well in the neighbourhood: Mr. Knight clearing 20 per cent from a young field, the crop of which he has sold at R56 per cwt.

COFFEE DELIVERIES.—The usual crop of complaints is springing up in connection with the delivery of coffee, now that the price has fallen. This is a grievance of periodical recurrence, leading to much angry feeling betweeen planters and buyers and too often to a waste of money in legal proceedings. Cannot the Chamber of Commerce and the Planters' Association, by a joint Committee, once for all establish some rule and indeed a Board of Arbitration for the amicable settlement of disputes. Samples of what constitutes "merchantable coffee" in various degrees would have to be kept for reference. In one case before us, we are told that the second consignment of coffee is refused as "unmerchantable" while the first, taken from the same heap, was accepted. Last year, it will be remembered, a parcel of coffee rejected as "unmerchantable" in Colombo fetched the highest price of the sales in Mincing Lane! The curious thing is that rejection of coffee is never heard of when prices are rising, but rather the planter is sometimes threatened if he do not deliver all he has. Of course, there are buyers who probably seldom or never have disputed. But certainly a good many coffee planters believe that the term "merchantable coffee" is regulated by the rise or fall of prices in Mincing Lane.

GAMBIER.—In a recent number of the proceedings of the Madras Agri-Horticultural Society, the following was acknowledged:—

A packet containing dried capsules and seeds of *Uncaria Gambier** (the source of *Terra japonica*), from N. Cantley, Esq., F.L.S, &c., Superintendent, Botanic Gardens, Singapore.

A BIG SUNFLOWER has been sent to us by Mr. J. Pieris, jailor at Hulftsdorp, where it was grown. It weighs 1 lb. 2½ oz. and is nearly 7 inches in diameter, but does not come up to the specimens sent us some years ago by Mr. C. H De Soysa. As we have before mentioned, sunflower cultivation on a large scale, does not pay, the demand for the seed being very limited,—unless for the feeding of poultry,—and it being a very exhausting crop.

CEYLON TEA IN LONDON.—Messrs. Gow, Wilson & Stanton's Tea Report for Jan. 20th, which we give as a supplement with this day's issue of the *Observer*, states that the week had been a noteworthy one in the history of the tea trade, for not only had the sale on the 16th been the largest ever recorded, but the total amount catalogued during the week had never been equalled. The offerings of Ceylons, however, had been lighter than during the previous week, and there was a marked absence of fine flavoured parcels. The average price for the 4,224 lots sold was 1s, and the highest figure was 1s 6½d for Adam's Peak.

PLANTING ENTERPRISE IN NETHERLANDS-BORNEO AND SUMATRA.—Amsterdam, Jan. 11th.—According to information received, the plan exists to commence the cultivation of lands in Netherlands-Borneo. It is the intention to work certain lands situated near the river Koetei, and the first article to be cultivated will be tobacco. A limited company will be established, the capital of which will amount to 500,000 guilders, divided into five series of 100,000 guilders each and shares of 1,000 guilders, and of which provisionally two series will be issued. The soil of Koetei is very rich and fertile, and the tobacco cultivated there is expected to be very good. It may be expected that the results of this first Netherlands Agricultural Company in Borneo will be satisfactory.—The subscription, opened by the Dutch Trading Company on the 5th instant, for 100 shares in the Deli Company went off as follows:—Thirty-two offers were made from 810 to 860 per cent, 78 shares were sold at 810 per cent, and the balance of 22 shares was sold afterwards by private contract at the same prices. —*L. & C. Express*, Jan. 13th.

NEW GUINEA.—The first annual report of the German New Guinea Company has just made its appearance. We cull from it the following interesting particulars. The aggregate area of Kaiser Wilhelmsland is, roughly speaking, 100,000 square miles, or nearly half the area of the German Empire. The company has devoted its attention principally to the exploration of the new territory, to the erection of stations and settlements in those parts which are capable of being put into cultivation, to the establishment of a regular government and of regular communication with the Continent of Australasia. The cultivation of tobacco has been commenced both at Hatzfeldthafen and at Constantinhafen; and the seat of the administration has been fixed at Finschhafen, where the company keeps three steamers intended to place both the stations of the mainland and those of the Bismarck archipelago in communication with the British India line. It is calculated that by means of this ancillary line the passage from Berlin to Finschhafen may be effected by letters in 45 days, by passengers in 56, and by goods in 66 days; all this however, is *günstigstenfalls*—that is to say, under the most favourable circumstances. The company employs 33 officials and 19 artisans—rather a small nucleus for a Colonial Empire to spring from—but perhaps the beginnings of the East India Company were not much bigger in proportion. It may be added that the Lutheran Missionary Society of Neundettelsau has sent out three, and the Rheinische Missionsgesellschaft of Barmen four, missionaries to convert the Papuans.—*European Mail.*

A POOR MARKET IN AUSTRALIA FOR CARDAMOMS AND CINCHONA BARK.—The following is from the *Fiji Times*:—The following from a well-known firm of wholesale druggists in Melbourne has been courteously placed at our disposal for publication:—"With respect to cardamom seeds, we regret to say that you would have to seek a market for these elsewhere than in these colonies; the demand here is very small, and the market, at the present time, overstocked. We lately had a consignment sent down to us from Ceylon, of very good seed, resembling yours in size and condition, but better dried and better colour. For these we were asked to make a return, if possible, of 2s per lb., but we have not, so far, been able to find any demand for them. For cinchona bark also, our market is very restricted, and for any permanent outlet for either of these lines, there is no doubt you would have to look solely to the London market. We subjoin clippings from the July *Chemist and Druggist*; giving detailed report as to present market value in London of both cardamoms and cinchona, and we trust this will cover all the information you require. In regard to Sassafras bark, there is even less opening for this than for the lines above referred to. We have any quantity of Sassafras in our own gullies in Gippsland and elsewhere, which it does not pay anyone to cut. What demand there is, is confined to druggists, and is for very small quantities, and preference seems always given to the American bark."

MESSRS. WM. JAS. & HY. THOMPSON ON CEYLON TEA.—The following remarks by this eminent Firm are on the whole encouraging:—

The average of Sales quoted over leaf 1s 0½d per lb. is not unsatisfactory, bearing in mind that supplies have included very few invoices of first rate quality, and a good deal of tea with the weak and pointless liquor usually characteristic of manufacture during the period which follows pruning. Apart from this defect—incidental to every crop—the make and firing, generally speaking, leave little room for criticism, and bear witness to a skill born of experience and a care in manufacture auguring well for the future. The December delivery of 742,000 lb. was encouraging, seeing that it was a short month and that deliveries of other kinds were much less than in the two previous months. We print beneath statistics for the year 1887, as well as the figures for the seven months of the current season dating from the 1st June. They are particularly good for Ceylon, in view of the severe competition both in price and quality of the Indian crops. Future prices and consumption will depend in some degree upon the rapidity with which supplies increase; but to a greater extent, we think, upon the maintenance of fine quality, and are therefore very much in the hands of planters, subject of course to climatic conditions. Given fine tea, we think that the increased production expected should find a market without serious disarrangement of values.

As regards the weakness of flushes from newly pruned tea, we suppose this can be a good deal obviated by mixing with such leaf that gathered from fields pruned from six to twelve months previously.

* A scandent shrub of Ceylon and the Malay Archipelago, whose leaves produce the astringent extract called "*Gambier*" or "*Terra japonica*," used for chewing with pan leaves and Arecanut, as Cutch is in India, of which large quantities are prepared and used throughout the Malay Archipelago. *Roxburgh, Flora Indica.*

SPONGES AND SPONGE DIVERS: THE DEPTH WHICH DIVERS CAN SAFELY ACCOMPLISH.

A correspondent, in sending us a portion of the *Daily Telegraph* of December 23rd, with the interesting article (quoted below) on sponge fishing and the nature of the very low marine animal organism called sponges,—some of which are very beautiful, but useless, and others not handsome, but exceedingly valuable for domestic and surgical purposes, —asks, with reference to the alleged depth of 175 feet to which sponge divers in the Levant are said to descend: "How does this compare with Ceylon pearl divers?" We can reply at once that it is not a matter of comparison but of violent contrast. The average depth of water over the banks on which diving for pearl shells is conducted in India and Ceylon is 42 feet, the oysters being found at from 6 to 10 fathoms, that is from 36 to 60 feet; and we have never heard of divers (without artificial appliances) going deeper than 15 fathoms or 90 feet. If, as is stated, the divers in the Levant descend to a depth of 175 feet, that is 29 fathoms, or very nearly twice the maximum depth we have mentioned, we can imagine a rapid enough descent to that depth by aid of a stone, but can equally realize a pressure at such a depth which would render the subsequent ascent very difficult. The average time taken in the Levant for an ordinary dive agrees almost exactly with that occupied by the pearl divers of the Indian seas, so that we take it for granted that dives to 175 feet, the depth where abundant sponge-growth ceases, must be exceptional and rare. Sponges are, equally with corals, sea anemones and shells, amongst the submarine growths in Ceylon, and some of the chank shells taken up during the 1887 fishery had sponges attached to them, curious as natural objects, but not valuable for domestic purposes. We remember, however, a few years ago seeing offered for sale a collection of sponges, small in size, but of very fair quality (soft and compressible), which had been collected on the reefs between Trincomalee and Mullaittivu, where sponge gathering was and perhaps still is (?) subsidiary to shell collecting. The family of sponges are deemed lower in the scale of animal life even than the zoophytes, propagation taking place by gemmules as well as by true ova, so that we suppose the sponge constitutes one of the nearest links between vegetable and animal life. As a general rule corals, sponges and shells do not seem to flourish at a depth much beyond the influence of full light, so that collectors have seldom to dive farther down than ten fathoms. Now that the question has been raised, can any scientific friend tell us the depth which can be reached in sea water, so as to avoid the limit (which we suppose must exist?) where mere superincumbent pressure would prevent re-ascension, even if death did not result from asphyxia? We know that at the latest Ceylon pearl fishery a diver far exceeded the local record by remaining under water for 109 seconds, and we suspect tales of ability to live without breathing for twice or thrice this period must be apocryphal. Let us suppose a limit of two minutes, or 120 seconds. In view of 109 seconds actually accomplished, 11 more seconds might possibly be endured. But to what *depth* can an unprotected human being descend in the sea, with the certainty of natural buoyancy sufficing to carry the body again to the surface, in resistance of the superincumbent weight? There must be some record of experience or some formula by which the question can be answered? In the article "Sponge" in Chambers's Encyclopædia (where, by the way, the illustration of living sponges closely resembles a representation of miniature volcanic craters ejecting showers of stones) we see it stated that a sponge was brought up from a depth of 185 feet in the Gulf of Macri. This refers, apparently, to ordinary diving. A man can, therefore, descend 185 feet, secure an object and come to the surface again. Could he go safely beyond 200 feet, and at what limit would pressure from above keep him below, and how far would he sink before pressure from below would arrest the sinking process? Can these questions be answered? Of course we speak of an average human being with normal organs, but trained to diving.

THE SPONGE FISHERY.

Some interesting particulars relating to the Levant sponge fisheries have been recently given by the United States Consul at Beyrout. It will be remembered that at the Fisheries Exhibition one of the most notable items of that varied show was a large model, very perfect to the minutest detail, demonstrating by what methods that strange, porous, cataractal living thing called the sponge is angled for and taken. Unfortunately, however, there was nothing in the model itself to let the spectator know how marvellous a piece of organisation the sponge is, though some idea could be formed of the picturesqueness of the art of fishing for it. Familiarity neutralises the appreciation of much that is wonderful. The sponge to most people is merely a useful and pleasant article of the toilet. Imagination will not carry them beyond that. Whence the soft mass they squeeze came, whether it be a fish or a vegetable, where it is to be met with, what aspect it presents whilst under water, naturally concern many as little as the manufacture of the tooth-brush or the method by which combs are made. Yet the sponge is quite worth knowing something about. The fishery according to the United States Consul at Beyrout, extends along the coast of Baytroon, Tripoli, Latakia, and the Island of Ruad north of Tripoli. Most of the trade is carried on by the Syrians, but many Greeks from Rhodes, Samos, and other places adjacent share in the toil. The boats used by the men are from eighteen to twenty feet long with four or five of a crew to each little craft. The season starts in June, and the catch continues to the end of October, not because the sponge like the herring or the mackerel is only to be taken at certain periods, but because the weather between those months is usually fine and the water smooth enough to suffer the fishermen to ply their trade without danger. Early in the morning, at the first peep of dawn, the boats start away for the grounds, and they continue to fish until sundown. As the work is carried on by diving, the labour, as may be supposed, taxes the strength so seriously that this kind of fishing is only practicable by young and middle-aged men of great physical robustness and strength. The period during which the diver remains under water averages from sixty to eighty seconds. His sole equipment consists of an open net, adjusted round the body so as to form a pouch, and the men are said to use no instrument of any kind in collecting the sponges. The depth to which they descend varies from twenty-five to a hundred and seventy-five feet, below which there are no sponges worth taking to be found. Three kinds are known in Beyrout, of which the red sponge taken near Baytroon is the most esteemed. The average annual catch is estimated at about thirty thousand pounds in value, but perilous as the pursuit is, the poor fellows who follow it are mulcted in a tax of ten per cent. upon the gross value of the catches by the local authorities.

It was formerly supposed that the Porifera or sponges belonged to the vegetable kingdom, but their animal nature has long been established. They are gelatinous in their inception, and, from the sticky mucous matter which forms their primitive organism, the solid parts are deposited, whence proceeds the whole growth of the mass. Microscopic inspection of the sponge discovers a wonderful composition of fibres of varying

thicknesses, int rlaced in such a manner as to form an incalculable number of cells and canals, the walls of which are coated with gelatinous stuff. Interwoven with this fibrous body are many particles of a mineral nature termed spiculæ, the character of which determines the species of the sponge. Their figurations are numerous; some are like a pin, others have three or four points; others, again, are sharp at both ends. The common sponge, however, that which is used for the bath and the dressing-room, is almost if not wholly without these spiculæ, and has in consequence the flexibility and compressibility which mainly contribute to its usefulness. The sponge sustains life by the perpetual passage of water through its porous conformation. If the fabric be closely examined, the holes with which it is pierced will be found of two kinds, one considerably larger than the other, but much less numerous. Through the minute passages the water penetrates the body of the substance, passes through the smaller canals, and is then ejected in some amazing way through the larger orifices. A great authority on the Porifera relates that he put a small branch of sponge with some sea-water into a watch-glass, in order to examine it with the microscope. He beheld, he says, for the first time the spectacle of a living fountain vomiting forth from a circular cavity an impetuous torrent of liquid matter and hurling rapidly along a succession of opaque masses which it strewed everywhere around. "The beauty and novelty of such a scene in the animal kingdom long arrested my attention, but after twenty-five minutes of constant observation I was obliged to withdraw my eye from fatigue, without having seen the torrent for one instant change its direction or diminish in the slightest degree the rapidity of its course. I continued to watch the same orifice, a short intervals, for five hours, sometimes observing it for a quarter of an hour at a time, but still the stream rolled on with a constant equal velocity." One may realise the spectacle submitted to an eye of microscopic power by motionless fields of the sponge at the bottom of the sea, multitudinously cascading in a vast area of glorious little fountains of diamond-like brilliancy. Yet it must be a melancholy existence. To begin and end as a spout offers but a mournful prospect even to a vegetable. A French authority on the sponge compassionately wites of it:—"The poor creature receives its nourishment from the wave that washes past it; it inhales and respires salt water all its life, and is insensible to anything that approaches its mouth, even though it should only be one-hundredth part of an inch distant."

The animal nature of the sponge is proved by its power of opening and closing its oscula at pleasure. Naturalists term it a simple organisation. Strictly speaking it is so. Yet it is furnished with so many mouths as to suggest an almost alarmingly complicated character. These mouths the thing can open and shut independently of one another; wherefrom it is supposed that the sponge is not lacking in some quality that corresponds with our notion of sense, for it is scarcely conceivable that Nature, who seems freakish only when her objects are not intelligible, should furnish it with irresponsible orifices over which it has no control. It is even possible that it may be supplied with something resembling a nervous system, for, in addition to its power to protrude from its orifices the gelatinous membrane which coats or clothes the channels, it possesses in these same membranes so lively a sensitiveness to touch that on one of the protruded parts being pricked by a needle it instantly shrank. It demands some effort of imagination, however, to conceive that the yellow bit of sponge as we know it was at one time an innumerable fountain, an animal formed chiefly of mouths and exquisitively-sensitive tongues, and some sort of faculty that might answer to mind in the very queer kingdom to which it belongs. That it should propagate its species is inevitable, and its manner of doing this is as strange as all other examples of its behaviour. First of all, minute globules of sarcode are ejected in the form of protuberances from the canals. They grow, and as they enlarge they furnish themselves with clothes to which the marine naturalist has given the name of vibratile cilia. When these globules think themselves sufficiently matured they quit their nests like the fledgling, and roll out into the eternity of waters. They wander awhile, and a good many of them get devoured by hungry fishes. Those which escape, in some blind fashion make their way to the rocks or the bottom of the sea, to which they cling with barnacle-like resolution. They are absolutely defenceless, nevertheless they manage to grow into very considerable sponges, and not only maintain their existence, but are spread over the depths of the water in vast living carpets. There are three hundred known species of sponges, but very few of them are of any use to man. The common sponge is chiefly found in the waters whose fisheries the United States Consul has described. When alive it is an exceedingly ugly object, of a rusty bluish-black above and dirty white beneath. Those which grow on the shore near the water's edge are many-coloured and even handsome, but they are quite worthless for household purposes. Some of them are of a bright scarlet or of a clear yellow, others of a gamboge colour. A great many different species, more than sixty it is said have been discovered in British waters alone. The most interesting specimen of this sort of growth is the minute parasitical sponge which will take up its abode in any holes it can find in the shell of the oyster, whence, penetrating deeper and deeper, it finally arrives at the vitals of the mollusc, until the softer parts of the shell rot away under the inexpressible nibbling. This may, perhaps, be adduced as another instance of the sensibility of the sponge.—*Daily Telegraph.*

PLANTING IN NETHERLANDS INDIA AND NORTH BORNEO.

(*Translated for the Straits Times.*)

The *Java Bode* draws attention to the interest taken there in British North Borneo, owing to the cheapness of waste land in that new colony. So easily is landed property given away to attract population and capital to that thinly peopled country, that land speculators will be sure to be unusually active in that quarter to profit by such a splendid opportunity. The B. N. B. Company follows this course in the interest of its shareholders so as to render their business a paying concern. The Netherlands Indian Government is not guided by motives of gain in dealing with the public land. In Java under a bureaucratic system of government, applications for land, as usual, wherever routine and the delays of office have free play, are leisurely dealt with to the disgust of selectors, who make no allowances for long custom. They naturally compare it unfavourably with the system followed in British North Borneo, with its ruling powers anxious to have the colony paying its way as soon as possible.

The Surabaya *Courant* affirms that this year's crop prospects in Java both as to coffee and sugar are not bright at all. The outlook is discouraging as bad weather has come on. The cane is yet too young to be blown down by the prevalent high winds which, may however, do other damage of consequence. The high wind has done much harm to the coffee trees. The young berries have largely been blown away, and the shade trees levelled with the ground. The prospects at the close of 1887 were so encouraging that, the gloomier outlook of the new year brings home to the planters the force of the adage:—there is many a slip between the cup and the lip. It is to be hoped that the event will belie this forecast which unfortunately rests on good grounds. The planting community has of late been so stricken by adversity, that the prospect of fresh trials does seem to come rather hard upon them.

The Samarang *Locomotief* of the 3rd January, says that, in Mid Java, an invention has just been hit upon, sure to prove highly beneficial to indigo planters should it stand the test of practical experience. The yield of that article is said to be thereby increased between 25 and 30 per cent. It is asserted that the secret of securing this heavier outturn lies in stopping the fermenting process just in time to admit of immediate operations being undertaken to turn out the dye. The secret in fact resides in knowing the exact time to take in hand the different stages of indigo making. The time is fixed by drops of a certain fluid, the composition of which is kept in the dark by the inventor, Mr. Van Prehm. It is to be hoped that, this time, inventive genius has really found out the philosopher's stone for indigo planters. Many previous inventors have made discoveries in this line which have only ended in bitter disappointment. Experiments on a large scale will have to be gone through before the merits of the new invention can be fairly tested.

SOME THOUGHTS FOR TEA DRINKERS.

Tea is so popular an article of consumption that any information tending to a better appreciation of its dietetic uses and of the part it plays not only in domestic, but in political, economy, must be of direct interest to a very large proportion of the people, who will derive much instruction from the paper on the subject read by Mr. Shand before the last meeting of the Royal Colonial Institute. There are probably few persons who, while sipping the "cup that cheers but not inebriates," have not been struck by the varieties of flavour and general quality possessed by different kinds of tea, and have not considered how far those differences are due to natural and how far to artificial causes; but to a very small proportion of tea drinkers probably has it occurred to inquire whether any questions of national importance are involved in this choice between a dear and a cheap tea—a tea grown in India or Ceylon and one produced in China or Java. Less than a generation ago the idea of "tea" was associated solely with the country which has given its name to the cups from which it is usually drunk; and, as a matter of fact, it is only within the last twenty-five years that tea from any other country besides China has been placed on the English markets. At the present time, however, the tea-drinking public have a choice of teas from China, India, and Ceylon, with an occasional chance of securing a parcel from Natal, Fiji, or the Straits Settlements, not to mention the Dutch East Indian Colonies. The single Colony of Ceylon, however, which at that time (1845) had not even dreamt of tea-growing, will in another two years' time send us a quantity equal to the whole of our imports in those days, while India, which was then in equal ignorance of its capacity to rival China as a tea-growing country, will be sending us three times as much. At the same time, the quantity of tea imported into this country from China is nearly three times as great as the "extreme limit of consumption" forty years ago. So far these figures merely indicate an enormous increase in the tea-drinking capacity of the people of the United Kingdom, who, as Mr. Shand states, are only beaten in this respect by their Australian cousins. The superiority of Indian and Ceylon teas over those of China is due partly to the natural conditions of soil and climate under which the particular varieties of the tea plant more particularly cultivated in Assam and Ceylon are grown, and partly to the greater care with which this produce is prepared for consumption. It is clearly then to the advantage of the English tea-drinkers to avoid Chinese teas and to give the preference to those grown in "British" soil. The slightly higher prices which the latter command is compensated for by the higher chemical properties possessed by them, and by the fact that a pound of Ceylon or Indian tea will yield a larger number of cups of "tea" for drinking than the same quantity of Chinese tea. But there is the still larger consideration, that in "patronising" the produce of the Colonies and of India Englishmen are contributing to the support of their fellow subjects, instead of to that of foreigners, and at the same time contributing to the maintenance of those bonds, material as well as sentimental, which unite the Colonies to the Mother Country, and to the general prosperity of the Empire. It is urged by the friends of China that as soon as she awakens, as she shows signs of doing, to a sense of the loss she is suffering through the carelessness or the malpractices of her tea growers and shippers, she will find that she possesses such advantages in an unlimited supply of labour, and an unlimited area available for tea cultivation, that she could swamp all competitors on the question both of quantity and of quality. It would appear, however, that a great deal of lee-way has to be made up before China can attain such a position as this. Mr. Shand's paper made it fully clear that the cost of labour is one of the principal elements in the successful conduct of a tea plantation, and that China has the advantage over Ceylon that she can get labour at about 1d a day, while in Ceylon it costs 6d. But there is already a difference of 5d between the average prices of Ceylon and China teas in the English market—a difference entirely due to quality: and it is evident that, in order to bring the quality of their teas up to that of the Ceylon varieties, the Chinese growers will have to incur considerable expense in improved methods of picking, curing, and packing.* On one point Mr. Shand's paper seems open to criticism, and that is on the matter of retaining, reducing, or abolishing the present duty of 6d per pound. Mr. Shand maintains that to reduce the duty would be to favour the cheaper Chinese teas; but it is surely open to argument whether a consumer who, thinking Ceylon tea dear at 2s per pound (of which 6d is accounted for by duty), would not be glad to pay 1s 9d for the same Ceylon tea (on which only 3d was chargeable as duty) rather than to fall back on the inferior China tea at 1s 6d on which, also, 3d was paid for duty. This question of duty, however, opens up the larger consideration whether, "after all," differential duties in favour of colonial produce would not in the long run be of general advantage. This is a question which the English consumers must decide for themselves, taking into account all the circumstances connected both with the immediate point of the advantages of good and bad tea and with the ultimate point of the benefits accruing to the Empire from the development of British enterprise in the Colonies and India.—*Colonies and India*, Jan 13th. [The day of differential duties is past, but we may hope for an ultimate reduction of the tea duty all round to 3d per lb.—Ed.]

SPICES AND DRUGS: TRADE REPORT.

London, January 12th.

Annatto without demand. Several parcels [illegible] were bought in at 3¼d for good Ceylon and West Indian. A small parcel rather dark *Java* seed is held at 2¾d per lb. Forty baskets Pará *roll* annatto were also brought forward but found no purchasers. The lots were bought in at from 1s 6d to 2s per lb.; less would be taken no doubt.

Bael Fruit.—Only five bags dull and slightly mouldy pieces changed hands at ½d per lb.

Cardamoms.—The auctions comprised the large quantity of 233 packages, all of Ceylon growth. The assortment was a pretty good one, but, owing to the bad light in which the samples had to be inspected, valuation was difficult. The bulk of the cardamoms catalogued was offered to-day, and sold at firm prices, occasionally a shade above the rates paid at the last auctions.

Cinchona.—A fairly heavy parcel [illegible] bark, rather pale, partly mossy; broken quill will not be reached until tomorrow; meanwhile one lot of ordinary quality sold at 4d to-day; 136 serons flat yellow [illegible] of

* The heavy export duty and "[illegible]" to which China tea is subject probably more than [illegible] the cost of labour, and as to improved preparation, machinery introduced a few years ago cannot be used except at the risk of a riot.—Ed.

new import sold well at steady prices, viz., 2s for sound, rather dark and papery, 1s 8d to 1s 11d for damaged, and 11d to 1s 3d for badly damaged. Ceylon reports dated December 20th state that a better feeling pervaded the Colombo market; no public sales had taken place yet, but privately a fair business was doing at better prices, and twigs, which were unsaleable before, again found buyers.

CLOVES.—The production of cloves in Java appears to be growing in importance. Until 1885 there were practically no cloves grown on private plantations in the island, but in 1886 the production amounted to 12,342 lb.

COCA-LEAVES.—A few parcels common thin to barely fair dark leaves were bought in at 9d to 1s per lb. Good qualities do not seem plentiful.

CROTON SEED.—Fair pale seeds sold at 11s per cwt.

CUBEBS.—At the commencement of the year our stock numbered 113 bags, but this is very firmly held, up to 27*l* being privately asked for genuine berries. At the auctions 34 packages were offered, mostly of the bold grey variety. For three cases spurious berries, imported *via* Calcutta, 20*l* was asked, but, no bid being forthcoming, the lot was bought in at 22*l*. Three bags good genuine berries, glightly stalky, imported *via* Amsterdam, sold at 27*l*. At Singapore, on November 28th, there was no stock left, and for the last lots sold there as much as $108 per picul, or 17*l* 12s 6d per cwt., had been paid. Nineteen bags arrived here by the "Glenlyon," *via* Singapore, a few days ago.

KOLA-NUTS.—One case dry slightly mouldy nuts was bought in at 1s per lb. Another case, about 50 lb. fine fresh nuts, dark red, sold at 1s 1d per lb., bidding commencing at 4d per lb.

THE DUTCH MARKET.

Amsterdam, January 11th.

COCOA BUTTER.—On January 10th an auction of about 22 tons Van Houten's butter of cocoa was held here. All were sold at prices running as follows:—For about 9½ tons, A, 77c. to 77¼c. per ½ kilo.; about 8½ tons B, 75c. to 76c. per ½ kilo.; about 4 tons C, 75c. to 75½c. per ½ kilo, or about 1s 1½d to 1s 2d per lb.

CUBEBS.—About 600 lb. genuine, rather stalky, changed hands at 3·25f. per ½ kilo. (= 26*l* per cwt.); also a few bales spurious berries at 2·80f. per ½ kilo. The latest news about the 1888 crop from Java is that it will yield a smaller quantity than last year, and that Singapore has already given high buying orders. Nothing certain can, however, be told as yet, as the crop is merely beginning now. Four bales *cultivated* cubebs, just arrived here, show a very fine quality. It is rumoured that some coffee-planters, who a few years ago tried to cultivate cubebs, have been successful, and are harvesting small parcels this year for the first time, but no influence will thereby be exercised on the market, as the shipments of that first crop will certainly not be important.—*Chemist and Druggist*, Jan. 14th.

PLANTING IN NETHERLANDS INDIA.

(*Translated for the Straits Times.*)

The Surabaya *Courant* calls attention to the disastrous effects of the present depression of trade in East Java, where affairs seem indeed to be going from bad to worse. Investments in estates have proved unremunerative. Continually, plantations, formerly deemed valuable properties, are coming under the hammer, from the load of debt having become unbearable. Sometimes, pecuniary losses in these cases amount to millions of guilders. The prices brought at auction, show only too plainly the depreciation of values so steadily going on of late. Many shareholders in estate ventures, have lost their all. Impoverishment has become so general that, at the chief towns, the value of real property has fallen fifty per cent. Many more estates are deeply involved, and can hardly meet claims, but creditors fight shy of foreclosing from fear of making matters worse. With matters coming to such a pass, the outlook is certainly gloomy enough. To add to the difficulties of the luckless planters they are burdened with a load of taxation, which they can ill bear at present.

In different parts of Java, a disease known by the name of *Sereh* has long been prevalent in cane fields. The canes are striken at the roots, become stunted, and finally wither away. It is spreading in some places, notwithstanding every precaution and care.

It is intended in the course of this year to hold a congress of sugar planters at Surabaya. Preliminary arrangements among growers in East Java are already in progress.

A female sugar planter has hitherto been seldom or never heard of in Java. Yet at the present moment an estate in the neighbourhood of Sourabaya, is actually managed by a Chinawoman. She keeps the cash, gives orders to the European engineer, manages cane planting with the plantation overseer, discusses, and settles matters with the native officials and headmen, and in short directs everything. She is so economical, that the sugar works have become dilapidated and grimy. Gain is set far above safety to life and limb.

MANILA NEWS.

(*Translated for the Straits Times.*)

The *Comercio* lately has been at the pains of enquiring whether the *abaca* fibre, better known as Manila hemp, can be grown of superior quality in other countries than the Philippine. To clear up this point, an expert at New York supplied particulars of a valuable kind. It appears from the sources of information available that out of the Philippines, no hemp of that description has yet been produced equal to the Manila article either in quality or powers of resistance. The plant yielding it is a species of banana and grows rankly in hot climates, but from some circumstance arising out of peculiarities of soil, or climatic conditions, does not produce a fibre of such great resisting powers as the Manila hemp. In that quarter the plant seldom bears fruit. When it does, the plant becomes sickly. When transplanted into other hot countries, it bears fruit, but the fibre loses the strength which had been its great recommendation in foreign markets. Fibres from other plants have been tried with unsatisfactory results. None of them have come up to Manila hemp. Inventive science has failed to devise a simple and inexpensive machine to clean Manila hemp for the market. Hand labour does the needful with appliances of a primitive kind.

INDIGENOUS ORNAMENTAL TREES.—The paragraph about the "Alstonia scholaris" and the difficulty about growing this and other ornamental trees about Colombo reminds me that excepting one specimen in the enclosure at the Victoria Park, no endeavour seems to have been made in planting a few kumbuk trees along the borders of the lake. Those who have seen the fine kumbuk trees along the banks of the Yala and Kumbukan Aru, will, I think, agree with me that they would be a grand addition to the ornamental trees about Colombo. Some of the finer specimens of our ornamental forest trees will not thrive in the open: hora and dummala, for instance, but I think the kumbuk will be found an exception, and well worth planting.—*Cor.* [In our reminiscences of a visit to the North-Central Province rivers and tanks, we wrote strongly on the picturesque grandeur of the kumbuk and the sweet perfume of its flowers. It ought to be planted on the sides of all streams and lakes of water.—ED.]

COFFEE GRAFTING.

There are many drawbacks to the adoption of the system suggested by Mr. Sloan, even should grafting succeed. The enormous expense it would certain would be a fatal bar to its adoption on a large scale, and the fact that grafts are not so productive, or long lived as those raised from seed—which your Nellore correspondent touches upon—would be another and stronger reason against it. I do not know if any attempt has been made to grow "Pedigree Coffee." It has been successful in the case of wheat and other cereals, and why should it not be in the case of coffee? I remember this idea was started some eight years back in the columns of the *Ceylon Observer* by a Mr. R. E. Creckett. He recommended selecting and propagating plants from selected seed of the healthiest plants that can be found, and continuing the selection for three or four generations. This is on the survival of the fittest principle. Whether this system was ever given a trial in the Spicy Isle I do not know. It was just about the time Tea was engaging the attention of Proprietors as a new product, and the chances are it was never given a trial at all. It is well worth the consideration of our Government, as it is beyond the means of private enterprise to give it a fair trial on account of the slow growth of the coffee trees.—Dry Cherry.—*Madras Mail.*

MANURING FRUIT TREES.

It is singular how long some fallacies retain their hold, even after they have been disproved by facts, and of these, one of the most mischievous is the belief that fruit trees and bushes are liable to injury rather than benefit from the application of manure. All sorts of diseases such as canker and other ailments to which fruit trees are liable, are set down as the result of applying manure to the roots; whereas, in nine cases out of ten, it arises from poverty of the soil, causing the roots to run down into the bad subsoil. I am continually hearing complaints from owners of fruit trees as to their unsatisfactory condition, and on examination have invariably found scarcely any surface roots or fibres of any kind nothing but large thorn-like roots that run right down into the subsoil. On inquiry I have usually found that manuring or top-dressing had not been practised for many years: their owners having come to the conclusion that such practices were dangerous. I do not say that manure will prove to be a cure for fruit tree ailments of all kinds, but I will briefly detail a few facts that have come under my observation at various times to prove that starvation of the roots is a more prolific source of injury than abundant feeding of the surface roots both with solid and liquid manures, and growers must form their own conclusions as to the best course to pursue. The fruitful or unfruitful state of the orchard trees in nine cases out of ten is entirely dependent on the attention which they receive as regards manuring. In the fruit-growing parts of Kent, where large orchards of standard trees planted on grass land is the rule, it is a well-established fact that if the grass is cut for hay and carried away, the trees soon become unfruitful and die out; while on the contrary if the grass is fed off so that the nutriment is returned to the root in the shape of manure, the trees keep fruitful and healthy. I have seen some of the most moss grown miserable specimens of starved orchard trees restored to a fruitful condition by making the ground beneath them the winter quarters of sheep and pigs, feeding them the same as if they were in the farmyard with the roots and corn. The finest old specimens of apple and pear trees are generally those in an orchard next to the homestead that is used as a run for calves, sheep, pigs and poultry the whole year round. In these orchards the turf is short, and, being full of nutriment, the trees keep healthy and prolific for an indefinite period. Ashes, garden refuse, or any kind of road scrapings or even scavenger's rubbish may be utilized for increasing the supply of orchard fruits. They should be spread roughly on the surface in winter and in the spring harrowed and rolled down firmly. The result will soon be a marked improvement in the size and quality of the crop. Difference of opinion prevails as to pruning or non-pruning trees, some adopting one system and some another; but, be that as it may, I never knew fruit trees continue to yield good crops any length of time unless the roots were supplied with manure in some form or another.—*Cor., London Garden.*

QUEENSLAND PLANTS.

At the last ordinary monthly meeting of the Royal Society, held under the presidency of Mr. A. Norton, M. L. A., Mr. F. M. Bailey read short notes on various botanical specimens which had lately been collected by members of the Field Naturalists' section. The following are some of the plants to which he referred, with his remarks concerning them:—

Entada scandens Benth. (matchbox bean).—This is the *Mimosa scandens* of Linnæus (foliage, flowers and fruit—a lomentaceous legume). These pods often attain the length of 4 ft. 6 in. in Queensland; but, according to some writers, in other parts they quite double that length. The separated articulations are conveyed by the great oceanic currents to the shores of the west of Scotland and the Orkneys, and occasionally to the Norway coast. Uses: In Australia the seeds are converted into matchboxes. The medicinal properties of this rampant climber have not been much examined by Europeans, but others seem to have some faith in them, as, for instance, in India. There the seeds are used as an antifebrile medicine. They are also employed in pains of the loins and debility. An infusion of the spongy fibres of the trunk is used with advantage for various affections of the skin in the Phillippines. In Java and Sumatra they are roasted and eaten like chestnuts, the deleterious oil being expelled by the heat, when the beans become inert.

Cæsalpinia bonducella, Fleming (foliage, pod, and seed).—This rambling climbing shrub, so common on our tropical coast, is known by the name of nicker-tree, and the seeds are called bonduc nuts, which latter is said to be derived from the Arabic word "bunduk." Necklaces of the seeds are worn by Indian women as a charm. The seeds in powder are a powerful tonic.

Cæsalpinia nuga, Ait (foliage and pod).—This is another climbing prickly shrub of our tropical coast, but, like the preceding one, found elsewhere. Rumphius says that a decoction of the roots has been found useful in nephritic complaints.

Cordia myxa, Linn. (foliage and flowers).—This is one of the sebestens of old European works. The wood is very light, averaging only about 33 lb. to the cubic foot, is soft, fairly strong, and in India is used for boat-building, well-kerbs, and gunstocks. The bark is also used for making into ropes. The fruit, which is eaten, is very mucilaginous; the viscid pulp is used as bird-lime.

Luffa cylindrica, Mill (fruit).—The sponge gourd. The fruits of this genus furnish the vegetable sponges.

[The Loofahs advertised by the druggists' sundry houses, and about the pleasantest things for washing ever discovered, are made from the fruit of this plant. Why should not some of our Queensland readers cultivate them in their back gardens, and start a small trade in them?—Editor. —*Queensland Agriculturist.*]

COFFEE AT HOME.

About Christmas time, as if to show what could be done in the way of furnishing berried plants, we received from Kew a branch of the Coffee shrub thickly laden with its berries. The branch evinced much good cultivation, and was so beautiful with its deep green, glossy leaves, forming a setting for a profusion of brilliant berries, that we sent it forthwith to the artist. Unfortunately the necessarily reduced size of the illustration, and the absence of colour are formidable obstacles in the way of reproducing the beauty of the original, but even in black and white the picture

of the berries is manifest. Planters speak of the berries as Cherries, with which they have little in common save the colour. The portion utilised is the seed. With the living plants in the houses, the museums in which the products and processes of manufacture are exhibited, the herbarium in which dried specimens of the various species and their allies are contained, the picture gallery in which are displayed Miss North's beautiful drawings, the laboratory in which the minute anatomy and chemical constitution of the plants may be investigated, and the library wherein the student may study the literature of the subject. Kew may well be proud of the completeness of the materials and opportunities she offers to the student. Those who are not interested in research will nevertheless find that the Coffee shrub, apart from its interest, is a beautiful shub for the warm greenhouse or stove, as it is beautiful alike in leaf, in its white Jasmine-like flowers, and in its fruit. The cultural conditions are thus summed up in Nicholson's *Dictionary of Gardening*:—A turfy loam and sand, abundance of water, and ample pot room. The plant is readily propagated from cuttings. The following note relating to the fertilisation of the flowers in India is so interesting that we venture to reproduce it from the columns of *Nature*:—

"The Jasmine-like flowers of the Coffee are borne in clusters in the axils of the leaves, and appear simultaneously all over the estates. After a prolonged drought of one or two months, or even more, at the beginning of the year, there is generally a heavy fall of rain, sometimes lasting only an hour or two, sometimes continuing for two or three days; the amount that falls must be enough to saturate the ground, and should not be less than 1 inch.

"In from six to eight days from the time of the first shower, the flowers burst into full blossom, last for a day, and then drop off. On the evening before the blossom is fully out, if the flowers are examined, it will be found that they are partially open, the stigma being protruded and receptive. During the night the hum of insects can be distinctly heard, and I am of opinion that the flowers are largely fertilised by night-flying insects which carry pollen from those flowers which happen to be open rather before the others, as some are delayed. On the following morning all the flowers will be found open, and the field of Coffee presents a sheet of white. These flowers are frequented by immense numbers of bees, of two kinds, one about three-quarters of an inch long, and black, the other smaller, and with white bands round its abdomen. The stigmas now are covered with pollen, and the anthers bursting, and the larger of these bees may be seen buzzing from flower to flower sweeping up the grains of pollen between its front legs, and rolling them into balls. Long before evening all the anthers are exhausted of pollen, and the insects have departed. Besides bees, some butterflies visit Coffee.

"The Coffee plant, by being proterogynous, is intended by Nature to be cross-fertilisd, but owing to all the plants in one clearing being usually grown from seed of a single estate, there must be a great deal of interbreeding, more especially as all the Coffee of Ceylon and most of South India is supposed to be descended from a single plant introduced into Batavia about two centuries ago. This may have something to do with the manifest deterioration in stamina of the younger Coffee."—*Gardeners' Chronicle.*

FLAX EXPERIMENTS IN ABERDEENSHIRE.

The experiments in flax-growing conducted under the auspices of the Royal Northern Agricultural Society in three different districts of Aberdeenshire, have, so far as the results are known, not been (says the *Free Press*) quite as successful as some anticipated they would be. Experiments were conducted on the farms of Craibstone, Tillygreig, and Auchnagathle; the quantity sown in each case, if we mistake not, being three acres. Neither in the case of Craibstone nor Auchnagathle has a final report been received, but Mr. George Walker, Tillygreig—whose flax crop was pronounced by competent critics to have been exceptionally good—writes to the society to say, that, all things considered, the prospect of flax helping the farmers in these parts is not very certain. The committee appointed by the Royal Northern Agricultural Society desire that the cultivation of flax should be more fully tested before throwing it overboard as unprofitable, especially with the view of trying if the cost of cultivation could be further lessened and the value of the crop increased. They submit that it has been already proved, that flax of a superior quality can be grown in Aberdeenshire, and desiderate further experiments before giving any definite statement as to whether the crop can be made a remunerative one or not. Mr. Walker, Tillygreig, has gone very carefully into the details of these experiments, and the facts which he has elicited will have a value for others contemplating a trial of flax. He puts the statement of his expenditure thus:—

Rent of three acres, at 13*s.*	£1	19	0
Ploughing, grubbing, sowing, &c., at 1*l.*	3	0	0
Manure	2	0	0
Carting and threshing bolls	0	10	0
Driving flax by traction engine to Aberdeen	2	18	6
Weeding and pulling	3	3	0
Drying bolls at meal mill	0	12	0
	£14	2	6

The returns are estimated as follows:—

Flax straw	£6	0	6
16 cwt. linseed, at 10*l.* a ton	8	0	0
40 bags bolls, at 1*s.* per bag	2	0	0
½ acre straw not realised	1	4	1
Linseed of ditto	1	17	2
Bolls of ditto	0	8	0
	£19	9	9

The balance of 5*l.* 7*s.* 3*d.* of income over expenditure which remains in Mr. Walker's hands, is not very much to speak of on three acres, and he remarks that, although his crop was admitted by everyone to be very good, the growing of flax does not appear to be very profitable. He kept the expenses attending the preparing of the land for sowing, and in regard to weeding, pulling, and carting, as low as he could, according to the rate of wages, but some additional expense was incurred owing to the distance which the crop had to be carried to the flax mills. The quantity of green straw which he disposed of to Messrs. Richards & Co., Aberdeen, was 7 tons 0 cwt. 2 qrs., from which they produced and returned to Mr. Walker 1 ton 19 cwts. 2 qrs. of seed bolls, leaving 5 tons 1 qr. of flax. This quantity, after being steeped and dried, was reduced to 3 tons 3 cwts. 1 qr. It was then scutched, and yielded 5 cwts. 2 qrs. of fibre and 1 ton of scutchings. The value of the scutchings has not yet been ascertained. The sum allowed for the 40 stones 2 lbs. of fibre was 13*l.* 3*s.* 5*d.*, being at the rate of 52*l.* 10*s.* per ton. From this there had to be deducted 1*l.* 19*s.* 6*d.* for rippling seed bolls 39½ cwts.; 3*l.* 3*s.* 3*d.* for steeping and drying 63¼ cwts. of straw, and 2*l.* 0*s.* 2*d.*, for scutching 40 stones, 2 lbs. of fibre being in all 7*l* 2*s.* 11*d*, leaving a balance to Mr. Walker of 6*l.* 0*s.* 6*d.* The yield of fibre, the Messrs. Richards admit, was rather disappointed, but, although this experiment has not given so gratifying results as were looked for, it would almost be a pity if the cultivation of flax, now that it has been taken up with some earnestness, should be dropped until further experience has been gained, which may lead to a saving in the cost of production, and a better knowledge of the kind of crop to give the best and largest amount of fibre.—*European Mail.*

CEYLON TEA PLANTATIONS COMPANY, LD.—In our London correspondent's letter we note he has fallen into an error, and made a statement which may be misleading. He gives the dividend of 10 per cent already declared as the *total* for the past year. This we are assured is not correct, as the 6 per cent and 4 per cent are both interim dividends. The final dividend may make the total declared anything over 15 per cent.—Well done!

RICE, &c.—It is estimated by the Local Government of Burmah and other reliable authorities that the total crop of rice in 1888 available for export will be about 200,000 tons less than the previous year. This will, no doubt, tend to further enhance the value of rice meal in this market, as the demand for English milled is extensive. Today's prices are about 1s per sack higher than those quoted in our circular of November.—*Downes & Co.'s Annual Circular.*

KAINIT.—With heavy imports in the spring of the year, the value of Kainit fell to £1 19s per ton, but subsequently improved, and the market now closes steady at an advance of 2s to 3s. This article has been repeatedly proved to be of great benefit to all descriptions of light and sandy soils, as such are invariably found to be deficient in potash. The value of best quality, guaranteed 23 per cent sulphate of potash, is 40s to 42s per ton, in bags, according to quantity. —*Downes & Co.'s Annual Circular.*

SUPERPHOSPHATE OF LIME.—Again this year mineral superphosphate has continued to decline in value, and has touched an unprecedentedly low price; the reduction has been of great benefit to the agriculturists, but, as the price is barely remunerative to the manufacturer, it is obvious that the lowest level has now been reached, so that the present is a favourable opportunity to purchase for spring delivery, of which many consumers are availing themselves. Very large consignments have been made to the United States, where the demand is enormous and rapidly increasing, but an advance of 2s to 3s in freights to America has recently checked exports to that quarter; other foreign markets, however, have bought largely, the shipments last year and so far this season showing a substantial increase; the home consumption has also been very extensive. The present quotations are for 26 to 28 per cent. £1 19s 6d to £2 0s 6d, and for 35 to 37 per cent. £2 16s 6d to £2 18s 6d per ton in bags.—*Downes & Co.'s Annual Circular.*

RICE.—Touching the nutritious value of various foods variously cooked, it may be well just now to point out that one pound of Rice, prepared for the table gives 88 per cent of nutriment, and, consequently, a relatively proportional ability to labour compared with other articles of food. A pound of beef contains only 25 per cent of nutriment; yet countless numbers strain a point daily to purchase beef, when they could get a pound of rice for one-third of the amount, the rice, moreover, having three times as much nutriment as the pound of beef, making a practical difference of 800 per cent.* There is, also, that additional fact to be considered that boiled rice is digested in about an hour, roast beef, on the contrary, requiring three and a half. There is meaning, after all, in the fact that two-fifths of the human family live on rice. Mutton is 5 per cent more nutritious than beef, plums 4 per cent, and grapes 2 per cent. Cod-fish yields only 21 per cent of nutriment. Contrary to popular ideas, apples yield 3 per cent more nutriment than milk.—*Country Paper.*

I DO not think the good qualities of rice meal as a flesh-forming food are sufficiently well known among farmers. My experience of the meal is highly satisfactory. I am at the present time feeding two animals on a diet of rice meal and barley meal, three parts of the former to one of the latter; and the rapidity with which the pigs increase in bulk, with every appearance of sound health, is really surprising. The meal is scalded every time they are fed, which is three times a day; the mess is then allowed to cool down to a suitable temperature, which is easily ascertained by thrusting the finger into it before it is placed in the trough for the animals to consume. I may add that rice meal, especially in these hard times, is well worthy of the farmer's consideration.—T. S. J., *in London Paper.*

CINCHONA.—Notwithstanding that no fewer than 300,000 cinchona trees were destroyed by a landslip in the Nilgiris in June of last year, and 20,000 more by a hailstorm earlier in the season, the sales during the year 1886-87 of ordinary and crystalline febrifuge were better by 385 pounds than those of the previous twelve months. Yellow and hybrid for red-bark cinchona trees were largely substituted during the year. The bark of the two former yields quinine, and it is the object of Government, by working out the red-bark growths, to have in its hands cinchona estates which will give quinine and some combination of quinine and cinchonidine at almost as cheap a rate as the febrifuge obtained at present from the red-bark trees. The cost price of the raw material used in the factory during the year amounted to R73,518, while the outturn yielded R113,152. Putting the realisations for febrifuge and bark during the year and the stock in hand at the end of it against the working expenditure, there was a profit in favour of the plantation of R18,464, a much less favourable result than was obtained in several former years. Commercially, therefore, the year was a bad one, but this is counterbalanced by the advantage gained in the cheapening of this invaluable drug which was the principal object of the Government in introducing cinchona cultivation into India. It is not expected that this fall in the price of quinine will continue. Meanwhile, the Government have asked the Superintendent to keep down expenditure on the plantations and to push on the experiments in the manufacture of quinine.—*Indian Agriculturist.*

GOVERNMENT BOTANICAL GARDENS, BANGALORE.—Of the Malta lemon seeds, sent by Dr. Bonavia, 81 vigorous seedlings were ready for planting out, and the older plants have established themselves kindly in ordinary garden soil. Dr. Bonavia has made experiments, the results of which establish that a decoction of this lemon is an excellent remedy in cases of quotidian fever and enlarged spleen. The roots of the seedless Breadfruit do not seem to thrive, and even where they have germinated, the growth seems to be slow. This is probably owing to the fact that like the coconut tree it requires a tropical sea board climate, and does not take freely to an inland and comparatively dry position. On the subject of the improvement of exotic and native fruits already in cultivation, the report quotes certain remarks of Col. Hill in which he expresses a desire "to see more systematic efforts made to improve the peach, apple, plum, and grape, by importation from England, and the Continent (Italy). I suggested at the last show that prizes should hereafter be given in seeds and in fruit slips, the prize holders being allowed to take the value out of the Lal-Bagh. I was at the Horticultural Show at Madras, and saw, that with the exception of crotons and foliage plants, how dependent they were on Bangalore for nearly everything. Also I have watched the quantities of vegetables and fruits (mangoes chiefly) sent from Bangalore to all parts of the Presidency and to Bombay, which must bring in a heap of money into Mysore. Therefore, I think, the Mysore Government should deal liberally in increasing the grant for the new varieties of fruit and seeds." When Mr. Cameron was coming out from England, on the expiry of his leave, he brought out with him a small quantity of six varieties of potatoes which has given a good crop within two-and-a-half months. The tubers are small, but he is induced to believe that they will admirably serve for another planting in season. He is surprised to find that although the croton oil plant (croton tiglium) is indigenous to the Province, no efforts are being made to extend its cultivation, which should prove remunerative, as the oil is in great demand in Europe, and fetches a high price. He is willing to supply plants or seeds if any planters would care to try the experiment. A ball of the [illegible] was collected from one or two trees in the garden, principally from one which [illegible] by the [illegible] will not run freely in winter, the [illegible] and it has had to be postponed. [illegible] the station have been trying to cultivate hops [illegible] the experiment has been successful so far.—[illegible] *Agriculturist.*

* This statement is astounding!—ED.

MOISTURE-PROOF GLUE is made by dissolving 16 oz of glue in 3 pints of skim milk. If a still stronger glue be wanted, add powdered lime.—*Electrical Trades Journal.*

A CURIOUS DISCOVERY.—In the tartar of teeth from skeletons of the stone age, Mr. Charles White, of the Odontological Society of Great Britain, has found specimens of the food eaten by our prehistoric ancestors 3000 years or more ago. The fragments identified include portions of corn husks, spiral vessels from vegetables, starch husks, fruit cells, the point of a fish's tooth, and bits of wool feathers and cartilage.—*Gardeners' Chronicle.*

THE ALLEGED ITALIAN QUININE BOUNTY.—Some time ago the statement was made that the Italian Government allow an export bounty on all quinine made in Italy and shipped to foreign countries. At the time this statement was contradicted in our columns by the London agent of the Fabbrica Lombarda at Milan. Now it is revived by Messrs. Powers & Weightman, the American quinine manufacturers, who privately state in a recent trade circular that the Italian Government does allow such a bounty.—*Chemist & Druggist.*

GROWING ORANGES.—I noticed in the *Gardeners' Chronicle* of December 31 a correspondent writing about an Orange tree bearing fifty-six fruits. I send you as a sample four Oranges gathered six weeks ago from a tree, which is carrying seventy-nine good-sized ripe fruits; in a green state upwards of eighty. The fruit was exhibited in the Oxford market at Christmas, and attracted much attention. Insects do not attack the tree.—J. MAYO, St. Mary's Road Nursery, Oxford. [The fruits were large and showy, and being the Seville variety, or else a wilding, were very suitable for the making of marmalade. Perfectly good edible kinds are as easily grown as the worst, but to ripen them properly, an intermediate temperature is required. ED.]—*Gardeners' Chronicle.*

LEMON DECOCTION IN MALARIA.—This remedy has besides its antimalarial efficacy distinct value as a tonic to the stomach. Its preparation is thus given by Tommasi-Crudeli who first introduced it to the profession. Take a fresh lemon (or limes) cut it into thin slices, rind and all; boil it in three tumblerfuls of water in an earthen pot which had not been previously used for culinary purposes; prolong the boiling till the liquid contents of the pot have been reduced to one-third, that is to the volume of one tumbler. Pass the decoction through muslin, squeezing out the residue of the lemon, and let it cool for several hours. Let the whole be taken in the early morning fasting. "The drink," adds Tommasi-Crudeli, "is rather bitter, but not distastefully so; it is easily taken by delicate women and children, and when it has reached the stomach it induces the pleasant sensation peculiar to tonic remedies. Its use is especially indicated in the Tropics."—[*Com.*]—*Ceylon Medical Journal.*

INSECT ENEMIES.—It is evident that at Rodriguez, a small dependency of Mauritius, the indigenous plants are threatened with extinction from an enemy of a peculiar character. In the Annual Report of the Acting Civil Commisioner on Crown Lands and Forests, it is stated:—"In my report for the year 1884, I pointed out the existence of a kind of white lice, commonly called here 'cochenille,' which had in a very short time multiplied enormously, and threatened to destroy the forests of Rodriguez. During the year 1885, matters looked more alarming still. It was reported to me that these insects had begun to attack the maize, manioc, and bean plantations: I myself while visiting the mountain, ascertained the correctness of the report. However, the bean harvest had not been bad, and the inhabitants had not to suffer from any scarcity of food. As regards the citron, lemon, and orange trees, for which this island has long been famous, hundreds of them have been killed by these insects. The mango and coconut trees felt their baneful influence, and yielded sour and unsavoury fruits. One of the best forest trees which grow here, the 'Bois puant' (*Fatidia mauritiana*), seems unable to resist their attack, and I am afraid that there will not be one of these trees left within a twelvemonth, unless, by some happy circumstance, these insects were to disappear altogether." We learn from Kew, that the interesting indigenous tree, whose complete extinction within twelve months is here anticipated, is very rare in Mauritius, and unless steps are taken to preserve it at Rodriguez, it will probably disappear altogether as a forest tree, from the flora of these islands.—*Nature.*

AUSTRALIAN ORANGES.—We have received from the purser of the P. and O. steamer "Thames," a small case of oranges which has been consigned to us under his care by Dr. Storer, of Sydney, N. S. W., the inventor of a new process of shipping fresh fruit for exportation by packing it in sawdust or paper dipped in an antiseptic preparation; this, Dr. Storer claims, has the property of preserving fruit if packed in sound condition, and moreover has the advantage of not necessitating any special stowage, but enabling the fruit to be carried as ordinary cargo. The purser writes:—"The oranges were sent on board at Sydney on the 11th November, and after being stowed in the hold have received no further attention; consequently, if not inconvenient to you, I should be glad to receive a report as to their condition. I may add that should this process succeed it will be possible to obtain Australian oranges in England in prime condition during our summer months." The oranges were delivered at Northumberland-street the other morning. They were packed without paper in what appeared to be very coarse sawdust. There were sixty-four altogether. Of these nine had decayed almost out of recognition as oranges, and twelve were unsound not mouldy, but of a livid colour. The rest were in first-class condition, and were far and away the best oranges we have tasted this season. They were sweet, juicy, and of a fine flavour.—*Pall Mall Budget.*

THE STUDY OF VEGETABLE PHYSIOLOGY.—The fact is, that vegetable physiology, apart from the investigation of the microscopic structure of plants has become chiefly a matter for students of physics and of chemistry, and students of these sciences have preferred to study the abstract sciences in their laboratories rather than follow up their applications in the living plant. Chemists, indeed, have told us a good deal concerning the chemical constitution of dead plants. They cremate them and then study their ashes—an odd method, it would seem, of studying the life-action of plants. Combined, however, with practical observations and well devised experiments in the laboratory and in the field or garden, such a method renders invaluable assistance. We earnestly hope, therefore, that the younger school of botanists now coming forward will see the great need there is of their services, and actively take upon themselves the task of unravelling the problems of plant life. As a precious aid in this direction we may call attention to Professor Marshall Ward's lately published translation of Sachs' *Lectures on the Physiology of Plants.** Those who are familiar with the *Experimental Physiology* of the celebrated German author and with his *Lectures*, as here translated, will know how greatly superior those works are in grasp and lucidity to his *Textbook*, and hence students will feel specially grateful to Professor Ward for this translation of the *Vorlesungen*, and for the admirable way in which he has accomplished it.—*Gardeners' Chronicle*, Dec. 3rd.

COFFEE & SLAVERY IN BRAZIL: NO. III.

THE SLAVE QUESTION—BRAZIL'S LAST WORD ON THE SUBJECT—A CRISIS AT HAND—THE FEELING AMONG PLANTERS—FREE LABOUR SUITED TO COFFEE AND SUGARCANE CULTIVATION—WANT OF PASTURE LAND—PROSPECTS OF COFFEE IN BRAZIL.

Rio, 21st Oct. 1887.

The important events during the last three or four weeks have been slavery and the coffee blossoms.

The first of these was brought about by a motion by Senator Antonio Prado in the Upper House for information regarding the measures taken by the Government to suppress the desertion of slaves *en masse* from some of the estates in the province of S. Paulo.

The motion derived importance from the fact that it was made by the former Minister of Agriculture, who, in his official capacity, had, as a member of the present Government, carried through Parliament the Slave Law of 1885, of which I have already written, and which gave the last word (*ultima palavra*) of the country on slavery, namely, that it was to collapse through the gradually diminishing value of the live property until in thirteen years it was to be quoted *nil*. The surprizing circumstance of all was the opportunity which was taken by the leading statesmen on both sides of the Upper House of showing how their opinions had changed in the remarkably short space of two years. Not the least important is the changing of opinions of the Government during the course of the same debate, and all in favour of almost immediate emancipation. Indeed, were it not that the Session had only a few days to sit, the Government would have been forced to make a law, either to free all slaves at the end of three years, or free them at once on condition of working for three years for their present masters! The finish up is that Government has promised to consider the matter during the recess, and after many days' debate the motion was withdrawn. Various bills were presented during the days the debate continued, and after it was over a noble Senator, Silveira da Motta, proposed urgency to consider the various bills presented for solution of the slave question, but this was negatived by a majority of two, the proposer of the motion which led to the debate—Senator Antonio Prado—and the most of the Conservative members who supported him voting in the majority against urgency. So this matter is shelved as far as altering the law is concerned for another six months.

It is expected that the bill to be introduced by the Government next year will either be to emancipate all slaves in three years or else to do so *at once* with condition of working for their masters for that space of time. It is difficult to say what has led to this change of opinion. In São Paulo ever since this law of 1885 passed, the wealthy planters led on by Senator Antonio Prado and his brothers (all of whom used to read the *Observer*) have promised to liberate their slaves at Christmas 1890. This same spirit is spreading throughout the country. In the sugarcane-growing districts of the province of Rio de Janeiro the planters are now doing the same thing. Voluntary emancipation cannot be carried out by all the planters, for unfortunately in the parts of Brazil where the coffee trees have died out, the lands and the slaves are mortgaged, and liberating the slaves on these, would reduce the value of the security. The liberation in a case like that has to be done with the consent of the mortgagee.

The promised freedom to the slaves and on so many of the estates in the province of São Paulo made those on estates where such freedom seemed more remote rather unruly, and the consequence was they left some fazendas in a body, and put the weak police detachments at defiance. At first at the request of the planters the president of the province sent armed men to restore order, but by and bye it get beyond his military resources and the Central Government had to be asked to send some of the regular troops. Simultaneously with these events the discontented spirits amongst the planters sent to the Lower House of Parliament a petition for extra protection, and not contented with giving facts they passed innuendos on those planters who had adopted the three years liberation system, misconstrued their motives, said it was not benevolence but fear which inspired these magnanimous acts. This then was the principal reason for the motion which has led to such a commotion—one may say which has shaken the Empire to its centre—for, while it was showing to the poor negro the coming of day in the dark night of his bondage, it was threatening absolute ruin to many people accustomed to a life of luxury.

Disturbances have taken place in many parts of the country between the pro-slavery party and the abolitionists, and these the Government have put down too often with little regard to the articles of the Brazilian constitution as respects the right of the citizens to hold public meetings. This has not improved matters. The abolitionist societies are showing the more activity, the more their proceedings are interfered with by the public powers. In all the large cities, Rio de Janeiro, São Paulo, Pernambuco, and Bahia, the agitation is working in favour of freedom, and this without regard to *political* partizanship. Only the other day the great emancipation advocate, Senator Joaquim Nabuco, who had been put out of his seat at the last general election by the pro-slavery party and had gone on a trip to England, heard there by telegram of a change in the office of Home Minister, and, knowing whoever was appointed for the post would have to stand an election, came out at once, and one of the members for Pernambuco being chosen for Home Secretary, Nabuco contested his seat after the appointment and gained it. The Home Secretary, of course, had to resign. Steam launches were waiting in the Bay of Rio de Janeiro the arrival of the royal mail steamer which was bringing Nabuco from Pernambuco after his election, and a procession was formed, which took him through some of the principal streets of the capital of the Empire.

Now that Parliament is about to be prorogued, things will remain quiet for six months. Unless that the work of voluntary emancipation for 1889 will continue, and the newspapers will not be slow to record these gracious acts. We cannot but applaud the expansion of these benevolent sentiments: they not only show the philanthropy of the donors, but they prepare the way for the passing of a law which is to declare all free in a short space of time. The country will receive the shock more lightly and the Government will have a much easier task in keeping order until the great *finale* comes. I am not one of those who think that the cultivation of coffee, cane, or anything else that the farmer produces, will be diminished after freeing the blacks. The two principal staples of the country coffee and sugar are admirably suited for production by free labour. The São Paulo planter finds that the colonist system, granting a free passage (which Government repays to the planter), of giving a house, a large enclosed pasture, and a piece of land for growing provisions, is attracting large numbers of European colonists.

principally Italians, to this country, and the example these show to the native of the country makes many of those who in your scented isle would be called squatters (nothing like the Australasian magnates of that name) try the same game and some do very well indeed.

Cane cultivators in the lower parts of the province of Rio de Janeiro are working successfully the same system. Cane is even better suited than coffee for the colonist who has a large family, for Indian corn or beans can be grown on the land while the cane is young, and he does not require to cultivate such a large patch of ground outside the cane field for provisions. While he weeds his cane he is also keeping clean his corn or beans.

The drawback I notice in the province of Rio is that the colonists have not enough pasture land. This is the fault of the proprietor of the estate; the owner does not complain so much of the cost of erecting fences, as timber is plentiful, as of keeping the pastures clean. This could be easily effected if the fields were put down with good grasses, and there are some grasses in this country that keep out weeds and brushwood, but there is a want of energy amongst the people in the way of improving these things. "The old pasture," they say, "has been in existence for years, my father and grandfather used to have time enough to weed it on rainy days with his slaves, and I need not bother." These things will all improve in time. It will soon be that the proprietor, who has the largest pasture for the colonists' cows and mules,—for they must have milk for their children, and they will not always be content to hire the proprietors' cattle or mules for their ploughs,—that that sugar planter will be the most popular and will get the best working colonists, and will lose less by their current accounts. The planter, in all cases, has to be careful that his colonists do not run up a large debit account, for it is in this that all experimentalists suffer. I think I noticed some of your correspondents asking if Brazil would continue to give large coffee crops. I can only coroborate what I have written previously, that I believe she will not only give as much as formerly, but more. At least she will keep pace with the rapidly increasing rate of consumption. The great market for Brazilian coffee is the United States, and there the consumption of coffee has doubled in ten years. The price of coffee has not gone up during the last three months as some expected. The crop now being picked is small, but there are large stocks in consuming countries. Those who have studied the subject make out that taking the stocks in Europe and the United States and those in Santos and Rio, and adding the crops now being picked in Brazil and those expected from other countries by 30th June 1888, there will be a surplus over equal to five or six months' consumption. If this be so, we need not expect a great rise above present prices.

Crops for 1888-9.—The season has been dry previous to the flowering time, and, as a consequence, on the high lands in S. Paulo and Minas Geraes, there has been a magnificent show of blossom. Towards the end of September there were nice gentle showers all over the country; and now towards the middle of October there is more rain, and the trees which showed little whiteness before will, in a few days, be in full bloom. October is generally the blossoming month, and this year the old planters will not have occasion to say that the flowering times are out of joint. News come from many districts that 1888-9 will be the largest crop that has yet been shipped from Brazil.

The movement during the first half of September is said to be similar to above; prices rose a little, but came back again towards the 20th of the month. Entries into Rio by rail are small, but this is explained partly by planters holding back for a higher price and partly that many are busy picking and preparing for market the current crop.

A. S. B.

INDIAN TEA.

Indian Tea Association Chamber of Commerce; Calcutta, 1st February 1888.

DEAR SIR,—In their Circular of the 29th October last, the General Committee gave a revised estimate of the probable outturn of the Indian Tea Crop of 1887, based almost entirely upon actual results up to the 30th September and showing the following figures:—

REVISED ESTIMATE OF CROP OF 1887.

	lb.
Assam	37,929,861
Cachar and Sylhet ...	27,198,186
Darjeeling Terai and Dooars	14,325,782
Chittagong and Cheta-Nagpore	1,432,030
Dehra-Dun, Kumaon and Kangra	3,750,000
Private and Native Gardens	1,500,000
	86,135,859

The Committee have now the pleasure to hand you the undermentioned figures giving the actual outturn of the Crop of 1887 from the returns they have been able to collect from Agents of Tea Gardens and from an estimate of the production of the North-West, Private and Native Gardens. The figures showing the Crop of 1886 are also given for comparison:—

ACTUAL OUTTURN OF CROPS.

	lb. 1887	lb. 1886
Assam	37,849,202	35,627,350
Cachar and Sylhet ...	27,156,589	23,703,163
Darjeeling Terai and Dooars	14,997,805	13,610,682
Chittagong and Chota-Nagpore	1,538,249	1,657,048
Dehra-Dun, Kumaon, and Kangra	3,750,000	3,500,000
Private and Native Gardens	1,500,000	1,000,000
	86,791,845	79,098,243

It will be noticed from these figures that the outturn of 1887 exceeds the revised estimate by 656,000 lb., which is entirely owing to the unexpected increase of production of the Dooars Gardens during the past few months.

The Exports to Australia, America, and other places being taken at 2½ million lb., and the consumption of Indian Tea in India itself and the requirements of Government being taken at 1½ million lb., there will remain about 82¾ million lb. for shipment to Great Britain against 75½ millon lb., during the season of 1886.—Yours faithfully, G. M. BARTON, Assistant Secretary.

ANNUAL REPORT IN CINCHONA BARK.

(From *I. A. Rucker & Bencraft's Weekly Price Current.*)

LONDON, January 19th, 1888.

CINCHONA BARK.—It may safely be asserted that the quotations current for bark and quinine during the greater half of the year 1887 were even lower than the very low ones contemplated by the greatest pessimists. If any article, year after year, be overproduced, say only 5 per cent sooner or later it gets into an abject state. In Ceylon barks, for many months, the policy pursued by large interests was as follows, the lower the price the larger the shipments. That such a policy may have been necessary in many instances, it is not for us to deny, that it may have suited individuals, and put money into their pockets, it is not for us to question, but the broad fact remains, about which there can be no dispute, viz., that when the unit fell to 1½d, a considerable proportion of Ceylon shipments were not paying charges, &c., &c. It has been calculated by Mr. Riedel, a Berlin wholesale druggist, that on the assumption that Ceylon barks average 1¼ to 1½ per cent., German quinine can be sold at 1s 3½d, without any profit either to planter or to manufacturer. We do not altogether corroborate this calculation, but the deduction from it is that any bark sold at 2 1-10d per lb. in London had better be burnt or destroyed in the country of production and we imagine that this deduction is to all intents and

purposes not far from the truth. The year 1887 opened with a unit quotation of about 3¾d to 4d. Bark then became a falling article, the lowest point being reached about the 8th of November, when we quoted the unit at 1½d to 1¾d. It then became evident that the price was stopping shipments, and the market rallied. The spirit of the times was in favour of speculation, the great corner in tin and the great advance in copper stirring up the gambling spirit all over Europe and America. Every article was about to be cornered according to some authorities, and naturally an article like quinine, abnormally depressed experienced a heavy advance. The bark sales on the 6th of December went with great spirit our quotation for the unit being 2¾d to 3d, but at the sales a fortnight later, prices were not maintained. The history of the year 1887, as regards bark and quinine can thus roughly be told in a very few sentences. It appears to us that the important feature to be observed is that as far as Ceylon is concerned, 1½d the unit, stops shipments. Turning to market prospects, experience has taught us that as regards Ceylon it is next door to impossible to estimate the shipments of the crop season. When the unit was about 1¾d to 2d, one of our most experienced friends advised us that on that basis he looked for very small harvesting, say 5,000,000 lb. On a basis of 2d to 2½d per unit, more would of course come forward, and as a check on too sanguine views, we always keep by us the Planters' letter in the *Ceylon Observer* affirming that at 9d per unit not a stick of bark would be left standing in Ceylon. As regards South America, at present rates the industry continues practically a dead one, but the rich cultivated Bolivian Calisayas increase, about 7,000 packages having arrived during 1887 against 4,000 in 1886. As regards barks from the Continent of India, arrivals are likely to increase from all the new districts, and we are promised rich Ledgeriana Bark from Wynaad. Java of course is an important factor. During 1887 barks from Java have arrived in London and Holland in some quantity. During 1888 it is estimated that some 20,000 packages will be put on the market in Holland, a considerable proportion being good to rich bark, about three-fourths being for private account. During 1887 about 3,500 packages of private barks have been sold in London alone, and this quantity is certain to be increased during 1888. It appears to us that the present position of the bark market justifies moderately sanguine views; now-a-days it is not wise to look too far a-head, but for the next twelve months the way appears to us to be fairly clear, provided that the information which reaches us be correct, viz., that Ceylon Planters, owing to their improved position, are not likely again to break the bark market by excessive harvesting, a considerable proportion of which would again, if shipped, inevitably prove unremunerative.

LOWCOUNTRY PLANTING REPORT.

DRY WEATHER—COCONUTS—CARBONIC ACID—THE VITALITY OF SEEDS.

1st February 1888.

January has passed away without yielding one drop of rain, or leaving the most minute symptom of a change from the bright hot days and the bright cool nights that have prevailed for 31 days. One week without rain on the uplands, and the grass ceases to grow; another week, and every stalk and blade is as dry as sun and wind can make it. The dry season is always a trying time for the stock on coconut estates, and makes the introduction of silos a case for serious consideration. It is neither pleasant nor profitable to see one's cattle reduced to walking skeletons every year.

The draught has not affected the coconut trees to any serious extent, but we have still a long spell to look forward to, which may or may not, be broken by the outskirts of thunderstorms, which is our sole dependence for the next two months. The crops on the trees are numerically satisfactory, but if we lose 10 per cent in the weight of our copra, as we did last year, it will touch us on the raw. One long-headed and heavy-pursed proprietor at Katukanda is setting up works, that by estimate are to give 6 gallons of water daily to every tree on a 700 acre estate. The result is awaited with deep interest by all the planters in the valley, though hardly any of us combine the necessary qualifications to follow a successful example, such as local facilities, available capital, and enterprizing spirit.

I have been searching in vain for the latest scientific decision as to the source from which growing plants derive their carbonic acid, so that I suppose the old theory holds good, that both carbonic acid and oxygen are solely derived from the atmosphere. I believe that carbonic acid, though always present in the air, is there in different proportions in different seasons and situations, but always sufficient for the wants of growing plants, the supply being kept up by the decomposition of organic bodies, and the restoration of their component elements to the source from which they were derived. Thus, while I admit that so far as I know plants derive all their carbon from the air, I am not prepared to accept the theory that smoke baths frequently administered helps the growth of any plant whatever.

About fifteen years ago, a coconut planter, since deceased, announced the discovery that smoke baths had a more beneficial effect on the growth and bearing of coconut trees than any other thing that could be done for them. I held it to be nonsense: I could not reconcile it to facts established by scientific inquiry, and neither before nor since have I seen any effect on coconut trees that I could not ascribe to far more likely causes than smoke. At the time I indulged in some chaff about manuring the atmosphere, and I heard no more of it till very recently when I found that my old acquaintance had left a school of disciples with earnest faith in the smoke bath. It would be easy to bring the matter to the test of experiment, but its conduct could only be trusted to an impartial party with any chance of convincing the advocates of opposite theories. I admit that I myself would be rather a refractory subject. I would admit nothing on the report of anyone committed to the smoke bath theory, nor would I expect more complaisant treatment from them.

I cleared a piece of jungle last season that could not be less than fifty years old; I got a very good fire, and after the first rains the usual crop of weeds appeared, and on a spot of less than an acre in the centre of the field there came up a number of plants of the pigeon pea, called dal in India. On inquiry I found that a tradition was current in the village, that this spot was sown with dal the last time it was chenaed. It thus appears that the seeds of this plant have retained their vitality in the ground, while jungle trees sprang up and attained a girth of stem from three to four feet. The ideas of the natives are rather loose and indefinite on many matters, and on none more so than the lapse of time, so that I cannot ascertain exactly how long it is since the land was last chenaed, but it was oldish jungle when I bought it twenty-years ago, and I have no doubt that the full half century has passed since it was last cropped.

INDIAN AND CEYLON TEA STATISTICS.

Messrs. Gow, Wilson & Stanton's valuable paper, illustrated by diagrams, issued as their annual report, will be perused with deep interest by all connected directly or indirectly with the tea enterprize. It will be seen that the consumption of tea in Britain has advanced until in 1887 the figures representing the consumption exceeded 183½ millions of pounds. Of this quantity Indian and Ceylon teas, the one dating only half-a-century and the other only about a dozen year back constituted 51 per cent., a percentage representing more than the actual figures imply, owing to the greatly superior strength of the Indian and Ceylon products. The Indian and Ceylon teas are gaining rapidly on China kinds in Britain, but, important as the British market is, it becomes evident from the [illegible] that increased [illegible] is essentially necessary if prices lowered in proportion to our fast increasing production are to be averted. In the nine years since 1879, fair medium Indian pekoe has come down from 1s 8d per lb. to 10d, that is exactly one half, while the simultaneous fall in pekoe souchong has been from 1s 3d to 9d. Economy in production which has enabled planters to bear so great a depreciation in the market value of their produce, must now be approaching its lowest possible limit, so that extended consumption in other countries

as well as Britain must be promoted if the enterprize is to remain fairly profitable. Ceylon tea continues to enjoy a moderate special advantage in regard to comparative price, but when, as at present, the demand is for the cheaper kinds, the difference between the Indian and Ceylon products becomes very small. Of course, a good deal of Indian tea and some of our Ceylon product must be included in the quantity of tea exported from Britain to other countries, and which they consume in addition to what may reach them directly. The chief countries to which tea is exported from Britain are Germany, Canada, the United States, Holland, Russia and Turkey,—Germany taking about 18 millions of pounds. The deliveries of Indian and Ceylon teas for export as well as consumption have now reached nine millions of pounds per mensem, and the quantity exported must be about one million of pounds per month, because we see that the deliveries for home consumption are a little under eight millions of pounds,—about one million of Ceylon to seven of Indian, with the rate, in each case, rapidly advancing. It is satisfactory to learn that the deliveries of British-grown tea increased in one year, 1887, as compared with 1886, no less than 25 per cent. But this was largely due to reduction in price, so that efforts to open up and cultivate new markets for our tea ought not to slacken, but be renewed with fresh energy. While in Britain and some colonies of British origin the consumption of tea has reached 5 lb. per head of the population, in other countries the rate goes down from 1 lb. per head to a few ounces.

It will be seen that America (United States and Canada) has taken 9 million lb. less of tea from China and Japan in 1887 than in the previous years and Canada 2 millions lb. less from England. This cannot mean a falling-off in consumption, but a lessening of stocks held by middlemen and retailers; and if, as is expected, China shows a further drop of 10 millions in her exports next season, there should be ample room for the increase from India and Ceylon. Hopeful signs of increased consumption are afforded by Germany and Turkey, and we are glad to hear that a gentleman now in Colombo shortly returning to the Continent of Europe is making arrangements for a supply of samples of our teas on a large scale with a view to an extended trade more especially in Germany. The Imperial German Consul in Ceylon, and indeed all the Consuls and Consular Agents in Colombo, might do the colony some service and promote the distribution of a really sound article of consumption, by sending to the countries they represent, special reports on our Ceylon tea enterprise and on the product so generally appreciated.

BULLETIN OF THE BOTANICAL DEPARTMENT, JAMAICA.

The number for November of this Periodical contains the first portion of a Short Treatise on Coffee Planting as applicable to Jamaica, by W. A. Sabonadière, formerly of Ceylon, and now of Arntully, Coffee Plantation, Blue Mountain District.

An article on grape culture follows. Jamaica is 10° further from the equator than Ceylon, but in Uva, Dumbara, Matale and other dry parts, of our island, we believe grapes could be successfully cultivated.

So could superior oranges, which, there is a paper in this Bulletin, calculated to prove, can be grown from seedlings true to kind. There is a notice of Sugar Cane Manures.

We quote as follows:—Weight of Bark from Cinchona Trees (Cinchona Officinalis). Enquiries having been made as to the amount of bark that may be expected from trees of various heights, 10 trees were cut down and barked with the following result:—

I.	II.	III.	IV.	V.	VI.	VII.	VIII.	IX.	X.	XI.	XII.
Number of tree.	Height in feet and inches.	Branched at—feet from ground.	Circumference at base in inches.	Circumference at first branch in inches.	Circumference at first branch in inches. The trees, Nos. 1 to 7 are from the Plantation at Newhaven Gap, which was first made in 1868. It is impossible now to ascertain the age of any of these trees, as some are seedlings and some are shoots from coppiced trees. There are probably very few of the original trees left, perhaps No. 7 is one of these. No. 1 may be taken as an example of a tree six years old.

Nos. 8 to 10 are from the Plantation called "Upper Buzza" made in 1879-80. These trees are therefore 7 or 8 years old.

The dry bark in the Table has been taken at one-third the weight of the wet bark. This would give 11 lb. 2 oz. for dry stem bark; the actual weight being 12 lb. Root bark does not lose so much in drying, for instead of one-third (viz. 4 lb.), more than one-half was obtained—1 lb. 12 oz. One-third, on the whole, is a safe estimate, for there is considerable waste in drying on a large scale on account of the constant shifting of the bark from the drying-houses to the barbecue which causes friction and reduces a good deal of it to dust.

It is instructive to take columns II. and IV. together and compare the amount of bark harvested. No. 2 for instance, is much higher than No. 1, but being more slender, gives much less bark. It therefore pays well to attend to thinning. Perhaps the most convenient time for Crown Bark is when the trees are 6 years old. If the plants were put in four feet apart, half the trees should be thinned out, and it will be well to uproot them, for the shoots would interfere with the other trees, and besides the root bark will be more than 50 per cent. of the bark from stem and branches.

The amount of bark per acre may be roughly estimated by taking an average tree and multiplying the weight of bark by the number of trees on an acre. Trees planted 6 feet apart, are 1,210 to the acre; 8 feet apart, 680 to the acre; 10 feet apart, 435 to the acre.

A DISEASE IN COCONUT PALMS.

The following is the Report on a disease which has appeared among the Coconut Palms in the neighbourhood of Bath:—

To the Acting Colonial Secretary.

On my return journey from Bath Gardens I rode up the hills from Bath on 9th September to inspect the coconut walk on a property called Ardsheil, belonging to Mr. George Donaldson, situated at an elevation of about 1,000 ft.

On examination I found that the disease was due to scale insects, and had evidently travelled from the point of its first appearance in the direction of the

prevailing currents of wind. The damage done by the last hurricane was evident, but it is in no way connected with the disease.

The effect of the disease is to cause the lower leaves, and then the upper, to turn brown, and eventually drop off. In time the terminal bud, (the "heart") is also attacked, and as the growth of Palms is confined to this portion of the plant, the whole coconut tree dies.

The scale insects (the females, which constitute the disease) do not fly, but are transferred from one plant to another by various agencies: birds, insects, spiders, dead leaves or twigs, to all of which they may be attached. Wind acts in a secondary way, not being able to detach the scale insects themselves but carrying spiders, &c., to which they adhere. The young larvæ are active in running about, but this method of spreading cannot affect tall palm trees. In the present case the scale insects appear to have been brought from a distance by some such agency as insects or birds, and then to have been spread through the coconut walk by means of the wind.

Mr. Donaldson told me that he had frequently noticed the scale insects on sugar canes in the plains during dry weather, but that they disappear during the rains. He observed that at Ardsheil there had been no want of rain during the present year.

A remedy against scale insects is published in number 3 of the Bulletin, which it is advisable to use when they attack orange trees. The expense of applying the solution is enormously increased in the case of a lofty Palm. I would suggest that owners of coconut palms should carefully watch their trees, and as soon as the disease appears, lop off the leaves affected and burn them.—(signed) W. F.

[The disease seems to be spreading fast, and will probably soon appear in the Liguanea plains, and elsewhere. An effectual remedy is the Kerosene emulsion advised in the last Bulletin, and the only question about its application is the practical one of expense.]

Amongst Plants in Flower or Fruit, we find the following noticed:—

The Champaca (*Michelia Champaca*) is another East Indian tree, 30 feet high which flowers of a rich orange colour, and exquisite perfume. It is sacred to Vishnu, and is planted round the temples. The bitter, aromatic bark is used in Mauritius as a febrifuge. The wood is fragrant, and is useful for cabinet-work, and for house-building. The Champaca is a near relation of the Magnolia.

Colvillea (*C. racemosa*) is a Madagascar tree named after a former Governor of Mauritius, Sir Charles Colville. It is a beautiful tree growing to a height of 40 or 50 feet, with scarlet flowers growing in dense clusters. It is allied to the Flamboyante (*Poinciana regia*), also a Madagascar tree.

Caryota (*C. ——*) is an Indian Palm 50 or 60 feet high. It is so valuable to the natives of India and Ceylon that it is largely cultivated. The inner portion of the stem is soft, and contains large quantities of starch which is made into an excellent sago. The natives make bread of this, and also a kind of thick gruel. During the hot season it yields an abundance of toddy or palm wine, the best trees giving according to Roxburgh, as much as 100 pints in 24 hours. This toddy is used, not only as a drink, but more important still, to make a kind of sugar, called jaggery. The leaves and leaf-stalks afford the *Kittul fibre*, the Indian Gut of the English market, which is very strong, and made into ropes, fishing-nets, lines, brushes, brooms, baskets, &c. It is said to be also useful in the manufacture of paper. The ropes used for capturing and tying wild elephants are made of this fibre.

Another Minor Industry.—The cultivation and preparation of the *Agave Americana*. The following is the opinion of the expert recommending this last easy road to wealth and fortune:—Mr. Stoddart says that according to his long experience in Yucatan, the cultivation of the Agave or Sizal Hemp will give a return of 75 per cent on the capital invested. This is promising to begin with. The "plant" (not the vegetable, but the machinery, etc.) is not expensive and a small capital is necessary. The market for the fibre, when properly prepared, is already established and the demand is almost unlimited. No ploughing or manuring is required for the establishment of the plantation. No drought can destroy the produce, no hurricane can blow the plants down, no animal can injure them, for none will eat them, and they are not subject to the attack of insect or disease. Once established no further planting is required and little or no attention, except a little care in cutting, and this work once begun, there is perpetual work all the year round. Mr. Stoddart says "The plant lasts according to the best authorities for at least 25 years in cutting state." At the most, 3 years are required to develop the newly-planted Agaves, after this period, the more it is cut the more it seems to thrive and the more leaves it throws out. Neglect of cutting, however, will cause it to throw out a centre pod or flower stem, and this determines the death of the plant. The soil never seems to become exhausted, but on the contrary, old, worked lands give the best yield. Here is a chance for the owners of Grand Savannah.—*Dominica Dial.*

Tobacco.—From Messrs. E. Jonas and Brothers' Circular:—The year just at an end has been a very eventful one in the tobacco markets throughout the world. A year ago we ventured to assert that the growers and handlers in the Straits could be trusted to adopt a course which would tend to place the market in a healthier position, and the subsequent course of events has fully justified our confidence in their common sense. As matters stand here now, prices continue to advance in the face of stocks of almost unprecedented magnitude, but we are not able to report that sales have been at all proportionate either to the bulk of the holdings or the needs of our manufacturers. The delay in sampling and the general outcry against the rough and bony character of the new strips have combined to restrict transactions very largely to old tobaccos, and holders will start the year almost entirely with their stocks of the new. For ourselves we are disposed to think more favourably of the last import than do most of our neighbours; we find it on the whole of good length and colour, somewhat drier than usual, and fairly serviceable; it is, however, lacking in body, and this deficiency has helped to make the want of good old style leaf more keenly felt than ever. Everything would seem to indicate that with the turn of the year we shall not only experience an increased demand, but also a corresponding rise in values. The shipments to this side for the next twelve months cannot at best be more than nominal, and as our stocks begin to shrink to something like their normal size buyers must needs become more anxious and less independent than we have known them during the past few years. At the same time we have little doubt that the very remunerative prices being currently paid in the West, together with the probable abolition of the tobacco tax, will prove a strong incentive to farmers everywhere to raise a crop of unexampled size, and will specially tend to largely increase the area planted in barley, thus paving the way to a relapse into the unsatisfactory condition of the past. In Virginia leaf and strips some large sales have taken place at prices which should be fairly remunerative to shippers. Really fine bright leaf and strips meet with a ready sale at rates which we can quote as firm, if not advancing; as usual, the unwieldy stocks of nondescripts are the most depressing feature in the market, and we would strongly urge intending shippers to confine their attention to those grades which are desirable and can be promptly realized. Western leaf occupies a strong position, but the stocks in first hands are not of sufficient importance to interest handlers.—London *Times*, Jan. 21st.

VEGETATION AND MOONLIGHT.

The letter of your Trinidad correspondent, given in *Nature*, vol. xxxvi, p. 586, referring to a committee appointed to determine moon influence, has a practical interest for me. Among the wood-cutters in Cape Colony, both east and west, there is a fixed belief, which no arguments can turn, that to cut timber at, or shortly after, full moon, is to cut it when the sap is up; and when, consequently, it is out of season. The same belief prevails in various parts of Southern India, notably in Travancore. I have always combated the belief, pending time and opportunity to test it, indulging in the provisional hypothesis that the bush-workers' belief may be due to the fact that they can only work by night at or near full moon; and that at night trees should contain more sap than by day, when watery exhalation is active.

It seems possible that in the habitually cloudless nights of certain countries the moon may exert influences not noticeable elsewhere. It is well known in Cape Colony that fish, pork, and other provisions go bad if left exposed to moonlight; though possibly this may be due to the light acting as a guide to insects.

D. E. HUTCHINS,
Conservator of Forests.

Cape Colony, December 8, 1887.

PLANTING AND CULTIVATION OF ARROW-ROOT AT PIMPAMA, QUEENSLAND.

The ground having been prepared by ploughing, harrowing, &c., and if more than the second successive crop of arrowroot, well manured, is marked by ploughing parallel and transverse furrows about four inches deep, the former 6 ft. apart and latter 3 ft. to 5 ft. according to fertility, &c., of soil.

The plants which consist of the choicest bulbs (of the later growth) of the previous season's crop—generally picked out and placed in separate heaps, and covered with rubbish, during the preparation of the bulbs for the mill—are now carted to the field and tipped in heaps at convenient distances apart; men take them in large canvas aprons and place nicely one large bulb at each intersection; if the ground be moist and in good order the covering is effected by throwing up a light furrow on each side of the parallel marking; if the ground be dry and lumpy, the covering should be done with a hoe, putting only fine soil on and firming slightly with the foot to ensure "striking."

The subsequent cultivation resembles that of Maize, differing mainly in that arrowroot needs tilling from soon after "planting;" the best months for which, here, are August and September until March.

In planting newly 'burned' scrub land, holes are made with a hoe, plants placed in, and the loose soil replaced and firmed slightly with the foot. Newly "burned" scrub land, or any good ground never having had the crop on before, gives the best yield of arrowroot.—*Chemist and Druggist.*

REPORT ON THE CAWNPORE EXPERIMENTAL STATION FOR THE RABI SEASON OF 1886-87.

Colonel Pitcher, in forwarding this report, states:—There is little of novelty to call for comment. Experiments with manures, organic and inorganic, with green soiling, deep ploughing, and irrigation were continued with but little variation on the old lines, the results of which are elaborately tabulated. Varying with the season, as the latter may be wet or dry, some manures show better in one season than others. It would only be after a long and continuous series, much longer than are yet available, that authoritative duductions could be drawn as to the precise gain or loss resulting from any particular treatment. For the past season the general outturn was very disappointing at least one-third less than we had reason to expect. The adverse causes were heavy hail, at seed time, and, most severe frost, at the time of flowering. On the other hand the crops were free to an unusual extent from fungoid growths. Experiments were made with English wheat seed sent out through the India office. The condition of the seed on arrival was bad; but still there was enough with which to show what we have shown before, viz., that we have better varieties, or rather, perhaps, local varieties that suit us well, and have even a European reputation. Local varieties were as usual subjected to comparative trial, and one now introduced for the first time on the station and known as Baxar appears likely to compete successfully with the best of our own Provincial varieties. Of all experimental work on the station, there is none of greater value than that touching the selection of seed and trial of varieties. Ensilage continues to be managed with success. One grass silo kept for the purpose was opened after three years; rain had evidently penetrated and the contents were useless, but it was hardly to be expected that with grass the result would be otherwise, as it is the material most difficult of all to manage. Usar grass from one of the usar reserves gave good silage after being stored for the ordinary time. The sale of implements appears on the whole to have been less brisk than formerly, exceptions being small English grain-crushers and chaff-cutters, for which there is increasing demand.

AMERICAN VINES IN FRANCE.

The excitement about the replanting of the ruined French vineyards has recently entered on an acute stage. Five years ago the dealers in American vine plants, seeds, and cuttings, had it all their own way; and the more enterprising of the vineyard proprietors were investing large sums of money in varieties of *Vitis Estivalis* and *V. Riparia*. One had no business in an agricultural society's meeting unless he could talk glibly of the Black Jacquez of Mississippi and Missouri, and knew all its seventeen other names, besides its supposed ancestor the Herbemont. Then there was Norton's Virginia from the Potomac, the Cynthiana or Red River, the Cunningham, the Clinton, the Solonis, the York Madeira, and the Taylor and its hybirds. But since then millions of Clintons and Taylors have been uprooted for their hollow failure in resistance to the phylloxera; while other supposed varieties of the same family, *V. Riparia*, are following in their wake, for they will not take grafts from the French vines; and 15,000 of these stocks have all perished together in one vineyard alone near Montpellier. The trust is that practical men are now waking up to the fact—long well known to botanists—that the hybirdizations of vines in their wild American habitats have been infinite, and that thus it is not easy to get a phylloxera-proof *Estivalis* or *Riparia* uncrossed by the worthless *V. Labrusca*. But the loss of years and capital is hard to bear; and hence there is just now a considerable amount of stir, and also of that mode of motion which we know as heat. I myself have cautiously experimented with American vines in south-western France for some years, but can as yet give very few positive recommendations. More time is required. So far, the Chasselas de Fontainebleau grafted on American Solonis stocks gives a good result; but the growth of the wood is slow. The Herbemonts on their own roots are unequal; some plants growing ahead fast enough, while others lag behind most discouragingly. One year their large bunches of small black grapes are delicious, the next nothing but verjuice is produced. The Elvira and the Noah, said to be American seedlings from the Taylor, produce a small golden-green luscious muscat grape, which has the fatal habit of dropping from its small bunches as it ripens. Useless for wine in France, it gives a fair brandy. The Cunningham, a southern *Estivalis*, seems to prefer an early grave.

Recent French vine congresses seem to have hammered out the opinion that it is no longer of any use to sow vine-seeds imported from America. The Yankees are on the opposite tack, of course, and allege that all their hybridizations of American by French vines are failures. The Viticultural Society

of Lyons points to a "king of hybirds," the Saint-Sauveur, obtained from seeds of the American Jacquez (*Estivalis*) gathered in France, which is said to resist both mildew and the phylloxera and to give an excellent wine. The Vala (at first named La Tourate) another French seedling from the American Clinton (*Riparia*), is also highly spoken of as a stock on which to graft the European vines; and there is a third hybird between the Spanish grape Pedro Ximenes—the wine so called was popular in England 300 years ago as Peter-see-me—and *V. Rupestris*, a common wild thing known in America as the bush-grape. Great things are prophesied for this novelty. These three varieties are, in reality, all that are left standing by the discussions in the congresses. Meanwhile the stern fact stares them in the face, that the French vintage of last year produced little more than two-thirds of the average of the last ten bad years, being a falling-off from 1885 of 750,000 gallons.—*St. James's Budget.*

REPORT ON THE ADMINISTRATION OF COORG FOR THE YEAR 1886-87.

BY GENERAL SIR HARRY PRENDERGAST, K. C. B., V. C., R. E.,
Offg. Chief Commissioner.

COFFEE.—The export of coffee amounted to 3,663 tons. The price of coffee has risen from R24 per cwt to R45 and that of cardamoms from R80 to R180 per cwt. The total area assessed for coffee was 80,570 acres, of which about 15,000 acres, situated on the steep ghat slopes and other uncongenial localities, are not under cultivation.

MINES AND QUARRIES.—There is nothing of importance recorded under this head. Recent researches indicate traces of gold and silver in several localities, but no practical result can be expected until the auriferous area has been surveyed by a trained mineralogist.

AGRICULTURE.—The extent of land under cultivation with rice and other food grains shows a steady increase, being 75,172 acres as compared with 74,905 acres in the previous year. There is but little arable land in the province which has not been occupied. The exceptions are in the Kiggatnad Taluk where the population in the southern portion is sparse, and in the north-east district outside the "barries" which mark Coorg proper, where the land has been thrown out of cultivation from failure of the old irrigation works which have not been restored. The area of land cultivated with coffee exhibits the considerable increase of 8236·38 acres; the figures for the year under report being 80,570·38 acres as compared with 72,334 acres in 1885-86. This increase arises largely from the inclusion in the revenue accounts for the first time of the *banes* which have been roughly measured and assessed at coffee rates.

Inclusive of the *bane* cultivation now included, the area of land now held by Europeans and Natives respectively is as follows:—

	Acres.
Europeans	39,661·26
Natives	40,909·12
	80,570·38

The return for 1885-86 gives the following:—

	Acres.
Europeans	36,315
Natives	36,019
	72,334

making the net increase in area 8,236·38 acres. Out of the total of 80,570 acres in occupation, it is computed that 52,365 acres comprise the area of plants in bearing, but these figures are subject to some modification, for they include several estates on the Sampaji Ghats and Forests in which the plants after reaching maturity have from various causes become unproductive, and in consequence of which the assessment has been reduced for a period of 7 to 10 years by two-thirds or half according to circumstances.

The actual area in bearing may be taken approximately at 36,700 acres, and computing the outturn of coffee at 3,663 tons, the yield per acre will be found to be very nearly 2 cwts. per acre.

EXPERIMENTAL CULTIVATION.—*Palua paddy.*—The endeavours which have been made by a planter for several years to naturalize this grain have failed and been finally abandoned. The quality of the rice was considered good, but no sale could be found for it and the yield of straw was short and scant.—Favourable reports have been received regarding the plants of *Erythroxylon Coca*, *St. Michael Orange* and *Jamaica Lemon*, which have been imported and distributed.

LABOR.—It was mentioned in last year's report that owing to the economy introduced in the working of estates, rendered necessary by the low price of coffee then prevailing, the demand for estate labor had been reduced, and this had affected the regular supply. This state of things has continued and many planters have suffered from the scanty importation of labor from the Mysore country, whence the supply was formerly abundant. This has been partly compensated by an increased supply from Malabar and South Canara, and on the whole no serious inconvenience has been felt during the latter part of the year. No change has taken place in the rates of wages.

WEATHER AND CROPS.—The rainfall registered during the year is as follows:—

	Inches.	Cents.
At Mercara	116	68
„ Somvarpet	84	77
„ Anandapur (South Coorg)	69	96
„ Fraserpet	36	29
„ On the Western Ghats (Kadamakal)	236·02	...

The rainfall is somewhat below the average at Mercara where the mean for 10 years is 129 inches. but generally the average has been fairly maintained. The rainfall was very unequal within the province. At Mercara the rain gauged during the months of March and April 1886 was 81 cents, while in South Coorg the rainfall in the same period amounted to 3·89 inches. The unusually heavy rainfall of 10·40 in the month of May coming upon a late blossom, affected prejudicially a large number of coffee estates, especially in North Coorg. Indeed, throughout Coorg, the actual outturn was generally much below the estimate.

HORTICULTURE.—No new land has been opened for cinchona cultivation during the year. The system of growing the plants between the coffee trees is being abandoned in South Coorg. According to Returns furnished by the Planters the area under cultivation on 31st March 1887 was 1,707¾ acres as compared with 1,800 acres in the previous year, and the number of plants of various kinds 13,66,237. The outturn of bark during the year was 49,744 lb. The price ordinarily realized was at the rate of 6d. per lb., but as much as 10d. per lb. has been realized.

TRADE.—*Exports.*—The exports of Coorg produce are limited to the following articles, viz., coffee, cardamoms, grain, hides, timber, fruit and wax. *Coffee Exports.*—The quantity of coffee exported in 1886-87 as taken from the toll-gate returns amounted to 3,631 tons or 72,620 cwts., valued at R32,67,900, average selling price locally being R45 per cwt; while the rate in the previous year was R 24 per cwt. This remarkable rebound after several years of low prices caused the greatest activity in the market, but coming at a season when the outturn was as a whole unusually small, the planters did not benefit as they might have done otherwise. On the other hand, the commonest native coffee, as well as the most inferior kinds of plantation coffee, were in great demand, being purchased chiefly by French and German firms on the west coast, and obtained frequently as high prices as the superior kinds. Most of the coffee from Coorg, estimated at three-fourths of the whole, was despatched to the seaports on the west coast, the remainder being sent to the curing establishments at Hunsur and Bangalore to the eastward. *Cardamoms.*—The quantity of cardamoms exported is returned at 940 cwts, valued at R1,11,[illegible]. The crop was a short one, being, it is estimated, about one-fourth to half of the usual outturn. The price which in the early part of the year

was as low as R80 per cwt. rose rapidly and averaged R180 per cwt. The spice is largely exported to the west coast, whence much of it is shipped to Bombay. The other products under this head call for no remark.

TABASHEER.

From an elaborate article by Sir D. Brandis in the *Indian Forester* on a curious secretion in the Bamboo, we extract the first portion, as follows:—

I wish, through the medium of the *Indian Forester*, to draw attention of my friends and former colleagues, as well as of younger Forest officers in India generally, to this remarkable substance, because the study of its formation may possibly lead to important results concerning the life history of the large bamboos, in the hollow joints of which it is deposited. Its great, and I may add unmerited, fame as a medicine, this substance has received mainly through the writings of the old Arab physicians, particularly of *Razi* + 923, and of *Ibn Sina* (better known as *Avicenna*) + 1,037. But the name is of Sanskrit origin *tvakshira, tavakkshira*, meaning milk in the skin.

The oldest detailed account of this substance known to me is contained in a letter from Dr. Patrick Russell to Sir Joseph Banks, dated Vizagapatam, November 26th, 1788, printed in Vol. 80 (1790) of the Philosophical Transactions of London. He notices the erroneous account given by Arab writers of its origin through the burning of bamboo stems, especially of such as have suffered from fire kindled by the friction of the reeds one against the other, an accident, he adds, supposed to happen frequently in the dry season among the hills, and he mentions that in the Latin versions of Razi and Avicenna, tabasheer is constantly but erroneously rendered by *spodium* (ashes). He adds, that the mountaineers, referring probably to those of the Vizagapatam district, say, they never look for tabasheer in the half burnt fragments of the bamboo. Here I may mention at the outset, that the erroneous notion, that tabasheer is obtained from the ashes of bamboos, is still current in books in Europe. Tabasheer was also formerly confused with sugar, this error, however, was cleared up by Rumphius (Herbarium Amboinense, IV., 11). He says that the *sugar-cane* has been confused with the bamboo and *sugar* with tabaxir, also called Sachar Mamboe. Rumphius wrote his large and excellent work about 1690, and it was published in 1750. Colonel Yule, in his delightful book "A Glossary of Anglo-Indian words" (1886) enters fully into this interesting question, and shows the absurdity of the idea, which has long been entertained, that the *saccharon* of Greek and Roman writers was not sugar but the siliceous concretion sometimes deposited in bamboos (pages 654 and 675).

The account of Dr. Russell's own researches forms the most interesting portion of the papers. After mentioning that tabasheer is only found in the joints of the female bamboo (in this case probably *Bambusa arundinacea)*, he explains that on shaking the bamboo, a rattling noise indicates the existence of tabasheer in large pieces, and that these are bluish-white, like fragments of shells, but softer in substance. In other cases there is only a rough friable white or cinereous powdery substance adhering to the inner wall of the joint.

In April he examined a bamboo of sixty joints received from Vellore (probably the place on the Palar river west of Madras is meant). On splitting it, no vestige was found in two joints, these were discolored within. The whole quantity collected amounted to 27 grains, and the largest quantity was obtained from the two middle joints. A small portion, about four grains, consisted of bluish-white solid pieces, but soft, the rest was cinereous and friable.

In July, 37 bamboos were split out of a large quantity of green bamboos, each containing 5-6 joints, which had been brought from the hills, 50 miles distant from Vizagapatam. In nine of these no vestige of tabasheer was found, the remaining 28 yielded small quantities, in the aggregate not much exceeding 2 drams (54 10-16th grains). The substance was never found in more than three joints of the same bamboo and the empty joints were sometimes contiguous, sometimes interrupted. The white smoother and harder particles adhered to the septum and to the sides at the ends, never to the middle. Instead of being chiefly found at the lower extremity of the joint, as might be expected from the sap settling there, they were found adhering indifferently to either extremity, and sometimes to both, forming a smooth lining, somewhat resembling polished stucco, generally cracked in several places, which could readily be detached with a blunt knife. In some joints the tabasheer was thus collected at one or both extremities only, and in such no rattling was perceived, but generally, while some adhered to the extremities of the joint on the inside, other detached pieces were intermixed with the coarser loose particles in the cavity.

Tabasheer has been repeatedly analysed. In one point all analyses agree, that it chiefly consists of silica, the proportion varying between 70 and 90 per cent, with a small quantity of moisture and organic matter. The other principal substances are lime and potash, but their proportions seem to vary. (See Turner's Analysis of Tabasheer, Edinburgh Journal of Science, XVI., 335, and T. Thomson, quoted on page 257 of the Pharmacopœia of India.) The silica, lime and potash were doubtless originally held in solution in the sap, which is taken up by the roots from the ground. The sap which fills the cells of the growing bamboo-shoot, holds these inorganic substances in solution, together with sugar, gum and other organic substances which have been elaborated by the action of the leaves. As the shoot grows older, cavities are formed in the joints and in these cavities some of the sap collects from the surrounding tissues. The existence of this watery fluid in the hollow joints of the bamboo is well known to all who have spent some time in the bamboo forests of India and other tropical countries.

There is little doubt, that tabasheer is the residue of this fluid, but it is not clear how it is formed. In any case, however, the fluid in the hollow joints is intimataly connected with tabasheer, this seems also to have been Dr. Russell's view of the process, and accordingly he paid attention to fluid found in the joints of the bamboo. The existence of such fluid, he observes, may be known by the sound when the joint is shaken. He never found fluid in more than two joints of one stem, and never in large quantities, 1½ ounces being the largest amount obtained from one stem. He adds that the fluid always had a slightly saline and astringent taste, that it was always transparent but varied in color and consistency. Some of a darker color had the consistency of honey, some on the other hand was perfectly colorless but nearly dry. Both kinds, he says, had the sharp salt taste of fresh tabasheer.

Dr. P. Russell also mentions, that in the bazars of Hyderabad two sorts of tabasheer are sold, the best at one rupee a dram, the inferior kind at half that price, the latter consisting chiefly of burnt teeth and bones. A Parsee informed him, that tabasheer was produced in great quantities in Sylhet, and sold there at R1 to 1-8 per pound, also that it formed a considerable article of trade from Bengal to Persia and Arabia.

A later volume of the Philosophical Transactions (for 1819), contains an important article by Sir D. Brewster on the very remarkable optical and physical properties of tabasheer. In that article Brewster mentions also, that Humboldt discoversd tabasheer in the bamboos which grow to the west of the *Pinchincha* in South America.

THE DRY CYCLE: ASSAM AFFECTED.—A correspondent writes from Debrooghur:—I have to record the driest season within the memory of the oldest inhabitant. On 23rd October there fell ·60 rain and then none till 19th instant, when we got ·29 only. Pruning generally is rather late this year. Extensions are on a smaller scale this season owing to the failure of the seed crop. Transplanting has been very unsatisfactory, but for those making bricks the weather has been everything that could be wished.—*Indian Planters' Gazette*, Jan. 31st

REMINISCENCES OF A VISIT TO THE HILLS OF CEYLON.

A VISIT TO MARIAWATTE—THE CHINESE INVASION OF CEYLON—SINHALESE LABOR ON TEA ESTATES—THE GAMPOLA VALLEY—THE SECRET OF THE HIGH YIELD OF MARIAWATTE—TIMBER RESERVES.

COLOMBO, Feb. 15th.

As I had not visited the model tea estate of Mariawatte since I saw the foundations of the big store being laid, I wrote to Mr. Jamieson that, if there was no objection, I would call *en route* to Kandy and Colombo. I was most cordially received, and curiously enough this visit was the occasion of my first ride in a jinriksha, a very nice specimen of which the Company have provided for the use of the Superintendent when visiting Gampola. Amongst the other advantages of Mariawatte not the least is its position on each side of a Government cart-road which winds for about 3½ miles through this long-stretching property, now, with all the additions recently made to the ancient royal lands of Sinnapitiya and Weyangawatte, aggregating not much short of 1,000 acres. The use of a vehicle of Chinese origin* in this classic valley might be mentioned as a very curious coincidence, if we could feel certain that Tennent was correct in identifying Gampola as the scene of a battle between the Chinese and the Sinhalese in which the latter were signally defeated, their King being carried away captive by the victors. The battle was, I believe, a historical event, although it is either not mentioned or slurred over in the Sinhalese records; but the late Maha Mudaliyar Louis De Zoysa showed that Tennent was misled as to the locality by the similarity of name of the real scene of the contest on the sea coast. But it needs no tradition of battle between the invading forces of Cathay and Sinhalese warriors defending their country and monarch against odds in numbers or military skill to impart interest to this, perhaps the most beautiful, certainly the most fully cultivated, of the upland valleys through which the Mahaweliganga flows on its course to the eastern shores of the island near Trincomalee, after almost encircling the mountain capital, Maha Nuwara, *en route*. When I said the most fully cultivated, I referred to the grand expanse of rice cultivation in the Gampola valley, much of which is being reaped a month at least in advance of the seasonal period in consequence of the intense and long-continued drought. The crop, I am happy to believe, is good, and I was much interested and pleased to learn from Mr. Jamieson, how great the benefits bestowed on the Kandyan small farmers and peasantry had been by another and very different culture, of which the dynasty and people of *Sri Ganga-pura*, "the stately [or sacred] city by the river" of the fourteenth century, when Ibu Batuta visited the court of "the estuary of rubies," little dreamed. In the intervals of cultivating and reaping the produce of their own lands, the natives seek and find ready and remunerative employment on the "Maha-te-watta," and Mr. Jamieson states, that, as a result of thus earning money, which is paid to them day by day, the people have greatly improved in physique and comfort of surroundings. Similar results are accruing over wide and widely separated areas in the lowcountry of Ceylon as well as in the hillcountry, so that directly, as well in so many ways indirectly, European enterprise and capital are operating beneficially on "native interests" in Ceylon, a more than sufficient answer to the narrow-minded cavillers at railway extension as if the benefits would be confined to Europeans. I have no hesitation myself in contending that it is the natives who have and who will chiefly benefit by every extension of this the most facile means of communication. The valley of Gampola looks bright and beautiful when viewed from the comparatively high ground on which the railway runs, but to get a full idea of the rich rice fields, the green tea plantations, the noble river lined by graceful bamboos, the town and railway station and the metalled highways and iron road, all framed in by hills rising to mountains, the lover of scenery ought to look down on the royal valley of the great river from the summit of Hantane Peak, or from a point of vantage on the remarkable rocky ridges which run from behind Kandy away into Deltota, Nilambe, and Hewaheta. Even Indian planters who have seen the finest tea which grows in the fat alluvials of Brahmaputra or the richest soil of the Himalayas deposited for ages over the Terai are surprised that a spot in the valley of Gampola should produce such grand bushes and such results in annually harvested leaf. But more intense is the surprise of those who, like the writer, have seen coffee in this, perhaps, the first scene of its regular and extensive culture, in Ceylon pass from decadence into ruin, apparently from the exhaustion of fertile matter in the soil. Over the whole property as now extended, there are, of course, varieties of soil, but the celebrated 100 acres at the entrance from Gampola possess a rich [rich for tea] soil, free and uniform in quality down to a depth of 7 feet. To this soil is regularly applied,—portions being operated on in alternate years,—manure collected from the neighbouring town, a great heap of which I saw collected and carefully protected with a good covering of earth until the convenient season for its application came round. The altitude of Gampola is under 1,600 feet, and I do not suppose that the highest portion of the gently undulating tea estate exceeds 2,000 feet above sea level. The height of Gampola railway station being 1,573, the 100 acre field can be nowhere much above 1,600. Here, therefore, we have all the conditions favourable to exceptional yield: good soil, abundance of manure, a good "lay of land," a hot, moist forcing climate, and a good jât of tea. Accordingly, year by year, the original 100 acres have continued to yield crops exceeding 1,000 lb. of made tea per acre (equivalent to 4,000 lb. of green leaf), until figures for the whole have been obtained in excess of 1,100 lb., a considerable portion giving over 1,200 lb. per acre! We are not aware that anything better than this stands on record in tea cultivation? Of course, here, as elsewhere in the island, although we have no marked winter, the flush is, in certain seasons and states of the weather, specially abundant. There have been pluckings equal to 50 and 100 lb. per [illegible] and I think I understood Mr. Jamieson to state that on one occasion, a 5-acre piece, the plucking of which had been from some circumstances delayed, actually gave at the rate of 200 lb. per acre in one day. Allowing for the fact that a proportion of the leaf was hard and not to be [illegible] gathering is this case be [illegible] I had previously heard [illegible] mention described as an exceptional [illegible] appearance, as a whole, of this [illegible] reminded me of the note which I made, when in the light of a bright morning in Java, I looked

* Or, rather, Japanese: though, indeed, I believe, the vehicle was the invention of a European missionary in Japan.

over a similar undulating expanse at a similar elevation at Sinagar near Soekaboemi in the western portion of the great Dutch colony: "a sea of verdure, broken into gentle waves." Sinagar had and still has advantages of soil, manure and climate, probably equivalent to those which have told so much in favour of Mariawatte. But the jât of tea cultivated at Sinagar in 1881 was China (Indian tea being only in course of introduction), and a very bad attack of *helopeltis* had compelled Mr. Kerkhoven to resort to severe pruning. The tea bushes, therefore, on the Java estate, could not for a moment be compared for size and luxuriance with the grand masses of rich vegetation I saw on Monday last at Mariawatte. Some of the bushes were still yielding well, although 18 months and in one case nearly 2 years had elapsed since they were pruned, experiments being tried as to the best system of plucking and pruning. While the big bushes on Mariawatte have sufficed in size, foliage and breadth of plucking surface to satisfy the most exigent of Indian planters, we did not fail to notice that with few exceptions they were true to the Ceylon many-stemmed habit of growth. Thick and large as the mature trees were, we noticed that "supplies" were doing well amongst them. These and the bushes in recently planted fields on this estate were, we understood, allowed to grow at their own sweet will without even "topping" until they attained the age of two years. It seems likely that this system, though sacrificing, especially at this elevation, some early gatherings of tea, will produce permanently stronger and better bearing bushes. The importance of the question of timber and fuel reserves in connection with tea estates may be realized from the fact that out of the 900 acres now possessed by the Company in the vale of Gampola, no less a proportion than 200 is to be devoted to the growth of trees. For fuel mainly I should say, because on Mariawatte timber for the flooring of the factory and sheets of lead-coated steel for the manufacture of tea boxes have been, and, in the latter case at least, continue to be imported. But my notice of the grandly luxuriant tea-fields of Mariawatte has extended to a length so much greater than I anticipated, that I must reserve the noble factory and splendid machinery for future treatment.

THE MARIAWATTE FACTORY—IMPORTED TIMBER &C.—ANDREW'S TEA BOXES—METAL *vs.* WOOD—JACKSON'S VICTORIA DRIER—THE VENETIAN AND THE SIROCCO—SPARE PARTS—BROWN'S DESICCATOR—MR. JOHN BROWN—WATER WHEELS AND TURBINES—GOW'S WITHERER—VISITORS TO MARIAWATTE.

In my former notice of Mariawatte, I mentioned that the deal flooring of the withering room and also metal sheets for tea boxes were imported. So, I might add, were all the materials of the factory except the brick walls at the ends. It is most difficult in Ceylon to season timber properly, and the warping of unseasoned or imperfectly seasoned timber in buildings is a source of much annoyance, expense, and even danger. It was a knowledge of these facts, no doubt, which induced the proprietors of Mariawatte to get the flooring as well as the ironwork of their factory (200 feet by 40*) from Europe. The deals have been an entire success, giving out no odour of turpentine and never having shrunk sufficiently to allow of a tea leaf falling between two of them. The iron supports of the withering floor and the galvanized iron roof seem equally satisfactory, combining as they do the maximum of strength with the minimum of lateral space. But the chief interest of my visit to the factory was connected with the metal sheets for Andrews' tea boxes and the simple but effective machines by which they are cut, bent and bound together in the shape of chests or half chests, no solder being employed and the only additions to the metal being screw nails to secure the top piece and a slab of wood under that piece. Paper is finally put over the screw nails to prevent their being tampered with, a very necessary precaution, it seems. My previous acquaintance having been with steel boxes lined inside with paper, I was much interested to find that means have been discovered to dispense with any internal lining, except the piece of timber beneath the lid. The steel plates are dipped in a bath of lead, such as, in the form of sheets, is used for lining wooden tea boxes, and the plates being thus coated, of course the trouble and expense of first making a box and then manufacturing a sheet lead lining for it and finally hooping the box are saved. The result seems to be that the iron boxes, which are said to be perfectly water- and air-proof, are, it is added, as economical as wooden boxes. They must certainly be of more value to purchasers on the other side. What the result of the competition between metal tea boxes and wooden ones, the latter locally manufactured or imported from Japan, may be, remains to be seen. I may, however, mention that an American missionary, now in Ceylon on his way home from long service in Japan, was greatly interested to learn that the tea planters of India and Ceylon were largely supplied with tea boxes, sawn from Japan timber, and prepared for export in shooks by American machinery. The missionary first heard from us of this enterprize by his countrymen, and we were interested to learn from him that very considerable attention is paid to forest conservancy by the governing authorities in Japan. It was a pleasant sensation to pass from the hot outside atmosphere into the extensive, clean and cool space formed by the lower floor of the factory. As we had seen all the machines, or similar ones, at work previously, it was no loss to us but the reverse that Monday, the day of our visit was a comparatively leisure day at Mariawatte, so that the genial and courteous superintendent was able to devote several hours to showing us and explaining what was to be seen outside, and in the factory. Jackson's Excelsior Rollers being familiar acquaintances, as were also the Siroccos, which are kept as reserves in the factory, our chief attention was directed to Jackson's grand Victoria Drier, which automatically converts rolled and fermented (oxygenated) leaves into marketable tea, the moist leaf being delivered from the fermenting boxes at the top of the machine, carried down over a series of metal webs and delivered below in a dried state. Mr. Jamieson was enthusiastic as to the excellence and the capacity of this machine, which has appliances for regulating the speed with which the leaf is passed down the series of webs and also the temperature to which it is exposed; while the rapidity with which a large quantity of tea is finally fired preparatory to packing (what the Indian planters call "pucka battying") was the subject of special approval. It is only large "concerns" like that of Mariawatte, which can afford one of these magnificent and necessarily costly machines. Mr. Jamieson understood that the cost as finally erected was R7,000, but was not surprised at the figure, when, in addition to the vast bulk above the floor

* These, I think, were the dimensions stated for the withering loft. The lower story may be wider.

and open to view, he took account of the immense amount of metal embedded in the shape of multitubular heating appliances, &c. The Victoria Drier seems certainly a triumph of ingeniously applied mechanism of which Mr. Jackson may well be proud, and which is most valuable to those who require and can afford to purchase and use such a machine. Apart from cheapness, the merit of the Sirocco Driers consists in their simplicity. But my experience leads me to press the necessity of having spare portions of all machines available, from simplest Sirocco to most complicated Victoria. This gigantic machine requires motive power for all its operations, while the similar but smaller machine, the Venetian (on the same principle, except that the webs are reversed by means of handles worked by coolies), requires only to have the fan at the top, which draws off the moist air, moved by water or steam. Still accidents will occur, and the Venetian in which I am specially interested managed to get one of its pipes burst recently, and a substitute had to be purposely cast. The agents, we submit, would do well to keep reserves of pipes &c. in stock, and a few in factories would be useful. In the case of the Venetian and we suppose in that of the Victoria, the bursting of a pipe does not disable the machine. From some other cause, however, the Venetian referred to broke down recently, and help in drying tea being sought from a neighbour, I hear most favourable accounts of the performances of a Brown's Desiccator which was brought into requisition for the purpose. [Apropos of the Desiccator, I may say that my enjoyment of the railway trip between Nawalapitiya and Talawakele a week ago was greatly enhanced by the companionship of and conversation with the inventor of that and other useful mechanical or engineering appliances, not the least of which are the aerial tramways which ply on the sides of Namunakulakanda. Of course there was a tendency to "reason rightly from wrong premises" if mention of a 2½ feet narrow gauge railway occurred, or, if the position was taken up that Badulla was "the hub of the universe," but on all other questions, moral as well as material, it was a real treat to listen to the views, sentiments and reflections of a shrewd, well-informed, good man. Alas! he and I have grown a good deal older since we met at Rajawella at the great turbine worked pumping machinery which he erected for poor Tytler, on which occasion he told me of the theft of an anvil weighing a couple of cwt. by the light-fingered thieves of Dumbara. I was glad to find him and Mr. Rutherford strongly in favour of my position that tandem water wheels will give double the power of one, proof of which Mr. Souter shows in Kotmale.* As to the relative merits of water-wheels and turbines, however, the two engineering authorities are not agreed. My travelling companion said, "Before you go in for a turbine, go and see the 30 feet wheel I have erected on Darawella." I could not go, but I should like to hear about it. Mariawatte has no "water privileges," but a 12 horse power steam engine does good work, the Burgher in charge making himself generally useful for mechanical jobs in the store. Next to the performances of the Victoria Drier, I was interested in those of Gow's Witherer, now that it has been supplied with a better heating stove. Mr. Jamieson spoke well of it as a helpful machine to finish off partially withered leaf, but he did not seem to expect that its use would preclude the necessity for further withering space, as the yield of tea increased, than was afforded by the loft of the factory, filled though it was with withering webs of jute hessian now so largely used in Ceylon in lieu of the gunny cloth and bags of coffee times.* Our impression was that the great (in length and width) factory can bear and if so must soon have added to it, an additional story for withering purposes, but that is a question for the able managing proprietor to decide. What we feel confident in our own ability to decide is that Mariawatte Tea Estate, Factory and Machinery in the valley of Gampola, Ceylon, are well worth seeing. This opinion seems to be very widely held, to judge from the names of many men from many lands inserted in the visitors' book. There is an inscription up (very necessary we can believe) requesting that visitors will not unduly engross the busy superintendent's time. Happily we accidentally hit on the very day when time could best be spared, and attention was ungrudgingly given. If we, taking none but mental notes, have failed to mention any details of importance, or stated others imperfectly, it is our fault and not that of our genial and hospitable guide over the rich tea fields and through the extensive and well appointed Factory of Mariawatte.

* I heard of several other cases,

* It is probable we shall soon hear of the withering difficulty being largely obviated by the introduction into the ground floors of factories of the steam pipes by which conservatories are warmed in Europe. A good authority when he heard from us of the designs expressed a strong opinion in its favour, as the pipe would give out not furnace heated air but warm moist air.

PLANTING PRODUCTS IN CEYLON:

COFFEE; TEA; CINCHONA; CACAO; CARDAMONS.
(*From the Report of the Planters' Association of Ceylon, held Feb.* 17, 1888.)

COFFEE.—During the past year the most remarkable feature in connection with this product has been the great rise in its market value, a rise that has undoubtedly influenced many in their reluctance to reduce the area under coffee. The favourable blossoming season resulted in remunerative crops being gathered on many Estates, particularly in the Uva Province, and portions of Dimbula and Dikoya. Green Bug and Leaf Disease continue to prejudically affect much of the remaining coffee, though the effects of the latter have not been so manifest in some parts of Uva. The Exports for 1887 were 179,490 cwt. against 179,210 cwt. in 1886.

TEA.—The progress made in this cultivation has been steady, and the increased export eminently satisfactory considering that the season again has not been particularly favourable in several of the Planting Districts. In the new Tea Districts of the Kelani Valley and Kalutara more estates have been opened and further fields added to existing estates. Notwithstanding however the marked decrease in the export of China tea to England, a regretable fall in the average price obtained for Ceylon teas has taken place. Still the prices that have ruled are as compared to those of Indian teas satisfactory, and it is hoped that the continued efforts of your Association to push Ceylon Tea will result in the maintenance of remunerative rates. The effect of the continued careful attention to manufacture with the aid of the many improvements in machinery should undoubtedly keep the quality of Ceylon tea at a high standard. The Exports for 1887 were 13,834,057 lb. against 7,849,888 lb. in 1886.

CINCHONA.—As anticipated by your Committee last year the large export of Bark has not been maintained, and it is unlikely unless there should be a very substantial rise in price to be ever approached in the future. The number of trees now growing in Ceylon can be but a fraction of those calculated on a few years ago. The Exports for 1887 were 13,113,037 lb. against 14,675,663 lb. in 1886.

CACAO.—Your Committee notes with satisfaction the increase of Cacao exports. "Helopeltis" is less troublesome than it has been for some past seasons, but the

dry weather of 1887 will probably tell unfavourably on the outturn of 1888. The area under Cacao has not increased. In fact some land planted with Cacoa and found unsuitable has been planted with other products. The exports for 1887 were 17,460 cwts. against 13,056 cwts. in 1886.

CARDAMONS.—The crop of 1887 has been an ample one, and the export has increased; but during the coming year, notwithstanding a larger acreage in bearing, it is unlikely that the same quantity will be again reached. The Exports for 1887 were 384,015 lb. and 55 packages, against 238,947 lb. in 1886

LIBERIAN COFFEE.—The Exports for 1887 were 3,419 cwts. against 3,834 cwts. in 1886.

THE DUTCH MARKET.

AMSTERDAM, January 25th.—CINCHONA.—Of the lots offered at our last auction 144 tons Java manufacturers' bark contained the equivalent of 4·2 per cent sulphate of quinine on an average; whilst 426 packages (about 26 tons) contained over 5 per cent; 142 packages (about 8 tons) over 6 p.c.; 7 bales, 8·10 p.c and 2 cases 9·38 per cent. These figures prove that Java is on the 4 per cent level, alluded to in your No. 400 (December 17th, 1887). It would be of great interest to know how much quinine the Ceylon bark, sold in London in the last auctions, contained on an average.

CUBEBS.—The 4 bales cultivated berries are not yet sold. The sample was sent to Louton, where parties interested in the article declared it mixed with spurious berries, and estimated the value to 20*l* per cwt. And yet these cubebs are prime in every respect, and no spurious ones amongst them. Buyers have been accustomed these two to three years to small shrivelled half-developed cubebs, and for this reason seem to suspect berries of finer appearance.—*Chemist and Druggist*, Jan. 28th.

WELL DONE OLD MATALE EAST FOR TEA!

A Matale East planter, writing on the 15th, asks:—

"What think you of the following tea plucking record from land over 45 years in coffee, and after a drought of 47 days? On the 13th, 73 coolies brought in 1,481 lb. green leaf, or an average of fully 20 lb. per cooly, while the following day 66 coolies brought in 1,122 lb., or 17 lb. average per cooly. Not so bad for Old Matale. Rain keeps threatening every afternoon now. I fully expect a downpour soon."

It will do the heart of Mr. Peter Moir good to see this news, and by-and-bye to see the fields, every yard of which must be familiar to him, clothed in their new mantle of green with vigorous rich cropping tea bushes.

TOBACCO.—The Samarang *Locomotief* says that a gentleman named Laurillard, on behalf of a firm at Singapore, has secured from the Sultan of Siak a concession taking in two thousand bouws of waste land on the river of that name. He is also entitled to take up six thousand more acres of adjoining land. The object of the undertaking turns out to be the cultivation of tobacco. Mr. Laurillard has since proceeded to Holland, where he intends to do his best to start for cultivation purposes, a company with a capital of three hundred thousand guildres. An experienced planter from Deli will manage the estate should all go well.—*Straits Times*.

THE PROFITS FROM COCONUT ESTATES.—We heard not long ago of a native gentleman, who was said to be getting R20,000 income from 150 acres of coconut land, or R134 per acre per annum. An old coconut planter waxes wroth on this:—"I don't like to call anyone bad names, but really ——— should be careful before he speaks of R20,000 income from 150 acres coconuts! and that I presume without any particular cultivation or large expenditure. Add the moderate sum of R5,000 for working expenses, and you have R25,000. To get this you want 1,000,000 (one million) nuts, for you can't calculate more than R25 per 1,000 as the value in Chilaw. This means 6,666 nuts per acre or 92 nuts per tree all round allowing 72 trees to the acre and no vacancies! Such a result from an estate is *possible*, but I must be excused if I don't think it *probable!* Coconuts pay well enough without exaggeration of this sort."

THE CEYLON TEA ENTERPRISE.—Says the *Pioneer*:—The tribute which Mr. Shand has paid to the energy and enterprise of the Ceylon tea planters in his lecture at the Royal Colonial Institute, a summary of which we give on another page, is in no way greater than is deserved. The pluck with which these men turned from their coffee plantations, converted in most cases by the deadly fungus from mines of wealth into a dreary desert of walking-sticks, to build anew their fortunes with the leaf their brothers had cultivated to so much purpose in Assam, is one of the most notable things in the history of the Colonies. And the success attained has been far more extraordinary than even that of Assam. It is little more than a decade since Ceylon exported her first pound of tea: last year she exported some 14,000,000 pounds, and as the immense acreage which has been filled up with plants comes into bearing, the amount will be trebled. This rapid growth is no doubt due in a great measure to the fertility of the soil and its suitability for tea cultivation: we should seek in vain in India for anything like the famous hundred acres at Mariawatte, which have again and again given their thousand pounds per acre of yield, and show no signs of exhaustion; but it is due in no less a measure to the indomitable energy, foresight and perseverance of the planters. So far indeed as pushing his teas in foreign markets goes the Indian planter might take a lesson from Ceylon, for the latter has agents not only in Europe but in India itself, in Australia and in America, and they are rapidly spreading all over the world. Men who work in this fashion deserve success.

TIMBER IN THE NORTHERN TERRITORY OF AUSTRALIA.—Mr. C.S. Copeland returned from a timber search down the coast on March 24 (says the *North Australian*) and reports very favourably on parts of the main land visited by him. He arrived at Melville Island the day after leaving here, but on account of the island being overgrown with dense high grass, which made travelling impossible, his party was unable to obtain any information as to the timber-bearing qualities of the island. He saw no natives at this place. Leaving the island the Ark cruised round the Gulf for a considerable distance, the general character of the weather being squally and wet, and the situation of the party at times being rather uncomfortable. On the main land, too, travelling was rendered extremely trying very often, through the swampy nature of the country, long grass, and other causes. The chief explorations appear to have been conducted in the vicinity of the Alligator rivers. Each of the three Alligators (the South, West, and East, as they are called) was sailed up for many miles; but of the South Alligator, Mr. Copeland is particularly lavish in his praises. The entrance to this river is calculated to be at least 2 miles wide, and for the whole of the 55 miles sailed up by the Ark it carried a depth of water sufficient to float the largest vessel of the day. Owing to the constant freshes, against which even a dingy could not be pulled, the hope of ascending any further distance had to be abandoned, but from information tendered by some natives who visited the cutter it was judged that the river was navigable for another 50 miles at least. Mr. Copeland discovered some very fine forests of timber, ample at any rate for railway purposes, though none handy enough to the rivers to do away with land carriage. The distance from Port Darwin to where the best forest is located is about 150 miles.—*South Australian Register*.

Correspondence.

To the Editor of the "Ceylon Observer"

TOBACCO PLANTING IN CEYLON.

SIR,—You do not state in your article on tobacco cultivation, that experts in London have discovered that there is a flavour and aroma about Ceylon tobacco that puts even the Deli tobacco completely into the shade. It was the discovery of this fact that brought to Ceylon one of the largest Sumatra proprietors in search of land. I am told that an application was made to Government to lease some 10,000 acres of land, but the application was not favourably entertained. More encouragement should certainly have been extended to this enterprising gentleman. He has left an agent, I believe, in the island, who has been purchasing land in different districts.

A friend, who knows how to take occasion by the hand, having heard privately of the value attached to Ceylon tobacco, applied to Mr. Ingleton to ask at what price he (Mr. Ingleton) would contract to deliver to him his entire crop. No answer was received, and now I see that Mr. Ingleton is "in the swim" as the saying goes.

Of recent years Deli tobacco has been considered by connoisseurs to be the best in the world, and it had become so valuable that it was only used as the outside wrapper of cigars. In 1885 I met some Deli planters on board a French steamer, returning home after four or five years at Deli, with their pockets very flush. I could hardly credit the stories they related of the rapid fortunes made.

Now, if we are going to treat Sumatra in the matter of tobacco as we have done India in the matter of tea, what I should like to know is going to be the future of this "Eden of the Eastern Wave"?—Yours,

SMOKER.

CEYLON TEA IN AMERICA.

Philadelphia, 3rd Jan 1888.

DEAR SIR,—Through the medium of your valued paper we learn that the sum of two thousand rupees has been voted for the purpose of advertising Ceylon tea in this country in the shape of distributed samples.

As the writer has had no official communication to this effect, he cannot well address the body of gentlemen, who have so liberally responded to our call for help. We feel called upon, however, to acknowledge in some way our appreciation of the feeling, which has prompted them to this action. We are much in need of the assistance thus afforded, and can assure the planting community generally that their interests will always be what they have been, *our* interest, and that the tea they send will be employed to the best possible advantage to the end that Ceylon tea may be established in this country as not only a marketable tea, but as a tea which can justly claim pre-eminence among all other teas for its purity, economy, wholesomeness, and fine flavour.

On the strength of what we have learnt, we have already entered into a contract for 50,000 sample boxes, which, with printed matter (the manuscript of which is now all ready, save a few items, which depend upon the quality of the tea sent, such as price and the amount required for making) will weigh 2 ounces and can be mailed [illegible].

We have entered into correspondence with Mr. Evan K. Morice (Milwaukie), late of Ceylon, with a view to enlisting him in the Ceylon tea enterprize, and have just received a letter from him acknowledging receipt of a trial consignment.

We shall send him a portion of the samples when ready, as Milwaukie is a good centre, and we are already acquainted with some families of great influence there, who would be glad to assist him in his endeavors to make the tea known.

From a letter in the *Observer* received today, we gather that Mr. E. Gordon Reeves is not sure about the advisability of distributing samples of tea *free*, as his agent has just sent him an order for 500 lb., all of which is bespoken. This is good news for us, but it scarcely proves that samples, sufficiently large to make two or three infusions, given out gratuitously to those who cannot be personally interviewed is a bad medium of advertizing. We do not refer to "a 1 lb. or two of Pekoe" to the Yankees indiscriminately. That would be absurd in the extreme, although we ourselves have had no reason to regret having given away a pound of Ceylon tea to a Yankee friend when we thought we might find in him a friend in the camp of the enemy. A sample, however, which is sufficient for only *one* infusion is too small, because the new flavor takes the people by surprize, and they don't like it enough to order more. A sample of about ½ an ounce stands the chance of being "dump'd" into the teapot like so much washy Japan. An ounce or 1¼ oz. sample is worth *attention*, will call for more or less careful perusal of the printed instructions accompanying it, and will receive careful treatment by a large percentage of those into whose hands it falls. We have now tried all the popular mediums of advertizing, throwing into the thing any originality of which we might be possessed. In co-operation with Messrs. Finley Acker, we think you may rely upon the most being made of the means placed at our disposal for advertizing Ceylon tea here. Mr. Pineo, in a letter received this morning, states his intention of proceeding to Ceylon *via* China and Japan, so you will hear from him something of *his* experiences in this country. Hoping soon to hear from those in authority regarding the tea for distribution, we are, dear sir, yours faithfully,

J. M. MURRAY & Co.

OUTTURN OF TEA.

DEAR SIR,—With regard to outturn of tea from leaf, A. S. H.'s inquiry,—10 per cent deduction from all leaf brought into a factory should allow of an outturn of 25 per cent of made tea as a general rule for the season.

This, one of the bones of contention between seller and buyer, is best disposed of by purchase without deduction.

C. S. A.

SELLERS AND BUYERS OF COFFEE.

10th Feb. 1888.

DEAR SIR,—Your informant notes that someone, signing himself a "Colombo Merchant," wishes further information *re* rejected coffee.

1st case, he asks were the first and second consignments taken from a bulked heap? Yes, they were: each daily lot cured being thrown on top of the heap, and the whole repeatedly turned over with shovels to prevent heating.

2nd, "if these two parcels were from a bulked heap, was the first delivery accepted without comment or with a caution?" Yes, it was. "Merchant" then remarks that if these two parcels constituted *one* heap, it is strange that both were not forwarded together. Does "Merchant" know that in January there is so much traffic that it is difficult to get carts? Your informant got carts to take 1,000 bushels to railway station, and in a few days he got more to take the 500 bushels, and he has a lot more to dispatch, but has not got the required carts yet.

3rd case, "your informant omits to mention how much triage had to be picked out of his parchment before it was shipped." To this question your informant cannot answer, as it has not yet been cured: but, being an old curer and planter too, he is certain there is not 5 per cent of triage (the allowed percentage in contract of sale) in it and is equally certain there is less. This is not given as a reason for rejection. Finally, "Merchant" thinks that only No. 1 size of last season fetched the highest price in Mincing Lane. For his benefit your informant sends you the prices of all sizes rejected here, and sold on 7th June last by Messrs. Matheson & Co., in Mincing Lane :—

1st size	..	112s per cwt.
2nd ,,	..	110s 6d ,,
3rd ,,	..	103s ,,
Peaberry	..	112s ,,
Triage	..	99s 6d ,,

And if "Merchant" doubts the truth of these sales, your informant will be happy to send Messrs. Matheson & Co.'s account of sales for his inspection through yourselves. PLANTER.

P.S.—The gentleman who acted as my arbitrator ast seasons is a buyer himself and has rejected one crop, I know, of this season!

CHOCHOS WANTED IN THE COLOMBO MARKET.

Colombo, 14th Feb. 1888.

DEAR SIR,—Can you kindly inform me whether the chocho plant which grows very successfully at Matale has ever been tried in Colombo. I have never seen this vegetable hawked about for sale in the Colombo streets, nor even brought to the Town Hall market. A friend of mine sent me some of these vegetables from Matale and I managed to raise a plant; and after the expiry of three or four months, the flowers appeared. Only one solitary fruit has at last appeared, and I don't see signs of any more coming. The creeper, besides, is gradually getting dried up, evidently owing to the present drought. I would be glad to hear of any suggestions you may be able to give. G.

[Let "G." buy and consult "Gardening in Ceylon," latest edition.—ED.]

COFFEE CULTIVATION IN 'PLANTATION AND 'NATIVE' FASHION: AN OLD COFFEE PLANTER ANSWERS "S."

SIR,—The writer of the letter signed "S" in your last issue labours under a strange mistake as to the causes of the collapse of coffee in Ceylon. All the world should know at this time of day, that the sole cause of that calamity was *Hemileia vastatrix*, and not extravagant expenditure. In the course of forty years, the combined experience of some thousands of intelligent men formed coffee planting into a system, which he calls a stereotyped fashion. To obtain the best results, certain operations were necessary, as proved by hundreds of experiments, and the standing of the practical planter depended on the efficiency and economy with which he performed those operations. The financial affairs of the estates were in the hands of commercial men, a class sufficiently alive to their *own* and their constituents' interests, who were not in the habit of paying more than the market price for the service of superintendents. The class of estate superintendents know to their cost, that the old rate of expenditure was not maintained, when bad times came hundreds were dismissed, and those who remained had either to do so on greatly reduced salaries or increased responsibilities.

There are hundreds of men in Ceylon, who could answer the question propounded by "S" in all the branches into which he divides it had he wished for information, but it is very evident that it was only asked as an introduction to the exposition of his own already settled opinions. It is, therefore, quite unnecessary to respond to it in any way. It is not probable that any of those, whose emoluments he grudges, and whose civilized surroundings he would remove, will entertain any worse wish towards him than that he may on his own places invest a lakh of *his own* rupees, and appoint Mr. Ramasamy Chetty his manager, on a salary of R10 a month. L.

A TALK ON TEA WITH A MINCING LANE AUTHORITY.

GALBODA, 17th Feb. 1888.

Coming up to Kandy in train yesterday, I had the company of Mr. Wm. Thompson, jnr., of Mincing Lane, who has been away from home for about five months spending most time in India visiting Assam tea estates. He was a passenger by "Rohilla," so I introduced conversation by remarking that they must have had a weary time on board during the quarantine. "Not at all," he replied, "we had a very jolly time. Dancing, games, amateur theatricals and concerts made time pass very pleasantly." Then I put a question about prospects of tea and planters on Indian estates. "Both are very good," he said, "the acreage under cultivation and yield are rapidly increasing and will continue to increase. For every thousand acres planted there are generally several thousand acres of forest belonging to the same estate, which, in course of time, will be cleared." "What do you think about the prospects of Ceylon planters?" I asked. "Oh, they are very good, only they must push their teas." "That is what they are doing, and they have got a pretty large fund now for the purpose. But do the Indian planters push their teas very much?" "Yes, they have been doing that, but push them as much as they like, they don't seem to take. Take Russia for instance. I know one of the biggest firms in London have a special traveller for Indian teas in Russia, but the Muscovites still prefer the China teas, to which they have been accustomed." "Perhaps their taste wants educating. At the last general meeting of the P. A. at Kandy, one gentleman actually suggested the adulteration of Ceylon teas to make them more acceptable to the existing palate." "Adulteration! What did he mean by that. Adulteration means mixing with some other substance. Tea is tea, all the world over, and whatever kinds you may blend that is only mixing." "Well, this gentleman prominently used the word adulterating, but his suggestion did not find much favour. But do you think Ceylon teas will really become more popular?" "They are popular already, and they are sure to become more so when they are better known. Your upcountry teas have got a splendid flavour." "Well, the quantity exported, as you know, is rapidly increasing. The estimate for this year is 22,000,000 lb." "Yes, but if they have not the purchasers, what will be done with it all? The motto must be 'push.'"

At Peradeniya Station Mr. Thompson was met by Mr. Webb, whose guest he will be. He has not yet decided whether to go back by the next P. & O. mail steamer or not.

"HOME-GROWN" TOBACCO.

A good deal has been heard of late of the possibility of developing tobacco culture in this country, and of thereby securing a new field for the operations of agriculturists in view of the prevailing depression. The Government even have done something to encourage this new industry; and only the other night it was announced in Parliament that the Inland Revenue authorities were willing to forego the exaction from intending tobacco-growers of sureties to the extent of £100 per acre for the protection of the revenue. In place thereof, they are to be content with a declaration made before a magistrate that the intending tobacco cultivator will at all times afford to the Inland Revenue Officials free access to their grounds, and that all the tobacco

grown shall be duly produced to the proper officer to be charged with revenue, and so on. A practically free opportunity being thus afforded for cultivating tobacco, the question arises—Can it be conducted so as to compete with other tobacco-growing countries, and to be in any degree remunerative?—It may interest many readers to know that a practical experiment towards the solution of this problem has recently been made in Aberdeen, and with "home-grown" tobacco, part of which was "raised" on Deeside. Messrs William Rattray and Sons, tobacco manufacturers, Queen Street, have just completed the manufacture into "roll" and "cut" tobacco of some tobacco leaf grown at Glasterberry, Peterculter, and in Sussex, by Mr Thomas Jamieson, F. C. I., of the Agricultural Resea ch Association. The samples of leaf which Mr Jamieson submitted from his Sussex farm appeared to Messrs Rattray to have more nearly approached maturity than those produced at Glasterberry, but both were very far from being ripe; and, in consequence, the manufactured article was very deficient in the flavour which American tobacco possesses. The leaves were well formed, and were in every respect suited for the purposes of roll-spinning had they been allowed to arrive at maturity before being cut; but for cut tobacco the samples were unsuitable, principally from the want of colour. We understand, however, that the samples were planted late and pulled early, and so were not quite up to the mark of what might possibly be produced.

The possibilities of tobacco-growing in this country, however, are hardly in question. Tobacco has been grown in all parts of temperate and torrid zones: it has been grown before now in some parts of Scotland and Ireland. But the serious question that intending tobacco cultivators have to face is whether they will be able to produce an article capable of competing with the American article. American tobacco, in fact, may be said to "hold the field" alike in general acceptability and in price; it is the only growth that has found anything like universal consumption. For several years past tobacco-growing in America has been a very profitable business for agriculturists acquainted with the method of culture, and who knew how to hand the plants over in good condition to the "stemmer," who prepares it for the market. But the large profits have had the natural tendency of greatly developing the cultivation of tobacco, the consequence being that there is now a far too large quantity grown, and that the price of the article has reached a very low figure. The *Western Tobacco Journal* (of Cincinnati) actually writes deploring the "depressed" condition of the tobacco trade and the tobacco farmer, and prophesying that, unless the crop be considerably restricted and greatly improved this year, a wide-spread disaster will overtake those engaged in tobacco-planting. For some seasons back, more attention has been paid to quantity than to quality, and now the journal named makes a vigorous appeal for the production of "good and fine leaf." Here is what it says—addressed, be it observed, to men practically acquainted with tobacco-growing and experienced in its culture—"A good crop cannot be obtained unless the seed is pure and no planter should attempt to sow seed in which he has not absolute confidence as to origin and pedigree. If it is many removes from the original, or from defective or carelessly-cultivated plants, the crop will be bad, no matter how intelligently or energetically it is worked and handled. You cannot produce a good Jersey or shorthorn from a scrub or hybird of these breeds." And again "The essentials to recovery from the present absolutely depressed condition of the tobacco trade are A crop grown from nothing but the best of seed, a crop that, so far as acreage is concerned, will cover far less than the average crop, but which will be cultivated and handled with more intelligence, caution, and energy than the past few crops." The British farmer, therefore, will start tobacco-growing handicapped by an American competition as formidable as the competition in grain and beef, and utterly unable, from want of experience to adapt himself to the new exigencies created by that very competition; and we are informed that even in the event of British farmers being able to grow first-class quality of tobacco—the probability of which may very well be doubted—they would likely be unable to command the highest prices from the manufacturers, partly owing to the manufacturers' probable distrust of a newly-produced article, and partly owing to the influx of a cheaper and more serviceable article from the other side of the Atlantic.

There is still another view of the matter to be presented. Reference has been made to the over-abundant supply in America of the "raw material," so to speak. It naturally follows that the supply of leaf tobacco in bond in this country is largely in excess of the demand. Here are some interesting figures as to the stock of tobacco in bond in the United Kingdom:—

At the end of 1884,	it was	72,072.838 lb.
,, 1885,	,,	92,391,997 lb.
,, 1886,	,,	116,604,398 lb.

Startling in themselves, these figures become more striking when we place in juxtaposition the statistics of tobacco duty-paid entered for home consumption in the United Kingdom:

In the year 1884,	it was	50,772,513 lb.
,, 1885,	,,	51,323.060 lb.
,, 1886,	,,	50,972,001 lb.

In other words, we have started the year 1887 with a stock of tobacco more than twice as large as a year's average consumption! Something like the same proportion, we believe, holds good all over the world; so that, obviously, there does not seem much "opening" for farmers or anybody else in a new development of tobacco-growing. In view of the prevalent depression of agriculture, that is certainly matter of regret; but we believe it is better to make agriculturists acquainted with the actual situation than do delude them with hopes of successfully prosecuting a new industry which seem utterly unrealisable.—*Aberdeen Free Press.*

TEA PLANTING ON THE NILGIRIS.

We learn from Colonel Nassau Lee's work on "Tea Cultivation in India," that the first consignment of China seed sent to this country was that despatched by Mr. Gordon in 1836. He remarks that:—"In both his missions, Mr. Gordon sent round to Calcutta several casks of seeds, some plants, and eight or ten Chinamen." From this seed 42,000 plants were reared, which were distributed as follows:—

Madras Presidency	2,000
Assam	20 000
North-Western Province ...	20,000

The plants sent to Madras for distribution were planted at Coorg, Mysore, the Neilgherry hills, and in the Horticultural Society's garden in Madras. Six months after they arrived (22 d August, 1836) the Chief Secretary reported to the Supreme Government that "the experiment had completely failed, and with the exception of a few plants on the Neilgherry Hills, and in the Nugger country, the rest had withered away." Colonel Lees states further on:—"It must not be concluded from this that no part of the South of India will grow tea, as from the unavoidable ignorance of those entrusted with these early experiments, no other results could have been anticipated." It appears, however, from statements made further on in the work above quoted, that the seedlings sent at this time to Assam and the North-West Provinces, fared with little better success, and that the first successful attempt at the introduction of China seed to India was made by Mr Robert Fortune some years after.

As far as these hills are concerned tea planting [illegible] in 1859. The seed from which the plants were raised was of the China variety, and, in Captain Mann's case, obtained direct from China. In consideration

of his being the pioneer of tea cultivation in this Presidency, Government gave him a free grant of land, and later on in 1862, when the estate came into bearing, sent down four Chinamen from the North-West Provinces to instruct his coolies in the manipulation and drying of the leaf. The knowledge brought to bear upon the subject by these individuals appears to have been of little use, as their mode of preparation was not only found to be more costly, but also to turn out tea of an inferior class to that which the proprietors had, without the assistance of the Chinamen, previously manufactured.

The real facts of the case are, that the sole information relative to the manufacture of tea in the earlier days of its cultivation on the Nilgiris, is gathered from descriptive accounts written by Chinese travellers, or from the pamphlet written by Dr. Jameson on the Kangra and Kumaon gardens, which were under his superintendence. Every work which contained any information on the subject of tea cultivation in China or Java was at a premium; and as the opinions expressed by the majority of these authors was at variance one with the other, there must have been some little difficulty in following out all the instructions given.

Dr. Jameson's treatise was based on his own experiments, carried on with the aid of a few imported Chinese labourers, and might be termed but a second hand and stale edition of the systems advocated by previous authors. The advice given in this report would hardly meet with the approval of the experienced planter of the present day. Mr. Fortune seems to have had a slight skirmish with Dr. Jameson on the systems of cultivation and manufacture in vogue in the Government Gardens, and Colonel Lees, in his work, sides somewhat partially with the latter gentleman. He remarks:—"Though not a practical tea planter, Mr. Fortune was a respectable botanist, a fair agriculturist, and I believe, an excellent horticulturist. He had visited the finest tea districts of China, and was fully competent to express an opinion on the suitability of the soil and localities selected in the Himalayas, and the health and vigour of the plants, as compared with those which he saw in China. * * * * That Mr. Fortune had not practical experience of tea cultivation and tea manufacture was well known."

The former portion of these remarks seems to damn with very faint praise one of the ablest horticulturists of his day; the latter to lead us to believe that he travelled in China with his eyes shut. For our own part we have not the slightest doubt that he was better acquainted with the subject in question than Dr. Jameson, and that had his recommendations been carried out, the Government Gardens and the Indian tea industry would have greatly benefited thereby. We doubt much if there is a single planter in the North-West Provinces who will not declare that the system of cultivation practised in the Government Gardens was a tissue of blunders; that it was left to private enterprise to undo the errors which Government Superintendents had led planters into, and that they had to pay heavily for the privilege of doing so.

As for the Chinese manipulators who, in those days, were considered a *sine quâ non* we are all aware that the Chinese are not a progressive race, that, the Chinese farmer is not a chemist, he knows little or nothing of vegetable physiology; but his forefathers have hit accidently upon certain systems which are found in practice to succeed, and to these he himself adheres, and hands them down to his children. And these remarks are equally applicable to the native of India. He considers that what was good enough for his fathers is good enough for him; that as they lived, so may he; and that any effort on his part to raise himself in the social scale is not merely a mistake, but almost an insult to their memory. And closely allied to this impression is the idea that those who try to raise him have no philanthropic object in so doing, but merely serve their own interests.

In China—a country teeming with population, and where labour and the necessaries of life can be obtained for an almost nominal cost, little inducement is held out to the peasant to improve himself. The system of tea cultivation differs entirely from that pursued in India. Instead of gardens extending, as in this country, over from 200 to 500 acres of cultivated land, there are small holdings of a few acres, each worked by the proprietor's own hands,—a system of land tenure analogous to that prevalent in many parts of Ireland to the present day. In India, a single estate may send home half-yearly a break of about one thousand full chests (of 82 lb.) in China, as many hundred estates as chests would be necessary to meet the demand. There, the tea passes through the hands of some half-dozen middlemen, each of whom has to make a profit on the article, and adulterates it if he has the opportunity. Here, it goes direct into the market.

In this country the labour difficulty is undoubtedly a drawback; but a remedy has in a great measure been found, viz., in the adaptation of machinery for the preparation of the leaf, in the improvements of the implements employed in the cultivation, and last, but not least, the impossibility of adulteration before the tea reaches its market. These advantages threw a great weight into the scale, and added to these, the superior strength and more delicate flavor (the latter especially in the case of hill teas) account for the high prices which they fetch in the European market, and the increased demand which arises year by year for Indian teas of fine descriptions. We believe the time is not far distant when Indian tea will be drunk throughout Great Britain to the *entire* exclusion of the China article; and we cannot fail to recognise how great an advantage would be gained thereby, not only by the consumers, but also by the addition that would be made to the revenue of the country.

The errors and mistakes made by the pioneers of tea cultivation have been remedied, at a great sacrifice to those concerned in the enterprise; and planters in Southern India have, as a rule, availed themselves late in the day of the experience gained in other districts. Better late than never though, and we believe a successful career lies before them.

The first real onward movement in the matter of tea cultivation, commenced about the year 1865 and 1866, when several estates were opened out at Kodanaad, and one or two smaller ones at Coonoor. Seed was imported from Bengal, and though in many cases as we have before stated, heavy losses were sustained by those concerned through the importation of damaged seed, the owners of the estates nothing daunted kept on; and it is probably owing to their energy pluck and perseverance that tea planting on the Nilgiris bids fair to prove an undoubted success.

These pioneers had not, as in other districts, large supplies of seed distributed gratuitously by Government to fall back upon. They had not grants of land procurable at the upset price of two rupees and a half per acre—the period of payment prescribed extending over ten years from the date of purchase—and their land free of assessment for ever; but they had from the very outset to import seed from Bengal at a great risk, to pay as much for their land here in the first instant as they would have had to pay in Bengal in ten years' time; and during the first three or four years of their occupancy, when they were spending money without getting any return, to pay an annual assessment of two rupees per acre for forest land, one rupee per acre for grass land in perpetuity. In purchasing the site for an estate, the purchaser has not only to consider how much land he requires for actual cultivation, but has also to ensure a sufficient supply of wood suited for building purposes, making boxes and fuel, in addition to a certain area of land required for grazing purposes. On every acre of this land a heavy assessment had to be paid annually, and it is only within the last few years that the Government have seen fit to remove this heavy burden, and to allow the planters to hold their land free of assessment for the first five years of their tenure.—*Nilgiri Express.*

CLIMATE OF MANIPUR.

In connection with Major Macgregor's paper on his journey from Upper Assam to the Irrawadi, read at a recent meeting of the Royal Geographical Society, and printed in the new number of the Proceedings, Dr. G. Watt made some valuable remarks on his own observations in the Manipur district. Manipur is a small valley surrounded by mountain ranges, and in this valley the rainfall was found to be only about 39 inches, but seventeen miles off, in the mountains which formed the north-east ranges, the rainfall was as much as 120 inches, and towards the Naga country to the north it became greater and greater in certain limited tracts. In the Khasia Hills 600 inches might fall in one place, and twenty miles off only 50 inches. Nothing in Mainpur struck Dr. Watt so much, as a botanist, as the remarkable transitions of vegetation in that small region. Dr. Watt gathered twelve or more species of oaks, many of which were new to science, and ten or twelve species of rhododendrons in Manipur alone. The *Rhododendron Falconeri*, found in the Naga Hills by Sir Joseph Hooker, is now here met with in the immense tract between the Naga Hills and Sikkim. This and the epiphytic *R. Dalhousiæ*, which grows on a hill thirty miles north of Darjeeling, Dr. Watt found in the Naga Hills at an altitude of 6,000 to 8,000 feet, and these rhododendrons never occur in Sikkim below 10,000 to 13,000 feet. There were many instances of plants falling in their altitude as the traveller passed to the east and south-east from Sikkim, until at Moulmein a rhododendron was found growing near the sea, a circumstance which was not met with in any other part of Asia. There is something in that region which, apart from pure geography, is of vital interest. Sarameti, which is under 13,000 feet high, the natives said, had now all the year round, whereas on the Himalayas the lowest point at which snow occurs is 17,000 feet. In Manipur, the whole valley, 3,000 feet high, was covered with hoar-frost in December. Dr. Watt thought this was a point that should be thoroughly investigated: what is the cause of this falling in altitude in the vegetation? General Strachey, who was in the chair, considered that the peculiarities of the vegetation of Manipur compared with Assam were connected with the evident lowering of temperature indicated by the low snow-line. There could be no doubt that the warm currents of air coming up the valleys of the Irrawadi and the Salween and meeting the snowy mountains to the north produced an enormous precipitation of rain, which during winter fell as snow. The consequence seemed to be that there was snow there at a very much lower level than in the mountains further to the north. That an immense quantity of rain fell in the upper portions of the valley of the Irrawadi there could be no question. Such a rainfall seemed in itself quite sufficient to account for the large volume of water that was drained off by the lower portions of the Irrawadi; and anybody who knew what Tibet was, General Strachey stated, must be aware that, even with a course of several hundred miles, the river would pick up but a small quantity of water in comparison with the enormous volumes which were collected from the rain which fell in Upper Burma. General Strachey had roughly calculated that a monthly fall of rain of 18 inches over a square degree would mean 65,000 cubic feet per second for the whole month.—*Nature*.

WATTLE-FARMING.

As the supplies of wattle-bark hitherto obtained from the natural forest are rapidly falling-off, and as the demand is steadily increasing both in the colonial and European markets, we propose laying before such of our readers as may wish to enter into the cultivation of wattles as a crop the fullest information obtainable on the subject. Hitherto the cultivation of the wattle for commercial purposes has not received much attention. The Victorian Department of Agriculture has, however, set a good example to the farmers of the colony by showing them that wattles can be easily cultivated, nearly 1,000 acres of Crown lands having been cultivated, and we understand that it is intended to plant an additional 200 acres every year. Several plantations have been made in reserves along some of the lines of railway, and more especially between Melbourne and Colac, and all are reported to be in a flourishing condition, and some sufficiently advanced in growth to be ready for stripping. In future the demand for wattle bark will have to be met in a great measure by the regular cultivation of wattle trees, and although a remunerative undertaking, there are doubtless many persons who may be without the information necessary to enable them to engage in its systematic cultivation.

Upon the important subject of the profits to be derived from wattle cultivation, Mr. J. E. Brown, the conservator of forests under the South Australian Government, in a valuable report to the South Australian Legislature furnishes the following tabulated statement of the probable revenue and expenditure during a period of seven years, in connection with a wattle plantation formed upon 100 acres of land specially purchased for the purpose, and upon which wattles had not previously grown.

REVENUE.

	£	s	d
To value of property increased and improvements, say	400	0	0
To value of 500 tons of bark, at £5 per ton	2,500	0	0
Total	2,900	0	0

EXPENDITURE.

By purchase of 100 acres, at £3 per acre	300	0	0
By cost of substantial fence all round, say one mile and a half, at £50 per mile	75	0	0
By ploughing 100 acres, at 8s. per acre ...	40	0	0
By cost of 30 lb. of seed, at 1s. per lb. ...	1	10	0
By labour sowing the seed in rows, say at 5s. per acre	25	0	0
By scarifying between the rows twice, at 4s. per acre	20	0	0
By thinning and pruning for two years, at 10s. per acre per annum	100	0	0
By forming firebreaks during the third to seventh year, say £5 per annum ...	25	0	0
By sundries	50	0	0
By interest on money expended during the seven years, say	280	0	0
By cost of shipping 500 tons of bark, at 25s. per ton	625	0	0
By cost of carting same to market, at 10s. per ton	250	0	0
Balance, being clear profit	1,108	0	0
Total	£2,900	10	0

This shows a return of seven per cent upon the purchase of, and improvements upon, the property, as well as a clear profit of £1,108, over and above that amount. In the above estimate the probable yield is given as five tons per acre, which may be regarded as a low estimate, as it only allows 10 lb. of bark to be taken from each tree. The value per ton is set down at £5, which at the rates now ruling is quite within the market quotations. An important point in connection with the cultivation of wattles is that both ordinary farming and grazing can be combined satisfactorily with the growth of wattles. After the first year, when the young trees in the plantation have reached the height of from three to four feet, sheep can be turned into the plantation without injury to the young trees.

Before proceeding to describe the different varieties of wattles and their relative tannic values and also the methods of cultivation suggested, the information collected by the board appointed by the Victorian Government to deal with the wattle-bark question merits attention. That report is of great value, as particular care was taken to elicit a general expression of opinion on the subject, and numbers of witnesses from all parts of the colony were examined.

First, as to consumption. The quantity required for consumption in Victoria alone was estimated at from 12,000 to 15,000 tons per annum, exclusive of

the large quantity exported to England, where higher prices are offered. The current price of good bark is in Melbourne from £5 to £5 12s. 6d. per ton, making £63,000 to £78,750 per annum. The numerous witnesses called before the board of inquiry agreed on one point—viz., that a less quantity of bark is obtained from year to year, as the wattle is disappearing. Whole districts were stated to have been already denuded of it, and unless steps were taken to encourage the growth of wattle-trees the total extermination of this useful native production can only be regarded as certain. Already the supply of tanning bark has become scarce in England, and we read that English tanners depend a good deal on Spain and other Continental countries for their supply of oak-bark. England can, therefore, always be regarded as a consumer of our surplus wattle-bark, and it is not at all likely that the market will often be so glutted as materially to affect the price. On this subject Mr. Brown furnishes the following extract from a letter received by him from a gentleman connected with one of the largest tanneries in England. He says:—"The matter of supply and demand can be pressed into a very small compass. British and Continental tanners are languishing for ample and continuous supply, and South Australia exports in such driblets that very many of the large firms in Great Britain have given over using it, falling back on Valonia and other barks more fully and regularly supplied. I may be allowed to remark here, reliable leather cannot be produced by intermittent and inadequate supply of bark, on which the tanner relies when laying down his hides; indeed, in large yards, such as with 50,000 hides always in the pits, it becomes a very serious difficulty, attended with anxiety and loss, not to be able through want of sufficiency of bark of a class to work them through succesfully. It therefore becomes a matter of necessity that the exports of bark may be abundant and regular to such an extent that tanners may confidently rely on. To such low export of wattle-bark have your growers now arrived at, that one yard could manage to take fully one-fourth—say, 1,000 tons—of all the bark shipped from your ports (South Australia) to England in 1882, and about one-third of shipments in 1883. I was very much gratified to notice your intention of planting the wattle extensively; the demand exists for as much as you can grow for many years, and, with new and increased growth, new and enlarged outlets will occur. I am aware French and German tanners highly approve of the wattle for tanning purposes."

According to the report of the Victorian Wattle Commission, wattles grow on almost any soil, even the poorest; but their growth is most rapid on loose sandy patches, or where the surface has been broken for agricultural purposes. When the soil is hard and firm, it is recommended that plough-furrows should be made at a regular distance of say six or eight feet apart, into which the seed are to be dropped. The seed should be sown in May, having been previously soaked in hot water, a little less than of boiling temperature, in which they may be allowed to remain for a few hours. The seed should be dropped at an average distance of one foot apart along the furrow, in which case about 7,200 seeds would suffice for one acre of land. The seed should not be covered with more than about one quarter of an inch of soil. On loose sandy soil it might even be unnecessary to break up the soil in any way. On such open sandy soil, the furrows may be dispensed with, and the seed sown broadcast, and after the land harrowed. On this subject the evidence given by the Conservator of Forests in South Australia before the Vegetable Products Commission in December last as that of an expert is worthy of reproduction. He states:—"In establishing wattle plantations the seed was thrown broadcast, and a flock of sheep were driven over it a few times to trample in the seed. To facilitate propagation he found it better to burn the seed slightly in the embers of a fire rather than soak or boil it. The golden or black wattles were in his opinion the most profitable of all forest trees. There could be no doubt about the superiority of the wattle over all other trees for tanning purposes, and it seemed to him an extraordinary circumstance that people should 'banker' after a foreign and inferior article for no other reason than because the wattle was a colonial tree, was easily grown, and consequently undervalued." —*Australasian.*

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

THE SOIL AND MINERAL MATTER—FOOD FOR PLANTS—LIME—CLINKERS—FODDER.

PARIS, January 28.

Increasing the productive powers of the soil, naturally draws attention to the products themselves, and it is here, where the present day farmer finds science coming to his aid. The products he utilizes in two manners: directly after submitting them to modifications, as in the case of saccharine or feculent matters, vines, fruits &c., indirectly, as when the animal itself elaborates from the products the materials to form milk, meat, and fat. The agriculturist having for aim, to realize the largest amount of plant-produce, the question of keeping up the fertility of the soil thus becomes closely allied to that of manures. Science hence, is intimately related to the conditions of the soil's richness; as well as to the laws which regulate the formation of the tissues of animals and the composition of plants yielding the nutrition for that tissue.

A great difference between plants and animals consists in the sources from whence they desire their aliments. The plant nourishes itself exclusively on mineral substances; that is to say, inorganic matters such as water, carbonic acid and atmospheric ammonia, which it decomposes by means of its green organs. By its roots, it draws from the soil, mineral acids, water, and salt. With these inorganic matters, the plant builds its tissues and effects special combinations that the animal later modifies, destroys, and works up to form and keep in repair its own organs.

Plants are thus the marvellous laboratory, wherein under the influence of heat and light are organised sugar, starch, gluten &c., intended by the plant as a reserve for the wants of its own reproduction but that man and animals appropriate for their food. The plant is thus the indispensable intermediary between the mineral and the animal worlds. With water, carbon, and hydrogen, it forms a host of compounds (called immediate principles), the rôle of which science for the greater part of them ignores. However, from a series of feeding experiments, we know enough about these compounds to practically guide us in the matter of alimentation. Thus the organic compounds that form the mass of vegetables, are either azotized, saccharine, starchy, fatty, or woody. These azotized or nitrogenous compounds are not all identical in various plants or even parts of a plant; as for example, the gluten of a wheat, the legumine of beans and the albumen and caseine of other plants.

An important fact to be borne in mind is that all these vegetable compounds are not equally digestible, that is, assimilated in the same degree by animals—hence, the important variations in the value of foods. They are all composed of carbon, oxygen, hydrogen, and nitrogen or azote: sulphur and phosphorus are never absent. Starch and sugar are found in cereals, the fecula of potatoes, the sugar of beet and fruits. They are composed of carbon, oxygen, and hydrogen, but no nitrogen; the second and third in exactly the same proportions as they form water. The starch and sugar can minerally transform themselves, and, circulating in the plant, accumulate in certain organs for reproduction in the grain as in case of cereals; in beet, in the root; in the potato, in the tuber.

The fatty matters, like sugar and starch, are composed of oxygen, hydrogen, and carbon, save, that here the first two elements are not united in same proportions as in the water. The hydrogen is united to carbon in a greater degree, hence, their industrial importance for illuminating and heating ends. In certain seeds they can replace completely starch and sugar while

performing the same nutritive function in the process of germination.

There remains the cellulose whose composition has much in common with starch. It imports volume to forage, predominates in straw, hay, clover, lucerne, &c. The younger the plant, the more digestible is the cellulose. When in the dense state, it forms the wood of trees and the kernels of fruits. Associated with the foregoing matters, sugar, gluten &c. and necessary for their action are sulphur, phosphorus and lime. Many substances in the food pass through the animal's body unutilized; while others, as starch, sugar, and fat, undergo profound modifications in the stomach and the intestines in contact with the juices secreted by these organs. They thus become metamorphosed, and so rendered, apt for entering into the organism of the animal to repair the waste of the system, sustain life, and maintain the animal's strength. The matters not utilized are eliminated from the system.

A few remarks respecting the present state of science on the subject of digestion: Hitherto it was held that the plant having formed sugar, starch &c. out of its atmospheric and soil food, rôle of the animal consisted in solely taking over these matters into its system by the process of digestion. It was denied that the animal itself could form starch, sugar, albumen &c., independent of what the animal received of these through the medium of its ordinary nations. It was Claude Bernard who demonstrated, that in the animal and vegetable kingdoms, plants and animals made independently of each other their sugar albumen, &c. Only the plant did so at the expense of inorganic matters of the air and soil, while the animal prepared its sugar &c. out of the materials elaborated by the plant. The latter in a word only supplies the raw material. It is in the blood that the animal finds the nutrition it requires. It was Claude Bernard who demonstrated also that the liver can form sugar and starch independent of what the food may contain of these two substances.

Blood totally devoid of starch and sugar before entering the liver contained on leaving that organ important quantities of these two substances, and which are as essential for the animal to fabricate, as the same substances are for the plant manufacture by its leaves. Every living being is in a perpetual state of change: all the atoms of his body are being incessantly renewed. We ourselves are not today, materially speaking, what we were yesterday, or what we will be tomorrow. In the space of twenty-four hours, we lose about the twentieth part of our weight. It is our elementation which covers his loss, brings us back to our weight of the eve; and the maintenance of this equilibrium we call health. Naturally the food or rations must vary following the object in view with the stock—whether for milk, work, or fattening. Science has shown us what rations are chemically composed of what the animal system demands for its sustenance, and in what proportions.

Twenty-two departments of France contain beds of phosphate of lime; the total capable of yielding 33 millions tons. The phosphate varies in variety from nodules up to the rock stage, and the percentege in phosphoric acid fluctuates between 15 and 37 per cent. The area of arable land in France is about 65 million acres, exclusive of vineyards, meadows, and forests. At the present rate of consumption of these mineral phosphates, the natural supply is not expected to last beyond 176 years. The total sales of the phosphates in 1886. in the three states of brut, smashed, and screened, was 200,000 tons, representing a money value of seven millions francs.

Respecting the dephosphorized scorie or clinkers: there are seven smelting establishments in France which produce annually 100,000 tons; not more than one-tenth of this total has been utilized for agricultural purposes, representing a monetary value of 162,000 fr. In the brut stage, the price is 4 fr. a ton; in small mossels, or powder, from 10 to 20 fr. The richness of the scorie in phosphoric acid varies from 7 to 18 per cent, and in lime from 35 to 50 per cent.

Stolen or intercalary crops commence to be more and more in favor as a means of cleaning the soil of those weeds that follow the harvesting of a cereal. A slight skin-ploughing, a few strokes of the harrow, a dusting of the soil with some cheap fertilizer and a sowing of a mixture of buckwheat, white mustard and millet, will, in addition to ridding the land of weeds, secure a green-bite for cattle, the more appreciated if the season has been dry.

Economy is still the order of the day in reference to fodder. Straw in this respect is receiving special attention: it is more employed as a ration. Instead of being filled into rocks, it is chopped, placed in alternate layers with sliced roots, grains, beet-pulp, or oil cakes, wetted with boiling water and allowed to ferment. Where straw is scarce and cannot be spared for bedding, heath, ferns, rushes, leaves, furze &c., make an excellent substitute for the latter. In Switzerland and in the south-west of France, the floors of cow-sheds are in wood, with relatively wide interstices. Behind runs a small stream into which the solid excrements are swept to join the urine. The stream is then led directly over meadow land. This plan can only have an exceptional application, but it is well to know where such can be applied, the plan suits.

THE FRUIT INDUSTRY IN FIJI.

BY J. B. C.

The growing and preserving of the tropical fruits of Fiji and its exportation, both in the raw and preserved state, has only recently become a leading industry in the colony of Fiji, although it has for some years been carried on by a few planters on Ovalau and Vanua Levu. Messrs. H. Maughan and F. Woodhouse, of Ovalau, may be said to have been the pioneers of this industry, and their success has induced many others to embark in so profitable an undertaking. The bulk of the trade is now centred in Suva, the fruit being grown at Navua, on the river Rewa, and at other places in the vicinity. The following account of a visit to one of the principal fruit plantations in the immediate neighbourhood of Suva will give a very correct idea of similar plantations in other parts:—

The extensive banana plantation of Messrs. F. W. Armstrong & Co., known as Mua-ni-kau, or Brighton, is situated at Armstrong's Point within 2 miles from the business part of Suva. Just before approaching Brighton, the road is crossed by the Leveta Creek, which is spanned by a substantial bridge. A little further on the handsome gates guarding the main entrance to the estate, are reached, and passing through these, the visitor comes upon a handsome avenue half a mile in length, which runs through the centre of the plantation direct to the residence of one of the proprietors. This avenue, which is planted with pine apples on either side of the tramway running its entire length, is shortly left, and turning down a by-path, a second avenue, also provided with a tramway, is come to. This second avenue, which is parallel with that first entered upon, is also connected with it by a loop line at the opposite end of the estate. On these tramways are trucks, and into these the fruit, when cut, is placed and conveyed to punts lying in the Leveta Creek. These punts are then towed to the steamer lying in the offing.

The quantity of land at present under bananas in all stages of growth is estimated at 100 acres, and more is being gradually cleared and planted. The present output is about 3000 bunches of bananas per month, which the proprietors estimate, they will be able to increase considerably, when the intended extensions and improvements are effected. The soil on the estate is evidently of a superior quality, the size, etc. of the fruit grown being a sufficient testimony of the rich nature of the ground, as their growth is rapid, the trees healthy, and the bunches of fruit large and well developed, in fact, the bananas from this estate are so much prized that those sold for shipment, bring an advance on the average market price. A flower and vegetable garden sur-

rounds the temporary homestead, which will shortly be replaced by a substantial residence: here a variety of imported flowers are flourishing luxuriantly; a nursery of date palms, blue gums, and other imported trees are thriving well; and pumpkins, water melons and tomatoes of enormous size and excellent quality grow almost spontaneously. A piece of ground at the rear of the housestead is being prepared for an extensive plantation of pure apples, of which comparatively few have hitherto been grown; and beyond the fence enclosing this, extends another 100 acres of grass, reed and bush land, on which are depasturing a herd of cattle. A short distance from the residence of the proprietor, houses have been erected for the preserving and canning of fruit, which industry has been actively commenced, and the product is already beginning to attract the attention of Australian buyers.

The houses for the laborers, hospital, &c., are convenient to the homestead, and it speaks well for the treatment of the laborers, of whom some 30 are employed, to find that the hospital has been hitherto untenanted, not one case of sickness having occurred on the estate. The proprietors speak hopefully of the prospects of the preserving industry, some of their goods forwarded to the Indian and Colonial Exhibition having attracted very favourable notice.

The only other firm which has as yet entered into competition with Messrs. Armstrong & Co. in fruit preserving is the firm of Anslow & M'Dougal on the Rewa, and they have also erected commodious works on their extensive plantation and are taking steps to place their excellent preserves on the Australian and home markets. Both these firms will be able to do this at a price at which our tropical fruits will compete successfully with those of more temperate climes.

Neither the pine apple nor the banana of commerce are indigenous to Fiji, but both have been long acclimatised. Prior to the introduction of the Chinese banana, as it is called, the only variety of this fruit in the islands of the Pacific was the plantain, which is much larger and coarser than the imported variety. The soil and climate of the group appear to be exceptionally suited for the production of both of these delicious fruits, as is abundantly proved by the avidity with which those sent hence are sought for in the colonies in preference to those grown in Queensland; the pine apples grown there, though of a large variety, being quite insipid in comparison, and possessing none of the luscious and exquisite flavour of their Fijian congeners: nor are the bananas of Queensland found to compare favourably with those of Fiji in point of excellence and flavour. There are at present three large steamers running monthly between Fiji and Sydney, and these convey each month an average of some 35,000 bunches of bananas, besides a large quantity of pines to the Sydney markets, while about 5000 bunches of bananas are shipped monthly by the Melbourne steamer, and about 3000 bunches to Auckland, New Zealand, whence they are transhipped to the southern ports. These figures will serve to show to what large proportions this industry has already grown. The bananas are at present purchased from the growers by the shippers at 1s. 6d. per bunch, but it seems probable that through the brisk competition now existing amongst growers, this price will soon be reduced unless sustained by the operations of the preservers, as the colonial markets are not capable of much further extension. Pines are purchased at about 2s. 6d. per dozen, and packed in boxes for shipment. The freight paid on bananas is generally about 1s. per bunch, and hitherto the principal shippers have found their business fairly profitable although their returns fluctuate greatly, for during the summer season, severe losses are sometimes sustained by the fruit becoming over-ripe in transit. So much is this the case that on some occasions the fruit has had to be dug out and thrown away on arrival at Sydney.

On the departure of one of the inter-colonial steamers, the scene caused by the presence in the harbor of the innumerable small craft arriving with fruit, is not only a busy, but an attractive and interesting one, presenting all the excitement of a regatta. The banana boats, as they are termed, are generally large, open or half-decked boats, similar to those used by the watermen of Sandridge. They carry a large spread of canvas, sail well, and are handled very expertly by their native or half-caste crews. Immediately on the steamer dropping her anchor in Suva, after her arrival from Levuka *en route* to Sydney, she is surrounded by some 40 or 50 of this mosquito fleet, amongst which will be found small steamers, the property of the large shippers, towing punts laden with fruit. A great struggle, in which fisticuffs are sometimes resorted to, ensues for a good position opposite the gangway, for the impartial rule "first come, first served" is invariably adhered to. The fruit is taken in from each side, and at both main and fore hatches. Stages are rigged on which to pass the fruit from the boats to the deck, and "taking in" commences. As each bunch is handed from the boats, it receives on the stalk a dab of point, the colour denoting the ownership. The owner or his representative is seated above, on the bulwarks, and keeps tally, rejecting all bunches which do not come up to the standard. An officer of the steamer opposite him, checks the owner's tally, while one of the crew receives the fruit on deck and passes it on down the hold, keeping up the monotonous cry of one, two, three, four, five, six, seven, eight, nine, ten, tally! continuously. The holds of the steamers are especially fitted up with stanchions supporting gratings on which the fruit is carefully stowed away, and when the whole of each shipment is received, the tallies are compared, and the shipper hurries ashore to get his bill of lading or shipping receipt signed. On several recent occasions, the fruit offered has been in excess of the stowage capacity of the steamer, and this has led to frequent disputes among the shippers, who have even come to blows in the course of the contention, to get their fruit shipped. Such instances are, however, rare.

After the departure of the steamer, a settlement is effected between the growers and the shippers who have purchased their fruit, and the money thus paid is soon put into circulation amongst the stores in town, making a considerable increase on their takings over the general daily average.

Besides the bananas and pine apples, coconuts in the shell are another considerable item of export, and the delicious Indian mango and custard apple being now thoroughly acclimatised, will, doubtless, with the paw-paw or mammy apple, soon be shipped in quantity to the Australian markets, both in a fresh and preserved state. It is to the fruit preserving business, however, that growers look to find in various parts of the world yet untouched a market for their produce.—*Melbourne Leader.*

PROCEEDINGS OF THE AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA
for January 1888.

Box-wood and its Substitutes.—About 30 years ago the Society, in view of the diminishing supply of European Box-wood, offered its gold medal, and the sum of R500 "to the discoverer of any wood indigenous in India, and procurable in sufficient quantity, which shall serve as an efficient substitute for Turkish box, especially for wood engraving." Several kinds of wood from various parts of India, the produce of other trees, were submitted for competition for this prize. It was eventually awarded to Capt. W. G. Hay for 10 logs of *Box-wood* from the Punjab, it being considered, on the authority of Mr. Whitly, wood engraver to the School of Industrial Arts, Calcutta, equal to that procured from the Levant. In consideration of the valuable information on a kindred subject, communicated by Mr. Geo. Jephson, and for the trouble and expense to which he was put by a second reference from the Society, a premium of R500 was also awarded to that gentleman. (Jour-

nal, vol. xi, p. 473). The Society has since received other communications on this subject, but not of sufficient importance to warrant further enquiries. Of recent years the continued diminishing supply of European Box-wood has been attracting attention, and notices thereon have appeared in several periodicals, notably in the *Journal of the Society of Arts*. The latest communications were published in the numbers of 10th and 17th April 1885, and of 19th March 1886, of that journal.

Insecticide for Tea.—In the Proceedings of September 1886, mention was made of an Insecticide to which attention had been drawn at a meeting of the Royal Horticultural Society of London, by Professor Church, and Mr. Elwes stated that he thought it might be made applicable to Tea. The manufacturers were communicated with, and very kindly sent a barrel of the Insecticide and a garden engine for applying it, to the Society. These were made over to Mr. J. Davenport, to whom the Society are indebted for a fair trial having been given to the wash. The following Report has been received from Messrs. J. Davenport and Co. —Calcutta, 9th December 1887. *The Secretary, Agricultural and Horticultural Society of India.* Dear Sir, —We have the pleasure to hand you our Manager's report on the Insecticide sent up some time ago, and to which we have, until lately, found it impossible to get any Manager to give a thorough and practical trial. As we expected, Mr. Jamieson's report is not very encouraging. The cost of material and labour puts the application quite out of the question, and Tea will have to go to the wall when we can only preserve the bushes from blight by such a costly process.—Yours faithfully, Davenport & Co.

Second Fallodhi Tea Co., Ld., 7th Dec, 1887. Messrs. Davenport & Co., Calcutta.

Insecticide.—This has been tried on half an acre of tea on Moripahar. A time was chosen when there was a break in the rains, and when the piece selected had, in common with the surrounding tea, been attacked by mosquito, but showed signs of a flush breaking through. As I had not much of the emulsion, I thought it better to test its capabilities as an eradicator rather than as a preventive. A dry time was selected so that the emulsion would not be washed off the bushes by the rain, and a piece attacked by blight as a test as to the destructiveness on the blight of the mixture. The strength used was two ounces to a gallon of the water, and 3 applications were given, one a day, on three consecutive days. The piece was then allowed to run for a week, and then plucked and yielded 32 lb. of green leaf against 500 lb. from the remainder of the block of 29 acres. In the first instance the insecticide certainly did good, as its application evidently caused the flush to develop better. No more insecticide was applied, and the result of a second flush was awaited. This, however, never came, as the piece experimented upon became as badly blighted as the rest of the block. It appears, therefore, from this experiment, that as far as a block of tea surrounded by other tea goes, a strong application of the insecticide does good temporarily only.

Cost of application.—Cost of insecticide not known. In the present experiment, it took four men daily to half an acre, but allowing that four men in work could do an acre thoroughly, to apply the insecticide within a month to a 300 acre garden, would require 10 machines and 40 men daily, one application only; and should the benefit derived from its use prove temporary only, as in the experiment under notice, the benefit derived would not pay the cost of application. Besides the cost of the emulsion, the cost of washing machines would have to be taken. To apply one application thoroughly with a strength of two ounces per gallon, would require 5½ gallons per acre, or for 320 acres 1,050 gallons.

Judging from the small experiment made, the insecticide does not seem likely to prove a success as an eradicator of mosquito blight. Mosquito with us lasts from two to three months, and seems to come and go during that time. For instance, a part of the garden may be blighted in August, yield fairly well in September, and be closed again in October. To apply the insecticide as a preventive, it would need to be applied within a few days over the whole area of the garden, and to do this would necessitate a far larger number of men than most gardens have at their command, leaving out of the question the enormous number of machines which would be required. On the other hand to take a month for one application over the whole area of the garden would be next to useless, as the first treated portions would, by the time the whole garden was finished, be blighted, as from the experiment tried, the effect of the insecticide does not seem to last for more than a week or ten days. Another matter to be considered is, the mosquito generally first appears in August-September, the two wettest months of the year. If the insecticide is to be used as a preventative, it should be applied during September. During this month it is very rare to have 24 hours without rain, which would wash the stuff off the bushes and nullify its effect. The opinion I have come to is, that would one application stay the progress of the blight permanently, the insecticide would be a great success, but if, as the experiment seems to show, its effect is only temporary, its repeated applications would be impossible on any ordinary tea garden. The washing machine can with difficulty be got through lines of tea planted 4'×4'. The leaf from the experimental piece having been allowed to run for a week after the application of the insecticide, no odour or taste was perceptible in the leaf or manufactured tea.—Yours faithfully, A. Y. M. Jamieson.

Castor Cake Tea Fertilizer.—Messrs. Macneil & Co. made some enquiries regarding the cultivation and machinery required for growing Castor, and for extracting the oil, they explained their object in making these enquiries as follows:—

"It occurs to us that provided castor seed can be "obtained in quantity and cheaply in Eastern Bengal "or Sylhet, Cachar, and a market could be found for "the oil, worked on a large scale the cake produced "would ensure a supply of manure suited for application "to the gardens, and on these points we would be "glad if you would give us the benefit of any imfor- "mation at your command."

The machinery employed for pressing is worked by hand-power, and is of simple construction, and is found to answer the purpose as well as those of greater power, as in practice it is found that the pressure has to be applied gradually, and the process cannot be hurried. A wood-cut of one of the presses in common use in Calcutta, with details as to its capacity was kindly furnished by Messrs. Jessop & Co. for Messrs Macneil & Co's information.

At the drug sales this week, a root was offered under the name of Ipecacuanha, which bears a distant resemblance to that drug externally, but internally has not the hard woody centre characteristic of true ipecacuanha. The drug is said to have been shipped from India under the name of "medicine root." It appears to have met with a ready sale, presumably in consequence of the now recognized value of ipecacuanha cultivated in the East Indies.—*Pharmaceutical Journal*.

Preservation of Flowers.—A method of preserving the natural colours of flowers recommended by R. Hegler, in the *Deutsche [illegible] Monatshefte*, consists in dusting salicylic acid on the plants as they lie in the press, and removing it again with a brush when the flowers are dry. Red colours in particular are well preserved by this agent. Another method of applying the same preservative is to use a solution of 1 part of salicylic acid in 14 of alcohol by means of blotting paper of cotton wool soaked in it and placed above and below the flowers. Powdered benzoic acid yields nearly as good results. Dr Schoeland, in a paragraph contributed to the *Chemiker Zeitung* (No. 21, p. 82), recommends, as an improvement in the method of using sulphurous acid for preserving the colour, that in the case of delicate flowers they should be placed loosely between sheets of vegetable parchment before immersion in the liquid, so as to preserve their natural form.—*Pharmaceutical Journal*.

FUEL FOR TEA IN CEYLON.

If the planters in mid-Dimbula and other similarly situated districts do not at once set about planting for fuel, it is quite certain there is a bad time coming for them. Already it is whispered that coolies are accustomed to "get a name" on some place or places, for going where they please, prowling far and near (on moonlight nights) over neighbouring estates and into Crown forests, no matter where, so long as they come back with a load of firewood! The way too in which coffee stumps are being cleared off for firewood for cooking purposes by coolies is a caution. Now what is being done to meet the absolute necessity for fuel? Some men, we know, have done their duty in planting quick-growing trees. But the case is one for general and immediate effort on the part of our planters generally, just as much as the re-planting of their coffee-land with tea has been. We want to see every tea plantation with a belt round its tea fields, within the boundary, of three chains deep of blue gums (see "J. L. A."'s testimony to their value the other day), grevilleas, or some equally good tree. Apart from the provision of fuel, such a planting—all over Dimbula, say—could not fail to increase the value and safety of property in many ways. Some men may be counting, as we hear, on a big central factory at Talawakele with machinery driven by the river and coal for drying purposes; but we suspect, even if such an establishment were erected, the circuit of gardens that could be economically served is far more limited than such planters suppose. One of the shrewdest, most particular men in the country assures us that, working with his own capital, a first-class garden and all appliances, with plenty of reserves for firewood, he cannot place his tea in Colombo under 33 cents per lb. He has done small parcels without counting tear and wear at 28 cents; but, even if gathering 500 or 600 lb. an acre, he does not consider less than 33 cents to be generally practicable. How then will it be for the large expanse of old coffee land yielding from 180 to 350 lb. per acre at present, or, possibly, even lower prices, more especially if there is to be extra expense about fuel.

THE BRITISH INDIAN TEA COMPANY, LIMITED.

The following is the half-yearly report, January 1888:—The actual out-turns at the several factories are given in the following table, showing the comparison with the original estimates, details of which were given in the last July report:—

ASSAM DIVISION.

	Estimates.	Actuals.	Increase.
	lb.	lb.	lb.
Mankotta and Rhea...	76,000	80,195	4,195
Sessa	100,000	113,505	13,505
Total Assam.....lb.	176,000	193,700	17,700

CACHAR DIVISION.

	Estimates.	Actuals.	Increase.
	lb.	lb.	lb.
Sildoobie	84,000	86,640	2,640
Dwarbund.....	160,000	178,710	18,710
Urrunabund.....	100,000	123,000	23,000
Kharspore.....	116,000	117,000	1,000
Total Cachar.....lb.	460,000	505,350	45,350
Grand Total ... lb.	636,000	699,050	63,950
Grand Total ... mds..	7,950	8,738	788

From the above figures it will be seen that the actual out-turns have exceeded the original estimates by 788 maunds, or 63,050 lb. of tea, the increases being mainly at Urrunbund, Dwarbund and Sessa. With regard to the quality of the part of the crop already sold, viz., 522,000 lb. the directors are sorry not to be able to report a greater improvement than has really taken place, but considering the great fall in the market value of tea during the past year, in which the prices were even lower than in 1886, added to the fact that the quality of the Cachar crop generally has again been very poor, the result is not altogether unsatisfactory. The price realised for the above quantity is 9·048. per lb. gross, showing a drop of only a ½d as compared with last season's average to the same time, although the market has declined considerably more than that. On the other hand there has been a reduction of about ¾d per lb. in the outlay expenditure, freight, dock dues, &c., so that at the present time, with a lower price obtained for the tea, the company stands in a better position than it did last year, on account of lessened expenses and increased out-turn; it is hoped that the cost per lb. will not exceed 7½d a very low figure at which to lay down tea in London, inclusive of all charges. The statistical position of Indian tea, both as regards imports and deliveries, being now so favourable. It is probable that prices will strengthen rather than decline during the next few months, when the balance of the crop will be sold.

ARTHUR R. CAPEL, Chairman.

CEYLON UPCOUNTRY PLANTING REPORT.

MERCHANTABLE COFFEE—DROUGHT AND PRODUCTS.

20th Feb. 1888.

The discussion as to what is "MERCHANTABLE PARCHMENT," which has come up again in the *Observer* columns, is worthy of the attention of planters generally. That it should crop up always when the market is against buyers, is suspicious enough, but where the shoe pinches most is, that, when the question arises as to whether parchment coffee or any other product in fact is "merchantable" or otherwise, it should have to be decided by arbitrators of whom *none* are planters. Such an arrangement is very one-sided indeed; and only wants on the part of the planters a firm and general stand to have it righted. The instance which your correspondent gave of how utterly unreliable some awards have been, points to the necessity of a reconstitution of Arbitration Boards. Merchants and brokers, who pretend to be alone clearly able to judge, and who sit in solemn conclave over disputed parcels, want the presence of a planter in their midst to help to guide them when a falling market has blinded their eyes, and otherwise dulled their senses. With the good case which your correspondent has, he might well being the matter before his district Association, so that means might be devised for a reform, which is certainly much called for, and cannot be inaugurated too early.

The DROUGHT, which for some weeks has been an everlasting topic of conversation, is somewhat put out now by the new theme of how to account for the irregular distribution of the late showers. When you hear of a place a few miles off registering 3·90 without counting hailstorms,—these I presume would require to go in by the hundredweight,—while other estates in the near neighbourhood tapered off from 0·25 to nothing at all and alike equally burnt up, you certainly have some food for thought. It is comforting, however, to mark how the men who have been overlooked, regard the unequal distribution, and how they establish a security of mind by concluding that the excessive downpour experienced by some must have done more harm than good; while a sprinkle of a quarter of an inch to tea trees with a big thirst in could only tend to worry and fret them more.

Its a good soaking that they want, they say, and they are prepared to wait for it.

Meanwhile much of the TEA is suffering exceedingly; CACAO, although willing to flush into leaf, is at a standstill as far as a spring blossom is concerned; while COFFEE in any kind of heart at all is sticking full of spike: what that spike will come to depends on bug and leaf disease more than aught else. PEPPERCORN.

BADULLA PLANTERS' ASSOCIATION.

From Report of the Annual General Meeting held 4th, Feby. 1888.)

COFFEE.—The coffee area has not been reduced ot any great extent during the past year: estimates of crop were in every case, so far as your Committee can learn, realized, and in many cases largely exceeded added to which the price of coffee has been more satisfactory than for a number of years past.

LEAF DISEASE AND GREEN BUG.—The past year has been one of comparative freedom from leaf disease, but your Committee cannot but view with anxiety the continued presence of green bug for which no remedy appears to have been discovered.

CINCHONA.—Your Committee regret the very low prices ruling for this product during the past year, the price having been quoted at one time as low as 1§d per unit of quinine, the lowest price on record. Your Committee, however, are hopeful of the future of Cinchona. Exports from Ceylon have fallen off to a very considerable extent, and prices in the London market have now improved. Your Committee are convinced that the stocks of cinchona bark in Ceylon are rapidly becoming exhausted. A large area of land once growing this product has been cleared out for tea, and, but little cinchona has been planted during the last few years. Your Committee, therefore, are confident that prices in the future must improve; they would urge upon growers to moderate their shipments as far as possible.

TEA.—Four years have now elapsed since the introduction of tea into the districts represented by your Association; but even so recently as that date, although it had been clearly proved by statistics that both soil and climate were eminently adopted for its successful growth, the cultivation was still looked upon by many with serious doubt. The success however of these experimental clearings was so great that confidence was at once esblished, and the following year saw many hundreds of acres of land, which had ceased to yield remunerative crops of coffee, successfully planted with tea. Since that time planting has gone on steadily year by year, and at the present date there cannot be less than 1000 acres under tea ranging from those just planted up to those four years old. The enterprize has now passed far beyond the experimental stage, and some practical results of a most interesting and encouraging nature are now available in the shape of yield per acre and prices obtain for the produce in the London market. Your Committee is much gratified in being able to report that the yield from fields now in partial bearing exceeds the most favorable opinion formed of them at an earlier stage of their existence. From tea embracing the period twixt one and a half to 2½ years old the yield over large areas has averaged from 80 to 100 lb. per acre; while tea a year older has given as much as 350 lb. made tea per acre in ten months, some estates have given from 10,000 to 20,000 lb. of tea as their maiden crop and estimates ranging up to 75,000 lb. of made tea are returned for individual estates for the current year. The quantity of the tea produced and the price obtained for it have been highly satisfactory, being fully up to the average of the most favored districts in the island. These are facts which commend themselves to the earnest consideration of everyone interested in Uva. The prospect with regard to the *production* of tea is indeed bright and promising, yet one thing remains to render the enterprize a complete financial success, that is, cheap, safe, and speedy transport, such as can only be afforded by a railway. Until such relief is given to Uva at some central point to which all or nearly all the traffic would naturally converge your Committee are of opinion that the enterprize will be heavily handicapped in competing with other districts enjoying greater facilities for transport.

CACAO.—Cacao cultivation is being extended in Monaragala with every prospect of it proving a permanent success. The older cacao has now been in bearing several years, and notwithstanding the long drought experienced in the past season, continues thoroughly healthy and vigorous.

Helopeltis and other insect pests have disappeared, and your Committee do not think that these need give any further cause for alarm.

THE SOUTH OF INDIA PLANTING DISTRICTS.

COFFEE estimates generally have fallen short of expectation in the Neilgherries and Wynaad, but prices ruling last year encouraged planters to manure highly, and they will reap their reward in due course, but it is in the more northern districts that coffee is "King" in every sense of the word. Coorg expectations were great and have scarcely been fulfilled, but in Munzerabad estimates have been largely exceeded and Koppa is not behindhand. Estates are being worked on a very liberal scale, and the demand for manures has been great.

CINCHONA.—Large shipments of this produce are being made from Beypore and Calicut from the Neilgherries and Wynaad and the falling-off in Ceylon exports in the article is much appreciated.

FREIGHTS are ruling cheaper and planters are recognizing the fact their West Coast agents are doing the best for the interests of their constituents.

CHOCHO.—Mr. Arnold Dias, of Panadure, living close to the seaside got three plants of chocho about four months ago and one has produced some 50 fruit of a very good size, judging by 3 Mr. Dias has brought to us, while the other two are in flower. Mr. Dias strongly recommends the people in the lowcountry to cultivate this vegetable.

PAPER MILLS having succeeded in Northern India so as to pay in some cases 20 to 30 per cent in capital invested, it is now intended by enterprising British capitalists to establish flour mills on a large scale. We are surprised, talking of mills, that neither Parsee nor Sinhalese capitalists have established a cotton mill in Colombo. One such establishment ought to pay very well we should think.

OPOPANAX.—The botanical origin of the gum resin opopanax, as well as that of sagapenum, has long remained a mystery. In the December number of the *American Druggist*, the editor points out that Dr. J. L. Schlimmer, in a valuable work entitled 'Terminologie Médico-Pharmaceutique et Anthropologique Francaise-Persane,' 1874, p. 410, states that the Persian name of the former is *djaw-chive*, and that Dr. I. E. Polak gives as the source of it *Diplotænia cachrydifolia*, which occurs in high mountains extending northwards of Teheran, particularly near Azadbar. The plants when in bud, or the young shoots are used by the Persians as a culinary vegetable, both fresh and pickled in vinegar. But it is not yet known whether the *Opopanax persicum*, Boiss, which Mr. Kotchy has found near Ostenbagh and Demeri in the same mountains, and which is said to furnish opopanax, is the same plant. In any case, the editor of the *American Druggist* is mistaken in supposing that the opopanax used in perfumery is the article which until within the last few years was known as opoponax, and which unquestionably may be ranged among the fetid gum resins, having an odour like bruised ivy leaves, but more disagreeable.—*Pharmaceutical Journal.*

Correspondence.

To the Editor.

THE CEYLON CACAO CROP OF THE SEASON NOT TO EXCEED 12,500 CWT. PROBABLY.

DEAR SIR,—Cacao shipments to date are 3,500 cwt. short of what they were at this time last year. With this early and extreme drought again during the twelve months, it is very unlikely that the balance of the season will ship what it did last year, but even allowing that it does, that would still only make a total shipment for the year off 12,500 cwt. CACAO PLANTER.

CEYLON TEA FUND: CEYLON TEA AT BRUSSELS.

Planters' Association of Ceylon, Kandy, 22nd Feb. 1888.

SIR,—I beg to invite attention to the following telegrams regarding the Brussels Exhibition.—Yours obediently, A. PHILIP, Secretery Ceylon Tea Fund.

Copy telegram to Mr. J. L. Shand, transmitted on the 20th February:—"If cannot sell tea cup withdraw (from) Brussels, wire reply."

Copy telegram received from Mr. J. L. Shand on the 22nd February:—"Cup sales, Brussels arranged.

CEYLON TEA AND THE GLASGOW AND BRUSSELS EXHIBITIONS.

24, Rood Lane, London, E.C., 27th Jan. 1888.

The Secretary, Planters' Association of Ceylon, Kandy.

Dear Sir,—I have been asked by Messrs. Reid and Cargill to keep you informed from time to time as to what we, as an Exhibition Committee, are doing.

I sent you copy of a circular letter addressed by us to the London firms chiefly interested in Ceylon, and I am glad to tell you the response to it has been very favorable:

Messrs. Matheson & Co. guarantee	£100
James Whittall, Esq. ..	50
Messrs. Baring Brothers ..	100
Do Spence & Aitken ..	50
Oriental Bank Estates Co. ..	20
Messrs. J. A. Hadden & Co. ..	20
Ceylon Land and Produce Co..	10
Messrs. Arbuthnot, Latham & Co.	50

And I have appointments fixed with others interested, which I am hopeful may result in further subscriptions.

The object of this guarantee is that we may do the thing properly, and that Messrs. Reid, Cargill and myself may not find ourselves with money gone and necessary work to do at the end, in other words as used by Sir Arthur Birch under similar circumstances "may run no risk of spoiling the ship for a haporth of tar." Judging by my Liverpool experience we shall require to go £1,000 out of pocket before we have any income:—

Tea-house will cost say	£400
Decorations and fittings of court say ..	150
Packing exhibits, freight by sea and land ..	200
Native servants say	150
Contingencies, attendance, &c.	100
	£1,000

But if the Glasgow Exhibition turns out as we all expect, this money and a good deal more will readily return.

The latest news about the sale of Indian teas at the Glasgow Exhibition is that a firm has paid £2,400 for the concession, so I think the arrangement made by the Ceylon Committee is by no means an unfavorable one.

Until the buildings at Glasgow are completed, we can of course do little towards getting on. I have sent down my attendant, who was at Liverpool last year and at South Kensington the year before, who will get on with the preparation of the site for the tea-house and with the gradual unpacking of exhibits, but not much can be done until we have the court ready for the reception of exhibits. I hear Mr. Aitken is expected in London in a day or two, and he will be able to tell us what has been done about a representative in Colombo, for there are several things, such as selection of native servants, which must be left in Colombo hands. I think I can pick up one or two on this side, but I found last year that if I had been in time and had some one looking out in Colombo I could have easily brought all my servants over for nothing, as home comers are often prepared to pay passage in consideration of services rendered on the voyage, but don't care to be burdened further. Some of my last year's servants would gladly return upon these terms. I hope the P. A. and others beside the P. A. are getting on with exhibits: we ought to have everything here very early in April if we are to be ready for the opening. Natural history exhibits are specially required.

BELGIUM.—I have had meetings with Mr. Lee Bapty once or twice since writing to you, and Mr. Reid and I went to a meeting at the Mansion House of which I enclose programme, all the resolutions were passed, but the Lord Mayor announced that the labours of the proposed Commsttee were simply honorary. Mr. Reid and I called yedierday on Mr. Bapty, who told us that he was spending a large sum of money upon erecting a building at the Brussels Exhibition, and that he looked to recoup himself by rent for space and letting out refreshment contracts. He is quite prepared to meet us in the matter, and we told him, provided suitable space was allotted for a Ceylon Tea Room, we were prepared to expend £300, half of which should be spent upon passage and wages of native servants. We, of course, should have control over the Tea Room and it should have a distinct footing of its own and be unconnected with any other refreshment department.

I think there is no doubt we shall be able to carry out this arrangement if after investigation we find the game is worth the candle, for of course it is possible to pay too much for an advertisement; but I would urge upon your Committee the desirableness of placing us in a position to apportion the Glasgow and Brussels grants, bearing in mind that the consumption of tea in Glasgow and the immediate vicinity is more every month than the whole annual consumption of the Belgian Kingdom. I shall soon let you know, I hope, that something has been settled. I am to see Mr. Bapty again tomorrow.—Faithfully yours,

(Signed) J. L. SHAND.

COFFEE IN SOUTHERN INDIA.—The two Coonoor coffee properties, which have done well last season, are the Hillgrove and Pillioor. The former has always been a model estate.—*Nilgiri Express*, 18th Feb.

CINCHONA.—We learn that the Quinologist has been deputed to visit the Government Cinchona Plantations at Darjeeling, Mr. Hooper will be absent from Ootacamund for about a month on this special duty.—*Nilgiri Express*, 18th Feb.

"GOLD, GEMS, AND PEARLS."—A gentleman who received an early copy of this volume writes:—"I beg to acknowledge with many thanks the receipt of 'Gold, Gems, and Pearls.' I think the community is greatly indebted to those who perform the laborious task of writing and compiling the exhaustive works with which your names are connected. I shall read this book with great interest."

"PITCH-BLENDE" OR "URANITE."—A specimen of this mineral, found by Mr. de Mel in one of his plumbago mines in the Kurunegala district, has been shown to us by Mr. George Armitage. Its specific gravity is very great, and from it is obtained "uranium," which comes next to gold, platinum being above gold, in specific gravity. Uranium is a very scarce and dear mineral sold by the grain and used in pottery painting we believe.

FRESHWATER FISHES AND THEIR CULTURE:

CARPS, TOOTHLESS, BUT WITH COMPENSATING ORGANS;

THE "LÉLÁ" AND "LÚLÁ" OF CEYLON.

We have received a letter from Mr. A. Haly, Director of the Colombo Museum, as follows:—

"The bones sent to you by Mr. F. W. Gray are not jaw bones. Technically speaking the whole of the carp family are toothless; to make up the deficiency the pharyngeal bones are more or less powerfully armed. As soon as I can procure a sufficiently large specimen, I will mount a skeleton to show this peculiarity. Some fish carry teeth both in the mouth and throat."

Then, if we understand Mr. Haly aright, the formidably armed bones which Mr. Gray sent us are not true jaw bones, but toothed portions of the throat of a fish, "the mighty mahseer," as Thomas calls the gigantic carp (gigantic as found in Indian rivers) *Barbus tor*. For a description he refers (in his "Tank Angling in India") to his great work "The Rod in India." It is evident from Mr. Thomas' smaller and more popular work just published that this perhaps greatest authority on the freshwater fishes of India was no more aware of the existence of the mahseer in the rivers of Ceylon than we were, until the recent discussion arose. Mr. Thomas states in his recent work that the habitat of this giant of the carp tribe is "generally throughout India, but in the largest size and the greatest abundance in mountain streams or those which are rocky." In the native synonyms given by Mr. Thomas the Tamil form is *Poo-meen-candee* ("flower-fish-*kendai*," the latter Tamil word being, according to Thomas, the lax generic term for carp); but there is neither Sinhalese synonym, nor the least hint that the great South of India Fisher was better informed than we have hitherto been as to the existence of the true mahseer in Ceylon. There is this to be said for us, that no one connected with the *Observer* is a sportsman. We knew of the "Lúlá" as our best fish, and we enjoyed eating a portion of one taken out of the great Kalawewa tank. But of "Lélà" as contradistinguished from "Lúlá" we never heard until Mr. Haly used the word as the Sinhalese synonym of *Barbus tor*, the mahseer. Although Mr. Thomas does not seem to have heard of the "Lélá" (which we have never seen mentioned in any leading work on Ceylon) he knew all about our "Lúlá," *Ophicephalus striatus*, the *Verálu* and *Kuruppu verál* of the Tamils. From Mr. Thomas' description of this snake-like but excellent edible fish, we quote as follows:—

"Habitat.—Fresh waters throughout the plains of India, Ceylon, Burma, to China and the Philippines, especially delighting in swamps and grassy tanks; they attain 3 feet or more in length. They take a bait very readily, especially a frog, and are said to rise to the salmon fly."

"*Ophio-cephalus*, the snake-headed or Marral is treated at length in *The Rod in India*, pages 174 to 186, and page 82 supra, and is figured in both books. The remarks are applicable to all the *Ophiocephalidæ* except *O. gachua* which is diminutive, and best suited for a bait, page 53 of *The Rod in India*."

Ophicephalus gachua mentioned above is a Ceylon fish, the *Para korawa* of the Tamils, but Mr. Thomas gives no Sinhalese synonym. We quote what he says of it:—

"Habitat.—Fresh waters throughout India, Ceylon, Burma, and the Andamans, also near Gwadur on the Mekran Coast. This fish is often found thriving at the bottom of wells, and in fact may be taken from the waters of the plains to the very high elevations. It attains at least 13 inches in length, is very voracious, and may often be captured in little watercourses, into which it has pursued the *Haplochili* and other small fish."

Is it not strange that Sir Samuel Baker, although he mentions the "Lúlá," says not one word about the "Lélá" or mahseer? We should, now that the existence of the great carp in our rivers, at least in the Mahaweliganga, is a settled fact, like to know who the naturalist or fisherman was, who first described the fish (identifying the Lélá as the mahseer) as an inhabitant of our river waters or mentioned having caught it? A couple of years ago in the Dolosbage district we met the veteran sportsman Mr. Watkin Williams Wynn, who interested us with a graphic account of a fishing trip on which he had been and its results. We do not recollect his mentioning the mahseer, but perhaps he may contribute to the fund of knowledge on the subject which we are now acquiring. "Fisherman," in a recent *Observer*, is overwhelming. He tells us that the fish of whose very existence we were not aware, and which to our knowledge we have never tasted (freshwater fish is generally carefully excluded from European tables, as either insipid or dangerous), is not rare, but exceedingly common, even in Colombo! Contrary to Mr. Haly's statement, "Fisherman" asserts that it exists in the suburban paddy fields and in the Colombo lake! When he next sees a good specimen "hawked about," we should be glad if he secures us a look at it. In India the mahseer attains a weight of 70 to 100 lb. Is there any record of the largest and heaviest ever caught in Ceylon? "Fisherman" mentions some the size of a seer fish, but seer vary greatly in size. Thomas describes five *Cybii* and states that they are commonly known to Europeans as seer fish. Of *Cybium guttatum* he writes:—"Grows to 6 feet in length, is good eating and salts well. Specimens under a foot in length are dry; from two to two and-a-half feet long they are the in the best condition, above that they become coarse." We presume that "Fisherman" meant medium seer of about 2½ to 3 feet long.

Of fifteen carps noticed by Mr. Thomas in his "Tank Angling," only two have Ceylon mentioned as their habitat. One, *Barbus mahecola*, is a small fish, only 6 inches in length and a quarter of a pound in weight. Another, *Barbus hexastichus*, referred to the Himalayan region and Assam, grows to 3 feet in length, and Mr. Thomas adds: "Ceylon examples, which seem to be a variety, have a longer dorsal spine, it being equal to or a little longer than the head." Mr. Haly, who says that the mahseer is so variable that five species have been made of it, has, we suppose, satisfied himself that Mr. Le Mesurier's local specimen is the true mahseer, *Barbus tor*, and not merely *Barbus hexastichus*? If there is an essential difference between the mahseer of Ceylon and that of India, it ought soon to be made apparent, for true mahseer fry from India are in the Nuwara Eliya lake. How they got there, Mr. Thomas records in his very interesting book on "Tank Angling":—

When lately sending Mahseer fry by request to Ceylon though by the way it has since been discovered that they have them indigenous, it was on mosquito larvæ that I relied entirely for their food. When first caught and kept in pots till their numbers were made up, it was on mosquito larvæ that they were fed. When they came off their rail journey of 327 miles from Mettapolliam to Madras, which they did at an hour when my engagements would not admit of my meeting them myself, I simply told my native servant see they have a good dinner when they come in. He knew from old experience that for fish a good dinner must mean mosquito larvæ, and could

not possibly mean anything else, and answered in that sense at once; and when the young Mahseer arrived there were tens of thousands of mosquito larvæ awaiting them. The next morning I looked them all over myself, and gave them their *chota hazari* (early meal) of the same, and, that they might not faint by the way, when putting them on board the steamer from Madras to Ceylon, I sent an extra potful of refreshments of the same sort, and the man in charge was instructed, on arrival at Colombo, to obtain a fresh supply in the bazaar and give the fry a substantial meal thereof before calling on them to undertake the fatigues of the railway journey from Colombo to Nuwara Eliya. This he did, and the result was that out of 21 Mahseer fry shipped from Madras to Nuwara Ellaya 19 reached their mountain stream well and vigorous, the two that failed failing by reason of extra vigour, jumping out of their pots where the covering net had got displaced.

The man no doubt found mosquito larvæ in abundance in the drains or pools in the vicinity of our bazaars, but we think we may safely assert that he did not find the juvenile mosquitoes amongst the commodities on sale. Mr. Thomas' book may lead to a change in this respect. He is about as enthusiastic on the virtues of the mosquito as a water clarifier and a food for fishes as he is about mahseer and *labeo*, and that is saying a good deal.

Since writing the above we have been able to refer to a paper on the freshwater fishes of Ceylon contributed to "The Friend" by the Rev. D. H. Pereira, in which the *lélá* is described as contra-distinguished from the *lúlá*, but neither does this writer seem to have had any idea of the identity of the Ceylon *lélá* and the mighty *mahseer* of India, which, in the pools of the Himalayan rivers, attains a size and weight so truly gigantic and affords sport over which anglers like Mr. Thomas became ecstatic. We were aware that Maskeliya derived its name from the abundance of fish in its Peak-born stream, and classic interest attaches to that stream from the reference made to it and its finny inhabitants in the elegant poem of Sri Rahula Sthavira of Totagamuwa, *Sela Lihini Sandese*,—"The Sela's Message." A bird identified by the late W. C. Macready in his scholarly translation of the poem with the *maina* is sent to deliver a message, and the various places it passes are described. Amongst the rest, Maskeliya :—

4..Thence flying, view *the ford* Maskeliya,
3..Where Lellu (*a*) fish are playing, making globes
Of foam and rippling eddies (*b*), 2..rolling o'er
And o'er each other, (*c*) leaping from the wave
1..Fearless, (*d*) *to snatch* the food which multitudes
Of people bring and throw *into the stream.*

(*a*)..Lellu fish are an edible fish found in many rivers of Ceylon.

(*b*) *lit.* wrinkles of waves; breakings or divisions of waves.

(*c*) *lit.* each other's bodies.

(*d*) *lit.* without alarm or shrinking; to snatch, *lit.* after the food, for the food, *dative case.*

It is quite evident that Mr. Macready was not aware of the identity of the "edible fish" found in many rivers of Ceylon with the mahseer; for in the Glossary which he appends to the poem he has simply: "ලෙලෙල්ලා, *s.* a fresh-water fish, called Lella. ලෙලෙල්ලන් *pl.* 51." As the pilgrims bound for Adam's Peak crossed the ford referred to, there can be little doubt that they were the multitudes of people mentioned as throwing food to the tame and confident fish. We presume the practice is continued, and that "merit" is supposed to be gained by feeding the fish? If we are correct in our surmise, that the fish are still fed as of old, mahseer of the largest size ought to be found near the Maskeliya ford. Can any local resident send us an account of the largest *lélá* ever found in the river? Mr. Pereira, in his notice of the *lélá*, refers to the passage in the *Sela Lihini Sandese*, but gives a prosaic translation of his own. We quote as follows :—

Lehel peti mahangulu
Luhul walapotu teli dalu
Rehemas rankakulu
Noyek kelená maskæsubu mulu.
Bun mini men dilí
Sililen pirunu nimalí
Dolak dæka wipulí
Iwura weta inda Bamunu ekalí.

The celebrated poet, Totagamuwe, who flourished in the reign of Buwanaka Báhu VI., A. D. 1464, is the author of the above stanzas, in which he describes a wandering Brahmin preparing to take his meals at the bank of a *dola*, replenished with pure crystaline waters sparkling like the broken diamond, on the surface of which were disporting the following fishes: *lélás*, *petiyás*, *maha* (large) *anguluwás*, *lúlás*, *walpaottás*, *teliyás*, *dalás*, *rémassás*, *golden crabs*, and *maskæsubás*, edible turtles. From these stanzas it is evident that some of the fishes we have described were recognized by the ancients as purely fresh water fishes. A *dola* is a large hollow which receives the waters of mountain streams situated in elevated districts.

Danan gena damana godurata nopækiliya
Pæna pæna diyen owunowunængehi peraliya
Lehelun kelena kara pena pidu rala ræliya
Etanin piyásarakara daku maskeliya.

In the above stanza, quoted from the "Sælalihini-sandésaya," a book of great poetic merit, the same poet alludes to the fish *lélás*. In a series of verses the poet describes the path which the bird was to take in carrying his message, and when he comes to Maskeliya ferry, he says, "You will find it turning with *lélás* leaping over each other in their attempts fearlessly to feed upon the food thrown to them by the people, and, by their frolic, rippling and producing foam on the water."

These beautiful fishes are still found in abundance in the Kalani and other large rivers in the island, and are daily fished, for the Grandpass fish market, along the banks of the Kalani river. They are caught with the line, the hook baited with boiled rice or the pulp of the young coconut.

On the specific character of this beautiful fish our notes supply us with the following description. The prevailing colour, greenish above, the sides and abdomen almost white, the whole shining with a brilliant silvery metallic lustre; scales large and semicircular; the belly large and protuberant; one dorsal, one ventral and two pectoral fins of a dusky hue; tail, forked and of a blue colour; two vents to each nostril; mouth large and gaping, no teeth, four berbules. Its average size is two feet, by twelve inches round, although sometimes it reaches three feet. The flesh is delicate, nutritious, and in good repute for the table except in one season, when it feeds principally on the flowers of the *induru* which grows on the margin of the rivers. It then produces a giddiness when eaten. It resembles the *Barbus Vulgaris* in the family *Cyprinidæ*, both in the beautiful arrangements of the scales and in the *cirri* at its mouth."

Here, it will be observed, the *lélás* and *lúlás*, distinct fishes, are represented in Mr. Pereira's first notice as disporting together with other fish in the same *dola* or pool. In the extract from the bird message poem the *élás* alone are mentioned, as so abundant that the waters of the river were continually "turned" (whirled or churned) by their lively actions, leaping over each other to secure the rice and other food thrown to them doubtless by the "merit-seeking," Peak-bound pilgrims. The scene was described nearly four and a half centuries ago, during the reign of Sri Prakrama Bahu VI., A.D. 1410-1462. Mr. Pereira confirms the statement of "Fisherman," that these fishes are found in abundance and are fished from the Kelani for the Grandpass market. Three feet seems the maximum size attained. The "delicate and nutritious"

flesh is described as producing giddiness at a particular season when the fish feeds on the blossoms of the *induru*. The *induru* is the *Susum anthelminticum*. *The hinguru*, with which a correspondent confounds it, is *Acacia concinna*. Gamble says nothing about the blossoms of this latter tree, but he states that "its thick fleshy pods are used for washing the hair, and the acid leaves are eaten." The question of the unwholesomeness of fish at certain seasons and the causes are worthy of investigation. Freshwater fish in Ceylon are in special disrepute amongst Europeans on account of the serious effects which sometimes follow the eating of them. A friend, who recently partook of some at the house of a native host, under the impression that he was partaking of sea fish, described to us the symptoms which followed, as determination of blood to the surface and heat which threatened apoplexy. It does not seem probable that the mere fact of fishes eating the blossoms of a tree would lead to such effects. We should rather suspect putridity, to which freshwater fish, especially those taken from muddy pools, may be more liable than sea fish? An analysis of the blossoms of the *induru* and the *hinguru* would be interesting with reference to their possession, fresh or decomposed in the rivers, of any property likely to affect injuriously the flesh of fish feeding on them. Mahseer and other fish cultivated carefully in lakes, tanks or ponds would be, of course, properly fed with rice and other suitable articles, and we might expect the flesh to be good in proportion and perfectly innocuous. Information from those who have eaten fish from ponds on estates would be valuable, with reference to fish culture in Ceylon. Its systematic pursuit has been too long neglected, and ought now to be encouraged and energetically pursued. We are far behind India, especially Bengal, in this matter. Of the *lúlá*, which has always been regarded as the best of the freshwater fishes, Mr. Pereira gives a most interesting account, which we quote to make this notice of two fishes so closely alike in quality of flesh and name, although so different in appearance, complete:—

Lúlá.—This fish, like the eel, is confined to fresh water, subsisting permanently in that element. It is called in Sinhalese *hál-pat-málu*, because its principal habitat is the undrained portions of fields in which the water is dark and the mud deep and therefore never cultivated. Other favourite resorts where it thrives best are the ponds and deep hollows where the water is not agitated by currents and especially where it has the benefit of shade from overhanging trees. If it enters a river it is by being forced out of its retreat by occasional currents produced by excess of rain, and there it has a poor chance of existence unless it is large, for it falls a prey to the *modá*. Its general colour is black above, but various intermediate shades may be observed according to the cleanness of the water; the sides are marked with a row of broad abbreviated white stripes increasing in length towards the tail; the belly and throat are marked with numerous dark spots. It attains the length of two feet; when full grown the lower jaw becomes the more projecting, it being furnished with but a few sharp teeth while the upper jaw has a considerable number of minute ones. The head is large and compressed, the gill covers small and produced backwards, the body long, and the scales small. It is a great feeder and extremely bold. It is treated almost as a domestic animal by the natives. They keep it in wells to free them of aquatic insects, tadpoles, and small frogs. It is a tyrant in its own retreat, keeping in awe all other smaller fish, and it has a special antipathy to the presence of the *kanayá*, a fish of the same family and very much resembling the *lúlá*, and the *kanaya* is eaten up wherever seen and so considered the best bait to fish the *lúlá*. There is an old saying among the natives in which these two figure to illustrate the assumption and tyranny of upstarts and of some subordinates in the absence of their superiors: "දුල නැති වෙළ, කනයා පණ්ඩිතයාවී," lúlá næti walé kanayá panditayálu, In the hollow where the *lúlá* is not, the *kanayá* presumes to display his authority. This saying is based upon the fact that the *kanayá* really assumes all the ferocity and boldness of the *lúlá* in its absence, and resembling it in appearance so very much that it is often mistaken for the *lúlá*. Although the *lúlá* commits great havoc among smaller fishes, it will not stand the attack of the *kávayyá* (*Anabus*). This wary fish would hide itself under some cover, and suddenly darting from its retreat snaps a piece from the *lúlá* and dart back again to its cover. If the *lúlá* is once wounded there is little chance for its escape as the wounded part offers a great temptation to the *anabus* to follow it and repeat its attack.

The *lúlá* is monogamous, living in pairs, and exhibits great parental instinct. In the breeding season the pair would leave their ordinary resort and frequent the shallow margins of ponds, which afford shelter from a quantity of grass growing about them and which are best adapted for the development of the ova. The female is said to deposit the ova quite matured and contained in a sack of two lobes among the grass and both the male and the female remain by its side till the spawn is hatched, guarding it with great solicitude against every foe. If driven from the spot by an enemy with which they cannot cope they do not remove far, and speedily return. The young of the *lúlá*, soon after their emersion from the ova present a beautiful appearance, the colour being purple; they keep crowding together around the parent fishes and being guided by them roam along the margin to feed. When the fry have attained a certain size, the parent fishes lead them to their own retreat and protect them with the most devoted care. But they are not long allowed to remain in a group; when they are able to provide for themselves food and protection, they are dispersed by force. For this purpose the parent fishes rush upon the shoal and sometimes bite them to effect their dispersion. This display of parental instinct for the better protection and maintenance of their offspring has given them a bad name among the natives as being fishes noted for the destruction of their own progeny.

The bony skeleton of the *lúlá* is of a peculiar construction—the vertebra has three short spiney projections extending through the whole length, one vertical and two lateral, and the flesh is embedded as if in three lobes between them. The flesh contains some thin flexible spines which renders the eating of it rather difficult to those who do not follow the primitive mode of eating with the fingers. The flesh is extremely delicate and of excellent flavour. The natives prize it so much that they consider it superior to every other fish both fresh water and the sea. Their doctors prescribe it when salted for patients suffering with fever and consumption as an article of diet suited to their health. It is not only thus prescribed for invalids, but when dried and pounded is also used in the preparation of a medicine called *chárne* by native doctors. This is prescribed to those who are afflicted with various cutaneous diseases, as the fat and flesh of the *ándá eel* are prescribed for persons suffering from hemorrhoidal diseases and hemorrhage from the stomach. Another purpose for which the flesh of the *lúlá* is used is in the manner of a poultice over ulcers infested with minute maggots which cannot be drawn out with pincers or by any other mode. For this purpose the dead *lúlá* is kept over one night to soften, and the flesh is freed from spines and applied over the ulcers—the native doctors say that the maggots enter the flesh of the *lúlá* abandoning their retreats in the ulcers.

Two other species, belonging to the same family, called *kalumaha* and *aré* attain the length of three feet and are seldom brought to the market. Their habits generally correspond with those of the *lula* and they afford excellent food for man. The *kalumaha* is blacker than the *lula* and has no white stripes along the sides, and the abdomen is of a dusky hue; the *aré* is black and spotted. These two species inhabit the deep streams which communicate with the rivers. The fishes belonging to the species *lula* are never found in the sea. We have not as yet been able to try the effect of sea water on this fish, but think it will have the same

effect as on the fresh water *modá* and *dalá* on which we have tried it, and that is it will blind them in a few weeks.

Since the above was written and the extracts made, we have seen the letter to a contemporary above initials which indicate a gentleman long resident on the banks of the Mahaweliganga in the vale of Dumbara. Here is his account of a fish which he thought resembled pictures he had seen of the mahseer, but which he now knows to be that fish:—

Sinhalese—*Cooriah, Layl Cooriah, Laylah.* Up to 5 or 6 lb. this fish is called *Cooriah*; after that it is called *Layl Cooriah*, abbreviated to *Laylah*; on the principle, I suppose, that the Grilse after a certain weight becomes a Salmon. A very handsome fish with large scales, much more gracefully shaped than the chubby *Pettiah*; in fact, he exactly resembles a picture I have seen of the *Mahseer*. I have never noticed teeth, but am told by the natives that he possesses them. Caught by the natives in deep pools, with varied baits of worms, jak fruit, rice paste, coconut poonac. Of its table qualities I cannot speak, for, as I know that at certain seasons it feeds on a poisonous nut that falls into the water, I have always declined to experimentalize. I think 'K. V.' may remember how, at a Dumbara elephant kraal many years ago, nearly the whole camp were turned inside out, and the midnight alarm of cholera we had, owing to eating this fish. Is an exceedingly game fish; when hooked runs lightly with a dash straight out into the strongest stream, and never gives in until he cannot help it, though he weakens his chances by always going up stream. Said to grow to 30 lb, but this is I fancy a mere guess. Largest I have caught 4½ lb, but I have weighed one fairly caught with reel and line 23½ lb. I did not see the catch, but was told he took out 100 yards of line, and flung himself clean out of the water three times.

Whether this fish is the Masheer or not I don't know, but I have never risen one to my knowledge with the fly, nor have I ever had a run trolling from any fish in the Mahavelliganga, though I have tried Phantoms, Spoon bait, Hearder's winnows,* and every other kind I could lay my hands on in every likely place.

The fact is, paddy cultivation spoils the river for fishing, and one has not much chance when, for eleven months in the year, it is thick with mud, and as soon as it is too dry for paddy cultivation, and the water becomes clear and low, fish kraals, netting, and dynamiting begin; so that it is small wonder that the unfortunate fish, harassed as they are, will not take a bait. The only wonder to me is that enough remain to propagate their species.

Just as I am sending this off I have seen Mr. Haly" letter. There is no doubt that he means the same fish that I have called *Cooriah* and *Laylah*.

As accounting for the multitudinous species which Mr. Haly mentions as having been formed out of this fish, it will be observed that the Sinhalese give it different names at different stages of its life, a very common source of errors which careful naturalists have to eliminate.† Instead of Mr. Pereira's noxious tree-blossom, this writer mentions "a poisonous nut" on which he says he *knows* that at certain seasons the fish feeds.‡ He has, therefore, never eaten it, and he alludes to sickness of a choleraic type brought on by eating freshwater fish at an elephant kraal in Dumbara. The species of fish eaten on that occasion is not mentioned, and it is just possible that the case, if we knew all the circumstances, might support our theory of decomposition before the fish was dressed. In any case the question of this the largest of our fishes being at certain seasons or after eating certain food poisonous is worthy of the most careful investigation. So is the statement that mud from rice fields is inimical to fish life in our rivers. We should have thought, on the contrary that the effect would be beneficial in supplying the fish with food in the shape of earthworms, &c. We are reminded of a very "interesting" statement made to us by an observant Highland gentleman with whom we travelled many years ago on the Caledonian Canal. He told us, in answer to our inquiries as to scarcity or absence of fish in rivers which once swarmed with salmon, that since the supersession of cattle by sheep in

* Minnows?—ED.

† Mr. Thomas, in writing of *Barbus neili*, states:—"There are many different fish that pass as mahseer I have seen at least three in a single river."

‡ A correspondent of a contemporary writes that "the best bait is said to be the berry of the '*makula*,' but, if that is used, the fish must not be eaten, as the berry is poisonous. The Sinhalese also ground-bait a pool for two or three days and then bait with a piece of sweet potato." *Makulu* is the Sinhalese name of *Hydnocarpus venenata*, which is also known by the significant name of *H. inebrians*. Another correspondent writes:—"One of the best baits for them is a little jungle fruit which the Sinhalese pronounce '*porter*.' They parboil it, to give it the necessary consistency, and then it is a deadly bait for 'Bettia' or Lella." We are unable to identify the plant thus referred to (*pótá-wel* not being described as having poisonous fruits), but a good many of our Ceylon trees seem to bear poisonous or intoxicating fruits and blossoms. The same correspondent confirms our impression that the mahseer in Ceylon is not the energetic giant he becomes in the mountain streams of India. He writes:—"If the Lella is really the mahseer, I am surprised and--I own, disappointed, for I have always, from what I have read of the mahseer, and from the elaborate tackle which I have seen in Farlow's shop intended for his destruction, held a much higher respect for him than I can get up for the commonplace Lella. Like 'E. J.' I have tried all sorts of spinning baits and flies for Lelloo without success, and I firmly believe that a chunk of coconut, plantain, or the 'porter' fruit above alluded to, will be found more effective than all the mahseer tackle to be found in Farlow's." We should think that a clue to the "porter" fruit may be found in the fact, that, in the language of the Kols of India, *Randia dumetorum* "the fruit of which is used to poison fish," is called *portoho. R. gardneri* is indigenous to Ceylon, and perhaps its fruits have the same property? *Strychnos potatorum*, the *ingini* of the Sinhalese, is the "clearing nut tree" of the Engliah. Its fruit can scarcely be poisonous, for the pulp is eaten, while the nuts clear muddy water. *Coculus Indicus* seems to be the substance chiefly used in India and Ceylon for stupefying fish so as to cause them to come to the surface. Of this nut Ainslie, in his "Indian Materia Madica," states:—

Kakacollie verei (Tam.) *Kakichempoo vittiloo* (Tel.) *Kakamari* (Sans.) *Kakmari ke beenge* (Duk.) *Cocculus Indicus.*

Menispermum Cocculus (Lin.).

Cl. and Ord. Dicœcia Dodecandria. Nat. Ord. Sarmentaceæ. *Fischetodtender Mondsame* (Nom. Triv. Willd.).

The name cocculus Indicus is, in all probability, taken from the Tamool appellation of the article, which signifies the "*crow-killing seed.*" The plant is the *tuba bidji* of the Malays, and the *natsjatam* of the *Hort. Malab.*

This narcotic berry, which grows in abundance in the woods of the Southern provinces, in the Travancore country, and in Ceylon, is employed by the *Vytians* as a useful external application in cases of inveterate itch and herpes; on such occasions, it is beat into a fine powder, and mixed with a little warm castor-oil. It is also formed into a sort of paste, with moistened rice, for intoxicating birds and fish, in order to catch them.

Our present article is the *tuba baccifera* of Rumphius. Orphila places the fruit of it amongst his Poisons; and, in his work, tells us, that Monsieur *Goupil* has given to the Society of Medicine of Paris some interesting facts, proving that it is not only a poison for fish, but for other animals; he supposes it to act like camphor. Nay, Marcet informs us, that it is a poison for even vegetable substances themselves.

the Highlands the supply of salmon in the rivers had greatly diminished. To our amazed inquiry as to how the sheep on the moorlands affected the fish in the mountain streams, he gave the very simple explanation that the droppings of the sheep constituted no breeding place for earth-worms. Those of the cattle did, and the earth-worms, the favorite food of the fish, were swept into the rivers by periodical floods. This case shows how the operations of man can disturb the balance of nature, but as earthworms must accompany the mud from the paddy fields into our rivers, we should think that good rather than harm to the fish would accrue from mud-laden affluents? But opinion founded on experience is worthy of respect, and what we feel is, that with reference to continued and increased supplies of a very important article of food, especially amongst the natives, the whole question of our freshwater fishes, their qualities and the best modes of securing the reproduction of the best kinds is worthy of careful investigation, by an expert or a commission of experts. We submit that the Ceylon Government might well move in the matter, and if so they could not do better than ask the Government of Madras for the loan of the services for a short period of that enthusiastic sportsman and naturalist, the Hon. Mr. Thomas, with whom could be associated local authorities like Mr. Haly, Mr. Le Mesurier, Mr. Cross and others. All the information now existing in a scattered form could then be brought together, properly arranged and profitable conclusions as to fish culture in streams and ponds arrived at.

Has any reader a copy of Mr. Thomas's great work, "The Rod in India," which he can lend us? We have sought for the book in vain in the Colombo Library and that of the Asiatic Society. Our recollection of extracts from this book and other notices of the mahseer in Indian publications is that the testimony in favour of the mahseer as an edible fish is unqualified by any statement that the flesh is affected adversely by season or food. We tasted portion of a mahseer taken out of the Teesta river, near Darjiling, in the hospitable abode of Mr. Gammie, Superintendent of the Government Cinchona Plantations in British Sikkim. The fish was excellent, and neither then nor at any other time did we hear that it was ever otherwise in India. If in Ceylon the reputation of this the noblest of Indian freshwater fishes is more qualified, it is time that the reason why, with other questions as to our freshwater fishes, were fully inquired into and set at rest.

We have several times mentioned what our late lamented friend Mr. Moens of the Java cinchona plantations told us, as showing that pisciculture in the Netherlands Indian Colony is scarcely second in importance to agriculture. "The natives here," said Mr. Moens, "get two crops of nearly equal value from their fields: first, the harvest of paddy and then the harvest of fish." The prevalent fish in Java is a good-sized carp coloured like gold-fish, which might well be introduced here if we have not got it already. In truth freshwater fish in Ceylon seem to be numerous and abundant. What appears to be needed is the culture and proper feeding of the best kinds in ponds, after the fashion which Mr. Thomas describes as so profitably prevalent in and around Calcutta. Mr. Thomas's chapter on the "stocking of ponds" is so interesting and calculated to be so useful, that we shall notice its contents in a future article, transferring extracts to the *Tropical Agriculturist*.

While we were writing an Indian paper brought us the following account of a "bag" of mahseer:—

DEHRA DUN FISHING.—Some good sport was obtained during December last at Raiwala on the Ganges, about six miles above Hardwar. Sixteen mahseer, averaging 24¾ lb. each, were caught by Major Durand and friends; the heaviest was 40 lb. and the lightest 15 lb., but there were only three fish under 20 lb. These fish were nearly all caught with natural bait, and after sundown. A lot of small fish were also caught by various members of the Association in the Song and Surwas rivers of the Eastern Dun, the favourite bait appearing to be a small gold or silver fly spoon.—*Pioneer.*

In Mr. Thomas' recent book we see no reference to fish poisoned or rendered poisonous. The fruit of *Ficus indica* is, we suppose, innocuous, being a fig. A writer in the local "Times" gives a graphic account of a scene he witnessed:—"Some twelve or fifteen years ago, several of us were fishing at the Butale aniout, and, getting tired of the small-sized catch which fell to my rod and line, I left it in the hands of a companion and strolled up the bank of the Kattregam-oya with a gun, following a curious bleating sound like a sick lamb, and which I then took to be a fawn, but turned out really to be the cry of the single-billed toucan. Hearing a great splashing and commotion in the river, and cautiously looking over the raised bank I saw a shoal of fish—mostly 9 or 10 inches in length—in a frightful state of excitement, jumping out of the river, and catching the fruit of a banyan tree (*Ficus Indica*) as fast as it fell, which, as the tree was a very large one, and covered with fruit, was continually dropping; and, with half-a-dozen fish trying for the same fruit, it may be imagined what a commotion there was the pool." He adds:—"I have caught fish in the Dimbula-oya with this bait, and I have seen dozens of little fishes rush at sapu fruit as they fell into the Badulla-oya. For the dark-green perch at Rugam, bits of meat, or worms, were very successful bait." To quote again:—"The most successful angling I have experienced in Ceylon was from a boat at Kanthalai, in the middle of the dry season." This revives the suggestion we offered after our visit to Kalawewa, that this and other large tanks ought to be systematically utilized for the stocking and breeding of the very best species of freshwater fishes, indigenous and imported.

THE YIELD OF TEA IN CEYLON ON OLD, WORN COFFEE ESTATES; ON PLACES IN GOOD HEART; AND ON VIRGIN FOREST SOIL.

(*By an Experienced Coffee and Tea Planter.*)

In reference to the yield of leaf from old estates my candid opinion—*not newly formed*, and, I may say, applicable to most old districts (I have tea 9 years old, giving this year 180 lb. made tea per acre, and this yield will represent the highest yet harvested from that field)—is, that quite one-third of *all* old coffee estates, *i.e.*, estates mamoty-weeded and washed as most old estates were a quarter of a century ago, and fully half of others will not yield more than 150 lb. made tea per acre, and that 8 to 10 years from planting will see that yield reduced to 100 lb. an acre, or in other words abandoned if no manure is applied, and on the question of manure my advice would be on no account manure tea, which, without it, affords less than 250 lb. per acre. The better portions of estates might, with occasional applications of manure, keep up the yield to 250 or 300 lb. an acre all round for 20 or 25 years where there is a fair depth of free soil. Where the sub-soil is of a quartzy or cabook nature, I would expect the crops to fall off in much less time. My system for the last four years has been to plant bare ridges and portions of coffee fields in course of transformation into tea, where the soil is of a light description, with fuel trees of various kinds, and last

year I planted some acres of six-year old tea in this manner, which was giving me barely 50 lb. tea per acre.

Some old estates, for instance in East Matale where soil is exceptionally good, and places like Mariawatte with great depth of free soil, will, with judicious treatment, be as vigorous fifty years hence as now, unless some unforeseen cause should impair the vitality of the bush.

Young land 20 years or so in coffee carefully drained and free from weeds will, with liberal cultivation, afford 250 to 400 lb. tea per acre, according to class of land, for a longer period than many of the present generation of planters are likely to see. Fields will, and probably small estates may, give 500 lb. or more per acre, but, as a general rule, over an estate of 400 or 500 acres, 400 lb. per acre should be the limit upon which to base calculations, if tea property is to be made a sound investment and not a speculative business. I will not go into the profits and value of tea estates, as I have made my letter longer than I intended when I began. [Let us have this second part discussed by all means in an equally practical way.—ED.]

ORANGES ALL THE YEAR ROUND IN LONDON.

AN INTERVIEW WITH THE IMPORTERS.

Few people ever take time to think of the number of countries whose ripest products are laid under requisition to furnish forth the table of an English gentleman. We read with wonder of the array of dishes filled from all quarters of the then known world which were set out to satisfy the gourmands of the Roman Empire. But the area laid under contribution even by Lucullus and Heliogabalus was comparatively trivial compared with that which is requisitioned in order to supply an Englishman's dessert. Lucullus is almost as famous for introducing cherries into Italy as for his eight years' campaign against Mithridates; but nowadays no one spares a thought when enterprising merchants enable the London "cit" to feast his guests with apples from Tasmania and oranges from New South Wales. Few things, however, are more interesting than the source of our fruit supply, and we therefore publish without more preface the report of an interview which our representative had the other day with a representative of a leading firm of fruit brokers in Pudding-lane, E. C., where the sales by public auction are held. Our talk ran chiefly upon oranges, owing to the development of a new trade in this fruit between London and Australia.

"We are now able to supply oranges all the year round, thanks to the Australians. The orange harvest there begins just as the Spanish crop is being cleared. The first Spanish oranges reach the London market at the end of October, but they are then sour, and it is not until December that the first ripe fruit begins to come in. The supply then goes on increasing until April, when it begins to fall off, and at the end of June the season is practically over, although there are always some cases come in July. Spanish oranges, however, may be said to supply our market for seven months in the year—from November to June. The Australian oranges come in in August, and continue till November—just filling the gap—so that oranges never go out the whole year round."

"Then you predict a great future for the Australian orange?"

"Yes, but it is badly handicapped, owing to the fact that the freight is at least four times as much from Sydney as it is from Valencia. Cases one half the size cost from 3*s.* to 4*s.* freights from Sydney, while 1*s.* 6*d.* is the freight from Spain. This handicaps the Australian orange very severely; but the demand exists and is growing, and if the Australians will but take care and pack their oranges as carefully as the Spaniards, there is a great future before the industry. It is all a question of packing, and if the oranges are in good condition and well packed, there is no difficulty in sending them all round the world in case of need. As an experiment and as an object lesson in the keeping qualities of oranges when well packed, I recently sent three cases of Spanish oranges just as they arrived at our wharf down to Tilbury Docks and shipped them to Sydney, where they arrived in excellent condition. The antiseptic preparations, to one of which you referred recently, are not needed. Oranges keep a long time—much longer than is occupied by a steamer in covering the distance between here and the Antipodes. Of course, towards the end of the season, when they are dead ripe, they are more delicate, and will not keep so long. But with ordinary care they will stand the voyage without difficulty."

"From what country do you draw your chief supplies of oranges?"

"From Spain: especially from Valencia. Last year there was 453,000 cases of oranges from Valencia, each case weighing over a hundredweight, and containing from 400 to 700 oranges. That is to say, averaging them all round at 500, there were imported from Valencia alone, 226,500,000, weighing about 32,000 tons. A few come from Lisbon, and some—bitter oranges for the most part—from Sicily. The St. Michael oranges appears to be going out. Of the five islands of the Azores which use to supply us with oranges only one now sends us any fruit. The trees have ceased to bear, being exhausted with overbearing and not being renewed. The Valencia orange at present commands the market. Of the orange imported only about 5 per cent are of the bitter variety, and are used for marmalade, for making candied orange peel, and for the production of orange wine. The prices of oranges vary. At present they run at about 9*s.* per case. It is wonderful to think that you can get from five to six hundred oranges grown, picked, wrapped in paper, packed in boxes, shipped in Spain, carried a nine days' voyage to the Thames, unshipped, and then sold at our mart for 9*s.* Prices run as low as 6*s.* or 7*s.*, and as high as 15*s.* or 16*s.*, and the demand keeps up wonderfully. The demand, indeed, for fruit is so great that in the case of grapes it threatens to destroy the quality of the fruit itself."

"How can that be?"

"Very easily. The moment a great demand sets in for any description of fruit (say, for instance, as a case in point, for Spanish grapes), every one that has any land that will bear grapes sets to work to plant vines in order to supply the demand which exists here for fresh grapes. Quality is sacrificed to quantity. The grapes are forced to bear more than they ought to, with the result that the quality of the Spanish grape is steadily deteriorating. It is becoming harder, sourer, less palatable in every way, and unless some check is placed upon the process, grapes will be as common as gooseberries and much less edible. Nearly all the grapes which you see in the shops come from Spain and from Lisbon. They are packed in ground cork in barrels, and it is astonishing how long they will keep. I have bought grapes in March which I have sold in the previous December. Spanish grapes used often to be kept without suffering any damage for six months at a time. That of course presupposes careful packing and the exclusion of the air. At present we do not get grapes over from the Cape or from Australia. Their produce is too soft to keep. No doubt they might cultivate the Spanish vine if they chose; but the supply from the nearer vineyards is so abundant that it is hardly worth while growing the same deteriorating commodity at the other end of the world. A barrel of grapes weighs from 45 lb. to 50 lb., and the average price runs about 10*s.* to 12*s.* when the season is at its height. Malaga grapes failed last season almost entirely, hence there were very few Malaga raisins to be had. With the Malaga raisins go the Jordan almonds, with which they are always eaten. Talking of over-supply in the market, the most striking instance of that this year has been the unprecedented crop of hazel nuts which has poured into London from Northern Spain. There never has been such a harvest, and we are simply

inundated by nuts. Fortunately they will keep well if necessary until next season. Hazel nuts come from Spain; chestnuts from the north of France. All the chestnuts which you see in the streets come from Northern France. As many as 150 to 200 tons of chestnuts will be delivered in a morning by rail. The Kentish filbert is almost the only nut with which England supplies her own people. The Brazil nut comes from the Amazon. Last year we had a cargo which was collected by a small steamer two thousand miles from the mouth of that great river. The coconut, of which there were about twelve millions last year, comes chiefly from Trinidad and Ceylon. Trinidad held possession of the field for some time, but Ceylon is pressing on hard, and driving down the price to a figure which renders the production of coconuts profitable. There is a ship in just now from Trinidad containing 320,000 nuts, half of which are in their husks and half peeled. The latter are stowed in the bottom of the hold to steady the ship, and the husk nuts piled on the top. The husks are sold at prices varying from 7*s.* to 15*s.* per thousand, and they usually command a sale for a great variety of purposes. The shell of the nut is worthless. The price of coconuts runs at about 9*s.* to 10*s.* a hundred, and they are mostly sold to be eaten. There is, however, one manufacturer in Red Lion-square who for the last three years has had an American patent for what is called desiccating the coconut. He buys the nuts, removes the brown skin, grinds the white kernel, and then desiccates and sends it into the market for use in cooking and for other purposes."

"Do you import tropical fruit?"

"No, for two reasons: (1) tropical fruit does not keep, and (2) it is not popular except among those who have lived in the tropics. The flavour of mangoes and such like fruit is not generally appreciated. Apples come from Canada, Tasmania, and from the United States. The apple crop was very short in the States, and they have not had much to spare there. We have not received many oranges from Florida, although the supply is likely to increase. Those that have come hitherto have been sent over when the market in New York was glutted."

"May I say," said Mr.———, in conclusion, "that it is a very wonderful thing to us that, with all the outcry on the part of the unemployed, we could not for some weeks obtain labour for unshipping the fruit? No doubt it is hard work; but an able-bodied man who was willing to carry could easily make 6*s.* a day. We have been at our wits' end again and again to obtain men to do work, and instead of unloading by hand we have been compelled to employ steam. It is this fact which makes me rather sceptical as to the reality of the distress among the unemployed. If they were suffering so much, and there were so many of them, we surely should not have to go a-begging for hands to discharge our cargoes. This often occurs at the wharf when the pressure takes place in November and December, when there are sometimes as many as five or six steamers, fruit laden, lying alongside Fresh and Nicholson's wharves." —*Pall Mall Budget.*

(From *Cassell's Family Magazine*, Nov. 1887.)

Japan Clover.—A clover of Japan, the *Sespedeya Striata*, is coming into use in the Southern States of America. It is said to be relished by all kinds of stock, and is grown largely in orchards, where it displaces weeds and some wild grasses. It also grows on waste lands where other forage plants would thrive but poorly.

Paper from Tobacco Waste.—The waste cuttings and stems of tobacco are now used in manufacturing paper pulp. They are much cheaper than waste linen rags; and the paper made from them is said to be as good as that from the rags.

Sugar-making by Diffusion.—In America, a system of extracting sugar from cane by diffusion, has been worked out. Instead of crushing the sugar-cane between rollers in the ordinary way, the cane is cut up and water is forced through the chips in confined cells, thus extracting the sweet juices, which are afterwards evaporated. The system is to be practically tried on the plantation of Governor Warmouth in Louisiana. It is expected to allow of the maximum quantity of sugar being extracted from the cane.

Safeguard Against Insects.—It is stated by the *Lancet* that weak carbolic acid sponged on the skin and hair, or on the clothing, is a protection against the bites of gnats and other insects. The safest place, according to the writer in question, is to keep a saturated solution of the acid. The solution cannot contain more than six or seven per cent; and it may be added to water until the latter smells strongly. This may be readily and safely applied with a sponge. Horses and cattle could, perhaps, be protected in the same way.

Vegetable Leather.—A process for making a substitute for leather from gutta-percha and sulphur, has been brought out in France. Raw cotton and oxide of antimony are well mixed with these ingredients, and the whole vulcanised by steam. The artificial leather is said to be useful for making the soles and heels of shoes.

Coal.—The *Civil and Military Gazette* states that it is quite true that anthracite coal of most excellent quality has been discovered in the hills along the Peshin Valley route from Sibi to Quetta. There is one seam, about half a mile in length, appearing like a black line on the side of the hill close to the station of Nasik.—*Indian Agriculturist.*

Useful Gum from India.—In a communication on Indian dyes and methods of dyeing followed in India, read recently before the Liverpool Section of the Society of Chemical Industry (*Journ., S. C. I.*, Dec. 31, p. 79), Mr. Elworthy calls attention to the gum known in India as "dhaura," derived from *Anogeissus latifolia*, which he thinks would be found a useful gum in English dye works, as yielding a thick viscid liquid much superior to dextrin or "British gum" and at the same time cheaper than gum arabic. When mixed with a small proportion of hydrochloric acid, Mr. Elworthy says, the liquid gum keeps good for several months, and although its adhesive qualities are lessened by this addition it still answers very well for labels. This gum, it may be mentioned, is referred to with approbation by Dr. Watt, in his 'Economic Products of India:' Professor Dymock also speaks of it (*Mat. Med. W. Ind.*, p. 324) as a valuable gum, occurring in vermicular pieces, very slightly coloured, translucent, tasting like gum arabic and readily soluble in cold water, with which it forms a strong, almost colourless, mucilage, having a faint peculiar odour. The tree is common in the Concan and Khandeish and the gum is collected by the Bheels.—*Pharmaceutical Journal.*

FUEL FOR TEA ESTATES: THE AUSTRALIAN ACACIAS.

Following Mr. Rutherford's warning about supplies of timber and fuel for tea estates, comes Mr Kellow's timely letter, giving the results of his experience as to the value of two of the Australian acacias, the "blackwood" and the "black wattle" (two allied but very dissimilar trees, which ought never to be confounded).—the first as a valuable timber-yielder; the second, as, to some extent, a source of timber, but chiefly and eminently valuable as a rapid fuel-producer, from its extraordiary propensity to form dense groves of plants, sent up from its many, strong and widely spreading roots. To give this propensity full play, all that is necessary is to scrape off the surface soil in the neighbourhood. Indeed, the great difficulty is to keep a path clear in contiguity to this species of wattle. Our interesting visit to Albion estate, to which Mr. Kellow refers, convinced us of the correctness of an opinion which we have held for many years, that while no greater plague amongst coffee, tea, or cinchona plants exists than *Acacia decurrens* (*A. dealbata* is just as bad), no better plant can be grown in a separate locality as a fuel yielder. Of course it could be grown along ridges, or on the top of knolls in the interior of estates and prevented by means of deep drains from spreading beyond certain limits, but it had far better, as a rule, have a separate site allotted to it. For shelter purposes we should prefer the beautiful and valuable *Grevillea robusta*, another acacia, but with no tendency to send up sprouts from its roots. This tree is a fairly rapid grower, and it sends out abundance of lateral branches which can, with advantage, be lopped and used for fuel as the tree advances in height. After large experience of the eucalypti which—especially the blue-gum—grow very rapidly, our two favourite trees for growing on estates (by road sides and round houses and lines) are Grevillea and toon (*Cedrela toona.*) The only fault of the latter is its liability, when young, to have its top broken off in storms. But it soon grows again and coppices well. Its fine timber is known popularly as "red cedar," although botanically it is wide—as under from the cedars, which, by the way, do not seem to take kindly to our Ceylon hill climate. The quality of grevillea timber is shown by the fact that it is the one most used in Australia for the staves of tallow casks. We have, on Abbotsford, some of these trees about 13 years old, fit for timber yielding, but they are cherished with the hope, not largely realized as yet, that they will yield supplies of seed. Blue-gum trees, from 10 to 13 years of age, have been cut down, and have yielded large supplies of white, solid timber, good for many purposes, but apt to crack (externally) and warp badly in seasoning. One specimen grown at 4,800 feet elevation, cut down in its thirteenth year, was considerably over 100 feet high and gave a very large number of cubic feet of timber. We have a memorandum of the really remarkable figures for girth at the root and at different distances up the noble stem, with the quantity of serviceable, though to the carpenter troublesome, timber yielded, which we shall publish when we lay our hands on the paper. The "blackwood" (*Acacia melanoxylon*) is by no means so fast a grower as *Eucalyptus globulus*, nor will it yield anything like so much timber, area for area, but the quality of the wood is immensely superior. It compares in truth with our ebony in density and grain, and is much better suited for a multitude of purposes, amongst which Von Mueller mentions "furniture, railroad cars, boat building, tool handles, crutches, organ building, casks, billiard tables, pianofortes, &c." The Baron adds that the fine-grained wood is cut into veneers; it takes a fine polish and is considered almost equal to walnut. Valuable as this tree is, it also ought to be excluded from plantations, except where it can have its power of root-spreading limited. Although in a much smaller degree, this acacia also sends up plants from its roots, sometimes at long distances away. There is a fine specimen near Abbotsford "old bungalow (now rebuilt, largely with blue-gum timber) which was allowed to grow permanently in a small wooden box in which it was received with other Australian seedlings about a dozen years back. t is now a fine parent tree, with half-a-dozen of its well-grown root-progeny around it, all with the same clean straight stems and handsome pyramidal habit of branch and leaf growth. Our common tree parasite, the *loranthus*, is apt to specially attack this tree, as may be seen in the case of old specimens in Nuwara Eliya, but this pest can be easily removed by a cooly armed with a long pole and a sickle or knife attached to it. "Blackwood" trees must have been cut down in Ceylon, and it would be interesting to learn how the timber of trees grown in our island coincided with the reputation attained in Australia.* There, when the eucalypts are mercilessly "ringed" with reference to pasturage, the "blackwood" trees are carefully spared. Although large numbers of the old gum trees in Australia are hollowed (the draft thus created adding to intensity of fires, as we were able personally to notice in a fire amidst the tall trees at Fernshaw), we have not noticed any tendency to "piping" (if that is, as we presume, another term for becoming hollow) in eucalypts grown in Ceylon. While we do not suppose that any timber tree can in rapidity of growth and cubic quantity of wood, for the carpenter or the furnace, excel the Tasmanian blue gum (*E. globulus*), and while the iron-bark, jarrah and many other grand Australian eucalypts and acacias are flourishing in Ceylon, we do not think we are wrong in the conclusion that the chief boons bestowed upon us in the shape of plants from Australasia, consist of the three acacias:—

Grevillea robusta (branches fuel; stem timber).
A. melanoxylon (do. do.)
A. decurrens (fuel mainly; larger stems timber).

We recollect Mr. W. Cotton telling us that nothing could be better for mamoty handles than stems of this latter plant, which can be easily propagated by seed as recommended by Mr. Kellow, or, more readily, we should say, by taking up root pieces and planting them where they can rapidly indulge their spreading habit. We do not dwell on the value of the bark of *A. decurrens*, but when large groves are grown, it may pay planters when coppicing them for fuel to separate the bark, grind and ship it.† We suspect Australia can supply all that is wanted of wattle

* On the Nilgiris, according to Col. Beddome, it has not been deemed equal to blue-gum timber. Some trees cut on Naseby, Nuwara Eliya gave a serviceable timber, and the late Rev. W. Oakley had some very neat cabinet work made from slabs of *A. melanoxylon*.

† For a full and interesting article on wattle cultivation for bark, we refer to the March number of the *Imperial Institute Journal*. Mr Brown, the Forester of South Australia, calculates that 100 acres of land, costing £3 per acre and yielding 2 tons of bark per acre, worth £5 per ton, would yield 7 per cent on expenditure and a profit over and above this of £1,105. It might pay a Company to form a plantation of 1,000 acres on Uva patana land, near tea estates, which could be supplied with fuel, while the bark was shipped for the use of English tanners.

bark, however. In a Florida nursery catalogue, which we have just received, it is stated of *A. decurrens* that in California it has grown over 50 feet in eight years and is useful as a wind-break besides being very rich in tannin and furnishing a gum which exudes copiously wherever a branch is cut, equal to gum arabic. Wood valuable for fuel and coopers' work. Of *A. dealbata*, which closely resembles *A. decurrens* only that its whiter foliage has obtained for it the name of "silver wattle," we learn that it reaches a height of 150 feet in Australia and yields a valuable tough wood: this species also might, therefore, be grown as a timber tree or as a fuel supplier, or for both purposes. For fuel yielding, however, experience is strongly in favour of the "black wattle," *A. decurrens*, and so, on their poor and waste places, or to replace pieces of forest cut down, planters ought to go ahead with its cultivation. *Cryptomeria japonica*, the Japan pine, the timber of which is so valuable for tea boxes, is being extensively cultivated in Ceylon. Our experience with some planted out near the Bund in Nuwara Eliya is that rats, which did not touch the toon trees, bit off the tops of cryptomerias. This did not kill them, however. Dr. Trimen doubts if our moist climate will suit this pine. The young plants look well, however, and the tree has been a success in Darjiling. The Himalayan station is much wetter, judged by rainfall, than Nuwara Eliya, but we suppose its northern latitude tells in favour of the pines? Even if cryptomeria succeeds here, we fancy it will grow slowly in comparison with the exotics of Australian origin.

COOLY EMIGRATION FROM INDIA TO DUTCH COLONIES.

The *Pioneer* of 18th Feb, has the following:—

"During the last week two officials, Mr. Lavino, Consul-General for the Netherlands at Singapore, and Mr. Van Ryn von Alkemade, of the Netherlands Indian Civil Service, have been engaged in negotiating at Calcutta the extension of the Indian Emigration Act to the Dutch Colonies in the East. This recently developed desire of the Dutch authorities to obtain Indian coolies ought to be gratefully received by Sir Edward Buck, who wrote in strong terms three years ago in favour of opening out these extensive labour-fields to the surplus population of South India, and pointed out the danger of their being otherwise absorbed by the Chinese. We published at the time the paper to which we allude, read before the Society of Arts in January 1885; and now reproduce in another column that portion of it relating to emigration. Another paper read before the same Society by Mr. Trendell, C.M.G., on the Netherlands India Colonies, has just reached India and entirely confirms the account given by Sir Edward Buck of the great agricultural wealth of the India of the Dutch. The area of the eastern islands is materially over 700,000 square miles, figures which can perhaps be better grasped if it is stated that this area is equivalent to 350 or 400 average districts of these Provinces; or by comparing it with the area of British India which is, excluding Native States, 760,000 square miles, of which one-sixth is unculturable land. The land held by the Dutch is much of it rich and nearly all culturable, while forests abound. Capital is pouring into it and only labour is wanting. Chinese are being already sent in ship-loads by cooly-contractors at Hongkong and Singapore. But John Chinaman likes working for No. 1 better than for his master No. 2; and planters in Sumatara, whence the loudest cry has come for Indian coolies, prefer the more docile and manageable Madrasi. The application which the Netherlands India Government have now made for the extension of the Indian Emigration Act to their colonies is stated to be partly due to the measures which Sir Edward Buck, when at Singapore four years ago, arranged with the Straits Government for the prevention of illicit emigration to Sumatra at the same time that emigration to the Straits Colony itself was relieved of many of the restrictions which had hitherto hampered it. The difficulty of obtaining coolies and the demand for them on the Dutch plantations have, since 1884, simultaneously increased. Hence probably the mission to Calcutta to which we have already referred."

In this case as in that of emigration to French colonies careful protection must be afforded to the coolies. The French treated them as slaves. We hope better things of the Dutch, but they also have been accustomed to compulsory labour. We have marked for the *Tropical Agriculturist* the extracts from Sir Edward Buck's paper and Sir Hugh Low's remarks, about extra Indian "moist equatorial lands" which are not liable to drought and famine, but which need Indian labour for agricultural purposes. The Chinese prefer mining and similar pursuits.

THE MERCHANDISE MARKS ACT.

Planters' Association of Ceylon,
Kandy, 25th Feb. 1888.

The Editor, *Ceylon Observer*.

Sir,—I beg to enclose copy of letter from Mr Delmege, London, on the subject of the Merchandize Marks Act 1887.—Yours faithfully,

A. PHILIP, Secretary.

17, St. Helen's Place, London, E. C.,
3rd Feb. 1888.

The Secretary, Planters' Association, Kandy.

Dear Sir,—As Director of a Company engaged in selling Ceylon tea in England, it is constantly brought to my notice, that China rubbish is sold as Ceylon tea. I estimate the consumption of Ceylon tea at over 5 per cent in excess of the production. A grocer, in Manchester, is at this moment sending the finest Ceylon tea retail at 1s 4d a lb. The most important point that can possibly engage the attention of your Association is to put a stop to this. The London Chamber of Commerce, of which we are members, held a meeting yesterday, to consider the Merchandize Marks Act. I enclose copy of a letter I wrote the Secretary London Chamber of Commerce, and copy of his reply, and draft of proposed Association. Here is a simple remedy. Let your Association become members of the proposed Association, which latter will conduct prosecutions. Then your Association engage any good man to represent them here. He should not be engaged in selling tea. It will give rise to jealousies. If you have not got the money to pay a man, get up a special collection, say each estate R15. If this is done without delay, it will soon put a stop to unscrupulous grocers adulterating our tea, and the price will be benefited at least 2d a lb. all round.—Yours faithfully

(Signed) E. T. Delmege.

1st February 1888.

Kenric B Murray, Esq., Secretary, London Chamber of Commerce, Eastcheap, E.C.

The Merchandize Marks Act 1887.

Dear Sir,—As I will be unable to attend the meeting of the Chamber of Commerce tomorrow to consider the present effect of the above Act, I would draw your particular attention to what appears to me to be an omission in the Act and suggest a remedy.

The Act is for the purpose of compelling traders to disclose the real country of origin of their goods. In the case of tea it fails to meet the requirements of the trade.

The production of British tea this year is as follows:—

Indian tea	...	...	84,000,000 lb.
Ceylon tea	...	...	20,000,000 ,,
			104,000,000 lb.

involving very many millions of British capital engaged in the industry, and entitled to thorough protection at the hands of our legislators.

The value of a pound of Indian or Ceylon tea may be roughly stated at 1s all round, whilst the value of China tea would scarcely average 6d to 8d. To my personal knowledge, tea is being largely sold by dishonest tradesmen as the produce of India and Ceylon, whereas it is largely mixed with or consists only of China tea.

A Ceylon Tea Company, with which I am connected and Director, is incessantly bothered to sell their original empty packages, and the price offered is much in excess of their real value for any possible purpose except to refill them with inferior tea, and sell them over again, as if the contents were the same as originally imported, the chests bearing the names of well-known tea gardens.

A remedy is impossible at present. I know of a man doing a large business, selling tea in chests marked with a fictitious name, who openly boasts that no one dare sue him, otherwise he would have heavy damages out of them. There is only one remedy: the dealer must be bound to prove how and where he got the article he is selling. The onus of proof should not be thrown on the prosecution, no honest trademan would for a moment fear to declare how and where he purchased his goods.

I may mention for your information that in Ceylon so far as regards tea, coffee, or other produce grown either by natives or Europeans, in the case of suspected theft the onus of proof does not fall on the prosecution, but the holder of the produce has to prove how he came by it.—Yours faithfully,

(Signed) E. T. Delmege.

London Chamber of Commerce, February 2nd, 1888.
Botolph House, Eastcheap, London, E. C.

E. T. Delmege, Esq., 17 St. Helen's Place, E. C.

Merchandize Marks Act.

Dear Sir,—Referring to yours of yesterday, I think the points to which you direct my attention appear to be fully met by the provisions of the Act, which distinctly provides for and imposes penalties in the case of the employment of packages for goods not of the same quality or belonging to the original proprietor of the original packages.

I have not the slightest doubt that an action entered by you would produce the required result. The weak point, if any, of the Act is that there are no public prosecutors, and that remedial action is left entirely in the hands of interested "persons." To meet this want in the Act, the London Chamber of Commerce, in conjunction with several of the country Chambers of Commerce, suggest the formation of a separate Association, by means of which prosecution and the application of the Act may be better enforced than by private persons.

I enclose draft of this proposed Association which will be submitted to the consideration of the meeting this afternoon.—Yours faithfully,

(Signed) Kenric B. Murray, Secretary.

Merchandize Marks Act Association,
Botolph House, Eastcheap, London, E.C.

Objects of the Association.

1. To assist by such means as may, from time to time, be determined in applying the Merchandize Marks Act, 1887, for the benefit of British trade.

2. To assist in promoting a general understanding of the Act.

3. To defend the interests of subscribers.

4. To promote such amendments of the Act, as experience of its working may suggest.

Services to Members.

1. To obtain, by means of test cases, decisions as to the construction of the Act on important trade points.

2. To advise members in all suitable cases which may be brought before the Association.

3. To assist in negotiating with the Customs and other authorities, in respect to any points which may arise in the application of the Act.

4. To keep for the use of subscribers as complete a record as possible, of all legal proceedings, cases, precedents, Customs regulations, *Gazette* notices, and other matters bearing upon the Act.

5. To influence Colonial and Foreign Governments to assimilate their legislation, in regard to merchandize marks and trade descriptions.

6. To give the service of the secretarial and legal staff of the Association in all Parliamentary or official enquiries connected with the Act.

7. To be a centre for diffusing information and forming combined action amongst traders and trade Associations in all questions relative to the Merchandize Marks Act.

Terms of Subscription and Management.

The terms of subscription shall be as follows:—

(1) For members of Chambers of Commerce, whether individuals, firms, or trading Companies, £1 1s per annum.

(2) For others, £2 2s per annum. The details of the working of the Association to be managed by a General Council of Members, which may depute its powers, and be represented by an Executive Committee.

(Kenric B. Murray, Secretary *pro tem.*)

Merchandize Marks Act Association,
Botolph House, Eastcheap, London, E. C.
Form of Application.

London, ... 188... .

(I or We) desire to join the Merchandize Marks Act Association, and agree to pay the annual subscription for the time being in force.

Signature (of Person or Firm) .....
Style of Firm (if any) .....
Address.....
Description of Business .....
Member of the ..... Chamber of Commerce.

Terms of Subscription.

1. For Members of Chambers of Commerce, weather individuals, firms, or trading Companies, £1 1s. per annum.

The Financial Year runs from the 1st January to 31st December.

This Form to be returned to "Kenric B. Murray (Secretary *pro tem.*), Merchandize Marks Act Association, Botolph House, Eastcheap, London, E.C."

PLANTING IN TRAVANCORE, SOUTH INDIA.

We call attention to the very interesting proceedings of the Travancore Planters' Association given in another column, which substantiate what we were able to say the other day of the planting prospects in this outlying or continental "district" of Ceylon. Originally pioneered, opened and planted mainly by Ceylon men—the late Mr. John Grant of Corriemony, Matale, being the leader,—we have always taken a close and special interest in the fortunes of our neighbour. Not much has been said about it of late years, for the very good reason, that Travancore, like Ceylon, was under a cloud—the heavy cloud of depression caused by the failure of coffee from the ravages of *Hemileia vastatrix*. It will be seen, however that the men who were enabled to keep on working their properties in Travancore have been able to follow the example of Ceylon in bringing in new products—cinchona and cacao and more recently tea—to support coffee. The acreage of the last-named staple is now not much more than one-third that of the total area in cultivation, tea making another good third; indeed, between them we have three-fourths of the cultivated area, while cinchona, cacao and doubtless some cardamoms together make up the balance of the fourth. Of cinchona however, 1½ million plants are reported as growing

amongst the coffee, besides 2,895 acres specially cultivated with this product. The large reserves of forest and other land attached to the estates, namely 68,994 acres against 12,156 acres opened, shows that Travancore cannot be troubled with the fuel difficulty, while for tea the rainfall of from 100 to 200 inches is all that could be desired, and we are told that labour is fully cheaper than the average in Ceylon. There is therefore great encouragement for the Travancore tea planter to persevere and do justice to his fields, while a little later on, when the area cultivated is in full bearing, we must ask the members of the Travancore Association to support the Ceylon Tea Fund in order to aid in devloping new markets for our joint staple.

TRAVANCORE PLANTERS' ASSOCIATION.

Minutes of proceedings of the annual meeting of Travancore Planters' Association held at Trevandrum on the 15th February 1888. Present:—Messrs. J. Cox, Chairman; J. Fraser, D. G. Cameron, R. Miller, D. Moncur, H. Inglis, E. C. Chisholm, J. E. Fowler (Honorary Secretary, Kannan Devan P. A.), W. Cox, and J. S. Valentine, Honorary Secretary.

The SECRETARY read notice calling the meeting and the Report for the year.

The CHAIRMAN in reviewing the chief events of the past year, referred briefly to the movements for the better that had set in. Coffee estimates had in most instances been exceeded, while prices, although not so high as some months ago, continued good. Cinchona also showed an improvement. The most satisfactory part to members of the Association was the position Travancore tea was taking in the market; reports received from London brokers spoke in high terms of the shipments already gone forward, and what was more to the point prices realized were in many instances better than was looked for. Experience was showing that in yield and quality, Travancore was not in future to be behind. The liberal spirit of the present Government of His Highness the Maha Raja was doing much to revive prosperity on the hills. Statistics made up to end of June last showed the area under tea, coffee, and cinchona on the hills to be as follows:—

Districts	Rainfall inches	Cinchona: Number of plants in Coffee Land	Cinchona: Cultivated acres	Tea acres	Coffee acres	Other Products acres	Cultivated Total acres	Forest and other Land acres	Total acres
Ashamboo.....	120	430,000	216	741	1,685	56	2,698	8,154	10,852
Central	160	383,000	297	1,595	718	67	2,677	24,547	27,224
Peermade	200	439,000	483	1,959	2,044	...	4,485	4,141	8,626
Kannan Devan...	100	...	1,899	264	132	...	2,296	32,152	34,448
Total...		1,252,000	2,895	4,559	579	123	12,156	68,994	81,150

The total area cultivated shows a decline since the days when coffee alone was looked to, but looking to the fact that there was still a large area suitable for tea, and that we possessed a plentiful supply of cheap labor and the now assured success of tea cultivation there was good cause to look for a return of confidence, and consequently a flow of capital into the country.—At the close of his address the Chairman paid a kindly tribute to the memory of the late George Mackay of Glen Brittle estate, and in doing so referred to his many sterling qualities and genial disposition; he was valued by all who knew him, native and European, as the upright true gentleman he was.

COFFEE, SUGAR AND SLAVERY IN BRAZIL.—No IV.

WET WEATHER AND COFFEE FALLING—THE BUMPER CROP OF 1888-9—CENTRAL SUGAR FACTORY SYSTEM AND SUGAR PROSPECTS.

The weather during the last four weeks has been showery, which has pleased all sorts of agriculturists unless those who may have been short-handed amongst the coffee and sugar planters. In any year, wet or dry, a good deal of the Brazilian coffee crop has to be picked off the ground; and when the October rains continue so long, as they have done this year, the latter part of the coffee crop, which may not have been picked before the beginning of November, is of an inferior quality. If the bean happens to fall amongst weeds, it soon germinates, and even where it is cleanly swept under the tree, before crop picking, which all good planters see to; the drop-dropping of rain from the branches mixes enough fine earth to adhere to the side of the fallen berry, as either to discolour the bean inside or to make it sprout.

I have already mentioned that the crop for 1888-9 is to be a *bumper*. All over Brazil, with this expectation, consumers are relying on the large stocks keeping the price in regular form until the new crop come in, which will commence about July 1888. Stocks in Rio and Santos continue almost the same. Sales have been more active and entries have been heavier, so that the quantity generally remaining for sale in each port, Santos and Rio, ranges, off and on, about 350,000 sacks of 60 kilos each. Holders here are beginning to loosen the grasp held so long, and beginning to see that the current short crop of coffee in Brazil is not to influence the markets in consuming countries to the extent they anticipated. You must have noticed a fall in prices. The long spell of showery weather has rather been against the cane planter. He had long a splendid run of dry weather for cutting and transporting to the mill. From beginning of June to the middle of October, there was little rain, and the cart-roads on the estates were hard like macadam. The weather being cool the cane could wait a few days without harm before being crushed, and a good outturn of sugar from the cane was obtained. During these four months those who were full-handed had very little left out in the field when the weather broke. Very few of the planters were full-handed, and although the wet weather for the last six weeks has been most seasonable for all growing crops without exception, growling is loud and continued amongst those who have stuck to the old system of growing their own cane and turning it into *sugar* or *rum* on their own estates.

This is notably a year where the Central Sugar Factory System is seen in all its valuable advantages. The cane grower, who sold to the Central Factory this season, could, during these dry months, concentrate all his labour force on the work of cane cutting

alone, the transport to the factory's tramway being very easy matter, and he would get finished and take advantage of the rainy weather to prepare new cane fields, and to plant corn, beans, rice, &c.

Even to the short-handed planter the Factory System has saved him from loss, in a time like this, for instead of having to stop, owing to all the roads leading from the cane fields to the mill being turned into rivers of puddle, he continues cutting between the showers, and he has not far to carry it to the Factory Company's wagons. Cane in a wet state does not pay the manipulator so well, as when it is dry it not only gives a smaller percentage of sugar, and requires the consumption of a larger amount of fuel to evaporate the juice; but, if it be not crushed at once, it soon turns acid. The sugar factory meets these disadvantages by having large crushing mills, and an extensive system of evaporative apparatus; and these establishments being all fitted up with gas, when a glut of cane occurs, a night shift is put on. By a recent invention the cost of fuel to the Central Sugar Factory is reduced to a minimum, so that those who have adopted it require very little of either coal or firewood; the green megass as it falls from the crushing mill and is fed directly into the furnaces is all that is required to supply all the engines with steam, and the exhaust steam from these engines assisted by a small quantity of direct steam from the boilers in rainy weather does all the evaporation required to bring the cane juice from its initial density to a mass from which the crystalized sugar is easily separated by centrifugal machines.

It is not my intention at present to give a description of the process of sugar making from cane, but I cannot let the invention as to saving of fuel to which I have alluded above be lost sight of. As you are aware, the great cost in the manufacture of sugar is in the fuel required. The sugar planter, "out of crop" as you would say, has to employ his hands, or the strongest of them, and all his bullock carts, in cutting and carrying firewood for use during the crushing season. The weight of firewood required and stacked during the idle time would be nearly half the weight of cane that would have to be carted during crop time. True, a great many used to dry, and still do dry, the megass and use it for fuel, and also collect all the dried cane tops and dry leaves from the fields, but both of these operations take away a great deal of labourers from the work of cutting, which is in the end quite as costly as using firewood. The invention I now allude to does away with the necessity of drying megass, and, if the evaporating appliances work up the juice at the same speed that the mill crushes the cane, that is to say if the mill has not to stop because of the other processes being delayed, then the green megass as it falls from the crushing mill is immediately fed into the boilers, and gives sufficient fuel.

The invention is by the firm of Thomson & Black, now Terris & Findlay, of the city of Campos, Province of Rio de Janeiro. It consists in the arranging of the [illegible] so as to heat the air used in combustion before it enters the furnaces. I have seen the furnaces working at some of the central sugar factories in the Province of Rio de Janeiro, and have satisfied myself, that, where the machinery and plant are properly [illegible] and proper [illegible] with the other, a large central factory can be worked without any other fuel than the megass or fibre of the cane after the juice is expressed. There are two other systems for burning green megass, but these to work successfully must be mixed with coal in the proportion of half coal to half of megass. They have both been tried in this country with a mixture of firewood instead of coal, but do not work well. Indeed, in some of the largest central factories, the two French inventions have been thrown out, and Terris & Findlay have been applied to, to put in Thomson & Black's patent. This, as you will observe, is causing quite a revolution in the manufacture of sugar from cane.

As I before hinted, the low price of sugar is putting all common kinds which used to be made by open evaporators and old-fashioned mills out of the market. The planter finds it pays him better to sell his cane to a central factory at so much per ton. He has then little risk to run, no old rickety machinery to keep in order, no early rising and late at night slaving, when he may have, after all, to wait some time for his inferior sugar being sold at a price which very often does not fetch the amount of advance he has received on it. Selling the cane to the factory, he can grow more than double the quantity, for the quantity of cane a planter could grow on the old system was always proportionate to that which he could cut, transport to the mill, crush and turn into sugar or rum during the crushing season. More than half the labour on it is saved by selling to a central factory, consequently he can grow more.

This system is only in its infancy as yet in Brazil, but does not receive the attention it deserves. The Government gave out a good many concessions giving a guarantee of interest, and many companies were formed on these concessions, both with local and European capital. Many of these concessions have been cancelled, particularly those working with European capital, and in consequence some of these latter have entered into liquidation. A strict examination into these matters would not, in any way, show in favour of the Brazilian Government, and would certainly discredit many enterprizes formed on *their* guarantee of interest.

It is notable, however, that all Sugar Factory Companies formed with Brazilian capital have not only held their own, but in spite of the low price of sugar, which has been ruling for the last three years, have made fair, and many of them large, profits. What has helped the factory system is the low price of cane; this has been consequent on the low price of sugar and rum, for the farmer could only make these himself *at a loss*, and was glad to sell his cane at a low price. In the factory the price ruling for the first half of this crop season was about 6 shillings and 9 pence per ton of cane: this would be equal to £4 5s on the ton of sugar. After two months' working, the price of sugar fell so low, the factory proprietors would not give more than *four milreis* per 1,500 kilos, or say *5 shillings and 6 pence per ton*, or equal to £3 8s 9d on the ton of sugar, making with the £5 for manufacture £8 8s 9d per ton as cost of sugar. By the adoption of Thomson & Black patent furnaces, sugar can be made from the cane at £5 per ton of sugar. I have examined the accounts of several factories, and find that the whole cost of the establishment for the [illegible] last exceed that sum, for crushing [illegible] salaries, administration, repair, & [illegible] 10 to 12½ tons of cane [illegible] there is a pipe of rum [illegible] every 100 tons of cane crushed. [illegible] from the heads and washings. In this country it is [illegible] to take care that [illegible], and in the majority of cases only one [illegible] from the canes after the first clear white crystals are separated, but nothing is lost, not even the washings of the various utensils, all go to the molasses tank, and are turned into rum or spirit

The price of sugar during the first half of the season was for Central Factory *firsts* £15 per ton in Rio. Within the last two months it has risen to £21 per ton in Rio and Santos. The price of rum, which was quoted at £3 at beginning of the season, remains about the same (a pipe about 110 gallons), I do not think it possible for beetroot sugar to compete long with these low figures as to cost of production. The question will depend on whether from 5s to 8s per ton of cane can pay the grower. Experience shows that it can in the low lands of the province of Rio. No doubt, with the emancipation effected, producers, instead of being large farmers, will be small. The large farms will be divided out to free negroes and to European colonists, and the land-owner receive a percentage from the produce; cane growing will suit these people admirably, for corn and beans can be grown between the rows of cane, while the latter is young, and while the small grower is treating what will bring him money, he will also at same time be looking after what will bring his family and domestic animals food. The question will now be asked, "What has led to the failure of so many Sugar Factory Companies?" Now this is a question I do not care to enter into; but you see by the above that it is neither the high price of cane nor the low price of sugar. I cannot leave this subject without mentioning the repeal of the export duty on sugar. There used to be a general export duty of 7 per cent, a provincial of 4 per cent, a municipal of 1 per cent. In all some 12 per cent or say about an eighth of the produce of the sugar planter went towards the imperial, the provincial, and municipal Governments, for which he received very little return. The protectors of his family and property were represented by a few policemen in some town 50 or 60 miles off. The roads or tracks through swamps and forests had to be made and kept in such order as to allow a mule to pass at his own expense, very few rivers were bridged, and he, in the rainy season, was often a prisoner for months. Indeed for the privilege of giving away the eighth part of his produce (not the eighth part of his profits) he got next to nothing. Within the last few years the Government guarantee on railways has certainly done him a great deal of good, and the way these have been extended in such a short time into very remote districts deserves our admiration.

The Government having withdrawn the guarantee of interest from sugar factories, and having sternly refused to grant any more concessions for these, the sugar-cane growers felt the tax very much, and it began to be made a political question, and political questions in these parts agitate this new country more than an older one. In the financial measure carried by the Chancellor of the Exchequer this year, the imperial export duty of 7 per cent on sugar was abolished. This came into effect as soon as it passed the signature of the Princess Regent, about the middle of October. The provincial duty is also being taken off, although the measure or rather the Provincial Budget is still undergoing discussion. The municipal tax will no doubt follow. As a consequence of the repeal of the export duty which extends over all the Empire, the price of sugar in the Rio market has risen about 50 per cent, and it is not expected that the price will come down very soon. The Province of Rio de Janeiro supplies only three-quarters of the consumption of the city of Rio: the rest came from the northern ports of Pernambuco, Bahia, Maceio, &c. These northern ports are finding a better market for their refining sugars in the United States and in Europe. Consequently the supply to Rio being less, the price has risen.

The political atmosphere has been rather cloudy for the last six weeks, and there is little chance of its clearing until this Emancipation question get settled one way or another. Parties are now divided, one holding that the *last word* has been spoken of the law of 1885 which reduces the value of the slave every year, until in thirteen years he is of no value, that is, he ceases to be counted as property. On this side are arrayed the Government and all officialdom from the postmaster of the smallest village up to the Prime Minister, including in it as well all municipal authorities. On the other those who are for ending slavery in three years. This party has amongst them those who wish to pay wages to the slaves during those three years, and also those who wish free and unconditional emancipation at once. Not having the Government on their side, they have a factor which is gaining in strength every day, and beginning to assert its right to be heard in unmistakable language,—the slaves themselves. Not long ago a large body of them left their estates in the province of S. Paulo, and commenced a steady and orderly march to the town of Santos, at least 100 miles from where they started. They paid for their food as they went along and molested nobody, but a body of policemen who attacked them (and these they only disarmed and sent them adrift) and a few cavalry soldiers, who were sent against them, they killed one of the latter after he had killed one of the slaves, and with a steady front kept the others at bay. They got into the forest near Santos, and although there were some eighteen runaway slaves who gave themselves up to the police from the same forest, as they had no food, it was found they were not of the ORDERLY band. These, no doubt, got absorbed in some way about Santos, and are no doubt doing honest work for wages. The people of Santos, although they live on the rich fazendeiro, have not the same fellow-feeling with him towards the agents, by whom he has made his riches. These and similar proceedings are on the increase. The same thing, I am told, is done almost every day in S. Paulo, and the public authorities are unwilling or rather unable to prevent them. From the bitterness which has sprung up between these two parties arise other disorders. The towns in the interior are often the scenes of disturbances between the abolition and the pro-slavery party. Notably amongst these is the town of Campos in the province of Rio and the sugar capital of the south. The other day an abolition newspaper editor posted up a notice on the door of his office, which the police did not like, but which had no relation to slavery at all. A few policemen, thinking the matter *personal*, proceeded at night to rub the objectional paper off, but received some shots from the windows above where the newspaper was being printed. There were no lives lost, but the police returned in a body with orders from the superior authority to search the newspaper office; they found nobody in it, but they threw types, presses, and furniture into the street below.

Only a week after this in the same town the local member of the Provincial Assembly, who is an abolitionist, wanted to address his constituents in the theatre: this was forbidden, and he went with his audience to his own house, and spoke from the balcony. The cavalry, however, appeared and charged the crowd; later in the day the streets got crowded, and the authorities tried to disperse them in the same manner, but were defeated; the police and soldiers fired, however, in their retreat, and killed some and wounded a great many.

Official despatches followed on both sides, and the Rio newspapers quoting these despatches and

telegrams *which give the lie the one to the other* followed with their comments, and thus the agitation is kept up.

I mention these two cases as a sample, and I give them because I got the particulars from eye-witnesses.

The slave question here is like the other white slave question in an older country: nothing will be done for the social or commercial improvement of the Empire, until it is settled in some way.

The question of the rights of property is the fundamental idea pervading both. The kind of property in the old country represents a few square acres of land, and in the new the right of ownership in human flesh. Thank God for many years we Britons have denied the latter right. Let us hope we may by-and-bye settle amicably the former.

A. Scott Blacklaw.

25th Nov. 1887.

COLOMBO COMMERCIAL COMPANY, LIMITED.

Report to be presented to the Thirteenth Ordinary General Meeting of the Company, on Wednesday, the 15th day of February 1888, at 12-30 o'clock p. m.

The following annual accounts are now presented to Shareholders, viz.:—

Profit and Loss Account for the year ending 30th September 1887.

Balance Sheet made up to 30th September 1887.

As shown by the first named account the year's operations have resulted in a profit of £568 16s 11d, which, with the balance of £32 2s 7d brought forward from last year, gives a total of £600 19s 6d at the credit of profit and loss. The Directors propose that £589 17s 6d of this sum be devoted to paying a dividend of 3¼ per cent on the Preference Shares for the year ending 30th September last, and that the small balance of £11 2s 0d be carried forward to next account. Judging from the Directors' last Annual Report Shareholders will at once see that the above result is disappointing to the Board, a considerably larger profit having been expected by them. The causes which have brought about this result are as follows.

A very heavy and unexpected fall occurred during the year in the value of Cinchona Bark, the price falling so low that it hardly covered the harvesting, shipping, and landing charges. In consequence of this depressed state of the Market the harvesting of Bark on the Company's Estates was stopped, and only a small portion of the estimated quantity came forward. The Coffee Crop also fell short of the small original estimate. It is found that Tea planted on land which has already been under Coffee takes longer to mature than was generally believed, and on this account the Tea plucked on the Company's Estates fell short of expectations. For these reasons the receipts of produce from the Company's properties were far below the estimated value, and to this falling-off is entirely due the poor result shewn in the year's Profit and Loss Account.

With regard to the above Products the Board are now able to report that the price of Cinchona Bark has slightly improved, the unit value begin about 2½d as against the extremely low price of 1½d per unit ruling for some time last year. The Coffee Crop will be about the same as last year, but prices have recently fallen considerably. The yield of Tea from the Company's Estates will very largely exceed that secured last season. The Company now has 1,071 acres under Tea, of which 621 acres are upwards of three years old, and should produce leaf freely, even allowing for the fact that most of the Tea is planted on land formerly under Coffee, on which account the Tea bushes require longer time to develop, the roots having to get deep down into the soil. All the Tea is reported to be growing remarkably well, and taking into account the age of the Tea a good average yield per acre is expected. The prices of Ceylon Tea are just now ruling somewhat lower than last years. The treatment and manufacture of large quantities of Tea on the Company's Estates necessitate the erection of extensive Tea factories with rolling and tea firing machines, and the motive power for driving them. On one of the Company's Estates this work has been satisfactorily carried out during the past year, and the Board are now proceeding with the equipment of the other Estates, the work being carried out with every possible economy consistent with efficiency.

Since the decadence of Coffee in Ceylon nearly the whole of the mercantile profits of the Company have been devoted to the planting and upkeep of the Tea on their Estates, and this has been the case during the past year. The Board are able to report a satisfactory increase in the Company's general business operations, and these should steadily extend as the Tea industry increase.

*** It will be seen that the estimate of this year's tea crop is nearly double that of last year. It is believed that there are nearly 200,000 acres now planted in tea in Ceylon.

	Coffee.	Tea.	Cinchona.
	cwt.	lb.	lb.
Estimate 1888..	170,000.	23,000,000.	11,000,000.

During the year the Machinery Account has been increased from £903 14s 2d to £1,000 7s 2d., and it is the intention of the Board to write off a portion of this amount each year so soon as profits permit.

Mr. John Brown, Chairman of the Board, left for Ceylon in December, and will inspect the properties in which the Company is interested. Mr. Brown retires from office on this occasion, and, being eligible, offers himself for re-election.

Messrs. Deloitte, Dever, Griffiths & Co., the Auditors, also offer themselves for re-election.—By order,

J. Alec. Roberts, Secretary.

London, 7th Feb. 1888.

PLANTING IN MAURITIUS

(From the *Commercial Gazette*, Feb. 10th)

SHIPMENTS OF SUGAR.—It will be observed that we are in advance in our shipments as compared with those of the previous crop to the extent of 2,060 tons, and with respect to those of 1885-86, to the extent of 318 tons. The total shipments during the last 4 weeks have equalled 11,860 tons.

VANILLA.—In spite of the unfavourable news received last mail from Europe, there has been a certain enquiry for best qualities and we have to quote the sale of about 120 kilos extra fine quality at R21 per kilo and *vanillons* at R12 per kilo. A lot of 250 kilos fine quality fetched R20 per kilo (about 6 inches average.) 220 kilos good quality were sold at auction at R17·60 per kilo.

Owing to the abundant rains which have fallen since last week, the dropping of the pods is considerable in certain parts of the island and we regret to say that the out-turn of the coming crop will be from 50 to 60 per cent. inferior to that of last year.

ALOE FIBRE.—The market is firm and the demand very brisk for superior qualities.

We have to quote the sale of 85 bales fine quality at R326 per ton, a lot of 50 bales good to fine, was sold at auction at R325.

Owing to the rainy weather, manipulation has been stopped in certain parts of the island. This will cause some delay in the shipment of this staple.

THE TEA TRADE OF CANTON.

We have been favoured with a copy of the following minutes of a meeting of the Committee appointed to enquire into the state of the tea trade at Canton, held at Messrs Deacon & Co.'s house on the 26th January 1888 :–

Present :—Messrs. F. Deacon (in the chair), K. D. Adams, E. W. Mitchell, and R. B. Allen (secretary to the meeting). Mr. F. O. Seaton was unavoidably absent.

The CHAIRMAN having read the notice convening the meeting, invited the members of the committee to give their views on the subject under consideration ; a prolonged discussion then ensued, and it was finally decided to put the following on record as being some of the points worthy of the consideration of the Chinese authorities unless the tea trade at Canton is to be seriously crippled, if not altogether annihilated by the yearly increasing competition with India.

Section I. Canton Scented Caper.—This description of tea, of which the bulk of the Canton Export consists, competes more keenly with Indian kinds than any other class of China tea, being especially useful for mixing purposes. The competition with India is now, however, growing so severe, and home prices have reached so low a range, that unless some steps are shortly taken to relieve the produce of the excessive burdens of Lekin and Export duty, a time must arrive when scented tea will cease so be an article of consumption altogether.

As regards quality, the districts from which the best descriptions of leaf arrive, being the most remote from Canton suffer most heavily from Inland Taxation, and this induces native merchants to admix inferior leaf, grown nearer Canton, and suffering in consequence lighter dues. One of the greatest complaints, however, that buyers have to make is in respect to the large proportion of dust found in the teas—the dust should if possible not be sent to Canton from the districts at all, as the likin dues have to be paid on it as well as on the whole leaf, and this of course increases the ultimate cost of the tea : this complaint is especially to be made about leaf arriving from the Loting and Hoyune districts.

Section II. Canton Scented Orange Pekoe.—It may almost be said that this class (both the long and short leaf descriptions) has already been beaten out of the field by the success of Indian teas. This is amply proved by the significant fact that during the past ten years the export from Canton has fallen from 3,870,000 lb. to 1,100,000 lb. : this decrease in export continues year by year, and it now seems impossible that this class of tea can regain its lost position on the London market.

Section III. Congou.—Of this kind, the best teas arrive from the Tayshan districts, and as a rule there is a steady market for these in London. The only suggestion that might be made is that better quality would be obtained if growers were contented with fewer pickings during the year. Experience has shown that teas plucked in the months of August and Sept. are deficient in every quality except "make" and the picking of the leaf in these months affects the supply as well as the quality of the Autumn crop which is the best produced from the district.

Section IV. Weights.—It is worthy of remark that teas shipped from Canton waters invariably lose in weight on the homeward voyage, whereas those shipped from Foochow and the northern ports always show a distinct gain. The remedy for this is in the hands of the Imperial Maritime Customs, for native packers are prepared to allow an extra ½ lb. per box provided no export duty is charged upon it, a concession which the Imperial Maritime Customs will not grant.

Section V. General.—The steady fall in exchange during late years has been of material assistance to the China grower, for it has enabled tea shippers to lay down their purchases in London at lower sterling prices year by year, while paying almost the same tael prices to the Chinese as formerly. The native grower must be looked to for any improvement in manufacture or production, and as long as he feels no necessity for such improvement, it need not be expected.

The members of the Committee have read with much interest the correspondence which has already been published by the Shanghai and Foochow Chambers of Commerce relating to the decline of the China Tea trade, and they heartily concur in the opinions expressed by those bodies, and consider that the only real remedy for preventing the total extinction of the trade is the abolition of all Lekin and Export duties, so that the China article may be on the same footing as the Indian, Ceylon, and Java, all of which are free from tax.—*China Mail*, Feb. 22nd.

THE KOLA NUT as an article of trade has a remarkable history of its own. It is said that slave-dealers were in the habit of carrying with them a supply of nuts for administration to their slaves as an antidote to the suicidal mania with which from time to time they were afflicted, and that it was through these salve-dealers that the Kola nut was introduced in the West Indies, Mexico, Brazil and Mauritius. In these countries, however, the population have never paid the slightest attention to the tree, of whose presence in their midst the vast majority are quite unaware. A regular export trade is even carried on in kola nuts from Lagos and Loanda to Brazil. It is also suggested that a large proportion of the kola nuts imported into England are used in the preparation of low grade chocolates with the addition of a little cocoa.—*Indian Agriculturist.*

COTTON OILS OF ASSAM.

In the course of a paper submitted by Mr. Oswin Weynton before the East India Association on April 4, that gentleman gave some interesting particulars respecting the cotton oils of Assam. Speaking of the last named he said: "If cottonseed can be obtained fresh, a clear 8 per cent of oil can be had, and, quite irrespective of the cake, the returns will be found highly profitable. The demand moreover is increasing, as not only is cotton oil under its proper name used all over Europe, especially the southern countries, for cooking, but a very large proportion of the Lucca salad oil retailed in the United Kingdom is now nothing more or less than cotton oil, and as it is a pure palatable vegetable oil, there is not much harm done by the deception. When crushed and ground, a moderate heat for pressing is recommended, but care is needed, as any browning of the cake during extraction will result in discoloration and consequent depreciation in value. The cake sells well either locally or exported. The gins will cost about £18, suitable for Assam cotton, and should be fitted with what is technically called condensers. The number of these machines must depend upon the locality and supply of the raw material. If it is eventually decided upon planting cotton on the estate, acclimatized seed from the Bombay Presidency should be procured, as that locally obtainable has been raised from the same stock for centuries, and has consequently so much deteriorated that no amount of cultivation and high manuring would have any improving effect for a number of years. There can be little doubt eventually that the cultivation will spread as the wilder hillmen are brought within the influences of civilization, so that he who is first in the field with gins and presses has a lucrative opening for the use of such. An efficient baling press might also find remunerative occupation, but the price charged for baling and packing must be low enough to suit the means of native dealers, who, keen as they are in most business transactions, are still at the same time slow to realize the advantages of economizing time, space and labor. Once, however, these advantages are thoroughly comprehended they are rapidly adopted."—*Oil, Paint and Drug Reporter.*

HARVESTING CINCHONA BARK.

With reference to the discussion now going on in our planting contemporaries on the relative merits of the several methods of harvesting at present in vogue, and especially as to whether it is better to shave all round the tree or only in alternate strips, we express a decided opinion in favour of the latter. We contend that in this way the bark renews from the edges of strips left on the tree as well as from the cambium outwards. We have seen this system of shaving in operation for some time past, and it has been most successful. The bark renews much better than when shaved all round the tree, and the tree suffers much less from being shaved in this way. The trees should be shaved five or six times before they are coppiced, and then the result of the coppicing will be found as satisfactory as the shaving. As regards coppicing, we advocate the felling of the tree two feet or so from the ground. Our reasons are, 1st, to prevent the harm done from excessive bleeding which often takes place and frequently causes death. By allowing the stump to remain the bleeding is more gradual, &c., and the shock is felt less than when the tree is sawn close to the ground. 2ndly, the stump affor is a good general protection for the *young* suckers, especially in coffee where constant works are going on. 3rdly, where there is wind, it makes a capital stake for the growing sucker, and, indeed, can be used for this purpose to advantage anywhere. After it has served these purposes, and when the suckers are large enough to be independent of it, it can of course, if preferred, be removed; but this is by no means a necessity. The general tendency of the growing sucker is to get a firm hold on to the root of the old tree and to strike into the earth. There are some suckers, however, which start higher up on the stump, and for the benefit of *these* the stumps may be sawn down to make more room for suckers, but there is certainly not the least necessity to do this in any other case, as the lower suckers, which are generally the strongest and most healthy, are not affected in any way by the stump at that stage.—*Nilgiri Express.*

PULSES AS FOOD.

It is commonly known that leguminous seeds such as Dholl and other pulses and lentils are very nourishing. In fact they contain more nitrogenous or flesh-forming substance than meat; and are hence specially recommended to those who are too poor to pay for meat and those who abstain from eating meat either on principle or through prejudice. But when put to the test of practice, they often fail to prove quite so nutritious as their chemical composition leads us to expect. Although the average amount of flesh-forming substance in meat is found by analysis to be about 20 and that in pulses 25 per cent, it is too frequently found by experience that pulses are not even equal to meat in actual nourishing property. One would naturally enquire how this apparent inconsistency between science and experience could be accounted for. The reason is not far to seek. Meat being an animal substance is capable of easier digestion and assimilation by our stomachs than pulses are.

While thus giving to meat its proper value as an article of diet, we should not however undervalue the real merits of pulses. They are good in their own place, and can be made agreeable and wholesome by observing the following hints which I have found very useful:—

1. The seed should be thoroughly decorticated. The husk of leguminous seed is difficult to digest and is apt to produce flatulency and diarrhœa.

2. A sufficient quantity of stomachic currystuffs such as ginger, garlic, pepper, &c., should be used in cooking the seed.

3. The seed should be cooked in the softest water available. Hard waters (those which contain an undue amount of lime) tend to harden the nitrogenous principle called legumin which pulses contain, and thus make them difficult to digest.

Soft waters can be made out by their readily forming a lather with soap. Rain water and most river waters are soft. The water in Jaffna wells is mostly hard owing to the coral stratum through which it percolates. If naturally soft water cannot be procured, the available hard water should be made as soft as possible by suitable means.

4. Pulses are sometimes apt to bring on constipation as they do not contain enough of oily or fatty matter. In such cases an admixture of such a substance in a suitable form will be beneficial.—E. T. Hoole, Mallaittivu Agricultural School, 2nd March 1888.

PEPPER ADULTERATION.

It is not only satisfactory from a trade point of view, but also most important to the consumer, to find that the authorities have at last bestirred themselves in the matter of Pepper adulteration, and that several prosecutions have taken place. In connection with this subject it may be pointed out that so long ago as October 10th, 1885, a letter was published in this paper from the importers of "poivrette" or "pepperette"—a substance consisting of ground olive kernels, and absolutely valueless, but which forms a cheap and easy adulterant for Black or White Pepper. Whether with the aid of olive kernels or not, there has recently, without doubt, been a very great increase in the practice of adulterating Pepper, and it is high time that it should be checked by the law. The consumption is so small that the saving to the retail dealers from buying adulterated Pepper is at the most quite infinitesimal, and they would only be likely to buy it in ignorance. Where doubts have arisen, even a proffered guarantee should not mislead the Grocers, for their best

security is to buy of a known house and to pay a fair price. The cost of grinding Pepper is about 3s. 6d. per cwt., or $\frac{3}{8}$d. per lb. when filled into kegs and barrels; and by adding that amount to the price of good whole Pepper, the retailers can easily see whether they are likely to be buying a pure commodity. What object can it be to any retail Grocer to buy his Pepper $\frac{1}{8}$d., $\frac{1}{4}$d., or even $\frac{1}{2}$d. below the prices offered by, say five or six of the leading wholesale Grocers or Drysalters, many of whom have been in the business for generations? The saving on a year's purchases would hardly be worth mentioning, while the risk of the disgrace of a conviction for the sale of adulterated Pepper is great. The profit to wholesale adulterators, on the other hand, would be very heavy on large transactions, and once they made up their mind to take to such practices, the further question of fervently asserting the absolute purity of their wares would be a small retail. Unfortunately, it is practically impossible before grinding to extract the whole of the earth and stones which are accidentally mixed with whole Pepper in the process of gathering and drying the corns. This particularly applies to Penang Pepper, which is often very dirty. The cleaner Peppers cost about 1d. more, and when sifted and brushed before grinding, can contain little dirt. In any case the original dirtiness of the bulk of the Pepper imported can be no reason for adulterating it in this country. It should be remembered that, owing to keen competition, there are few prepared substances which have left so little profit to wholesale grinders, as Ground Peppers have done for many years past, and that this state of things existed long before the recent developments of the trade. An ordinary average wholesale profit is $\frac{1}{4}$d. per lb., and when old-established firms are undersold by $\frac{1}{4}$d., $\frac{1}{2}$d. 1d., and even 1$\frac{1}{2}$d. per lb., suspicions should immediately be aroused.—*Produce Markets' Review.*

THE USE OF THE ORANGE.

[Translated from the French of Louis Figuer.]

The orange is extensively cultivated in order to extract from its flowers and leaves the essential oil which they contain. In the south of Italy, about Sorrento, whole forests of oranges exist, the fruit of which is carefully harvested of which Lamartine sings.

"On the sonorous shore where the sea of Sorrento
At the foot of the orange unrolls its blue wave."

The orange sometimes attains great age and dimension. In the orangery of Versailles, a magnificent bitter orange (*O. Bigaradier*) familiarly called the Great Constable, is known to be 450 years old. Its trunk is 30 inches in diameter. It was planted in 1421 by the gardener of the Queen of Navarre. The orange tree at the Convent of St. Sabina, at Rome, dates from the year 1200. It is about 33 feet in height. At Nice there was in 1789 a tree which usully bore upwards of 5,000 oranges, was more than fifty feet high, with a trunk which it took two men to grasp.

The substance to which odoriferous plants owe the qualities which render them so useful at the toilets is a volatile oil. It happens sometimes that distinct oils exist in the same plant. The orange furnishes an example. The essence drawn from the flowers of the orange is very different to that furnished by the leaves, and the latter differs from that furnished by the fruit. The mode of extracting these essences varies according to their nature and condition. Some of them may be extracted by simple pressure. But the greater part of the essences are obtained by distillation, but even this practice is being superseded. The essential oils obtained by distillation dissolve readily in fatty oils or alcohol, but very imperfectly in water. The condensed water, however, which passes over with the oil is a true watery solution of the essences, in fact, orange flower water. A large proportion of the essences used by the perfumer are not made by distillation at all, they are extracted from plants by the agency of fat.

At the season when the flowers are in bloom, clarified fat, generally lard, is melted in a water bath, such as a double glue pot, and as many flowers, such as jasmine, orange, or rose are put into it. These are allowed to remain commingled about 24 hours at a temperature just sufficient to keep the fat liquid; the fat is then strained off. It is strongly scented; the flowers have lost their perfume. The same fat is melted again and further flowers are added. The process is repeated in all seven times and is then very highly scented and is ready for use or exportation as pomade. To obtain the spirituous essence or tincture suitable as a perfume for the handkerchief, pomade is macerated in spirits of wine which dissolves the greater portion of the perfumed oil; what remains, however, is sufficient to render the grease a rich pomatum for the hair.—*Oil, Paint and Drug Reporter.*

HOW ORDERS FOR "ARTIFICIAL" QUININE WERE FILLED.

The *British and Colonial Druggist* is relentless in its pursuit of Dr. Hewett, the alleged discoverer of "artificial" quinine. In a chapter devoted to his operation, it details as follows how pressing orders for the stuff were filled:—

"At length so pressed was Hewett on the subject of the execution of orders, and so emphatic were the representations of his partner on this point, that he seems to have become impressed with the necessity that quinine must be supplied. At this time, as already stated, the Atlas Quinine Company were in possession of various orders, and of these Hewett appears to have selected one of the smallest for execution. It was an order from Messrs. Samuel, Davidson & Co., Palmerston Buildings, Old Broad street, E. C., for 100 ounces for shipment to Brazil.

"At this time Cresswell Hewett, according to his own representations, had accumulated in a laboratory at Clare Market (which scientific retreat, by the way, is undiscoverable), a supply of artificial quinine made by himself, and exceeding 1$\frac{1}{2}$ tons. From this stock he ostensibly drew the quantity of quinine necessary to execute the order referred to, and during his partner's absence from the offices at St. Mary Axe, a tin containing that quantity was delivered there without apparently any record as to how it came.

"Now either Hewett's statement about his stock of a ton and a quarter was true or it was not; and if it was true it is strange that he should have gone to a wholesale house in London for the quinine which he supplied as his own manufacture. Some days prior to the execution of Messrs. Samuel, Davidson & Co.'s order, Hewett in person, accompanied by an acquaintance, drove in a cab to Messrs. Moore & Co.'s, 154 Houndsditch, and then and there, as we believe, purchased 100 ounces and brought it away with him. It appears to be the case—at any rate it is asserted by a person who claims to have seen him—that Hewett on his way back to the offices of the Atlas Quinine Company entered a wine bar with the package containing the quinine, and in a corner therescraped off the labels and any other marks which might enable the source from which it was obtained to be traced. It was then taken privately to the office of the company and half emptied upon some papers on the floor.

"In the course of our inquiries we have seen Mr. Moore and Messrs. Samuel Davidson & Co. the suppliers to and the purchasers from Hewett of this parcel of 100 oz. The latter firm did not hesitate to give the particulars required, and we had, therefore, no difficulty in ascertaining that the quinine was supplied to them at one shilling per ounce. On the other hand, Mr. Moore, though he received our representative with all possible courtesy, not unnaturally declined to give any specific information relative to any of his trade transactions. We are, therefore, unable to say for a certainty the exact amount paid to Messrs. Moore & Co. for the 100 oz. of quinine, but it is beyond doubt that Hewett purchased the parcel at about the market rates for the express purpose of supplying it to Messrs. Samuel, Davidson & Co., at half what it cost him."—*Oil, Paint and Drug Reporter.* [How any one believed in the transparent impostor is the wonder.—ED. *T. A.*]

THE MANUFACTURE OF PERFUME.

During this season the factories work to their full extent, though the treatment is so slow, and in some instances requires such constant repetition, that flowers are only received twice a week. If, however, one should happen to visit a factory on a receiving day, one will find the floors of the reception rooms covered, perhaps, with a mass of violets, upon which probably recline two or three young ladies, enjoying the perfume and delighting in the reality of an imaginative dream. Every flower, before arriving at the perfumery, is removed from its stem, when, according to its nature, it undergoes one of the three processes—distillation, submersion in hot grease, or absorption by cold grease, all utensils used in the manufacture being made of copper.

The first is the costly but ordinary method of the retort, placed over a small furnace, carrying the vapour as it condenses into a receiver, with glass tubes on the outside, to catch the essential oil. Verbina, geranium and lavender are treated in this way. The second is very curious, and seemingly ought to be disastrous. Flowers in certain proportions are flung into good-sized kettles of hot pork and beef grease, kept warm by placing the vessels in boiling water; they are well stirred together, and left still hot for twelve hours, after which the mixture is heavily pressed. The flowers are then thrown away, and the operation is repeated with fresh ones, until the liquid grease is sufficiently charged with odor, when it is placed in a cold receiver half-full of spirits of wine, which in a few days becomes impregnated with the perfume and is drawn off for sale. If the grease is not subjected to the spirits of wine on the premises, it is sold in its congealed state to the London scent-makers, who treat it at their leisure. Roses, orange blossoms and violets are some of those requiring this method. The third, to the eyes of a novice, does not appear so hopelessly destructive or so wilfully barbarous, yet the sacrifice of beauty is the same. A layer of olive oil or cold grease carefully prepared, is placed upon a frame, the flowers being dotted over it, face downward and remaining for twenty-four or thirty hours. The process is very tedious, requiring to be repeated with the same grease many times, after which the perfume is absorbed by spirits of wine, as in the previous manner. The delicate scents can only be caught in this way—will only give out, so to speak, their exact salves according to nature. It is no extraction, but literal absorption, the catching of sweetness freely imparted to the fresh air of native hillsides. Jessamine, tuberose, jonquil and others not of tough formation, must be submitted to this treatment. The industry is of great value; there are upwards of fifty perfumeries, and though the London market is the best outlet, yet their products are being gradually shipped to almost all parts of the world. There is no toil about the work, no grinding poverty, no din or rattle of machinery, no emaciated children, everything is quiet and peaceful: in fact, if it would not be a paradox, one might call life in these factories the "Nirvana" of labor. The manufacture being a very profitable one, the perfumers are naturally the men of the place, and besides possessing good means, are large owners of property at Cannes and Nice, as well as at Grasse.—*Spectator.*

FLUID EXTRACT OF CINCHONA BARK.

BY A. C. ABRAHAM.

For the preparation of fluid extract of bark with water only I have always advocated the employment of that water at or near the boiling temperature.

This preference, together with a very suggestive article by Dr. Paul (*Pharm. Journ.*, vol. xvi., p. 56), prompted me some time since to try to effect the removal of the alkaloids soluble in water with water only, and the subsequent removal of those insoluble in water by means of an acid menstruum.

The three following experiments were tried upon a bark bought from a good house as containing quinine 1·91; quinine and cinchonidine 4·31. Total alkaloids 6·53.

It was a quill bark, and was, therefore, chosen in preference to others richer in quinine, which, being in the state of scrapings, did not answer the description of the Pharmacopœia.

It was, as will be seen, well over the Pharmacopœia standard, and as the resulting fluid extract had to be estimated, I did not consider it necessary to confirm, in any way, the guaranteed analysis under which I had bought it.

1st Experiment.—Five lb. treated exactly as ordered in the Pharmacopœia, produced 51·2 fluid ounces of fluid extract of the required strength.

2nd Experiment.—Five lb. was percolated with boiling, distilled water until 6½ gallons had passed (the same quantity as was collected in experiment 1), and when evaporated with the quantity of glycerine ordered in in the Pharmacopœia, produced 48·52 fluid ounces of product of the standard strength.

3rd Experiment.—The residue from the last was percolated with 2½ gallons distilled water acidified with 2½ fluid ounces of hydrochloric acid; produced 35·88 fluid ounces of the required strength, viz., 5 per cent.

Since making these three tests, I have repeated with another bark experiment No. 3. The percolate in this case was natural and consequently of course very weak, and I found it necessary to double the acid before I could produce any decided effect in the way of taking out the remaining alkaloids.

It will be seen that by the official process, a product of 51·2 fluid ounces was obtained, and that by the use of boiling water and subsequently of the acid, the product was altogether 79·4 fluid ounces, showing an increased yield of 28·2 fluid ounces by operating in this way. The conclusions which I draw from these facts are:—

1st—That if we want to have a fluid extract representing as far as possible the bark from which it is made in an unaltered state, we should certainly let water do what it can, and then, if we wish to add an acid solution of the cinchona alkaloids to it, treat the residue with an acid menstruum.

2nd—That in the latter case the acid menstruum should be at least double the strength of that ordered by the Pharmacopœia. I may say that my preference for boiling water is not founded upon any experiments with such barks as are now official, but with the old flat calisaya. Nevertheless, I have every reason to believe that what holds for the one holds for the other, and that in either case a given quantity of boiling water will remove more than can be removed by an equal quantity of cold; partly by its superior solvent action and partly by removing certain matters—which are afterwards thrown out on cooling—which interfere with the action of the menstruum.—*Oil, Paint and Drug Reporter.*

THE BETEL LEAF.

Some time ago, attention was drawn in our columns to the medicinal virtues of the betel vine. Additional information since then tends to show that its curative properties are becoming more and more appreciated. It is well known that betel leaves play an important medicinal part in this quarter of the world, in combination with lime, arecnuts, and gambier. But in Europe very few people are aware of their healing powers. Hardly any of the pharmaceutical handbooks in circulation say anything of its usefulness as a medical remedy. This omission is the more surprising, considering that, from a sanitary point of view, the betel vine occupies a prominent position in these tropical regions, and bears a high reputation among the native races. To them, chewing betel leaves has become indispensable. They would much sooner forego meat and drink than deprive themselves of the enjoyment derivable from the highly-prized sirih leaf, which has, indeed, become to them a necessary of daily life. Several Dutch botanists inquiring into the subject have come to the conclusion that the chewing of betel leaves does indeed promote health in the damp and miasmatic climate of these tropical lands. Ancient Hindu writers make mention of the utility of betel

leaves, and recommend their regular use. Marco Polo in the thirteenth century not only alludes to their use for mastication, but also brings into notice their favourable influence on health. The Netherlands Indian Government profited by this experience of centuries, in the direction of serving out betel leaves to invalids and even convicts. Betel leaves have a favourable effect, especially in affections of the throat and windpipe. British, German, and Dutch physicians have taken note of this in the East. British medical literature confirms this experience, so far as India is concerned. It must hence arouse surprise that betel leaves which are grown from the Himalaya to New Guinea and are highly valued among the inhabitants of the intervening countries, have to this moment, not been turned more to account in Europe. The same was also the case until very lately with the coca leaf, which yields the medicine styled cocaine, now coming into such extensive use. Yet, betel in the Far East lays claim to greater importance than coca in South America. The reason why in Europe, no use has hitherto been made of the betel leaf, probably is that it does not keep long. Leaves only a few days old are not used by the natives, but are thrown away as worthless. When dried, they lose wholly their aromatic, spicy, and stimulating odour, which arises from a volatile oil to be found in the leaves. This volatile oil has now for the first time been fixed by an apothecary in Java. It is readily separated from the leaves. He drew the inference that the healing powers of betel leaves depended on the quantity of the oil they contained. This has been amply confirmed by physicians of notice in Java and Germany. These facts bring into prominence an article of Straits Produce hitherto neglected, but which may yet figure conspicuously in our export lists.—*Straits Times.*

THE TOBACCO LAND OF THE FUTURE.

At last a serious effort is to be made to bring into cultivation a portion of the vast dominions which the Dutch hold in Borneo, the third largest island in the world, New Guinea being probably a little more extensive than the father-land of the orang-outang, as far as geographers know. The Dutch have had so much on their hands elsewhere in the East Indian Archipelago that Borneo has been long neglected. They hold the southern, a portion of the western, and the greater part of the eastern coasts, but their authority does not extend very far into the interior, which is little more than an impenetrable wilderness. When the British North Borneo Company was formed, with the aid of an imperial charter and important concessoins from native sultans, there was some soreness in the circles of Dutch officialdom at this new "British aggression." Count Van Bylandt, the Netherlands Minister in London, received instructions to protest against what was regarded at the Hague as a violation of both the letter and the spirit of the treaty of 1824, which was supposed to define the sphere of activity of Britain and Holland in the Malay Archipelago. Lord Granville would not admit that the granting of a charter to a private company constituted a breach of the convention, as Britain did not assume sovereign powers in North Borneo. So the British North Borneo Company proceeded on their mission of progress and civilisation. The Dutch colonists then commenced to see the advantages they could reap from the efforts of the newcomer. They had established extensive tobacco plantations at Deli in Sumatra, where many of them amassed large fortunes from the kindliness of a soil which only wanted "tickling" to surrender its riches. Gradually, however, land and labour became dearer at Deli. Then these shrewd planters set sail for North Borneo, where they discovered that the soil was at least as "obliging" for tobacco as Sumatra. The first crop, necessasily very small, fetched high prices in Amsterdam, and the Deli people immediately afterwards secured all the cheap lands they could get from the company. Several Dutch-Indian tobacco growers are now hard at work in North Borneo, and Mr. Alfred Dent firmly believes that they will be some of the best customers of the New Bank of North Borneo, which he proposes to start in a short time. Meanwhile his company, as announced by Sir Rutherford Alcock at the last meeting of shareholders will not sell any more lands at purely nominal prices, nor dispose of large tracks as hitherto. Some disappointed Dutch tobacco planters, who came too late for business, have now turned their attention to Dutch Borneo, where millions of acres of fertile soil are waiting for tillers and scientific growers, as was pointed out quite recently by Dr. Guillemard, in his interesting book, the "Cruise of the 'Marchesa.'" A small company is to be formed tentatively to acquire vast tracts of land on the banks of the Kuti River, in Eastern Borneo, where tobacco growing will be commenced immediately by virtue of a concession obtained from the Dutch-Indian Government. There has hitherto been so little demand for these waste lands in Borneo that Government regulations are not yet in existence, but they must soon follow, if it be true that the Kuti experiment is to be followed by others on a larger scale. This is probably enough. The soil and the climate of North and East Borneo do not differ materially from those of Deli, and there is no reason to suppose that Kuti tobacco will be less prized than Sandakan or Sumatra. It is a singular thing that the Dutch in Malaya should have been taught by British "aggressors" in North Borneo the value of their own colony; but history, which repeats itself, is full of those economic contradictions.—*Financial News.*

THE MOSS LITTER, CHARCOAL AND MANURE COMPANY, LIMITED.

We have heard of late years a great deal about Peat Moss Litter or bedding for horses and cattle, and all who have tried it are and should be grateful to the above-named company for having introduced it to this country. The Managing-Superintendent of the company, Mr. R. J. Wells, for some years worked the business alone, but the merits of the article which he had brought into use became so widely and rapidly recognised that a limited company was ultimately formed, by which the business has been greatly developed to the advantage of farmers, stock-raisers, railway, tramway, and omnibus companies and others all over the country.

The admirable qualities of the Peat Moss Litter make its popularity no matter of astonishment. To begin with, it has been proved beyond doubt to be the best and most economical bedding for horses, hounds, cattle and stock of all kinds. One ton of Litter will do the work of two tons of straw at less than half the cost, and produces a manure very much more valuable. It absorbs all the ammonia from the urine, and being a perfect deodoriser, drains are unnecessary; without them, stables, kennels and cattle-sheds are kept sweet and clean. It makes a soft and elastic bed, and its cooling and antiseptic power upon the feet of tramway and other horses after running all day upon the hard sets is simply wonderful, the animals' feet and knees, it is affirmed, keeping sound double the time they do when bedded on straw. Moreover, it quickly restores a rough and unhealthy coat to a bright, clean, and healthy condition, and as a plant-food or manure, is worth about double that of wheat-straw. Upon this last point we may quote the following extract from the *Engineer* of September 24, 1880, from a letter by G. A. Vassard, Esq., Expert Chemist to the Board of Trade:—

"Farmers spend annually large sums of money in Artificial Manures, such as Guano, Phosphates, Nitrate of Soda, &c. and yet not one of them contains so many of the necessary constituents of plant-food as Peat does. A very large quantity of Humus is annually removed from the soil by all plants, and must be replaced in order to keep it fertile. Peat is of immense value as a Humus producing material, and in Humus there is found all the ingredients necessary for the formation of the plant, and in such a condition that the plant can absorb and untilise them."

This testimony is confirmed by all the leading agricultural chemists and by practical agriculturists without number. We may say that this Litter has been used by Her Majesty's Government, and by many of the leading railways, tramways, collieries, and more than a thousand of the nobility and gentry in the kingdom.

A very emphatic word of caution should be given here against the Peat Litter imported from Germany, which, the success of the article we are noticing has induced German traders to put upon the English market. This foreign material comes from the dead and decayed bogs of North Germany, and lacks all the health-giving and antiseptic properties possessed by the Company's Moss Litter which is manufactured from *living* and *growing* vegetable matter and fibre, in as good a state of preservation as hay or straw.

On national grounds thanks are due to Mr Wells, for his object orginally was a national one. When he first attemped the utilisation of Peat as a commercial industry it was with a view to make this enormous national waste a labour-producing and paying commercial enterprise. After much hard work and expenditure he has abundantly succeeded, and apart from any commercial success which he has realised, he has the satisfaction of knowing that he has not only turned a vast waste into a great national profit, but also provided remunerative labour for hundreds of the unemployed. A most interesting article might be written descriptive of the philanthropic side of his enterprise above.

The Pure Vegetable Charcoal manufactured by this company may also be termed a national blessing, in connection with sheep and cattle breeding. There is abundant testimony that 80,000 sheep had been cured up to 1882 by the use of this charcoal of fluke or rot, for which it has been proved that there is no other preventive or cure.—*Railway Supplies' Journal.*

FIGS:—A PROFITABLE INDUSTRY.

SOME PRACTICAL POINTS IN FIG GROWING.

The great impulse which fig culture has of late received in California has elicited numerous questions as regards culture, pruning, etc., many of which are of the utmost importance for success. The fig is in many respects a tree which requires entirely different methods of pruning and culture from ordinary deciduous fruit trees. But here as with different varieties of peaches, etc., different kinds of figs need somewhat different treatment, dependent upon the habit of the varieties, the soil on which they are grown, and the purpose for which they are grown. The only tested fig which in California has proven of superior value is the Adriatic, and our remarks will therefore only apply to this variety.

The most suitable trees to be set out in orchards are those which are well matured as to wood and which have been grown on dry, sandy land. As the only suitable place for this fig is dry, well drained soil, the drier and sandier the soil in which the trees were started better of course. The trees will stand transplanting. In connection with this I may mention that not all figs require dry soil; some varieties do well in, or even prefer, moist and rich land.

The question if the trees should be headed low or given a standard of 3 to 4 feet is of less importance, as the trees in course of time grow to an enormous size, and really outgrow our possible calculation. If we want the trees for drying only, then the Smyrna way of raising the standard to 6 feet may be imitated, as it allows us to undisturbed pick the dropping fruit from the ground without being interfered with by low branches. But when the fig is only cultivated for the sake of table figs, a low head seems more profitable, as it enables us to pick much of the fruit without the aid of a ladder. In young, low-headed trees the quality will be better than in standard, but when the trees get old, I believe the difference in quality will be none.

From the very first, the pruning of the fig tree is of the greatest importance, much more so than is generally realized. In forming the head of the tree, the branches should be started at least six inches apart, as, if the branches start out too close, they are apt in after years to break or split at the junction. The branches to form the head is enough. If more are left they will soon crowd each other, and some will have to be cut off, much to the detriment of the tree and its fruit. After the head is formed, the trees should be left alone, and only occasionally a branch which crosses another branch be cut off. The tops of the branches should never be cut off except in great emergency, because any such trimming will *seriously for years to come injure the quality of the figs.* Several cases of such sudden deterioration of the figs after pruning have been reported to me, and one has come under my ocular experience: Two years ago a friend of mine owned a good-sized tree of the Adriatic which had been bearing the choicest kind of fruit for several years. That year all the branches were topped and the consequence has been that the figs for two seasons have been very inferior as to quality, sweetness and flavor, and only little larger as to size. A marked difference was also found in the skins, while the same formerly were thin as tissue paper; they became after the trimming thick and coarse. So great was the change that if I had not been positively acquainted with the quality of the figs from that very tree, no one could have made me believe that the figs produced were of the same variety. I have heard of old fig tees which, after being pruned, did not recover for ten years. This seems to me undisputably proving that figs should not be topped.

Deep and constant ploughing of the fig orchard is not necessary. In Smyrna where the finest figs are grown the orchards are seldom worked to any depth, only the weeds are cleared away, so as to allow the figs to be seen when they drop to the ground, and from the same be picked up without being injured by sand and dust.

I regard the *mesa* soils of Southern California as specially suited for fig culture.—GUSTAV EISEN.—*Rural Californian.*

PLANTING AND MINING IN NORTH BORNEO IN 1887.

The year 1887 having passed away, it is again our task to review, at the beginning of the New Year, the events that have happened, and the progress made in the Territory during the by-gone twelve months.

Planting.—First and foremost, the year 1887 is to be noted for the large extent of land taken up in the planting interest, more especially in regard to the cultivation of Tobacco. Thanks to the operations of Mr. Gibson in Sandakan Bay, and Mr. Persyn, the manager for Count Geloes d'Elsloo at Ranow in Marudu Bay, it has been demonstrated to the satisfaction of all concerned, planters, and buyers, that the soil of British North Borneo is capabie of producing an article not inferior to the famous Sumatra leaf for which Deli has so long been pre-eminent. The prices realized by the Suan Lamba and Ranow tobacco have had the effect of bringing many other planters to our shores eager and ambitious to "go and do likewise." In Darvel Bay, Baron von Stein's Company have taken up 20,000 acres at Labad Datu, have cleared a large quantity of ground, and erected bungalows, offices &c. At the Segannan river further to the Eastward of Labad Datu, Messrs. Stephens, Muller,—the latter gentleman formerly Mr. Gibson's right hand man at Suan Lamba,—have commenced operations, and we learn it is Mr. Stephen's intention to take up some land on the Segama river, somewhere in the neighbourhood of the resthouse on the left bank. He should certainly find no difficulty in suiting himself in this locality, nor would he have much trouble in connecting his land here by road with the Segannan Estate, the intervening jungle being flat, with only a few low ridges, and the river distance some six to eight miles. In Marudu Bay, Count Geloes d'Elsloo has taken up more land, while the German Borneo Company have also applied for land in the same locality. Selections have also been taken up on the Labuk and Sugut rivers, and we hear likewise of ap-

plications made for land in Province) Dent. In all the applications for land cover over 200,000 acres, and from signs and indications the Land Office is likely to book many more before the applicants cry a halt. From the above it will be seen that the Commissioner of Lands has had, and is likely to have his hand full, a fact upon which we may fairly congratulate the Territory.

It is not, however, for Tobacco alone that land has been taken up. The British Borneo Trading and Planting Company has opened an Estate on the Segaliud river, and at Boccara, a few miles distant from the capital in Sandakan Bay. Mr. Alexander Walker, a planter of experience in Mysore and Coorg, has put down pineapples and Manila hemp at Baccaro, for the purpose of treating the fibre with Death's patent fibre machine, for which the Company have bought the right for British North Borneo. In the Segaliud, pepper is being tried. Near Kudat, Mr. Christian has a plantation of Liberian Coffee, which is looking very well, and the bushes coming on fast. At Tamoy on the Kinabatangan are some three hundred sago palms which are looking very well, and the natives up the river are anxious to secure cuttings to plant valuable product on a larger scale. Arrangements have been made, so we understand, for planting out the Willoughbeia rubber which being an indigenous product is likely to prove a remunerative speculation. In all, the amount of land taken up, and applied for at the Lands Office for all these various products adds up to 220,000 acres.

Mining.—In mining matters we have to note the arrival of Messrs. Skertchly and Allard, representing the British Borneo Gold Mining Company. Mr. Skertchly has made a flying trip to the Segama and Bole rivers in the neighbourhood of Itok Batu and from what he has seen of that part of the river he is sanguine of a field near the head of the river that will pay. Captain Beeston with a party of four Europeans left Sandakan in August last to explore the sources of the Segama. His report will be found in another column. It is the opinion of the whole party that an extensive and payable field is awaiting development; the extent of whice it is at present impossible to estimate. Above a certain point on the main river, and from thence to the head waters, the country is composed of slates, diorites and serpetines, the favourite Australian gold formation, all the affluents, creeks, gullies and ravines carrying gold in addition to the main river, while quartz reefs carrying gold are in great numbers and of large size. The expedition were four months away from Sandakan returning in the middle of December. —*British North Borneo Herald.*

INDIAN COOLIES FOR DUTCH COLONIES.

In our leading columns, attention is drawn to the negociations for extending the Indian Emigration Act to Netherlands India. In connection with the subject we reproduce the following extract from a paper on the Agricultural Resources of India read before the Society of Arts, by Sir E. C. Buck, on the 25th January 1885. He said:—

I now pass to a subject which has not always received the attention which I think it merits emigration. As there is beyond England a "Greater Britain," so there is beyond India a "Greater India." I do not mean a greater India for the Empire, but a greater India for the five-acre holders, and the surplus members of their families. To whatever nation the proprietors may belong, the equatorial sea-girt lands offer an unlimited labour market. I have already indicated their superiority to India in the absence of any struggle with desiccation. The fact is that they have a moist, equable, not unpleasant and extremely fertilising climate all the year round. In Java, for instance, there is a little rain every day. In an interview, which I was permitted to have with the Governor-General of the Dutch Indies, his first words were: "We in India do not suffer from famines as you do in British India." (India to the Dutch is not British but Dutch India.) So it is throughout the equatorial sea-watched lands, inclusive of Northern Australia, and parts of Africa and South America. I have not figures at hand to show the magnitude of size as compared with India, when I mention that if a line be drawn from Calcutta to Bombay, the whole of India below that line will be just equal to Borneo. But if we compare culturable land with culturable land, it is probable that Borneo is double the size. Nature, however, in bestowing rich vegetable wealth on these regions, has accompanied her gift with the drawback of a lazy population, lazy because the climate is enervating, and because nature pours food into their lap. They are not braced up by the hard fight with nature which produces the patient, sinewy and hard-working Indian cooly. So it happens, therefore, that the capitalists in the Fiji Islands from which the Australians in vain attempted to obtain sufficient labour for their tropical lands, have now themselves procured labour from India. Is not this a significant fact? So again, the Governor of the Straits Settlements, to which colony I was deputed on a mission connected with emigration, sent me the other day up to the top of the mountain range between Siam and the protected States of the Malay Peninsula, in order that I might see the coffee berries rotting on the bushes for want of Indian labourers to pluck them. I hope that arrangements are now such that he can get the labourers he wants, and there will henceforth be the same ebt and flow of Indian labour to the Malay Peninsula thas there is to Burma and Ceylon, to which countries thousands of agriculturists migrate—like swallows—every year. Rather, perhaps, I may compare them to a line of ants, which go backwards and forwards to rich heaps of grain, from which they bring back a welcome store to their own homes. This is the point. By his labour abroad, the Indian agriculturist accumulates a capital to be expended on the five-acre farm at home, and that is, above all things, what is wanted, not an increase in the number of five-acre farms, but expenditure of more capital on those existing. It is often said that, while there is waste land in India, why send labour abroad? I have given one reason, but there are two other strong reasons. One is that the Indian labourer cannot settle without a capitalist protector, and that there are few capitalists ready to risk money in new land in India; they make more and risk less by lending money on the cultivated area—whereas in the "Greater India" every capitalist is (like Sir F. Weld's coffee planters) ready to give (at once) double wages. The other reason is that if we neglect any opportunity of letting the labour market be supplied by Indian cultivators, it will be occupied by Chinese, the only other labourers of the East to whom a hard struggle with nature in a dry climate has given energy and patience. In 1883, 100,000 Chinese went to British Malay possessions against 4,000 Indians.

Sir Hugh Low in the discussion on the paper said:—

He had had the pleasure of meeting Mr. Buck when on the mission to Siam to which he had referred, and he was thoroughly satisfied that there was a great field for emigration there. They got large numbers of Chinese, who were very useful for many purposes, but they did not take much to agriculture. The object of the Chinese seemed to be to make money as quickly as possible, and mining *paid them* better than agriculture. When Mr. Buck was there, it seemed to be a question with the Indian Government whether its subjects should be permitted to migrate freely to this land of promise, where Mr. Buck saw them earning wages far beyond anything they could get in India; where they were well fed, well clothed, and although they were not so well housed as he should like them to be, the climate was genial, and the housing was not of much importance. That country was very anxious to induce them to come, and since he left, a year ago, the regulations were so modified that there was a fair chance now, he believed, of getting a sufficient supply of labour, which was the only thing necessary for cultivation. An ordinary man from Madras, who got in his own country 6 to 7 rupees a month, would easily get 12 to 15 dollars a month in Perak; and it

seemed very remarkable why there should be so much difficulty on the part of the Indian Government in allowing its subjects to go there, for even now he believed it would be very difficult for planters to import anything like the numbers they would like. He should like to see free emigration permitted. There was sufficient protection for life and property in the Malay States, which were under British protection, and he could not understand why there should not be perfect freedom for the people of India to go there if it were found that they could better themselves, and live more comfortably, and add to the wealth of England, by fostering the cultivation of those provinces, which were in fact English though they were called native States. This was the point to which Sir Frederick Weld's Government at the Straits Settlements had given a deal of consideration, and he thought every one who considered it fairly would agree that everything ought to be done to induce the Indian Government to look at it in the proper light. The land such as Indian settlers would occupy was very fertile, and it was no uncommon thing to see paddy produced two hundredand two hundred and fifty fold, with a minimum of cultivation on lands some of which were irrigated and some cultivated entirely by the rainfall, which was very heavy. The only cultivation he had ever seen the present occupiers of the soil use was cutting down the weeds in the beginning of the rains. The most approved system was to drive a herd of buffaloes over it to drive the weeds in. There were some salts, but they could not be much in excess, as he had seen the finest sugarcane growing where the soil was quite white with efflorescence, which he thought was caused by carbonate of soda. It was found that if plenty of water were put on the land, it washed the salt away or converted it into manure. The Government was most anxious to favour Indian labourers coming into the State, and had offered to give them land on almost any terms, if they could only get them to come and settle down as permanent cultivators; of if they would not do that, they were willing for them to come there, and return to their own homes, to which they always carried back considerable wealth after having lived in comfort and happiness all the time they were there.—*Pioneer.*

RICE AND COCONUT CULTIVATION.

Siyane Korale, Ceylon, 17th Feb. 1888.

The January number of the *Tropical Agriculturist* is rather freely interspersed with communications on a variety of subjects from the Agricultural Instructor stationed at Bandaragama, in the Rayigam Korale. If it will not be considered impertinent for me to offer advice, I will advise him to absorb all the information he is able to afford the public into one communication, confining each subject within the limits of a paragraph, something after the manner of the writer on Agriculture from Paris.

His communication on the benefits arising from pulverising soil is very interesting. Would that he were able to impress his views on the subject on the rice growers in his immediate neighbourhood. He seems to be afflicted with a large quantity of poonac for which he can find no use in paddy cultivation. Mr. Hughes has recommended a mixture of castor-cake, bones and fish for our paddy fields. Cocoanut poonac certainly is a very poor substitute for castor-cake, as analyses have proved that the latter has over twenty times as much nitrogen as the former; but it can be used in larger quantities, and the benefits of so much more organic matter in the soil cannot but act very beneficially. If I may be permitted to offer an unprofessional opinion, I think that a good mixture for paddy will be bones, poonac and [illegible] this not in possession of Mr. Hughes' letter, as all the ingredients for the mixture can be more easily available [illegible] whether time should be mixed with the poonac must be answered in the negative, as time is said to dissipate the ammonia from all manures containing it. But at the same time, I think that lime can beneficially be added to a paddy field after the first ploughing, to help in the decomposition of the vast amount of vegetable matter that abounds in the fields in the form of stubble and weeds. This more especially if water, the decomposing agency now in use, is not to be turned on them.

The communication on the benefits of irrigation is not very easily understood. What authority is there for the statement that "irrigation is little attended to," or that the wealthy and intelligent cultivators have abandoned the practice? The general complaint hitherto has been that water is wasted in over-irrigation. I do not believe that many people will subscribe to the dictum that irrigation will give large crops "without impoverishing the soil." The promise that if occasion requires the benefits of irrigation "with other concomitant advantages shall be more particularly enumerated," must be redeemed, for the occasion for it has arisen in the scepticism on the subject, despite Mr. Rodrigo's belief in it.

A very interesting communication on "Paddy Cultivation and Manuring," appears from the pen of "W. A. D. S." the Agricultural Instructor stationed at Minuwangoda. What amused me was the foot-note to his communication by "an experienced European agriculturist in the lowcountry," to whom it was referred to solve some of the knotty problems propounded in it. "W. A. D. S." will, I am sure, not fail to be grateful for the appreciative tip on the back administered to him in the remark: "It is quite a new thing for a native to have attained even so much theory as to write about nitrates and phosphates," probably in ignorance of the fact that this particular native has a right to dilate on nitrates and phosphates by virtue of a special training on the theory and practice of agriculture. The fears that bulky manures, such as cattle manure, will so raise the level of the fields as to render them unfit for paddy cultivation, are, I think ungrounded, as the average native has not command over sufficient cattle-manure to raise the level of his fields to any appreciable extent. Indeed, I doubt whether he produces sufficient to scatter very finely over his whole field. Agricultural experiments conducted by eminent scientists disprove his assertion that the effects of cattle manure are so evanescent as not to be discerned after a few months. If the effects of cattle-manure be so short-lived, why give it the premier place as a manure for paddy, and accord the second place to bones?

I learn for the very first time from the letter of your Hapitigam Korale correspondent, that smoke baths have been seriously recommended by a coconut planter, since deceased, for increasing the growth and crops of coconut trees. What idea he had of the functions of leaves or of the composition of smoke, is not stated. Combustion of any vegetable substance sets free carbonic acid gas and nitrogen, but are they visible to the eye in the form of smoke, and do the leaves absorb carbonic acid as fast as it is generated by burning? Carbonic acid and nitrogen play very important parts in the building up and growth of trees; but can either add to a fruit crop? This is not a subject for us, who merely retail the experiences and experiments of scientists, to attempt to solve or throw light upon, but it is eminently a subject for agricultural chemists, that is, if they consider it sufficiently serious to deserve consideration.

Many people seem to labour under the delusion that cattle dung is something else than the refuse of the food eaten by cattle after the valuable portions of it have been abstracted for the sustenance of the animal. The value of cattle manure is solely dependent on the quality of the food given to the animal, and is so much appreciated as affording plant-food in a readily available form. So with ashes which are the residue of organic matter mixed with [illegible] I am afraid [illegible] hope, at the annual meeting of the Horticultural Society, that the "much-vexed question" of fibre refuse will be set at rest by Mr. Carey's discovery that it can be used as fuel in dry weather, will not be realized, for the very ashes will rise up as a spectre to haunt him. Sir J. B. Lawes and Professor Gilbert are said to have carried on experiments in this direction, and the results of their

investigation are entitled to much weight. Farmyard manure was burnt and applied to a field of wheat which yielded no better results than a totally unmanured field, and in succeding years "the ash constituents were found to be but very slowly available as plant-food." Besides, nitrogen is an essential in plant growth; and to drive it out of any substance before using it as manure, is not wise. It is accepted as a general rule in agriculture, not to burn anything that will rot in the soil. In a sandy and hungry soil what better substance can be found than fibre dust, which is so finely divided, to be ploughed into it both to give body to the soil and to increase its retentiveness? Sand is distinguished for its extreme porosity, while the fibre dust is so retentive of moisture as to render it a matter of extreme difficulty to dry it. Its decay can be accelerated by lime. Humus is of great value agriculturally. The carbonic acid gas set free in the process of decomposition acts as a solvent and renders available the insoluble plant-food present in a soil as also the temporarily insoluble constituents of artificial manures. "Plant-food in most animal and vegetable residues used as manure costs less than in commercial fertilizers." I think I have written sufficiently before and now on this subject, to convince all but those who refuse to be convinced, that the wisest and most economical course would be for the Directors of the Horrekelly Company to see that the vast stores of plant-food that are lying idle on their property be ploughed into the soil with the commercial fertilizers already in use: at least they can experiment with it, on say 10 acres, and carefully note results.

Natives in the cinnamon gardens of Colombo have given up to a great extent the pernicious habit of heaping fibre dust round the stems of coconut trees, to cover the adventitious roots that spring from the stem, owing, I believe, to water lying so near the surface of the ground, and now bury the dust either in shallow trenches all over the ground or spread it out on the surface and dig it in. The dust can be had at the mills for the mere carting. If the mill owners can devise some means to compress it so as to render transport easy, I believe it will be largely used on coconut estates either to be turned into the soil or for bedding for cattle, either in sheds or in shallow trenches round trees. I believe it will also do very well for a compost with bones, poonac and potash in the form of spent soap-lay; but the bulkiness of the manure must be overcome by compression.

WATTLE CULTIVATION IN SOUTH AUSTRALIA.—A Mr. Clifford, formerly of the Indian Forest Department, is projecting extensive cultivation of wattles in South Australia. In connection with his scheme, interesting details of a previous experiment are given as follows:—Mr. Clifford hails from Melbourne, and met Mr. Brown at Border Town on Wednesday. Today they proceeded to the Mount Muirhead Wattle Plantation, where 40 acres were planted about six years ago. The success of the experiment may be gauged by the results. The wattles at the Mount Muirhead Plantation have been thinned out for the first time, the yield being 1½ tons to the acre. The bark is worth £10 a ton, so that the return per acre from this source is £15. The cost of putting in these wattles was 3s per acre. Next year the return per acre will be a great deal more.

NITRIC ACID TEST FOR GOLD.—It would appear that this pretty generally used test for gold is likely to be no longer reliable. It is stated that an analysis of "mystery gold" found in a chain, disclosed an alloy of copper, silver, gold, aluminium, and iron, the latter being present probably as an impurity. The aluminium resists the nitric acid test, and even where present in only small proportions renders that acid no longer a trustworthy test.—*Burgoyne, Burbridges, & Co.'s Price Current.*

THE BLISTERING POWERS OF THE ALOE have been again attracting attention. According to M. Decroix, a veterinary surgeon at Algiers, the pulp of the *Agave Americana*, especially that from the young leaves or from the foliaceous envelopes of the bulb, possesses blistering properties similar to those of mustard flour. M. Liquistin has also used the aloe pulp for the same purpose in Mexico. It is unknown to what principle the juice of the aloe owes this property, but the effects of the pulp do not appear so reliable as those of mustard.—*Ibid.*

EXTENSIVE CULTIVATION OF THE EUCALYPTUS.—Along the embankments and cuttings of the Tunis-Algiers Railway, nearly two hundred thousand young red gum trees (*Eucalyptus*) have already been planted, and the number will ere long be probably increased to fully a quarter of a million. About half as many plants of a tree yielding a fine tanning bark (*Acacia cyanophylla*) are also in the ground, and appear to be doing well. If the Railway Company's experiments in forestry succeed in the long run, their vegetable property will be worth something in the early part of the 20th century. There ought to be some shade along that line, too, by-the-bye.—*Ibid.*

PASTURE LAND.—Mr. Martin J. Sutton has recently published a detailed account of the experiments made by him in co-operation with Dr. Augustus Voelcker on the effect of various manures on temporary and permanent pastures. The pamphlet is published at a low cost by Messrs. Hamilton, Adams & Co., and is worth the serious attention of all concerned in the management of pasture-land. The experiments are conducted on a similar plan to those at Rothamsted; but whereas the experiments made under the auspices of Sir John Lawes for the last twenty-five years or so have been made with a view of determining certain abstract questions in chemistry and physiology, they have often been made under conditions which would not arise in ordinary agricultural practice. Mr. Sutton's experiments apply especially to the effect of artificial manures in such quantities and under such conditions as might resonably command themselves to the grass-land farmer. The plots do not all form part of one field as at Rothamsted, where the conditions of soil, exposure, and natural vegetation are fairly uniform throughout, but occupy six different positions in which the conditions are also different, one being old pasture, another has been laid down for five years, two others have been sown since 1884—the one with, the other without perennial Rye-grass; while the two remaining experiments have been made upon plots representing a three years' ley, with, and without Rye-grass. The manures employed consist of nitrogenous manures, such as ammonia sulphate, or soda-nitrate, superphosphate, farmyard manure, cotton cake, guano, coprolites, bone-meal, &c., each substance being used either alone or in various combinations. It is too early to arrive at definite conclusions from experiments where so much depends upon the varying amounts of light, heat, and rainfall in various seasons, but it is interesting to note that the Rothamsted experiments are confirmed in many respects, as in the effect of nitrogenous manures, in benefiting grasses and discouraging the Clovers, while potash manures do the reverse. We do not find any notes concerning the degree and date of ripeness of the crop under varying conditions of manuring, but doubtless these will follow in due time. Decorticated cotton-cake is proved to be valuable manure, and the value of Rye-grass is insisted on. An incidental point of great practical value comes out in the circumstance that sheep do serious injury to young pastures by destroying the Clover. It is possible that the trampling of the sheep does as much injury as the destruction of the foliage. The cost of the manures per acre varied from 14*s.* to £1 1*s.* 3*d.*, with a nett gain on hay per acre of from 11*s.* 9*d.* in the case of plot 3 (nitrate of soda) to £1 8*s.* 3*d.* in plot 4 (superphosphate and kainit). We cite these figures merely by way of illustration, and to call the attention of our reader to a series of experiments of great interest to those concerned in the management of grass-land. The addition of tables showing the cost per acre, the increase or decrease in value of the hay per acre, and the nett gain or loss on the hay per acre will render these tables specially useful to the farmer. There is, however, so far as we can see, no indication of the cost of the labour employed.—*Gardeners' Chronicle*

POSITION AND PROSPECTS OF FIJI.

Sir Arthur Gordon receives credit or the reverse amongst many of his fellow countrymen, for having declared that the Fijian Archipelago, with its generally rich soil and wonderfully fine climate, was "no place for the white man." Sir Arthur's anxiety was to prevent the black man being ousted from his heritage by the more energetic and enterprising race, and his policy was directed towards this end. The object was doubtless benevolent, whatever may be thought of some of the details, especially the system of revenue being paid in kind and the conservation of the powers, so frequently and grossly abused, of the native chiefs, the highest in rank significantly named "*Bullis*." Mr. Leadingham, the retiring Chairman of the Chamber of Commerce, differs so essentially from Sir Arthur Gordon's views, that he believes Fiji to be a country not only for the white director of labour but for the white labouring farmer. His review is so interesting, and on the whole so hopeful after long and sad depression, that we cannot help making a rather long quotation from the *Fiji Times*:—

The deep depression which still casts its gloom over the land, has already left sad memorials in the numerous foreclosures that have taken place. Our white population has very sensibly decreased in the past twelve months. The markets for our raw products during the same period have been very unsatisfactory. For some time back, money has not been available for industrial enterprises, and the result has been that the colony has passed through the most trying year we have experienced since its foundation. Although the records of the Insolvent Court show several failures, they are, as a rule, comparatively insignificant, and we may, therefore, I think, congratulate ourselves that we have passed through the ordeal so well. We have good reason for believing that the prospects of the colony for this year will considerably improve. We see with great pleasure the sharp advance in the price of our staple product—sugar. * * *

The planter, as well as the business man, enters upon the new year with every confidence that the results of 1888 will show a vast improvement on those of 1887. A close estimate of the total output for the season 1887 and 1886, gives in round numbers 18,000 tons, shewing an increase on the former season of fully 6,000 tons. With even an advance in present prices of from 15 to 20 per cent. we should soon find a very great expansion in this important industry. Large areas of rich sugar lands are available all over the principal islands; with our beautiful climate, and virgin soil—rich to an extraordinary degree, and our labour laws regulated on the lines of common sense, there must be a grand future for this country; a country so richly endowed by nature must prosper, and the deep depression which we have felt so long has, no doubt, been intensified by the pernicious legislation of the past. Our Government, however, have for some time back shown a disposition to amend the mistakes of the past. We gratefully recognise their efforts in this direction; let them be continued and extended; let the success of the struggling planter and settler be their especial care; let settlement on the waste lands of the colony be encouraged. Government should endeavor to direct here a portion of the great stream of emigration to this colony that flows out of Europe every year. We have room here at once for 10,000 small farmers; land is abundant and cheap; labor can be equally so. The returns from a proper cultivation of the soil here will far exceed in value the returns from similar ventures in the Australian colonies. Farming in the colonies, as most of you know, is notoriously a poor speculation. I have no hesitation in saying that a practical farmer, with his family to help him, and a small capital wherewith to commence operations, will improve his position infinitely beyond what he could hope to do with equal resources in the colonies. Settle such men on a hundred and fifty or two hundred acres of land, let them supplement their own by the help of local labor, and let them plant maize, peanuts, fruit, coffee, tea, &c., and, in the vicinity of sugar-mills—cane, and I venture to say that in the course of three or four years the settler's position will be an eneviable one. That is what the country needs—population; without population no country can become of importance. The people are the source of all wealth; let it be the aim of our Government then to plant settlers all over the islands. The country is admirably adapted for European settlement; for nine months in the year Europeans can work and do work out of doors without inconvenience; then assist and encourage such settlers in every possible way and the result would soon be seen in an overflowing treasury and an enormous increase in the trade and commerce of the colony.

Copra.—The product still next in importance to sugar, is copra, but the palms are now only recovering from the effects of the hurricane of 1886. The exports for the past twelve months will show a great falling off compared with that of former years, but promises of an abundant yield is to be seen on all lands. As this product is a great source of wealth to the Fijians, we may fairly expect to see a considerable revival of trade with the natives.

Tea.—This, as you know has now passed the experimental stage. The industry promises to be one of the most remunerative and safe investments that capitalists can put their money into. Fiji tea is held in very high estimation in the colonial markets. The reports from the only two estates at present yielding, are most encouraging. In connection with this industry I am reminded of the sad intelligence received last mail from England of the death of Mr. James E. Mason, C. M. G., the gentleman who started the first tea estate in Fiji, now known as the "Alpha Estate." Alpha tea is justly celebrated not only in Fiji, but in the Australian colonies.* In desiring to pay a slight tribute of respect to the memory of the man who was the pioneer tea-planter of Fiji, I am sure you will agree with me that Mr. Mason was the stamp of a colonist who would do honour to any colony; he was full of energy and enterprise, and a most intelligent man; he did good work for the colony as its Commissioner at the Indian and Colonial Exhibition, work that entailed great labor and great expense and which, I fear, was but very inadequately recognised or rewarded.

Coffee.—Passing from tea to coffee it is much to be regretted that this industry has not been more generally developed. The low prices ruling for the past few years, and the fear of leaf-disease, no doubt had a deterrent effect, and to this cause may be ascribed the limited area on which coffee was attempted to be grown. Now that the price has jumped from 5d to 6d up to 1s and 1s 1d for the raw bean, there should be a strong inducements for the small planter to devote a portion of his energies to cultivate this produce in suitable localities.

Beche-de-mer.—The returns for the year 1887 are not yet available, but I have no doubt that the export figures will show a considerable advance.

* All credit to its superintendent and we believe part owner, Mr Arthur Stephens, a Ceylon planter —Ed. *T. A.*

on those of last year. It must be confessed, however, that the industry has not grown in the proportions we anticipated, when freed from the restrictions which formerly hampered its prosecution. It was chiefly owing to the forcible representations made to the Governor by this Chamber, in conjunction with the Suva Chamber, that the drawbacks attending the prosecution of fishing for beche-de-mer were removed. The prices in our local markets have been well maintained throughout the year. This should prove to be a very profitable occupation.

Annexation to Victoria.—Our efforts to obtain the incorporation of this colony with Victoria have as you all know, proved fruitless; the Government of Victoria, while giving us their sympathy, did not see their way to give us anything else; they could not be induced to make representations to the Imperial Government on this subject, but they would favourably entertain the proposal for a reciprocity treaty that might prove to be of mutual advantage to both colonies. I am afraid if the question comes to be considered on the basis of present mutual advantage, we can have poor hopes of its accomplishment. Our reciprocity, I am afraid, for the first year or two would be like that of the Irishman—pretty well on one side. However, if Victoria would only act magnanimously with us a commercial agreement might be entered into that would have a beneficial effect on both countries. No doubt this matter will not be lost sight of by Sir J. B. Thurston.

Steam Communication.—Our steam services with the Australian colonies and New Zealand have been maintained during the past year with great regularity, while the Tongan and interinsular service has been kept up by the U. S. S. Co. The manager of the latter Company informs me that arrangements have been concluded with our Government for the mail service for the current year. We are fortunate in having our communication with the outside world so regular; and now, gentlemen, I have one more subject to touch upon, and I am done.

We have just said good-bye to Sir Charles Mitchell, whose tenure of office as Governor of the Colony was barely twelve months. We shall soon be called upon to welcome his sncccessor, Sir John Bates Thurston, a gentleman who has been identified with Fiji in a private as well as in a public capacity for nearly a quarter of a century; he has been the foremost figure in public affairs since the establishment of the Cakobau Government; he has passed through different departments of the public service under the English Government, and now her Majesty has appointed him to the high office of Governor. Like his predecessors in that office, no doubt his appointment thereto will be highly gratifying to some, while to others it will be the reverse. Men occupying prominent public positiens are usually keenly criticised, and in these democratic days men do not hesitate to express their opinions freely. The Chamber has unfortunately had differences with our new Governor, but I feel sure that they will in no way affect us in according the Governor a most loyal welcome. His Excellency is thoroughly conversant with the difficulties under which the colony labours; no man can be more so, and if he comes to his post unfettered, I am certain his administration will have a most beneficial influence on the destinies of this country. Every one will admit that he is an able and practical man. Let us then forget the differences and mistakes of the past; let us loyally co-operate with his Excellency in all his measures for advancing the interests of the country. May his coming be the advent of brighter days for Fiji; may it be the province of the future historian of the colony to point to the administration of Sir J. B. Thurston as the period when, freed from the fads and follies of the past, the colony made a bound on the onward path of progress and prosperity.

CINCHONA CULTIVATION, CROPS, EXPORTS AND PROSPECTS IN CEYLON AND JAVA.

SHORT SUPPLIES, RATHER THAN EXCESS OF BARK, LIKELY AFTER 1889.

[☞For the letters referred to in this article see pages 673-76.] Cinchona Bark is a subject of very considerable importance still to a large number of planters and merchants in this colony as well as to not a few in Southern India and Java. And we are glad to say that the outcome of the large amount of information which we are enabled to lay before our readers today is, on the whole, reassuring to holders of bark *in esse* or *in posse*—to those ready to place their crops on the market during the present or next year, as well as to those who may be counting on a better market a few years hence.

This reassurance arises mainly from the fact, that, while the available supply of bark in Ceylon is by no means the unlimited quantity that our exports of recent years led many to suppose, we have abundance of evidence to show that the possible supply from Java has been greatly exaggerated. The two great factors to a proper understanding of the future course of the Bark and Quinine markets are undoubtedly the extent of the Ceylon and Java supplies. In respect of the former, we trust in a very few weeks now, to be able, from the information collected for our Directory, to give the best approximation that can be made of the number of trees and quantity of bark available in Ceylon. In the case of Java, the discrepancies in successive reports are so great that very many consider it will be impossible to make sure of the quantity of bark that can be sent from private plantations in that island until a competent and thoroughly trustworthy Ceylon Agent has been sent to travel over the cinchona plantations there and to draw up a reliable report. Mr. Wm. Mackenzie has been nominated to us as the kind of planting representative specially adapted for this duty; but unfortunately this gentleman has just gone to Europe. It is possible, however, that after all the information now available is digested, the necessity for a special mission may not be so apparent. In the first place, we take to ourselves blame for not more distinctly keeping before our readers during the past three years the great fact that everybody interested in the Java Cinchona Industry is specially inclined to exaggerate its importance—to magnify the approaching and future exports both in quantity and value of bark, for the very simple reason that only by so doing can they imagine it possible to put a stop to the further development of the marvellous resources for cinchona production possessed by Ceylon. About three years ago, the Chairman of a Java Planters' Association, while on a visit to Ceylon, frightened well-nigh every holder of bark with a very exaggerated picture—to say the least—of the cinchona planted area in Java; he spoke of 35,000 acres planted on private plantations (within his own ken), mainly covered with trees 5 to 7 years old, so far untouched, because the shaving process had not been understood, and he went on to anticipate that on his return everybody would begin shaving, with

the result that several millions of lb. of rich bark would very speedily take the place of the few hundreds of thousands of lb. hitherto exported. It is quite possible that the warning so freely given upcountry and through our columns by the Java Chairman had somewhat to do with the enormous exports of inferior bark from Ceylon in seasons 1885-6 and 1886-7; for it was natural to give some weight to the statement that there would be no market at all for ordinary Ceylon bark after the period named by Mr. Mundt. That period has long ago elapsed; but the exports by millions of lb. from Java have yet to come, and so far as we can judge, we may wait many years before Java sends treble the comparatively moderate quantity shipped last year.

We may as well at once give our latest experience of the exaggeration attending Java cinchona information. We were favoured with a call a few days ago from Herr Anton Kessler, the owner of an extensive coffee and cinchona plantation in Java. He called on us on his way to Europe a year ago, and rather added to the prevalent alarm as to what Java was to do. On the present occasion Mr. Kessler was full of a statement which he had seen attributed to the Director of the Government Cinchona Gardens in Java—a statement made, he believed, at a public assembly—to the effect that he (the Director) could easily export from the Government Gardens alone, 2 million lb. of bark of fine quality (5 or 6 per cent) and keep this up for many years. If that be the case, Mr. Kessler added, we, private planters, can easily send three or four times this quantity and of bark rising to an average of 6 per cent! But here the will was clearly father to the thought. The day after Mr. Kessler left us, came the Director's Official Report for the last quarter of 1887, which, specially translated for our issue, can be read in another column, and in it not one word occurs about an export of "2 million lb." On the contrary Hr. van Romunde estimates his total crop of 1888 at 850,000 half-kilograms or 930,000 lb. There are some other interesting facts in the Report—in reference to the prices obtained for seed (the highest being R28 per ounce for ledgeriana) and the 80 lb. of bark got from a famous mother ledgeriana tree probably twenty years old, which had to be uprooted. But the great fact of all is that from the eight plantations (ranging from 1,250 to 1,900 feet above sea-level) under his charge, Hr. van Romunde expects a crop of less than one million lb. in 1888, while his total of trees planted out is 867,000 ledgeriana (including 180,000 grafts on succirubra well spoken of), 171,500 officinals, 36,000 others, and about 600,000 succirubra trees: total 1,665,500.*

As regards private plantations in Java, our correspondents, Messrs. Rivers Hicks and John Hamilton, enter into calculations which cannot fail to show the absurdity of the pretensions made by Java alarmists as to the quantity which they can year by year henceforward throw on the markets of the world. Without going so far as 170,000, the Java Planters' Chairman was certainly responsible for stating 35,000 acres as the area planted with cinchona in private plantations. Now, in place of discussing the Amsterdam Circular or Market Report (furnished to the London *Chemist and Druggist*, which is responsible for its publication), and its rather wild figures, or an extract from the *Indian Agriculturist* (probably taken from our own columns, ciphers being strangely dropped in the reprinting in Calcutta),—we may fall back upon the report made by British Consul Neill of Batavia to the Ceylon Government on the 18th Jan. 1887. In it, he embodied the estimate of the Java Planters' Association, framed in answer to an official application, to the effect that 21,000 acres was the area privately planted; the number of trees planted was given at 30 millions (of which 14 millions were succirubra), and the crop for 1887 estimated at 1,433,250 lb. At the same time the area planted in the Government Gardens was given at 1,778 acres, and we feel sure it cannot be over 1,900 acres now for the 1,665,500 trees planted out. That would give about 880 trees per acre, a much more likely proportion than can be deduced from the statement of 30 million trees on the private plantations. Unless this latter figure includes plants in nurseries, we would certainly feel inclined with our correspondents to reduce the number by one-half and say 15 million trees, of which not more than half can be ledgers capable of giving 2 to 3 lb. of bark on being coppiced. We call attention to Mr. Hamilton's estimate, based on very similar figures, for the Java export from next year. But it must be especially noted that it is, in Mr. Hamilton's opinion, a maximum estimate when he puts down 4½ million lb. of ledger bark from private plantations and ¾ million from the Government Gardens, besides 1½ million succirubra bark from both sources or a total of 6¾ million lb. Mr. Hamilton does good service by contrasting the results in quinine of the Java maximum bark export, with the total consumption of the world, showing that Java is not likely to supply *one-half* the requirements. All this is very reassuring. But when we turn to Mr. Rivers Hicks' calculations, the competition of Java shrinks into even less proportions. We would be inclined however, in view of the larger acreage taken to exceed Mr. Rivers Hicks, while cutting down Mr. Hamilton's estimate, and to put the Java exports for 1889 at quite ¾ million lb. less, that is

Bark from Private Gardens	Led. 3 millions Suc. 2 millions	5 million lb.
Govt. do.	Led. 750,000 Suc. 250,000	1 million lb.

But even more important is our alteration of the proportions of ledger and succirubra bark based on the admission of the Java Planters' Association itself that nearly half the trees in the private plantations were succirubra. This is very important; for it reduces the result in quinine as follows:—

lb. Bark.	per cent.	oz.	
3¾ million	@ 3½ =	1,950,000	Quinine.
2¼ ,,	@ 1½	630,000	
		2,580,000	

—a reduction of 570,000 ounces of quinine. That would leave about 5 million ounces of quinine to be made up by Ceylon, Indian and American barks, and if this Colony had only three out of the five millions to provide for, we should have to ship of our two per cent average bark at least nine million lb. In other words even when Java comes into full competition from next year onwards with her private supply of bark, there ought, year by year, to be a fair demand and remunerative price for as much as nine or ten millions of Ceylon Bark.

* A large number of the trees in the Government gardens must be much older than any in private plantations.

OCEAN CURRENTS, THE GREAT ENEMIES OF THE PEARL OYSTERS.

Capt. Donnan's official report on the loss of the oysters which so lately teemed on the pearl banks and afforded reasonable hope of a series of fisheries, the greatest on record, proves that the Inspector of Pearl Banks did not originate "the floods" theory which was so strangely embodied

in the telegram which reached Government and was communicated to the press. It looks as if Mr. Twynam shared the belief, so strongly expressed and tenaciously adhered to by a correspondent of our own, of the large influence on the pearl banks of the rivers, especially the Arivi-aru, which pour their waters (sometimes in great abundance and with great force) into the Bay of Silavatturai, in which, about ten to twelve miles from the shore the two most productive banks—the Cheval and Modaragam—are situated. We have indicated our own leaning to the belief that the volume of fresh water carrying organic as well as inorganic matter into the sea, must have some effect on the oysters, probably in aiding the growth of the algæ which constitute the chief food of the animal which secretes the precious nacre. But the writer of this article never admitted the idea that even the heaviest flood of fresh water which ever rushed down the Arivi-aru into the sea could have force enough adversely to affect or sweep away the oysters on beds ten miles away from the mouth of the stream. Had excess of fresh water mingling with the salt proved fatal to the oysters, the very argument on which Captain Donnan rejects the skate theory would apply,—the young oysters would not have survived, but perished even more readily than those of mature age. Formidable as the rays are, it is quite incredible that they could in two months destroy 156 millions of oysters and "leave not a wrack behind." Equally inadequate as a cause would be any small and isolated case of "poaching," which could occur without the discovery of the illicit proceeding. Fishing of chanks is, for good reasons, forbidden over the area of the pearl banks, and we have never heard of a case of poaching better authenticated than that in Miss Martineau's sensational story, in which she represented a native woman adorned with jewels accompanying her husband on a midnight raid to the preserves so cruelly "monopolized" by a tyrannical Government! We have not the slightest doubt, in view of the report made to Captain Donnan of the prolonged existence of a 4 knot current sweeping across the banks with their average depth of seven fathoms, and especially in view of the crucial and conclusive experiments he instituted, that the sudden and terrible destruction of the beds of oysters which promised so well for three successive fisheries was due to the Gulf current, —due, if not to its absolute force, yet to the persistent, long-continued action of that force. The mechanical effect of the current, operating for a lengthened period affords a quite sufficient cause for the separation of the oysters from their anchoring cables and their removal into the very deep water which is found in close contiguity to the banks, and well might the poet say that

"Full many a gem of purest ray serene,
The dark unfathomed caves of ocean bear,"

if the millions of pearls swept into those caves survive attrition, which is doubtful. *No pearls have ever been found in sand collected on the banks brought to the surface and searched. The oysters cannot survive in deep water*—their voluntary change of locality by means of the "foot" with which they are supplied being limited to localities in depths of not more than ten fathoms, and their movements are generally towards the portions nearest the surface of the fragments of rock and coral to which they generally adhere—although they often fix themselves on other shells and adhere to each other in clusters. No doubt Captain Donnan has rightly judged, that, beside the probably greater strength of their more recently forme cables, the less resisting surface offered to th currents accounts for the young oysters being spared while the older and larger shells were successively torn away. The survival of so many young oysters is a consolatory element in the face of the great loss incurred, and since Captain Donnan wrote, more than a fortnight ago now, the actual results of the fishery, in number of oysters fished and especially in prices obtained, have gone far to justify the hope, that, although we cannot look the promised series of fisheries, which former estimates justified, yet the present fishery will bring an appreciable and very welcome addition to the island treasury,—not probably below the sum cautiously calculated on, R400,000. Some of the prices paid, up to R109 per 1,000, will go far to compensate for the enormous tribute claimed from the pearl banks by the Gulf currents and the profound depths into which they sweep all the objects they capture. Capt. Donnan says nothing of the influence on the pearl-bearing animals of mud or sand carried by the current which will henceforward be memorable, but it is only natural to suppose that enough of either or both must have been present, to be a factor of some importance in the destruction of the bivalves. It may be true, as Capt. Donnan is represented as having said, that he has never found deposits of mud on the pearl banks. That would not prove that some of the enormous quantities of mud which are being deposited in the lagoons on our north-western shores and on the coast of Southern India has not been swept on to the pearl banks and off them again, doing mischief in the process. Currents alone are quite sufficient to account for the frequent destruction of the pearl oysters, but it seems only probable that the currents carry an appreciable quantity of sand and mud across the banks and beyond them.

(*Official Report.*)

From the Inspector of Pearl Banks to the Hon. the Colonial Secretary.

SUBJECT—"FAILURE OF OYSTERS ON CHEVAL PAR."

Barque "Sultan Iskander," Silvatturai, 19th Feb. 1888.

Sir,—I have the honor to report my return to this place yesterday from the pearl banks.

2. I went out from here on the morning of the 6th inst. to lift samples of oysters from the Cheval Par, and to buoy off the various parts of the bank for fishing; but to my deep regret I found the whole bank almost clean swept of oysters.

3. I was employed seven days in carefully going over the bank, four days on the east side and three days on the west side, with the following result. On the north part of east side I found only about 459,000 oysters, on centre part of east side only about 4,948,000 oysters, on south part of east side only about 2,438,000 oysters, and on the whole of the west side only about 493,000 oysters; making in all about 8,338,000 oysters left on the whole Cheval out of 164,429,684 oysters estimated to be on it in Nov. last, thus showing a loss of about 156 millions of oysters in two months.

4. On the 13th inst., when I had ascertained the state of the Cheval, I sent the "Active" to Mannar with a telegram to the Government Agent, Jaffna, reporting the very serious loss of oysters, which he no doubt duly communicated to Government.

5. As regards the cause of the disappearance of the oysters, I found as an unmistakable fact that the oysters had been forcibly removed from the bank. The divers employed in its examination brought up from the bottom pieces of rock and large pinna shells on which there were numerous oyster byssus attached, quite fresh looking, showing that the oysters had only recently vacated their positions. In one spot on the centre part of

east Cheval there were obtained in ten dives made alongside the vessel only 37 oysters, but on the pieces of rock and pinna shells brought up at the same time there were counted 250 fresh oyster byssus, which would have made, had the oysters been attached, 287 oysters in ten dives, or an average of 29 nearly to a dive instead of 4.

6. I was at first inclined to suspect that the banks had been poached, as in all my experience I have never found old oysters to voluntarily quit their ground or slip their cables; but when I considered the magnitude of the loss of oysters, and that it would have taken 100 boats an equal number of days to have removed so many oysters; that I had been in the neighbourhood so recently as the 29th December last; and that in December and January the "Active" was on the bank as a guard vessel; also that the weather in December and January is such that people would not be likely to venture out so far off the land in open boats with the risk of being blown out into the Gulf with the strong N.-E. winds which then prevail, I at once abandoned the idea of poaching as being untenable.

7. The divers employed at the inspection were of opinion that the oysters had been eaten up by a vast shoal of skate of the species they call "Sankoody Tyrica" or "Koopu Tyrica," which they say eat up shells and all, even chanks are eaten up by them, and thus a bed of oysters might be cleared off by them without a trace of the cause being left behind; the divers say that the smaller species of skate called "Vulvaddy Tyrica" crush oyster shells between their teeth, suck out the flesh and reject the broken shells, thus leaving behind evidence of their depredations; but I can't believe in the existence of such a large shoal of the skate referred to as would be required to devour 156 millions of oysters scattered over a very large area of ground, 21,746,745 superficial yards, without leaving some evidence of the fact.

8. The engine driver of the "Active" who has also charge of the vessel reported that for eight days in December last he found when out on the Cheval Par a very strong current running to the southward, 3 or 4 knots he estimates it to have been, but it was so strong that he had to let go a second anchor to prevent the "Active" from dragging. I subsequently tested the effect of a current in displacing oysters by towing astern of the "Active" a group of 4 old oysters attached to a pinna shell. They held on for about an hour at a speed of 4 knots, when it was increased to 6 knots they dropped off one by one. That test proved that oysters would withstand a 4-knot current for a short time, but I am inclined to believe that the strain of a 3-to 4-knot current prolonged for some days would dislodge old oysters and sweep them away. At any rate the current reported by the engine driver of the "Active" appears to me to be the only plausible theory to account for the disappearance of the Cheval oysters.

9. I have searched for the missing oysters from the southern limit of the Cheval to the southward to Karaitivu island, where inquiries were made of the fishermen whether any oysters had been washed up on the beach of the island, but they had seen none: they however confirmed the existence of a strong southerly current for some days in December, saying that their nets when laid out off the western shore were rapidly swept to the south. Search was also made between the Motarakam Par and Karaittivu shoal, down the west side of Karaittivu to the large coral reef which lies off Dutch Bay; and from the Cheval in a S. W. direction out to the edge of the bank of soundings, but all without avail, not a trace of the missing oysters was found anywhere.

10. The young oysters on west Cheval referred to in my report of the 1st December last were found to be still in existence in large numbers, and it is interesting to know that they kept their ground while the old oysters were swept away; but young oysters have much greater holding on power in proportion to their surface than old oysters, and they would no doubt be able to hold on against a current that would carry off old ones. The fact of their existence is also against the divers' skate theory, for skates would not be likely to have devoured old oysters and left the young ones untouched.

11. I found some old oysters still remaining on the north and south parts of the Motarakam Par, about three millions on the north part and two millions on the south part, the latter however mixed up with oysters about a year younger. The current has evidently not affected the Motarakam, but it being placed further in shore and more to the southward than the Cheval, the current there would be likely to have less force. Indeed it is only on the extreme eastern side of the Cheval where any oysters are left, and the existence of any there is probably owing to the current losing force thereby being embayed as it were by the obstruction offered to its southerly course by the island of Karaittivu and the large space of confined water between it and the main land, whereas on the west side of the Cheval the current would have a free run to the southward.

12. Between the oysters on the Motarakam and the remnant on the Cheval, there may yet be about 15 millions lifted, affording 25 or 30 days' fishing, but the resulting revenue must necessarily fall far short of what was, until a few days ago, most reasonably expected from what promised to be one of the largest and most successful fisheries on record.—I am, &c. (Signed.) J. DONNAN, Inspector of Pearl Banks.

CEYLON EXPORTS:

TEA, CINCHONA, COCONUT PRODUCE, &c.

If, as we hear from mercantile passengers by the "Preussen," the opinion of leading London houses in the "bark" trade is very hopeful of a better market in the early future, there is nothing in this week's export return to damage that prospect. It will be seen that the comparative falling-off in shipments on the 8th instant was as much as 2,760,000 lb. It is not at all unlikely, however, that, for the rest of this month, the shipments may be very considerably increased owing to the long drought stopping the flushing of tea and forcing planters in districts where cinchona is still available, to find work for coolies in doing some more harvesting of bark. Should this turn out to be the case, our friends at home may rest assured that it will be but a temporary spurt, and that, as from the present date onwards, tea-planters here are certain to be exceptionally busy, there will be very little attention given to cinchona, save in Uva, unless indeed prices should again suddenly go up to a tempting quotation. Moreover, it is stated, that seldom if ever before (within the past five years) has the stock of bark in Colombo been so low. The estimate is from one half to three-quarter million lb., but the Secretary of the Chamber of Commerce will shortly publish the exact figures.

In connection with our recent deliverance on cinchona bark, we ought to have mentioned that, while a fraction over 2d per lb. is given as the lowest price at which Ceylon bark can be laid down in the London market, counting cost of harvesting, transport, packing, freight and all charges—but allowing nothing for cultivation; in the case of Java bark, the minimum cost of the same operations is given as between [illegible] and 5¾d, and for South American bark [illegible] to [illegible] per lb. As regards the latter, "the fact seems to be [illegible] established" say Messrs. Lewis & Peat in their Annual Report "that, except in the case of Calisaya, actual cutting has [illegible] ceased, prices becoming [illegible] and [illegible] absolutely unremunerative." The wonder is with the short stocks of bark in London at the end of 1887 and the continued falling-off in Ceylon shipments

that a greater rise in price has not yet taken place; this is no doubt accounted for by considerable stocks held by manufacturers and by the large quantity of quinine held in second hands, especially in America. There ought to be a good time coming for planters however, if they wait a little longer.

As regards tea, our shipments, while 3 millions ahead of last year, are not now quite double the quantity. The drought has, in fact, given a check; but we may be quite sure of an exceedingly busy time very shortly in the preparation and shipment of tea. The question has, indeed, been asked us if planters are certain of having boxes enough ready in which to pack all their tea! A satisfactory feature in the Distribution Return is the fact that Australia has taken some 207,000 lb. of this season's tea. Indeed the orders for Australia and Mauritius, which has taken 34,000 lb., have done a good deal towards strengthening the local sales and enabling many to get a better price in Colombo than they would in London for their teas. We wonder if the shipments for Mauritius are intended for South Africa. If we only had direct communication, Ceylon ought to command the Cape and Natal tea supplies as well as those for Australia. "America" this season so far has only taken 16,000 lb. direct.

The shipments of Cocoa do not keep up to last year's standard, while Cardamoms are a good deal in advance. Cinnamon shows a comparative falling-off, but the produce of the Coconut—in oil, copra, poonac and nuts,—shows a steadily expanding trade, and the same may be said of Coir yarn and fibre. So also with the export trade in Essential Oils—citronella and cinnamon—steady development is the order of the day. Nor are the diggers of plumbago and the gatherers of deer horns behind: the export of the latter 1,066 cwt. being quite unprecedented at this date in the season. Altogether it will be seen that the Export Trade of the Colony for the present Commercial Season is in an exceptionally healthy, strong position, the only marked falling-off (always excepting cinchona) being in the case of poor old coffee; but for this, tea will far more than compensate in the months to come.

TEA ON OLD COFFEE LAND: PRACTICAL HINTS FOR THE PRESENT AND FUTURE.

(By an experienced Planter.)

Your correspondent, who gives his experience of the small yield of tea grown upon old coffee lands probably adopts too low an estimate of what may be expected from such lands, but he touches a point of deep interest to the future of the tea enterprize, and one deserving of special attention. To be forewarned is to be forearmed, and therefore, whilst we all rejoice in looking at the bright side of our prospects and give all praise to the amazing energy which has transformed our ruined coffee estates so magically into tea plantations, we shall do well to look fairly on the darker side, and prepare betimes to meet the difficulties it threatens.

For my own part, I am not so apprehensive of the failure of old lands, in general, as of the consequences of the manner in which some of them have been converted into tea. Old Capt. Jolly used to distinguish between planters and cultivators, that is, between those who stuck coffee plants into the ground, and so created coffee estates in a rough and ready style, with scanty regard to the future, and those other planters, who remembered that the planting of an estate is a work to be done once for all, on which the whole future prospect of the estate largely depends, and who therefore took care to do the work thoroughly well. These did not regard only the present show, but the future and permanent result. Now, as regards tea, there have also been both planters and cultivators: those who have stuck in the plants or seed without due care, and others who have done the work in a thorough and workmanlike manner. A few years hence the work of the former, especially where it has occurred on old lands, will be a serious discouragement to the enterprize and great disappointment to proprietors. It must be borne in mind, however, that on many of the old estates managers have really had no choice. They have done what they *could* and not what they would have liked to do. In several cases within my knowledge the choice lay between getting the plants or even the seed into the ground within the time and means at their command, or losing the chance altogether. There are, in fact, some tea estates in existence, which are such almost in spite of instructions, and which, but for some innocent frauds practised by their managers, would now have been waste lands. From these and other causes there are considerable tracts of tea on old coffee estates which have had but a poor chance. These, therefore, cannot be expected to do as well as others more fortunately circumstanced. Judging, however, even by some of these less fortunate properties, I am inclined to take a less despondent view than your correspondent of their capabilities, especially of those which had been hand-weeded and thoroughly drained. Wherever the mammoty or other scarifiers had been in use for many years, or where draining was imperfect, the chances are, of course, the worst. The best that can be said of these estates is that many of them were amongst the first planted, and were on selected land of the best soil and in the best districts, chosen when there was plenty of land to select from. In spite of the treatment they received in those early days, they, therefore, yet possess fair capabilities.

There will, doubtless, be much disappointment with regard to tea planted on the old coffee estates. Their yield will be small, and the result unremunerative, and they will, therefore, tend to discourage the enterprize. This is the dark side of the prospect. The question is to consider what should be done to make the best of these inferior places. The planting of fuel trees, as your correspondent suggests, is good as far as it goes, and applies to land that has been gnawed down to the bone, and has become unfit for the growth of tea, but the treatment of the tea actually planted is the important consideration.

Mr. Bethune, Chairman of the Agricultural Society of Scotland, when in Ceylon, remarked to me, that he had heard of our soils that they were very poor, but he had been astonished to find them so good. "I suppose," he said, "that people must have expected to find alluvial soil and vegetable mould on these steep hill-sides. I call them good *mountain* soils, and they have proved so by the wonderful crops they have yielded." Now it follows that wherever wash and waste have not been excessive, or where the soils were not originally shallow, there still exists a fair depth of soil which would be good if it were effectually broken up and rendered pervious to the deep-feeding roots of the hardy tea plant.

It stands to reason that on all old lands draining should be made as effective as possible if this has not already been done. It is the first essentail to any reasonable hope of success. When this has been done, deep forking on the system of

opening up without turning over the soil may be carried out, and will give the tea plants the best chance. Neither of these expedients will convert naturally bad soil into good, nor will they atone for a poor jat, nor for bad work in planting, but they will do what remains possible to be done in making the best of the old soils. Wherever the tea has been dibbled in, or has been planted in the little skimpy holes which have lately become fashionable, deep forking is the only remedy, and this can only be done where the draining has been thoroughly provided for. This work is more than ever necessary, and should be done on principle, in order that it not only provides against surface wash but regulate the absorption of the moisture into the soil. In very wet climates the water is to be hastened off the land, but in the drier places it should be detained by means of slow gradients and broad-bottomed drains. On our steep estates, and more especially on those old lands which have no soil to spare, draining will go far to determine the duration of the tea, and is absolutely necessary to the work of deep forking being done with safety.

Manuring will eventually become necessary everywhere, but experience shows that when once commenced it must be followed up. Hence the importance of thoroughly working up the soil before that work is begun.

Natal Tea at the Grahamstown Exhibition is thus noticed in the *Natal Mercury*:—Natal's single exhibit has attracted a good deal of attention. Yesterday the jurors announced their awards in this class, and one may conveniently include it in this communication. It is as follows:—"Tea.—J. L. Hulett, Natal, is the only exhibitor. His excellent teas we cannot too highly commend as a new industry. The quality of the various kinds is very superior, and if mixed with China teas would command a large sale in this colony. This exhibit should receive a gold medal." This, one thinks, must be regarded as very satisfactory, and offers further encouragement to the tea-growing interests in Natal.

Effects of Helopeltis and Green Fly on Tea Yield in India.—As yet tea estates in Ceylon have suffered but little from insect blights,—not to an extent worth mention, in truth, and we trust the immunity will continue. How very different the case is in India and how disastrous the effects of insect pests are is exemplified in the Reports of three Indian Companies, from which we quote as follows:—

Indian Terai Tea Company's Report for 1887.—When submitting the estimates for the current season in December last, we informed you that the crop had fallen considerably short of the estimate due to the garden having suffered very severely from an attack of mosquito blight. The estimated outturn was placed at 132,000 lb. but the actual quantity packed only reached 108,950 lb. being a decrease of 23,050 lb.

The Soom Tea Company, Limited.—The original estimate was for a crop of 116,000 lb. tea, but the actual quantity packed only amounted to 107,200 lb. During the months of June and July the whole garden was covered with "greenfly" blight, causing a short fall in the quantity of crop and stunting the growth of new wood in the bushes. In September, "greenfly" was again active on portions of the garden.

Punkabaree Tea Company, Limited.—A considerable area of the garden has off and on been almost entirely closed by mosquito blight. This coupled with a short rainfall has seriously affected the outturn and only 634 maunds has been manufactured as compared with 837 maunds last year which, however, it must be remembered is the largest crop the garden has ever yielded. The quality of the tea has been better than last year, but even this has not compensated for the heavy deficiency in outturn.

Sanitary Effects of Transplanting.—It not unfrequently happens that a disease assails some choice plant which one would give much trouble to preserve. It may be a really scarce plant, or one that has some special association connected with it—perhaps the gift of a departed friend, or the happy "find" on some distant mountain top—the recollection of which is a constant pleasure; and to witness the growing sickness of our favourite from the attack of a destructive fungus without knowing how to cure, it is exceedingly vexatious. I observe that the usual advice is—destroy it at once, or it will affect others. But this requires much courage and self-denial to carry out, and I am not sure that to recommend such drastic treatment is in every case wise advice. Certain I am that he who has such an afflicted favourite, will be thankful for any suggestion which offers a chance of success. Let me recommend transplanting it to a new soil and a new situation. That disease will very often disappear by this treatment is absolutely certain, as any one accustomed to introduce diseased plants into his garden for the sake of studying the features of the disease perfectly well knows. I may give two examples of the curative effects of transplanting in illustration of this. Some years ago I had in a border some clumps of Star of Bethlehem (Ornithogalum umbellatum), the leaves of which were annually destroyed by a black mould, Heterosporium ornithogali. I removed them to another situation in the same garden a hundred yards distant, and the fungus has never appeared on them since. The second case is that I saw in a friend's garden six miles from here: some Chives (Allium schœnoprasum) badly suffering from a severe attack of Puccinia mixta, and I begged some to bring home to plant near my Onion bed, to see if the Onions would catch the disease. The result was that the Onions did not take the disease, and the Chives were cured.—W. Phillips, Shrewsbury.—*Gardeners' Chronicle*.

Foresters for the Colonies.—About the middle of last year the Government of India had addressed a communication to the Secretary of State, that as they are frequently called upon by the colonial Governments for the loan of the services of officers on the active list of the Indian Forest service, besides meeting similar requisitions from the feudatory princes in the country, which could not be conveniently complied with, the Government of India suggested that Dr. Schlich, Inspector-General of Forests, now on deputation at Cooper's Hill College, might be asked to prepare a Note, describing the special arrangements in force in that institution for the professional training of candidates in the Forest service, which might be communicated to the Colonial Office for the information of the colonial Governments, which might aim at having a Forest Department of their own. In conformity with the instructions conveyed, Dr. Schlich has drawn up a paper from which it appears that, as far as the available accommodation permits students other than those nominated for the Indian Forest service may be received into the College. They may pass through the course of instruction prescribed for the nominees of the Indian Forest service or may take up certain subjects only. There will be a preliminary examination such as handwriting, orthography, English composition, arithmetic, algebra, geometry, plane trigonometry, elements of physics, botany, mechanics, and mineralogy and geology, inorganic chemistry, geometrical drawings, &c. &c. But if they can produce a University diploma, or other similar certificates granted by a recognized examining body, the President may dispense with such preliminary examination. On attaining the prescribed minima of marks in the several branches of study and totals at the final examination, they will receive either the college diploma in Forestry, or special certificates showing in what subjects they have followed the instruction, and with what result.—*Indian Agriculturist*, Feb. 4th.

The Java Coffee Crop, this year, bids fair to be a short one (says the *Straits Times* on Java authority). The Bali crop, on the other hand, has every prospect of being abundant.

Canton Teas.—We call attention to the interesting Report of a Committee of merchants on the Tea trade of Canton given on page 656. Canton has always been famous for its fine teas; but Indians are fast taking their place.

Bark for Tanning.—A Haputale planter, who adopted a suggestion made some years ago, and sent a consignment of the bark of our patana oaks to Australia, is anxious to warn brother planters against any thought of making money by tanning. For himself he has never got a cent for his labour or expense in return for the consignment!

Tea Cultivation in Russia.—The *Journal de St. Pétersbourg*, quoting from the Russian *Nouveau Temps*, states that one of the largest tea firms of St. Petersburg has sent six of its employés to China to study the cultivation of the tea-plant on the spot. On their return to Russia they will be employed in establishing tea plantations in the neighbourbood of Soukhoum.—*H. & C. Mail.*

The Tea Trade do not like the idea of having to pay more than 3d a chest, 2d a half chest, and 2d per box for sampling. Several influential firms have, therefore, given notice to those warehouses whose charges are on a higher scale that, after the 1st prox., they will not draw samples at any warehouse where the rates are higher than those referred to, or the terms in any way more unfavourable to the buyer.—*H. & C. Mail*, Feb. 17th.

Ceylon Tea in London.—In their Tea Report of Feb. 17th, Messrs. Gow, Wilson & Stanton emphasize the importance of the *quality* of our tea being kept up, the recent falling-off having proved very injurious to the Ceylon tea trade. The 3,606 packages auctioned sold at an average of 11½d per lb., the highest price being 1s 9½d for Meriacotta, Fordyce getting 1s 8¼d, and Gorthie 1s 6¾d.

The Arabian Coffee Crop having partially failed, the demand for the Indian berry is become very brisk. Reports from the Wynaad state that the Moplahs thereabout are offering high prices for tails, cherry and mere sweepings, which it is supposed in a revolving course will find their way to Arabia to be ticketed and labelled as the "Best Mocha Coffee." In the very home of coffee itself the berry is being sold at R1 the seer, and R2,000 worth of refuse was bought up locally a few days ago.—*Egyptian Gazette*, Feb. 16th.

Cinchona cultivation has been introduced into the Ayassa territories of Central Africa, and Mr. Consul Hawes reports that it has every prospect of success, some of the plants, three years old, having a height of six feet. No estimate of the quality of the bark has, however, yet been formed, and there is the further question whether, if satisfactory, it can be placed in the market at a cost that will allow of remunerative sales at present prices. A new small plantation of one thousand plants has been recently formed at Zomba.—*Pharmaceutical Journal*, Feb. 18th.

Tea.—We notice from the Scotch papers by the mail that the experiment, first made last year by a Glasgow merchant, of importing Indian and Ceylon tea direct to Scotland is likely to prove a distinct success. The teas are now arriving regularly from all the tea-growing districts in India and Ceylon, and a conclusive argument in favour of the new plan is the fact that buyers are now able to buy Indian tea at 14d. per lb. Direct importation is of course all in favour of the Indian industry; for the nearer the plantations can be brought to the market, the more chance is there of an extended sale.—*Pioneer.*

Consumption of Tea, &c., in Ireland.—According to a recent paper in the *Nineteenth Century*, the annual consumption of the following products in Ireland is as follows:—

Tea	23,376,000 lb.
Coffee	3,928,000 ,,
Cocoa	1,968,000 ,,

There is plenty of room for an increase here, considering the population, if only a time of settled peace, industry and prosperity arrived for the long and much troubled "Emerald Isle."

Indian Tea in China.—In the *Chinese Times* published at Tientsin (close to the capital of the Chinese Empire) we find an advertisement, which, as showing that what is equivalent to "sending coals to Newcastle" is not always unprofitable, we quote:—

INDIAN TEA!!!
DIRECT FROM CALCUTTA.

The success which attended our first shipment of the above was so marked, we have arranged for regular supplies. By one of the last steamers we received our
SECOND SHIPMENT,
which is now unpacked, and we are offering same at the following
REDUCED PRICES:—

	per 2 lb tin
Kangra Valley Pekoe	$1·30
Do do do Souchong	$1·20
Assam Orange Pekoe	$1·00

We may some day find a market for Ceylon tea in China!

Tea for the Million in India.—We are glad to see that the Indian Tea Supply Company, whose object is to induce the sale of Indian tea among the natives by distributing it in small packets among agents throughout the bazaars, has now commenced operations. The tea has been made up in small packets containing from 1 to 4 oz. and varying in price from 3 pice to 3 annas, so that it should thus be brought within reach of the very poorest classes. To protect the tea from injury during the damp season while in the retailers hands, the small packets are themselves packed in close-fitting tins, each containing a few pounds. Every precaution seems to have been taken to ensure that success which the undertaking, both from good that it may do to trade and the good that it may bring to the people, certainly deserves.—*Pioneer.* [This is an enterprize which may have most important effects. If the 250 millions of India could be brought to consume even ¼ lb per head per annum, there would thus be a market for over 62 millions of pounds; or one half what India is expected to produce in 1890. —Ed.]

The Home of Cinchona.—Dr. H. H. Rusby, of New York, who spent two years in South America, recently lectured on South American cinchona before the Pittsburgh College of Pharmacy. His remarks were occasionally of a most extraordinary character, and, if correct, certainly reveal a state of things hitherto quite unknown. He said:—"The home of the cinchona-tree is a belt of about 500 acres far up in the mountains of Bolivia, where gigantic cliffs and equally mighty forest trees have conspired to break the storm-clouds which sweep constantly over it from the Pacific. For this reason the atmosphere is always humid, and moisture is necessary to the existence of the cinchona-tree. The temperature of this belt sometimes falls to 70°, but, as a rule, ranges at 90°. When cinchona was first introduced into the materia medica of Spain, the opposition to it was so violent that no one would use it. Finally, the Countess of Cinchon tried it, and was cured of her malady. Then fashion did what science had failed to accomplish, and cinchona sprang into a demand which could not be met. Natives were put at work gathering it. This they did with such industry and ignorance that the supply was soon entirely exhausted. There is not an ounce of the drug sold today but what is the result of cultivation.—*Chemist and Druggist*, Feb. 18th.

Correspondence.

To the Editor.

CINCHONA BARK:
THE JAVA AND CEYLON SUPPLIES OF CINCHONA BARK.

5, Savage Gardens, Trinity Square
London, 10th February 1888.

Sir,—In your issue of 14th January of the overland edition just received here, you have a paragraph on some figures taken from "an apparently reliable report" tending to show that Java may be able in 1889-90 to send enormous quantities of bark of phenomenal richness. The figures referred to are not given in the overland edition, and I necessarily write in ignorance of them and of any further remarks by which you may have sought in a later issue to allay the apprehension which would arise in the minds of Ceylon cinchona owners on reading such figures in your paper. Planters are so accustomed to look to you for guidance in difficulties that I hope to be allowed to assist you in showing how little ground there is, in the present state of the bark market and prices, for any exaggerated fear of what Java may send. Your estimate of 200 acres an estate for the 60 cinchona estates in Java will be felt to be, as you say, liberal by all those who know what expense and trouble are incurred during the eight years of waiting which have to be gone through by those who wish to bring a bark estate to a successful yearly cropping. Your estimate of 12,000 acres will, therefore, be a fairly safe basis for calculations. I shall endeavour to show that it is impossible for 12,000 acres of cinchona to bear anything like 15 to 25 millions of full-grown trees; that even if the trees could exist, they could not possibly be expected to give 3 lb. of bark per tree at eight or nine years old, and that a richness of three to four times that of the average Ceylon bark is one impossible to obtain in cultivation although it may be reached in the nurseries or under specially selected circumstances. 12,000 acres planted 6 by 6 would give a total of about 14½ millions of trees being about 1,200 trees to the acre. 12,000 acres planted 4 by 4 would give a total of about 33 millions of trees being about 2,700 trees to the acre. The calculation of 15 to 25 millions will probably have been based on some combination of the recognized 6 by 6 or 4 by 4 original planting.

Now I will simply appeal to the experience of any cinchona planter, whether it be possible for 1,200 cinchonas to grow to the age of eight or nine years on one acre? And whether if they managed to exist they could give anything like 3 lb. a tree? It is simply impossible, for 6 by 6 means that from the extreme end of the branches on one side of a tree to the extreme end of the branches on the other side of the same tree, that tree has only 6 feet in which to grow! If Java can get one acre to carry 500 cinchonas of 8 or 9 years old, she does better than others do, and if such trees give 3 lb. per tree, she is very lucky.

Now, if you take 12,000 acres at 500 trees per acre, you have, for the whole of Java, 6,000,000 trees, and if you take the trees at 3 lb. of bark each at 8 or 9 years old, you would have 18 millions of lb. of bark ready to be taken in 1889-90 *if all the estates reached that age in that same year of 1889-90 and if you were going to exterminate the industry.* Some estates and some portions of estates will have reached that age and the trees will have been cut down or uprooted before 1889 (for experience shows that bark will not renew in Java) and from those 18 millions of lb. of bark must be deducted the bark from mature trees cut down before 1889. During the 5 years 1st July 1882 to 30th June 1887, Java has shipped 6,482,603 lb. of bark, and her 1887-88 shipments are so far at the rate of over three millions for the whole year, and much of these barks must have been taken from trees that had reached the age of 8 or 9 years and have been cut down.

The remainder of the 18 millions will constitute their capital account, and will be all the bark they can count on until they shall plant fresh acres beyond the 12,000. It would be as unreasonable now to expect that Java could take 18 millions of lb. of bark in 1889-90 as it would have been unreasonable in 1884-85 to expect Ceylon to send in 1886-87 the 66 millions of lb. which constitute the total of her shipments during the 10 years from 1st October 1877 to 30th Sept. 1887. As the 18 million lb. in Java in 1889-90 (less bark off mature trees sent away before that date) will constitute the capital account of Java, fresh acreage of cinchona must be added before Java can afford to send in one year more than some 3 millions or at the outside 4 millions of lb. of bark without trenching on the supply for later years.

Ceylon with her 40,000 acres of cinchona (writing from memory I believe this to be the *Observer* estimate of Ceylon cinchona) has given during 10 years 66 millions of lb. of bark, and yet in no one year has she had a *crop* of even 14 or 15 millions. Her shipments of 15,364,913 lb. in 1885-86, and of 14,389,184 lb. in 1886-87 were made up by trenching on crops belonging to later years, as the present partial exhaustion of supply shows. To what extent this depletion of capital account in Ceylon has reached can only be fully known when she shall have settled down to a small regular yearly crop. Now, if Java with her 12,000 acres exceed some 3 or at most 4 millions of lb. of bark shipments in one year the same process of extinction of capital must be gone through.

With regard to the proportion of quinine yield which Java bark may be expected to bear to that of Ceylon, it is more difficult to give figures.

Hitherto Java bark has averaged about 50 per cent above that of Ceylon, and this figure seems far more likely to approximate to the proportion of the future than the 3 or 4 times which are sometimes quoted.

It is a well-known and much regretted fact among cinchona growers that yields of 8 or 10 per cent obtained from small lots of selected and specially-cared-for trees are no sort of guide to what may be expected from the same description when planted out in quantity. Large yields are not to be expected from trees grown in great numbers. Until fresh evidence of the yield of large quantities shall be obtainable, it will be safe to estimate Java bark as 50 per cent richer than that of Ceylon, so that 2 lb. of Java bark may be called equal to 3 lb. of Ceylon.

It would doubtless suit Java planters very well if Ceylon cinchona owners should take fright at suppositious large quantities of bark to be expected from Java in 1889-90, and should commit the happy dispatch by shipping now what bark they have and selling it for the mere nothing which they would get for it, for then Java would, in a year or two, have the practical monopoly of a rising market. It would be as unwise for Ceylon now to ship large quantities of bark and drive the unit down to a mere nothing, as they would most surely drive it if they were in the present state of the market to ship large quantities: as it would be unwise for Ceylon now to plant on average soil their comparatively poor barks to com-

pete with the rich Java bark which is now reaching 8 to 9 years old; for Java is most likely, having waited so long, to be wise enough to ship only such portion of her bark year by year as will permit her to continually have rich mature bark to send.

A Ceylon shipment of 8 or 9 millions of lb. for 1887-88 will assuredly bring the shippers back as much money as a 16 millions shipment would.—I am, sir, yours faithfully, RIVERS HICKS.

17th February 1888.

Sir,—I wrote to you by last mail and now send you enclosed a cutting from the *Planters' Gazette* of the 8th instant, which I shall be glad if you will reprint as a portion of this present letter, as it supplies governmental figures showing that your estimate of 3 lb. dry bark to be expected from cinchonas of 8 or 9 years of age, is probably rather over than under the mark. These Jamaica Government figures show that 10 trees gave a total of 178⅜ ounces, or 11 lb. 2 oz. of dry stem bark and 16 ounces dry root bark which the article says should be calculated at 1 lb. 12 oz., or in all for the 10 trees about 13 lb. being at the rate of under 1¼ lb. per tree. The ages of the tree do not however seem to have been accurately ascertained, and for the purpose of calculating the bark-producing capability of Java in 1889-90 and later, your 3 lb. estimate will probably be the safer guide. I am sir, yours faithfully, RIVERS HICKS.

5, Savage Gardens, Trinity Square, London.

WEIGHT OF BARK FROM CINCHONA TREES.

The following interesting information is given by the Director of Government Gardens and Plantations at Jamaica:—

Inquiries having been made as to the amount of bark that may be expected from trees of various heights, ten trees were cut down and barked with the following result:—

I. Number of Tree	II. Height in feet and inches	III. Branched at — feet from ground	IV. Circumference at base in inches	V. Circumference first branch in inches	VI. Circumference of first branch in inches	VII. Weight of wet bark from stem in ounces	VIII. Weight of dry bark (taken at one-third)	IX. Weight of wet from stem and branches in ounces	X. Weight of dry bark (taken at one-third)	XI. Weight of wet bark from root in ounces	XII. Weight of dry bark (taken at one-third)
1	6.4		6½			15	5				
2	7.8		4¾			10	3 1/2				
3	10.0		7¾			28	9 3/8				
Average.....	8.0	6½	6.1-6	4	2 5	17⅜	6	33	11	10	3 5/8
4	9.10	4	10	7¾	4			60	20	24	8
5	10.0	4½	11	10½				120	40	14	4⅔
6	15.3		15					156	52	16	5⅓
7	20.6		16½					92½	31		
Average.....	13.11		13					18	6		
8	10.0		6					46	15⅓		
9	11.0		12					48	16		
10	14.3		9½					37½	12½		
Average.....	11.9										

The trees Nos. 1 to 7 are from the plantation at Newhaven Gap, which was first made in 1868. It is impossible now to ascertain the age of any of these trees, as some are seedlings and some are shoots from coppiced trees. There are probably very few of the original trees left; perhaps No. 7 is one of these. No 1 may be taken as an example of a tree six years old.

Nos. 8 to 10 are from the plantation called "Upper Buzza" made in 1879-80. These trees are therefore seven or eight years old.

The dry bark in the table has been taken at one-third the weight of the wet bark. This would give 11 lb. 2 oz. for dry stem bark, the actual weight being 12 lb. Root bark does not lose so much in drying, for instead of one-third (viz. 1 lb.), more than one-half was obtained —1 lb. 12 oz. One-third, on the whole, is a safe estimate, for there is considerable waste in drying on a large scale, on account of the constant shifting of the bark from the drying houses to the barbecue, which causes friction and reduces a good deal of it to dust.

It is instructive to take Columns II. and IV. together and compare the amount of bark harvested. No 2, for instance, is much higher than No. 1, but being more slender gives much less bark. It therefore pays well to attend to thinning. Perhaps the most convenient time for crown bark is when the trees are six years old If the plants were put in four feet apart, half the trees should be thinned out, and it will be well to uproot them, for the shoots would interfere with the other trees, and besides the root bark will be more than fifty per cent of the bark from stem and branches.

The amount of bark per acre may be roughly estimated by taking an average tree and multiplying the weight of bark by the number of trees on an acre. Trees planted six feet apart, are 1,210 to the acre; eight feet apart, 680 to the acre; ten feet apart, 435 to the acre.

JAVA BARK.

12 Great Tower St., E. C., London, 16th Feb.

Dear Sir,—Your editorial in the *Overland Observer* of 14th January (page 41) regarding the possible, output of Java bark based on a circular headed "Amsterdam, December 14th," and unsigned,* inserted in *Overland Observer* of January 21st, page 50, invites criticism and calculation, hence I am prompted to write the following remarks. In the first place the very high analyses quoted averaging 10 per cent sulphate of quinine are no more likely to be realized over large parcels of bark continuously than are the favourable assays we frequently see quoted in gold-mining prospectuses as derived from samples of gold-bearing quartz when crushings extend beyond the experimental stage. So far Java barks do not appear to be more than 50 per cent richer than those from Ceylon. With reference to this the remarks in the *Tropical Agriculturist* for January (page 502) bear me out:—"Java bark containing 11 per cent of quinine was sold in London at 37½c and planters realize a good profit at present market value." Commenting on this the writer of rest of the article says:—"Upon careful inquiry at headquarters in London we find that a small lot (11 bales) of Java bark was sold at 1s 6d to 1s 7d, which contained a fraction over 9 per cent of quinine, not 11 per cent as stated. If planters could rely on producing such high test bark, it would probably pay them very well to cultivate the cinchona trees, but such bark is very rare, the great bulk testing on an average only about 2 per cent and realizing about 4d a lb." An instance of a parcel of bark not realizing anything like individual analyses from picked trees of hybrids came under my own observation some five years ago. It was bark from a well-known estate in Dimbula. Samples had been taken from some 20

* From London *Chemist and Druggist*.—Ed.

trees and tested with a result shewing about 7 per cent sulphate of quinine, but the parcel which included bark from these particular trees, and other trees supposed to be equally good scarcely analysed 3¾ per cent, much to the chagrin and disappointment of the owner. From this and from the present data we have to go upon, I would infer that at no period will shipments from Java average an analysis of 4 per cent sulphate of quinine in any year; in fact I do not expect that the future average of all Java bark will exceed 3 per cent. I do not, therefore, believe that the richness of the exports of Java bark is going to shut out all barks produced under 4 per cent from any profit whatever, as the writer of this Circular would lead some people to suppose. I am rather suspicious of that heading to the circular "Amsterdam" and no name attached to these marvellous statements. I can quite understand that it is to the interest of some good people to so frighten all connected with bark, that holders and growers, fearing the deluge, would be urged to rush all their bark on to the market, and by selling at any price bring about the result so much desired by an interested few. I well remember the time when we were told Jamaica would swamp the market, but on inquiry there was found to be but 1,000 acres planted with cinchona, and only another 4,000 acres available for the cultivation in the whole island. Then again Bolivia was to destroy the market by sending over supplies, and strange to say the Java planters themselves seemed more afraid of Bolivia than Ceylon, but why this extreme nervousness, if they 've got the ball in their hand, as the writer of that article would make us believe? Now, as regards acreage under cinchona in Java in private hands, what a scare, sir, was given to some Ceylon people about two years ago through reading in your columns that there were 170,000 acres in Java under ledger, well-grown. I think the astute Chairman of the Java Planters' Association had the credit (wrongly of course) of leaving that impression behind him after his tour through the Ceylon hills. In the same number of the *Tropical Agriculturist*, as I have already quoted from, I find the following paragraph on page 450:—"Cinchona in Java.—In Java the area planted with cinchona on private account is estimated at 21,000 acres, and the number of trees at 3,000,000, of which about 1,400,000 are of C. succirubra. The estimated crop of the year is about 1,433,250 lb. The average proportion of sulphate extracted from the bark is estimated at about 3 per cent.—*Indian Agriculturist*." Now of course the author of the "Amsterdam Circular" would say the editor of the *Indian Agriculturist* or his source of information is quite unreliable. I am not so sure, however, that the *Indian Agriculturist* isn't considerably nearer the mark than the other. Certainly as regards the probable average analysis of Java bark. The acreage given however must carry a very much larger number of trees than three millions. As it is impossible to get any accurate information on the subject, I hope you will kindly allow me to add my own suggestions as to what may be the real state of the case, or approaching thereto, which cannot do harm if they elicit discussion.

Let us suppose there are 20,000 acres under cinchona in private hands in Java. If this acreage carries an average of 700 trees to the acre of mature growth, it would be a very good return. We have then a total of 14 million trees, of various ages, of this total say 10 million trees are ledgeriana species, capable of producing if coppiced 2½ lb. of dry bark on an average per tree after 1889 has commenced, which gives a total of 22,500,000 lb. available bark averaging 3½ per cent. Divide this quantity over 4 years, which it would probably take to complete the harvest of these ten million trees in a judicious manner, and we have an annual export of ledger bark of 4,500,000 lb. averaging 3½ per cent. Even supposing it were possible, and desirable to harvest and export this quantity in two years' time instead of 4 years, barks under 4o per cent would not necesssarily become value less, as the above-mentioned 'Circular' tries to make people believe. The new stem from the coppiced tree has not been considered as giving any return for four years in these calculations. The fact must not be lost sight of that "ledgers" will have to be harvested in a totally different way to the Ceylon method of taking bark by shavings, as the renewed barks are not so rich as the original, and it is quite unlikely that the Dutch planters will proceed to cut down everything in two years, but will gradually feed the market by yearly instalments. The balance of the 14,000,000 trees is probably made up of 4,000,000 succirubra variety, to be harvested in the usual way and yielding about 1½ million lb. annually and averaging from 1½ per cent to 2 per cent. The Government gardens would, perhaps, yield ¾ million lb. of ledger, but I have no report before me to give me any idea of what their yield may reach.

From these calculations we should have therefore, say, in 1889:—

	lb.	
Private Gardens	4,500,000	Ledger
Government	750,000	Ledger
Succirubra Crop	1,500,000	
	6,750,000 lb.	

Result of Java Crop.

lb.		Per cent.	Equal to oz.
5,250,000	at	3½	2,730,000
1,500,000	at	1¼	420,000
			3,150,000 oz.

Estimated consumption of quinine in world

In 1889	7,500,000 oz.
1890	8,000,000 „
1891	8,500,000 „
1892	9,000,000 „

My own impression is the above figures represent the very utmost that Java can do in 1889 and the three following years; and I think I have proved conclusively that the market is more likely to suffer from short supplies than any plethora of bark. I quite expect to see some well informed correspondent reduce my figures by *one-third* if not more. Apologizing for trespassing on your limited space, I remain, dear sir, yours faithfully,

JOHN HAMILTON.

AFRICAN OIL PALMS IN LOWER HAPUTALE.

19th Feb. 1888.

Dear Sir,—As you generally have sent me a sample of the first fruit of a new product, I have now the pleasure of sending you what I believe to be African oil palm nuts, grown on Rosebury estate. Out of about 100 seeds received from Colombo in September 1880, only two grew into trees, one of which is now bearing large clusters of nuts similar to these sent you. With fresh seeds I expect to be more successful in raising plants, but would like more information than I possess before making large nurseries. With this object in view I turn to the Planters' Friend, the *Tropical Agriculturist*, and in vol. iv, page 606, find a description of the tree, how the oil is extracted, and that palm oil and seeds are solely an African export, but that the town of Bonny alone does a business in oil and seeds amounting to several thousand tons a week. Still this is not what I require, and on turning to vol v, page 472, find "Udagama" has already worn the shoes that

now pinch the writer, as he in November 1885 asks of your readers the information I require; but I do not find he succeeded in gaining it, and it is not a matter for surprize that he did not, as hitherto African negroes are the collectors if not cultivators of the fruit, and the trade in the hands of native brokers there, who are the sole exporters of this produce. Will you kindly ask "Udagama" now to give your readers the benefit of his experience in palm oil cultivation since 1885, and in the words of Van Thaer on cover of *T. A.* "acquire thereby a right to the gratitude of his fellows and of those who come after,"—Yours truly. J. W.

[On what points does "J. W." want information? It is very probable that Ceylon planters are the very first to cultivate *Elæis guineensis*, the African oil-palm, and therefore they have to make the history of cultivation for themselves. The negroes of Africa can scarcely give them information as to nurseries and culture. As to the fruit we fancy they must be largely exported uncrushed from Africa to Britain, and the trade has developed enormously of late years. But, as will be seen from our extracts, a good deal of the oil is extracted by the natives after a very primitive fashion. There is often confusion between African "palm oil" and "palm nut oil," but we believe the only difference is that the former is got by pressing the soft yellow outside fruit—the husk almost—and that for the latter the kernel is broken and crushed, giving a white oil. The former, the yellow oil, is the great rival of coconut oil. We quote from Simmonds a few passages of interest:—

"THE AFRICAN OIL PALM (*Elæis guineensis*, Lin.) is, after the coconut palm, one of the most important in a commercial point of view, since it furnishes to British commerce about 50,000 tons of oil annually, of the value of one and a half to one and three-quarters of a million sterling, besides the quantity locally consumed as food in Africa, and sent to other countries. It is distinguished by its decumbent trunk, and bears clusters of one-seeded fruits (drupes), with oily husks of a bright vermilion or a more or less yellow colour. The range of this palm is not as yet well defined, but appears to extend from the coast of Guinea to the south of Fernando Po, and grows as far up in the interior as Zheru, a distance of 400 miles from the sea, or the mouth of the Min, one of the embouchures of the Niger.

"The process of extracting the oil is simple. The clusters or branches of fruit, which contain perhaps as many as 4,000, are gathered by the men, and thrown indiscriminately into a trench or pit, and so left until they become somewhat decayed. The fruit is afterwards pounded in a mortar to loosen the husky fibre covering the nut. This done, they are placed in large clay vats filled with water, and two or three women tread out the semi-liquid oil, which comes to the surface as disengaged from the fibre, when it is collected and boiled to get rid of the water. The inner surface of these clay vats having at first absorbed a small quantity of oil, is not afterwards affected either by the water or oil. The oil is collected in pots, containing from three to twenty gallons. M. Boussingalt has shown, from information collected that the average production of oil from palms is at the rate of 900 kilos. per hectare, that is to say, superior by a third to the production of oil from the olive in the south of Europe.

"PALM-KERNEL OIL.—The kernels, with the exception of an insignificant quantity used for the manufacture of oil for domestic purposes in Africa, were formerly thrown away. Attention was first drawn to their utilization in Liberia. Within the last fifteen years they have been more generally collected and employed. The shell being broken, the kernels are shipped to be pressed for oil, &c. Vast extension of the African trade has arisen out of this new article of export.

"It has been estimated by competent authorities that from the 50,000 tons of palm oil shipped there must be 10,000,000 bushels of kernels, equal to 223,000 tons in weight. The average yield from these kernels being about 30 per cent, if all were utilized this would furnish 76,000 tons more of oil, worth at the price of coconut oil (which it closely resembles) about 2,700,000*l*. If we add to this the value of the oilcake, 112,000 tons at 6*l* per ton, we should have a very large increase to the value of the oil-palm trade with Western Africa. Palm-nut oil is obtained on the coast from the seed or kernel, by roasting, beating, and boiling. In Liberia, on a small scale, a bushel of kernels was found to yield two gallons of oil, but with good presses a very much larger yield than this is obtained. The palm kernels are quoted in London, January 1877, at 12*l* 10*s* to 14*l* per ton. The kernel, which is nearly white, is covered by a thin brownish layer of woody fibre, and in consequence of this the palm-nut meal has a light-brown or dirt-coloured appearance. The size of the kernels varies from that of a hazel nut to that of a small pigeon's egg. They are very hard, nearly inodorous, rather insipid to the taste, and extremely rich in fatty matter, possessing the consistency of butter, with the useful property of not readily turning rancid. The extraction of the oil necessitates the reduction of the kernels into a tolerably fine powder, and the application of powerful crushing machinery and gentle heat. Notwithstanding these means, the cake or meal left in presses contains usually a larger proportion of fat than is found in most other kinds of oilcake."

If Udagama superintendents or any other cultivators of the African oil palm in Ceylon can add to our stock of knowledge we shall be much obliged.—ED.]

FUEL FOR TEA ESTATES: THE AUSTRALIAN ACACIAS.

Albion, Nuwara Eliya, 25th Feb. 1888.

DEAR SIRS,—As the fuel question is at last attracting attention, I send you a few particulars, which may perhaps be useful, at this juncture, to anxious proprietors, who see their stock of available timber and fuel growing smaller by degrees and beautifully less. A few days ago a correspondent sent you some interesting particulars about blue-gums for fuel in tea manufacture, and although I cannot go the same length, being as yet only a tea-grower and not a manufacturer, I must say that my small experience would lead me to advise the planting of acacias in preference to any of the eucalypti, as my belts and groves described a year ago by Mr. A. M. Ferguson in his letters headed "New Galway Revisited" give ample proof that, for the first few years at least, the *Acacia decurrens* makes much more wood fit for fuel than blue-gum, and being a much harder wood it makes better charcoal, whereas the gum burns more to ashes and does not give out as much heat. The *Acacia melanoxylon* as is well-known gives splendid building timber. From some trees about 20 years old I have had sawn beams 18 ft. long, and could have got them longer if required; it also makes a very pretty ceiling, and the branches and crooked portions made good smithy charcoal.

For acacias a detached piece of land should be chosen owing to their tendency to spread, but they are not particular as to soil, and the most exposed ridges and poorest soil will suit them. Although the gum does not spread from its roots, it is a very wide feeder, and when planted in a grove does not, in my experience, thin like the acacia; it has also, I have heard, a tendency to "pipe," which would reduce its value as a timber tree, and if tea is going to last as long as our Ceylon pioneers predict, it behoves every proprietor to provide for a good future timber supply.

It may not be generally known that the seeds of the acacia should be soaked in hot water. The plan I have found most successful is to pour boiling water over them and allow them to remain twenty-four hours, then pick out for planting all the seeds that have swollen, and repeat the process as often as necessary. Some of the seeds will take a week's soaking before they begin to swell, but should on no account be planted until they do. Seed can be procured from Messrs. Law, Somner & Co., Seedsmen, Melbourne, Australia, and for my last supply they charged me 8s per lb. rather a difference from the R2 per ounce demanded by our local seed-sellers. It can also be had from Ootacamund, from the Government Botanical Gardens. A friend, writing from there in 1883, quoted R4 per lb. as the price. How is it that our Colombo chemists have not turned their attention to the blue-gum? The extract imported from Australia is a regular cure-all.*

No rain here since 2nd January, making to date 54 consecutive rainless days.—Yours faithfully,

ARTHUR J. KELLOW.

"Ootacamund, 23rd April 1883.—I am sending you by Foreign Parcel Post (as I sent the last) 2 lb. of black acacia seeds (Acacia melanoxylon). I am only sorry I have not gathered you more, but I will do so whenever I have the opportunity. You can get any quantity of seeds of both Acacia dealbata, and Acacia melanoxylon, and in fact seeds of any other trees or shrubs, both indigenous, and foreign, by writing to Mr. Jamieson, Superintendent, Government Botanical Gardens, Ootacamund. You can also get from him seeds or plants of tropical and sub-tropical fruits, spices &c. For temperate fruits, like pears, apples, peaches, plums &c. for plants apply to Mr. W. Misquith, Ootacamund. Jamieson charges R4 per pound for both kinds of acacia, I should advise you to go in for cultivating Acacia decurrens, in preference to the other kinds; it is far more valuable; at the preent moment its bark is fetching from £30 to £40 per ton, for tanning; and its wood makes one of the best stave woods for casks besides being good fuel. It is called the black wattle in contradistinction to the silver wattle (Acacia dealbata.) I have sent to Australia for 10 lb. of seed, the seed costs about 10 shillings a pound in Australia. I mean to go in for growing it extensively if I can get sufficient land."

CONSUMPTION OF WOOD FUEL ON TEA ESTATES AND BY GOVERNMENT ON THE RAILWAY.

Nuwara Eliya, 25th February 1888.

Sir,—I was pleased to notice in your issue of 23rd instant your warning note to tea planters on this subject of fuel consumption. As it is a matter of very serious import to those engaged in the manufacture of tea, I will make no apology for occupying your valuable space.

Mr. J. L. Shand's estimate of our probable tea exports for 1890 is I think likely to prove correct, Mr. Maitland-Kirwan's statement to the contrary in the London *Standard* notwithstanding. The estimates which I framed some time ago and previous to Mr. Shand's excellent lecture on the subject of our teas were for year ending 30th September 1889, 35¼ millions, and for 1890, 42½ millions of lb., and this latter tallies almost exactly with Mr. Shand's estimate.

When our exports will have increased to this extent and with a further annual addition for some years to come of five millions of lb., *then* the question of our firewood reserves will indeed have become in a double sense a *burning* one. During the last few years I have kept a record of the fuel necessary to produce large quantities of tea, and from these data we are now in a position to arrive at a fairly reliable estimate of the quantity of fuel that must be consumed to manufacture our tea crops. I have not been able to ascertain the quantity of fuel per head of our labour force necessary for domestic purposes, but I have assumed it as being equal to the amount consumed in the manufacture of the tea, and I am of opinion that this quantity is under, rather than over, the mark. The districts of Dimbula, Dikoya, Maskeliya, and Pussellawa are those, which, it is presumed, will first feel the scarcity of fuel to be an expensive item in the cost of manufacture of tea.

In 1890 these districts will probably produce 15,000,000 lb. of tea, and if we assume that only one-third of the factories work their machinery by engine power, while the remaining two-thirds use waterpower, we have a consumption (including that required for domestic purposes) of 180,000 cubic yards, or say 45,000 tons per annum. In the younger districts there is a considerable quantity of felled timber still on the estates, but this will soon disappear, and new wood will have to be cut. I do not think the average standing jungle will give more than 300 cubic yards of firewood per acre; so that in these districts alone in a few years, there will be an annual consumption of fuel, equal to 600 acres of growing timber, and this consumption will be a rapidly-increasing one.

The consumption of wood fuel for the island tea crop of 1890 would be on this basis 480,000 cubic yards including that required for the domestic purposes of the labourers. The consumption of wood fuel on the railway (irrespective of coal) is 65,000 cubic yards, and this quantity will, of course, increase with the accession to traffic brought on the line by the increase in tea production.

It is not, therefore, difficult to foresee, that in a very few years the tea enterprize and our railway system will be consuming some 600,000 cubic yards of wood fuel annually, or (at 300 cubic yards to the acre) the growing timber on 2,000 acres of land.

Under these circumstances, I would strongly impress upon all planters, especially in the higher districts (if they wish to produce tea at the minimum cost in the future), to at once set about planting quick-growing trees for firewood.

The Government also, who have in their possession road and railway land reservations, should take immediate steps, as large consumers of fuel, to plant up these lands, especially those contiguous to the railway with fast-growing timber.

It is needless also to point out the growing scarcity in the tea-districts of timber for building purposes, and in planting up certain portions of estates with trees, this question ought to be considered as well as the matter of fuel.

Planters, no doubt, will soon realize the necessity of immediate action in planting trees, but I greatly doubt if the Government will really awaken to the fact that valuable time has been lost until the island has passed through another decade of its history.

H. K. RUTHERFORD.

THE DISCUSSION ON CEYLON FISHES; THE NEED OF PROTECTION AGAINST WHOLESALE KILLING.

Central Province, March 6th 1888.

Sir,—This piscatorial debate cannot be otherwise than intensely interesting and instructive to a very large proportion of the community both European and native, which comprises a far greater

*Has Mr. Kellow overlooked "Sander's Eucalypti" advertisement.—Ed.

number of enthusiastic fishers and true sportsmen *in esse* and *in posse*—than one would suppose, as well as being of signal value in quite a variety of other ways. Indeed, a considerable amount of information not previously known to casual fishers has been the outcome, and it would be a boon to many of us if it could be reprinted in that most valuable reference book, the *Tropical Agriculturist*. But, at the same time, it is obvious that the important question has not been settled, and the identity of the lélá with the "mahseer" remains as doubtful as ever. In fact all the evidence points to the conclusion that they are *not* the same, and appears to accentuate the opinion that the true "mahseer," the *Barbus tor*, the 100 lb. king of Indian mountain lakes and streams, does not exist in Ceylon. The difference between the respective descriptions of the Indian mahseer, and the would-be mahseer of Ceylon is marked, and this is significant; also the fact that there are no less than five varieties of "mahseer." "Fisherman"'s statement that there is "lélá ("*mahseer*" *so-called*) in the Colombo lake and that he has seen it hawked about is not so startling when one remembers that bales of dried (but not salted) lélá, lúlá, moddu, and other fresh-water fish from northern tanks are taken by Moormen to Matale and other places where they are eagerly bought by natives. Lélá is also to be found in the Mahaweliganga and tributary streams, and is said to be perfectly wholesome except in the months of April, May, June, and July. I have eaten it in September-October, with impunity, and found the flesh white, well-flavoured but rather soft. It ought to be cooked with the least delay possible; incipient putridity sets in surprisingly soon. The alleged unwholesomeness of fresh-water fish for four months of the year is exceedingly curious and distinctly peculiar to Ceylon: some reliable information would be valuable on the subject. It is not surprising that they should, like fish in European waters, be sometimes "out of season;" but there is an essential difference in being merely "out of season" and being actually poisonous.

Now for a word on another question of no small importance. It is a customary thing that when a pool is known to be "stiff" with fish, it is systematically drugged, and the fish killed in a most unsporting way by Sinhalese and still more often by Moormen who say that if the stomach and inside be removed no ill effects happen from eating the fish even though it has been poisoned! How this sort of thing can be allowed I cannot imagine; but it cannot go on for ever, and it stands to reason, that, no matter how prolific, sooner or later the waters will have to be protected, and the sooner they come under the "Mundella Act" the better!

A. L. O. M.

MAHSEER IN CEYLON.

SIR,—In your issue of the 9th instant, I see "A. L. O. M." again raises the question of fish in Ceylon. The only freshwater fishes worthy of notice in our island are lúlá, lélá, and verálu, and these you have fully described in your issue of the 25th ultimo. I would like, however, to say a few more words about them. The first, lulá, I have fished just below Kitulgala resthouse in the Kelaniganga, some weighing 75 lb. and over, two of them making a heavy load for a Sinhalese man, slung upon the ends of a stick over his shoulder. I have also fished some of equal size in the Mahaweliganga near Haragama in the holes amongst the rocks when the river was low, about 2½ miles below Gonawatta ferry on the Dumbara and Padapelella road, and I think I can safely say that these fish can be found in all freshwater either tank, stream, or river, in Ceylon. I can vouch for its existence in every Province except the Southern, where I have never been. I am inclined to think that this is the mahseer and not Mr. Haly's lélá described in his letter of 1st February which led me to think he meant the lúlá, and that his spelling of it as the 'léloo,' was a mistake. My reference to these fishes is by their common vernacular names, not scientifically. The lúlá varies in colour according to the water in which it is found: some are lighter and some darker than others; and the female is higher in colour (especially on the belly) and more slender in make, never attaining the same size as the male. I have eaten the lúlá at almost all seasons of the year, and never found any ill effects from it; and further I never heard of its being poisonous.

The lúlá can be seen and may be identified (if anyone cares to do so) as the mahseer, I think, in a glass case in the verandah of Henderson dubash's premises facing Chatham Street, the corner house. It is a good specimen, although light in the colour owing to the sandy bottom of the case.

The lélá never attains the same dimensions as the lúlá; its average length being 12 inches, and the largest is never over 1½ to 2 feet long. Common in almost all Ceylon rivers and lakes; is poisonous at certain seasons through eating the seed or flower of some trees, I have heard it said sapu flower in high districts. The centre bone has a green and sometimes blackish appearance, the flesh sometimes tasting bitter, proving soft and disagreeable to the pallet; of a silvery grey appearance and very easily distinguished from the lúlá or verálu.

The verálu is a fish very much like an eel, it is common in most rivers and tanks, grows three to four feet long (but not thick in proportion like the lúlá), the flesh is good and tastes like our English eel, but not so oily. Tamil coolies are very fond of this fish and are very persevering in their endeavours to capture it.

Several other fishes are found in our rivers and tanks, but they are so full of bones that they cannot be eaten with any relish, even after a good cook has gone over them, the same as a glazier would putty with a knife, to get out the bones before converting them into cutlets. The largest of these, a very scaly fish, nearly attains the dimentions of the lúlá, but is thicker and has a smaller head.

FISHERMAN.

FRESHWATER FISH, PORCUPINES, AND LONG DIVES.

March 12th, 1888.

DEAR SIR,—In your issue of the 9th instant, I notice a correspondent mentions the alleged unwholesomeness of the lélá, during the months of April, May, June, and July. From personal experience, I am able to state that they are unwholesome (in the Kotmale district) during January and February. I attribute this to the fact that they spawn at that time of the year, and if eaten give rise to symptoms resembling dysentery. I have eaten this fish from August to November and have then found it both good and wholesome: in the months March to August I have no experience one way or the other. I have never seen lélá from the Kotmaleganga over 2 lb. in weight, but have seen a 3 lb. fish in another district; the fish which seems to attain the greatest weight in the Kotmaleganga is the "palanga" (Tamil), a kind of eel. I heard of one some years ago having been caught below Meddacumbura estate and purchased by the manager: it was said to scale 16 lb. They are very good eating, perhaps better than any other Ceylon fish. They are, I believe, invariably caught with night lines by the Sinhalese. Many fish have been destroyed by dynamite in the Kotmaleganga. This should be put a stop to if possible. I have never seen fish rising on the above river, but have seen them rising very freely in the Kaluganga, north of Ratnapura. I was unable to procure a specimen, but the fish on the rise seemed to be a good size. With regard to porcupines shooting thei

quills, I have seen many killed by dogs and have caught others alive, and am convinced they cannot do so; when pursued closely by dogs they stop suddenly and back, thus causing a collision and forcing their quills into the dog. I have had many dogs seriously hurt, one large dog having a quill penetrating 9 inches into the chest and being otherwise so much crippled that it had to be carried to the kennels apparently dead, though it subsequently recovered. The same dog on another occasion had a quill so firmly embedded in the bone of the skull above the eyes that on attempting to withdraw it the point broke off and remained in the bone. When disturbed in the thick cover they generally frequent, they have a habit of rattling their quills which make rather a startling noise, no doubt with the idea of frightening away the intruder. When in captivity I have observed them do the same when disturbed, but I never saw quills become detached from them, nor do I see how they could shoot or jerk them off with sufficient force to do any damage.—Yours truly,

KOTMALEGANGA.

P.S.—The diving record is held by J. B. Johnson of Leeds, who has remained under water for 3 min. 35 2-5th sec. (see *British Rural Sports*, p. 722). This beats the Ceylon divers.

[Thanks for a very interesting communication. If the *lélá* is the true mahseer and is unwholesome while breeding and also when certain flowers and fruits are in season, the fish seems to be of far less value as a food contributory in Ceylon than in India, apart from the fact that the larger specimens are said here to defeat the wiles of the angler bait he never so wisely. The *lélá* receives its scientific name from its likeness to a snake, but our correspondent seems too well informed to confound this fish with an eel.—What is stated about the quill-like hairs of "the fretful porcupine" is in agreement with commonsense as well as with science. The quills are powerful as weapons of defence, but the rodent can neither project them, nor carry water to its young in them. We believe it to be true that no Ceylon pearl fishery diver has approached the endurance under water of the gentleman mentioned by our correspondent. As the performance is most interesting in a physiological point of view, as well as in connection with pearls, sponge and shell diving, we should feel obliged for the details. Mr. Johnson must have had good lungs to begin with, and they must have been well educated to bear the deprivation of atmospheric air for such a really long period as over 3½ minutes?—ED.]

CINCHONA IN JAVA:

OFFICIAL REPORT.

The following is the official report on the Government cinchona enterprize in Java for the fourth quarter of 1887, just received:—

With the exception of the first half of October, in which only a few showers of rain fell, the past quarter was very rainy: in fact, during November and December there was not a single dry day recorded. The continuous rain was very favourable to the growth of the young plants and the nurseries. At the beginning of November a commencement was made with the putting out of plants in the open, which operation was carried on uninterruptedly. In consequence of the wet weather and in the absence on most of the establishments of artificial means for drying the bark, the harvesting was greatly hindered. At the end of the last quarter, 629,424 half kilograms of the harvest of 1887 had been dispatched to Batavia, whilst about 50,000 more half kilograms of this harvest's bark remained in the packing-houses and on the estates, which will be sent off during January. The outturn of 1888 promises to be considerably greater than that of the past year, and is estimated at 850,000 half kilograms of bark. Indeed, this outturn can be obtained without much exertion, as the six artificial drying apparatus requisitioned and promised should be erected, and the harvesting can proceed uninterruptedly independent of the state of the weather. On 8th September and 20th October sales of Government cinchona bark of the crop of 1886 were held in Amsterdam. The average prices realized at these sales were 49·84 and 43 cents per half kilogram. At the sale of 20th October the prices, especially for manufacturer's bark, went down to a point lower than any yet known. However, for ledgeriana barks an average price of 39·13 cents per half kilogram was paid, so that, with the rich harvests from the Government plantations, an appreciable profit was realized. The much higher prices that have been lately paid in the European markets for pharmaceutical barks in quills, not only of *C. succirubra* but also of *C. calisaya* and *C. josephiana*, have led us to try the experiment of packing ledgeriana bark also in boxes, so far as the harvest of that product yields fine unbroken quills. The inducement to this was all the greater, because in a few years the production of calisaya and josephiana barks will be a thing of the past. The experiments made with the grafting of ledgeriana and succirubra in the open air, which at first were crowned with little good result, have lately given encouraging results. On 30th December a sale of cinchona seed was held at Bandoeng. Seven hundred grams of succirubra seed found ready buyers at the upset price of 20 cents per gram; of the ledgeriana seed offered for sale only 20 grams sold at the upset price of f 1 per gram, whilst for the ledgeriana grafts put up at the upset price of f 10 each there were no buyers of any description. The fact is deserving of mention, that the ledgeriana mother-tree No. 89, which had to be dug out on account of disease, yielded a crop of 146 half kilograms of wet and 72 half kilograms of dry bark, and is of value as a new argument for the opinion held by us throughout, that the future of cinchona cultivation must be sought chiefly in the creating and upkeep of old plantations. In the month of December many old ledgerianas and also a portion of the grafts at Tirtasari began to blossom, so that, contrary to the expectation put forward in the report for the third quarter of 1887, the seed crop of ledgeriana during 1888 promises to be pretty considerable.

VAN ROMUNDE,

Director of the Government Cinchona Enterprise.

Tirtasari, 10th Jan. 1888.

Total of plants in the Government cinchona gardens at end of 1887:—In the nurseries—1,595,500 ledgeriana (including 45,000 grafts), 680,000 succirubra: total 2,275,500. In the open—867,000 ledgeriana (including 180,000 stocks and grafts, and excluding the more or less 3,000 original ledgerianas), 32,000 calisaya and hasskarliana, 591,000 succirubra and calotera, 171,500 officinalis, 4,000 lancifolia: total 1,665,500. Grand total 4,041,000 of all kinds.

PAPER TREE.—One of our American exchanges has an interesting note on what is called the "paper tree," known to the natives as "Aeuta," though it fairly deserves the name of *Rumal-tree*. It is a species of mulberry found at the Otaheites, in South Pacific, from which a cloth is manufactured that is worn by the principal inhabitants. The bark of the trees is stripped and deposited to soak in running water, when it is sufficiently softened, the fibres of the inner coat are carefully separated from the rest of the bark; they are then placed in lengths of eleven or twelve yards, side by side, till they are about a foot broad, and two or three layers are put one upon another. This is done in the evening, and the next morning the water is strained off, and the several fibres adhere in one piece. It is afterwards beaten on a smooth surface of wood with instruments indented lengthwise, with small grooves of different degrees of fineness, and by means of this it becomes as thin as muslin. After a bleaching process in the sun, to whiten the material, it is fit for use.—*Indian Agriculturist*.

CITRUS FRUITS.

In the report for 1887 of the College of Agriculture of California, Professor E. W. Hilgard gives some analyses which have recently been determined at the College, of Citrus fruits, which are not only interesting, but most important, as showing the points of difference between the several fruits.

Table showing the Chemical Composition of Citrus Fruits.

Description.	Average weight. Grains.	Percentage Results.						
		Rind.	Pulp.	Seeds.	Juice.	Sugars. Cane.	Glucose.	Acid.
Oranges:—								
Mediterranean Sweet	288	33·5	65·3	0·9	?	4·47	1·67	1·10
Riverside Navel*	284	30·0	70·0	...	41·4	5·04	2·10	0·92
St. Michael ...	158	17·3	80·1	2·6	52·6	4·09	1·68	1·01
Malta Blood ...	139	26·8	73·2	...	48·6	3·92	1·81	1·52
Lemons:—								
Lisbons ...	115	35·7	63·9	0·4	43·4	...	...	6·79
Eureka ...	157	22·4	77·6	...	45·2	...	...	7·21
Limes ...	54	15·9	83·4	0·7	56·5	...	..	6·86

It will be noted that the Navel and Malta Oranges and Eureka Lemons were found seedless, the largest proportion of seeds being found in the St. Michael oranges. The Navel shows the highest total sugar and lowest acid of all. "It thus would seem," says the Professor, "that, apart from its inviting outward appearance, the Riverside Navel orange owes its place in public favour to three chief points: a high degree of sweetness, with a low degree of acid, and the firmness of flesh which invites it to be actually eaten instead of being 'sucked' as one is tempted to do with the softer oranges. The Mediterranean Sweet and the St. Michael dispute precedence, according as individual tastes differ in respect to size and flavour; but the St. Michael seems to have a greater firmness of flesh in its favour. The refreshing acidity and peculiar flavour of the Blood orange place it in a different category from the other three. The first six columns of the foregoing table, however, furnish material for additional considerations, especially when oranges are sold by numbers and not by weight. The Mediterranean Sweet shows a slightly heavier weight than the Navel, but the larger proportion of pulp in the latter more than makes up the difference. The St. Michael shows the highest percentage of pulp of all, notwithstanding the relative abundance of seeds; and hence a given weight of this variety would furnish the largest amount of eatable pulp, while if bought per thousand, the light weight of the fruit would leave the consumer materially 'short' as compared with the Navel or Mediterranean Sweet. It was found that there is a true deterioration in oranges kept beyond the point of proper ripeness that amply justifies the preference of consumers for the freshest fruit."

As regards Lemons, the comparison between the Lisbon and Eureka tells strongly in favour of the latter. It is larger, and has a higher precentage of pulp as well as of juice, while at the same time the latter is considerably richer in citric acid. The Limes stand nearly at the same point of acidity as the Lisbon, but show a considerably higher proportion of pulp, as well as of juice than either of the two Lemons, being fully 13 per cent above the Lisbon in the latter respect. It is understood by the trade, that oranges especially deteriorate materially after a certain period, independently of any actual decay; and in special tests made in this regard last season it was shown that this deterioration manifests itself in diminution of both sugar and acid, as well as in a loss of flavour. The fruit gradually becomes tasteless.—*Gardeners' Chronicle.*

* Sample taken from a plate of fine Oranges which received the first prize for the best budded Orange, and best Orange on exhibition at Riverside Citrus Fair.

THICK AND THIN PLANTING.

It is often asked by the inexperienced—Should we plant thickly or thinly? So much depends on soil, situation, or aspect and shelter, that it is difficult, even impossible, to give an answer to the question without full knowledge of the circumstances just named, and also of the sorts of trees that are to be planted. Another consideration which is of paramount importance in coming to a conclusion on the point is whether the object in planting is to establish an ornamental feature in the landscape merely or to obtain shelter, or simply to grow timber for commercial purposes. The latter is rarely the sole object of planting in this county, because the other two objects named are those that are chiefly sought after. But where waste land is planted with the view of improving the climate by providing shelter, thick planting should be the rule or, say, three feet apart. The plants grow more quickly when they give close shelter to each other. This consideration should always be the guide in planting for profit. Rapid growth is the point to be secured, and in bleak positions and bad aspects there is no means whereby that object can be attained more speedily than by thick planting and moderate thinning afterwards. Open woods are not those to which the timber merchant would resort for the best quality of timber for whatever purpose. Growth is well known to be too slow and the fibre too short and brittle in such woods. The highest quality of timber is always produced in plantations that present an almost unbroken canopy of foliage. This is especially the case in plantations of pine or other coniferous trees when kept in reasonably close order they grow more freely upward and reach their ultimate height more quickly than if they are kept in open array. The soil in which the trees grow should be shaded more or less at all times by the ascending tops, but at the same time each tree should be allotted as much root space as will enable it to exist healthily. In ornamental planting, or where effect is the principal object, wider distances apart should be allowed. It is not necessary that this should be determined at the time of planting. The plants may be put in as thickly as if they were being planted for profit alone, and with advantage. They will shelter each other and encourage rapid growth during the first years of their existence. But thinning must be begun at an earlier period, and the individual trees must have free space all round that is their branches should not overlap or intertwine with each other. The treatment should rather be to build up strudy constitution that will last than to force the trees to early maturity and marked value. The soil in which trees are grown should always, if possible, be sheltered from sun and wind and it is always better too if it is protected from heavy, battering rains. The leaf canopy overhead has this effect of breaking the fall of heavy rain which in heavy land especially prevents the surface from becoming battered into a hard close condition which is inimical to perfect health in the trees.—*Indian Agriculturist.*

A FRENCH inventor proposes to use a lye consisting of milk of lime with an addition of sea-salt in the manufacture of paper. His allegation is that this lye contributes to the bleaching of the fibre.—*Indian Agriculturist.*

A PATENT has been taken out for treating fibres of the grass kind, first by means of oil or oleic acid, which is said to have the property of softening or dissolving a resinous matter which cements the fibres together, then by alkaline solutions which remove the oil and resin, and makes the pectates soluble in water, producing a soft and clean fibre.—*Indian Agriculturist.*

THE Japanese have long been famous for the manufacture of paper, especially the finest and tougher sorts. One of their latest achievements in this line is the production of a paper belt, suitable for driving machinery, and said to be stronger than ordinary leather. Now that European machines are being adopted in that country, this invention will prove exceedingly useful, for the Japanese are inferior tanners, and do not make good leather.—*Indian Agriculturist.*

COFFEE, SUGAR, AND SLAVERY IN BRAZIL:

THE BUMPER COFFEE CROP OF 1888-9 SAFE—TO BE THE BIGGEST EVER SHIPPED FROM BRAZIL.—COFFEE DISEASE IN BRAZIL.—AREA OF FOREST LAND FOR COFFEE INEXHAUSTIBLE—THE LABOUR SUPPLY—SUGAR—BRAZILIAN POLITICS AND SLAVERY.

Rio de Janeiro, 15th Jan. 1888.

The lucky coffee planter continues to have it all his own way. The weather, after the customary dry month before Christmas, which by the way was not so very dry after all in many places, changed to the real tropical New Year routine: days on end, of steady downpour and high rivers, and flooded fields all over the country. Woe betide the lazy coffee planter who has been idling during these last six months of his picking season, for what is left outside now will be showing beautiful young sprouts. We must not forget also that the cane, which has been left of the present crop, *cut or uncut*, will be preparing itself for the fermenting vats, and instead of being turned into the necessary article for seasoning "the cup which cheers but not inebriates" will be made into a mixture for another cup which stupefies, and sometimes turns men into beasts.

The bumper crop of coffee for 1888-9 is now secure. We never mind the reports which are coming from many places in the interior, which state that the dry weather burnt up many green berries which are now falling off with the rain, for your old coffee planter has noticed, that after a full blossoming season, when the young berries begin to swell, the strongest of those on the clusters push off the weaker, there not being room for all round such a small circumference. I fancy you have seen the estimates for the coming crop of 1888-9. Rio is expected to ship 5,000,000 sacks and Santos 3,000,000 sacks of 60 kilogrammes each. This total of 8,000,000 sacks or 480,000 tons will be the largest coffee crop shipped from Brazil.

In 1882-3 Rio shipped over 4,500,000 sacks, but then Santos, or rather the province of São Paulo, which supplies Santos, was producing only half of what it now grows.

The crop for 1887-8, of which six months have already run, shows:—

Shipments for six months ending 31st December 1887 from Rio ..	888,355	bags of 60 kilos.
and a stock of at 1st January 1888 ..	215,000	do do
and estimated in the interior	1,000,000	
	2,103,355	do do

I have not the exact figures for Santos, but think it is somewhere about

for six months ending 31st Dec. 1887	600,000	bags of 60 kilos.
and in stock at 31st Dec. 1887	350,000	do do
estimated in the interior	750,000	do do
	1,700,000	do do

The price for *good* has ranged during the last six months per 10 kilos from 9$165 at end of June to 7$000 at end of December (18000 at present is worth about two shillings, say from 9$165 to 10$000 = 2s. 6d.

The high price seems to have lessened the demand in consuming countries, if we are to judge by a table I saw the other day, relating to the consumption in the United States for the eleven months ending November 1887, of which here are the last six:—

	1887 Bags	1886 Bags of 60 kilos.
June	104,151	1[illegible]
July	90,507	2[illegible]
Aug.	166,151	3[illegible]
Sept.	200,177	2[illegible]
Oct.	195,608	2[illegible]
Nov.	177,178	2[illegible]

The consumption in the principal markets of *Europe* in the eleven months has amounted 1,175,900 bags.

The downward tendency of the market at sight of these figures shows that small crops sometimes produce prohibitive prices. It is to be hoped that when the[y] have it again plentiful the consumer may return to his old tastes, for in the present crisis Brazil requires extensive open markets and good prices for her produce.

At the present time, when this country has reached that crisis which all looked on with apprehension, I mean that transition state of the labour market, from servile to free labour, it may be entertaining to those who think they have an interest in the results of such transformation to look at the quantity of coffee grown, say the quantity shipped to Europe and the United States during the last ten years. The rapidity with which public sentiment has turned in favour of the bondman and is changing in his favour every day warrants us in expecting that slavery by the *end of this year*, if not a thing of the past, will be so circumscribed in its action, that its existence will depend on the voluntary action of the blacks themselves. It might be interesting to some people to note, if the exports of coffee will be less for the next few years. The figures below do not refer to the crop years, but for the calendar year 1st January to 31st December:—

Shipments from Rio de Janeiro, ditto from Santos:—

	Rio: Bags of 60 kilos.	Santos: Bags of 60 kilos.
1878 ..	3,031,199 ..	1,000,000
1879 ..	3,535,183 ..	1,210,000
1880 ..	3,563,054 ..	1,050,000
1881 ..	4,377,418 ..	1,210,000
1882 ..	4,200,590 ..	1,530,000
1883 ..	3,654,511 ..	1,840,000
1884 ..	3,897,113 ..	1,930,000
1885 ..	4,206,911 ..	2,170,000
1886 ..	3,580,965 ..	1,660,000
1887 ..	2,241,755 to 15th Sept.	2,400,000

The figures for Rio are taken from the yearly review of the *Jornal do Commercio* of Rio, and those for Santos from a correspondent of same paper, who leaves out fractions. The consumption in Rio, 72,000 bags a year, is not included.

I have from time to time noticed numerous reports, in your and other papers, of a coffee leaf disease destroying the trees in Brazil, and various prophecies that the crops will be reduced in consequence. I have several times written to you on the leaf-miner, *Cemiostoma coffeellum*, which did a deal of damage to the coffee trees during the sixties, remnants of which remain on all good patches of coffee to the present day. The damage it did in the province of Rio was such that scientific men were engaged by the Government to investigate it. It was after it had been identified with the *Hemileia vastatrix* of Ceylon* that I gave you all the information about the *Cemiostoma* that was then known, which briefly summarized was this:—A small moth moved about shady places and damp hollows, deposited an egg on the coffee leaf, the egg turned into a small worm, which ate the soft part inside the leaf, leaving

* The Ceylon disease is a fungus and has nothing to do with a moth.—Ed.

the upper and under skin whole; in a few days it found its way out, and from the chrysalis state emerged again as a moth. At the time I gave you these particulars—about 1874 or 1875—it was found only on the best fields of coffee, and was also abundant amongst trees of the forest. It is still in the same state, and I would rather have the coffee fields where it is most plentiful than those where it is scarce. The effects of it are seen in coffee and forest trees in dark brown blotches on the leaves, and it is rarely that these cover the space of a square centimetre: indeed it is noticed generally in round dark brown spots about a quarter of an inch in diameter. When about eight or ten years ago the coffee in the province of Rio de Janeiro began to decay, Professor Jobert discovered a small worm about the roots of the coffee trees, which he supposed to be of the genus *Anguillula* of prodigious fecundity, but his observations were not sufficiently numerous to enable him to arrive at any definite conclusion as regards its mode of life. Since then the estates in the lower part of the province of Rio (Serra Abaixa) have died out, and even now you cannot find two planters of the same opinion as to the causes of the decay of so many coffee plantations. I have given you mine oftener than once, and it is still my opinion that through constant heavy cropping, want of treatment, and want of manure, the trees got so weak they became a prey to diseases of various kinds, these assumed an epidemic character, and young healthy trees caught the infection.

Within the last few years distemper has appeared among the plantations along the valley of the Parahyba, the higher part of the province (Serra Acima), and many plantations are following the example of the lower parts of the province some years ago. The Government, on being applied to, sent a scientific gentleman from the staff of the national museum. A report has appeared but not a final one, but it confirms Professor Clement Jobert's story of the worm at the roots, and amidst a fair quantity of technical terms, the report issued by the national museum says, it is a nematoid, perfectly reviviscent in its feminile sacs of procreation in the interior of the pathological nodosities of the roots of the coffee tree; from which we infer that procreation takes place inside the bark at the knotty parts of the roots. The report is a laborious one and reflects credit on the perseverance of Mr. Emil Goldi, its author. He hesitates in including the parasite in the genus *Anguillula*, and proposes the name of *Meloidogyne exigua*, (exigua as according with the form of the worm in the *bolsa matrix*.) The cause of the disease is not mentioned. It is said to be contagious and epidemic in all the regions which the scientist visited. As a *preventative* the farmers are advised to be careful in selecting good seed, and to apply manure, thus showing that in his opinion natural causes have something to do with it. Now, no one need be alarmed at this *coffee disease*, nor need there be any apprehension of its spreading to the new and vigorous districts opened during the last ten years, through the rapid extension of the railway system of transport. The valley of the Parahyba and the higher parts of the province of Rio are now receiving the same visitation which the lower parts of the province received from ten to fifteen years ago. In all the old districts of Brazil coffee trees are dying out, but new districts are opening far beyond the reach of the old and decayed ones, and the extra produce from these will continue to increase the yearly exports, and the diminution from the old plantations will be lost sight of as far as the consuming world is concerned. After all the disease-stricken parts produce but a small fraction of Brazil's enormous coffee crops. The quantity of forest land available for coffee in Brazil is, one might almost say, inexhaustible. The same system of cultivation will continue; well I am wrong there,—I mean *growing*, for cutting down the weeds three or four times a year, in many instances only twice, once after crop picking and once before, and picking the crop *is not cultivation*. Old districts will continue to die out as they have done all over the world ever since coffee planting began, and particularly where the system of coffee *growing* has been adopted. I will admit that the decay of coffee planting in Ceylon is an exception to the rule I am now laying down, for the disease *Hemileia vastatria* was a visitation similar to the potato disease in Great Britain forty years ago. In Ceylon the coffee trees in the young and vigorous districts of Madulsima were the first to show signs of the disease *Hemileia Vastatrix*, and the latter spread all over the country in a short space of time, sparing neither old nor young districts, *Coffea arabica* and *Coffea liberica* being both subject to its ravages. In Brazil there is not, nor has there been a coffee disease of such a devastating nature.

It will not be from disease amongst the coffee trees that the exports of coffee will suffer, the momentous labour question will certainly in a social point of view make great changes amongst the former producers, and might affect exports for a short time only, but it is being solved in a way that will make little difference to the consumers of coffee, and I would not advise producers in other parts of the world to look for a rise in prices owing to any of the above-mentioned causes affecting the exports from Brazil.

SUGAR, which has been king in the northern provinces of the Empire for many years, has been affected by the beetroot competition of Europe, and the production has been much less during the last ten years from this cause. The introduction of the central factory system, which takes the manufacturing part from the hands of the cane grower and gives it to scientific manipulators, has effected a change.

I cannot give figures as regards the northern provinces, but these, as well as the province of Rio, will feel a relief by the abolition of the export duty payable to the central Government of the Empire of 7 per cent *ad valorem*. The provincial duties of 3 per cent and 4 per cent *ad valorem* have in Rio de Janeiro and most of the other provinces been also abolished. The former exemption, that for the central Government took, effect in the middle of October, and the provincial duties from the beginning of the year. This is a decided relief, for if we add municipal taxes, the loss indirectly to the planter was say 12 per cent on the full *value of his produce*, not *12 per cent on his profit*, and meant a great deal. He can now look on it in the same light as if his cane fields were giving him one-eighth more without his requiring to spend more money on them. Or to make it appear plainer still: formerly he was at the expense and labour of tilling his ground, transporting his cane to the mill, underwent the *daily* and *nightly sweating* in the sugar-house and sent it to the shipping port, and after all *one-eighth* ($\frac{1}{8}$) *of his produce was handed over to the Government*. The planters in the province of Rio had much need of this relaxation, for it was found that the abandoned coffee fields gave excellent crops of cane, but the price of sugar fell so low, they could make nothing by the old system of manufacture. They will now receive a fair price in the city of Rio de Janeiro, which receives, or has until now received, one-third of the sugar required for its consumption from the northern ports. Now that the

export duty is taken off, it will pay better for the shippers in these latter to sent their sugar to Europe or the United States, and since the middle of October large shipments have been made from Pernambuco and Bahia to these countries: there was exported from Pernambuco alone 25,000 tons in the month of November 1887. The bulk of the sugar produced in the north is *mascava*, or ordinary brown, and a demand is springing up for this class of sugar for refining purposes. Within the last two months prices for these inferior kinds have risen 30 per cent. The price of central factory sugar has risen 25 per cent during the last few months. The increase in the production in the province of Rio is owing to the central factory system. The supply of cane to these is likely to increase. The price of sugar, although so low as to leave nothing to the small farmer who manufactures his own, has still left a profit for the central factory owners. The price of cane is always regulated by the price of sugar in Rio de Janeiro or the local market or according to the *nett* proceeds of the account sales. So the factory is secure of its profits. Five shillings a ton for cane pays the farmer if the factory has a tramway near his cane fields to transport his cane, and the factory owners never calculate on less than five pounds sterling profit per ton of sugar; while the sale of the rum which would be about a pipe for every three tons of sugar goes towards repairs of machinery and upkeep of tramways.

By the figures I give below, you will notice that the produce of the province of Rio does not supply enough for the local consumption, and although the increase of production, as shown by entries into Rio during 1887, has risen to nearly a third, the extra consumption as judged by the table of sales in 1887 in Rio has risen in equal proportion, and of the total sales effected in Rio for local consumption, about the usual proportion a third of that consumption has been supplied from the *northern ports* from the provinces of Pernambuco, Bahia, and Alagoas. The increase in the sales for consumption in the country seems large, but this goes to prove, but in an inverse manner, what we observed above in regard to coffee consumption in the United States during 1887, the high or the low price of the article affecting the purchase of it. Other factors as regards the consumption of sugar in Rio have to be counted on also. *One* is the increase of sugar-consuming subjects, such as through immigration from other countries and through liberation of the blacks. In a state of captivity they (the negroes) use little sugar unless direct from the cane, their own molars doing duty for the crushing mill, their strong lungs that of the evaporators. In a state of freedom they are large consumers, and we may expect a still larger consumption amongst these within the next few years. Another agent in the trade is the manufacturer of *falsified wines*, cordials, and all kinds of spirituous liquors. This trade has been carried on for years in Rio and other towns in Brazil, and only now and then Government interferes. During the year before last, however, it got a decided impetus through the agricultural interest in Parliament appearing as champions in favour of the trade, against some measure for regulating it. It was proved to the satisfaction of many, that *adulterated liquors* made from the *superior spirit* and *wine farms product* of this country were no better for the health of the consumers of them than the base imitations shipped from Hamburg, Antwerp, Bordeaux, and Lisbon to Brazil, and to show that they had convinced the Government of the expediency that since we cannot prevent other people from making a *profit* on the poisoning of our people we ought to make some ourselves, a heavier duty was put on all imported liquors, and the *pinchbeck trade* in beverages is fostered. But here are the figures:—

Sugar Market in Rio de Janeiro in Sacks of 60 Kilos=17 to a Ton.

	1887.	1886.
Stock in Rio 1st January ...	63,107	33,420
Entries into Rio from northern ports	212,186	130,553
From the province of Rio *coast* and *rail*	433,846	324,227
Total...	709,139	488,200

	1887. Bags of 60 kilos.	1886. Bags of 60 kilos.
Sales in Rio for export	36,078	33,127
" " local consumption..	616,446	391,966
Stock at 31st December.. ..	56,615	63,107
Total as above ..	709,139	488,200

Sugar consumption in Rio de Janeiro and vicinity.

	1887. Bags.	1886. Bags of 60 kilos.
Sold in Rio for local consumption ..	616,446	391,966
Receipts during year from north ..	212,186	130,533
Supplied by province of Rio equal to ⅔ consumption	404,260	261,413

On comparing the table below it will be seen that the monthly sales have been equal to the receipts; so that there is little room for inference, that towards the end of the season dealers may have been laying in a stock. In October some 30,000 bags were shipped to London, which explains the heavy sales in that month.

Movement of the Sugar Market in Rio de Janeiro during 1887 in bags of 60 kilos each.

Of the sugar produced at the central factories 70 per cent will be 1st, 20 per cent 2nd, and 10 per cent 3rd qualities. The first *two* are classed with *white*, and the last as mascava or *muscovada*. A fourth is often taken. All molasses are turned into rum.

The movement of the Rum Market for 1887 was as follows:—

		Pipes.
In Rio de Janeiro Stock at 1st Jannary ...		1,524
„ „ received during the year...		19 773
		21,972
Sold for consumption in Rio and suburbs...	19,402 pipes	
Exported to other parts of Empire	160 „	
„ River Plate ...	25 „	Pipes
Stock in Rio 31st Dec. 1887 ...	1,710 „	21,297

The price in Rio has ranged between 70$000 the *lowest* and 85$000 the *highest* all the year through.

I have entered more largely into the sugar question than is usually done by correspondents in your paper. No doubt you number amongst your readers of the *Tropical Agriculturist* many sugar planters: if not it is because they do not know its value to all engaged in tropical agriculture of any sort. To these the figures may prove interesting. I would advise those sugar planters in other countries not to be alarmed at the spread of sugar planting in the province of Rio, through coffee having failed, for it will be a long time before enough sugar can be made there to supply the local market; and with the emancipation of the slaves, which all believe will be effected before the end of this year, consumption will be largely increased. In districts where coffee can be grown, the people *grow no cane*, but they consume and will continue to consume a large quantity of sugar.

I expected to have had time to make allusion to the great social question which is agitating the community, but I must leave that for another occasion; at present I shall merely summarize the course of events.

The leading politicians of the province of São Paulo of both shades of opinion—liberal and conservative—towards the close of the last Parliamentary Sessions began to show signs that the law of 28th September 1885, giving slavery a lease of thirteen years from that date, recognising anew the right of ownership in human flesh, and the right of compensation for the loss of same, and making rules for carrying out the latter principle on certain conditions, was not to be considered as the "last word" or final settling of the question. And the Government itself when very hard pressed—if they did not say so—showed that this treaty of settlement "must be read between the lines."

The fazendeiros in the cane-producing districts in the province of Rio de Janeiro, notably those in the vicinity of the city of Campos, began liberating their slaves on condition of working for three years. The more advanced amongst the São Paulo coffee planters soon followed suit. These, headed by the family of Senator Antonio Prado, who had just given up his post as Minister of Agriculture, Commerce, and Public Works, not only liberated their slaves on condition of short terms of service, but promised them wages during the remaining term of servitude. They soon collected a following and large numbers of the wealthiest coffee planters joined their standard and preached their *propoganda*.

The less fortunate of the bondmen, whose masters could not in honesty,—or shall we say in conformity with their contracts and hypothecation bonds to their creditors, could not—grant them, supposing they were inclined to, the long-wished-for concession of freedom, those slaves which through no fault of their own could not receive the same advantages as their fellows on neighbouring estates began to see there was some truth in the famous words, "Who would be free himself must strike the blow," and began to leave their masters, but in an orderly and pacific manner, joining in bands and proceeding to the nearest town. Public opinion was so strong in their favour, that the authorities, even if they had the means of enforcing the law which they had not, could do nothing more than advise them to go back. If they had a good home and could trust their masters' word as regards early hopes of freedom they went, while others got merged amongst the free population.

During December a large meeting was held in the town of São Paulo, at which the principal coffee planters attended, and resolutions were passed and signatures obtained for an Association for freeing all the slaves in three years. At the same meeting there were dissentients in favour of immediate emancipation, and these refused to sign as members of the new Association. To "suit the action to the word" these same dissentients went home, and immediately declared their slaves free, and told them (the slaves) they would now work for wages.

Within a short time, "a month, a little month," as if some spirit of goodness had passed over these productive regions of the province of São Paulo, and left its humanizing influence in many households, dozens—I cannot as yet say hundreds—have given unconditional liberty to their slaves, and these are staying quietly with their old masters and receiving wages.

The daily newspapers have their columns filled with the lists of those who have freed their slaves; not a day passes, but large announcements are made of this quiet and orderly manner of changing the social habits of a great Empire.

But what of the other provinces? It has suddenly been discovered that those of the *north* have been for years dependent principally on free labour. Ceará declared herself free of slaves some two years ago. Pernambuco and Bahia were mulcted of the most of their slaves when sugar went down and coffee went up, some ten or twelve years ago, and they are now settled with free labourers. The coffee planters in the south gave at that time fabulous prices for the black labourers from the north. The pastoral provinces of the extreme south have never much leaned on the captive for their labour force. The three coffee-producing provinces S. Paulo, Rio de Janeiro, and Minas Geraes are left to play out the game. The first-named takes the lead and the other two have in the natural order of things to follow.

But what is to make up for the "increment" in the productive economy that will be effected by the reduced labour of the black? This in the province of São Paulo is being supplied by labourers who get their passage and that of their families paid from Europe. 35,000 came during 1887, and a law has just been passed in the Provincial Assembly for 100,000 during 1888. Do not fear, the people in S. Paulo have energy, and heaven will help a righteous cause.

A. SCOTT BLACKLAW.

THE PROPOSED CLEARING-HOUSE FOR COFFEE.

We understand that the negotiations for the establishment in London of a clearing-house for foreign and colonial produce are assuming in more definite shape, and that it is almost certain that a workable basis will be established by the firms promoting the enterprise. The clearing-house is to commence with a capital of 500,000*l*., and to turn its attention, in the first place, to coffee and sugar. Its object may be defined as the facilitation and reduction to certain fixed rules of speculation in colonial produce, and the creation of greater security than now exists that parties to speculative contracts will fulfil their

obligations. The London terminal market is to be modeled on the system of the "Caisse de Liquidation" existing at Hâvre, an institution which for the last decade has played an important part in the commercial affairs of that port, and which has been a source of huge profit to its promoters, who last year, we understand, received a dividend of something like 87½ per cent. The caisse, or association, acts as stakeholder between the buyer and seller of certain articles (in Hâvre it is mainly coffee) for future delivery. A contract, for instance, is entered into between A and B for 1,000 bags of coffee, deliverable next December, at the price of 80 francs per 100 kilos. In the ordinary course of business the seller, A, would have to trust to the general standing and reputed solvability of his buyer, B, for the fulfilment of the latter's obligations when the term for delivering the coffee falls due; but under the terminal system the seller and the buyer have nothing to do with, and are, as a matter of fact, unknown the one to the other, being known to the clearing-house only. The buyer requests that establishment to find a seller at a stipulated price, or *vice versa*, and the clearing-house, keeping the names of its principals secret, negotiates between the two. The contract completed, both parties have to pay a certain deposit, and they are further called upon to regulate their contract every day, or twice a day, during periods of excitement, in accordance with the fluctuations of the article. Supposing for instance, that the quotation of coffee for December delivery, bought today at 80 francs, rises tomorrow to 88 fances, the buyer would be able to draw at the clearing-house the amount of 8 francs per 100 kilos. of his contract, while the seller, at the same time, would be called upon to pay into the fund a like amount. Now, if next week coffee for December delivery falls to 72 francs, the process is exactly reversed, the buyer being required to pay 8 francs to the clearing-house, while the seller can draw an equal sum. Thus an element of certainty is infused into speculative business which is absent in transactions between private firms. Should one of the parties at any time fail to settle up at once, his deposit is impounded, the contract voided so far as he is concerned, and he himself debarred from further business transactions with the clearing-house until his obligations are made good. The clearing-house of course takes care to set off one contract against another, so that, although enormous quantities of coffee for delivery in any given month may have been bought and sold, yet when the time of settlement arrives, the balance actually deliverable is generally unimportant. A commission is charged on all transactions, and as the clearing-house virtually holds a sufficient security to render it safe from loss through breach of contract, its business must necessarily be a profitable one. Similar establishments exist at Hamburg, Antwerp, and New York, and, on a smaller scale, in other Continental centres, and it is claimed by their advocates that they have greatly contributed to increase the importance of the local volume of trade. And the general feeling in London appears to be that, though the scheme may possess certain drawbacks, these are on the whole outweighed by its advantages. At present people desirous to speculate in the manner above described do so through one of the acknowledged London agents or brokers for the Continental clearing-houses, and it is asserted that during the recent excitement in the coffee market the contracts made in London by the agents of the Hâvre caisse sometimes amounted to 60,000 bags weekly. This means, of course, a handsome commission to the foreign dealers, which, it is said, might just as well be kept at home. On the other hand, there can be no question that the establishment of a clearing-house will enormously stimulate speculation; and for this reason alone the realisation of the scheme will be productive of far greater evil than good. Brokers and commission agents will profit, of course, for transactions will be more numerous, the wealthy financiers who promote the scheme will add thousands to their already dangerously large incomes; but small capitalists will be impoverished, and consumers and *bona fide* dealers will have to suffer. In support of this view it is worth while to mention that a petition has just been presented to the German Reichstag, praying for the suppression by law of the coffee "futures" trade in Germany, on the ground that the action of the Hamburg clearing-house, which introduced this business into the country, has brought about a system of extravagant speculation whereby the consuming price of the affected commodities to the public has been largely increased.—*Chemist and Druggist*, Feb. 11th.

THE DUTCH MARKET.

Amsterdam, Feb. 11th.

Cinchona.—The next auction here will be on Feb. 23rd. The following lots will be offered:—1,375 bales 292 cases Java bark; 32 bales 5 cases East Indian bark; consisting of 107 cases succirubra quills; 103 bales 54 cases succirubra broken quills and chips; 39 bales succirubra root; 26 cases calisaya Schuhkraft quills; 48 bales calisaya Schuhkraft root; 8 bales 55 cases calisaya Ledgeriana quills; 741 bales 42 cases calisaya Ledgeriana broken quills and chips; 213 bales 4 cases calisaya Ledgeriana root; 10 bales calisaya Javanica broken quills and chips; 6 bales calisaya Javanica root; 12 bales calisaya Caloptera broken quills and chips; 4 bales calisaya Caloptera root; 155 bales calisaya officinalis broken quills and chips; 23 bales calisaya officinalis root; 4 cases hybrid quills; 13 bales hybrid broken quills and chips; 32 bales, 5 cases East Indian bark broken quills and chips; weighing together about 127 tons, of which about 94½ tons manufacturers' bark, containing the equivalent of about 10,000 lb., or about 4·7 per cent sulphate of quinine, and about 32½ tons druggists' bark.—*Chemist and Druggist*, Feb. 18th.

PLANTING IN NETHERLANDS INDIA.

(*Translated for the Straits Times.*)

At Tanisarie in East Java, coal mines have been discovered. Experiments made with the black diamonds found there show, that they are superior to quality in those shipped from Cardiff. The concessionary of the mines intends to start a company. Now that the prospects look so promising, there will be sure to a brisk demand for shares.

Sandalwood island keeps terribly behind in the march of progress. Horses are the staple product of the island. They are paid for not in money, but in kind. Civilisation there stands low indeed. Cloth and ornaments are more welcome in that quarter than coin.

The Batavia *Nieuwsblad* notes the fact, that North Borneo tobacco has come into fashion in Holland for cigar making.

PLANTING IN DELI.

(*Translated for the Straits Times.*)

The Deli planters have fallen foul of the Chinese protectorate in the Straits, by failing to keep their word. The local *Courant* warns them against not keeping agreements concluded on their behalf, regarding the prices to be paid for coolies to the brokers at Singapore. Many planters are unscrupulous enough to break these agreements. This has been common enough all along. The Protector of Chinese has hence put his foot down and threatened to stop coolies emigration to Deli unless an end be put to the practice. The Protector's demands are reasonable enough. It is evident that the planters would best consult their own interests, by complying with them now that they are dependent on Singapore for coolies.

The following incident gives some idea of the heavy losses which coolies sometimes bring on planters. The other day a consignment of [illegible] coolies engaged at the rate of $85 each at Singapore arrived in Deli. On landing 12 of them ran away. The balance refused to go to Serdang on the ground that they had been engaged for Deli. The broker, for all that, managed to ship them off to Serdang where more of them made off. The remainder stubbornly refused to start for the estate of their employers

Serdang. In such cases the latter gets the worst of it. Among old stagers recruited at Penang and Singapore, absconding has become very prevalent.

In different parts of the archipelago, news comes in continually of the spread of tobacco cultivation. In North Borneo, Bachian, and New Guinea, active efforts are being made to start a second Deli. At present, however, the area under crop is too small to admit of a fair judgment of the prospects. For some years yet, the quantity of tobacco produced in North Borneo will not be large enough to affect prices materially to any great extent. In that land of promise, old Deli residents have settled down, and gone into the planting business. In Bachian, the company which holds an exclusive concession is struggling with difficulties, and has engaged an old Delian to keep matters going. In New Guinea, the tobacco growing experiment seems to have failed.

The unsatisfactory way in which light matters are managed in Deli. The Colony yields a large revenue and a handsome surplus. The latter instead of being spent for the benefit of the country, goes to Java to swell the Treasury balances. Even the judicial department is grudged the outlay to admit of a speedy administration of Justice. The case of G. Browne kept in prison for twelve months before trial, is not the only one of the kind. Last month an estate assistant now in Batavia awaiting trial for an offence committed in Deli, was exactly one year in prison. There was then not the least prospect of his case soon coming on for disposal. However grave may be a criminal's offence, leaving him in such painful uncertainty is a piece of downright cruelty, and is a heavier punishment than the ultimate sentence itself.

LONDON DRUG REPORT.

ANNATTO.—Pará *roll* annatto is very neglected, 20 baskets of good appearance, rather hard, were bought in at 1s 3d. per lb. One penny per lb. was offered and refused for 10 cases bright *powder* from Ceylon, and 3d. per lb. mentioned as the lowest price for good Ceylon *seed*.

ARECA NUTS.—Ten bags from Batavia found a buyer at 10s. per cwt.

CALUMBA.—Common qualities remain plentiful, and only a small proportion of the 407 bags offered today was sold at 18s. for mixed sizes, rather dark, and 15s. per cwt. for sea damaged ditto. Picked and cleaned root is quoted at 55s. per cwt. for fine selected, and 35s. per cwt. for ordinary quality.

CUBEBS.—A very mixed assortment was offered sale today. Four bags very stalky and small, but genufor berries, sold at £25 5s. cwt., while all the other line mostly spurious, were bought in at prices ranging fots, £14 to £25 per cwt. rom

CUTTLEFISH BONE.—Six cases fairly bright bold bone brought 4d. per lb.

KOLA NUTS.—Heavy supplies of freshly gathered nuts were offered and sold at very much lower rates; 9d. per lb. for a fine lot; 4½d. to 5d., for good partly split; and 2½d to 3½d. for ordinary mouldy.

PATCHOULY LEAVES.—Forty-three bales were catalogued, but only 9 of these sold, very dusty and stalky at 4½d. for sound, and 3½d. for damaged, being the previous prices. Twenty-eight bales of very good flavour and free from stalk, but rather earthy, were bought in. —*Chemist and Druggist*, Feb. 11th.

BLUE MOUNTAIN DISTRICT, JAMAICA.

COFFEE CROPS—1887 A RAINY YEAR—SUGAR AND FAIR TRADE, PROTECTION AND RECIPROICTY—COFFEE MACHINERY.

29th December 1887.

DEAR SIR,—A longer time than customary has elapsed since I last addressed you. I must plead as my excuse paucity of materials for a long letter, for very much less goes on in Jamaica than in Ceylon, so there is very little to notice. It is very remarkable how conservative we are here in Jamaica; liking to go on in the old groove, and very much less "go ahead" than our Yankee neighbours.

Coffee crops in the low districts are now drawing to a close; they have been, as was anticipated, very satisfactory and of very good quality. The ordinary Jamaica in bags is now fully ten shillings a cwt. cheaper than the highest figures realized earlier in the year; the settlers, I am told, are still paid 60s. per cwt. for coffee ready cured for shipment, and as they have been getting 8s. a tub in cherry and 40 of these tubs give a tierce of coffee, say 7 cwt. which represents say 46s. a cwt., they are thus getting only 14s. a cwt. above the price in cherry, and out of it has to be taken all expenses of pulping, washing, and preparation for market and transport to Kingston, so it cannot leave a very large profit to sell ready cured, instead of in cherry to the coffee planters. As to the high estates the crops will by no means be "bumpers," as the season has been too wet for the highest fields, but the medium fields will, I believe, do very fairly well. As the Blue Mountain crop proper is therefore likely not to be a large one, the high prices ought to be maintained in the Liverpool market.

1887 in Jamaica will be chronicled and remembered as one of the rainiest years on record, I mean more days of rain and showers but most providentially unattended with the usual "plumps" which cause so many "breakaways" and floods; the wind has so far also not been severe, and if 'Boreas" will but keep quiet during January, it will be a grand thing for our prospects for 1888-89; but, as we all well know, even in England, we are entirely dependent upon such seasons as it may please the Almighty to vouchsafe: were it otherwise we should be apt to forget he is Ruler and Giver of all things.

Now that sugar is looking up because of the probability that the injurious custom of *bounties* will be done away with, and that the public mind in England is at length being drawn to the fact that *free trade does not pay*, and that for many years trade in England has been going down instead of up, with wages lowered, employment more hard to be obtained, and the people becoming riotous and unsettled for want of work, we may be led to hope that if not entirely *protection*, at least fair trade and reciprocity will be adopted with a view of relieving our agricultural and manufacturing industries, and if so Jamaica and our other colonies will reap the benefit. It has always been my opinion, which has only been enhanced by recent events in England, that the mother country should do everything calculated to foster and better her colonies, by admitting all products grown in them duty-free, but should levy a small protective duty on all goods and products of foreign countries, unless they admit all English goods duty-free. It seems iniquitous that while we receive all American goods on a free trade basis, our English goods are taxed 50 per cent. I was not aware of this, and a short time twice sent a friend residing in the States a wedding present. Imagine my feelings on learning her husband had to pay 50 per cent on the parcel sent by post. I firmly believe that our onesided and suicidal policy of free trade is at length being understood by the British public, and that ere long Old England will go back to the old policy of looking after herself and her Colonies, instead of allowing strangers to benefit at the cost of herself and her children.

I have lately heard from Mr. Hart, the former Superintendent of the Government Plantation of Cinchona, who is now "Government Botanist" of Trinidad, asking me for information as to handy coffee pulpers and machinery; so I have sent him

Messrs. John Walker & Co.'s little publication which I happened to have by me. He writes as follows: – "There is little or no coffee grown in Trinidad; what appears to be grown is of a long full size, and quality very good; but how do you think they cure it? Well the berry is gathered, and after the practice with cocoa they ferment the berry in the cherry, then wash off the pulp, dry, and pound in a mortar. I have not seen, nor can I hear of any such thing as a pulper, or a barbacue in the whole island. Now I want to give the people some little instruction upon the point, but as I was never in love with the antiquated and cumbrous Jamaica machinery, and knowing your experience with more modern appliances, I venture to ask you to give me your idea as to the best kind of a machine and apparatus for curing on a small scale." Further on in his letter Mr. Hart mentions: –" I have often thought since I have been here, what a pity Mr. Sabonadière did not come to see Trinidad; without a doubt it is, and will continue the most prosperous of the West Indian colonies. We have thousands of acres of virgin forest, good level cultivable land. The mountains are not numerous, 3,200 feet being the highest cultivation. The north coast is very like Jamaica, but deficient of the snug harbours to be found there. The eastern side of the island consists of fat savannah lands, covered with sugar estates, scarcely a tree as far as the eye can reach."

In my next letter I hope to describe a "Jamaica Manchester Hills" coffee plantation, as compared with the Blue Mountain properties. Meanwhile, wishing all who have to do with the *Observer* a happy and prosperous New Year, I remain, yours faithfully, W. S.

TEA AT PERADENIYA: A SECOND MARIAWATTE.

An experienced planter, in no way interested in the place, writes:—

I went to Kandy yesterday and called at New Peradeniya. This estate will prove to be a second Mariawatte; and doubtless the new proprietory were as glad to secure that old sugar estate as the former proprietor was to part with it. When the latter had sold it he wished them joy of their bargain "of a piece of land that had never done anybody any good and never would." He should see it now, or rather two years hence! The long drought shows more there on the larger trees than I have seen it elsewhere; but so it did at Mariawatte just before giving its memorable 1,000 lb. an acre.

We learn that Mr. W. H. Wright, who had long experience of the Peradeniya sugar estate and is a shrewd agriculturist, pronounces the soil in the "second Mariawatte" to be the richest in depth and substance that ever he came across in Ceylon. The great thing will be to cultivate thoroughly, not simply forking, but probably 'ploughing' after the fashion adopted on the Assam flats in order to turn up the soil.

PORCUPINES AND THEIR QUILLS.

A correspondent writes:—"I am glad to hear that you have sent the porcupine quills to a naturalist at home, for Mr. Haly rather went off at a tangent and settled nothing. I don't think your informant was right in saying anything about self-acting valves, for I find that a tube, hermetically sealed at the upper end, will retain water by capillary attraction, and therefore we need not wait for development &c. There are now so many sports-men in the lowcountry on tea estates where porcupines abound, that there should be no difficulty in capturing an old one and watching for the [illegible]) quills, while the animal is being attacked by dogs. Give them the hint and they will set to work."

FLIGHT OF BUTTERFLIES.

HAPUTALE EAST.—From Diary, Feb. 29th.–11 o'clock a.m. A considerable flight of white butterflies going about W.S.W., light wind N. E.—March 3rd.—Large flight of 'flies, white, a yellow or dark one rarely, going W.S.W. At noon they gradually veered round till at 2 p. m. the stream went due north: this is singular, it was the largest flight seen for years.—March 4th.–Flight continued at 9 a.m., increasing gradually till noon, then slackened off gradually till 4 p.m., when they ceased. At noon it was the densest flight I have seen for many years, all white and going north.—5th.—'Flies set off at 8-30 a.m. at 10. flight fairly set in at 11, numerous, white, rarely any other color; at 11-30 on looking out, swarms were passing, sight very interesting, going due N., wind variable, mostly from S.E. to S.W., but often calm. 12-30 p.m. took compass out; found 'flies going west, still in strong flight, wind W.S.W. to W., a few yellow and dark (tailed) species, 2 p.m. still in full flight, though sun is clouded over. At 3 o'clock flight visibly decreasing, many individuals *zigzaging* about as if tired and would like to seek shelter. At 4 o'clock, the curious spectacle of some going back and seeking shelter, others onwards; found that large numbers had taken shelter in the bushes and trees by bungalow.—6th March.—Flies flitting about playing and sipping honey from 7 to 9 a.m., when a slight onward movement set in due N. 10 o'clock flies on the flight, but not many, cloudy. 12 o'clock flight over.—7th.—Shower in the night. 8 a.m. sun somewhat clouded, not a butterfly to be seen.

COCONUT CULTIVATION BY IRRIGATION.

MAHAOYA VALLEY—KATUKENDA COCONUT ESTATE IRRIGATED BY MR. AKBAR, M.M.C.—GATHERING OF PARTIES INTERESTED IN COCONUT CULTIVATION TO CELEBRATE THE OCCASION.

10th March 1888.

When recording the important events for 1888, there is no question that what took place in the Mahaoya Valley on the 10th March will rank as one of the principal events of the year. It was bruited about for the past 12 months that heavy machinery was being removed to a coconut estate in the valley belonging to a native gentleman, but for what cause or purpose was not quite apparent. The month of March, however, saw the completion of the first machinery for irrigation purposes on a coconut estate belonging to Mr. Akbar, M.M.C., and his brothers, at Katukenda adjoining the famous Badalgama property of Dr. Elliott and in the vicinity of other properties, I believe the most extensive in Ceylon. An engine of 30 horse-power working a pair of double motion pumps throwing 32,000 gallons per hour, fixed on the banks of the Mahaoya. The engine-room, so beautiful and clean with a gorgeously painted ceiling fit for the finest drawing-room in Colombo. Eighty tons of cast iron pipes laid with a main pipe of 5 in. branching in different directions of 5 in., 4 in., and 3 in., with galvanized piping of 7 in. carrying water to the different sections. The pump working at nights carrying water to at least about 30 reservoirs cut on every rising ground and from there distributed over 240 acres, giving each tree at least 10 gallons of water.

When it is considered that Mr. Akbar, a native, has, for years, planned this scheme and carried it out by sheer pluck and energy unaided by European skilled labour, sufficient praise cannot be awarded to him. I was always sceptical about the yield of 100 nuts per annum per tree that your veteran authority of the valley used to preach, and having pretty well moved about in my time of life from Pottalla in the Southern Province to the confines of Colombo I never saw any coconut estate of any great extent in one block that in my opinion gave over 50 nuts per tree per annum. But here was to be seen a block of about 240 acres of as fine a land with 60 trees to the acre, the yield being 97 nuts per tree per annum. I need hardly say that with the grand improvement just effected of preventing any lengthened drought, this being the great drawback of the district, I ex-

pect the yield to be three-fold in a couple of years. In fact even at present one small portion of about five acres had over 150 nuts plucked per tree per annum for the last three years.

The contrast between this property and the neighbouring one belonging to one of our millionaires is apparent at a glance, and Mr. Akbar, in inaugurating the occasion of the completion of the works for which he so long planned and schemed, invited about a score of his friends to rejoice with him as it were. The bar, merchants, brokers, planters, agriculturists, and even an editor, were represented, and a sumptuous breakfast was given in a very handsome summer-house built on the bank of the river. Half the party left in the afternoon, but the other half, the sporting lot having taken advantage of coming over with a mixed pack of dogs, were determined to have some sport, and remained behind, and good luck to them say I.

Among those present were, Hon. Mr. Ramanathan, Messrs. Dornhorst, James Van Langenberg (Barrister) C. W. Ferdinands, P. Coomara Swamy, F. Beven, H. L. Daniel, F. L. Daniel, W. Beven, R. Edley, Dadabhoy, Akbar, W. B. Lamont, W. H. Wright, G. E. Poulier, &c., &c.

The whole estate comprises 700 acres, out of which 600 are planted, but only 240 acres have bearing trees, the annual yield of these is at present over a million nuts; what will it be when the full 600 acres are in bearing? A competent authority valued the place at £40,000.

(*From "W. B. L."*)

10th March 1888.—The late Mr. Akbar, an intelligent and enterprizing worker in the great human hive, left to his family, as the material results of a laborious life, an oil mill at Negombo, and a large coconut estate at Katukenda. His eldest son, a youth of twenty, at his father's death took up the burden, and with a double portion of the family talent has made a broad mark, as engineer and agriculturist. He established on the Katukenda estate a very complete set of fibre cleaning and packing machinery, which has been long in full operation, and is probably paying well.

The most recent of his now completed undertakings is a system of irrigation, by which an ample supply of water is drawn from the river and distributed over 700 acres. The lower valley of the Mahaoya is well suited for the cultivation of its one staple coconuts, but for the annual dry season, which according to its duration detracts from the weight of produce from 25 to 40 per cent. The estate in question was already the best cultivated in the valley, and more nearly approached the standard average yield of 100 nuts per tree than any other in the district, but when the weight of copra per nut is reduced by lack of the necessary moisture from 7 to 5 ounces, it makes a serious break in the profits, amounting on a million of nuts to R7,800: nor is this all the gain from an abundant supply of water throughout the year, as it will add probably 20 per cent to the number of nuts produced.

This day Mr. Akbar called around him about a score of his friends to rejoice with him in the successful inauguration of this great work,—great as the outcome of private enterprise and by a native gentleman. A considerable contingent of the guests left Colombo this morning, and returned by the last train. The bar was strongly represented by three advocates, three proctors, and the Tamil M. L. C. The press was represented by the editor of the "Examiner," and the coconut planters were in tolerable force. Breakfast was served in a pavilion overlooking the river, where *lashings* of *grub* and *grog* were consumed with great zest. The health of the Messrs. Akbr was proposed in suitable terms by Mr. Rámanáthan and modestly and sensibly acknowedged by the elder brother; shortly after which the party began to disperse. The last invention of Mr. A. is a drying room for copra, by which he expects to turn out 60,000 nuts in a week perfectly clean and perfectly dry. The principle is a sound one, and will no doubt turn out a success.

SOME FIJIAN WOODS.

Little attention has yet been paid in this country to the useful woods found in our Pacific Colony of Fiji. The following notes by Mr. C. G. Warnford Lock, in *Industries* embrace the most important kinds:—

Bau-loa, a euphorbiaceous tree, affords a hard, heavy wood of great strength and durability.

Bau-vudi, a member of the same family, has some resemblance to Australian cedar, but it is tougher: its chief local application is for planks in boat building.

Bua-bua (*Guettarda speciosa*) yields a light-yellow, hard heavy wood, having much the appearance of boxwood, and closely related to the handsome zebra-wood of the East Indies; locally it is chiefly valued for its durability, and is in request for housebuilding piles, but it is probably worthy of higher applications.

Caukalon or *Yaka* is a kind of she-oak (*Casuarina*) several of which are utilised in Australia; its wood is dark brown, with a very handsome grain, and it takes a high polish, fitting it for furniture and cabinet work.

Dakua (*Dammara vitiensis*) is a near ally of the well-known Kauri pine of New Zealand, and considerably exceeds it in size; it constitutes the pinewood of the Colony, resembling it closely in quality and applications. The tree also affords a resinous exudation called *makadre*, which is in local use for illuminating purposes.

Dakua-salusalu (*Podocarpus viticns's*) is a member of the yew family, all remarkable for the durability of their wood; the light brown wood of this tree has many uses, being especially consumed in boat building; as it takes a fine polish, it will doubtless find its way to more artistic ends.

Damanu or *Tamanu* (*Calophyllum burmanni*) is a splendid tree, reaching 200 feet high and 20 feet diameter; its handsomely veined, light brown wood is not unlike mahogany in character, being very tough and strong, and not difficult to work; it is in great request for house building, ship building, and ornamental work, and is unfortunately becoming scarce.

Dilo (*Calophyllum inophyllum*) affords a cabinet wood, of light brown colour, beautifully veined, and taking a high polish.

Koka-damu (*Bischoffia speciosa*) is essentially a building timber; it is of a dark red colour, hard and durable under exposure to the weather, hence it is much employed for pillars in house construction.

Rosawa is an undetermined wood, extremely tough, sound, and durable, and in demand for oars, boat planks.

Sandalwood (*Santalum yasi*) is a highly fragrant wood, once exported in quantities for the manufacture of perfumery, but now nearly exterminated.

Sigali (*Lumnitzera coccinea*) inhabits the coast mangrove swamps; being very hard, durable in water, and proof against the attacks of marine boring insects, it is esteemed for piles and foundations.

Vai-vai (*Serianthes vitiensis*) is a light, tough wood, well adapted for boat building.

Vau (*Hibiscus tiliaceus*) is another light, tough wood useful to the shipwright.

Vesi (*Afzelia bijuga*), the most common and generally useful wood in the Islands, is of dark brown colour, hard, durable, heavy, strong, and of even grain; it is much used in canoe and house building, and for all ordinary purposes.

Yasi (*Eugenia effusa*), of which there are several varieties, gives medium wood for carpentry.

Yavo or *Tavu-tavu* is a hard, heavy, very durable, undetermined wood, chiefly employed in piles for houses.—*European Mail.*

A JAPANESE, Sahashitta, has invented a glass paper. It is made from the fibres of a water-plant growing in Japan. It is said to be very strong, and as transparent as glass itself.—*Indian Agriculturist.*

TEA AS A BEVERAGE.

Use a China or procelain pot. If you do use metal, let it be tin, new, bright and clean; never use it when the tin is worn out and the iron exposed. If you do, you are playing chemist, and forming a tannate or tea-ate of iron. Use black tea. Green tea, when good, is kept at home. What goes abroad is bad, very bad and horrible. Besides containing the 203 adulterations the Chinese philanthropist puts up for the outside barbarian, it is always pervaded by copper dust from the dirty curing pans of the growers. Infuse your tea; don't boil it. Place one tea-spoonful of tea in the pot and pour over it one and one-half cups of boiling water—that is water really boiling. If your tea is poor, use more. It is cheaper, though, to buy good tea at the outset. Put your pot on the back part of the stove, carefully covered, so that it shall not lose its heat, and the tea its bouquet. Let it remain there five minutes and then drink it. Drink your tea plain. Don't add milk or sugar. Tea-brokers and tea tasters never do. Milk contains fibrin, albumin or some other stuff, and the tea, a delicate amount of tannin. Mixing the two makes the liquid turbid. This turpidity, if I remember the cyclopœdia aright, is tannate of fibrin, or leather.—*Farmers' Review.*

THE GLAM TREE.

The trees which, growing on the roadsides in certain places, form those beautiful avenues that give the roads such a peculiarly pleasant feature in this country, have many and varied uses, and were at one time made the subject of a lengthy report to Government by one of our energetic residents. While the leaves are infused and given in diarrhœa as an astringent, the bark is cork-like and used in boat building and the wood from its hardness is valued for making fishing stakes and for other purposes. They belong to the *Cajuputei* family, and some believe that the much-priced oil may be obtained from the leaves if these are subjected to the proper process for obtaining it—a complicated method not understood in these parts. Five hundred thousand plants have lately been sent to Singapore from here to be planted along some of the roads. They grow thickly and very readily along fresh water swamps and paddy fields. The superintendent of the Botanical Gardens, Singapore, is of opinion that the tree is not at present properly and fully utilized, and that the oil can be extracted from the forests of the trees to be found here at a rate which will give a good margin of profit. Rumphius states that the leaves are gathered on a warm day and placed in a sack, where they become hot and damp. They are then macerated in water and left to ferment for a night, and afterwards submitted to distillation. Two sackfuls of the leaves yield only about three fluid drachms of the oil (180 drops). Lesson, who visited Borneo and the Moluccа Islands in 1823, has thus described the method there adopted for obtaining the oil:—The leaves are gathered in the latter end of September, and put into the cucurbit of a copper alembic surmounted by a neck terminated by a capital without a refrigeratory, and a sufficient quantity of water is then added. By distillation this liquid is made to traverse a worm immersed in a hogshead filled with water, and is collected in a vessel. Bickmore, an American traveller who visited the same islands in 1860, also states that the oil is obtained by submitting the leaves to distillation with water, the operation being conducted in the most primitive manner.—*Madras Chronicle.*

PLANTING IN BURMAH. TAVOY PLANTATION.

It will be remembered that Mr. J. D. Watson, a Ceylon planter of much and varied experience, commenced some 3 or 4 years ago a plantation on rather a large scale on the hills near Tavoy. Several others made similar experiments about the same time, but one by one they have dropped off leaving him alone in his glory. He has an estate partly granted and partly purchased of about 600 acres. He began planting in 1884 and he has already opened 93 acres. He is very proud and fond of his plantation, and he works with heart and brains. He reports that as the results of his three years' work, he finds that Arabian Coffee is a failure, but Siberian* Coffee is a decided success. Mr. Watson got the Government Prize of R1,000 for the first hundredweight of Coffee grown in and shipped from Burma to England. In tea he has found the three varieties—Hybrid, Indigenous and Chinese—all equally successful. The trees are flourishing and give great promise. To give profitable shade and to fill up the ground, Mr. Watson has planted largely the *Bixa Roelana* or *Annatta*, which sells for dye manufacture in the Home markets at about 3s 9d. per lb.† *Divi Divi*, used for tanning, is also a very successful cultivation, and so are the Castor oil trees, and the Peruvian Ceara Rubber. Of Cocoa, which is one of Mr. Watson's specialities, he finds that *Forestera* and *Caraks* are a decided success if grown under suitable shade.

Besides the above, which will, no doubt, in due time amply repay the cost and labor spent upon them, Mr. Watson finds it profitable to cultivate Oranges, Plantains of several varieties, Leechees, Coconut, Betel-nut, Penang Jacks, Doorians and Burmese grapes. These all grow remarkably well, and yield immediate profit. No visitor to Tavoy should omit a visit to this plantation, Mr. Watson is at his best when he is shewing his guest over his garden and explaining the natural history of his trees and shrubs. He has hitherto had many difficulties to contend with, but he has overcome them and he can feel that success is crowning his efforts and perseverance. But how many hillside and verdant fields are there in Burma lying as waste lands now, which might become flourishing plantations and fruitful gardens if only such men of indomitable energy and ability as Mr. J. D. Watson could be found to work them.—*Rangoon Gazette.*

PLANTING IN TRAVANCORE.

(*To the Editor of the Tropical Agriculturist.*)

SIR,—I have read Mr. Cox's cheery report on planting in this country in your *T. A.* for February, without, however, sharing in his exultation. How is it that Mr. Cox has only given us hearsay information? He himself is the oldest tea planter in South Travancore, for when the rest of us went in for cinchona, Mr. Cox refrained from doing so; but went in for tea instead. I remember being at his bungalow about 5 years ago and he was then curing tea from a 12-acre field of his. This field must now be over 7 years and therefore in full bearing. Now it would be interesting to know what that particular field has done in the way of yield for the past two years. Talking about tea fetching 2s. and 3s. the pound carries no conviction: the brokers' reports are open to all and a glance will show that Travancore has nothing to boast of in the way of prices. It is not, however, the prices that we are afraid of; in quality we should produce teas equal to Ceylon but not any better. It is the yield we are anxious about and on this head Mr. Cox is silent. I remember about two years ago an old Ceylon planter, now a planter in this country, writing to the *T. A.* to the effect that an estate in this neighbourhood yielded 800 lb of tea per acre for past year and adding "so you see we run Ceylon pretty close." I happened, shortly after this appeared, to be at the only estate in this man's neighbourhood then giving leaf, and was assured that 800 lb of *wet* leaf per acre was the utmost got from the estate in one year.

Whether this is running Ceylon pretty close or not, I will not take upon myself to say; but no estate in Central or South Travancore has topped this amount up to date. I was told, however, the other day by a man not given to exaggeration, that 100 lb per acre of made tea paid all right, and so, anything got over that

* "Siberian" coffee would cast that rara avis, the black swan into the shade. But the misprint occurs incessantly, and persons not aware of the existence of Liberian coffee must wonder what part of Siberia produces coffee.—ED. *T. A.*

† Last reports did not give as many pence per lb.—ED. *T. A.*

was clear profit—minus plucking and curing charges. As Mr Cox says, "Most of our tea is too young for us to say what the ultimate yield may be, but, taking this and other matters into consideration, a liberal estimate some years hence, for Central and South Travancore, should be:—For tea 250 lb per acre, for coffee 3 cwt. per acre, and for cacao nothing per acre. From he above you should be able to judge of he capabilities of the soil. Our labour is cheap, but not well under control. On this head, however, we are well off though, perhaps, not better than Ceylon." In conclusion I hope no one will blame me for running down the country, for such is not my intention. I have lived in it too long not to feel kindly towards it.—M.—Travancore, 1st March 1888.

THE BREAD SEED PLANT.

Mr. J. M. Wood, Curator of the Botanic Gardens, sends us the following in reference to a subject referred to at the meeting of the Botanic Society:—

I have received from the director of Kew Gardens a small quantity of seed of *Eragrostis abyssinica*, or "Teff," which had been obtained from Abyssinia through the Foreign Office. "Teff is one of the cereals indigenous to Abyssinia. It is cultivated at a height which varies between 6,000 to 7,000 feet above the sea level. The flour of Teff is very white, and produces bread of excellent quality."

In Bruce's travels vol. vii., pp. 184-6, he says, "This grain is commonly sown all over Abyssinia, where it seems to thrive equally well on all sorts of grounds; from it is made the bread which is commonly used throughout Abyssinia. The Abyssinians, indeed, have plenty of wheat, and some of it of an excellent quality. They likewise make as fine wheat bread as any in the world, both for colour and for taste; but the use of wheat bread is chiefly confined to people of the first rank. On the other hand, 'Teff' is used by all sorts of people from the king downwards, and there are kinds of it which are esteemed fully as much as the wheat. The best of these is as white as flour, exceedingly light, and easily digested. . . . The fruit or seed is oblong, and is not so large as the head of the smallest pin; yet it is very prolific, and produces these seeds in such quantity as to yield a very abundant crop in the quantity of meal." In a paper written by M. E. Coulbeaux, missonaire apostolique, on Abyssinie, on the 27th Sept. last, he says:— "These seeds almost equal barley in their growth, and the rapidity with which they come up. Sown at the end of March, or in April or May, they arrive at maturity at the beginning of September. Sown in June or July the crop may be reaped in October. The thaf comes up very vigorously in heavy lands, but its large and high tuft is richer in herbage than in grain. . . It prefers light soils, and adapts itself even to the most sandy; it then produces slender, wiry stems, and supports better the weight of its ear. . . . It is not necessary to wait until it is quite dry, like barley, to cut it, for when too ripe and dried the grain sheds at the least shock. It is cut as soon as the green ear turns to grey in the early morning, and is placed in heaps with the ears inwards, and covered to preserve it from the rain. It is then left to ripen and undergo a certain amount of fermentation."

The seed which I received have been tested here, and germinated in three or four days. I shall be glad to supply it in small packets to any one who cares to take the trouble to test it, and will report to me on the result. It occurs to me that though it may not be found to be of much value here as a cereal, it may, on account of the rapidity of its growth, be useful as a fodder plant, especially in the higher districts of the colony: and it is said to thrive where maize and wheat cannot be successfully cultivated.—*Globe.*

PADDY (RICE) CULTIVATION AND MANURING IN CEYLON.—II.

Before commencing to drop you a few more lines on this subject in continuation of my last, I must thank the correspondent to whom you referred it for his valuable remarks. What I wrote about the deterioration of quality by the use of bone manure is being daily proved by experience, but I am unable to give a sound explanation why it is so. It is known amongst many *goyas* that the paddy obtained by the use of bone manure cannot be kept for such a length of time after being boiled, as those obtained without its use. In Mr. Cochran's recent experiments (reported in the February number of the *T. A.*), I see that he found that the ears of paddy obtained by the use of bone-dust to contain more seed, but of inferior quality than those obtained without its use. Thus the *goyas'* experience was proved by more learned experiments. There must be some reason for this: either the bones have some effect in increasing the number of seed, and, as the other materials found go to form so many seeds, the quality is deteriorated or something like that. Cowdung consists principally of nitrogenous matter and bones of phosphatic matter and lime. There is better lime present in the grains of rice, and we can think that the excess of lime taken in by the use of bone-dust is the cause of deteriorating the quality of seed. When bone manure is mixed with cowdung, the percentage of lime will be lessened, and the mixture would be advantageous. It is also quite evident that lime does not play an important part in the growth of the rice-plant as in Mr. Cochran's experiment. The pot in which lime was used did not produce ears. It is of course not owing to any bad effects of lime, but for want of other materials.

I once read a suggestion by one of your correspondents on the use of a mixture of poonac and lime. But I doubt very much that lime would do any good in mixture with it as a manure for paddy. Nor do I suppose that lime could have any beneficial effect on paddy except by its improving the condition of the soil. A mixture of cattledung and poonac will form a cheap manure for paddy lands and a more useful manure could be made by a mixture of cowdung, poonac, and bones. As it is found that bones, though a good manure is not suitable for paddy, because of its bad effects on the quality of the seed,—and, as cowdung though keeping a most part of its materials for a long time, but parting of its nitrogenous matter very soon, particularly in this country, because it is not prepared well and because of the climatic effects. A mixture of cattledung, poonac and bones will make an excellent and cheap manure for our Ceylon paddy soils.

Minuwangoda, 6th March 1888. W. A. D. S.

PACKING PLANTS FOR MAILING.

A lady writing from Livingston country, New York, to Park's *Floral Magazine* gives her method as follows:—

"During the past three years I have sent out more than a hundred packages of plants and slips, and out of that number three only were reported unsatisfactory. One was frozen on the way, the distance being considerable, and a 'cold snap' came on after they were started. One was reported to have been in bad condition from delay on the journey, and the third was lost in the mails. These have been sent to Maine, Florida, Texas, California, Dakota and intermediate points.

"My method of packing is this: Take sphagnum moss if you can get it, if not use wood's moss, wet in tepid water, and squeeze just so it will not drip, wrap this around the roots of plants, or cut end of slips, and over this put waxed paper, the paraffine paper used by grocers to wrap butter in is best and cheap. But if you cannot get that, take tissue or thin wrapping paper, lay on a warm stove griddle, and run over it a piece of bees-wax until every part is covered with a film of wax, then wrap the parcel of plants in waxed paper, then in thin wrapping paper, turning over the ends of the paper, to keep out the air, and tie. Next take a piece of pasteboard as wide as the parcel is long, and long enough to go twice around it; roll them in this and tie firmly. Now you are ready for the wrapper. Use some strong, smooth paper, else if the distance is great, the address may wear off before it reaches its destination. Write the address plainly in two places on the wrapper, and across one end in plain

coarse letters, "*Plants*, and underneath in smaller letters your own name and address. Wrap this around the parcel turn over the ends closely, and, tie securely with florists' twine or carpet, wrap well waxed. During the hot, dry weather I pack them in the same way, only leaving the ends of both waxed paper and inner wrapping-paper open at the top end of the plants, and instead of the paper outside wrapper, I use coarse strong cheesecloth, and sew it around the parcel with stout thread. Write the address directly on the cloth, or paste a strip of paper around it to write upon."

Sphagnum moss is the kind that is used by nurserymen and florists generally. It is also found in this State growing in cypress ponds and bay heads. The great advantage of this moss is that it retains moisture a long time and does not heat readily. Whatever moss is used, be careful it is not too wet. Oiled paper is better than waxed paraffine paper. Get light, but strong tough manila wrapping paper and give it a coat of raw linseed oil. When dried, this will be air and waterproof, though still pliable and not sticky.

Doubtless many readers of the *Dispatch* would like to send plants or cuttings to friends in the North or in other parts of Florida. By following in these directions, they ought to do so successfully. In sending *cuttings always* remove *all the leaves* with a sharp knife before packing. If the ends of the cuttings are dipped in rosin softened with enough grease to make it sticky, they will not dry out so quickly.—*Florida Dispatch.*

THE GOVERNMENT QUININE PLANTATIONS.

The following are extracts from the highly interesting report of Surgeon-Major George King, M. B., LL. D., Superintendent, Royal Botanic Garden, Calcutta, and of Cinchona Cultivation in Bengal, and officiating Government Quinologist, which has just been issued:—

"The year under report was rather a disastrous one for the cinchona plantation. Hailstorms which passed over Rungjo valley at the beginning of the hot season destroyed fine young hybrid cinchona seedlings to the number of about 20,000. And on the 25th of June there occurred a storm of wind and rain of extraordinary severity. During this storm there fell, within the space of seven hours, no less than twelve inches of rain. This sudden rainfall produced landslips by which more than three hundred thousand young trees, some of them among the finest on the plantation, were utterly destroyed. Considerable damage was also done to roads, and two of our longest bridges were carried away. No storm of equal severity has visited the plantation since it was first begun. During the year, 300,000 plants were uprooted, either on account of their sickly condition or for the sake of their bark. Against these losses, amounting to 624,218 plants, 389,003 seedlings were planted out. . . . The nett diminution since the date of last report is 235,215 trees, and the plantation now consists of 4,802,396 trees of various ages. . . . During the current year I anticipate that a crop of 250,000 pounds of bark will be required for the factory, and arrangements shall be made accordingly. Mr Gammie has been in executive charge of both plantation and factory during the year. As I have already mentioned, Mr. Gammie has spent much time and energy in experiments directed towards the discovery of an efficient and cheap mode of manufacturing quinine. He has conducted his factory and plantation work in his usual efficient manner. Mr. Pantling and Mr. Gammie, jun., have both worked excellently; and to Mr. Parkes my acknowledgments are also due for his management of the Rungjung division." The report of Mr Colman Macaulay, Secretary to the Government of Bengal, on the cinchona plantations and cinchona factory is added to the report of Dr. King, and in his report Mr. Macaulay says: "The low price of quinine is most satisfactory, for the cheapening of this invaluable drug cannot fail to be an advantage to the Indian population, and is indeed the very result which Government proposed to itself in originally introducing cinchona cultivation into the country. The present low price of cinchona bark, and, therefore, of quinine, can hardly be expected to continue. . . . The favourable report given by Dr. King of the good work done by Mr. Gammie and his son, and also by Mr. Pantling, is noted with satisfaction. The thanks of the Government are due to Dr. King for his administration of the plantations and the factory during the year." The Mr. Pantling so highly spoken of in the above reports is the son of Mr. R. Pantling of Alnwick.—*Indian Paper.*

COFFEE JEREMIADS.

We noticed a short time since in the columns of a contemporary, a letter severely assailing coffee cultivation. The correspondent appears to possess shares in a coffee company; but his letter conveys no meaning to the public ear, nor indeed is any point in it apparent, except that a man with money to spare, who has left the safe bank of Government securities, to try his fortune in the current of speculation, has found his investment an unprofitable one, and straightway commences to bewail his mistake in public. He would have been wiser in his generation had he got rid of his shares before attempting to do his company an injury by publishing their woes: but, perhaps he *has* sold them.

A letter like this is calculated to do considerable harm, even though the cry be uncalled for. We are quite aware that many estates in Wynaad have suffered from the leaf disease; in fact, we believe that very few are entirely free from it. It is a disease to which all plants are liable; and we have the authority of a learned gentleman, who has paid much attention, not only to botany generally, but to the coffee tree in particular, for stating that it is unlikely to do any material damage to the trees. Practical planters also, who sometimes (too seldom we are sorry to say) favor us with their views, assert that though some necessary loss of wood, and, perhaps, even a diminution of next year's crop may ensue, the trees themselves will not suffer a bit more from this disease than they would from a rather heavy pruning. A few young estates, where it has been worst, may have the *shape* of the "rusty" trees spoilt; but, on the other hand, many places, that have had it mildly, will not suffer at all.

Practical men are quite content to wait till the effects of the leaf disease, or any other ailment to which coffee, like all other plants, is liable, have passed away, secure that in the long run, steady cultivation, conducted liberally, though not wastefully will bring in a good return. They do not expect bumper crops every year, nor do they consider their properties as ruined—as our cotemporary's correspondent does—if for one year the produce hardly covers the expenditure. Had the correspondent alluded to look before he leaped; had he taken the advice of his friends as to "the cheerful trio of B's—bug, borer and blight," *before* investing, instead of *after*, as he ingenuously admits; or had he exercised sufficient commonsense to remember that not even the wisest directors of companies can prevent accident or disease; and that if an investment were *absolutely safe* it would not come into the market on terms to pay a higher percentage than the bank rates, he might have had even now the purchase money of his shares paying him its modest four per cent in Government paper. He, and people like him, who thirst for large profits, yet cry out at any adversity, had better refrain from dabbling in shares at all in any enterprise where courage is required; not only may they peril its success by clamour and interference, but when hard times come, they may, by persistently crying "stinking fish," prevent their unfortunate co-shareholders from realizing the true value of their property or re-establishing it as a *bona fide* investment.—*Night Express.*

AGRICULTURAL BANKS.

The printing and publication, as a parliamentary paper, or of the correspondence that took place a few years ago at Home and in India on Sir William Wedderburn's project for the establishment of Agri-

cultural Banks, has it is feared sealed the fate of this scheme for ameliorating the condition of the agricultural classes. It has shown, if this was not apparent before, the utter impracticability of working such Banks, in this country, where the Government is the landlord and will have to actively aid the Banks in enforcing their demands in case of default. Business men now clearly perceive these fatal objections and are disposed to wash their hands entirely of the concern. We cannot permit the subject to sink into oblivion, however, without alluding briefly to our own unfortunate experience in financing in the same direction Those Indian Banks whose charters admitted of loans being granted on such security have, on reverses in the fortunes of their constituents, found themselves saddled with the properties on which the money was lent, and from Bankers converted into Managers of estates, their securities coming to them only on second mortgage, the Government, as the dominant landlord, never losing their lien for the annual assessment made by law a first charge, and moreover by law able to extinguish the claim of other mortgagees. For special products such as coffee, tea and cinchona, Investment Companies have been tried without success, and such companies, have, after a short existence, gone into insolvency. The Indian Government have endeavoured by Loan Acts to improve the agriculture of the country and save the impoverished ryot from the grasp of the sowcar, but these enactments have also had a very partial operation, and the condition of the peasant proprietor has not been improved one iota. Here on the Nilgiris, the authorities in working these Loan Acts, are met at the outset with an insurmountable difficulty in the indebtedness of the Badaga or Koter borrower to the local Sait. He applies for a loan, alleging that the money is to be utilised for the improvement of a particular holding, perhaps to construct stone retaining walls, to open up communication, or more generally, to reclaim waste land and clear away heavy scrub jungle. The money we will suppose, is sanctioned and perhaps reaches his hands wilhout material deductions. The first demand on the loan is for repayment of heavy advances previously obtained from the Sait and for which the land has already been mortgaged. The Sait contrives to post himself in every stage of progress of the application to Government, if he has not originated it, and pounces upon the money the moment the ryot gets it. The latter cannot resist the demand for fear perhaps that a knowledge of the previously concealed incumbrance might reach the ears of the Collector, and a compromise is affected by which the projected improvement, for which the money was specially given, cannot be carried out. This is no hypothetical case. Loans have been refused and applicants restrained from applying for them for these and similar reasons.

Planters, as a rule, do not seek for loans under these Acts, the amounts that can be obtained being quite inadequate for their requirements.

The means of helping the impecunious Indian cultivator has yet to be devised, and until money is forthcoming for agricultural improvements, the depresssion of the landed industry of the country must continue.—*Nilgiri Express.*

SPONGE FISHING.

To the Editor of the "Chemist and Druggist."

Sir,—In the *Daily Telegraph* of December 23, a leader appeared, having for its theme a report of the United States Consul at Beyrout on the Syrian fishery. The report has been either badly summarised or is inaccurate in some of its details. We therefore beg to offer a few remarks which will correct any wrong impressions your readers may have received by its perusal.

In the first place it is obviously incorrect to state that the sponges "have to be freed from sand." Seeing that the sponges never contain any sand in their original condition, there is no necessity to free them from that which would have practically suffocated the living animal as it is found by the divers.

Secondly, the *Daily Telegraph* writer states that "the common sponge is chiefly found in the waters whose fisheries the United States Consul has described." Now the Syrian Fishery referred to furnishes it is true sponges inferior in quality to those fished on the more important grounds off the coast of Barbary and elsewhere; but there are much commoner sorts obtained from other Mediterranean fishing grounds, notably, those off the coast of Tunisia, and these latter alone furnish more than all those of Syria. But the great sources of supply, of the common sponges are the West Indies, the Bahamas of Cuba, &c., and also the Keys of Florida. In these localities useful sponges grow in greater variety and quicker than elsewhere, and they are also fished by simpler means. These kinds we now import into this country to a very considerable extent, and they are used in the smallest villages, where sponges were scarcely even thought of years ago.

The Consul's report also states that below a depth of 25 to 175 feet, there are no sponges worth taking to be found. This may apply to Syria, but it is far from applying to the more important fisheries of the Mediterranean. We employ divers who regularly descend in diving apparatus to the great depth of thirty fathoms. The pressure on their bodies at this depth is about 75 lb. to the square inch, and as the effect of this is to temporarily impede and almost suspend the circulation of the blood, it may readily be imagined what sufferings these brave fellows undergo. But the very reason which induces them to face it is that they find the best sponges at these greater depths. They are all Greeks, and of course are of exceptionally fine physique. We have been assured by the best submarine engineers that no English divers go down so far. Our Greeks can consequently be allowed their claim of being the best divers in the world, although it may be that there is something in the temperature or specific gravity of the waters of the "tideless sea" which favours its native divers.—Yours faithfully,

CRESSWELL BROTHERS.

[It will be observed that the sponge grows at a depth of 30 fathoms, or 180 feet. We have never heard of pearl shells being found at a greater depth than one-third of that specified, most of the fishing is done in 6 and 7 fathoms. It will observed that even with diving apparatus, descending to a depth of 180 feet produces very serious effects in the shape of pressure and otherwise.—ED. *T. A.*]

THE PRODUCTION AND PROPERTIES OF THE FINEST FIBERS.

At a meeting of the Physical Society in London, March 26th, a paper was read "On the Production, Preparation and Properties of the Finest Fibers," by Mr. C. V. Boys, M. A. *Engineering* has made the following abstract:—

The inquiry into the production and properties of fibers was suggested by the experiments of Messrs. Gibson and Gregory, on the "Tenacity of Spun Glass," described before the Society on February 12th, and the necessity of using such fibers in experiments on which Professor Rucker and the author are engaged.

The various methods of producing organic fibers such as silk, cobweb, etc., and the mineral fibers, volcanic glass, slag wool and spun glass were referred to, and experiments shown in which masses of fibers of sealing-wax or Canadian balsam were produced by electrifying the melted substance.

In producing very fine glass fibers, the author finds it best to use very small quantities at high temperatures, and the velocity of separation should be as great as possible. The oxhydrogen jet is used to attain the high temperature, and several methods of obtaining a great velocity have been devised. The best results obtained are given by a crossbow and straw arrow, to the tail of which a thin rod of the substance to be drawn is cemented. Pine is used for the bow, because the ratio of its elasticity to its density (on which the velocity attainable depends) is great. The

free end of the rod is held between the fingers, and when the middle part has been heated to the required temperature the string of the crossbow is suddenly released, thus projecting the arrow with great velocity and drawing out a long, fine fiber. By this means, fibers of glass less than 1-1000 in. in diameter can be made.

The author has also experimented on many minerals, such as quartz, sapphire, ruby, garnet, feldspar, fluor spar, augite, emerald, etc., with more or less success. Ruby, sapphire, and flour spar cannot well be drawn into fibers by this process, quartz, augite, and feldspar give very satisfactory results. Garnet when treated at low temperatures yields fibers exhibiting the most beautiful colors.

Some very interesting results have been obtained with quartz from which fibers less than 1-100,000 inch in diameter have been obtained, it cannot be drawn directly from the crystal, but has to be slowly heated, fused and cast in a thin rod, which rod is attached to the arrow as previously described.

Quartz fiber exhibits remarkable properties as it seems to be free from torsional fatigue, so evident in glass and metallic fibers, and on this account is most valuable for instruments requiring torsional control. The tenacity of such fibers is about 50 tons on the square inch.

In the experiment on the fatigue of fibers, great difficulty was experienced in obtaining a cement magnetically neutral, and sealing-wax was found the most suitable.

An experiment was performed illustrating the fatigue of glass fibers under torsion, and diagrams exhibited showing that the effect of annealing them is to reduce the sub-permanent deformation to about one-tenth its original amount under similar conditions

Annealing quartz fibers does not improve their torsional properties and renders them rotten.

Besides the use of quartz for torsional measurements, the author believes that quartz thermometers would be free from the change of zero, so annoying in glass ones. He exhibited an annealed glass spiral capable of weighing a millionth of a grain fairly accurately, and also a diffraction grating made by placing the fine fibers side by side in the threads of fine screws. Gratings so made give banded spectra of white light.

The author regretted that his paper was so incomplete, but thought the results already obtained would be of interest to the Society.

Professor W. G. Adams congratulated the author on his most interesting paper, and considered the results to be of great importance. He believed the banded spectra exhibited by the grating were probably due to internal reflection withing the fibers.

Mr. Cunyngham asked whether the glass mirror used in the torsional experiments was magnetic, to which the author replied that this was probably, but even this assumption did not explain all the peculiarities observed.—*Oil, Paint and Drug Reporter.*

A TRAINING COLLEGE FOR PLANTERS.

There has lately been an interesting correspondence in our columns on the subject of coffee grafting. One of the correspondents urged Government to try by a series of experiments to improve the coffee bush, so that it may withstand leaf disease, whilst another strongly deprecated all Government interference. Why should Government move in the matter, or be asked to do so? Any person employed by the Government to carry out a series of experiments might just as easily be engaged by the planters of India and Ceylon, and would be under their direct control. There are over one thousand European planters in Ceylon, and the total number in South India must be considerable, yet very little has been done by them to gain reliable information, to gather statistics, to carry out a series of experiments, and to publish notes on practical agriculture. The Editors of the [illegible] have done a great deal for Ceylon, and the Messrs. Ferguson are already trying to produce a planting literature for that Island. The Ceylon Planters' Association some years ago gave prizes for a series of essays on coffee planting, and did much good by their action.

But in spite of the results already obtained, and the existence of several Planters' Associations in Southern India, it must be admitted that Planters, as a body, are not compact enough, they do not all hold together as they should, and in many ways resent any interference with them by the Government, even when it is for their good. For years, the Government of India has sent papers to the Planters to be filled in, showing the elevation of their estates, the acreage, the extent under cultivation, the products cultivated, and so forth; and yet these are in too many instances either not returned at all, or are filled in in such a careless manner that the information is of little or no use, and this, even, when the assurance is given that the statistics called for are not of an inquisitorial nature, but are simply desired for the instruction of the Government of India as to the real state of the planting industry in the country. If Government does not know the extent of land under cultivation, and its value and importance, the Planters are themselves greatly to blame for this want of knowledge. It is necessary that the various local Planters' Associations should look sharply after their own interests in the way of roads, cattle trespass, and coffee stealing, but something more is wanted. Some attempt should be made by the estate proprietors to start a College for giving to young planters the training necessary to enable them to think and reason on true scientific lines. Youths are brought out from Europe who have had no special agricultural training, are put on already opened plantations, and are supposed to learn everything by experience. Though there is no doubt that what a man learns by experience he is not likely to forget in a hurry, still, that experience may often be bought at too great a cost either to the man himself, or to those who employ him. What is wanted is that theory and practice should go hand in hand. In forestry, a special training is considered necessary. It is found that if a man would succeed in arboriculture, he must have a certain knowledge of the habits and formation of plants, the difference of orders and species, and the effect of climate, soil, and cultivation.

Planters, taken as a class, are a superior body of men to those usually engaged in agriculture in other parts of the world. In intelligence, resource, and adaptability they can hold their own anywhere, but it is doubtful if there is a similar class of men employed in any other profession who have less special training before commencing to earn their own living. In nearly every case the youth who intends to be a planter begins by supervising work, about which he knows nothing. Cannot, therefore, some scheme be devised whereby, either in India or Ceylon, a College could be started at which young men who wished to take up planting as a profession could go through a two years' course of training? Botany, agricultural chemistry, surveying, a knowledge of the steam engine, drawing, practical gardening, including grafting, pruning, and all the operations connected with arboriculture, are all necessary to a planter, as are book-keeping and a thorough knowledge of business habits and principles. A College, having around it a considerable acreage of land planted with various tropical products, should not be very difficult to maintain, and it would prove of immense benefit in training on scientific principles a most important body of men. One other great advantage of such a scheme is that young men getting the diplomas and certificates of such a College would be known, and those who have to engage Superintendents would have some guarantee of proficiency in those whom they employed. There can be no doubt that in the past men have been engaged at haphazard, and too often those with influence have had posts given to them for which they were unfit, though that could not be found out except by actual experiment. Some such scheme as proposed here might well be helped by Government; it is one in which all owners of tropical estates might join. It will commend itself to all those who have watched the vicissitudes of coffee as a more certain way to improve the plantations by improving the men who manage them, than by experimenting with seed or grafting.—*Madras Mail.*

TEA CULTURE IN JAPAN.

Mr. Consul Jernigan gives the following particulars of Japan tea culture in a report of his visit to the tea districts and warehouses.—"The cultivation of tea was introduced into Japan from China during the ninth century. The first mention of it is in the reign of the Emperor Kuaumu, when a priest named Saito brought seeds from China, and had them planted at Uji. But it was not until the twelfth century that the tea shrub came to be appreciated in Japan. For a long time, tea was an expensive luxury, only to be indulged in by the nobles. Kaempfer, in his history of Japan, describes how the tea used at the Imperial Court was then grown and prepared at Uji, under the care of the chief purveyor of tea, and that for at least two or three weeks before the gathering of the leaves, the persons who were to pick them were prohibited from eating any unclean food such as fish, lest their breath should contaminate the leaves, and, how during the gathering season they had to wash themselves two or three times a day, and were not allowed to touch the leaves except with gloved hands. Tea is now grown throughout Japan—the provinces of Surgua and Totomi being the chief producing districts. There are two varieties grown, one (Mécha) being large-leaved, and the other (Ocha) small-leaved. Both have similar habits, and the height of the shrub is from 3ft. to 4ft., the stem being bushy, with numerous and very leafy branches. When in the third year of its growth, it bears leaves ready for picking, and is considered at its best from the fifth to the tenth year, although age does not deteriorate the plant; but as it grows older more manure is required. The plantations are started from seed sown in circles of 2ft. in diameter, an average of 30 seeds being sown in each circle, the centre of which should be at least five feet from the next circle. The soil should be well drained. The plant will grow well on level land or on the hillsides, the latter being usually selected because cheaper. These hillsides are terraced and cut so as to form small level patches, and prevent too violent rushes of water during the heavy rains. When the seeds begin to come up and grow, they develop into a compact bush, some of the shoots of which bear leaves of a darker colour and harder texture than others, and often smaller. This is a drawback to the quality of the tea, but it has been found that it can be obviated by proper care being taken as to the source of the seed. The insects so destructive to the tea plant in India have not yet made their appearance in Japan, so that the Japanese farmer is free from the spoilations of the red spider, the tea bug, the green fly, and the orange beetle. He has, however, one enemy in the *mino mushi*, which, if not arrested in due time, often proves quite destructive to the tea plant. The harvesting of the crop consists of two, and frequently three, pickings. The first picking of tea commences about the 1st of May, and lasts about twenty or thirty days. The second crop is gathered in June and July, and, when there is a third one, about the end of August. The picking is done almost entirely by females, who average about 4lb. per day, and who receive about 7d. per day. Travellers along the roads leading from the tea districts to the towns and cities, seldom find them during the tea season free from men who are carrying baskets full of green leaves from the fields to the buildings, where they are steamed and fired. Generally the tea plantations are owned by small proprietors, who fire the leaves at home, and then sell the leaves to large dealers who send on their purchases to the Treaty Ports, where they are purchased by the marchants and exported. When the leaves are picked, they are steamed as early as possible. This is done by placing them in a round wooden tray with a brass wire bottom over boiling water, the tray filling up the mouth of an iron cauldron set in plaster over a wood fire. The process of steaming is complete in about half a minute. The moist leaves, with their nutural oil, rise to the surface, and they are then placed upon a wooden table, and within a few minutes, are taken into the firing-room. Firing is considered the principal manipulation, and is conducted in a box-shaped wooden frame about 4ft. long by 2½ft. wide. This box is coated with plaster and forms the oven. Charcoal, well covered with charcoal ash, is a light at the bottom, and about a foot and a half above the charcoal, rests a wooden frame with tough Japanese paper, stretched across it to form a tray. About 6½lb. of green leaves are thrown into one of these paper trays, the box is shut up, and the weight reduced to 1½lb. It is said that so strong is the Japanese paper, that one of these paper trays will last a whole season. The next operation is that of sorting. The tea is passed from the firing room to men who sort the leaves by jerking them up and down in hand-trays made of bamboo, thus separating the heavy, from the light, leaves. It is then passed to a sieve, which generally hangs suspended from the roof, and swings backwards and forwards with a circular motion, whereby the fine and thin leaves are collected in a heap on the floor, and the larger and coarser leaves are retained and thrown into a separate box. The tea is then placed on a long and thin table, around which sit girls, who pick out any seeds, stalks, or rubbish that may be found mixed with it. After this operation, the tea is packed in wooden boxes, which are nailed, corded, and marked, and sent to the nearest Treaty Port for sale. These are all the operations performed by the grower, but at the Treaty Ports it has to undergo further operations before the foreign merchant can ship it. These operations are either pan-firing or basket-firing, together with the colouring, when the latter has to be done. The two former processes consist of further drying the tea either in iron pans or bamboo baskets, thus giving employment to thousands of poor Japanese women, who work from 4 a.m. to 6 p.m. for the munificent wage of from 6d. to 7d. per day. The shrinkage at the ports by firing is from 12 to 15 per cent. The operations of sorting and sifting are again repeated, after which the tea is weighed and packed in boxes, which are labelled ready for shipment to England, or whatever other part of the world they may be consigned to."—*Home and Colonial Mail.*

TEA AND COFFEE AT HOME.

The Indian Planters' Associations did a good work in bringing together such a number and highly interesting variety of exhibits of the two allied beverages, tea and coffee, at the Indian and Colonial Exhibition of last year at South Kensington, and more especially by affording the English public an opportunity of judging of the merits of these two popular drinks, by presenting them in a pure and unadulterated form. Visitors had the opportunity, after viewing the wonderful display af the raw material, of stepping down to the adjoining stalls and tasting a cup of coffee or tea free from any admixture of other compounds. It has been most truly remarked, as far at least as the general work-a-day people of London is concerned, that they failed to appreciate, in many instances, the virtues of really genuine coffee when given to them, having hugged the delusion for so many years that the stuff they had drank as supplied to them at the numerous coffee taverns and stalls, was in reality a decoction from the wonderful bean, and it would seem that it has come to this, that unless some means be devised to educate the working class of England, which is without doubt the largest coffee consuming class in the country,—into a full appreciation of the high value of pure coffee as an invigorator for work and restorative of strained nerves and faculties, adulteration in all its vile forms will be continued and the working man in England be left to swallow his daily pint or quart of coffee, or rather the filthy and nauseous liquid sold under that name as the only drink bearing that name he can procure. There are many places, no doubt in London and other towns, where good coffee can be had; but these are reserved for the upper classes and wealthy, the working population is forced to fall

back on the low class of coffee taverns where it is simply impossible to obtain a good cup of unadulterated coffee. I can speak with some confidence on this matter as I have been to the trouble of visiting numbers of these houses in all parts of London, and in no case did I ever obtain an article even in the faintest way resembling genuine coffee.

To those who entertain doubts regarding the alleged extent of coffee adulteration, the following facts may be quoted. An analysis of forty-three samples of coffee and coffee mixtures purchased in London, during March and April 1886, showed an average proportion of coffee in these samples of just fifty per cent added to fifty per cent of burnt sugar, and various vegetable substances, such as roasted and ground roots of dandelion, carrot, and parsnip, beans, lupins, and other seeds. Nine of these samples contained from 62 to 93 per cent of chicory &c., averaging 70 per cent of other substance than coffee. These mixtures were sold at from 10 pence to 1s. 4d. per lb. The price of the pure Indian coffee sold at the Royal Commission's Stalls was 1s. 4d. per lb. The enormous percentage of profit derived by the vendors of coffee adulterated as above, may be seen from the figures, and of course the worse the mixture, the greater the gain, and risk of discovery is not very great after all. From the report of the Local Government Board for 1884-85 may be taken a story which shows adulteration *in excelsis*. Coffee, says the evidence, continues to be one of the chief subjects tampered with, and about one-fifth of the samples examined were condemned. The peculiarity in one case was that the berries were actually shown to the inspector and were ground in his presence, so that there seemed to be no likelihood of adulteration; chicory, however, was found on analysis to be present, and the vendor was fined. It is possible that this fraud was due to the revival of an old practice of compressing chicory by machinery into the size and shape of coffee berries. These sham berries are mixed with real ones, and the purchaser, who sees, what he believes to be coffee being ground before his eyes, is hopelessly deceived. As chicory costs only 3 pence or 4 pence per lb., the fraud is very profitable. It is no rare thing for so-called coffee to be sold which proves on analysis to be composed of "one-fourth part of coffee added to three-fourths of chicory."

The low prices of Indian coffee which have prevailed for so long, taken in connection with the simultaneous extensive falling off in production may, I venture to think—be traceable in a great measure to diminishing consumption amongst the working people, resulting from the almost utter impossibility of their being able to obtain anything under the name of coffee, save a beverage from a deleterious compound, the sale of which, however beneficial to unscrupulous dealers, is most certainly anything but agreeable to the palate of the consumer, and worse than useless as an article of diet, as well as being highly prejudicial to the best interest of the fine industry of coffee planting.

Tens and hundreds of thousands of working men in this great city of London are, of necessity, compelled to obtain all their meals at what are commonly called coffee shops, and which are found almost as thickly planted all over London and its suburbs as are public houses, thus testifying to the lucrative nature of the calling.

The nature of their work, and long hours of toil prevent these men from ever having a meal at home, excepting Sundays and holidays. Tea and Coffee are in great demand as a beverage amongst this class; and there can be little doubt, that could these be easily obtained in anything like a palatable form and free from adulteration, that the increase in the consumption of these two drinks and the corresponding decrease in the consumption of alcoholic liquors, would soon become very marked and extensive, but so long as the working man is supplied with vile decoctions such as are on sale in the London coffee shops, it is hardly to be wondered at if he should sometimes take beer instead. I have no hesitation in giving it as my opinion, that in the great majority of this class of coffee shop in London liquids are supplied to their hard working customers under the names of tea and coffee, which are highly deleterious as an article of diet, and in very numerous instances totally unfit for human consumption. Workmen frequently after a few days' trial of so-called coffee leave it off in favour of tea, but the change in most cases, is like the one of "out of the frying pan into the fire," the so-called tea consisting of an infusion of the coarsest and cheapest samples served up with little sugar and less milk after being stewed and even boiled for many hours previously in large copper urns heated by gas, and bearing as much resemblance to a genuine cup of tea as a snowdrop does to a Banyan tree. The so-called coffee is treated in a similar way, and is generally placed in the urns over night with water, sugar, and milk, all of dubious quality and left above a low gas jet to stew and simmer till the early morning, when it is served out to the unhappy workmen who have been obliged to leave home, before their wives have had time to wake, dress, and kindle the fire, and who are only too glad, during these early hours, to obtain something to drink be it ever so nauseous a compound, if it be only sweet and hot. The manner of serving up these drinks by the attendants as well as the general surroundings of these coffee "Palaces" must be repulsive even to the roughest man who enters them. To begin with the odours that regale the sense of smell on entrance are not conducive to enjoyment of the meal, or subsequent good digestion. Attendants in too numerous instances appear to dislike the use of water quite as much as a Toda does, and indeed the general appearance of many of the places would convey the idea that the water had for some considerable time been entirely cut off, save for the purpose of supplying the copper urns above mentioned.

The drinks are served up in cups of different sizes of the coarsest ware and generally quite ¼ inch in thickness and frequently of the most curious shapes and patterns and with saucers to match. These are brought to the tables *both* filled with the dubious looking dark liquid, and placed before the customer with a bang and a rattle which is quite startling to a new customer and accounts for the necessity for having the cups and saucers of such a degree of weight and thickness. As this paper professes to deal only with Indian produce in the shape of tea and coffee I have nothing to say with regard to eatables supplied to the public at these coffee taverns, the quality of which, and the manner of serving them up, I will leave to the imagination of my readers.

It certainly does seem a misfortune to the planting community of India that their products both of tea and coffee, produced at such cost of persistant labour and courage, should be doomed to such vast wholesale manipulation at the hands of the adulterator and seller as is described above, and that the matter is in no way exaggerated or coloured may be proved in London any day at the expense of a very little trouble. All the care and trouble expended upon the growing, manipulation, curing and packing by the planter in India is therefore in a measure lost and thrown to the winds. True he gets a certain price for his produce, but does he get such a good price or ready sale for his produce as if, on leaving his hands, it were never subjected to treatment that not only changes its high value as an article of food into one of no value at all, but in many instances into one highly deleterious, checking consumption and keeping down prices accordingly?

Perhaps it would be a difficult thing for the planting interest to put a stop or even check on such a state of things, but if proper action were taken the difficulty might not be found to be insurmountable.

There can hardly be a subject of more pregnant interest at the present time when national taste is slowly but surely turning from intoxicating drinks, if we are to believe the figures of each recurring Budget—than the best mode of supplying to the public at large tea and coffee in a pure and unadulterated form. The fault does not lie at the door of the Indian planter. He has ever supplied the English market with a pure article. It has been the aim continually of the planter to produce, at whatever cost, an article of superior quality; and who will venture to declare that he has

not succeeded? But all his care, toil, and courage has been expended hitherto mostly for the benefit of unscrupulous British adulterators and vendors, surely, then, any scheme for the wide diffusion of Indian teas and coffee in their pure state benefiting alike the English public and the Indian producer, might obtain the combined support of the Planters' Associations of India and capitalists and other influential gentlemen in England interested in India and Indian products.

Companies exist in England having agencies all over the country, with the declared object of supplying tea, coffee and other beverages, as well as eatables in a pure state, and at a very cheap rate to the working population. Of the prices no one will be found to complain, but the quality of the drinks is by no means satisfactory, coffee and tea so-called are only produced from inferior or adulterated samples and prepared in the usual objectionable way. As to the appearance and cleanliness of the Companies taverns no objection may be taken, but as regards the tea and coffee—and I am judging from repeated trials—the public is paying for an article which they receive only in name. There surely must be spirit enough, capital enough, and energy amongst Planters and their associations in India on the one hand, and gentlemen in England interested in such matters to attempt the experiment of forming a wealthy Company in London for the opening on a large scale of places for the supply of pure Indian tea and coffee as beverages to the public where the produce would never leave the hands of its agents from time of gathering in India till handing it across the counter in London; and thus avoiding the remotest chance of adulteration. That such an experiment would pay and pay well there could be, I think, little doubt, altogether independently of benefit likely to be derived by the planter by increased consumption, which of course would be the main object to be obtained from a planting point of view. To those interested in such a question, and what planter is not? I would recommend if they entertain any doubts of the exact correctness of the above statements with regard to the abominable mixtures palmed off on the London working man under the name of tea and coffee, to test the matter for themselves should they happen to visit England or make enquiries through friends and then say whether the time has not arrived for some kind of combined action for the better protection of the planting interest of Southern India. The Kensington Exhibition of Indian teas and coffees was most assuredly a step in the right direction, but to do any real permanent good the matter ought not to be allowed to rest there.

The Nilgiri tea planters would do well to look to their laurels, or they will be outdone by those of other districts. Ceylon tea is now largely sold in London and is much liked. It can be had at nearly every grocer's shop now and is widely advertised. Not so the produce of the Blue mountains, this is comparatively little known, is little heard of in London, and is not to be had in a pure state in many London shops. This is not as it should be surely. Has the quality of the product degenerated, or can the planters find remunerative prices in India without sending it home.—*Nilgiri Express.*

SEEDS REQUIRED FOR GARDEN PLOTS (*B.*).—The following seeds and space the quantities named may occupy, has been determined by experiments, the seeds being good and uniformly covered at a proper depth in suitable soil:—Asparagus, bed of 15 square yards, ½ pt.; Beans, Broad, per row of 80 feet, 1 qt.; Beet, row of 50 feet, 1 oz.; Broccoli, per 4 square yards, ½ oz.; Brussels Sprouts, per 4 square yards, ½ oz.; Cabbage, bed of 8 square yards, ½ oz.; Carrots, drill of 120 feet, 1 oz.; ditto, bed 12 square yards, 1 oz.; Cauliflower, 4 square yards, ½ oz.; Celery 4 square yards, ½ oz.; Cress, 3 square yards, 1 oz.; Endive, 4 square yards, ½ oz.; Kale, 4 square yards, ½ oz.; Kidney Beans, row 80 feet, ½ pint; Leek, 2 square yards, ½ oz.; Lettuce, 4 square yards, ¼ oz.; Mushroom, 7 square yards, 1 bus.; Onions, 9 square yards, 1 oz.; Parsley, row 80 feet, 1 oz.; Parsnip, drill of 200 feet, 1 oz.; Peas, early, row of 60 feet, 1 pint; Peas, large, late row of 80 feet, one pint; Potatoes, row of 30 feet, ¼ pkt.; Radishes, 4 square yards, 1 oz.; Savoy, 4 square yards, ½ oz.; Spinach, 10 square yards, 1 oz.; Spinach, drill of 120 feet, 1 oz.; Turnip, 4 yards square, ½ oz.—*Journal of Horticulure.*

FIBRE-CLEANING.—Our readers will remember that in 1883-84 the reward of R2,000 offered by the Government of India for the best fibre-cleaning machine, was awarded to Messrs. Death & Ellwood, but subsequent experience has proved that this machine is not all that was claimed for it. We now learn from the Glasgow correspondent of an exchange, that demonstration of the working of the *new* fibre-extracting machine invented by Mr. Death of the above-named firm was recently given in the premises of Grant & Sons, Broad-street, Mile End, Glasgow, in presence of a large number of local manufacturers. It is stated that rhea stems "plantain and hemp leaves were used, and the demonstration generally was regarded as highly satisfactory. By this inventionthe patentees state that the long-standing difficulty of effectually separating the fibre of rhea or China grass from the stem, and at the same time discharging the prejudicial gum present in the plant without injury to the fibre, has been successfully and economically treated, and that other vegetable products which hitherto have had no commercial value can be utilised for manufacturing purposes. Our readers are aware, however, that the Calcutta trials of Smiths' machine, which was admittedly inferior to the one above referred to, were considered satisfactory by the judges, but these demonstrations with comparatively small quantities of the raw material really proved little more than that the machine will extract the fibre. The practical question is: will it pay the planter to employ these machines on a large scale? still remains, so far as we are aware, unanswered." We entirely endorse the truth of the concluding sentence.—*Indian Agriculturist.*

A "RED BANANA," very commonly cultivated as a shade and fruit plant, and the supply of which is said to be almost inexhaustible, has been brought forward as a possible source of commercial fibre. A sample of fibre prepared from this red banana was recently sent to Kew, and the opinion of Messrs. Ide and Christie obtained upon it. Their report, dated October 29, 1886, is as follows:—"We think highly of this fibre, for which we consider there might be a considerable demand, provided it could be produced of a better colour. We are inclined to think its dull hue is probably the result of inexperience in its treatment, either by allowing it to steep too long in rather foul water or from the leaves being too old and discoloured before treatment. The attention of preparers should be directed to the production of a fibre of the bright natural colour of the enclosed specimen of Manila hemp, and were quantities of the new fibre produced of this appearance, we think they would command 24*l.* or 25*l.* per ton today in the London market. Colour is of great consequence when fibres are used for the production of 'white hemp' ropes. Of course, in the manufacture of tarred rope, colour is of no moment, but the white 'hemp,' Manila, Sisal, and New Zealand are seldom tarred." It is quite possible, Mr. Morris says, that, in spite of many years of experimental trial, the fibres of the banana and plantain may not assume great commercial importance. In that case attention might be turned in another direction, and they might be partly prepared on the spot and utilised for paper-making. But to compete successfully with esparto and wood-pulp, the fibre or "half-stuff" of banana and plantain, he says, should be delivered in Europe at a cost not exceeding 4*l.* to 6*l.* per ton, depending on condition. For paper-making it might be sufficient to cut the stems into short pieces, and then divide them longitudinally into numerous narrow strips. These, after being passed between rollers to get rid of the water and mucilage, might be dried in the sun, and afterwards put up in compressed bales for shipment. The whole subject, however, as Mr. Morris rightly observes, resolves itself into a question of cost, and it can only be practically solved in countries like Demerara, Trinidad, and Jamaica, where several thousand acres are occupied by banana plantations, and where sufficient material lies close at hand to maintain a modrately large industry.—*Colonies and India.*

COCONUT PLANTING IN CEYLON:

REVIEW OF THE PAST TWELVE MONTHS' EXPERIENCE IN THE WESTERN PROVINCE.

THE FIRST THREE QUARTERS.

We paid the penalty of the drought that extended from the middle of Dec. 1886 to the middle of April 1887, not so much in numerical deficiency of nuts as in size. The June-July gathering was of very small nuts and the August-Sept. much smaller. Under this dispensation the dealers suspended business and the estates had to prepare the copra for themselves. The outturn ran from 1,400 to 1,700 to the candy, the average being about 1,500, or from 300 to 400 over the usual rate. At the same time the price of copra fell 3 to 4 rupees per candy, and as the next three gatherings were expected to be scanty, it was thought to be a rather bad time for coconut planters.

Some of the most intelligent of the owners of coconut property are beginning to employ their minds on the question of whether we are about to overdo coconuts as has been done with cinnamon and cinchona. It is being asked if the fall in the price of copra is likely to be permanent or the mere annual decline that regularly takes place between May and November. In that half of the year two-thirds sometimes three-fourths of the annual crop is gathered, and the large supply tells on the prices which invariably go up in December and the best prices are obtained when the planter has least to sell. The supply of coconuts has doubled within the last twenty years, and will probably be again doubled in the next twenty, and other lands are beginning to compete. The Yankees who do everything on a vast scale are laying down plantations of 350,000 plants in a single concern; but I do not fear much from Florida. The coconut is essentially a tropical plant, that disappears in our own landscape, within eight degrees of the equator, at under 2,000 feet of elevation; the south point of Florida is about two degrees outside the tropics and not far from the line where frost occasionally manifests itself; it seems therefore probable that Florida will be a failure, but the West Indian Islands are being roused to a sense of their advantages for this cultivation, and they find a ready market close at hand in the United States, so that they will not within this current century interfere with our market. Year by year coconut oil is getting into more favour for soap making. In 1886, in addition to one of the largest exports of oil on record, the equivalent of 12 per cent more was exported in copra besides nearly 10,000,000 of nuts. In 1887, the export was 300,000 cwt. of oil and 15 millions of nuts. The supply is probably in excess of the demand for the time being, but the supply of the present commercial year will be at least 25 per cent less than that lately closed, so that low prices are not likely to rule throughout the year.

Whether consumption will increase proportionately to the increased supply is a question that only time can decide, but the future may be looked to in hope, if not confidence. Civilized humanity is multiplying at the rate of three or four millions annually, and though much of the increase must belong to the class of the great unwashed, the consumption of soap must go on increasing by many millions of pounds annually. It would appear, that, besides this outlet, the use of coconuts in domestic economy, both in America and Europe, is advancing, and human ingenuity is ever finding fresh uses for such products. I therefore think that the outlook is not a specially gloomy one, especially as Ceylon has the lead of all other lands in having twenty and odd millions of trees that cost but little for upkeep, and can continue to feed the markets with a profit at the lowest prices ever likely to be reached.*

I have already recorded my dissent from the theory, that phosphate of lime acts as a stimulant on the coconut tree. My understanding of a stimulant is a substance that without imparting fresh strength produces the effects of strength in the being it operates on, by temporarily drawing on the latent strength of the individual. All vegetable tissues are a combination of certain elements, in definite proportions always the same in every individual of the same species. However rich the soil it occupies may be in one or more of the elements it combines in its substance, a plant takes up no more than the due proportion its specific constitution requires to complete its tissues. Thus if you place a bushel of bone dust within reach of the roots of a coconut tree, it will take up exactly as much and no more than is necessary in its specific combination. Phosphate is therefore not a stimulant to the coconut tree, but an indispensable element to healthy fruitfulness. If reaction takes place, it indicates the exhaustion of some one or more of the equally necessary elements, and reaction may take place while an abundant supply of phosphate remains in the soil. According to my experience the earliest tree is the best and other things being equal continues the best throughout. A practical Welsh gardener told someone, years ago, that the fibrous roots round the stem of a tree supply it with fruit-forming materials, while the larger roots, which spread further away, supply materials for the formation of wood and leaf. Had a Welsh gardener, or any other presumptuous ignoramus, advanced such preposterous nonsense in my presence, I would have told him what he was on the spot. I deny that there is any difference in the functions of roots, and I maintain that the most active foraging roots are near the extremities of the mains.

Note.—I do not know the proportion of oil obtained from copra in the great manufactories; but I wrought chekkus for a dozen years, and always got three gallons of oil from 45 lb. At 9 lb. 3 oz. to the gallon this is 27 lb. 9 oz. or 61·8 per cent. I cannot believe that the chekku can extract more oil from the same copra than the hydraulic press, from thoroughly ground material; but the chekku will only operate satisfactorily on copra as dry as sun or fire heat can make it. If then a recent statement as to the outturn of the mills be correct, it indicates the average of superfluous moisture in commercial copra to be 8·5 per cent supposing the chekku and mill machinery to be equally effective.

* Our estimate in last "Handbook and Directory" was as follows—"The calculation up to 1869 was that there were 250,000 acres of coconut palms (belonging to natives and in European-owned plantations) in Ceylon, covered with twenty million full-grown trees, but considering the extension of planting chiefly by natives in the last twenty-five years we feel bound to raise the number of trees to about forty millions covering 500,000 acres of which all but about 30,000 acres are owned by natives. There is scarcely a native landowner or cultivator in the country who does not own a garden of palms, coffee or other fruit trees, or vegetables besides his paddy-field. Our estimate is still far below the figures given in the Government Blue Book for 1881, which, however, we cannot help thinking exaggerated as regards acreage." Our conclusion seems to be justified by the Galle figures since published by Mr. Elliott.—Ed.

THE FOURTH QUARTER OF 1887 AND PART OF 1888.

The coconut planters of the Mahaoya Valley have paid the penalty of a drought that continued from the middle of December 1886 to the middle of April 1887, broken by only a few scanty sprinklings of rain. The coconut loves the sun, and responds gladly to its influence, but at the same time it needs much moisture in the soil it occupies, and if the due balance of heat and moisture be not maintained, the plant suffers. On grey loamy sands and level surfaces the tree can stand drought with little or no damage, but this district is composed of undulating uplands with very little level land, and none of the true coconut soil. The soil is, however, of good quality for the greater part, and very fit, but for the annual recurrence of long droughts. During the year 1887 the district was severely tried, and the consequences are very disheartening to the planters. At the end of 1886 there was on the trees the largest crop the district had ever borne, but the drought arrested the growth of the fruit half way to maturity, and though the two largest gatherings of the year were numerically better than the corresponding ones of any previous season, there was a loss of from 30 to 40 per cent in the weight of copra as compared with the average outturn.

As the planting of coconuts still goes on with unabated vigor, the question is being seriously mooted, whether they are not being overdone, like cinnamon and cinchona? There can be no doubt that production is rapidly increasing, that prices are not holding their ground, and there seems little chance of any permanent improvement on present rates. On a former occasion I ventured to name something over 20,000,000 as the number of coconut trees in Ceylon: it was objected that a Government official had estimated them at more than twice that number; it is therefore evident that he and I have proceeded on different methods. I do not know his, but here is mine. In the last closed commercial year, we exported:—

C'nut oil 300,000 cwt. equivalent to	150,000,000	nuts
Copra equivalent to	18,000,000	,,
Nuts exported	10,000,000	,,
	178 millions.	

Take 20 nuts as the average crop per tree, and the result for exported produce is 8,225,000 trees, double that for local consumption 16,450,000, and add 3,650,000 for barren trees and young plantations, and we have 20,000,000. Allowing the average of 100 trees to an acre, this gives 200,000 acres. I have stated the average bearing at less than the truth, and I rather over-than under-rated the local consumption, while the proportion of nuts to copra and oil is in accord with my own experience, as an old planter and oil maker; I have therefore to ask what becomes of the fruit, if from 40 to 50 million trees exist in the island. *

It would be well to know what is being done in coconuts on the Malabar coast, which is our chief competitor in the European market. If the enterprise is going ahead there as here, the period of glut will arrive the sooner. The doings of other lands is of little consequence to us, as the Australian colonies and China will probably absorb all the produce of Oceana, and the United States and Canada will take all the West yields, so that outside local competition we have only Cochin and the African palm oil to meet. If uncle Sam with his grand conceptions happened to be inside the tropics, we might soon expect him to supply himself and have some to spare for other markets; but I have great faith in the fact that the coconut is a strictly tropical plant, needing both tropical heat and tropical moisture to its perfect developement. In this island we can do nothing with it 2,000 feet above sea level. The amount of sun heat or of air heat it will enjoy has never been measured, but we know well that it will not succeed where the temperature, even on rare occasions, falls below 60 degrees. I must, therefore, demur to the pretension of the gentleman who professes to know more about the coconut than any other in the world when he plants 3,500 acres to the north of Cape Sable.

Breaking up the soil, either by plough or mamotie, and systematic manuring, are making way among the proprietors in this district, but to manure economically we need an analysis of poonac that can be depended on; we know that the two heroic elements are nitrates and phosphates, but we need to know the due proportions necessary of nitrate to maintain a head of from 25 to 30 green leaves, and of phosphate to put 100 nuts per annum on such a tree. We know that we have no provision to make for the formation of oil, because all the elements of that product are derived from air and water, and few soils are deficient in the bases derived from the earth.

Mr. Akbar, the owner of a large estate at Katukanda, has now completed a system of irrigation, by which he proposes to raise from the river nearly 400,000 gallons of water daily, which is to be carried over the property in pipes and drains. If this work should be sufficiently successful to add 250 nuts per acre to the average annual crops, it will be a very profitable investment; but if it succeeds at all, it will do much more than this, as witness the scores of germs that drop from every bearing tree during the three dry months. The most perfect success, however, can only be taken as an example by estates bordering on the river, as an inexhaustible supply of water is an indispensable requisite for such an enterprise. We, who have no such convenience, must rest content, with keeping the soil in good heart, and trust to the rapid recovery of the trees when rain comes, as however forlorn they may look at the end of the dry season, they have generally put on a good heavy crop by the end of October, and if the dry season is not unusually protracted and unbroken, the crops are perfectly satisfactory, if 60 nuts per tree over a whole estate without manure can be gathered.

Writing this on the 23rd of February, it is the 57th day without one drop of rain, but we have suffered much less than at the same time last year, owing probably, to the heavy rainfall o December. W. B. L.

[Since then rain has fallen.—ED. T. A.]

* We certainly do not see much room for criticizing these figures, save that the local consumption of nuts may be even larger than "W. B. L." makes it. What about the trees devoted to "toddy and arrack"? Has our correspondent not left them out of his calculation altogether?—ED. *T. A.*

PROGRESS OF TEA IN HAPUTALE.

A correspondent sends us the following:—

"The progress made by the district of Haputale in the cultivation and manufacture of tea is surprizing, and in a short time nearly half the estates will be plucking and making tea. The Haldummulla end of the district seems the furthest advanced in this respect, Needwood, West Haputale, and Berragalla being hard at work, whilst the Ooslanda and Poonagala end still chiefly adheres to its old love, coffee. Old Needwood has got a

good start over the others, and is now possessed of the biggest and most complete factory in the district, with driers and machinery complete. Mr. W. Mills' place in the Kalupahani Valley, "West Haputale," is said to be doing well with tea, and has already distinguished itself in the local market, having twice, I think, earned the proud distinction of being "mentioned" in the brokers' reports as having sent one of the "best invoices in the sale." Being somewhat out of the way, the estate cannot buy leaf of others, but it will soon be making large quantities of its own, for the tea planted is coming on there really wonderfully well. Berragalla, the property of the late Mr. Carson, has been making tea for some time, and buys leaf from its neighbours, all the Gonamatava pluckings—until its own factory is erected—being carted down there at present. Berragalla, I think, is making the most tea of any estate at present, for not only has it a large acreage, which is coming on capitally, but Mr. Davidson buys largely from his neighbours, and, having machinery already erected (a Little Giant roller and a Sirocco) is able to show his brother-planters the way to make tea. Amongst other estates at this end of the district that are making tea is old Kalupahani, and, if Mr. R. E. Pineo really is coming back to the island and the district, as alleged, he will be not a little astonished to see his store partly converted into a tea factory. The Pass estates, as a rule, have not yet made much progress with the new product, and the same may be said of some of those above it. Pitaratlillie, however, has chulas erected in its store, and is buying leaf from Dambatenne and neighbouring estates, which themselves promise well for the future. This is especially the case with Dambatenne, where the tea is really a good cover. Beyond the Pass, Gonamatova is the most advanced, and has not only a very large acreage of new land under tea, but is erecting a factory and will shortly commence manufacture instead of sending its leaf down the Pass to Berragalla. This estate has a large acreage of rich patana land opened, some of which once grew cinchona; and the tea there is coming on as if the soil suited it down to the ground, so that I expect that it will soon form a fair cover. The same may be said of Niabedda, which keeps a number of chulas at work, and tea seems to grow, if anything, almost better on the rich patnas which surround estates in this part of the district, than it does amongst the best coffee. Some years ago Craig, then the property of the Messrs. Mackenzie, cleared a large acreage of patna near Windy Corner for cinchona, which came on, as cinchonas always did on Craig, wonderfully well. These have been cut down, and right up to the Windy Corner ridge as fine a sheet of tea for its age as could be desired now exists, and will prove a mine of wealth to the new proprietory. Leangawella has not done much yet, but doubtless will do so soon, whilst Broughton has a fairly large extent in plucking, leaf being sold to Ampitiakande, the next estate, where the Lanka Plantations Company have erected a temporary factory—rather unwisely, I think it is generally admitted, as it is so far removed from the cart-road, whereas Arnhall would have been more convenient. In that valley both the Meeriabeddes and Diacullaare plucking but not making yet; but there are no factories in the Poonagalla valley. Lyegrove, an estate belonging to Mr E. Swyney, however, is both plucking and making, and Dickapittiya has just begun plucking, and its store is now in process of conversion. Great difficulty seems to have been experienced in this part of the district in getting the tea to start, and the percentage of vacancies in most clearings has been very great indeed. Once fairly started, the tea does very well but it is gradually being found out that soil which grew magnificent coffee is not necessarily good for tea; and in one or two instances the new product can hardly be get to grow on it at all, though the climate is all that could be desired, and the soil is deep and rich. The absence of iron from the rock is generally very detrimental to the growth of tea. I must not forget to mention Kelburne, or else its "Laird" will indeed have cause for wrath. A new factory has just been put up on it with rollers and a Brown's dessicator, and planting (plucking) has, I think, already commenced. Thus nine estates at least are already making tea in the district, and, by the end of the year, nearly twenty factories ought to be at work—not bad progress this for Haputale, and some incentive for the Government to give it a railway. On the whole, I am inclined to think that, though tea will yet be very successful in the district, it will not be so universally. There are a few estates in the district that do not as yet, at all events, seem to be able to grow it at all. On the other hand, one of the most cheering incidents connected with the cultivation is the fact, vouched for by numbers of men in the district, that all through the long drought, now I hope at an end, tea has flushed better—more regularly and more abundantly—than ever before. This is a most hopeful sign, and I think it may be relied on that the drought to which this district is subject generally in July and August will not retard flushing in the very least.—Local "Times."

TEA: THE EXPERIENCES OF DIFFERENT COMPANIES IN 1887; MACHINERY, LAND SLIPS, BLIGHT, AND DIVIDENDS.

HOPE TEA COMPANY.—The report of the Managing Agents shows that satisfactory progress has been made with the garden, and that the property is fully equipped with machinery of the most modern type. The prospects of the current year seem excellent, and point to a good dividend for the shareholders should nothing unforeseen occur. The area under plant is 1,210 acres.

LACKATOORAH TEA COMPANY.—The report of the directors shows that 1,188 maunds of tea and 98 maunds of tea seed were produced. The former sold at 8 annas 1½ pies per lb. net. The revenue was R53,322 and the expenditure R45,343, leaving a profit of R8,079, and adding the balance from 1886, the amount at credit of Profit and Loss is R8,119. A dividend of 3½ per cent is recommended, carrying forward R243. An unprecedented rainfall in May did extensive damage to drains, and entirely buried about 20 acres of fine plant. [*N. B.*—20 acres buried is a serious loss.—ED.] The estimates for 1888 are for an outturn of 1,200 maunds tea and 100 maunds tea seed at a cost of R32,136, which includes a new extension of about 25 acres.

CENTRAL CACHAR TEA COMPANY.—The report of the directors for the year 1887 shows that 467,789 lb. of tea were manufactured against 395,813 lb. in 1886 and 296,562 lb. in 1885. The net price realised was annas 9-2 against annas 8-2½ in 1886 and annas 10-4 in 1885. The result of the year's work is a profit of R70,431, and adding the balance from last year, the amount at credit of profit and loss is R75,567. The directors recommend the payment of a dividend of 6 per cent., which will exhaust R60,000; that R10,000 be carried to reserve fund and R5,567 be carried forward. The estimates for the current year are for an outturn of 472,000 lb. at an expenditure of R166,634.

KURSEONG AND DARJEELING TEA COMPANY.—The report of the directors shows that the outturn for 1887 was 180,525 lb. against 182,031 lb. in 1886, the average net price realised being annas 10 against annas 8-3 in 1886. The result of the season's working is a profit of R25,430, and adding the balance from 1886, the amount at credit of profit and loss is R26,255, which will admit of a dividend of 4 per cent. The estimates for the current season are for an outturn of 188,000 lb. at an expenditure of R84,158. The offer of R70,000 which the directors received for the purchase of the Darjeeling division of the company's property has fallen through, owing to the purchaser being unable to find the money.

BARGANG TEA COMPANY.—The report of the Managing Agents for the past year shows that 129,120 lb. of tea were packed, or 40,541 lb. in excess of 1886. Almost the entire crop has been sold at a gross average of 11 13-16th d per lb., or about 9¼ annas in this market. The revenue was R74,928 and the expenditure R44,674, leaving a surplus on the year's operations of R30,254, and the Profit and Loss account shows a balance of R29,331. The directors recommend a dividend of 16 per cent., which will exhaust

R23,280, the transfer of R5,000 to working capital, and that R1,051 be carried forward. The estimates for the current season provide for an outturn of 1,500 maunds of tea at an expenditure of R52,100. The area under cultivation is 259 acres.

SELIM TEA COMPANY.—The report of the directors shows that the outturn of 1887 was only 499,369 lb. against an estimate of 560,000 lb., mosquito blight being answerable for the deficiency. The average price realised was annas 7-9·53 per lb. The revenue for the year was R2,44,354 and the expenditure R2,47,394, leaving a loss on the working of R3,040, and resulting in a debit balance at Profit and Loss of R1,662. The estimates for the current season are, for 7,100 maunds at a local expenditure of R1,88,228; but the directors add that, after their experience of blight, it is impossible to say whether this will be realized. The directors all retire at this meeting. [We visited Selim in 1876 as one of the leading Darjiling estates, planted with Assam hybrid. Connected with it was a group of estates, some in the Terai. The report shows what a fearful evil helopeltis is, and how thankful we in Ceylon ought to be at the continued exemption of our tea from this pest.—ED.]

BALASUN TEA COMPANY.—The report of the directors shows that the actual outturn for 1887 was 1,029 maunds against an estimate of 1,000 maunds. The entire crop sold for annas 11-11·81 per lb., and the net profit was R17,814, the balance at credit of Profit and Loss being R18,428. An *ad interim* dividend of 5 per cent has exhausted R10,000, and it is now proposed to pay a final dividend of 3 per cent which will absorb R6,000; transfer R2,000 to credit of Reserve Fund, which will then stand at R16,000, and carry R428 forward. The estimate for 1888 is for an outturn of 1,050 maunds.

GIELLE TEA COMPANY.—The report of the directors shows that 131,248 lb. were manufactured, which realised an average of annas 11-4·04 per lb. and left a profit of R23,343 and an available balance at Profit and Loss of R24,705. The directors recommended a dividend of 6 per cent, and that R705 be carried forward. The estimates for 1888 provide for a crop of 1,650 maunds.

CENTRAL TERAI TEA COMPANY.—The report of the directors shows an outturn of 1,976 maunds against an estimate of 2,120 maunds and a crop in 1886 of 1,916 maunds. Mosquito blight [Helopeltis again.—ED.] is to blame for the difference. The average price realised was annas 7-2·7 per lb., and there is a balance at credit of Profit and Loss of R392. The estimates for the current year are for 2,100 maunds of tea.—*Pioneer*, Feb. 28th.

THE NEW MINCING LANE COMPANY.

For some time past Mincing-lane has been in a condition of suppressed excitement about a new Company, which was to be started to revolutionise the Produce Markets there. This morning the Prospectus of that Company makes its appearance in our columns, and puts the public in a position to estimate the character of the project which has occasioned so much talk. It discloses, for one thing, that the Company is to be most powerfully sponsored. Upwards of two dozen firms, containing among them the first houses in London, have been found willing to figure on the prospectus as "founders" or underwriters of the half-million of capital to be offered to the public next Monday. Barings are there, and the Rothschilds, and Frühling and Goschen, and the Hambros, and the Huths, and the Schröders—as imposing an array of names as ever propped a foreign State or launched a Brewery. There must be something good, one would think, in a project which finds so many merchant princes and princely financiers to back it. Certainly it looks a modest and innocent scheme enough. "The object of the Company," says the prospectus, "is to place on a secure basis, by a system of deposits, the dealing in produce for future delivery, which has become such an important development of trade both in Europe and America." By the "facility" and the "security" which the Company will provide, it is contended that business which now goes past London will be brought back to it. Mincing-lane, in a word, will become again the leading market of the world for coffee, and for other produce too, should this Company succeed, and will no longer be the dead and alive spot it now is. In proof that this happy revolution is about to be effected, the "eminent success" of similar Institutions elsewhere is pointed to. A "Caisse de Liquidation" has existed for a number of years at Havre, and a similar Institution was recently established in Hamburg, and these have been "very profitable undertakings"—a fact which we can believe. They have also, say the promoters, given important and safe development to local trade—which is a statement that requires a great deal of independent proving before it can obtain credence. For an important distinction has to be drawn between the prosperity of the Caisse or Clearing House and the prosperity of its patrons. There is no reason to doubt that the keepers of the gaming tables at Monaco prosper, but it does not follow that the gamesters do so. In like manner, some of the Stock-gambling agencies which take deposits and deal on "margins"—the "bucket-shops," as they are familiarly called—appear to make money; but it is at the expense of their customers. The fallacy underlying such statements as those in this Prospectus is that they treat gambling as if it were a productive industry, which is exactly what it is not. A thousand bags of coffee may be passed from hand to hand fifty or a hundred times at ever-varying prices, and be worth just the same money at the end of it all as at the beginning. All that happens in the transit is that a certain number of people are made poorer by so many commissions, and the differences which they have to pay.

Regarded in this light, then, we are bound to say that the new Company appears to promise a prosperous career to its shareholders—at any rate for a time—at the price of a very great deal of loss to the public. Its ways of earning money are plainly and honestly set out in the prospectus. Each contract or bargain will carry a brokerage, money will be lent at interest, and members will pay entrance fees and subscriptions. By and-by, when metals, cotton, corn, seeds, &c., are added to the coffee and sugar with which the concern is to be started, the range of chances of gain will be immense. No broker in Mincing-lane will then be able to stand outside the Company's doors. They must become members of the huge produce "bucket-shop," or perish. The Company will thus grow to be the most powerful controller of the Produce Markets which it is possible to imagine, able to dictate its terms to the brokers, and to "rig" or depress prices at its pleasure. At present, and owing to the opposition it has met with at its inception, it modestly promises that the leading brokers in each article shall be consulted by the Directors in the framing of regulations for dealings; but that is a condescension which is pretty sure soon to become unnecessary. Profits are assured to the Company, but the more its gains expand, the more money the public lose. Such has been the experience at Havre and at Hamburg, where the reckless speculation in produce fostered by the Caisse de Liquidation has brought about commercial failures and wide-spread ruin. It stands to reason that such consquences must follow this mode of doing business. The Clearing House now to be started is not merely a centre where bargains can be adjusted, set off against each other, or liquidated. Within such limits, it would have been a useful Institution. But that work would not require the intervention of a Joint-stock Company, any more than the "Clearing" of bankers or of the Stock Exchange. The brokers of Mincing-lane could easily have formed themselves into an association for this purpose, had they been so inclined, and might have done so without modifying their ways of doing business in the manner now proposed. The true function of the new Company is that of stake-holder in a gamble. It is designed to open the markets of Mincing-lane to the man in the street, the loafer in the Clubs, the frequenter of City taverns—anybody and everybody able to command a

five pound note. Were genuine dealings in sugar and coffee alone in question, a capital of fifty thousand pounds would have been quite enough for any Company of the kind; but the aim is free gambling, not honest business, and hence this great parade of money. The Comany must have enough margin of means to be able to attract deposits and to guarantee the payment of differences; to lend, also, to its unlucky customers From this point of view the proposed business wear an extremely repulsive appearance, but—such is the extent to which speculative habits now prevail-it may be all the more profitable for that. There, indeed lies the sole justification, such as it is, for the creation of this Company. "People will gamble," it is said' "and if we do not enable them to do so at home they, will go to Havre or Hamburg." This is quite true, and were the project based openly and frankly on this ground there would be little more to be said. Its existence would have to be regretted, but it would at least not come into being under false pretences.

The founders of the Company, however, hold altogether lofty language. They are quite the Gladstones of commerce. They euphemise gambling bargains as "special transactions," and announce that by placing these on "a good commercial basis" the Company may be "considered as of general advantage to British trade," which is now "injured" by so much "business" being diverted to other channels. Take the cant away from this language, and all we have left is an assertion, probably true, that the people who have hitherto thrown the dice at Havre or Hamburg will now do so in London. They will do this, and their example will draw thousands of people after them to lose money for the good of the "Clearing House." But this has nothing to do with the prosperity of British trade. All the gambling in the world will not make the English people larger drinkers of coffee than they have been, or greater eaters of sugar. But it is quite possible that a considerable portion of the large transit trade in produce of all kinds which now centres in London might be lost to us as the result of "bear" speculations conducted under the wing of the "Clearing House." Or there might be an excessive importation, as the consequence of a "rig up" of prices which would end equally disastrously. The best that can be said for such an Institution is that it may provide a readier market than Mincing-lane now does, with its old-fashioned ways and prejudices. Producers may be always, or almost always, sure of finding their goods saleable here, at some price or other. That is a plausible view, at least; but is it an advantage which outweighs the positive mischiefs sure to follow the introduction of the Havre system? Let us allow that under the present quiet, half-secret modes of doing business the market sometimes takes the merchant or the producer, or both, at a disadvantage, and still it does not follow that some plan less objectionable would not have met the necessities of the case. But there is no complaint hinted at against London modes of doing business. They are not gambling modes, that is all. Tom, Dick and Harry cannot now stake their "fivers" at a public table in the Lane, and lose them for the good of the keepers thereof; so the promoters of this scheme—foreigners, we believe, and men themselves of little standing in British commerce—mean to give them this additional chance. Genuine business cannot be helped by such means; but it does not follow that consumers will, on the average, suffer. They might gain. Now and then, no doubt, they would have to pay an unjustifiably high price for some article in which the crowd had a fancy to speculate for the rise, but this would be compensated for by the long periods of collapse and low prices which always follow escapades of this sort. There would have been no adverse criticism if the Mincing-lane brokers had formed an association, or groups of associations, like the cotton brokers of Liverpool, in order to adjust or control their own or their customers' time bargains. Such speculation would then have been for the most part legitimate, conducted by men who knew their business. It is because this "Clearing House" scheme is intended to attract the mad trade that it is so objectionable. The more striking its success, the more will it demoralise business.

THE CANTON TEA TRADE.

The minutes of a meeting of the Committee appointed to enquire into the state of the tea trade in Canton have been published. Mr. E. Deacon, the Chairman, having invited the members of the Committee to give their views, a long discussion followed and eventually it was decided to put on record some of the points worthy of the consideration of the Chinese authorities, unless the tea trade at Canton is to be seriously crippled if not altogether annihilated by the yearly competition with India. The Committee say that Canton scented capers, of which the bulk of their export consists, competes more keenly with Indian kinds than any other class of China tea, being especially useful for mixing purposes. But the competition is now growing so severe, and home prices have reached so low a range, that unless some steps are soon taken to relieve the tea of the excessive burdens of *lekin* and export duty, a time must come when scented tea will cease to be an article of consumption altogether. These scented teas are produced in districts the most remote from Canton, and are therefore subject to high inland taxation, which leads the native merchants to mix with it inferior leaf grown in Canton, and suffering therefore lighter dues. Buyers also complain of the large proportion of dust found in the teas, and the committee say, "the dust should if possible not be sent to Canton from the districts at all, as the *lekin* dues have to be paid on it as well as on the whole leaf, and this of course increases the ultimate cost of the tea; this complaint is especially to be made about leaf arriving from the Loting and Hoyune districts." Canton scented orange pekoe has—both in the long and the short leaved descriptions—been already seriously beaten out of the field by their Indian competitors. This is amply proved by the figures, which disclose the significant fact that in the last ten years the exports from Canton have fallen from 3,870,000 pounds to 1,000,000 pounds, and the decrease continues year by year, so that, as the committee say, it now seems impossible that this class of tea can regain the position it has lost on the London market. There is a steady market, as a rule, in London for the congous of which the best come from the Tayshan districts, and the only suggestion which the committee offer about them is that the growers should be contented with fewer pickings in the year, experience having shewn that the teas plucked in August and September are deficient in every quality except make. Of course, too, the picking of these teas in these months affects the supply of the autumn crop, which is the best produced from the districts. So much for the remarks which the Canton tea exporters make upon their trade, which are pretty much to the same effect as those offered by our own experts and by the Chamber of Commerce in Foochow. The Canton Committee sum up their minute by concurring in the opinions of the Foochow and Shanghai Chambers of Commerce, and consider that "the only real remedy for preventing total extinction of the trade is the abolition of all *lekin* and export duties, so that the China article may be on the same footing as the Indian, Ceylon and Java, all of which are free from taxes." The Canton committee make no reference to the valuable suggestion offered by the gentlemen who were deputed to make the report for our Chamber of Commerce, that the Chinese Government, if it is really anxious to improve the production of tea, should throw the country open to foreigners, so that they may establish tea hongs with modern machinery. This may however be dealt with in the report which the Canton merchants will doubtless make, for as much of their trade is, or rather should be, in scented and fancy teas, there would seem to be more necessity for reform in their production than in plain congous. But the Chinese authorities from the minutes leading to their views that the native merchants take the same view on this point as the Shanghai Chamber of Commerce. "The native grower must be looked to for any improvement in manufacture or production, and as long as he feels no

necessity for such improvement, it need not be expected." The Tsung-li yamên has now before it the opinions of the merchants at the principal tea marts, the gentlemen who drew up the Shanghai Report being all thoroughly acqainted with the trade of the river ports, and cannot fail to see in the concurrence of their views very striking testimony to the necessity of prompt action. There are one or two special points in the Canton Minutes. As to weights, they say that it is worthy of remark that teas shipped from Canton waters invariably lose in weight on the homeward voyage, whereas those shipped from Foochow and the northern ports always show distinct gain. The remedy for this is in the hands of the Imperial Maritime Customs, for native packers are prepared to allow an extra ½ lb, per box provided no export duty is charged upon it, a concession which the Imperial Maritime Customs will not grant. And the Minutes say that the steady fall in exchange has been of material assistance to the China grower, for it has enabled shippers to lay down their purchases in London at lower sterling prices year by year while paying almost the same tall prices to the Chinese as formerly.—*N.-C. Herald*, Feb. 24th.

THE COST OF THE PHYLLOXERA TO FRANCE.

To the end of the year 1884 the area of vineyards destroyed in France amounted to about 2,500,000 acres. In addition to this range of total extirpation of the vine 1,500,000 acres were under attack, being planted with vines that were diseased although not destroyed. M. Lalande estimates the loss on those vineyards as equivalent to at least a total destruction of 500,000 acres; giving a total loss of 3,000,000 acres, or half the entire acreage of the French vineyards. He points out that the damage thus inflicted on the country is not to be measured by the mere value of the vines. This may be taken, according to the usual French allowance, at about £100 per acre, being valued according to the net returns derived from the average crops. But, in addition to this profit or net return, a further and hardly less considerable loss to the country is inflicted by the failure of the labour formerly devoted to the vineyards. The value of the naked soil remains, but the greater portion of the vineyards are situated on land unfitted for other culture. In estimating the loss incurred from 1875 to 1884 at three hundred millions sterling, M. Lalande thus keeps within the limits of probability.

With regard to the loss of the annual remuneration of labour, it is difficult to give an exact valuation. M. Lalande, however, considers that an approximate estimate may be formed from observing the importation of wine and of dry grapes that is rapidly increasing into France, and which is caused by the need of providing a substitute for the perished crops, in the production of wine. The increase in these imports have been very striking. In 1875 the value of the foreign wines imported into France was £333,000, and that of raisins or dried grapes £230,000. In 1887 these figures had increased to £21,000,000 for wine and £3,920,000 for grapes. The value of the total importations of these articles for the thirteen years—1875 to 1887 inclusive—amounts to an aggregate of 152,000,000, so that the estimate of £400,000,000 for the loss inflicted on France by this destructive pest is probably far under the mark. When it is considered that this whole devastating army is the progeny of very few invaders—possibly of a single egg—the extraordinary energy of the prolific power of nature has never before been so signally illustrated. Nor does there appear to be any compensation for the mischief. The best energies of French science have been worthily taxed in the struggle with the microscopic devastator, and down to the present time the swarming aphis has got the better of mankind.—*St. James's Budget*, Feb. 18th.

QUININE AND HEALTH.

An urgent correspondent of the *Independent* is anxious to know what it thinks of the bearing of quinine upon human health and longevity. We do not wonder that such a question is asked in many localities. Although we have never been able to verify the statement that in certain portions of the Western country it is the chief medium of exchange in place of silver, we fear that the idea has some foundation. It is certain that no other drug has such a large consumption, and that it has come to be regarded as a necessity of civilization. We almost wonder how our forefathers could have lived without it.

To those going into new regions of country, it is a companion if they are wise. Scarcely any one now doubts its efficiency, not only in malarial seizures, but in warding off that most insidious miasm. It certainly fortifies the system, and acts as a prophylactic. So true is it, that those passing for the first time into a malarious region are the most liable to attack, that it almost seems rash to neglect it as a precaution. Not less indispensable is it in the treatment of intermittent and remittent fever.

It seems to have been provided as the great specific of nature. Even to the physician who over and over again has witnessed its mastery it is little less than miraculous how the shaking ague will yield to its control unless there are special complications, or unless a habit of malarial subjection has been established. It has even extended its domain far beyond this. In other forms of fever, and certain conditions of innervation or want of general tonicity, it is largely available although needing to be used with great discernment. There probably never was a time in which the use of some form of Peruvian bark, under the name of china, cinchona, quinidia, etc., has been so extensive as at present. It may be said in general that the use of bitters did not begin with this, and that it has substituted many of them only because of its greater convenience and its more concentrated and effective forms. It is well known that most of the bitter herbs have allied powers. They will diminish the amount of mucus in the stomach, fortify the nervous system, and in giving tonicity to the tired and to the exhausted vitality.

There are some reasons why such bitters as dogwood, wormwood, hops, rue, and some others, should not be set aside. They have certain additional or modified effects which are recognized by those familiar with their use, and should be valued for their tonic effects. In the use of medication as well as in foods, even a good medicine needs a change, and there is benefit in some other form, just as we change, with advantage, from one form of flesh to another. We believe that in this age of strain and stress there is no class of materials that are so often needed as some of the multiplied forms of bitter trees, vegetables, or herbs. Indeed, they belong so closely to the vegetable world, and contain so much that is allied to foods, or convertible thereinto, that they should hardly be regarded as medicines. The depressions from exposure to long winters and to excessive heat undoubtedly respond to and are relieved by this kind of nurture. Enfeebled stomach digestion is often relieved thereby.

But may there not be over-use, and especially of the cinchona preparations? Undoubtedly, and for this reason skilled medical and dietic advice is often needed. There are cases where the liver has become so engorged, or where by reason of some organic change either the power of quinine is suspended or made harmful. When the spleen has become enlarged by reason of severe or frequent attacks of malaria the absorbent or lymphatic systems is so involved that the quinine when used has no effect, or may even irritate. It is admitted that its continuous and uninterrupted use tends to produce congestion of the minute vessels of organs. So what in many cases what

is a stimulus in the direction of cure may become, in an overtaxed organ a congestant. The same might be true of a food. The effect on the nervous system and the circulation is shown by the sense of fullness in the head produced by large doses. We think that it can be asserted that it is one of the most valuable of medicines, and has more claim to be called an accessory food than alcohol. Surely it should not be used at random, and the medical adviser may need often to be consulted as to indications and contra-indications for its use. But it can safely be said that it is less abused than most medicines, and that we may easily rank it as among the most valuable of American discoveries. While there is no such danger of acquiring a quinine habit as a morphine habit, the abuse of the drug is not uncommon.—*N. Y. Independent.*

THE FUTURE OF CINCHONA.

A correspondent, who takes much interest in cinchona bark, writes:—

"Of course 2 million lb. has been about the normal stock in Colombo for a considerable time, so the surplus here is only 1 million lb. With regard to future exports I heard bad news of cinchona upcountry, viz. that the drought had killed a large number of trees. This will add to the exports. Then, if prices go up to any extent, many would harvest and exports would go up to a large figure. With coffee failing in Uva, and little tea to fall back upon there as yet, cinchona will be harvested wherever available. All these circumstances make me think it best to prophesy as little as possible. It is the opinion of an old planter that in three years cinchona will be almost finished in Ceylon, the decadence is so great. And he strongly advocates the introduction of fresh seed. He says there is no seed here worth sowing, the deterioration is so great in this country. This is undoubtedly a very important subject." A fresh supply of seed should be got from South America through correspondents in Bolivia or Peru.

THE MINCING LANE SYNDICATE OR CLEARING-HOUSE.

(*By a Mercantile Correspondent.*)

It was, we believe, the boast of the Messrs. Rothschild that they never employed their enormous resources to control the produce markets, or to interfere with the regular course of trade although they would have been justified in doing so by the example of one of the founders of their race, who was the inventor of the system of forestalling now carried on by syndicates, rings, and trusts, but we see by the prospectus of the London Produce Clearing-house, that their virtuous resolution has at last succumbed to surrounding influences, and they are now giving their powerful assistance to the formation of a Joint Stock Company incorporated, we presume, alternately to regulate dealings in commodities on the Stock Exchange system of dealings in monetary transactions. Though the first syndicate, according to Mark Twain, was formed by Joseph and Pharaoh, the system now intended to be regulated, though known through succeeding ages as forestalling, has only been carried on on a large scale during the last thirty or forty years. It received a great impetus during the American war, when operations in cotton became extremely risky. The merchants in the cotton trade naturally wished to make the result of their purchases safe by a sale to arrive. The buyer actuated by the same motive resold his purchase at a small profit; and in this way a single transaction developed into enormous proportions. The system has gradually extended to nearly every article of produce, and is now carried on by Associations of very mixed character, none of them, we fear, very good, and many of them formed for the purpose of making losses pecuniarily safe, which would be irrecoverable by law.

The Press has generally denounced this public attempt to regulate and encourage transactions, which, though now almost universal, are in themselves illegal when they are not based on actual possession of goods dealt in or when they are merely what is called "time bargains." The law making forestalling in England illegal was repealed in 1844. The American and German Governments are now threatening to suppress rings and trusts, and every merchant who carries on a legitimate trade is calling out against them. We fear, however, that all attempts to put down one of the practices of the age will be as fruitless as it is to suppress all the vicious customs by law. And we have no doubt the shares of the London Produce Clearing-house will be eagerly sought for, and that those who are fortunate enough to get allotments will make a good thing out of them.

We notice that Produce Brokers generally are opposed to the formation of the Company. There is only one of them amongst the founders. We are rather surprised to see so many capitalist merchants amongst the promoters. We should have thought it would have been confined to the large foreign agency firms, whose business was being interfered with by their Continental competitors.

CINCHONA IN JAVA AND IN BADULLA DISTRICTS.

Mr. Macfarlane of Cannaverella may well write with some exultation, with such splendid results before him from his fields of cinchona—which we pronounced about the finest in the island over two years ago when in Badulla helping to inaugurate the new province. We remember we urged Mr. Macfarlane to commence shaving his five years old trees in 1886, and we are glad to see he has done so to such good purpose. In Java, it is said, the shaving and renewing process is not a success. We quote from Mr. Macfarlane as follows:—

"I have been reading all about cinchona in Java in the *Observer*. As far as Cannaverella is concerned I don't fear Java in the least. 12,000 lb. of bark from here analyzed 5·11 per cent sulphate of quinine the other day in Colombo, this being the fifth time the trees from which the bark was taken had been shaved. Only 1·86 of rain has fallen here since 1st January."

PEARL FISHING.

THE INDUSTRY IN WESTERN AUSTRALIA—HOW THE GEM IS FORMED—CURIOSITIES AND IMPORTANCE OF A DEEP-SEA CALLING.

An important industry of Western Australia is the pearl shell and pearl fishery. It is only of late years that the presence of the pearl oyster in this part of the world has been discovered, the coasts of Ceylon and other parts of the East Indian seas, and also the Gulf of California, having previously supplied, as, indeed, they probably still do, the larger part of the pearls of commerce. But the number of vessels trading on the north-west coast of Australia has been increasing rapidly during the last few years, and there are prolific banks there in abundance, on which are found both the large oyster, the shell of which is principally valuable for the mother-of-pearl of which it is composed, and the small oyster, which is the true pearl-bearer.

The larger kind is from 6 in. to 10 in. in diameter, and the pair of shells weigh from 2 lb. to 4 lb., or sometimes more. These oysters not infrequently contain pearls, but it is for their shells that they are sought. The true pearl-bearing oyster is scarcely larger than an ordinary oyster, and the shell is of very little value. Single pearls have been found on this coast valued at £500 to £1,000, but the most curious pearl discovery that has been made either here or elsewhere, was made on this coast a few years ago, when the new farmers "Cœur Australis," or Southern Cross pearl, was revealed. This is a perfectly natural cross of nine pearls, all in one piece. The finder of this

unprecedented gem was, as often happens, unware of its value and sold it for 100 dol. The purchaser considered himself fortunate when he was offered 2,000 dol. for it by four gentlemen in Perth. They sent the curiosity to England and had it mounted and exhibited in the recent Colonial and Indian Exhibition in London, where it attracted a great deal of notice and was offered for sale at the advanced price of 50,000 dol.

Whether a purchaser has yet been found for it is not known. The exhibitors hoped that His Holiness the Pope might consider it his duty to become the possessor of so marvellous a natural production of the Holy Tree; and perhaps some pious devotee may before now have purchased it for a jubilee offering to the Pontiff.

Curious enough, the largest single pearl on record has recently changed hands on the death of its late proprietor, Beresford Hope, an English member of Parliament. This gem, which, till the discovery of the Southern Cross, was the most valuable pearl known, weighs no less than 30 oz., is 2 in. long and 1½ in. in diameter.

Pearls are not as valuable in modern day as they used to be in ancient times. There is a pretty story told in the Talmud which illustrates the fact that in the very earliest days they were considered the most precious of all gems. This is not, however, to be wondered at, when it is remembered that all the gems which in modern times have eclipsed the pearl owe a great part of their beauty to the skill with which they are cut and polished, while the beauty of a pearl is purely natural.

Pearl fishing has been going on during the last few years all around the north coast, off Port Darwin, in Torres Straits, and off the coast of North Queensland generally, but just lately the fisheries off the western coast have been coming into the highest favour, and boats have been arriving there from the other parts of Australia and from Singapore. Mr. Streeter, the famous jeweller, of Bond-street and Cornhill, in London, has himself had a boat there for the last year or two, and only towards the end of last year or the beginning of this lost one of his sons, who was engaged in the pursuit of pearls.

These new comers have introduced the use of the diving dress, in which white men descend to collect the shells, but a large part of the fishing is still carried on by Australian natives, who are very good at diving, and can stay under water for a long time.

Most of the boats which boast a diving dress are strong lugger-rigged craft of seven or eight tons burden, built for the most part in Sydney. They are generally manned by seven men, one of whom combines the functions of skipper and diver. He goes down to the bottom, and one of the crew keeps hold of the single rope.

Oysters are not such stationary creatures as might be supposed, and the divers say that they remain detached from the bottom and allow the tides to drift them about constantly. Thus the different patches of shells are always shifting.

For deep sea fishing, of course, the diving dress is a very great advantage, but the price of the outfit is considerable, and on the shallower banks at any rate the natives do very well. These of course wear no sort of clothes, but dive to the bottom, carrying with them a sack or basket in which to collect the shells. They can stay down for a full minute and sometimes longer, and they occupy their time in busily loading the receptacle they have brought down with shells.

In this they make a good deal of use of their toes, with which they can pick things up with marvellous dexterity. Their great toes can be moved out from their feet as easily as a white man's thumb from his hand, and this is the way in which they habitually pick up any small object off the ground, thus saving themselves the trouble of stooping.

The life is a very trying one, owing to the great pressure of the water at the depths to which they have to descend. Sharks also introduce a formidable element of risk, and a pearl diver's life is rarely, if ever, a long one. The poor fellows get so little for it, too, that one cannot but pity them. On the coasts of India the diver gets one-fourth of the produce of his labour, * but not so the poor West Australian though for the matter of that he would be no scrap the better off if he did but rather the worse for having no idea beyond the beast f the field what to do with money, he would assuredly spend it all either in drink or in clothes, both of which would be most injurious to him.

The export of pearl shells from Western Australia during the year 1885 was valued at over 217,000 dols., and the pearls for the same year were worth about 75,000 dols. Probably the take last year was considerably larger, but this year it will be very small indeed, for last April, just at the end of the fishing season, a most terrible catastrophe overtook the whole fleet or boats which was fishing off the coast in the neighbourhood of Roebourne and Cossack.

A hurricane of the very violent and local type known as "cock-eyed Bob," or by the native name of "Willy Willy," dispersed the fleet, and sank nearly all the boats. Some six and twenty boats, most of them luggers, and laden with shells, were lost, and a considerable number of white men, with as many as 140 native Australians, were drowned.

The business of getting the pearls out of the oysters is an intolerably disagreeable one. The oysters are thrown into large vessels, and left to die when the shells open of their own accord. The shells are then removed, but the oysters themselves are left in buckets till they become decomposed, when they are well stirred. The pearls sink to the bottom, and the remainder is poured off. It may be readily inferred that the odour in the camp of pearl-seekers is more powerful then pleasant. The innumerable flies, sandflies, and mosquitoes that swarm around do not tend to make the neighbourhood more soothing to the feelings.

If the end of the pearl's connection with the oyster is offensive to our nostrils, the beginning of it is supposed to be not less offensive to the excellent bivalve itself. The pearl has its origin in the efforts of the oyster to protect itself from the irritation caused by the presence of some foreign body between the shell and its mantle, as the soft skin of the oyster is technically termed. The foreign matter may perhaps in some instances be a grain of sand, but is believed to be more often either a parasite of some kind, or perhaps an egg belonging to the oyster herself. To mitigate the suffering caused by this vexatious intruder, the oyster deposits thereon a coating of the same material as that of which the shell is composed, and, when once this process has begun, it continues, till the time the pearl grows large enough to kill the oyster. If this occurs the shells open of their own accord, and the pearl is lost to man. This danger, and others that attend the lives of oysters, even in their deep sea home, makes it inadvisable to leave the banks too long unfished, though, of course, so long as the oysters continue to live, the older they are the larger the pearls they contain. It is thus still a matter of doubt at what age it is most advisable that oysters should be fished for, but the general opinion seems to be that they are at their best, on the average, when four years old.†

If the pearl is buried in the soft substance of the oyster it is round or pear-shaped generally, and is called a pearl, or, if very small, a "seed pearl." If, on the other hand, one side of the pearl is adhering to the shell, while the other is round, it is called a "button pearl." Sometimes a boring parasite makes its way through the shell, but before it gets quite through the oyster feels the irritation and pressure which it causes, and deposits a layer of pearly matter on the shell itself. This is called a pearl blister. These are often found of curious shapes, but they are not of great value, except as curiosities.

The formation of pearls is thus in point of fact common-place enough, suggesting even to the prosaic

* In Ceylon the proportion has been one-third for sum years back.—ED. *T.A.*

† The belief is that full maturity is attained in the seventh year, but oysters so frequently die off, or are swept off by currents before attaining this age, that it is deemed advisable not to delay fishing beyond the fourth year.—ED. *T. A.*

mind the formation of the common corn on the human toe.

To the fanciful minds of Oriental nations no such crude explanation has occurred, and they still attribute to pearls a much more poetic origin. The oysters, they say, rise by night to the surface of the water, and, opening their shells, receive therein a single drop of dew. This in time becomes a pearl, and, if the dew has been pure and clear, the pearl will be a beautiful one, but, if the drop of dew has been soiled with impurities, then the pearl will be opaque, and of no value.

Before leaving the subject of pearls, it may interest some to hear that there are fresh water pearls as well as sea pearls. These are found in a species of mussel which grows in most temperate latitudes. Pearls have thus been found in several rivers in America, as well as in the British Isles, Germany, where there is a considerable trade in them, China and other countries. These pearls are more lead-coloured, and have not the beauty of sea water pearls.

Linnæus, "the father of naturalists," received the honour of knighthood for demonstrating the possibility of artificially producing the formation of pearls in the pearl-bearing mussel. But, as has been the case with other European inventions of which we have thought a great deal, it has since turned out that John Chinaman has been doing this thing for a couple of thousand years or so. The Chinese method is to take the mussel from the river, carefully force the shells a little way apart, and insert between the mantle of the oyster and one of the shells a few-pellets of clay, tiny pearls, or foreign bodies of some kind. When this has been done the oyster is turned over, and the poor fellow is obliged to submit to a similar uncomfortable process on his other side. He is then put back into a pond, where he is kept well and fat by a diet more nourishing than nice. After a few months, or sometimes a year or two, he is again taken from his bed, his pearls are taken out, and he is eaten.—*San Francisco Chronicle.*

TEA AND ITS PREPARATION.

Mr. R. G. Andriesz, well-known for his statuary sculpture, modelling and other artwork, has been employed by Mr. Rutherford to make models (in composition) coloured to life, of cooly men and women in the different operations connected with tea from the carrying in of the leaf in baskets to the hammering of the tea-chests. The result is 18 well-executed and very interesting miniature models showing everything very clearly. Two models are of the Superintendent and his Assistant. The set is, we believe, intended for the Glasgow Exhibition, and we may mention, to encourage a deserving local artist, that Mr. Andriesz is prepared to make duplicates at R3 each model.

CHINA TEA.

The following letter has been received by the Liverpool Chamber of Commerce on the subject of the export duty on China tea:—Foreign Office, Feb. 15th, 1888.—Sir,—I am directed by the Marquis of Salisbury to acknowledge the receipt of your letter of the 7th instant relative to the amount of the export duty on tea from China and the advisability of an application being made to the Chinese Government for a revision of the tariff established under the treaties with China of 1842 and 1858. I am to request that you will inform the council of the Liverpool Chamber of Commerce that the subject to which they have drawn Lord Salisbury's attention shall be taken into consideration, but that inasmuch as the treaty of June 26th, 1858, was not ratified until the signature of the convention of Oct. 24th 1860, the tariff under the former instrument must be considered as having been established at last-named date only, and it will therefore not be open to Her Majesty's Government to demand a revision of the tariff until the year 1890.—I am, &c., P. W. Currie.—*L. & C. Express*, Feb. 24th.

OYSTER AND SPONGE CULTURE FOR JAFFNA?

The lack of fuel, or other motive power must be always a bar to any extensive manufactures. With no rivers or coal beds, large factories cannot be looked for here. A tide mill might be erected at Tondimanaar, but compared with the great factories of other places, that would not be worth mention. What then has Jaffna that other places have not? Some say it has exceptional facilities for tobacco, both in soil and climate, and that, if only scientific methods of curing the leaf be adopted, it can furnish a superior quality. It is true that tobacco has brought a considerable amount of money into the province, and will probably continue to do this for some time to come. But in the end it will not pay. To say nothing of the deterioration of the lands, which is sure to follow, the deterioration of the health and the morals, which always accompanies the increased cultivation of tobacco, is a very serious consideration. What then can Jaffna produce better than her neighbours? Let us look at the place geographically. A low coral peninsula, near the equator, near a continent teeming with human beings, a strong sea current on one side, on three sides a shallow sea of comparatively quiet waters, with no large rivers pouring fresh water into them. Such rivers seem to be necessary for pearl oysters to thrive, albeit they sometimes destroy them. These circumstances seem to be especially favourable for two industries, sponge growing and fish breeding. It has been demonstrated that an acre of water will give a better harvest than an acre of land, if properly cultivated. Jaffna may reap a harvest over ten times its own area. Sponges already grow in these waters, but not the good qualities. The best sponges must have a temperature never below 60. They must be free from river water, and comparatively quiet. Some person familiar with the sponge industry, might give an opinion, and if favourable, a few live sponges might be brought from the Red Sea, and protected for a time and then the industry is started, bringing in ultimately thousands of pounds income. Hindus do not use many sponges now, but 100 years from now there will probably be a greater demand in India than in Europe. The advantages of Jaffna waters over the Red sea are that they are more equably warm and adjoin a deep sea current. The circumstances are strikingly like Key West, where sponges are gathered. We must leave fish culture, and another point until the next time.—"Morning Star," March 1st.

INTRODUCTION OF TROUT OVA TO THE NILGIRIS.

[It will be seen from the following extract from the *Madras Mail* that success has not yet crowned the efforts made, but that it is certain to be attained.—Ed. *T. A.*]

Mr. H. Percival Hodgson writes to us from Ootacamund:—

"I arranged while at home last year for the purchase of 150,000 ova from Mr. W. J. Silk, of Burghley Park, Stamford. It was thought best to divide the ova into two lots of 75,000 each, so that if the one failed, the second batch might succeed. The first lot left England by the P. & O. steamer 'Rohilla,' and arrived in Madras in January. They were cleared and sent forward at once—but on arrival they all proved to be dead, having hatched on the journey. The second lot came out by B. I. Steamer 'India,' and arrived in Madras on the 4th of this month. On this occasion Mr. Marsh went down to meet them, in order to see that a proper supply of ice was kept round the ova box during the hot railway journey from Madras. When opened here, some of the eggs in the upper drawer of the box appeared to be alive—but all the rest had either hatched out on the journey, or appeared to have died from the effects of a sort of fungus that had grown

over them. The best eggs were put into hatching boxes that had been prepared for their reception, and in the course of the same day of their arrival, two young trout hatched out alive. Our hopes were now raised that we should succeed in at least obtaining a sufficient number of young fry to form a stock from which to propagate in the future. But the young fish as they came out appeared to be weakly, and although some fifteen in all have hatched out, we have only some eight left alive, and it is very doubtful if we shall succeed in rearing them. The fungus already spoken of seems to attack the young fish, although they were at once separated from the infected eggs, and is probably the cause of their death. The experiment therefore may be considered a failure—but I have no doubt from the experience gained that it can be successfully carried out. I believe the eggs were in a too advanced stage when they left England. Mr. Silk was anxious that none but good ova should be sent out, and with this view he kept the ova in England until the eyes appeared, with the result that the fish hatched on the journey. In future it should be arranged that the ova are despatched as soon as taken from the fish, and as it takes some sixty or seventy days to the time of hatching, this would give ample time for their transit to this country. Some improvements in the boxes in which they came out might also be made, and I have every confidence that, when the experiment is renewed next season, it will be successful. We have shown now that it is possible, and I hope to induce the Nilgiri Game Association—which has considerable funds at its credit—to take it up, and to import several boxes of trout ova next winter. We have beautiful streams and brooklets on these Hills in which it is certain trout would do well if once introduced. We have only to turn to the success of the experiment in Ceylon to prove this and, in spite of present failure, I yet hope to walk the brook sides of the Nilgiris rod in hand, and with a few 'speckled beauties' in my basket. I would take this opportuinty of publicly tendering my thanks to the British India Company for the sporting way in which they at once came forward and offered to bring out the ova free of charge. My thanks are also due to Messrs. Arbuthnot & Co., who took considerable trouble and interest in landing and forwarding them."

TEA AND COFFEE ADULTERATION.

There is one virtue which the opponents of Indian and Ceylon tea are reluctantly compelled to allow these teas, viz., that they are free from adulteration. The public analyst for the City of London (Dr. Sedgwick Saunders) in his annual report for the past year refers to tea as follows:—"This article does not very frequently come under the official notice of the public analyst, as teas are now examined in bond by the analyst to the Commissioners of Customs, who in 1886 received no less than 2,546 specimens. These represented consignments amounting in the aggregate to many thousands of packages. No less than 7,255 of these came under the prohibitory provisions of the Act, and were either seized or restricted to exportation: 5,113 of these were 'capers,' and were adulterated with exhausted leaves to an extent varying from 10 to 20 per cent., besides being loaded with from 7 to 11 per cent. of sand; 1,693 were congous, 1,575 of which were China teas from Marseilles, the remainder from China (these teas were all adulterated with exhausted leaves varying from 20 to 30 per cent.); 420 were tea-dust from China, and 21 tea-dust from Japan, containing 10 and 18 per cent. of mineral matter respectively; 4 packages green tea from Singapore with 6 per cent mineral matter, and with leaves other than tea. There were also four packages which were unfit for human food, and which were seized and destroyed accordingly. As distinguished from the above the teas from India and Ceylon seem to be rarely adulterated. That this inspection is very thorough is shown by the fact that in the same year public analysts examined 511 samples, only one of which was reported to be adulterated. In former years, when tea was a highly priced luxury, it was tampered with to an alarming extent; and in this connection it may be interesting to quote from an Act of George III which recites that 'great quantities of sloe leaves, and leaves of ash, elder, and other trees, shrubs, and plants are manufactured and sold in imitation of tea, and that such evil practices are increased to a very great degree, to the injury and destruction of great quantities of timber, woods, and underwoods, the prejudice to the health of His Majesty's subjects, the diminution of the revenue, the ruin of the fair trader, and the encouragement of idleness.'"

Of coffee, Dr. S. Saunders says:—There is little doubt that the article when ground is largely mixed with chicory (I have found 40, 50, and even 60 per cent.), but it seems to be a recognised custom in the trade of a retail grocer, especially in the poorer districts, to sell such a mixture when coffee is asked for, and, as a rule, the purchaser is well aware of the fact. A few months ago a large number of samples of coffee were privately purchased by my directions from small traders in the poorer districts of the city; half at least of them were found to be mixtures of coffee and chicory in varying proportions. The matter was followed up and samples taken under all the complicated *minutiæ* of the Act, by the inspectors at the shops of the chief offenders. With only one exception the samples that reached me were coffee pure and simple. In the exception mentioned the amount of chicory was estimated, and the "foreign ingredient" photographed under the microscope, thus proving the undoubted presence of chicory in case of any appeal. The whole of this work was in vain, and it subsequently came to my knowledge that the vendor had informed the inspector that the sample was a mixture before the purchase was completed. These coffee-sellers may have become aware that their wares were under surveillance, and hence the failure to get a conviction; but the following is probably the true reason why no adulterated samples were secured:—When the first batch of coffee samples were taken unofficially an ounce of coffee only was asked for; the inspector who called a few days later demanded a pound. As these small traders are generally asked for ounces or pennyworths only, such an unusually large order may have excited suspicion. In one case, where an ounce had in the first instance been found largely adulterated, it was discovered that the trader was in such a small way of business that he was unable to execute an order for a pound, as he had not sufficient on the premises. The grocers doing a better class of business, when asked for coffee, as a rule said, "Do you want pure coffee?" and pure coffee was also supplied when demanded. Those citizens who require pure coffee can, therefore, procure it without any difficulty; in fact, there are establishments in the City where the purchaser can have the berry roasted and ground before his own eyes free of any extra charge.—*H. & C. Mail*, March 2nd.

CHINA TEA.

At the outset of tea cultivation in India, we have been told, two great mistakes were made. It was thought China possessed a monopoly of "drinkable" leaf, and so Chinese shrubs were brought round and planted in Assam; and it was thought every Chinaman knew by instinct all about the growth and preparation of tea, and so every Chinaman who could be got hold of in the Calcutta bazaar was enlisted and taken to the scene of the new enterprise. The last mistake was easily rectified; the Chinamen were very soon found to possess no monopoly of knowledge, and were sent back; but the effects of the first mistake were ineradicable. The Chinese plants took root and inter-married, producing a hybrid which is now declared to be much inferior to the native leaf. We are reminded of the incident by a passage in the letter recently addressed by certain gentlemen interested in the tea trade, to the Commissioner of Customs

at Shanghai. The whirligig of time brings about some strange revolutions, but never has it effected a more complete one than is here indicated. The despatch is now recommended, of "a number of intelligent and practical Chinamen" to learn the modes of cultivation and curing in vogue in Ceylon and India! "so as to become teachers to their fellow-countrymen on their return." *Sic transit!* Well may Rogozin argue that the Yellow Race has shown itself capable of originating nearly everything, and of carrying its inventions to a certain point—but no farther. China was the first to introduce tea to the knowledge of the Western world; but the Chinese grower has not only been left behind, but has retrograded in the struggle for existence.

Apart from the natural incapacity of the Chinese for the thoroughness which foreigners bring to bear on any given pursuit, we should not be surprised if this question of taxation were really at the bottom of the whole difficulty. May not taxation be in a great measure responsible for the decadence? Driven to compete somehow, under a heavy handicap, with teas that are almost free from taxation, have not the Chinese tried to produce cheapness by skipping labour,—with the inevitable consequence of inferior production? The mandarins will of course be apt, if remonstrated with on the subject, to reply with a *tu quoque*, by pointing to the heavy import duty in England. But that has nothing to do with the question. The 6d. a pound is levied here on all alike—India, China, Java, and Ceylon. The handicap is at the other end—where Indian teas start free, and China leaf is weighted with an average 30 per cent. duty: for "the average price of Shanghai Congou, this season, has been (we are told) about Tls. 14½ duty paid," and "duty and *lekin* amount to Tls. 4.10 to Tls. 5.40, according to districts." How is it possible for the Chinese grower to compete under such disadvantages? "It is an unchallengeable axiom that a trade gravitates to the country that can produce the cheapest article, and in the instance of tea we find it going to the countries that are most lightly taxed. The black tea trade is going to India, Ceylon, and Java; the green tea to Japan." For the cheapest article, it may be remarked, does not necessarily mean the lowest-priced, but that which affords best value for the money. And this conclusion brings us back to our suggestion that the Chinese tea has become so bad, because the grower has been trying to meet his handicap by lessening the cost of production; overlooking—driven possibly to overlook the fact that in so doing he was slowly killing the goose. And the curious point is that the thing originated—or at any rate assumed its grievous form—through an initial blunder. Tea was intended to bear, like other articles, a 5 per cent *advalorem* duty; but the "value" was fixed at an absolutely unheard-of rate; so that, instead of bearing 5, it really paid a 10, 12, or 15 per cent tax, according to district and quality. And then came *lekin* to aggravate the evil! Foreigners have, then, a solid standing-ground in recommending that a reduction in export duty be effected, by lowering the tariff to the actual value; and we can only trust that a gleam of common sense may convince the authorities of the necessity of relieving the leaf from *lekin* also, unless they are willing to leave themselves eventually with no trade to tax.

The Chinese Government has appealed to foreigners interested in the trade, for aid; and advice has been frankly given. In this matter of taxation, the remedy is clearly and simply in their own hands, for "the people" would certainly not object to relief from impost! It is equally within their power to press home the recommendations of the Foochow Chamber about more careful cultivation and packing, and the cognate suggestion of the Shanghai merchants about smaller chops. It is easy to understand the deterioration of leaf and mixture of qualities that result from an effort to produce a 1,000 or 3,000 chest chop, and the superior advantage of the Indian practice of making the day's pickings into a 100 or 150 chest chop which comes out, naturally, of even quality. Whether it would be equally easy to enforce the suggestions about foreign machinery, foreign supervision, and foreign planting, is another question. We have had some experience of the difficulty of introducing machinery into English agriculture in days when population was less dense than at present and we have heard, lately, the opinion of more than one competent observer, of the risk that might attend the experiment in densely populated China. The displacement of labour by the introduction of tea-rolling machinery might not be very great, but the Chinese would probably not take it quietly; and the Government, though strong to oppress the individual, is weak to control the masses. All that, however, may come in time. There is, as we have said before, more urgent and less dangerous work ready to the official hand. The moment is not opportune for remitting taxation, in face of the heavy demands for money arising from the Hwang-ho inundation but the necessity is pressing; and the Government has been so startled by the deficiency of 30,000,000 lbs. in last season's export, that we have some hope of its realising the fact. It is equally within the power of the officials, if they choose, to stop fraudulent packing; and it should not be without the power of foreigners themselves to impress on Chinese dealers the wisdom of preparing smaller chops, of more even quality. When these objects have been attained, we must possess our souls in patience till time and circumstances bring about "cultivation on scientific principles," and till every process (in tea preparation) become as clean as human care and invention can make it."—*L. & C. Express*, Feb. 24th.

INDIAN TEA DISTRICTS ASSOCIATION:

Meeting to Open up Market for Tea in America.

As briefly stated in our last, a largely-attended meeting of the members of this representative body was held on Thursday, Feb. 23rd, to consider a scheme proposed by Mr. A. E. Allies for opening up a market for British-grown tea in America.

The Chairman then introduced the subject and dwelt specially on the importance of opening up to British produce the large field for tea in the United States, recommending that the tea should be retailed in small packages or packets, and sold through agents at a fair price, but not too cheap.

Mr. George Williamson referred to the urgent need of finding new markets which, he said, we must try to open, as we could not look forward to any very great further expansion of consumption in the United Kingdom. The Anglo-Saxon races were those to whom we should first look. A movement of this kind demanded perseverance and continued support, and he thought the method of that support should be pecuniary and not simply in kind. He thought that probably the object in view would be best served by forming a small limited company or syndicate.

Mr. A. G. Stanton (Gow, Wilson and Stanton) supplied some interesting statistics as to the consumption of tea in the United States which he said was only 1 lb. per head, while in Canada it is 3½ lb. per head as compared with 5 lb. per head in the United Kingdom. China and Japan supply the bulk of the tea used in the United States. He further adduced figures to show the steady and pretty rapidly increasing consumption in the States

Mr. John Holl who had recently visited Canada, said that Japan tea was chiefly used in Toronto but China black tea in Montreal. He found from actually sending over tea to friends there that Indian tea was liked. (A member interjected "yes, when it costs nothing.")

Mr. Allies explained that his view was to go direct to the consumers. He proposed to fix the price of the tea at such a figure as to pay for agents and advertise freely so as to create a demand. He thought that a good market would be found at once among the large mass of fresh emigrants from the United Kingdom constantly arriving out there. He also indicated that while he had suggested the contribution of tea as a means of more readily inducing the planting community to subscribe, he was quite at one with the meeting, and with Mr. Williamson as to the still greater advantages of having money subscribed, and he further believed that the scheme would imply persistent effort and some considerable cost at the outset, which, however, he had every confidence would be amply repaid in the end.

Mr. A. Thompson deprecated paying heavy fees for agents. He advocated a good blend of Indian tea being offered in packets. The tea required was a mild, sweet-tasting tea, drawing a dark liquor, to sell at 24 cents. There was little risk of not finding a market. £1,000 would start such a scheme; all that was wanted was an efficient man. He also read extracts from letters from correspondents in the States, giving information on the point.

Mr. A. Bryans (P. R. Buchanan & Co.) put some questions as to details of the scheme, and expressed an opinion in favour of, in the first place, introducing a blend which would have some similarity to what was at present used.

Mr. R. Rowe said he had sent several consignments to the United States and would advise a suitable blend of Indian tea being offered retail.

General Keatinge pointed out the danger of trying to commence on too large a scale, and the necessity of persistently persevering in the attempt for at least three years. He agreed with Mr. Bryans as to gradually accustoming the Yankees to Indian tea by first introducing a blend of China and Indian. (The meeting rather dissented from this, the opinion of the majority being that our teas should stand or fall on their merits).

Sir Edmund Drummond referred to his own experience in tea drinking. At first he began by drinking a hill tea (Kumaon), and disliked Assam teas, but he had now come to like them, the change being gradual. It would be a mistake to blend the Indian teas with any other but a selected Indian tea—a soft, pleasant tea to drink was wanted, and this could be supplied. He considered that probably the scheme should be of a terminable nature, as all that was wanted was for those interested to set the ball in motion, and then leave it.

Mr. Seton thought the discussion had elicited some valuable expressions of opinion. He believed however, that many of the views expressed were entirely participated in by Mr. Allies himself. He considered that although it might appear to some members that Mr. Allies had not put forward many details of his scheme, he had "up his sleeve" plenty of alternative suggestions, having thought the matter out in detail. He thought that perhaps *the* strong element in Mr. Allies' scheme was that he left himself open to be guided by circumstances and by experience, when the time came, as to the exact line which it would be best to follow.

General Hopkinson then put to the meeting the following resolutions, which having been duly proposed and seconded, were passed unanimously.

Resolution I.—"That this meeting of growers and members of the Indian Tea Districts' Association cordially approves of the proposal to take measures for opening up the American market to Indian teas."

Resolution II.—"That a committee be formed to discuss details of Mr. Allies' scheme or otherwise, and draw up a plan of operations to be submitted to a subsequent general meeting to be called for the purpose."

Resolution III.—"That this meeting considers it desirable that this Association should ascertain through the kindred Association in Calcutta the views entertained there regarding the project and the amount of support that may be absolutely depended on from that quarter to any well-conceived scheme, with a view to further strengthening the movement"

A sub-committee to consider details having been nominated, the meeting closed with a vote of thanks to the chair.—*H. & C. Mail*, March 2nd.

COFFEE NOTES FROM BRAZIL.

"The coffee crop in 1889 [Ceará] should be nil. The planters have uselessly called for the December rains."—*O Paiz*, Jan. 20th.

The Pernambuco correspondent of the *Jornal do Commercio* says, under date of the 10th inst., that coffee cultivation in that province has been very much extended, and the product already meets local consumption at exceptional prices.

We hear of a planter of the province of Rio de Janeiro who refused 12$ per arroba for 14,000 arrobas of coffee, and would now accept an offer of 8$. Here is a loss of nearly 60,000$ to this one man, and we suspect similar cases are numerous.

Late advices from Tiété, São Paulo, state that the next coffee crop will be one-third less than the first estimates, because of injuries suffered from wind and rain. This is quite within our expectations. Something must injure the crop, and if it is not to be drought, then of course it must be rain. [Kinder sarkastik.—ED. *T. A.*]

A case has arisen in Santos, growing out of the coffee speculations of last year, which will be watched with much interest. The firm of Garcia, Irmao & Co. have entered a protest with the *juiz de direito commercial* in the matter of five bills owing Berla Cotrim & Co. on account of differences in the purchase of 5,000 bags of coffee for their account in New York. The petitioners state that they have reasons for affirming that the coffee was not purchased, and that they have paid for the same the sum of 67,050$200 in cash and bills to meet losses. The five bills, amounting to 24,500$800 will not be paid and an action is to be begun for the recovery of the amounts paid with interest. It is altogether probable that the courts will decide against the validity of any contract for the purchase of "futures" in New York, in which case no "bull" movement in Brazil hereafter will be possible without the deposit of *cash*.—*Rio News*.

THE NEEDS OF JAFFNA.

In our last number we spoke of sponge-culture, as being likely to be successful in Jaffna waters. A torrid climate necessitates frequent bathing, and when the Hindus get enough respect for decency not to bathe at the well, the demand for sponges will be very general. If Jaffna waters can supply this demand it will be a large source of income, tending directly to the well-being of all concerned. But we fear that time is still far distant. Fish-culture is more easily developed and is more certain of speedy success. A female fish produces thousands of eggs at each spawning season. Some kinds of fish produce even as many as a million. As these are dropped in the water, a large proportion of them, not being impregnated by the milt, never hatch. Of those that do hatch, much the largest proportion are devoured by other fishes. Thus probably not one egg in a thousand develops into a fish, and we might say not one in ten thousand of many varieties of fish. It has been found that when the eggs and milt are stripped from the fishes by hand and mingled in a vessel, nearly all the eggs hatch. Then if the little fish are kept in an enclosure and fed until they have attained some size, they are able to take care of themselves, and most of them will grow to maturity. This process was only begun in the year 1831, but is now practised very extensively in all civilized countries. Jaffna has many square miles of shallow waters kept from stagnating by the tides and gentle currents, protected also from mud because there are no large rivers to bring it from the land. Thousands of millions of the young of the best kinds of fishes might in this way be set free in Jaffna waters every year. Some might object to supplying the whole

ocean from Jaffna. But the fact is, a large proportion of these fish would come back again. How fishes find their way in the sea, we cannot tell, but they do, and come back year after year to their spawning ground. This could be made more sure by furnishing food for them by securing the growth of their favourite varieties of seaweed. Thus the whole Indian Ocean might be a pasture ground for the fish that go forth from Jaffna waters and would in immense numbers year by year revisit the place of their birth. The strong current that passes our eastern shores would be the line of railway to bring not only these finny travelers to their own doors but abundant supplies of food for them. Then fishes will be caught, not singly, but by the net-full and the boat load.

There is no food so important in the tropics, after grain, as fish. Beef and mutton require a large acreage to supply even one family, and are moreover too heating to be partaken of freely in the tropics. Men can live in health on vegetables, but they do not as a rule attain the same vigor, as those who eat some flesh. Jaffnese already appreciate fish as an article of diet, but much more might be profitably consumed. The Northern Province now exports nearly two lacs worth of dried fish. This might be increased tenfold, and in addition supply immense quantities for the millions of India.

In three years time the fish that came from the sea into the Connecticut river U. S. A. were increased by thousands of tons, and the profit of the experiment in 1867 was more than a thousand fold. These were sea fish which come into rivers for spawning. The experiment would not be much more difficult for other fish which spawn in the sea, as they come near shores for the purpose. Efforts are being made to introduce good varieties of fresh water fish in some parts of Ceylon, and this is very commendable, but this cannot compare in importance and magnitude with the culture of sea fish. We doubt if there are any more favourable places for culture of sea fish than in these Jaffna waters. This is our second point; we must reserve the third to our next number.—"Morning Star," March 15th.

LIMITS TO THE BENEFICIAL EFFECTS OF MANURING.

The following paragraph from an Australian paper has been sent to us:—

"This condition of things is not peculiar to Victoria; the same tale is told in other countries newly occupied by Europeans. Thus we read how in America splendid crops were at first grown on the newly-cleared lands with the most meagre cultivation; but, as the lands first opened up became exhausted, the settlers had to move farther and farther inwards, until at last their distance from the seaboard became a set-off against the fertility of their land, and now the Americans in nearly all their States are studying the art of scientific manuring. Another instructive instance has been seen more recently in the coffee plantations of Southern India, Ceylon and Brazil. In the two former countries coffee growing is now almost a defunct industry. Low prices and the coffee leaf-disease are the causes to which the planters attribute the failure of their industry. Low prices due to increased production are no doubt part of the causes, but the leaf-disease and the diminished yields are undoubtedly due to the exhaustion of the soil. In one case which came under the writer's notice, where a planter had been at the expense in the first instance of burying, instead of burning, the timber on the cleared land, and had so supplied the soil with a store of nourishment not easily washed away, the coffee trees were as healthy and almost as productive a few years ago as when first planted, whereas the surrounding trees were in as poor a condition as those of his neighbours."

The statements regarding exhaustion of soil by repeated cropping and the necessity of resorting to manuring are of course true. But, as a matter of fact, few agriculturists in the world paid more attention to manuring than the coffee planters of Ceylon. When leaf disease came, however, no amount of manuring could do more than delay the inevitable. Indeed many planters ceased to manure on the express ground that the more they manured they merely the more supplied for the food of the fungus. The trees exhausted their energies in successive crops of leaves. We know nothing of the case referred to and we refuse to credit the statement that even the fearfully expensive experiment of burying the timber instead of burying portions of it (for only portions could be burnt), enabled the trees to resist *Hemileia vastatrix*. The case of Ceylon does not illustrate a correct principle: on the contrary it shows that man and science are powerless in the presence of certain natural pests.

WITH "PHILOSOPHER SMITH" IN TASMANIA: A TRIP INTO THE INTERIOR; MINING PROSPECTS.

(*By "Old Colonist."*)

On the 11th ultimo the following telegram appeared in the morning papers of the colony:—

Waratah, Jan. 11.

The Hon. James Smith, with others, arrived by yesterday's train, and the party started with knapsacks for the west coast this morning.

It sounds uncommonly like the Gampola appu's "gentleman and two coffee planters," but never mind, let us follow our veteran bushman as he trudges along with his ample swag. The road leading from Waratah to Corinna is characteristic, and in every way worthy of Tasmania,—a bush track recently completed and already condemned. The gradient for the first two miles is about one in five, then a mile almost level; here we cross the river Arthur, which wends its way N. W. and falls into the sea near Bluff Point; after this we again ascend a burst-my-gall path of 1 in 4. Just see how the old philosopher plods on! No mistake about it, these water-drinking men can walk. This villainous road is made upon what is here called the *corduroy* principle, which simply consists of placing logs of wood side by side. The cost is said to have been about £100 per mile, and, considering the gradient adopted in a by no means difficult country, the men who sanctioned such expenditure ought to hang on the highest gum tree. This is the Saffragam of Tasmania; the wettest portion of the island, the rainfall varying from 86 at Corinna on the coast to 94 inches at Waratah on the hills, the distance between the two points being about 50 miles. There are literally no inhabitants, save perhaps a few adventurous miners and vagrant prospectors like ourselves, but there can be no doubt that there is a great future before this portion of the island, containing as it evidently does the richest deposits of gold, silver and tin in the colony. Ample indications of both gold and silver have already been discovered, although the locality even yet has been but partially explored owing to the impenetrable nature of the vegetation. Tasmania if only equal to the Western Province of Ceylon in glossy greenery far surpasses the jungles of any portion of that island in the magnitude of its timber trees. Varied, however, as the heavy and verdant mantle is here, [illegible] to differ materially from that of other portions of the island, the gigantic eucalyptus still preponderating, but nowhere have I seen the singular looking celery pine (*Phyllocladus* [illegible] perfection, while the beautiful [illegible] (*Dicksonia antarctica*) seems to specially delight in this moist climate, growing into noble trees from 100 to 150 feet in height, in shape like a stately conifer the

glossy green leaves taste exactly like sarsaparilla, and I believe it is the bark of this tree which gives the pleasant flavour to this favourite decoction. In beer, and even infused as tea, it has long been used by settlers here. The *Auodopetlam* or horizontal bush is here forming a barrier, breast-high, everywhere obstructing the traveller who would venture from the corduroy track. "Good thing this horrid nuisance like your devil is peculiar to this island," I said as I stumbled over it in trying to reach a beautiful specimen of native pepper. "It might be worse," said our ever amiable philosopher. "How?" I said, as I gathered myself up. "Well, it might have thorns," was his ready reply. "Ah! you 're right," I said, "like our wait-a-bit in Ceylon. Let me tell you about this *Acacia horrida*," and here I looked as learned as I could, gaining thereby a little rest for my weary limbs, as I told them of how the ancient Kandyan kings needed no other fortification than this terrible thorn, how the British ultimately cut their way through it, how exasperating the thing still is to those who have to leave the beaten tracks, that the best of men can hardly help swearing when caught by it. But to return to my pepper. *Tasmania aromatica*, sometimes called *Drimys*, is a very pretty red-stemmed shrub with lanceolate leaves, strongly pungent, and black berries quite equal in my opinion to the best alspice. I am surprised that this handsome plant is not more common in our English greenhouses or on the hills of Ceylon. There are other plants here growing in great profusion, which I do not remember coming across at home, such as *Aristotelia* and *Drimophila*, the brilliant coloured berries of which surpass in beauty anything of the kind I have ever seen. It may be that Tasmania has no indigenous fruits worth eating, but few countries can show more beautiful ones to look at. For more than one reason I would have preferred more leisure on this journey: the day is very hot, the shade under the noble tree-ferns is very inviting, and the undergrowth of vegetation in this humid climate becomes most interesting; but the strides of my guide and philosopher seem to increase as the sun gets higher, and the gradient becomes more abominable. Midday, however, came at last, and by a unanimous vote a halt for dinner was agreed to. In a trice the billy is hung from a tripod, and a fire speedily blazing under it. In 10 minutes the tea is being handed round, or rather each man helps himself, for alas! no kindly cooly waits upon master in this benighted land. The tea is pronounced excellent, and indeed it would be a strange concoction that the empty stomach of a weary bushman did not relish, but I may say once for all that the metallic-tasted liquid universally imbibed in Tasmania is no more like tea than turpentine is like sweet milk. There were not many "courses" at this dinner, nor like the gubernatorial repast supplied by the Scoto-Ceylon planter, was it "ower lang atween the coorses," for the half hour was too soon up and so was our philosophic guide, who has no taste for after-dinner libations and abominates smoking. The corde du roi (cord of a king, forsooth!) did not improve, nor did the scenery much vary; the giant eucalypt still towered aloft into the sunny air above, while the grateful shade below is a perfect fern paradise. Polypodiacæ in untold variety nestle under the protecting fronds or cling to the trunk of their big brother the Todea fern, while the queer-looking orchids *Diuris Pterostylis*, *Caladonia* &c. peep out in every odd corner.

How strange that all this loveliness should be born to blush unseen! We have not met nor seen a living creature, and no sound greets the ear, not even a buzzing bee in "these matted woods where birds forget to sing." The temperature became quite tropical, and it was not without a feeling of relief that I noted some little black thunder clouds obscure the sun as we trudged along, now climbing over a ridge which the surveyor had evidently gone out of his way to embrace, and now rapidly descending to what proved to be the Whyte River, here there is actually a small hut prepared at the expense of Government for the reception of travellers. Never was the sight of four walls and a roof more welcome, for rain now fell in heavy drops, and the prospect of shelter was hailed with delight by more than myself. Soon the swags were thrown on a prostrate tree, while one of the party ventured to inspect the interior. It was not inviting: the earthen floor had evidently never been swept since it had a roof above it, while a heap of suspicious looking rags disclosed the fact (so it was said) that the place is permanently inhabited by "*Jerusalem travellers*. This settled the question! "Anything would be better than this," we said, as with a creeping sensation we shoulder our swags and depart. Henceforth let me never despise the humblest Sinhalese ambalam, and to the little ladies and gentlemen who periodically tramp barefooted along the north road I lift my hat: I have seen the lair of an Australian tramp. Silently we now trudged on, up one ridge and down another; the situation was getting decidedly tedious and uninteresting, when all of a sudden our guide turned at right angles and went scrambling into the bush. Follow him we must, but it was past a joke, and I felt that after this it would be a rest to follow "Peppercorn" up his near cuts. At length an opening came, a plot of knife and button grass, and beyond two tiny tents, to which we hurried, and presto! all sense of weariness was soon forgotten in the agreeable surprise of seeing some 50 tons of rich silver ore. Yes, the philosopher's hammer has again been at work, and to some purpose, for here is what may probably turn out to be the richest silver mine in Australasia, though, strange to say, as yet, the Tasmanian newspapers have not had an inkling of the fact. And now all ye young Indian planters, who vainly seek to extract rupees, quantum suff, from tea leaves or shuck coffee, here is your chance of reaching the metal more directly. The old miner I have been talking to declares he could easily put out an average of two tons per day, and as this means 240 oz. of pure silver, and 70 per cent of lead, there is evidently money to be made even if we reduce his estimated output by one-half. To me, however, I must confess, the life of a digger has but few charms. Some must dig, I daresay, but, compared with the life of a planter, it is a barbarous and demoralizing business.

LETTERS FROM JAMAICA:—No. 22.

COFFEE—A VISIT TO MANCHESTER PARISH AND BROCKENHURST PLANTATION—COFFEE PROSPERING UNDER SHADE—CINCHONA.

Blue Mountain District, Jamaica, Jan. 1888.

DEAR SIR,—Coffee crops in the lower districts may now be said to be completed and the greater part of it already sent away to Kingston for shipment: the yield as formerly reported has been large, and the quality much above the average, in consequence of the wet season. In the Blue Mountains proper, crop is just beginning to ripen up; the heaviest pickings are in February, March, April, and May: what the eventual result will be would need a "seer" to predict. I am of opinion that the yield, though much better than last year's, will by no means be a bumper; for, after the

many months of almost continuous showery weather, which fortunately did no damage in the way of floods, or "breakaways," one can hardly expect a heavy crop from the topmost fields, which require very dry weather, such as we are now experiencing, to make them put out good blossoms. After the long continued rains of 1887, December turned out a glorious month for coffee curing; and the weather is still so dry that the coffee in the low-lying lands is beginning to droop. This is by no means a cheerful prospect, as February is the driest month in Jamaica, so that, unless we get some good showers speedily, it may become a serious question for those possessing coffee at a low elevation. Since I last addressed you, I have carried out my contemplated visit to the parish of Manchester, and will now write what I saw for the entertainment of your numerous readers. The first part of the journey is accomplished by rail from Kingston; the line passes close to the old capital, the "St. Jago de la Vega" of the Spaniards, but not near enough to the town to see the large public buildings for which it is celebrated; the present terminus is at "Porus," and until the train reaches Calrendon Park the country is very uninteresting, as seen from the carriage, the track passes through bush principally, probably portions of various cattle pens, where logwood and other indigenous trees have a home. After Clarendon Park, one again sees signs of civilization and cultivation, settlers' houses dotted here and there, surrounded by coffee, cacao, coconut, banana, orange and other tropical vegetation. From Porus, a steep road of a few miles, through pretty cattlepen lands, brings one to the summit of the plateau, not far from a place named Willlamsfield, whence the road is undulating until it reaches the town of Mandeville, very prettily perched on the summit of a hill. There is a veritable "village green," an old-looking church with a squat spire, and several substantial Government buildings, stores, shops, and lodging-houses surrounding this nice open space. Mandeville is a favorite spot for Kingstonians seeking a change; and there are pretty drives in several directions.

The coffee property, I had been so anxious to visit, is named "Brockenhurst," after the well-known village of that name in the New Forest, Hampshire. It belongs to a family named Morant, descendants of one of the first "buckra" families that settled here when the Spaniards got their "congé;" it is leased for a long term by the present manager. I believe the place was opened in the early forties, a few years before emancipation, and subsequent free trade, both which helped to ruin so many colonial interests. Most of the original coffee fields have already been exhausted, as I was informed the trees do not last much over 20 years in the red clay soil, similar to Devonshire, which is characteristic of the Manchester Parish. Limestone also abounds, but unfortunately this fine soil has no great depth; and as soon as the coffee roots reach the substratum of marl, they come to premature decay. The coffee fields of Brockenhurst are now some little distance from the works; the land is most charmingly easy and undulating, reminding me of the lands at Gampola, first opened by Mr. George Bird, and I only wish I had 150 acres here, of the same evenness, then should I indeed possess a magnificent property. The Manchester coffee thrives under self grown shade of *trumpet* trees,—not the datura, but a curious looking tree with long, thin, horizontal branches with few leaves, so the shade is by no means dense, but quite sufficient for the purpose. These trumpet trees grow up as soon as the land is burnt off, and it is remarkable that the coffee will not thrive where they do not exist. Brockenhurst is now 180 acres in extent, a new field is usually added every year to make up for old land falling-off, and as there is still a large acreage of virgin land belonging to the property, there are therefore, it may be safely inferred, many more prosperous years in store for this fine property, given of course good seasons, with sufficient rainfall, and such prices as will make the expenditure remunerative. The only drawback is that every new field has to be farther away from the works, and makes transport longer and heavier, but the chief drawback in Manchester, as against other advantages, is that there are no rivers or springs, the whole population is dependent on tanks and ponds: the water for pulping and washing at Brockenhurst has to be pumped out of the tank, and in times of drought Mr. Wynne has had to supply his work-people with a small allowance of water daily from his tank. Imagine the feelings of a Ceylon planter, at having to pump up the water for pulping and washing, and having men to remove the tails by hand during the process of pulping, there not being sufficient water to carry them off into the pulp pit. The barbacues at Brockenhurst are about one acre in extent, well supplied with huts, the store is larger than most I have seen on Jamaica coffee estates, and I was pleased to observe that notwithstanding difficulties as regards water, the coffee appeared to be very well cured, and from this having been such a favorable season, the sample was also very good. It is generally sold in London, and will, I trust, realize the fine prices the enterprizing and clever lessee deserves as the reward of his labors.

The Manchester coffee tree is not so sturdy or long-lived as its Blue Mountain brother; the stem is smaller and the primaries much thinner, but the yield is fairly good, especially in favorable seasons, say 4 cwt. an acre all round, which, as the cultivation is not expensive, gives a fair margin for profit. A great advantage is moreover afforded by cart roads, and the railway being only 10 miles off, so that Brockenhurst coffee is cured and casked on the estate, and is sent direct to the shipping place, thus avoiding heavy Kingston expenses. I have omitted to mention the Manchester system of establishing a coffee field: the forest is felled, burnt off, and cleared up ready for planting by the man who is going to lease the land. It is planted by the owner who of course has free access at any time, then it is handed to the lessee for three years; he has to keep the land free of weeds, and may plant bananas, yams, cocos, and other products grown in native gardens; meanwhile the coffee and the trumpet trees are growing, and the planter takes over at the end of the three years. This plan must pay both the "Buckra" and "Quashie," or surely it would not still be carried on, and as regards the coffee itself all Manchester planters aver no harm is done either to the soil or the coffee by the process, which the comparatively poor soil of Ceylon could not have stood without injury.

There is another large property in the district, but the overseer thereof, though twice invited by my kind host to let us see the estate, gave us no encouragement. This conduct appeared to us uncommonly strange, as coffee planters have generally a natural desire to compare notes, and are too liberal-minded to be influenced by any jealous motives. To give one an idea of the hilly lay of land at Brockenhurst, I may say it is quite guileless of cut roads through the coffee, simple rideable tracks answer the purpose.

As regards cinchona, I have been pleased to

notice an improvement in prices in the home market, as the over-abundant supply appears to be somewhat exhausted, and shipments from Ceylon more moderate. At the same time I read in the Bulletin of our Jamaica Botanical Department, that a Java planter, who has visited Ceylon, crows over his Ceylon brother-planters, advises them to make the most of what cinchona they have left during the next two years, and predicts grand things for Java-grown cinchona in the future, which he avers to be far superior to what is grown in Ceylon, as it consists in the main of the better kinds of calisaya, more especially ledgeriana, and he believes these qualities will be preferred by the manufacturers as containing far more quinine, and goes so far as to say that one million pounds of Java bark will be equal to several millions of Ceylon. Now it appears to me that officinalis has always found a ready sale in the market, and who knows but some canker, or unsuitableness of soil, may yet prevent our Java friend's "castles in the air" from being realized; he should not so confidently "count his chickens before they are hatched." W. S.

THE DUTCH CINCHONA AUCTIONS.

(*Chemist and Druggist*, Feb. 25th.)

AMSTERDAM, Feb. 23rd.—At the public auctions of cinchona bark held this day a supply of 1,704 packages (including 57 of British Indian origin) was offered for sale, and of this quantity 1,496 packages were actually disposed of at an average unit of 12 to 13 cents. per ½ kilo. (=2 1-5th d. to 2½d. per lb), or just a shade below what is said to have been paid at last week's auctions in London. Druggists' bark, broken quills and chips to fair quill realised from 20 to 79 cents per ½ kilo. (=3¾d to 1s 2½d. per lb.), and ditto root from 19 to 22 cents. per ½ kilo. (=3½d to 4d per lb.). Manufacturers' bark sold at the following prices: Common chips and broken quills to fine strong rich quill, from 4 to 126 cents. per ½ kilo. (=¾d. to 1s 11*d.* per lb.), and root at 22 to 94 cents. per ½ kilo. (=4d. to 1s 5d. per lb.). Moderate competition prevailed, the chief buyers, named in order, being the Brunswick Quinine Work, Zimmer & Co., of Frankfort-on-Main, and the Amsterdam Quinine Works.

TROPICAL PRODUCTS.

ANNATTO.—Thirty baskets Ceylon *seed*, fair to good bright quality, sold today at 2¼d to 3½d. per lb. Pará *roll* remains very neglected. Thirty baskets were offered today, but no bid was made, and the whole bought in at 1s 3d to 1s 6d. per lb. for rather dark to fair quality.

ARECA NUTS.—Eleven bales of good quality sold at 16s.

CALUMBA.—The value of ordinary root, which is in large supply, seems likely to fall still lower. About 300 bags were offered for sale today and all bought in, dark mostly small at 17*s.*; fair yellowish mixed, partly cleaned, at the same price (16s. being refused for this lot); common pickings at 5s. per cwt.

COCA LEAVES.—Several lots ordinary leaves were bought in at nominal prices.

CUBEBS.—At the auctions today ten bags good genuine, but stalky berries (slightly mixed with pale fruit) were bought in at £26 10s. per cwt., while two bags spurious berries, from New York, sold at £16 5s. per cwt. Seventeen bags were imported from Singapore per steamer "Glengyle" this week, and today we received another consignment of twelve bags *via* Amsterdam.

KOLA NUTS.—Only 2 bags sold cheaply, at 3d. per lb. for whole but partly mouldy seeds.

VANILLA.—Over 440 tins were offered for sale today, and mostly disposed of at irregular prices, dearer for good, but rather cheaper for low-class beans. The following rates were obtained:—Common lean to ordinary chocolate 3½ to 6½ inch, 4s 6d to 8s.; fair to good uncrystallised ditto, 4½ to 7 inch, 8s to 13s.; good to fine, 6½ to 8 inch, 13s 6d to 20s 6d.; fine, 8 to 8½ inch, 21s 6d.; rather brownish, 4½ to 7½ inch, 6s 6d to 10s 6d.; ordinary dry, 3½ to 6 inch, 3s 9d to 5s 9d.—*Chemist & Druggist*, Feb. 25th.

A CAPTAIN of the Netherlands Indian army has been making vigorous efforts to start a steam paper-mill in Java. The raw materials such as rags, baling, bamboo fibres, &c., are admittedly obtainable there in great abundance. But the chance of carrying on such a line of business enterprise remuneratively there, looks so small despite the glowing prospects held out by the officer that the scheme has fallen flat so far.—*Indian Agriculturist.*

MARKET FOR TEA IN AMERICA.—We call attention to the proceedings of the Indian Tea Districts Association reported on page 707, in reference to steps about to be taken to try and induce a greater consumption of Indian Tea in America. Mr. Allies struck the key to the way to start an immediate trade when he spoke of getting at the emigrants. Could not the Ceylon Tea Association offer to co-operate on condition of Ceylon tea being proportionately supplied.

ARTIFICIAL RUBIES.—At the Academy of Sciences meeting of February 27th, M. Frémy reported the progress accomplished by him and M. Verneuil in their attempts to make rubies of merchantable size. By heating barium fluoride with alumina and traces of potassium chromate, they have obtained this time rhombohedric crystals of pinkish ruby in the midst of a colourless gangue, from which they are easily separated by washing. The artificial stone contains no baryta, but solely alumina with traces of chromium; it is perfectly transparent, and will scratch topaz, as natural ruby does. So far, with the apparatus at their disposal, they have been able to produce ruby crystals measuring from 1 to 2 millimètres (1-25th to 1-12th of an inch) in their largest diameter. But on increasing the size of their appliances they hope to soon turn out rubies that will not be mere curiosities. MM. Frémy and Verneuil were complimented on their success.—*Chemist and Druggist*, March 3rd.

COFFEE LEAF DISEASE.—Recent Java journals give particulars of a remedy for coffee leaf disease, discovered by Dr. Burck, manager of the Government Botanic Gardens at Buitenzorg, near Batavia. The specific is said not only to cure the disease, but also to prevent its recurrence. For preventive purposes, he makes use of a highly attenuated solution of chloride of iron applied to the under portion of the leaves by means of a pulverisator. The sticky nature of the solution enables it to adhere two months to the coffee-leaves. It is a powerful antidote to the *Hemileia vastatrix*. To stay the progress of the latter when it has once taken hold, a different method is employed. The coffee-leaves in which the *Hemileia* first manifests itself in the form of orange-coloured spots are at once taken in hand. Holes are picked in the spots with a needle dipped in a strong solution of sulphuric acid, which kills all the germs of the disease in the leaf.* Dr. Burck estimates the cost of the preventive specific at 2½ guilders per 133 lb., and the healing remedy at 4 guilders. He anticipates that the price of coffee will be enhanced in consequence. The second rpecific in particular is said to have yielded good results and to be easy to administer. The economic value for Java of the discovery of the remedies, should they prove successful, can scarcely be over-estimated. In Ceylon the disease in the coffee-plant produced a revolution in planting; year after year the coffee crops were failures, many planters were ruined, and ultimately tea-growing took the place of coffee with results which are just now astonishing the world But the period of transition from one staple to the other was one of economic disaster, from which perhaps Dr. Burck has saved Java.—*Nature*, Feb. 9th. [We are having Dr. Burck's paper translated in full for the *Tropical Agriculturist.*—ED. *T. A.*]

* How practicable this remedy is, all who have seen a coffee bush covered with the disease can judge. A cooly would take a week to a bush, and then the leaves would drop off to make room for another crop for the spores to fasten on.—ED. *T. A.*

Correspondence.

To the Editor.

CEYLON TEA IN THE HOME MARKET.

Dear Sir,—I do not need to tell you that I am not a planter. I have never owned either tea or coffee; but I have a very lively interest in the prosperity of the tea enterprise in Ceylon.

Of the increasing consumption of Ceylon tea there cannot now be any doubt. It is not many years since some of us at home had to take some trouble and incur some expense in order to bring the new and unknown tea under the notice even of "the trade"; but now neither the trade nor the public require any coaxing in that direction. The tea has spoken for itself, and to a large extent the verdict has been in its favour. I have met with Ceylon tea in very out-of-the-way corners in England, and it would seem to have introduced itself into nearly every part of Scotland. And the prices, up till very recently, were, I believe, fairly satisfactory, leaving a fair profit to sellers at home, and giving a remunerative price to the planters. This, I think, is a fair statement of the case as regards Ceylon tea, up to a certain point. It cannot be questioned, however, today, that a change is taking place, and that the high position to which our tea so speedily rose a few years ago is not being maintained either in Mincing Lane or elsewhere. What is the explanation of this? I cannot say, but I can give you a fair report of an interesting conversation which I recently had with a very well-informed dealer.

This gentleman sells wholesale for one of the large London houses, and has had twenty years' experience in the trade. He states that they looked to Ceylon tea for two things. It had its own rich distinctive flavour, and it had strength without the harshness of most of the Assam teas. But it is not keeping up its character in these respects. He says that apparently many of the Ceylon planters are going in for quantity, hoping to get a high average price for souchong. But planters could not, he thinks, make a greater mistake. There has already been, as was sure to be, a very serious fall in the prices of souchongs; for if it is to be souchong, then Ceylon comes into direct competition with the cheaper Assams of that quality, and the price cannot be maintained.

Another point to which my friend called attention was a tendency in the Ceylon teas to deteriorate in quality very rapidly. He had referred to this point in a conversation with me some months ago, and now he brought it up again. He says, that, as a rule, the Ceylon teas are too "soft": they do not retain their sharp distinctive flavour: they give you plenty of colour, but after being kept for some time they are flat, dull and flavourless. He mentioned a parcel that was sold in London some months ago at 1s 8d: the purchaser kept it for a short time, but found that it was losing in quality, and he sold it for 1s 6d. But this purchaser had just the same experience. It deteriorated very rapidly in his hands, and he was glad to part with it at 1s 2d. These are, of course, the prices in bond. Now, we may be sure that the trade will not long continue to keep stocks of such tea. They may buy to execute orders and no doubt will buy, so long as the tea is asked for, but they will be chary of putting it into stock. And let me say here that I can corroborate this complaint as to deterioration. In my small household we have for the last six years used only Ceylon tea. We have most frequently had it in small Ceylon-made boxes of 12 or 20 lb. But latterly we found it advisable to buy it in tins of 4 lb. at a time, because of the great deterioration in quality by the time we got to the last half of the 12 or 20 lb. box.

Is n't this "softness" in the Ceylon teas something which it concerns the planter to look into? Is it that by the very perfection of the machinery now so largely in use in Ceylon the tea is too rapidly pushed through the various stages of manufacture? Or does the fault lie—as is more likely—in some known or unknown defect in the withering or fermenting processes? My friend could not enlighten us on these points: he could only state most strongly that the defect was there, and that it was for planters to find out the cause and get rid of it. *

Another point to which he called my attention was the great proportion of large and coarse leaves that are to be found in some of the Ceylon samples. He showed me some such samples, and said that this was a decided fault. It made a tea bulky in proportion to its weight; and as it is the fact that as yet, both in England and Scotland, tea is put into the pot by the spoonful and not by weight, this bulky tea gives but a poor result from the family teapot, and the character of the tea suffers. On this point he showed me what he considered a model sample as to sizing and mixing, and he named the estate from which the sample came, an estate on which one of the best sifting machines in Ceylon is at work. I mean to see that a small sample of this tea shall find its way to the *Observer* Office in the course of a week or two, and you will have the pleasure of showing it if you think it worth while.

But I dare say my letter is long enough, and I will close with my friend's advice to Ceylon planters. "If asked advice," he said, "I would say, aim at a good average price, rather than at a large quantity and low average price. If you make your aim a low-priced tea, you will be beaten both by Assam and China.† Aim at such a tea as the trade can sell *pure* to those who know really good tea; and thus nurse a taste and create a demand for pure Ceylon tea. It has both its rich peculiar flavour and inherent value to recommend it."

I trust that these remarks may be of some interest to my old friend, the proprietor of Abbotsford, and to a few others, and with salaams, I remain, yours faithfully. W. W.

INFLUENCE OF FRESH WATER ON PEARL OYSTERS.

March 1888.

Sir,—Will you permit me to state my views with reference to the destruction of the pearl oysters on the *pars* in the Gulf of Mannar off Silavatturai? I do not pretend to be a naturalist or a *savant*, but I pretend to some knowledge of the ways of the pearl oyster since the time of that eminent but now lamented naturalist—Dr. Kelaart.

I speak from observation and would invite discussion to the due ventilation of my theory. I am at one with Capt. Donnan's view of the "ocean current" or "stream," or whatever you like to call it, but I go a step further. I think that the fresh water poured into the Gulf of Mannar by the several *aruas* from Arippu up to Negombo carried over the *pars* by the ocean

* High firing would seem to be the remedy for the "softness," and "going-off" complained of. But, when high firing was resorted to, the objection was offered that the tea was burnt. Of course planters will give serious attention to the points stated in this letter of a true friend.—Ed. *T. A.*

† Parcels of China tea have lately been sold here at 4d and 5d.—W. W.

stream of Capt. Donnan proved fatal to the oysters, and you must bear in mind that according to the evidence of Mr. Twynam, the water of the *Aruvi* has been detected 10 miles up in the Gulf.

The sudden destruction of the banks in 1864 was preceded by heavy rainfall the previous year: this is an undeniable fact. I think if a reference was possible as to the quantity of rainfall during the latter parts of 1886 and 1887 in those parts of the island, whence the *arus* derive their waters, it will be patent that the fall has been heavy: this I am informed was actually the case, and oysters were found rapidly dying in 1887 and almost completely swept away in 1888.

The question next arises as to the escape of the patch now being fished. It will be interesting to trace the position and situation of the patch to find out, whether the "Gulf stream" with its volume of rain water affected it less than the other parts?

In 1864 notwithstanding the careful search by the authorities and the adventurous attempts of some who were supposed to know more of the Gulf, not an oyster could have been picked.

That fresh water and more so rain water is fatal to the life of the oyster, every fishery has proved. One has only to remember the state of the oysters in the Government kottus after a rainy night: I have placed pearl oysters in fresh water and have found it to prove fatal to the oyster, and lead to quick decay.

Finally allow me to make a suggestion; now that the Pearl Fishery has proved a success, would it not be the right thing for Captain Donnan to go in search of the oysters about the coasts of the Eastern Province, where I am told pearl oysters have been found in places where they were unknown before?—

Yours truly,

NEMO.

[Our correspondent adds in a private letter:—"Here is another experience. During one of the fisheries I had made up a few bags of oysters for some friends in Jaffna; the night happening to be very rainy, I ordered the bags to be kept in the drain running close to the house, intending thereby to have them fresher for shipment the next morning; but what was my surprise to find them mostly dead and putrefying rapidly."]

THE MAZAWATTEE CEYLON TEA COMPANY.

Dear Sir,—Our attention has been drawn to the report of the meeting of the Dimbula planters in November last, at which the name of this Company was mentioned. From the tenor of the report it is very evident that the Ceylon planters have been utterly misled as to the character of the business carried on by this Company. We will thank you, therefore, to allow us to give, through your columns, a few particulars as to the nature of our business, so that those interested in the tea industry in Ceylon may judge as to whether we are working in a manner prejudicial, or favourable to their interests.

About two years ago, believing there was a great future for Ceylon tea, we determined to put Ceylon blends before the public in a practical and attractive form in packets. For our own protection it was necessary to register a trade-mark or name; we chose the latter. "Mazawattee" is a corruption of the two Eastern words "Mazadar Watte" signifying Luscious Garden, or growth. At 3s and 2s 6d, we decided that we could offer Ceylon tea judiciously selected and blended of sufficient body and quality, to create a large and permanent demand. We also decided to offer at 2s and 2s 2d blends of which Ceylon tea would be the predominant feature, but containing also a certain proportion of Indian tea, it being a well-known fact that the lower medium grades of Ceylon tea, although very serviceable for blending, have not sufficient briskness and point to make really first-class palatable blends without a proportion of pungent Indian tea. The fact that these two lower price blends are not entirely composed of Ceylon tea has always been prominently stated on the labels.

To avoid any chance of misleading the public, the medical report has never been affixed to any, but the two higher price packets. We have spared no pains in introducing these teas throughout the United Kingdom, and in endeavouring to develop and cultivate a taste for Ceylon tea. We have succeeded in this far beyond our expectation, and our success has justified beyond doubt the soundness of the lines on which we started. It is well-known on the London market that the great amount of competition in the Ceylon packet tea trade, which is greatly the result of our successful pioneering, has done more to popularize Ceylon tea, and to keep up the high level of average prices, than any other factor. There is scarcely a grocer in the Kingdom now, but who has his packet Ceylon tea either pure or blended and in the majority of cases he is selling the public really first class value.

On seeing the report refered to at the commencement of this letter, one of our proprietors called at the offices of the Ceylon Planters' Association and had an interview with Mr. David Reid, and offered to allow him or anyone whom he should depute to inspect our books and examine our employees in order to satisfy him, that from the very first packet that was sent out of our warehouse, there has never been a leaf of any other than Ceylon tea put into the 3/ and 2/6 packets which we have always guaranteed to be absolutely pure Ceylon. We also take this opportunity of inviting any Ceylon planter when in London to call at our offices and we will afford him every facility for satisfying himself as to whether we are and have been working in his true interest.—Yours truly,

THE MAZAWATTEE CEYLON TEA CO.

"THE QUILLS UPON THE FRETFUL PORCUPINE":

SOME INTERESTING FACTS AND SPECULATIONS BY A PRACTICAL NATURALIST.

Dear Sir,—So the 'fretful' porcupine has been flinging its quills about again and carrying water to irrigate its young with. How is it that the Tamil and Sinhalese have different legends on the subject? They have equal opportunities of knowing, but they must needs differ, which surely throws doubt on both legends, and Europeans, who can't think and examine for themselves, it seems must go to be taught by the "ignorant villager," and of course get the legend confirmed. It does not strike them that it may be nonsense, but swallow it all at once, so hungry are some for what is marvellous, and not content with the wonderful and beautiful with which nature really abounds. Mr. Haly's letter was quite to the point, but it seems that the hungry for the marvellous are not satisfied. I wonder why the young of porcupines are supposed to require water to be carried to them more than the young of other creatures, hares, rats, and such like. Milk runs short, I suppose, so the sagacious mother mixes them a little sky-blue! But then there are the hollow quills to account for. Well, there is no need to rush off to the marvellous for that: they are simply the animal's *rattle*. "Rattle, nonsense!" I hear some exclaim, who are not going to have their favorite and interesting legend knocked over by a rattle; "too absurd." Well, I do not want them to believe it, but it is nothing else. I have met with porcupines both wild and tame, by night and by day, dead and alive, and have satisfied myself that nature has given the animal the hollow quills they sound more than solid ones) as a means of

communicating by sound to some distance, they being devoid like the hare of any vocal note for the purpose; the hare thumps her hind foot on the ground to give alarm, deer and sheep stamp the forefoot sharply on the ground for the same purpose, the rattlesnake rattles its tail, and so does our friend, when angry and also when roaming about at night as a signal to other porcupines, and can be heard to a considerable distance. Though this is a very beautiful arrangement of nature, it probably will not suit the many who pine for the marvellous; and a word on the bow and arrow business. If a porcupine shoots its quills it must have some muscular arrangements for the purpose: that won't be denied, but I have failed to find such, simply because they do not exist; powerful skin muscles it has, and which are necessary to move the giant hairs, developed into effective weapons of offence and defence as they are, but it would require quite a different arrangement of them and much stronger ones to shoot them out, and which power is in no way required by the animal; they are effective enough without it. There is nothing more wonderful in some of the quills coming out which were ready to be moulted very likely and even to be jerked a few inches, than there is in feathers coming out of a hen when she shakes herself, especially when the animal erects them violently in anger, but to *shoot* them with malice aforethought at an enemy is out of its power, the bowstrings are wanting, which presents a difficulty to those who inquire for themselves in believing such nonsense.

Your correspondent in 9th's issue, who writes seemingly because he is entirely ignorant of the subject, and who must be an admirer of bull-baiting and badger drawing, would find no difficulty in inducing the natives for a consideration to catch an adult wild porcupine; he could then shut it in a room and attack it himself with only the weapons nature has endowed him with. He would then become acquainted to a certainty with how the quills got in his legs whether shot or not: that would be rather more unselfish than suggesting that planters might try the barbarous experiment with their dogs, and he might arrange to have a few friends looking in at the window for fear his account of the result of the encounter should not be believed; take care that one of the spectators is a doctor.

ZOO-ZOO.

"EXHIBITION BOXES" FOR FLOWER SHOWS; POT PLANTS; BOUQUETS, &c.

Hakgala, Nuwara Eliya, 13th March 1888.

Dear Sir,—I have been frequently asked for information as to the make and size of exhibition boxes used at English flower shows, and as this information may be useful to intending exhibitors at the Nuwara Eliya Show, which is to be held on the 3rd and 4th of next month, I give below measurements of a very good form of show box, and also a few notes on exhibiting plants and cut flowers, which, if you think interesting enough, I shall be glad if you will give them a place in your columns.

The best size box for showing 18 blooms of roses or chrysanthemums is one 3 feet long by 18 inches wide and 4 inches deep, inside measure. The wood used may be of ¾ inch deal, or any other light wood. A little block of 1 inch wood 2½ inches long should be placed in the angle of each corner, and a piece of half inch in the centre of each side. 1½ inch broad and 2½ inches long. These are to strengthen the box and for the inside tray to rest on in travelling. At the back of the box, 5½ inches from each corner, a strip of wood ¾ inch broad, inch thick and 5½ inches long should be fixed on with a screw, the screw to be put in at 2 inches from the bottom and not screwed tight. The object of this being to give the tray a slope when being shown. The strip of wood to be turned down at other times.

The lid of the box should be 4¾ inches deep, to allow room for the flowers, and may be fitted on with a pair of hinges, or with little pegs such as are used for almirahs.

The tray for the flowers must be 3 feet long, 18 inches broad, and half inch thick. A strip of wood ¾ inch deep and ½ inch broad to be nailed on edge on the under side of the tray at each end. It will be necessary to cut out a little piece at the ends to make it rest evenly on the blocks in the corners.

The holes for the tins should be 3 inches from the edge and 6 inches apart, the diameter of the holes to be 1¾ inch. These distances will give ample room for large sized blooms of either roses or chrysanthemums. This box will also answer for such things as carnations, pansies, verbenas, etc., if the holes are made a little closer, 4 inches being fabout the right distance for such flowers. With regard to the tins that are to fit in the holes to receive the flowers, I think there is nothing better than the old-fashioned sort, which can be easily made by an ordinary tin-smith for about 6 to 8 cents each. They are made of tin and are 3 inches long, 1¾ inch in diameter, with a half inch rim round the top. Of course, the joints must be soldered close so as to hold water.

Witlh such a box as the above the exhibitor can arrange all his blooms at home, and when he arrives at the show building, he has nothing to do, but to take off the lid, lift out the tray, turn up the 5½ inch strip of wood, replace the tray, and the exhibit is well staged and ready for the judges. The boxes should be painted green, and fresh moss, or other suitable material, should be laid over the surface of the tray among the blooms and a little healthy foliage of the kind belonging to the flowers shown placed here and there round them will add much to the beauty of the exhibit. I have often known the best prizes lost for want of attention to these little details.

It also adds much to the appearance of pot plants if a little green moss is placed over the soil, the pots washed and dead leaves removed, and if necessary the foliage should be washed before they are brought to the show grounds. I mention this, because if a plant is worth showing at all it is worth showing clean, and I regret to state that I have seen very fair plants sent to be shown in such an untidy state as to completely spoil them, when, with a little forethought and attention, such plants might have secured a prize.

An exhibitor of pot plants will find it a useful precaution to take with him to the show a few small wedges of wood to tilt this or that pot into a more advantageous position, and also a few neat stakes and tying material, for it often happens that the beauty of a plant is lost for the want of a little attention in this direction.

When collections of vegetables are shown, the exhibitor would do well to provide himself with a light tray, say 6 feet long and 2 feet wide, with a 2 inch rim all round, and divide it into as many compartments as he has different kinds to show. A couple of light rails placed at a distance from the bottom of 5 and 9 inches at the back to support such things as celery, leeks &c. would be an improvement. An arrangement like this would save much trouble and would keep the exhibit distinct, the want of which has been a difficulty experienced at all the Shows I have attended in Ceylon, and has, in one case at

least, been the means of the 1st prize being awarded to the wrong person, simply because one person's exhibits were mixed with another's.

This letter is altogether too long already, but I would like to write a few words about bouquets. No doubt many pretty and graceful bouquets are made in this country, but I must confess I have seen but very few. The worst feature I have noticed is to pack the flowers too close together, and another equally bad mistake is to crowd in too many colours. I write particularly of hand bouquets, these should be light with a small handle, and every part properly fastened, so that none of the flowers would fall out if the bouquet was turned sharply upside down. In my opinion not more than 3 or 4 different shades of colour should be used with fern fronds or other suitable green according to the taste of the maker, and these should be as firmly fixed as the flowers. The whole bouquet with paper should not exceed 15 inches in diameter or be less than 10 inches.—I am, dear sir, yours faithfully, W. NOCK.

ANTS ON CROTONS.

17th Mar, 1888.

Dear Sir,—I shall be obliged if you can tell me of some simple remedy for getting rid of ants that settle on, and gradually blight and kill crotons (garden ones).—Yours faithfully,

F. LIESCHING.

[We referred the inquiry to a practical authority, who writes :—"I have never been troubled with ants in the way Mr. L. states, but I think if he syringes them occasionally with tobacco water, or with the following :—One wineglassful of kerosine oil to a gallon of water, *well mixed*,—he will soon get rid of them."—Ed. *T. A.*]

FAST-GROWING SHADE FOR COFFEE.

March 18th, 1888.

Sir,—Would you or any of your correspondents oblige me with advice as to the best *quick-growing* shade for coffee ? The elevation is 4,000 feet.—Your obedient servant,

NORTH TRAVANCORE.

[Shade at 4,000 feet ! Only certain trees will grow at that elevation. Probably some of the Indian figs would answer. Mr. Anderson of Mysore went very fully into the question, in a small volume some years ago.—Ed. *T. A.*]

FRESHWATER FISH, DOGS, AND PORCUPINES.

Sir,—The big fish I have caught in Ceylon streams, and which is certainly dangerous at some period of the year, also very troublesome to eat on account of the great number of small hair-like bones all through the flesh. I was poisoned by the last I ate although it was caught in the morning, and I had it for breakfast. I have seen them up to 12 lb. The natives called them lélu.—Porcupines can shoot their quills with a vengeance as I know, but they shoot the whole body at the same time. I once knew a little mongrel bitch that was death on them ; she had been more than once badly spiked, but so cunning they could not do it any more. She so liked to get a young dog with her when a porcupine was run down ; they run while they can, then stick their head in a hole or corner, pat their hind feet like an angry buck rabbit, the unwary dogs make at them, when whish they go astern, often leaving 3 to 6 quills fast in the poor dog. The little bitch would bark and get the young dog to do the attack ; immediately the porco made the stern rush, she would jump in and grab him by the neck. The hollow tubes in the tail are said by natives to be for carrying water : this I don't say, but with the bunch, 8 or 10, they can make a most horrid row either standing or more so running.—Moderate rains and weather beautiful, bug commenced again. No hope for poor coffee. UDAPUSSELLAWA.

RICE-GROWING AT MULLAITIVU.

Office of the Director P. I , Colombo, 13th March 1888.

To the Hon. the Colonial Secretary,

Sir,—I have the honor to report that Mr. Hoole, Agricultural Instructor at Mullaittivu, has just reaped his paddy crop with the following results :—

(*a*) 1½ acres, cultivatod with the improved plough and sowed broad-cast with 3 bushels of seed paddy, yielded 41½ bushels, *i. e.* approximately 28 bushels an acre, the yield being 14 fold.

(*b*) ¾ acre, cultivated with the improved plough, but "planted out" (instead of sowed broadcast), with only 9 seers of paddy gave 39½ bushels, *i. e.* approximately 53 bushels an acre, the yield being 140 fold.

1. The yield of the native crops cultivated with the native plough only and not "planted out" is reported to be 7 fold, or 14 bushels an acre only.

2. The improved plough, as usual, has thus doubled the crop, while the planting out system in addition to the new plough has had its usual large results.

3. Two new ploughs have been brought by the people who saw these results and 15 persons have stated that they are going to buy the new ploughs.

4. I have the honor to ask permission to publish these results as before.—I am, &c.,

(Signed) H. W. GREEN, Director.

IMPROVED PADDY (RICE) CULTIVATION IN CEYLON.

Office of Public Instruction, Colombo, 14th March 1888.

Sir,—I have the honor to annex for your information copy of a letter No. 72 of 2nd instant, addressed by me to the Hon. the Colonial Secretary concerning work done at the branch agricultural school at Minuwangoda. As the subject is interesting to many, I should be glad if it could find a place in your columns.—I am, sir, your obedient servant, H. W. GREEN, Director.

Result of Paddy Cultivation at Minuwangoda.

Colombo, 2nd March 1888.

Sir,—I have the honor to forward copy of a report from the Agricultural Instructor at Minuwangoda, and of the headman's report, showing results of his paddy crops worked on the improved system, and I request permission to publish the results for general information.

2.—It will be seen that by sowing seven bushels broadcast in three-and-half acres, we obtained by the use of our plough 114 bushels and 12 seers against 62 bushels from the same sowing and extent worked by natives in the same field. That is 16 19-56ths fold against 8 6-7ths fold, or roughly 32½ bushels an acre against 17½ bushels an acre.

3.—By "planting out" in addition to the use of the plough we obtained (without manure) 10 bushels and 1 seer, from 1 seer planted out on a rood of land, *i.e.* 321 fold, or, taking bushels to the acre, rather over 40 bushels to the acre *from only 4 seers* planted out.

4. When it is considered that the use of 2 bushels (*i. e.* 64 seers) seed paddy per acre for broad-cast sowing produces with our plough 32½ bushels, and with the native system 17½, and that *only 4 seers planted out* (a 16th part of the amount *sowed broadcast*) will give 40 bushels an acre, the saving of food otherwise wasted for seed and the increased results of the planting out system are at once seen.

5. Owners of large tracts of land object to the "planting out" system on account of having to hire coolies.

6. But the numerous owners of tiny plots of paddy land who do all their cultivation themselves have no excuse but idleness or ignorance for not transplanting, *i. e.* for not using one or two seers only instead of a bushel for sowing their little tracts ; and it is these small holders of land, who are the sufferers from scarcity of food.—I am, &c., (Signed) H. W Green, Director.

SLAVES IN BRAZIL.—According to the *Jornal's* investigations, there are now only 204 slaves in Brazil owned and registered by religious orders, and 11 by religious brotherhoods. Nearly all of these [203] are held in the province of Maranhao.—*Rio News.*

COCONUTS IN FIJI.—I have lately had occasion to traverse this island in various directions, and the coconut trees are looking splendid. I never saw such a crop of nuts as the trees are bearing at present, and, always provided there be no hurricane, there will be a large quantity of copra made.—*Cor.*, *Fiji Times*, Feb. 6th.

CINCHONA CULTIVATION IN CEYLON.—The Hon. Secretary of the Udapussellawa Planters' Association, in sending us information respecting his district for the Directory, expresses the opinion that there must certainly be three million cinchona trees in Udapussellawa alone, without counting the Nuwara Eliya estates! Well done Udapussellawa: if proprietors can only hold on long enough, there ought to be good returns for them by-and-bye.

CEYLON TEA AT HOME.—A Ceylon proprietor, writing from London by last mail, says:—"I have just been told by a traveller to a large teahouse that with regard to Ceylon tea, more half-chests are wanted containing about 50 to 60 lb., that in fact *all* might be sent home in half-chests. Grocers generally keep 3 or 4 varieties of tea, and whole chests deteriorate before they can be used up; hence the demand for half-chests, and this points specially to Ceylon tea, which has inferior keeping powers to Indian and China. China tea now-a-days is packed almost universally in half-chests."

TOBACCO.—The Chancellor of the Exchequer will probably be startled by the proposal of the secretary of the Royal Botantic Society that he should allow tobacco to be grown and manufactured in England free of duty for five years. It is Mr. Sowerby's opinion, founded on nearly 50 years' experience of tobacco culture in the society's garden, that a taste would in that time be developed for the home-grown weed, just as a taste has been created for Indian tea, which a few years ago people would not drink. What does Mr. Goschen say to it?—*Globe.*

CACAO CULTIVATION in the Dumbara Valley has, we learn, been much benefited by irrigation, so much so that it is anticipated Mr. Vollar may fully utilize the Rajawella waterworks originally erected by Mr. Tytler with reference to his coffee. This reminds us of the admirable land presented below Kalawewa, with the opportunity of irrigation, for cacao or even tea, as well as paddy, cultivation. All three would pay well doubtless, and Government would probably give easy terms to a pioneering Company taking up 1,000 acres and cultivating at once 100 acres, say, with each product.

TEA SHOPS are thus noticed in the N. W. Provinces and Oudh Agricultural Report for Sept. 1887:—The efforts made to popularise consumption of tea are undoubtedly giving good results. The shop first opened in Cawnpore under salaried management did not do well. A committee of native gentlemen then took the matter in hand; the furniture was made over to them together with a sum of R30, and with this small beginning it appears the shop was maintained and much resorted to throughout the last cold season. In Lucknow, also the shop originally started is now successfully managed by a committee, and, besides, a large number of private shops have been opened which appear to do a very good business. Two native gentlemen of good standing have obtained sanction to an advance of R2,000 in the manner of *takávi* for trading in tea.

INFLUENCE OF IRRIGATION WATER ON CLIMATE AND RAINFALL.—We quote the following paragraph as bearing on our remarks with reference to the probable influence of the restored Kalawewa tank on the arid climate of the district. We believe that in modifying climate it will be marked, and that, though to a much more limited extent, it will favourably affect absolute rainfall:—

A correspondent in the *Christian College Magazine* says:—"The carrying out of the Periyar project will give an opportunity of making a very valuable series of observations on the effect of irrigation on rainfall. The parts of Madura which are to receive a supply of water from the Periyar are at present but scantily provided with water during a great portion of the year, and the rainfall is comparatively small. When the irrigation project is completed more than 100,000 acres will be supplied with a large quantity of water, and the local evaporation will be greatly increased. This may well have an influence on the rainfall of the surrounding districts, and it would be worth while to take some pains to obtain an accurate series of observations at selected stations before and after the completion of the project. Some stations already exist, but probably not enough, and as a period of some five or six years (at the least) will elapse before the water of the Periyar can reach Madura, there is still time to supply any deficiency in this respect. We venture, therefore, to call the attention of the Meteorological Reporter to Government to this matter.

"THE MIGHTY MAHSEER," about which and the sport it has afforded him the Hon. Mr. H. S. Thomas of Madras is so enthusiastic, is treated by a local writer who claims to be a F. Z. S. L., after an irreverent fashion which, we suspect, would rather surprise the author of "The Rod in India." The mahseer in India was pronounced by the Zoological Fellow's friend "G." to be for angling purposes a fraud, and similar testimony is borne to the unsatisfactory tendencies of the "Cooriah" in Ceylon. The large fish refused to be lured by fly or bait. Neither the Indian "G." nor the Ceylon F. Z. S. can have ever met Mr. Thomas, or apparently his book recording a long series of successes and the means by which they were attained. To us the principal question in the discussion is the quality of the mahseer as human food, his alleged unwholesomeness at certain seasons, and, if he is poisonous, the reason or reasons why. The gratification of the sporting instincts of the few is, after all, a secondary matter to securing a plentiful supply of wholesome fish food for the people. If both ends can be simultaneously secured good and well. The zoologist doubts the permanent naturalization of trout, even in our hill streams, and he advises the introduction from the rivers of Jamaica of a fish, which he believes to be a species of trout, although it is called "the mountain mullet." We are told of it:—

"There undoubtedly is in Jamaica a species of fish, delicious for the table, that will take the fly, and that would in every way answer our requirements, and would be general from the low country to our highest mountain streams."

This is just the species of fish we want for our freshwaters, and we should think Mr. Nock must know something of the Jamaica "mountain mullet" and be the means of its introduction to Ceylon, unless it should turn out as in the case of the mahseer that we have the fish surreptitiously sailing under false colours. Since writing this we have an interesting letter from "Kotmalegama," which see and our note to it.

The *Foochow Echo* of February 25th says :—The report given by native papers that the losses of the Foochow teamen during last season amount to $400,000 cannot be true, for in such were the case, we fear there will be no native teamen left for the coming season. When a Chinaman says that he has lost the above-mentioned, or any other amount, we must understand that he means he *could not squeeze that amount from us.* We doubt not that some of our native teamen did suffer severe loss, but to such an alarming amount is next to impossible. The actual loss, we are given to understand, does not exceed $50,000 and this amount is shared by few teamen, while many made, as usual, their fortunes.—*China Mail*, March 14th.

Different Uses of Cement.—A bushel of cement may be turned to a variety of useful purposes on the farm. Mixed with three or four times its bulk of bright, sharp sand it is almost invaluable on the farm for purposes aside from building or patching of walls, cisterns and wells. Common cement is as good as any, but where it is used to hold water it should be made to set very slowly by the frequent application of moisture while it is in the process of drying. Where this is done cracks will not appear causing the cistern to leak. Cement may be used in making permanently tight boxes,old tin or iron basins or even old baskets. Supposing for instance, a watering place is wanted for horses it can be made from an old dry goods box. Having mounted it in its place a serviceable trough can be made by smearing a quantity of very wet cement all over it inside repeating the operation before the first coat has dried and until the cracks and corners are completely hidden. Cement can also be used for making water basins for poultry or young ducks. An English writer says that he simply scrapes a hole in the earth a trifle larger than the basin desired, smoothes the sides of it a little and applies the soft cement an inch thick. This quickly-made receptacle should prove of great service throughout the season.—*Indian Agriculturist*, March 17th.

Sisu, Oranges, &c. in Northern India.—Mr. Jas. Gibson of Yatiyantota writes to us from the Gorakhpur district, N. W. P., India, as follows :—

"As I see no chance of being back for a month or two, I send you the sisu tree seed I promised. It is counted very valuable here, and fine belts and avenues are planted all over. It should grow high, I think, as in winter it is cold here, even on the plains, as cold as Nuwara Eliya at coldest, but I believe in the hot season it is as hot as the low-country in Ceylon; so perhaps elsewhere would suit too. The pods are just sown in nurseries as sent about three inches apart and transplanted. The orange seeds sent in envelope among the sisu are wild Nepaul oranges, and are the best oranges I ever ate: we get them at one rupee a hundred here, carried down from Nepaul, small and bright orange color when ripe, and their skin somewhat like mandarin. Got our first strawberry plate for season yesterday. The trees are now all over the country coming into leaf and the weather milder; it is spring time, and what a paradox—harvest is just beginning, wheat and peas ripe and begun reaping everywhere, flax and dal nearly ripe, indigo is being sown now. Did I tell you the railway here, Bengal and North-Western, cost only 45,000 and 50,000 rupees a mile to complete? A very substantial one and well ballasted, but I must tell you there is not a rise of 30 feet from one end to the other, about 150 miles long I think, and here in the plains is only about 120 feet above Calcutta, 800 miles south. I find men's wages two annas a day only here, and young ones one anna. House servants seven rupees a month and koki and gardeners two and three rupees a month, bread 6½ cents a loaf, fat beef nine cents a lb., and all vegetables more than can use in everyone's garden and natives have baskets of them in presents daily.",

Planting in Netherlands India.—Says the Amsterdam correspondent of the *L. & C. Express* writing on Feb. 29th:—A limited company, styled the Borneo Tobacco Company, Sugut, has been established at Rotterdam for the purpose of working certain lands for tobacco cultivation situated near the river Sugut (North Borneo.) The territory comprises 50,000 acres. The company's capital amounts to fl1,000,000, divided into two series of fl500,000, and of 500 shares each, the first of which is nearly taken up. Reports have been received that the Royal sanction has been granted to the statutes of the Cultuur Maatschappy der Vorstenlanden, so that the establishment of this company may be expected in a few days. This company is the consequence of the proposed plan of reorganisation of the business of the Dorrepaalsche Bank der Vorstenlanden, which latter bank failed last night.

Indian Products.—The late Colonial and Indian Exhibition appears to have led to some interest being taken in the exportation of Indian drugs of various kinds on trial. One of these articles received during the past month was a sample of white musli, the root of *Asparagus ascendens*. It has an ivory-white colour and is hard and twisted, the pieces being about an inch long and two lines in thickness. It has a sweetish taste, and forms, according to Dr. Dymock, an excellent substitute for salep, than which it is nicer and is more relished by Europeans. At the present time, when salep is dear, it would form an excellent substitute for it as food for invalids. Large quantities of different varieties of gum arabic are also now being sent from India. Some of these, however, are imperfectly soluble in water and very dirty, being evidently collected without much care. Nevertheless, those that have been examined possess a considerable amount of adhesiveness, and appeared to contain mere traces of tanning matter. A valerian root, apparently that of *V. Wallichii*, and costus root (*Aplotaxis auriculata*), are also among Indian drugs that have been sent to this country on speculation recently from India.—*Pharmaceutical Journal.*

Mr. Marshall Ward on "Dry Rot" in Wood.—From a paper by the mycologist who reported on *Hemileia vastatrix* in Ceylon, we quote as follows :—

It will be evident from what has been stated that the practical application of botanical knowledge is here not only possible, but much easier than is the case in dealing with many other diseases. It must first be borne in mind that this fungus spreads, like so many others, by means of both spores and mycelium: it is easy to see strands of mycelium passing from badly-diseased planks or beams, &c., across intervening brick-work or soil, and on to sound timber, which it then infects. The spores are developed in countless myriads from the fructifications described, and they are extremely minute and light: it has been proved that they can be carried from house to house on the clothes and tools, &c.,of workmen, who in their ignorance of the facts are perfectly careless about laying their coats, implements, &c., on piles of the diseased timber intended for removal. Again, in replacing beams, &c., attacked with dry-rot, with sound timber, the utmost ignorance and carelessness are shown: broken pieces of the diseased timber are left about, whether with spores on or not; and I have myself seen quite lately sound planks laid close upon and nailed to planks attacked with the 'rot.' Hartig proved that the spores can be carried from the wood of one building to that of another by means of the saws of workmen. But perhaps the most reckless of all practices is the usage of partially diseased timber for other constructive purposes, and stacking it meanwhile in a yard or outbuilding in the neighbourhood of fresh-cut, unseasoned timber. It is obvious that the diseased timber should be removed as quickly as possible, and burnt, at once if used as firewood in the ordinary way, it is at the risk of those concerned. Of course the great danger cousists in the presence of many ripe spores, and their being scattered on timber which is under proper conditions for their germination and the spread of the mycelium.

A RAILWAY THROUGH A PLANTATION OF PALMS.—A railway through a Palm grove is a novelty to most gardeners, we therefore avail ourselves of Mr. C. B. Clarke's kindness by giving an illustration taken from a photograph made by that botanist, who also kindly furnishes the following particulars:—This view is from a photograph of the railway near Theria Ghat, in the Khasi Terai, in East Bengal. The Palm is Areca Catechu, which is largely cultivated at the foot of the Khasi Hills, where it grows as luxuriantly as in the islands at the mouth of the Megna, and attains 80 feet in height. It is the Palm which supplies the betel-nut chewed throughout South-East Asia and Malaya; and from its exact erectness is likened by the Sanskrit writers to an arrow shot down from heaven. The railway depicted is worked, at the foot of the hill, by a locomotive; it ascends the face of the Khasi Hills, 3,000 feet at an angle varying from 3° to 45°, and is there worked by a wire rope. This route through Theria Ghat has always been the chief approach from the plains to Khasia; and it was this route which Sir J. D. Hooker traversed and described in the second volume of his *Himalayan Journal.—Gardeners' Chronicle.*

ANTS AND PLANTS.—In the last volume of the *Nova Acta Regiæ Societatis Scientiarum Upsaliensis*, Professor Lundström publishes some remarkable information on the relation between ants and plants. Studying the nectar produced on the leaves of the Cow-Wheat (Melampyrum) he found that ants were attracted by the nectar on the leaves, and that some while walking over the leaf bore the seeds of the Cow-Wheat in their mouths down towards the ground. Professor Lundström was as astonished by the great resemblance of these seeds to the "ant-eggs" (the cocoons of the ants), and he found that the ants took these for cocoons; for when he strewed some seeds on the ground the ants saved them as they did their cocoons. Lundström afterwards found that the thin membrane which surrounds the seed and causes it to resemble an ant egg so closely, falls off soon after the seed is brought by the ants to the soil, and that it remains there untouched by the ants. Another observation of the same author, noteworthy for arboriculturists, is the following. At Christineberg, near Hudiksvall, the soil in an avenue of Populus tremula was dug and the ants, which were formerly very numerous, disappeared in consequence. In the next year Professor Sundström found that the leaves of these Poplars were destroyed by insects in a short time, whilst those of the other Poplars, where the soil had not been dug up, were quite intact. Careful observation showed that the first leaves of the trembling Poplar have short round petioles with nectar glands, whilst the petioles of the older leaves are much longer, flat, and without these glands, as Trealease showed in the *Botanical Gazette*, vi. (1881). Lundström's notion is, that the ants are attracted by these glands, and preserve the tree from the attacks of caterpillars, &c., for the first time. At a later season the leaves with the long, flat petioles are so much disturbed by the movements of the leaves that no caterpillar can go on them. The author found ants in every situation where the trembling Poplar grew.—*Gardeners' Chronicle.*

CULTIVATION OF THE SOIL LEADING TO INCREASED EVAPORATION AND RAINFALL.—In recently noticing the completion of the great irrigation tank at Kalawewa and the giant canal to Anuradhapura, we ventured to suggest that the arid climate of the region would be modified by the water captured and applied to the tilled soil. From the United Sates there comes a curious exemplification of the scientific principles involved. It is believed that the rainfall of the region formerly known as "the Great American Desert" has increased since its cultivation. Mr. C. F. Adams gives reasons for crediting such a result, thus:—

The whole region in question is a gentle slope, stretching for about 600 miles east and west, north and south. It is drained by a number of rivers which receive contributions from small streams in the nature almost of gutters or ditches, most of which, as you go west are dry for the larger portion of the year. The region is not like any which is found east of the Missouri River, but it rises to a considerable altitude only in its western portion. This vast territory, from a time so far remote as to be almost incalculable, was regularly burned over by fire, and during certain periods of the year was grazed over and trampled by countless herds of buffalo. Never being broken by the plough, its surface gradually assumed a brick like consistency. It was impervious to water. Upon this brick like surface there grew a mossy vegetation known as "buffalo grass." Water flowed off from this surface much as it would from the roof of a house. It passed into the ditches or gutters above referred to, and was slowly carried down into the Missouri. In fact, the whole country was literally one vast tile-roofed watershed, of which the Rocky Mountains were a species of rude ridge pole. It followed, of course, that the rainfall of the country, instead of sinking into the soil, and in some form remaining in the country, was carried off to the Gulf of Mexico. As population advanced all this changed. The brick or tile-like surface was broken, the water percolated into the soil and was held there, the moss-like buffalo grass gave place to growing crops, and consequently all the meteorological conditions were changed. Before this took place, there was no more evaporation from that country during the greater portion of the year than there is from the roof of a church. After the soil was broken regular evaporation began. Consequently both soil and atmosphere became impregnated with a moisture unknown before, which lasted all through the year. This seems a natural explanation of the alleged increase of rainfall, which has unquestionably taken place. Neither is there any safe ground for believing that the climatic changes have yet reached their limit. As the soil is broken further west to the base of the Rocky Mountains, there can hardly be any question that the atmospheric conditions will change correspondingly. Water which formerly poured away will be held, first in the soil, and then in the atmosphere, returning again to the soil in the form of rain. Consequently, there seems no good reason for doubting that the entire area of country west of the Missouri and east of the Rockies will within a few years enjoy a rainfall sufficient to admit of raising crops without any considerable degree of artificial irrigation, the general breaking up of the present tile-like, impervious surface of the soil being the single condition precedent. The question is not only one of scientific intrest, but it is of vital importance to all the companies now building railroads through that region and any explonation of it derived from observation and experience can hardly be otherwise than of value.—*Leader*, Feb. 4th.

THE CEYLON SPINNING AND WEAVING COMPANY, LIMITED.

Under the above heading we welcome the introduction into Ceylon of a new industry which, we believe, after the initiatory difficulties are overcome, will be nearly as successful here as it is proving to be in India. For many years back, at intervals, we have urged the subject of establishing a Colombo cotton goods manufactory on such local capitalists as Mr. C. H. De Soysa. The realization of the long-desired result has come from another direction, as may be seen by the prospectus issued as a Supplement to the daily papers. We predict a great future for the manufacture of cotton in the East, and as far as regards the manufacture of fabrics for local consumption, we think the Ceylon Spinning and Weaving Company, Limited, has a profitable field before them. We have here all the advantages enjoyed by Bombay, so far as suitable climate, cheap and abundant labour, cheap land, and moreover if so required a large number of buildings constructed for carrying on our moribund industry which may easily be converted into cotton factories.

The promoters of the Company have set forth in their Prospectus all the advantages which Ceylon possesses for the manufacture of cotton goods; but we would not be doing our duty as guardians of the public, if we did not point out, where, in our opinion the promoters are somewhat over-sanguine. We do not blame them for this, because it is not after all a matter of special importance. We do not think too much stress should be placed on the advantage of the Colombo climate over that of Bombay, nor do we think that the nearness of Ceylon to Tuticorin, or to China, will be found to be of much benefit.

We believe that the chief portion of the cotton which will be required by the Company will have to be imported, not from Tuticorin, but from Bombay and Egypt. No doubt the short-stapled Tinnevelly cotton can be mixed with the longer-stapled Indian and Egyptian products; but we doubt if it would answer to put up machinery exclusively for the manufacture of Tinnevelly cotton. If Bombay cotton has to be used, our proximity to China will be of little advantage. We recommend the directors of the Company to put out of their calculations any benefit to be derived from the manufacture of goods for the China market, the spirit of progress is brooding over that vast empire, and there is little doubt that the example of India will, in time, be largely followed by the awakening "celestials" who have little to learn in the manufacturing art.

Cotton of suitable quality can no doubt be grown in small patches here and there in the island; but it is questionable whether Ceylon or its people are suited to its cultivation in sufficient quantities to meet the requirements of the Company. There has always been a market for cotton here, and if the enormous prices paid for the article, during the American war, could not stimulate the production, it may be asked if present prices can be expected to do so?

The Tamil and Sinhalese coffee pickers of Colombo will welcome the new employment, and will, no doubt, in time prove to be skilful spinners and weavers; but they will have to be taught, and the art of manufacturing cannot be acquired in time to influence the first dividends. The Indian Companies referred to by the promoters are now flourishing institutions; but we think it would have been more judicious if comparisons had been made with similar institutions when the industry was in its infancy. The prospects of the Company for manufacturing goods for local consumption are sufficiently good, to render it unnecessary to go beyond them.

The native industry will be protected to the extent of 6 per cent import duty, and the Bombay manufacturers' profits and charges. And these should be sufficient inducements to encourage the applications for shares; but we must not shut our eyes to the fact that every new industry has to undergo the usual infantine troubles before it reaches its prime, and Ceylon will be no exception to the rule. At the same time, there can be no doubt, that, profiting by the experience of Bombay, the Ceylon Company may escape many of the mistakes made in the early days of the industry in India. We have no hesitation in assuring intending shareholders of the soundness of the enterprise, and especially in calling upon our native friends to subscribe liberally to the formation of a Company, which cannot but in time be of incalculable benefit to their unemployed compatriots. Even if the first returns are not quite up to the more sanguine expectations, yet eventually we have no doubt the results will be equal to the hopes of the promoters of the first Ceylon Spinning and Weaving Company.

We asked a gentleman of wide knowledge, founded on large experience, to give us his thoughts in regard to the prospectus of the enterprise intended to introduce for the first a purely manufacturing industry on a large scale into Ceylon. The above is the result thrown into editorial shape, but, as we cannot without qualification adopt all the conclusions arrived at, we add our own ideas in regard to a project which, if successful (and we do not see why it should not be), will mark an important era in the industrial history of Ceylon.

We are surprised to see the advantage of our contiguity to Tuticorin, the port of the vastly extended cotton fields of Tinnevelly, undervalued. We had conceived of such contiguity and the large supplies of cotton available of a special sort as one of the grand reasons why the experiment here was likely to be successful. Our only fear was of competition in still nearer contiguity to the source of supply, at Tuticorin itself, where, a recent visitor informed us, a large building intended for a cotton factory is being erected. On mentioning this fact and our apprehensions to a gentleman who has taken an active part in starting the enterprise, he made light of the effect of the Tuticorin factory, stating that probably the same engineer would be employed on both the Tuticorin and the Colombo buildings. From Tuticorin this authority told us that cotton could be brought over in an unbaled condition in native craft, considerable expense being thus saved. He said nothing of our competing with the India mill owners for supplies of Dharwar and other cotton in Bombay, or in Egypt with European purchasers of the fine cotton of the land of the Pharaohs, but we see that the prospectus contemplates such contingencies as possible.

As to cotton being locally grown, we may say that it was at one time (about fifty years ago) largely produced in the north and east of the island for the numerous handlooms of the natives. Gradually British thread and twist came to be used, and, finally, the handloom industry was practically extinguished by the superior quality and cheapness of Lancashire fabrics. Attempts to grow cotton on a large scale in Ceylon by European planters, failed, chiefly, we believe, because the boles ripened and opened in the height of the monsoon rains, the wool being thus damaged. But seed could be sown at different seasons and irrigation could be used so as to render cultivators

independent of the rains. Here is an additional argument in favour of the restoration of the ancient irrigation works. It certainly reflects little credit on enterprise in Ceylon that the high—the unprecedented—prices to which cotton rose during the American Civil War led to no renewal of the industry here. But capital is often as timid as are the natives, and a quarter of a century ago we had no Agricultural Branch of the Public Instruction Department at work, and no Mr. Green to encourage his "Agricultural Instructors" to combat native prejudices and dissipate native apathy. We submit that it will be part of the duty of Government, in view of this new departure to give all legitimate encouragement to the local cultivation of cotton, in connection with irrigation works or otherwise. Indeed, much cotton could be grown by the natives in corners of their fields, in fences and so forth. Seeds of superior kinds, if required, can be obtained from the Indian Agricultural and Horticultural Society from the various Indian Governments and from many societies and individuals. The leaders of the spinning and weaving enterprise will, of course, use every effort to encourage the local production of the raw material for their manufacturing operations. A new industry of this kind, if remunerative, and the provision of employment in the factory on good wages for the men, women, and children, who were wont to be employed in the coffee stores, would be such real blessings to the country, that on such grounds the new enterprise has our best wishes for its success. Of course the men, women and children employed will have to be taught the management of spindles and "mules" and "jennies," but the natives are apt of brain and delicate of hand in such matters. So are the Chinese, but we doubt if they will, for some time yet, do their own spinning and weaving. If no market, save the local one, were available, we fear there would be little chance of success to the experiment; for it is not contemplated here any more than in India to manufacture the finer kinds of cottons for which Lancashire is so justly famed. We shall thus hope to escape the interference of the Manchester men with our cotton duties of 6 per cent, not meant to be protective but yielding about R200,000 per annum, which we could ill afford to lose. The friend, to whom we have already referred, was good enough to hand us the following memorandum of the staples contemplated for manufacture in the mills:—

"We hope to spin chiefly 20s for export, but will also be able to turn out the finer counts of yarn, such as 40s and 50s or higher. The mills will probably weave

Grey long cloths
Grey T cloths
Grey drills
Towelling

Scarfs or Dhootise, colored check goods, and the plainer descriptions of sarongs."

Such is the modest catalogue of manufactures contemplated. But even so, large buildings, a very large and perennial supply of water and steam power which may rather surprise some of our friends will be required. An engine of 30 horse-power was ample for the largest coffee store, but for the cotton factory twenty times 30, or 600 horse-power will be required. A full and never failing supply of water is so essential, that we suspect he site chosen for the erection of the works will be somewhere on the side of the Kelani river,—where a firm foundation of gneiss or *sound* laterite can be obtained close to the stream, but beyond the influence of floods.

Such are the main thoughts which occur to us and the leading observations we have to make on an enterprise, the very boldness of which we admire and which we trust even the pressing allurements of the tea enterprise will not deprive of that support necessary to make it a great success

DELI NEWS.

(Translated for the *Straits Times.*)

It must be acknowledged that Chinese coolies have been the making of Deli, which has hence enjoyed a prosperity exceptional among Dutch colonies in this part of the world. These golden times are now receding into the background. The struggle for existence has become harder. Many of the recently started estates are in difficulties, and can hardly get on owing to the impracticability of securing serviceable coolies at fair rates. A decline in the power of the coolie brokers' ring at Singapore, and a considerable fall in the price of coolies would be a sensible relief to them. The success of the negotiations now being carried on by Mr. Lavino at Calcutta would supply them with a class of labour in many respects preferable to Chinamen.

SARAWAK NEWS.

(*Sarawak Gazette*, 1st March.)

Pepper planting is proceeding very favourably at Sibu and Kanowit; thirty-two gardens have been opened, and are doing well, being well looked after; in a short time Rejang will commence exporting pepper. The small monthly grant given by Government to those opening pepper gardens has not only been of great assistance to the planters themselves, but, securing the interest and supervision of Government, encourages those with money to advance capital. It will be a wise policy to encourage to the utmost pepper cultivation and similar industries, as the jungle produce, upon which the trade of this river is almost entirely dependent, is gradually but surely falling off.

THE "DAILY TELEGRAPH" ON CHINA TEA AND ITS COMPETITORS.

Some persons of a gloomy turn of mind maintain the lugubrious doctrine that, although the present age may be one of intellectual and scientific progress, it is also one of marked deterioration in the excellence, not only of manufactures, but of the natural products of the earth. English cheese, lament these social Jeremiahs, is no longer so rich or so tasty as it was wont to be; first-rate Havannah cigars are "played out" more brandy is made from whiskey than from wine and cognac; while at Bordeaux "Val de Penas" from Spain, Barolo and Chianti from Italy, and dried currants from Greece are systematically fabricated into a so-called claret. There are no more ribston pippins, the canned peaches which we import from America are poor in flavour; not enough real butter is made to feed the world, who are fain to eat animal fats and coagulated oils as substitutes for the real article; mustard, and nearly all condiments are largely adulterated; coffee does not always own on the label of its packages how much chicory it contains; ostensible Welsh mutton frequently comes from New Zealand; much strawberry jam is made from pumpkins; houses are jerry-built; the breed of horses, especially those used for railway purposes, is inferior to that of a generation since; there are no great tenors coming to the front; no lyric poets; Punch and Judy are fading out of the land; shoddy clothes are worn by tens of thousands; and, to complete the dismal catalogue, it is openly stated that Chinese tea has appreciably deteriorated in quality. The Chinese Government lately invited a special committee of experts of the Shanghai Chamber of Commerce to hold an inquiry into the cause of the decline of the exports of tea from China. Between 1881 and 1886 the quantity of tea shipped from the Celestial Empire decreased by about twenty-four million pounds; while, on the other hand, the

exports of India and Ceylon teas increased by nearly thirty-five million pounds. The report of the committee actually recommends the Chinese Government to despatch a number of intelligent and practical Chinamen to our Indian Empire and to Ceylon, in order to study the methods of cultivation and preparation in use in those regions. Things, indeed, seem to be coming to a pretty pass when the tea-growers of the Middle Kingdom are to be despatched to foreign parts to learn the art of making their tea fit for the market. What next, and next? Will pig-tailed students travel to Sévres to take lessons in the manufacture and painting of porcelain? Will they go to Lyons to pick up a few hints about silk-weaving, or visit Hatton-garden in order to acquire the art of turning and carving ivory? It must be added, however, that the committee of experts have recommended the Government of Pekin to set up, at the Imperial cost, in the tea-producing districts, one or two factories fully supplied with modern machinery, in order to teach the people how it is that foreign competition is not gradually, but swiftly, beating them.

It would be idle to inquire for how many centuries teeming millions of the Chinese Empire have been growing and manufacturing tea. There does not appear to have been at any time any departure from the primitive modes of preparation handed down from generation to generation. The charge at present made against the Chinese is that they fire or dry their tea too rapidly and too negligently. So soon as the leaves are gathered, and even before they are sifted, they are spread on iron plates, and when they are quite hot rolled in the palm of the hand. The heat is applied to deprive them of the narcotic qualities which they possess, while the rolling enables them to be kept in a restricted space without losing their aroma. In some districts the fresh leaves are thrown for a few seconds into hot water; it is said to be another way of killing the narcotic element. These operations, simple as they seem, demand much delicacy and skill in their performance; for, if the leaves are fired at too great a heat, they will lose their colour, and consequently their price; whereas, if they are not made hot enough, they will not keep the fold into which they have been rolled, and require to be placed on the chafing-plate again and again. The experts of Shanghai point out that native growers are in such a hurry to fire their tea that in the course of a few months the leaves become vapid and flavourless. This carelessness also tends to the interruption of fermentation; and it is to this fermentation that Indian and Cingalese teas owe the strong rich liquor on which they depend for their repute. Green tea, such as Hyson, Twankey, and Young Hyson, has never, it would seem, been subject to fermentation, and is only very slightly rolled. As for the Imperial tea, which only the Emperor and the members of the Imperial family are privileged to imbibe, it appears to be cultivated and manufactured with some attention to cleanliness. The cultivators are forbidden under the severest penalties to eat garlic or to smoke opium, lest the young leaves should be infected by unlovely exhalations. The Imperial tea is also "pearly," from the circumstance of the leaves being very small and very tightly twisted; while cousin-german to the Imperial is gunpowder tea, which is even a smaller leaf, and should be of a darkish green shot with a slight silvery tint. Black teas are exposed for a certain time after being gathered to some degree of moisture, so that they may ferment, during which process they lose their pleasing green hue to take that of a blackish brown. Black tea in China, especially Bohea, is by all accounts often shamefully adulterated. Leaves of different species, but having some slight analogy in flavour and colour to the products of the tea-plant, are mixed with a small quantity of genuine tea and exposed to a high temperature in bamboo baskets, while fermentation brings about a vast amount of amalgamation. This last is "brick" or "hoe" tea, as the Celestials appropriately term it—may be known by its badly rolled, broken, and half pulverised leaves, its want of uniformity of tint, and the reddish, insipid infusion which it produces after coction but Congo and Souchong should be much more carefully prepared. Then come the luxurious black teas. Ponchang leaves are so scrupulously selected from Souchong that the proportion kept for producing the first-named commodity is not more than two per cent; and Pekoe—meaning white down—chosen from young leaves of the first crop, should be recognisable by the leaves being covered by a minute downy deposit, and its odour should be as sweet and aromatic as that of the rose; the infusion will be of a pale golden tint. There are many fancy teas which scarcely ever reach Europe. "Ball tea" is a conglomeration of leaves kneaded together to the size of a walnut and wrapped in a sheet of rice-paper. "Pigtail" tea presents a certain resemblance to pigtail tobacco; and then comes a class of coarse and, to Europeans, repulsive teas which are greedily consumed by the Oriental races. There is the tea pressed into the shape of a tube, which is eagerly imbibed by the peoples of Central Asia, and which, to suit their palate, is generally boiled in a cauldron with salt, flour, and rancid butter. "Brick tea," so called from the form of the tablets into which it is pressed, is consumed to an amazing extent by the Russian peasantry and by the Calmuc Tartars. It is drunk boiled and flavoured with grease, camel's milk, and a little flour.

If the Chinese are ambitious to keep that hold on the European and American markets which they have possessed for so many generations, they must export such a tea as that described by the special committee of experts at Shanghai. They seem, on the contrary, to have fallen into a very stupid and vicious system, of attempting to make large quantities of tea ready for exportation under one mark or "chop," and this hasty and often dishonest mode of procedure is said to be one of the main causes of the deterioration and consequent depreciation in the market of Chinese teas. The "one chop" system means that undue time is spent in getting a sufficient quantity of leaves together, and the leaves are consequently stale and void of their juices before they are roasted. In India the "chops" are of moderate volume, consisting as they do of the pickings of a single day, when the leaves are fresh and full of their best qualities. Frequently inferior qualities are mixed with tea purporting to be of one standard of excellence alone; and, although this fraud may escape detection in China, the voyage to Europe or to America brings out the coarse flavour. The skilful, steady, and upright Japanese are gradually depriving the wily Chinamen of their green tea trade, just as India and Ceylon are rapidly taking from the Celestials the trade in black tea. The unfortunate Chinese tea-growers are also heavily handicapped by onerous transit dues imposed in the Empire itself; still, they no doubt find it profitable to continue to send to the red-headed barbarians extensive consignments of "lie tea," or the sweepings of Chinese warehouses. The United Kingdom, United States, Australia, and New Zealand want more and more millions of pounds of tea every year—full, rich, honest tea—and it is highly gratifying to Britons to learn that our fellow-subjects in Hindostan and Ceylon can send us such a tea in practically unlimited quantities—tea carefully grown, scientifically gathered, skilfully cured, deftly rolled, cleanly sifted, well packed, and in every respect superior to the dirty and inferior stuff which the Chinese have been for some time past exporting.—*Daily Telegraph.*

CEYLON UPCOUNTRY PLANTING REPORT.

The Drought—Coffee—Cocoa.

15th March 1888.

We are still suffering much from the want of rain. How much money the prolonged dry season is going to cost us would be hard to estimate. Our coolies suffer, as well as we do, in fact the far-reaching-ness of its effects is more than can be told. Estimates are getting short beyond all hope of recovery; the bushes, especially where the tea is young,

are tried, so that they look almost hopelessly broken down, you get miserable pluckings, and the quality of your tea is about on a par with your plants.

COFFEE, however, has been out in fine blossom, the spike being strong and healthy. So favourable has this season been for flowering, that you can see in abandoned land, stray struggling trees, clothing themselves in bloom. All kinds of native coffee has also been full of promise, but how much will set remains to be seen.

It is perfectly wonderful how CACAO has stood out, and on the whole how well it looks, but the spring crop will be a very scant one, although blossom does struggle out, here and there, showing a commendable willingness. Most of the cacao shade trees have shed their leaves, but our local scientists don't fret over that. The sap of the cacao is all the better to be warmed up a little, and they prophesy that with a good fall of rain we will have fresh cover, and a profuse show of the little blossom.

JACKSON'S NEW TEA ROLLER.

3rd April 1888.

Jackson's new roller "The Rapid" is evidently a fine machine, and certainly turns out nice work in a short time, the twist of the tea being good, and hardly any broken. It spills a little when first started, jerking the leaf off the table on to the floor: this is doubtless caused by an inequality in the distance between the table and the box. It will be a much more difficult machine to set than any of the others, and this tendency to spill will be the trouble. Still it is not very much after all, and as soon as the leaf begins to twist the spilling ceases. As to the amount of power required to drive it, I fancy it has not been fairly tested yet—in Ceylon I mean,—and it will be interesting to know if the saving claimed is really a fact. That it will take less power than the "Excelsior," is clear to anyone who studies the construction of "the Rapid," but how much less is the question. By and bye, this too will be demonstrated. The device for lifting and lowering the lid, and applying pressure is very effective and simple. Here, however, the planter works very much in the dark as to how much weight is being applied. By noticing the contraction of the spring a rough kind of guess may be arrived at, but what is really wanted is an index to show exactly the pressure on the leaf. With this index the present haphazard style will give place to exact knowledge, and when the planter has learned, after experiments, what weight produces the best results, he can keep at that, and have a more regular out-turn of tea than ever he had before. Besides this, the index would be one step nearer towards scientific tea-making which will certainly come in time. PEPPERCORN.

PLANTING IN NETHERLANDS INDIA.

(*Translated for the Straits Times.*)

The *Java Bode* of the 25th February states that the Government coffee crop there, this year, has been estimated at 483,400 piculs. The value of planting land continues steadily to fall in Java, in proportion to the decline of produce quotations. Recently, a sugar estate in the province of Bezukie which had cost half-a-million of guilders was sold for hardly one hundred and fifty thousand. A coffee and cocoa estate in the Prenager Regencies changed hands the other day for 41,000 guilders. Four hundred thousand guilders, had been sunk in it. The value of dwelling houses has also fallen. They have become almost unsaleable when mortgaged. In such cases the mortgagees has been obliged to become owners as well, from the impossibility of otherwise recovering the money they had advanced on them.

The Netherlands India Government has placed restrictions on the emigration of coolies from Java. Power is however reserved to the Governor-General to grant exemptions. This dispensing power was lately exercised in favour of the Cocos islands. Messrs. Tidman Balfour & Co. have received permission to recuit thirty natives of Netherlands India for service on the islands in question. The contracts must be entered into with each coolie individually, and be officially certified separately. Certificates will be withheld until it is satisfactorily established that the coolies are perfectly aware of the conditions of their agreements, and fully accept them. The advances to the coolies must be paid to them in the presence of a Government official. The firm binds itself to send the coolies back free of charge to their homes on the expiration of their contract, unless they wish to remain in the Cocos islands of which however satisfactory proof must be adduced.

In Banda, the new year was ushered in by a fearful hurricane accompanied by heavy rains, which wrought wide spread havoc in the nutmeg plantations. The force of the wind uprooted numbers of nutmeg trees, large and small. In nine plantations alone, 280 fine and large trees came to the ground. One estate, on an islet, lost 4,000 fruit-bearing trees. From the trees left standing, all the fruit expected to ripen in February and March, have been blown down, thereby destroyed all hopes of a heavy crop. How grievous this untoward event has proved to the planters may be judged from the fact that they had every prospect of an abundant crop. The short crop in prospect during the first quarter of the year, has had a marked effect in raising the local price of nutmegs and mace.

Disease among sugarcanes is spreading in East Java. Plant cane from Borneo has been introduced on a large scale from its being proof against the disease. The Borneo canes have moreover the advantage of larger size, and heavier yield than the ordinary kinds. They attain an enormous size, and are expected to prove a powerful stand-by to the sorely tried Java sugar-growers.

MINCINGLANIANISM.

Messrs. Brookes & Green, a Mincing Lane firm of drug-brokers, are in the habit of periodically favouring a select number of their customers with a report containing their views of the cinchona market. They take special pains to prevent these fortnightly outpourings from falling into the hands of anyone outside the immediate circle of their business friends, which, whether for good or for evil, does not include *The Chemist and Druggist*. Somehow, it is true, a copy of their circular regularly finds its way into the editorial office of this journal; but that is a matter of minor importance, to which we would not allude were it not that in Messrs. Brookes & Green's market report of February 15th the greater part of a letter from our Amsterdam correspondent, which originally appeared in our issue of December 17th last, is quoted verbatim though without acknowledgment. In that letter our correspondent pointed out that large quantities of cinchona of a very high alkaloidal standard are likely to be harvested in Java two or three seasons hence, and he warns cinchona planters that when these supplies pour in growers of low-class barks may find it no longer profitable to collect their produce. In commenting editorially upon our correspondent's letter, we pointed out that the Ceylon planters would do well to study the signs of the times before the, possibly, fatal hour comes upon them, and we stated that though the Java exports might not reach the 15,000,000 lb. shipments from Ceylon in bulk, they might surpass them in alkaloidal yield.

Messrs. Brookes & Green, after quoting "a letter headed Amsterdam in a public paper to hand by last mail" (in other words, our correspondent's letter to us), repeat what they allege to be remarks made by

the paper to which the letter was sent. That paper, according to these Mincing Lane authorities, suggests that by 1889-90 forty-five to seventy-five million pounds of bark, three to four times as rich as the average Ceylon bark, or, in other words, the equivalent of six years of the world's consumption, will be ready for export from Java. Upon this alleged statement Messrs. Brookes & Green build an eloquent denunciation, more remarkable for capital letters than for lucidity, of the wickedness of spreading exaggerated accounts and sensational reports. Upon comparing the words ascribed by our critics to "the paper to which the letter was sent" with those really appearing in *The Chemist and Druggist*, the former prove to be nothing better than an absurd travesty of our comments. So far from saying that from forty-five to seventy-five million pounds would be ready for export from Java in 1889-90, we emphatically declared that her exports would probably not come up to the 15,000,000 lb. standard of the Ceylon shipments, and thus the whole edifice of exaggeration and sensationalism denounced by Messrs. Brookes & Green proves to be a perfect myth.

Mr. Gustav Briegleb, of Amsterdam, whose letter will be found in our correspondence columns, and other readers of our journal who have seen Messrs. Brookes & Green's circular, are naturally under the impression that "the paper to hand by the last mail" is *The Chemist and Druggist*. It is right to say, however, that, upon communicating with Messrs. Brookes & Green, that firm stated that they did not quote from *The Chemist and Druggist*. At the same time, they refuse to reveal the name of the paper which, they aver, contained our letter and the travesty on our comments. They also challenge our right to even read, much less reply to, a circular which, they say, was sent to their friends only. We may urge upon Messrs. Brookes & Green, if they so particularly wish to retain the strict privacy of their publications, to take greater precautions in selecting their friends than they have hitherto done. And we may add that, as far as we can follow their arguments the greater privacy they can secure for their reports the better for the cause they advocate.

Truly amazing ideas are entertained by several people about Mincing Lane with regard to the functions and duties of the press. We could name a number of gentlemen in that locality, who profess every desire for the welfare and prosperity of this journal so long as it confines itself to what they would call its own particular sphere, but bristle with indignation whenever we dare to trespass upon the sacred precincts of Mincing Lane. It has been observed that the wholesale druggists do not interfere with *The Chemist and Druggist*, and therefore demand not to be interfered with by it. With regard to the former part of this proposition, we can only express our belief that if a tithe of the (fortunately ineffective) boycotting tactics pursued against us had been set into operation in another part of these islands, several eminent boycotters might be now undergoing a comfortable diet of skilly, and reposing luxuriously on the plank bed. It is surely a perfectly legitimate branch of the business of a journal devoted to the drug trade to comment upon adulterated and spurious articles openly offered for sale by public auction. Wholesale druggists who have a reputation to preserve are as much interested as are the retailers and the public at large that no spurious goods shall be sold under a false denomination, and the brokers, we should say would find it an easy matter, were they so minded, to virtually render impossible the sale of admittedly worthless goods in the open market. We may claim for ourselves the credit that if the authorities charged with the execution of the provisions of the Food and Drugs Act should in the near future include the Mincing Lane markets within their sphere of activity, it will be in no small degree owing to the efforts of this journal. We have no desire whatever of encroaching upon the private affairs of our Mincing Lane friends, and we would ask them whether it is worth the while of a few of them to continue their efforts to put obstacles in the path of our legitimate duties.—*Chemist and Druggist*, March 3rd.

JAVA CINCHONA BARK.

Sir,—You have probably noticed that Messrs. Brookes & Green, in their fortnightly report upon East India cinchona bark, have reprinted part of my letter, published in the *Chemist and Druggist* of December 17th last, omitting the last two sentences. In the omitted sentences the opinion was expressed that a minimum of 4 per cent quinine in the bark may be considered as the vital question of cinchona plantations, when Java in a few years will fall into the market with full crops of bark.

Messrs. Brookes & Green state that the paper containing the aforesaid letter (your issue of December 17th) reached them by mail, that the market was dull and lower just about the time the above report reached London, that the interests of owners of Java bark are being seriously damaged by the report of probable future immense supplies from Java, and that they have had four years ago a large assortment of samples of Java bark testing up to 15 per cent sulphate of quinine, but then anticipated that the commercial shipments later on would be of a lower grade of quality, whilst they find that the average contents of the Java bark sold last year fall below 3½ per cent of crystallised sulphate of quinine.

The impartial reader of Messrs. Brookes & Green's report, if he is acquainted with their former special reports directed against the Amsterdam market, will see, as I do, in their comments upon the Amsterdam letter the search for a dark background to the brightness of their virtues. Nobody, I should think, ever accused them of having tried to induce shipments of Java bark to London; but we at Amsterdam, and, I suppose, many a serious London merchant with us, do not approve of their putting things in a wrong light. Their criticism of the Amsterdam letter is a specimen.

Messrs. Brookes & Green state that the paper containing the Amsterdam letter of December 14th reached them by last mail (from Ceylon?), and possibly damaged the London market then. Without commenting further upon the unlikely suggestion that your journal should have totally escaped the attention of the London drug trade interested in the drug line until it came back from Ceylon, I would ask whether it is probable that a market can be influenced by things to happen two years in the future?

The last London sales and ours of today are the best answer to that question. At the former a distinctly firmer tone predominated, and our auctions also went off well, putting values again very near the values of the highest December figures.

Messrs. Brookes & Green must admit that their imagination has played them tricks. Their solicitude for the well-being of cinchona-planters in Java has made them see spectres, and the same rich fancy has induced them to prophesy, as a certain consequence of the mischievous Amsterdam account of probable large Java crops of rich bark after 1888, grave harm to property and produce of planters of Java bark.

They have been asked whether the Amsterdam letter was written with a purpose. No doubt it was, and that purpose is so intimately connected with the interest of their confreres (the Java planters) that one may wonder at their not finding it out for themselves.

The letter was written simply for the purpose of drawing the attention of cinchona-growers—no matter whether in Java, Ceylon, the East or West Indies, Africa, or South America—to the risk they will run in spending money for the cultivation of bark containing less than 4 per cent. sulphate of quinine.

Messrs. Brookes & Green say they have yet to see they obtained rich Java samples testing up to 15 per cent., on the basis of which they might have written a report calculated to frighten bark-users and sellers of Java bark; but that they did not write such a report, as they realised at the time that the samples were single pieces cut from the stout barks of the tallest tree, and that the average test of shipments later on would be of lower quality. They do not state what they reported on those remarkable samples; it may however, be presumed that their report was written

as not to frighten planters of cinchona bark. Would it not have been better for planters—and especially for those in Ceylon—if Messrs. Brooks & Green had laid full stress upon the fact of Java being able to produce bark up to 15 per cent. sulphate of quinine? They might have realised also that where one tree grew bark producing 15 per cent. more trees of the same richness may grow; and they might have known that multiplying by grafting and budding is done successfully in cinchona plantations.

Cinchona-growing requires a large outlay of capital for years before the first crop worth mentioning is harvested, and even when, after the eight years, regular harvesting is possible, the yearly expenses amount to 1,500*l.* to 2,000*l.* on a middle-sized estate, say of three to four hundred acres.

How many thousands might have been saved if brokers like Messrs. Brookes & Green, instead of treating the high tests of the Java samples as a matter of small significance, had fully forewarned planters of the danger they were running in continuing or extending plantations from which merely low-graded bark could reasonably be expected!

In Amsterdam the analysis of every lot of bark is published. In London this custom does not exist, and it can, therefore, not be stated, with official precision, how much quinine was contained in the Ceylon bark sold in London last year. According to Messrs. Böhringer's annual report the average was 2½ per cent. of sulphate in 1887, or higher than in former years, owing to the fact of low-graded bark and twigs not having been shipped for Europe. Java, on the other hand, ships all its bark; and although there are still cinchona estates in Java where the owners have been unlucky in the choice of seed when they began growing six or eight years ago, and which, consequently, produce low-graded bark, the average percentage of Java bark for manufacturers' use sold in Amsterdam on January 19th was 4·2 per cent., and in February 4·7 per cent., and a steady increase may be expected in proportion as the poor trees are harvested and replaced by rich ones.—Yours very truly, GUSTAV BRIEGLEB.
—*Chemist and Druggist*, March 3rd.

PLANTING IN DELI.

(Translated for the *Straits Times*.)

New tobacco estates, so says the *Deli Courant*, are being opened out on all sides, in the coast districts adjacent. Siak in particular turns out to be the land of promise for pioneering efforts. About fourteen estates have already been started. A greater number of land contracts have been entered into. In Assahan and Pagurawan, affairs have taken the same turn. The Government, however, lags behind so far as regards the departments of police and justice. Nothing has been done in the direction of ensuring the safety of life and property. The planters themselves must see to their own protection and the safe-guarding of their coolies. In case of disturbances among the latter, they are obliged to rely upon mutual help. They know that such proceedings are contrary to law, but cannot help it. The police force on the coast hardly meets the requirements of Deli. The few policemen in the neighbouring districts are powerless to cope with the lawlessness and turbulence sure to follow the starting of numerous estates. Finding a remedy for this unsatisfactory state of things is the bounden duty of the Government, which can no longer defer taking action on the matter. The planters otherwise will have no choice but that of taking the law into their own hands on the plea of necessity.

CULTIVATION OF TROPICAL PRODUCE IN SAMOA.

We had no idea, until we had read an account of a visit by Rev. Joseph King, of the extensive scale on which the Germans in Samoa have engaged in the culture of tropical products. We quote as follows:—

Some things have very much changed, and nothing surprised me more than the extensive cultivation of the land by German enterprise. I rode through thousands of acres of well-kept plantations, which were covered with dense tropical forest when I left Samoa 15 years ago. The German overseers of these plantations with much courtesy, allowed us to inspect everything. A most interesting visit Mr. and Mrs. Spicer and the British consul and myself, paid to Otumapu, a plantation of about 5,000 acres, situated on the slopes of the mountain at the back of the port, the harbour of Apia. In this plantation six different articles of commerce are being cultivated, and, by a strange coincidence, the name of each article begins with a C—Copra, cotton, coffee, castor oil, cinnamon, and cocoa. The growth and treatment of each plant was described to us by Mr. Goldberg, the overseer. We saw the machinery used in preparing some of these articles for the market turned by a waterwheel, which was fed by a most beautiful mountain stream. All the work on those plantations is done by imported labourers. We were taken to see a gang of Solomon Islanders clearing a valley in which cinnamon was to be planted. We went also to their sleeping quarters, and gleaned much information about their treatment and their habits. The Samoans cannot be induced to work in the plantations. Their instincts are too aristocratic to allow them to lend themselves to the work of field labourers. It is entirely by imported labour that the Germans are working. In connection with these plantations, which are beautifully kept, good roads have been made. In some parts we rode through hedges of citron and avenues of mango trees. Business men will ask does it pay? It is a pity we can't get away from such a sordid idea, and enjoy the poetry of palm groves and citron blossom without being plagued by thoughts of material profit. If I am obliged to answer this question, I should say it doesn't pay. Not yet. The outlay has been tremendous. It coasts 200 dol. to clear an acre and plant it. The firm of Goddefroy & Sons, by whom the enterprise was commenced in Samoa more than 30 years ago, failed some years since for £130,000. The present trading company which bought the estate, seem to have plenty of money, accounted for probably by the fact that Bismarck, the German Chancellor, is officially or otherwise connected with this scheme to develop Samoan resources. I have referred to the labour trade, and I feel bound to say that I saw nothing and heard nothing of cruel treatment, but what I saw convinced me that this system, unless supervised with infinite care, is fraught with immense harm to the hired labourers. It may be managed by a right-spirited man with undoubted advantage to all concerned. I met in Samoa Mr. Arundel, of the firm of Holder Bros. of London, and travelled with him to Sydney in the "Lubeck." This firm owns 14 small guano islands in the Pacific, and Mr. Arundel takes periodical voyages to inspect them. All the work on these islands is done by labourers taken from the Harvey Group and Niue. Sixty of these men were in Samoa with Mr. Arundel on their way back to their homes, and I had an opportunity of talking with them. They had been well paid, and were most gaily dressed, and what was most cheering was the fact that they had with them a native pastor, who had been engaged by Mr. Arundel to instruct them, and conduct worship and preach to them. Mr. Arundel is a Christian man, and recognises his Christian responsibility to those whom he employs as labourers. If this element regulated the traffic in labour, there would be no need for strict legal enactments to prevent abuses.
—*Argus*, Feb. 24th.

NEWS FROM DELI, SUMATRA.

(*By an ex-Ceylon Planter.*)

21st March.—I continue to receive and read with the greatest pleasure the *Overland Observer* and *T. A.*, and now that you are good enough to send the *Literary Register*, there is an additional interest attached to the "Old Rag": long may it flourish. There is one thing which palls upon an outsider, and that is, the interminable Railway

Extension discussion; it is enough to drive one wild to see the same arguments repeated year after year. I can only explain the matter in one way, and that is, that four-fifths of those who write and speak about a narrow-gauge line know nothing about the matter, but they like to see themselves in print. Well! I do hope, however, that ere long you will get your Extension, and that on the existing gauge; here the Dutch only allow the heads of firms or departments to speak, hence, although they are slow to move, there are no endless discussions when the time comes, the thing is done. There is one thing, however, that I will give you people, especially planters, credit for, and that is, unanimity in blowing your own trumpet, and quite right, too; surely, it is time some of you were making your fortunes. At different periods you have produced the finest coffee, cinchona, cocoa, cardamoms and coconut oil in the world, and now you are going in for the teas: the finest tea, tobacco and trout. Oh! where, oh! where, will it all end? Your tea, however, deserves well, and is much appreciated here by those who drink it (but, unfortunately, there are not many of them). The trout, I trust, will multiply and give exceeding joy to many ardent sportsmen. Tobacco, I trust you will forgive me, if I write and say that I am *very, very* sceptical about its proving a success in your fruitful isle. This you will put down to jealousy, but not a bit of it. Here, I am sure, we can hold our own for many years to come; and, though two Deli men *are said to have taken up* land in Ceylon (and both of them are hard-headed fellows), I fancy they will find the producing of tobacco to pay, a hard nut to crack in Ceylon, and the nut they will have to crack with you is labour. If you will allow those gentlemen to introduce Chinese labour, there may be a chance of success, but with the mighty "Kling" or Tamil you might as well ask them to make "silk purses out of sows' lugs," as get a Tamil to sort tobacco PROPERLY. I shall be glad if I am mistaken, and, after all, perhaps, tobacco is to be cultivated in a quite different style from here. Our prices keep up favourably and fortunes are made every year, but unfortunately all do not participate in these fortunes, or the writer of this would not be here. Yes, "Peppercorn," over R600 per acre has been netted here, over and over again in estates ranging from 400 to 600 acres, that is about the maximum cultivated here on any one estate in one year. "The Deli Matschappy" paid over 800 per cent last year. Think of that, ye planters of Ceylon, does it make you wish you were all tobacco planters? Eh! [Our correspondent should tell us all about the Deli mode of cultivating tobacco, or send us the local Dutch manual on the subject.—ED. *T. A.*]

QUININE FOR CHOLERA AND IN HEROIC DOSES.

We call attention to a letter from Southern India on the use of quinine as a preventive for cholera and also on the advantage of "Heroic doses" in cases of fever. When cholera is epidemic many persons suffer from abnormal symptoms, especially of the digestive organs. Indeed, what is called the preliminary diarrhœa of cholera often gives warning for days before an attack. The value of quinine as a prophylactic, therefore,—in preventing bane or restoring it to the system,—can be easily understood. Something more is wanted, however, than one medical man's persuasion by way of evidence of special benefit.

What Mr. Martin has told us, however, about "Heroic doses," together with recent information from home, induces us once more to return to the subject; for there can be no doubt that the importance of it to the island industry of cinchona planting fully warrants the attention we are desirous of attracting to the topic. We can quite understand that a paper devoted solely to professional matters, such as the *Lancet*, and having for its subscribers mainly gentlemen engaged in the practice of medicine and surgery, should desire, before admitting to its columns the discussion of an innovation upon usual practice, to have the *imprimatur* of qualified medical men, and we feel sure no one will adjudge blame to the conductors of such a paper for the resolution expressed on this point. But it certainly seems strange, that, common as the practice has now become of administering quinine in far larger doses than have been formerly used, such an *imprimatur* should not be forthcoming. What can be the reason that among the many practitioners, Englishmen in the tropics and Germans on the Continent, whom correspondence in our columns following upon previous writings on this subject showed to be converts to the new treatment, none have been found to write their experiences and advocate their theory in the home medical journals? We fear the answer must be found to this query in the too strict conservatism of the noble profession of the healing art. There is perhaps a tendency among that body to regard innovators on old-established practice as being men too inclined to wander out of the safe path of routine practice; and yet it is to such men sometimes, men who have been willing to incur that obloquy, that we owe many of the greatest medical discoveries of modern times. We can recollect that when the celebrated Simpson of Edinburgh first ventilated his discovery of the effect of chloroform as an anesthetic and advocted its free administration, he was by a large body of the medical profession, regarded with a jealous eye, and his proposed practice stigmatized as a dangerous empiricism. Had this great benefactor of the human race occupied a less distinguised position in his profession than he did at the time he announced his discovery to the world, we can realize how he would have been "poohpoohed" to use a homely expression, by every young student of the medical hospitals. It is, possible, to the want of a man of similar professional standing to take up the question we are discussing, that we must attribute the disinclination of the home medical journals to direct attention to it.

We should have thought that Messrs. Howards' position might have overcome such a disinclination; but we can readily realize that a firm of manufacturers would hesitate to urge a recommendation which might savour of having a personal pecuniary interest to themselves. In a certain degree, though perhaps not to an equal extent, the position of Mr. Thomas Christy as a drug importer might operate in the same way, and unless therefore those who, with the gentlemen above referred to, are interesting themselves in this matter can find some professional man [illegible] repute to put himself forward as the advocate of the practice, it is possible that their efforts will have but small result. [illegible] we look to [illegible] way someone or other of the doctors resident among ourselves, who may be acquainted in his own practice with the essential results of the treatment with large doses of quinine, would not step into the breach. No doubt our local medicos may have a not unnatural dread of being thought to be presuming by the magnates of the profession. We trust that such a feeling will not, however, long operate to induce them to keep silence as to a matter which we feel assured is of consider-

able importance to the well being of our fellow-creatures. To that primary advantage must be added the beneficial effect the advocacy of the change would have upon the future of an important industry in this colony, which is now languishing owing to production being in excess of the demand created by existing European practice. For both of these reasons we deem that the medical authority among us who shall take the initiative in bringing this question to the notice of his fellow-practitioners in Europe will confer a boon both upon humanity generally and upon his fellow colonists.

We must say one word as to Mr. Christy's recent observations respecting the prejudice entertained at home against the Anti-Opium Society. There can be no reason why, because opium is in many ways a blessing to men, the abuse of it should not be attacked. The Society referred to is, in point of fact, a Temperance Society, and its aims are as deserving of appreciative recognition as are those of the Societies whose object is to reduce the evil effects of alcoholic intemperance. If the objects of the Anti-Opium Society were as popularly known as are those of the Temperance Societies, they would be as widely approved of as are the aims of the latter by the greater proportion of our fellowcountrymen.

The latest indication of interest in this subject comes to us from Chicago, where a leading paper has been especially calling attention to the letter advocating the more general use of quinine and its value as a substitute or antidote for opium.

THE CULTIVATION OF TEA ON OLD COFFEE LAND.

The discussion on this subject has excited very considerable attention, to judge by the several letters which have reached us. We have a strong opinion that the most economical and profitable way of cultivating a good many groups of estates transformed into tea in Ceylon will be through the agency of Limited Companies, each of which, by establishing a central and well-equipped factory, can work 800 or 1,000 acres of tea in a far more effective and inexpensive way than say half-a-dozen distinct proprietors each with his separate factory burdened by a considerable bill for buildings, machinery, &c. Districts which present favourable conditions for the application of the principle of Limited Companies, are, it seems to us, Rangala, Hewaheta, Kotmale, Ambegamuwa and Rakwana among others. It will be remembered that in his last letter the correspondent who originally started this discussion wound up with a very encouraging report on tea land giving 250 lb. per acre and upwards, valuing the same at R500 per acre. A good many have been interested in the experience of manuring old tea land which we quoted, and among others Mr. J. H. Hadden of Wewelmadde asks "What was the manure or manures that at an expense of R20 per acre gave so good a result, and what quantity was applied per acre?" On inquiring further, we learn that the actual cost of the manuring in question was R30 per acre, the effect lasting over two years, and therefore the outlay was only equal to R15 per acre per annum. No special account was kept, but those concerned are positive the fields manured yield quite 300 lb. per acre and nearly double what they gave before being manured, or what is got now on adjoining fields. Our informant has perhaps had as much experience of manuring tea as any planter in Ceylon, having had 150 tons of castor cake alone put out on land belonging to him or under his care during the past three years. Here is one instance of results and some further practical remarks we venture to quote:—

"A field of four years old tea on very old coffee land, manured with white castor cake about the end of 1886, at the rate of one ton to three acres, costing under R73 a ton delivered on the estate, and the forking and application cost between R5 and R6 an acre, or say in all the three acres cost R90. The manuring was done during November and December 1886, and commenced to yield heavily in May last year, and has continued to yield well ever since till the recent dry weather, and now promises to go ahead again. The trees looked so vigorous and well during the last pruning season, that the manager of the estate and I both decided not to prune it till this season. I do not wish to get into a controversy about the matter, but I am thoroughly satisfied of the beneficial effects of careful manuring and thorough cultivation of tea. On the other hand, if the land is so bad as not to be able to produce more than 50 to 100 lb., it must be very uphill work indeed.

"I have used fish manure during the last two seasons with advantage. I got it from R25 to R27·50 a ton delivered at Matale, Gampola, and Nawalapitiya, and costing say about R35 a ton on the estates that I am concerned with, and by applying about 14 cwt. to an acre still kept within the R30 an acre for the two years. Tea does not want heavy applications of manure like coffee; we want leaf only from tea, while fruit required larger quantities of manure. Small doses of manure, well forked in, make a wonderful difference in the flush.

"A weekly report, just in from another old district, says tea flushing badly, owing to the dreadfully dry weather, excepting where manured."

Just as we are closing these remarks we receive a paper with an article by an Indian tea planter discussing the subject of tea on old coffee land with reference to what he considers the mistaken notion prevalent in Ceylon that tea draws nourishment by a long taproot rather than by surface feeders. He undertakes to prove that tea is a surface feeder, and we shall quote his remarks in an early issue.—We add here, for the present, some further remarks by an authority, who had previously written, and what he says is of a reassuring character:—

(*By an Old Planter.*)

The note of warning, sounded by your correspondent on the yield of tea on old coffee lands, has done good, by directing attention to this very important branch of our new enterprize; and by eliciting evidence from different quarters. The subject is one of vital interest to many old planters whose only remaining capital left after the wreck of their coffee is the land on which it was grown, with the buildings, roads, drains, and stock thereupon. There may be some who would do well to abandon the whole concern, but these are very few. The great majority of the old coffee estates will repay the cost and trouble of replanting them with tea, if ordinary care be used. The only cases of utter failure and disappointment will be those where bad work or a bad jât cause it. These may probably yield even less than your correspondent estimated; but as regards others I entertain more hopeful views than he from the experience I have had. Nevertheless, his warning will do good. Few, if any, will be frightened by it. Our old planters are not of the kind to be easily scared or discouraged. The energy and skill that made the coffee estates what they were will not be soon daunted. Some may perhaps persevere to their hurt, but none will abandon anything worth sticking to.

So, whilst Alpha inspires caution, and Beta favours manuring, Gamma will encourage hope in the potency of draining and working up the soil. Alpha's experience of forking is not in harmony with mine, which agrees with the universal practice of agriculturists. Soils that have been cropped

for ages continue to respond to this treatment. The strongest advocate of forking up tea lands that I have met was an old Indian who had been connected with the enterprize in Assam and Darjeeling from its beginning through all its vicissitudes. He also deprecated manuring, because of its excessive cost and its forcing effect. Spade husbandry, all the world over, is proverbial, and its specialty is the breaking up of the soil. In fact all modern mechanical cultivators are adapted for pulverizing the soil. On our old coffee lands this operation is made more necessary, than on lands in general by the incessant tramping of the coolies over it, and the battering effect of our tropical rains.

The specialties of tea cultivation in Ceylon consist in the steepness of our lands, the weight of our rains, the mineral character of our soils, and the continual trampling of their surface; all of which are in greatest force on old lands, and need the special attention of those who are cultivating tea on the old coffee estates. Hence it is that draining and forking attain their utmost importance and value on these lands. Even the trampling of their surfaces by weekly pluckings and monthly weedings is more injurious on old than on newly opened lands, as the small quantity of organic matter they originally possessed has been almost entirely consumed. As a rule, they have lost all their surface mould, and the large roots of the virgin forest have long since been assimilated by the coffee roots, or lost by decay. Hence the porosity they had whilst new, by virtue of the vegetable matter they possessed, no longer exists, and they are therefore caked and made impervious to air and moisture in a greater degree than new lands by the trampling of the coolies and the battering effect of the rains. The failure of Alpha's forking must, I think, be due to some local circumstance, or to some peculiarity of his method; for, in its nature and effect, the opening up and pulverizing of the soil are found to be universally efficacious. They are more particularly applicable and necessary in the special circumstances of tea cultivation on old lands.

Lucknow Horticultural Gardens.—The management of these gardens under Mr. Ridley was, as usual, successful and economical. Fruit crops were on the whole good, and large numbers of trees and plants were added of new varieties. Interesting experiments with fodder grasses were carried out—some new. A variety of cotton was obtained from Madras, not hitherto tried at Lucknow, which seems likely to do well. The frosts, severe as they were all over the country, were particularly so in their effect on the arboricultural and exotic plantations and did considerable damage.—*Agricultural Reports N. W. Provinces and Oudh, September* 1887.

Saharanpur Botanical Gardens.—The monsoon season was favourable, but severe frosts later on damaged both trees and crops. Nevertheless there was a very considerable increase in income, as the fruit crop was good and there was a good demand for young trees. Work in all departments was actively and scientifically carried on. Some interesting notes were made on a number of new varieties of vegetables from Florida and from Singapore. A large quantity of drugs was supplied to the Medical Department, representing a saving to Government over Bombay prices of Rs. 2770. The Arungabath gardens are now yielding an increasing income. More gardeners were sent out than in any previous year. From the 1st April nominally, but actually from the beginning of August, the scheme of establishment for the gardens was remodelled on a more economical basis. The Superintendent, Mr. Duthie, was appointed Director of the Botanical Department, Northern India, and Mr. Collan, Head Gardener, was appointed Superintendent on a much lower salary than that drawn by *his* predecessor. Mr. Duthie, however, continues to reside in the gardens, where his office and herbarium are kept as before, and the gardens are still open to him for botanical purposes.—*Agricultural Reports N. W. Provinces and Oudh, September* 1887.

Drying Flowers in their Natural Colours.—Dr. Schonland gives the details of his system of drying flowers:—"Take two pints of a saturated solution of sulphurous acid in water (which can be had at any chemists, and is very cheap if bought in large quantities); add to this 1 pint of methylated spirit. Keep this mixture in a wide-mouthed bottle, which should be so tightly closed that the contents do not evaporate when not in use. Leave ordinary flowers in this mixture for about ten to twenty minutes; inflorescences of Bromeliceæ and Aroideaceæ must be left in it about one hour. In most cases, the colour will completely disappear, but it will gradually return during the process of drying, or even after the plants have become apparently quite dry. Having treated the specimens with the mixture for a short time as stated above, take them out and shake of the adhering drops of fluid. Leave the plants in a dry warm place, in order to dry them superficially (they must not be allowed to shrivel), and then dry them in the usual way between blotting paper. If artificial heat is used in the latter part of the process, excellent results are obtained, and it is not even necessary to change the drying paper. If hot water pipes are available it is very convenient to place on them the bundle containing the plant to be dried, which need not be subjected to very great pressure. As it is sometimes difficult to prevent flowers from collapsing when using this method of preservation, and as often it is almost impossible to spread out those flowers when they have collapsed. I often put them loosely between sheets of vegetable parchment before immersing them in the fluid.—*Indian Agriculturist.*

Opium Cultivation in Persia.—Mr. Pratt, the United States Minister at Teheran, in a recent report states that opium occupies the most direct cash return to the producer, and, as a natural consequence, the area under cultivation is increasing greatly. The two principal markets are Hong Kong and London. In 1886, 4,993 chests, worth 374475*l*., wore exported from the ports in the Persian Gulf, exclusive of what was sent away by land routes or was consumed in the country itself. The quantity of morphia contained in Persian opium is 11½ to 12 per cent., while in other opium-producing countries it rarely exceeds 9½ per cent The *Papaver somniferum*, or white poppy, of which opium is the inspissated juice, is grown principally in and about Ispahan, Yezd, and Shiraz, that of Ispahan being superior both in quality and quantity. The preparation of the land begins about September 5, and consists in ploughing, harrowing, fertilising abundantly with ashes and detritus, and laying, off into squares to facilitate irrigation. After sowing the fields are irrigated three times at intervals of fifteen days. After that there is only one more irrigation,—about the middle of the winter. In the spring irrigation takes place on March 20, after which the land is repeatedly harrowed and hoed in order to extirpate all parasitic weeds. The plants are thinned and thinned and then watered every ten days until flowering begins, when all work must cease. When the heads have formed and have fully ripened a last flooding is given. Then six slight incisions are made at about the junction of the stem with the head. This should be done at noon. The juice that exudes is collected the next morning and the morning following at daybreak. When three first incisions have ceased discharging others are made lower down, and the operation may be thus three repeated, the opium obtained after each successive incision being proportionably inferior in quality. Next the plants themselves are cut down and the heads sold, the natives using the seed on bread as a substitute for butter. The end of May is the season for harvesting.

TINCTURA EUCALYPTI, B. P. C.

Sir,—*Re* the Unofficial Formula published in the *Chemist and Druggist* of September 3rd. Tincture of eucalyptus being one of the tinctures, the formula is given for "eucalyptus leaves," 4 oz.; rectified spirit, a sufficient quantity, &c., to one pint of tincture.

We have in Australia perhaps one hundred species of eucalyptus, the leaves of some of which contain much more bitter extract, and are, I believe better febrifuges than those of *E. Globulus*, the species adopted by the Formulary Committee. Why is the tincture directed to be made with rectified spirit? The leaves contain a large quantity of resin, which I believe to be inert. Rectified spirit dissolves all the resin and keeps it in solution. When water is added, it is at once precipitated, and a very unsightly mixture is the result. If proof spirit is used, only a very small portion of the resin is dissolved, and an equally good, but a much more sightly tincture is obtained. I have made tinctures with rectified spirit, and then precipitated the resin with sufficient water and filtered. I prefer spirit not stronger than proof for eucalyptus tincture. I would like to know the experience of others on this subject.—Very truly yours,

DAVID CLARKE.

Maryborough, Queensland, November 30th.

BRITISH GUIANA.

GREAT OPENING FOR SOME MINOR INDUSTRIES.

In a recent report, the United States Consul at Demerara urges his countrymen to establish a steamer line and fruit-growing company in British Guiana, of which he says "the profits must, in view of the magnitude of the trade, be necessarily large." As the opportunity is equally favourable for British merchants and investors, it may be well to summarise the Consul's statements on the subject. The soil of the colony along the coasts is extremely rich; cocoa-nuts grow near the shore, and large quantities of bananas may be grown within three or four miles from the sea. The long yellow bananas are in every way superior to those grown in the West Indian Islands, and equal to those of Port Limon and Aspinwall, which are so deservedly popular in the American markets. The first cost of planting an acre with bananas is from £10 to £12, the production being from 600 to 800 bunches a year. The plants mature in nine months, and the fruit can be gathered every week in the year after it is well started. In Guiana all carriage is by water; hence bananas can be delivered at the steamer in better condition than in any other part of the West Indies, where they are carried by springless carts, on negroes' heads, &c. Hurricanes which decimate the plantations elsewhere do not prevail in Guiana. Demerara is 2,200 miles from New York; the course crosses the Gulf Stream, which is said by shippers "to cook the fruit" in a much shorter time than that from any other West Indian port; Bermuda and Barbados might be made ports of call to the greatly-increased profit of the voyage. Vessels drawing 18ft. 6 in. can enter the Demerara river at high water. In 1885 bananas to the value of £400,000 were imported into the United States, mainly at New York, New Orleans, Boston, and Baltimore. The cargoes realised from 4s. to 12s. per bunch for the best quality, and it is, Mr. Bunker thinks, highly probable that contracts could be made in Guiana for their delivery alongside at 10d. to 1s. per bunch. A vessel of 1,000 tons dead weight could carry a cargo of 20,000 bunches; the loss on the voyage rarely exceeds 15 per cent., and, if the balance were sold at the low price of $1 per bunch, the estimated profit on the trip would be not less than £1,400 after payment of all charges. This does not include profit from general freight, passengers, or mails. Cocoa might be cultivated at the same time as the banana, the letter giving the best shade for the young cocoa plants. Banana plants yield an excellent fibre, and the papaw, lime, orange, mango, guava, and pineapple might be added to the cultivation. Guiana being a sugar-producing colony, a trade in canned fruits might be developed.

The climate, the Consul thinks, is much maligned; Guiana is not, as is commonly supposed, a hot-bed of fever; there is little variation in the temperature, and the thermometer giving an almost uniform reading of 84 degrees Fahrenheit. Sea breezes prevail for the greater part of the year; cases of yellow fever are comparitively rare, and may be generally traced to dissipation or indiscretion.—*Sugar Cane.*

NATAL: TEA AND TOBACCO.

Natal has been called in scorn, with just enough truth perhaps to sustain the epigram, "a country of samples." We produce a little sugar, a little tea, a little coffee, a little of everything in fact, but nothing in large quantities; so say our detractors. Not till recently at any rate could Natalians meet this somewhat serious charge with a direct negative; for did not some ugly facts stare us in the face? Was it not true that on one celebrated occasion a man-of-war which put in with orders to ship Natal coal, had to be sent empty away as far as the colonial product was concerned? Natal's best defence was that her industries are in their infancy; that every beginning is difficult, as the German innkeeper said; Natal's beginning doubly so, on account of the wars on her frontier, which enriching her in one way have greatly impeded her in another, by taking away her young men, and generally disturbing the repose so necessary for the internal progress of every country. At length, however, a brighter day seems to have dawned. With some reason we may claim to have changed all that, for lately Natal's coal has been sold in Durban at two shillings and sixpence a hundredweight. Natal coal is being used throughout the railway, and travellers from up-country state that a really large transport business is going on between Dundee, Newcastle, and Ladysmith; and all this points to a hope that in the near future, talking of carrying coals to Natal may sound as ridiculous as carrying coals to Newcastle in England. Take next the cultivation of tea, which, according to the great authority of Mr. Hullett, has been proved to be an industry capable of a large development in this colony; so far, tea has been produced of most excellent quality; but not in such quantities as to have much effect in keeping down the importation of the same. This year, according to Mr. Hullett, the yield may be estimated at 150,000 lb., something over 4 lb. a head of our white population. This is not a very large amount, inclining as we do to take a somewhat more hopeful prospect than Mr. Hullett, of thee xpectations of the Natal Tea Company's gardens at Isipingo, whose Managing Director is known to be a gentleman of capacity and experience, acquired in another great tea-producing country. We cannot but hope that this estimate will turn out to be rather under than over the actual yield of Natal tea for the current year. At any rate, 150,000 lb. cannot be called a sample, especially when we remember that it has grown from a yield of 2,000 lb. in 1881. While on the subject of tea, it will be interesting to examine the returns of another country with far greater facilities certainly than Natal possesses in the matter of labour as well as other things, but not more than five years her elder as a tea-producing country. We refer to Ceylon. In 1877 the amount of tea exported from that country was also some two thousand pounds in ten years the amount has grown to nine million pounds, while there are some hundred thousand acres under cultivation. By a calculation based upon those figures the yield per acre would appear to be far greater in Natal than Ceylon; but allowance must be made for the amount grown for home consumption in the latter country, which it is not easy to estimate with any certainty in the absence of information; yet it is unlikely that it would amount to a very large proportion. In quality we certainly need not fear comparison, and assuming Mr. Hullett to

be correct in stating that "at least for a distance of twelve miles from the sea coast tea will give a maximum yield," there would seem to be nothing to prevent our Natal tea industry from equalling, or even surpassing in its dimensions, that of Ceylon as at present established. The coffee and sugar industries of Natal cannot be said to be in a flourishing condition. The farmer will very probably be able to produce enough for our own wants; and we have no doubt that Sir Donald Currie was correct in saying that it was better than that he had tasted in the Red Sea, though whether this remark involved any great compliment to Natal coffee is doubtful, for we imagine that most of the coffee drunk in the Red Sea has been bought in London and served better or worse, as the worse may be, on board the various steamers traversing that dangerous and disagreeable portion of Neptune's domains. But a blight seems to have fallen upon the industry here, as in other countries. Sugar growing also is in a bad way all over the world, and in Natal no better than elsewhere. The produce of sugar is assuredly more than a sample. Coming to gold, the reproach is justified in a manner, however entirely unmeant by the jester, and it thus affords another instance of the manner in which jesters do oft prove prophets. We have as yet produced only sufficient gold to give great hopes for the future finds of that precious metal in more abundance; and if the Capetown people could find as much gold in the "Lion's Head" as has been already unearthed at Umzinto, they would assuredly be not ashamed of their sample. With regard to wool, tobacco, &c., the first-named we have recently discussed in these columns. Tobacco is not much more than a name. On the whole, we think we may fairly state in conclusion that Natal no longer deserves the reproach of being a country of samples.—*Natal Mercury.*

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter*).

PARIS, February 25th.

M. Mounier suggests the following plan for the eradication of ferns, and which has succeeded in his case. Lucern has a very voracious appetite for potash, and so has the fern. He sowed lucern on the infested soil, and found it so disputed the potash with the fern, that the latter dwindled and died out. New Zealand could well try the experiment.

Among not a few of the upheaving causes that have deranged Continental farming, is neglect of irrigation, and the danger in wooded districts of felling trees, and thus diminishing the annual rainfall. Professor Studnicka, of the University of Pragul, has just published an important volume on the hydrography of Bohemia, in which he demonstrates that to augment the rainfall of a region the best means is to plant its hills with trees. The influence of forests on the rainfall is notably illustrated in the meteorology of Palestine. At Jerusalem, the height of the rainfall is 570 millimetres, while at Nazareth, it is 612. But Jerusalem is 550 yards higher than Nazareth, and following a series of observations made at Juffa, for every 100 yards of elevation, there ought to be a corresponding augmentation in the rainfall of 14 millimetres. The difference is simply due to one district being planted, and the other bare. As far as 28 or 50 miles round the Holy City, the territory is bare of trees while Nazareth is in proximity to wooded mounts Ephraim and Carmel. The annual rainfall at Nazareth also, after series of observations, is uniform more than at Jerusalem.

The co-operation of farmers into Syndicates or Societies, for the purchase, wholesale, and direct from the producer, of machines, seeds, manures, &c. is making vast strides in France; so is the Italian system of banking and of insurance where the Syndicate becomes security for all its members. The agriculturists are still further extending the system of united action; they are establishing a central depot or warehouse for the sale of their grain, wine, hops, &c. It is thus that their syndicate has been able to contract for supplying military centres with their provisions, and many other public establishments.

PARIS, March 17th.

At the beet-root sugar exhibition lately held at Arras, the prizes were awarded to roots yielding from 16½ to 17½ per cent of sugar. This is treading closely on Germany and Russia.

In the South of France and in Algeria, where fodder as well as litter are very scarce, the prunings of the vines—about 16 cwts. of twigs per acre, are crushed, and employed to feed and bed stock, like straw. The Comte de Troguindy has invented a machine which cuts and crushes the twigs at the rate of one cwt. per hour. It will also bruise rushes and furze; its price is 150 fr.

Germany is ever the vanguard for novelties. A new kind of ensilage has been adopted, which at least has the merit of being inexpensive. A trench 80 inches deep is made in the soil, into which are piled alternate layers of marigold leaves, beet-pulp, or whole roots and potatoes. A layer of beet leaves is spread over the bottom to the depth of six inches, well trampled down; next follows a layer, 12 inches thick, of whole roots of marigolds &c. or potatoes; over these is a layer of sliced beet, pulp, or leaves well trodden down: next a stratum of whole roots as before till the level of the soil be attained, when the same plan of piling is continued, only the layers are less thick, till the mass rises three feet over the surface. It is then thatched with a coat of beet leaves six inches deep, over which is battened a layer of soil, two feet thick. The mass at first heats rapidly, attaining a temperature of 86 degress F. The tendency of the potatoes to emit puffs is destroyed, and all symptoms of decomposition are checked. The heap rapidly cools down, and the mass conserves well. It may be said that success depends on the exclusion of the air. Many millers in Germany now press the bran into cakes, and find ready purchasers for the preparation, at fr. 4½ per cwt.

In parts of France and Italy, and near large towns farmers and gardeners purchase bones after they have been boiled to extract their fat &c. The bones on being well dried are placed in layers, after being broken, six inches thick, mixed with earth, ashes, and lime. The heap when a yard high is wetted from time to time with liquid manure, care being taken to cover the mass with earth. In the course of five months a rich, friable compost will be produced.

SUGARCANE CULTIVATION IN INDIA

The usual method of cane culture may be called *broadcast* as opposed to *planting*, as the term is understood by European and Australian planters. The difference in results may be approximately obtained by asking any ryot the difference in produce between *cheetwa* and *roap dhan* (broadcast and planted). We had peculiarly favourable opportunities of noting this, having been engaged in sugarcane cultivation at one time in Coimbatore and elsewhere. The root of the sugarcane is a small collection of thin fibres or rootlets; there is no tap root. On these depend the health and vigour of the plant with its long succulent stem and succession of long broad leaves; it should, therefore, be placed in the best possible condition to enable it effectually to meet the heavy demand on it.

By the native method, the root is on or near the surface of the ground. The field gets twelve or fourteen surface ploughings giving a seed bed only four or five inches deep. The little manure (if any is given) is scattered irregularly over the surface, a plough goes round the field in a continually decreasing circle, and the cuttings are dropped into the shallow-track so made. There may be a little manure where they fall, or there may not be any. The cuttings are covered with about three inches of earth by a piece of wood drawn over the surface, a man or two standing on it, each supporting himself by holding the tail of the bullock in front of him. This surface covering soon dries; the surface is then loosened a little by the

hoe, the roots being carefully avoided. A little manure may now be placed round each plant by hand, and water is let on till the field is submerged or waterlogged, thus sealing up the roots from air in plastic clay or loam compressed by the downward course of the water, and hardening as it dries. As the hoe avoids the roots, the compression of the soil around them increases just where it should be most friable. The hoeing is repeated about three times, followed by a *melwanee* watering, that is, till the ground is water-logged each time. When the plants reach a certain height, and the leaves begin to shade the field, hoeing is stopped, and as they grow, being close together with no regularity, a thick jungle is the result, excluding sun and free circulation of air. Considering the nature of the plant and the work its root has to do, this treatment of it is most irrational. In Queensland (Australia) and other places where cane cultivation is under European supervision, the cuttings or seedlings are laid at least nine inches under the surface of the ground, either in carefully-made rectangular oblong holes in rows three-and-a-half or four feet apart, or in continuous channels or furrows made by hoe; or double mould-board plough, the bottom being flat, and eight or nine inches wide, that is, wide enough to receive three cuttings placed some distance from each other. A field planted in this way will take as many cuttings as are usually put in by the native method. The space between the rows need not be ploughed, only cleaned of weeds by hoe, these are left on the ground, and are covered by the earth from the channels or holes.

Previous to planting the cuttings, manure in proper quantity is spread over the bottom of the channel and mixed with a little earth. On, or in this, the cuttings are laid end to end either in single, double, or triple rows as the width of the bottom may allow, and covered by hand with about three inches of earth. The "hole" system is used in Queensland, the ground is hilly and undulating, rain is frequent, and each hole retains what may fall into it. In India, where irrigation is necessary, the channel or deep furrow method is best. After some days the surface of the soil in the bottom of the channels is loosened by hand. This may be done by women or children, whereas the hoeing of the ryot's field has to be done by men. If water is now necessary, a little is allowed to flow from one end of the channel to the other, and then shut off. As the plants rise, more earth is filled in around them with a little manure where it may be needed; the loosening of the surface, watering and filling in is repeated till the channel is filled; after which as the plants grow, the earth is drawn from the spaces between the rows and heaped round the roots till a ridge is formed at least nine inches high over the original surface. Subsequent irrigation is given in the hollows between the ridges, the water not being allowed to reach the top of the ridges by four or five inches which are thus left friable, and open for the action of the air and expansion of the roots.

Our ryots have for years seen and acknowledged the considerable economy of labour, water, and manure in this method as compared with their own. They have also seen the common *mongoo* cane of the district so improved that they had to be assured it was nothing else, yet none of them have had the enterprise to adopt it, though several among them have been at work on the cane fields on the West Indies and Mauritius, and known the method and its results.

Cane culture should be more of the nature of garden than field cultivation, and if done with a reasonable consideration of the nature and necessity of the plant, a third of the land now yearly devoted to cane could be put under other crops with no falling off in the weight of sugar produced.

The industry, as a whole, and in its details, from the preparation of the land till the crude produce is ready for the market, is in a very backward and wasteful condition; there is no reason except the inertia of the ryot why this should be so. This might be overcome, and a better rut opened out by some sustained effort on the part of the Government, probably a graduated set of prizes for the best cane fields cultivated with reference to the nature and requirements of the plant. We know by experience the ryots understand what this means when explained to them in terms with which they are familiar.—*South of India Observer.*

THE INSECT PESTS OF INDIA.

Circular.

Indian Museum, Calcutta, February 1st, 1888.

The trustees of the Indian Museum have had under their consideration the means whereby a useful scientific examination of the insect pests of India can be best effected. Bearing in view the great economical importance of the investigation, they have directed the first assistant, Mr. E. C. Cotes, to consider it an essential portion of his duties, and have instructed him to communicate with those interested in the subject, and those likely to aid its object, in order to ascertain the facts and collect the materials which must form the basis of all really scientific work of permanent value. Mr. Cotes will gradually record the entire life histories and practical methods of dealing with the principal insect pests, publishing from time to time, as materials accumulate, the information collected, and distributing it to those interested.

It is only by the active co-operation of those who live in the districts where the insects occur, and who have actual experience of the pests, that really useful results are to be expected in this undertaking; but if all will contribute what is brought to their own knowledge of the subject, there will be no considerable difficulty in collecting complete and reliable accounts of the various pests, and hence of arriving at the most suitable methods of dealing with them. With regard to the value of such inquiries, it is only necessary to point to the success that has attended similar work carried on by Miss Ormerod in England, and by the Entomological Commission under Dr. Riley in America, where considerable advance has been made within the last few years in methods of combating insect pests, and in diffusing reliable information about them.

The following are the principal points upon which information is wanted:—

1. The occurrence of a pest
2. Details of the crop attacked.
3. The extent and nature of the damage done.
4. Estimate, where easily procurable, of the pecuinary loss occasioned by the pest.
5. General particulars of the pest and its method of attack.
6. The *egg* of the pest:—
   - *a.* Description of the egg.
   - *b.* Where deposited.
   - *c.* Time taken to hatch.
   - *d.* Period of the year during which eggs are found.
   - *e.* Measures taken to destroy the egg.
   - *f.* Ichneumonidæ and other natural enemies to the egg.
7. The *larva* of the pest (grub or caterpillar):—
   - *a.* Description of the larva.
   - *b.* Habits and localities selected.
   - *c.* Food plants other than the crop attacked.
   - *d.* Number of moults.
   - *e.* Period of the year during which larvæ are found.
   - *f.* Time taken to complete larval growth.
   - *g.* Measures taken to destroy the larvæ.
   - *h.* Natural enemies, especially birds, ichneumonid and tachinid parasites, predacious insects, and fungoid diseases.
8. The *pupa* of the pest (chrysalis or cocoon):—
   - *a.* Description of the pupa.
   - *b.* Exact locality selected for pupating (whether on the food plant, underground, or elsewhere).
   - *c.* Period of the year during which pupæ are found.
   - *d.* Time passed in the pupal state.
   - *e.* Measures taken to destroy pupæ.
   - *f.* Natural enemies and parasites.

9. The *imago*, or perfect insect.
  a. Description of both the male and the female.
  b. General habits.
  c. Localites frequented.
  d. Food.
  e. Date when copulation takes place.
  f. Period of the year during which imagos are found.
  g. Date and method of oviposition.
  h. Measures taken to destroy the imago.
  i. Natural enemies, diseases, and parasites.

10. Alternation of generation, dimorphism, parthenogenesis, and any other points connected with the natural history of the species.

11. Other measures actually adopted for prevention or cure: their cost and effect.

12. Insecticides, especially such as contain kerosine or compounds of arsenic.

13. The history of damage done in former years, with supposed causes of immunity from attack at one time and undue multiplication of the pest at another.

14. The introduction of the pest, the supposed date of its occurrence, and the way it was introduced.

15. The spread of the pest: its direction and pace.

16. The effect of varying soil, moisture, temperature, and other natural conditions on the pest.

Special attention should be directed to the positions selected for oviposition, pupating, and hybernating, the state (whether as egg, larva, pupa, or imago) in which the insect hybernates, the number of generations in the year, and the food plants other than the crop actually attacked, as on these preventive measures can frequently be based. Individual observation will of course often be confined to single points in the life history of each pest, but if these are jotted down and forwarded as they present themselves, they will frequently be of value as filling up what would otherwise be gaps in the history of the pest. The complete history may take some time to record, but when once the main facts are known about each pest it wil be easy to specify the exact information wanted to complete the record.

Each pest should be dealt with entirely separately, and observations should in all cases be accompanied with specimens illustrating, as far as possible, the pest and its method of attack. Specimens of the pest itself should be sent, where possible, in all stages of development and in considerable numbers: eggs, caterpillars, and other soft-bodied insects in strong alcohol or spirits of wine; chrysalids or cocoons alive and packed lightly in leaves or grass; other insects dried and pinned or wrapped in soft paper. Live insects are always preferable to dead ones, and should in all cases be sent where there seems to be a reasonable probability of their surviving the journey. Specimens of leaves and green plants damaged by the pest may be sent wrapped in damp cloth; grain, wood, and such like being packed as occasions suggest. Observations on economic insects should be written clearly on one side only of the paper, and sent with the specimens to Mr. E. C. Cotes, Indian Museum, Calcutta; they will be gratefully received, in all cases acknowledged, and, so far as possible, any information about them will be given, or sought for from experts in Europe and America.

RICE CULTURE IN JAPAN.

The prospects of rice culture in Japan have formed the subject of some interesting articles in the *Fiji Shimpo*. The salient feature of this branch of agriculture has been, for some years, a falling market. Omitting the early quotations of 1885, since they were abnormally influenced by the Korean complication, we find that the prices per *koku* in the first month of the past three years, including the present, were [illegible] *yen*, [illegible] *yen*, and [illegible] *yen*, respectively. There has, in fact, been a steady decline, and farmers are naturally very anxious to know whether such a state of affairs is to be anticipated in the future also. The total annual yield of rice in Japan, on the average, has usually been put at thirty million *koku*, representing, at 5 *yen* per *koku*, a value of 150 million *yen*. A trifling failure in the harvest, such as would reduce the yield to 27 million *koku*, for example, may thus mean a loss of fifteen million *yen* to the agricultural class. On the other hand, a small rise in price, as fifty *sen* per *koku*, would nearly make up for this shortage of yield. There is no difficulty in seeing how largely the commercial condition of the country depends upon a crop so important, constituting, as it does, the staple production and source of wealth of six-tenths of the population. Appearances at present seem to portend a further fall of price. Some are disposed to hope that a remedy will be supplied by the development of sericulture: rice-fields, they say, will be converted into mulberry gardens, and prices will be driven up by the consequent reduction of supply. Nothing warranting this view has come to the knowledge of the *Fiji Shimpo*. If the area devoted to mulberry cultivation has increased—as it certainly has—the increase appears to have been effected by reclaiming waste lands or encroaching upon tea-gardens rather than by converting rice fields. Statistics do not support the idea that the latter operation is in process, for whereas the area of wet rice-fields was 4,850,000 acres in 1877; it was 5,850,000 acres it 1885; an increase of a million acres in eight years. Such figures as these, if quite trustworthy, are very conclusive. Tea planting, on the other hand, is said to have gradually diminished during the past four or five years, in consequence of the greater profits offered by sericulture. On the whole the conclusion may be formulated that, up to the present, what sericulture has gained is not at the expense of rice-growing. Taking the average yield of rice to be 5 *koku*, or 25½ bushels (approximately), per acre, it appears that the total production of rice in Japan has been increased by five million *koku* since 1877. An addition of sixteen or seventeen per cent. to the supply of the staple could scarcely fail to effect its value. Something must of course be allowed for increase of population and something also for the more extended use of the cereal, but it is very doubtful whether these sources of demand could absorb the extra supply, especially in view of the fact that other agricultural products have also been more largely cultivated. Consider the following table:—

PRODUCTION OF CEREALS OTHER THAN RICE.

	1878.	1884.	INCREASE
	KOKU.	KOKU.	KOKU.
Barley	9,411,460	13,105,841	3,694,381
Beans	1,142,185	2,323,435	681,250
Maize	85,501	106,775	25,274
Millet	2,475,876	2,896,637	420,761
Buckwheat	575,054	673,241	98,187
	KWAMME.	KWAMME.	KWAMME.
Sweet Potatoes ...	223,417,388	362,086,828	138,669,440
Potatoes	8,633,588	10,715,902	2,082,313

This record shows that agriculture has flourished amazingly under the Mediatized Government. Articles of food have been produced in rapidly increasing abundance, with the natural result that prices have fallen. Helping materially to depress the rice market we have a marked decline in the manufacture of *saké* during the past eight years. A difference of three million *koku* of rice is attributed to this cause. Thus, on the whole, it may be said that the nation is now able to consume 8 million *Koku* more rice, 5 million *koku* more barley and other cereals, and 141 million [illegible] more potatoes [illegible] in [illegible], in [illegible] of [illegible] and half a million [illegible] of potatoes. [illegible] to the question of [illegible], we find that the total area of mulberry [illegible] in 1884 was [illegible] acres [illegible] million [illegible]. [illegible] has not yet been [illegible], and we know that the yield of cocoons was about 51 million [illegible], so it may be estimated that the total extent of mulberry gardens was [illegible] acres, approximately. The development of sericulture has therefore been much

more rapid proportionately than that of rice; but, on the other hand, if we compare the areas of land devoted to the two industries, it will be apparent that the increase of sericulture cannot have caused any appreciable diminution in the extent of land devoted to rice growing.

All this is extremely gratifying from one point of view. But in examining such figures the question is forced upon us whether Japan may not be producing more than she can consume at prices remunerative to her agriculturists. Out of every hundred units of her population, sixty are engaged in farming, and of the latter 49 support themselves by agriculture alone, while 11 pursue other occupations simultaneously. It follows, therefore, that out of her total population of 38 millions, she has nearly 23 millions more or less dependant on agriculture, and that fully one-half of her people live by farming alone. Thus the price of agricultural products is a vital question for her. Before the country was opened to foreign commerce, any failure of the rice crop made itself immediately felt in the market, as supplies from abroad were not procurable. Much suffering was often inflicted in this way on the lower orders, but the farmers, on the contrary, often fared best when crops were short. Now-a-days, nothing of the kind can occur. The price of rice cannot rise above the point of profitable import from Saigon, Formosa, and elsewhere. Neither, however, can it fall much below the point of profitable export to Europe. Looking at the returns for the six years ended 1886, we find that the export of rice was carried on thus:—

EXPORT OF RICE.

	YEN.		YEN.
1880	210,862	1884	2,170,678
1881	261,757	1885	766,759
1882	1,652,040	1886	3,300,598
1883	1,000,910	—	—

This table does not indicate any particularly steady increase. It merely shows that, under certain circumstances, there is a market abroad. England is Japan's best customer. She took 625,577 tons in 1886, against 167,579 tons by Germany, 55,874 tons by France, 218,572 tons by Korea, 55,874 tons by China, and 30,666 tons by Russia in Asia. Australasia took 129,302 tons, so that altogether Great Britain and her dependencies figure for 754,879 tons. Japanese rice has to compete with Indian in the London market, the demand of which is moreover limited. Asiatic Russia and Australasia probably offer steadily increasing sources of demand: Korea is a tolerable customer, and China may at any moment become temporarily a large buyer. Her famine, in 1877, had the effect of increasing the Japanese export to four million *yen*, and the Yellow River's ravages may exercise a similar, though smaller, influence this year. But on the whole it is plain that the growth of Japan's outward trade in rice must be slow, and that it ought not to be relied on so far as to encourage any rapid development of production. The home market is evidently well supplied: prices prove this. A continuation of the present downward tendency could not fail to cause considerable distress among the agricultural classes. The wisest course seems to be that recommended by the *Fiji Shimpô*—development of sericulture. For Japanese silk the market abroad is practically unlimited.—*Japan Weekly Mail.*

THE TEA INDUSTRY:

INTERESTING LETTER FROM MR. HULETT—NATAL'S TEA PROSPECTS—SCHEME FOR SMALL SETTLERS—A GOOD OFFER: EUROPEAN OR COOLIE?

We have received the following interesting and instructive letter from Mr. J. Leige Hulett, M. L. C., of Kearsney:—

Permit a few remarks upon your sub-leader in last Friday's issue regarding tea culture, &c. You say it "has been proved to be an industry capable of large development in this colony; so far tea has been produced of most excellent quality; but not in suc quantities as to have much effect in keeping dow the importation of the same." It is self-evident that every pound of tea of home growth consumed must displace a like amount of the imported article. Upon the surface of things, in view of Customs returns, it would appear that we are making no impression upon the importation whatever; but the fact is the other way. The importation during the past two years has been abnormally large in consequence of increased demand for the Gold Fields, &c. Had there been no special demand, the present season's output would have materially affected the importation, and as far as the colony itself is concerned, I reckon that now out of every three pounds used at least two pounds are of colonial growth. The normal importation of tea was between 250,000 lb. and 300,000 lb., of which perhaps 100,000 lb. went across the borders; that would leave about 150,000 lb. to 200,000 lb. for Natal. The actual amount of Natal tea used during the past year 1887 would be from 80,000 lb. to 85,000 lb., so a considerable reduction in amount of imported tea consumed must have taken place. The quantity of Natal tea which may be estimated for the year 1888, will amount to probably 17,000 (this is judged by the year, and not the season; the latter may be considered as from October to following June). The year 1889 will probably give a return of 250,000 lb., or amount equal to what was generally used before the Gold Fields trade set in. Unquestionably the need for care on the part of merchants will be necessary in regard to future importations of tea. The flooding of the colony and interior states with low qualities of China growth will not advantage the merchant or grower. The grower will be obliged to sell, and the merchant also. If the importations are regulated with care, so as to gradually give way before the home-grown article, no loss to either interest need accrue. It is worth nothing that on 1st January, 1887, only about 9000 lb. weight of tea was in bond, and on January 1st, 1888, the large amount of about 165,000 lb.

Natal has a future before it in the tea enterprise that the public generally little dream of, especially if we are able to secure the whole of South Africa's trade by free entry of all colonial produce into the neighbouring colony and states. Both sugar and tea, together with various other products, will be stimulated and largely increased in supply. The advantage to the mercantile community must be very great. The saving effected by keeping large sums of money at home instead of in advance sending the same to a distant foreign country will be considerable, and the becoming exporters in the place of importers will bring a corresponding advantage.

To return to your article. You compare Natal with Ceylon. I fear Natal will not be able to take its position side by side with Ceylon, not for want of capability, but for want of push on the part of its people. Our back country drains away so many of our young men, the Zulu war demoralised them, and the excitement of gold keeps them unsettled. The Ceylon planters had to face ruin in connection with coffee failure, and were forced into tea growing, and all at once, so that the country became a tea-producing one almost by magic. They had the land ready to hand, under the best system of culture to be found anywhere, the buildings and bungalows all to hand, no preparatory work; out with one crop and in with another; their knowledge of planting and the characteristics of climate they were accustomed to. The consequence was that with a bound they sprang forward and took the first place as a tea-growing community, and they will hold and keep it too. The class of cultivation pursued in Ceylon is scientific, and the result is that their yield per acre surpasses that of North India and Assam to an enormous extent. As far as cultivation and yield is concerned we in Natal may hold our own. The result of the past two dry springs proves that we have nothing to fear; but it will depend upon care in the cultivation of the soil. I am certain that with proper management and ordinary seasons, after the plant has arrived at five

years' growth, not less than 1000 lbs. per acre of made tea should be obtained. Indeed I fully expect to pick and make over 1000 lbs. per acre on a block of 32 acres of land this season; if the season continues good this block will give me 1200 lbs. per acre. Requisites necessary—average land, good culture (and all that is contained in that term), and liberal scientific pruning, and above all things, not too close planting.

Natal possesses a climate suitable for Europeans, and advantages can be taken of circumstances peculiarly suitable to the colony, I refer to the Central Factory system. One plant of machinery, &c., for 20 to 40 small growers. The maximum yield per acre can be thus obtained by individual attention to small areas of cultivation, and the manufacture of large quantities of leaf together insures a better average turnout of tea. No difficulty as to fair proportion as in sugar, a fixed price for the green leaf per lb. The Chinese grower sells his leaf to a manufacturer. With the introduction of small settlers, no reason exists why Natal should not in a few years' time produce its 40,000,000 lb. of tea, as Ceylon expects to do in two years time. This enterprise thus conducted, means the support of thousands of white people.

Feeling assured of the desirability of this central factory system, I am prepared to throw open 4000 acres of land to settlers of small means on some such terms as the following:—To each settler a block of 50 acres of suitable land for a term of 10 or 15 years. No rent for three years; afterwards a rental of 1 shilling per acre per annum; at the close of period, purchase can be effected at £1 per acre, half of the amounts previously paid in rents to be allowed on account of the purchase. Should the lessee desire not to purchase, two-thirds of the value of improvements below a fixed amount to be paid to the lessee. A reserve block of 50 acres adjoining each occupancy to be laid off for purchase or lease by the occupant at a fixed rate. On the estate only 20 settlers to be located in various parts, the remaining 2000 acres to be held by myself as owner for purposes of the estate generally—grazing rights allowed within certain restrictions to the tenants. I would erect suitable buildings and machinery for making the tea, and agree to purchase green leaf at a price fixed according to the market price of the article. I will find tea seed for planting *gratis*.

The occupiers would be required to plant five acres of tea the first season, and each following season the same quantity for five years, unless special circumstances prevented. Each occupier would be required to plant one acre a year with forest trees. All other cultivation at option of the occupier, which would doubtless consist of food supplies. No occupier would be allowed to keep a regular store or canteen. Each occupier would have to prove his capability to carry out the conditions. The amount of money necessary would greatly depend upon the individual. From £150 to £1000 would be about the minimum that an industrious man could do with. The estate in question is situated about nine miles from this place, on the Tugela. I have one of my sons upon it opening out 40 acres of tea. All occupiers would receive the practical advice of one capable of giving the same. If white settlers can be obtained so much the better; but if not, I intend getting Indians who will pay rent at once.

I consider the principle embodied in the above scheme worth the attention of landowners in various parts of the colony.—*Natal Mercury*.

TEA CULTIVATION IN INDIA.

Die Theekultur in Britisch-Ost Indien, mit Berücksichtigung der Theekultur Japans, Java's, Ceylon's, Assam's, Nord-Indiens und Süd-Indiens, Dr. Ottokar Feistmantel. (Prague: O. Beyer, 1888.)

The subject of tea cultivation in India is one to which innumerable writers have devoted their attention, and not the least valuable portion of Dr. Feistmantel's work, "Die Theekultur in Britisch-Ost Indien," is the bibliography of the subject with which, while recording his indebtedness for much of his information to many of the English and German authors enumerated, he commences his remarks. In his preface he explains that in the course of an address on the products and exports of British India, recently delivered by him in Prague, he alluded to the fact that on the Continent of Europe tea was generally known only as either Russian or Chinese, and that it was barely known that India produced a large and annually increasing quantity of high-class teas, which are largely used in London for mixing with and improving China tea. The correspondence which ensued when these remarks were reported by the local press, induced him to publish the present work as the result of information he had the opportunity of collecting, while serving in India for eight years as palæontologist to the Geological Survey.

It is Dr. Feistmantel's aim to place before the German-speaking peoples of the Continent as complete an exposition of the conditions of the tea industry in India, as has already been laid before English-speaking people by other writers; and he therefore begins with an abstract of the early history of the tea-plant in India, the dates of its first discovery as an indigenous shrub, and its first introduction into the different districts in which it is now cultivated. He mentions the first export from India to England in 1838 of twelve chests of tea, which sold for 19*s.* 5*d.* per pound.

He points out the differences between the indigenous, the "China," and the hybrid varieties of the plant which are cultivated in India, and enumerates the various pseudo-tree which are known either in the frontier countries of India or in other countries: such as *Osyris nepalensis* or *arborea*, in Kumaon-Garhwal, and lately in Kashmir; *Elæodendron per steam* in Burmah, from which, when mixed with oil, salt, garlic, and assafœtida is prepared the nauseous compound, to European taste, known as "pickled tea" *Ilex paraguayensis*, the Paraguay tea, or "Mate," of South America; *Ledum palustre*, or Labrador tea; the Tasmanian tea, made from various varieties of *Melaleuca* and *Leptospermum*; and the Faham tea, *Augræcum fragrans* of Mauritius; and others.

The number of plantations in the various provinces, area under cultivation, and annual yield of tea for all India, are given in detail; and the difference between the various kinds of China and Indian tea, as proved by analysis, are very fully treated of. The principle black teas made in India are flowery pekoe, orange pekoe, souchong, pekoe souchong, congou, and bohea; as also the several varieties of broken leaf, such as broken pekoe, pekoe dust, &c. All these are not, as is commonly supposed, the produce of different plants, but are prepared from one and the same plant, the classification being caused by the difference of age and development of the leave used for the several varieties. The principal kinds of green tea are gunpowder, hyson, and young hyson, and these are manufactured almost exclusively in the North-West Provinces and Kangra.

It may be accepted as a fact that Indian tea is very rarely adulterated, being packed on the plantation, and shipped direct from the garden to the market; but "China tea" passes through many hands before it is packed for shipment, and is frequently mixed with willow or other leaves, or with artificial colouring-matter. But the adulterated tea is not now readily saleable in London, and is therefore re-exported to the Continent. A direct importation of tea from India to the Continent would insure the purity of the supply.

In a lecture given before the Society of Arts, in May last, by Mr. J. Berry White, and quoted by Dr. Feistmantel, a table is given showing the growth of the Indian tea crop from 1866 [illegible] to 76,585,000 pound's in 1886; and Mr. White estimated that the crop for 1887 would not fall below that of 90,000,000 pounds. The amount of tea exported from India between October 1, 1886, and September 30, 1887, is officially returned as 67,000,000 pounds, of which 66,000,000 pounds went to England. Nearly the whole of this tea is consumed in Great Britain, a small quantity being sent to the Continent direct

with inferior China teas, and consequently sold as China tea. The percentage of Indian tea used in England has also been steadily rising, for whereas in 1865, China tea formed 97 per cent of the entire consumption, in the first quarter of 1887 the proportion was 51 per cent of Indian to 49 per cent of China tea.

Notwithstanding the steadily increasing production in India, China tea is still imported into the country; in 1885-86 about four million pounds were imported, but mainly into Bombay, where none is grown, and much of it for re-export to the Persian Gulf, Afghanistan, and some to Trieste, where it arrives as Indian tea.

Statistics concerning the consumption of tea show that the greatest tea-drinkers are the Australians, who in 1881 consumed 81 ounces per head of the population. England ranked next with 73 ounces, while the United States of America came next with 21 ounces. Russia, Belgium, Holland, and Denmark rank highest among Continental nations as tea-drinkers, but they only consume from 7 to 8 ounces per head of the population.

Dr. Feistmantel fully indorses the prevalent English opinion as to the superiority of Indian to China tea, and attributes its being almost unknown on the Continent mainly to the fact that "China tea" is a much older, and therefore better known, product throughout Europe. Even in England, Indian tea took years to establish its reputation. It will in the end be as much appreciated on the Continent as it in this country if a few merchants and tradesmen in different Continental cities, whose commercial standing will be a guarantee for the purity of the goods they supply, are induced to keep it.

A special chapter is devoted to the cultivation of tea in Ceylon, and shows the marvellous progress made by this new industry in consequence of the coffee disease having caused the conversion of so many coffee plantations into tea plantations. In 1875 only 1080 acres were under tea, whereas in 1885 no less than 102,000 acres were occupied by it, and the exports rose from 82 pounds in 1875-76 to nearly four million pounds in 1884-85. The plantations are principlly in the western and southern provinces of Ceylon.

Dr. Feistmantel's work concludes with an interesting chapter on caravan teas, compiled from an article by Herr Walter Japha, published in the *Revue Coloniale Internationale* for September-October 1887.

Some amongst us are apt to feel a certain amount of jealousy at the not infrequent employment of foreigners in Government appointments, and this feeling is perhaps intensified by the knowledge that in this matter, as in Free Trade, there is no apparent reciprocity—for we seldom hear of the employment of Englishmen by Continental Governments; but the present is an instance, and by no means a solitary one, of the great service done to us by foreigners who avail themselves of the information they have collected in the course of their employment by our Government to diffuse among their fellow-countrymen such an intelligent knowledge of the productions of our distant possessions, as is calculated to largely benefit commerce or by leading to an extensive demand for the goods of which they write.

It would seem, however, scarcely just that the work of diffusing this knowledge should be left to other nations, seeing that the benefits are to reaped by ourselves. It is hardly likely that in England it will be recognized, as it is in some other countries, to be part of the duties of any Government Department; but why should it not be part of the work of such a body as the London Chamber of Commerce, or the new Imperial Institute, to disseminate information regarding our Colonial and Indian products among Continental nations, and to translate and circulate any useful works on commercial and kindred subjects, published in foreign languages, among such classes of the community as they would be likely to interest?—J. R. ROYLE.—*Nature.*

TEA IN CEYLON AND NATAL.

Mr. Percy Swinburne, manager of the Natal Tea Company, Isipingo, writes:—In an interesting article to-day, touching on the various products of the colony, you compare the progress made in the tea industries in Ceylon and Natal. To understand how it is that Ceylon has been able to make such extraordinarily rapid strides, it is necessaray to explain the peculiar conditions which favour tea planting there. Ceylon is, as is well known, an oval-shaped island, about as large as Ireland. It is nearly all flat and level with the sea,* and dotted with swamps, villages, and cocoanut plantations, and here and there pimpled with isolated blocks of hills of a few thousand feet; but in the centre of the land there is one block of hills about 40 miles square, and it is in this spot, which is thus only about as large as Lincoln County in England, that the whole of the coffee plantations were collected together. Here, in a lovely valley, with enclosed ornamental waters, in which the Swiss-like cottages and dense foliage of the hillsides are reflected, lies Kandy, the terminus of the railway; † and further up, winding along splendid macadamised roads, Nuwara Elliya, the sanatarium can be reached. Whole valleys and hillsides for miles were covered with coffee, in all about 400,000 to 500,000 acres. Many of these estates have for years given from £10,000 to £30,000 profit annually; but the owners were too greedy, and killed the goose that laid the golden eggs. Successive heavy crops weakened the trees, which were again revived by heavy pruning, only at last to succumb to a virulent disease, which has found its way even to Natal—another case of the sins of the fathers being visited upon the innocent children. But to come to the point, the half-million acres are generally in a high state of cultivation, and it is only necessary for the planters to run out there tea seeds between the rows of the coffee trees, and to convert their coffee mills into manufacturing houses. With reference to ourselves at Isipingo, the bulk of our tea seed is not yet sown, and we cannot expect to produce more than a few pounds of tea this year; but next year we hope to obtain 10,000 lbs. to 15,000 lbs. from a part of the estate which has been very closely planted in order to give us a quick return and cover expenses while the other tea is growing.—*Natal Mercury.*

STOPPING VINE SHOOTS.—In the *Bulletin d' Arboriculture* M. Pynaert, alluding to the common practice of stopping the shoots at the second leaf above the bunch, says that in the vineries at Manage, in Belgium, an interesting experiment has been made. In a span-roofed house in which fifty to sixty Vines are growing: those on one side of the house had been pinched-in to the second leaf beyond the bunch, while on the other side of the house the shoots had been allowed to attain a length even of 6 or 7 feet. The bunches on the Vines where the shoots were allowed to extend unchecked, were quite as good as those on the pruned Vines, and, moreover, they were three weeks in advance of them—a point of the greatest moment in Vine forcing. M. Burvenich confirmed the statement of M. Pynaert. It is greatly to be hoped that someone will try this experiment here. The vineries at Chiswick offer excellent opportunities for carrying out such an experiment, and at no pecuniary cost. Will the Chiswick Committee of the Council kindly note?—*Gardeners' Chronicle.*

* But for the fact that one-sixth of the island is hilly and mountainous, it would not have been the scene of the great coffee enterprise to be succeeded by the probably much greater tea industry.—ED.

† The terminus now is close to Nuwara Eliya.—ED.

AN EXTENSION OF THE TEA TRADE.

(From the *British Trade Journal*, March 1st.)

Is there scope for a much larger development of the tea trade than has as yet been experienced? It seems curious, perhaps, that such a question should be asked in connection with a trade which has grown marvellously during recent years. It may be thought to indicate a very dissatisfied and grasping state of mind to be continually desiring more. Nevertheless, if it is possible to increase the amount of business done, surely it is advisable to do it. Some very important customers of this country are largely interested in the trade, and anything that will promote their prosperity by extending the market for their produce will indirectly benefit us, because they will be in a position to purchase more freely. One phase of the subject which is of importance in this respect, is that, although our total trade in tea has increased, the demand for Chinese tea has fallen off. During the past twenty-five years the competition of Indian tea has become so successful that during last year the average monthly consumption of Indian and Ceylon tea in the United Kingdom exceeded that of Chinese tea. We are the largest purchasers and consumers of tea in the world. For a long time the consumption here has been growing. Last year we consumed 30,000,000 lb. more than we did ten years before. It is very satisfactory to note that the proportion of Indian and Ceylon tea used by us has grown enormously. In 1877 it was 28,000,000 lb.; last year it had increased to 93,000,000 lb. In fact, as we have already indicated, more than half the tea used here in 1887 was grown in India or Ceylon. In 1885 the proportion of Indian and Ceylon tea consumed in this country was 39 per cent. of the whole. In 1886 the proportion was 42½ per cent., and in 1887 it had risen to 51½ per cent. This is satisfactory so far as it goes; but shall we be able to keep up this rate of increase in consumption? The production of tea has increased greatly, and promises to continue to do so. Shall we be able to take it? If not who will? Up to the present time consumption has been facilitated by reducing the price. The reduction of import duties here has done something, but the more recent fall in prices has been owing to competition resulting largely from increased production. In 1879 fair medium pekoe was quoted at 1s 8d per lb.; at the close of last year it stood at 10d. During the same time useful pekoe souchong fell from 1s 3d. to 9d per lb. That is a process which cannot go on indefinitely. To some extent the lower prices have been balanced by a smaller cost of production, the introduction of machinery, improvements in communication, and the like, but that is a kind of thing to which there must be an end. At present prices it is doubtful whether the people of this country can be expected to consume the continually increasing quantity which we may except to receive from India and Ceylon. But if we cannot take the tea there will be a serious crisis in the trade, and a loss and depression in the tea-growing countries that will be keenly felt here. Consequently the question with which we commenced this article arises—Can the tea trade be increased? If so how and where? One firm of London brokers has called attention to this matter, and they urge that steps should be taken to develop a demand for tea in other countries. It is not an easy thing to beget a new taste and fashion amongst a whole people; but with energy, tact, and perseverance, much can be done. Great Britain consumes more than 5 lb. of tea per head of her population. No other country, except our colonies in Australasia, approaches that amount. No Continental nation uses much more than 1 lb. per head, and in the United States the consumption is very little above that. The suggestion that efforts should be made to push the use of tea amongst those nations which now use comparatively little of it is worthy of attention. This is desirable in the interests of our fellow-subjects in India and Ceylon, who have invested considerable sums of money in plantations there. True, up to now it is the Chinese who have gone to the wall, and Indian and Ceylon tea planters have been able to rejoice in a regularly increasing sale. But, as we have already intimated, that has been largely facilitated by equally regular falls in prices. Further, the competition of Chinese tea is likely to become more severe. Up to now Indian teas have had the advantage of Chinese in the important matters of quality and preparation; but their rivals are not disposed to allow their most important industry to be taken from them without a struggle. Already steps have been taken to ascertain the reason for the falling-off in the sales of Chinese tea and to remedy shortcomings to which attention has been directed. More care is to be taken in cultivating, collecting, firing, and packing the article. The introduction of improved methods and modern machinery is to be encouraged. We may therefore anticipate that shortly China will make a great effort to recover lost ground, and will put on the market an article that will make competition very keen. Consequently an extension of the tea market is very desirable. How it is to be done is perhaps not very easy to see. The growers are the persons mainly and in the first place interested, and they will do well to give the matter their attention. The brokers to whom we have referred say, "The importance of pushing forward in some manner the consumption of British grown tea is so great that it might even be worth the consideration of planters, whether the establishment of some central institution for the development of new markets might not be established; for even though a considerable expense might at first be entailed, it would be far preferable to an eventual reduction of many pence per lb. in the average price of British grown tea, and the lose of income to thousands our own fellow-subjects.

RUBY MINES OF BURMAH.

ROYAL GEOGRAPHICAL SOCIETY.

The ruby mines of Burmah formed the subject of the paper read on Monday night at the meeting of the Royal Geographical Society, Burlington House, General R. Strachey, C. S. I., presiding. The reader of the paper was Mr. Robert Gordon, C. E., who stated that he surveyed the ruby mining district north of Mandalay when the concessionaires, Messrs. Streeter, were requested to send representatives to the mines. This district, which had hitherto been closed to travellers, could now be reached very quickly compared with what was the case formerly. Rangoon could be reached by mail from London in 23 days, 150 miles thence to Prome occupied by rail a few hours, and a three days' journey from Prome brought the traveller to Mandalay. The country was described, and a railway, which was stated to have already brought about economic changes of the highest importance, was pointed out as possessing great interest as the first instalment of the great iron highway for British commerce to South-Western China. A continuation of the railway 600 or 700 miles along the old trade route to the capital of Yunnan and a further extension to Soo-Chow-Foo and to Chung-King-Foo would open up the principal marts and the navigable channel of the great artery of China, the Yangtse-Kiang. The expenditure of £14,000,000, of which £3,000,000 had already been incurred, would bring Central China within 26 days' reach of London. He described in detail the country from Mandalay to the ruby mines noticing its flora fauna, diversity of race among its peoples, and its general features, speaking of it as presenting hill and vale, the ranges of hills varying from 6,000 ft. to 8,000 ft. in height. The principal villages of the mining district were Mogok, Kathay, and Kyatpyen. Everything indicated the possession of surplus wealth among the people. The residents in the larger villages rarely did any heavy work in the mines themselves, but engaged labourers. In regard to the relations of the people with the old Burmese Government, inquiry elicited that, though theoretically the people had no rights, yet practically everything indicated considerate treatment and kindly relations. All tended to show a settled and peaceable condition among the inhabitants in recent times, with a greater accumulation of wealth among the headmen than was possible elsewhere under native rule. No per-

manent mining works of any value existed, but numerous artificial water-channels were carried with easy slopes on the hillsides, the ravines being crossed by temporary aqueducts on bamboo framing. The mines were of three kinds—the first, which was of the least importance at present, but which might be the most valuable in the future, consisted of workings in fissure veins of soft material found embedded in the crevices of the hard rock, caused by shrinkage in long past ages. It was probable that volcanic action accompanied the upheaval of these mountain ranges, and that the already formed rubies were thrown up with a matrix of complex structure, since disintegrated by long weathering together with the metamorphic rocks clothing the skeleton of the old mountain limestone, whose ribs still protrude. There was no sign of any recent volcanic action in the neighbourhood; and the corundum was now found distributed through the clay formed from the breaking down of the gneissic rocks, and also in layers or beds in the valley bottoms near the river, apparently discriminated and arranged by water action. The crevices in the older rocks gave origin to cave mines, which were called "loos," where the soft earth was excavated in a primitive fashion and on a small scale. The second class of mine was called "myaw," or washing, and corresponded, but on an insignificant scale, with the hydraulic mining in California. The water was conducted by the channels to the lower hillside, which consisted usually of the softer remains of the secondary rocks in reddish or lighter coloured clays, containing rubies and sapphires though few and far between. The clay was cut into thin slices with a gardener's spade and washed from the funnel-shaped excavations through flumes or open timber channels, where the clay was dissolved away or carefully examined for the stones. No attempt has been made to wash the hillsides by water under pressure. The third, and at present the most important class of mines, was found in the flatter lands of the valleys, where, whatever be the absolute height of the ground, or whether in the neighbourhood of Mogok, or Yay-Boo, or Kathay, or Kyatpyen, at depths varying from 10 ft to 30 ft., there was found a layer of corundum from a few inches to a few feet in thickness. It was difficult to account for the existence of this layer of nearly pure corundum lying on a bed of earth in which no stones were found, and covered by a similar layer of porous earth. It was premature to forecast the future of the Ruby region, but with the careful handling which it was sure to receive from the new governing powers we might fairly expect a rapid development of the mineral wealth.

Subsequently, Mr. Streeter stated that information had reached him that the Mogok town contained 3,392 inhabitants, Kathay 1,725 inhabitants and Kyatpyen 1,553 inhabitants, and that the Government, in not carrying out the concession entered into by Lord Dufferin, had lost in the year three and three-quarter lakhs of rupees, or £37,500.—*Times' Weekly Edition* March 1st.

PLANTING REPORTS FROM THE HILL COUNTRY OF CEYLON:

TEA AND THE SHADE OF CINCHONA IN DRY WEATHER.

Nanuoya, 5th April.

The dry hot weather, following on previous abnormal rainfall, has been most favourable to the health and flush-production of our tea bushes at this altitude, while the cinchonas have suffered but little. The belief here is that it was well we had not labour to spare from tea plucking to carry out the long-delayed work of trimming away the dense lateral growth of our groves of *C. officinalis* growing amongst the tea. The shade afforded during the drought is believed to have been entirely beneficial. The flushing of the tea bushes under the influence of the cinchona shade has certainly been and still is all that could be wished, and it does not seem probable that the flush thus partially shaded is likely to be to any appreciable extent deficient in the active principles which give tea the strength and aroma for which the dried leaf is valued. When the wet weather sets in, however, one of the first works to be taken in hand will be to trim away the luxuriant growth of side branches on our cinchonas, and with them the large clusters of seed, such as, at the commencement of the enterprise had such high market value. The cultivated tea has not flowered and fruited to the extent which might have been feared in such weather, and the clearing away of all blossom and fruit which exists, is understood to be part of the work of the pruners. But what a desolate sight an expanse of pruned tea is, unless or until the prunings can be forked into the ground. The absence from the tea of any affection worse than copper-coloured leaves, contrasting curiously with the general green and the golden flush, (and which we consider of no consequence) is matter for congratulation. Especially ought we to be thankful that the grubs of the beetles now so plentiful, from stag beetle to cockchafer, seem to find no attractions in the roots of any of our living trees, except poor old coffee. Tea, cinchonas, and exotic, or other cultivated trees seem to enjoy equal immunity, so that rotten timber and coffee roots seem to be at present the only homes of the voracious white grubs, so acceptable to our no less voracious Australian "magpies." The parent beetles can be obtained in large numbers, simply by repeatedly slapping one of our *gum* trees with the hand. The reverberation produced is sufficient to send the beetles which are feeding on the secretion exuded from the bark, tumbling down. An enormous collection of these hideous insects are climbing over each other in a wide-mouthed glass bottle, preparatory to becoming food for the great and greedy Australian shrikes, which yesterday at Nuwara Eliya were, I suppose, the first of their kind exhibited at a Show in Ceylon.

House flies abound this season, and I never knew horse flies and mosquitoes so troublesome in this district. A curious specimen of stick mantis was found today. It was about four inches long, and the resemblance to a twig was carried out to the extent of knobs, like buds on the body and colouring as of broken withered wood near the tail. Many may not know that this queer creature is so fierce and voracious as to be called "the tiger of the insect tribe." In addition to insects, which it saws to pieces, it feeds on small frogs and lizards.

April 6th.—Yesterday evening the dark volumed thunder clouds came rolling down from the north-east as if they meant business, and a few big drops fell, but only enough to show 1 cent of an inch in the rain-gauge. There has been a dead calm since the 3rd, with really oppressive heat, so that the rain cannot be far off. This morning rises fine with some haze on the mountain ranges.

CEYLON PLANTERS AND TEA CONSUMPTION.

No one can doubt the practical wisdom of the scheme which Mr. H. K. Rutherford formulates as an extension of that which, generally commended, is already associated with his name. Mr. Rutherford acts on the old proverb that "God helps those who help themselves." The experience already gained of what can be done by tea producers and their friends to influence consumption is most encouraging. It can safely be said that the Ceylon planters and their numerous indigenous and foreign agencies have done much to stir up those interested in the much older enterprise of India to a due sense of the responsibility resting upon them. "Ceylon tea" has been advertised

far and wide, and its consumption pushed in a way that has never been parallelled in the case of any other tropical product. No Exhibition has been allowed to pass without a special effort at representation. The Southern colonies have been invaded, and even a small effort made at reaching and influencing far-away North America. In proportion to the wealth (or rather comparative poverty) of our planting and mercantile community during the time of depression, the expenditure of money, time and thought, given to this matter, has been quite wonderful, and, if India Tea Companies, Agents and planters, had only exerted themselves in the same proportion, there would not have been a corner of the civilized globe, where the virtues of Indian and Ceylon teas had not, by this time, become as familiar in the mouths of the people as "household words." But it is no use crying over a want of energy in the past. Indian Tea Agencies did of course a good deal of work in the United Kingdom before Ceylon appeared in the field, and, as we have said, new life and vigour have latterly been infused into their efforts to promote consumption in other directions. Notably, are we following with much interest, the attempts made with the countenance—nay the direct support—of the several Governments to promote a local consumption of tea in India itself. This is a most important movement from a sanitary and temperance point of view, apart from its commercial and planting aspect. The people of China and Japan—and more especially the overcrowded millions of the Celestial Empire—are very justly supposed to owe their comparative immunity from cholera and typhoid fever, to their dread of drinking "cold water." In other words they have been accustomed for centuries probably, to drink the mildest possible decoction of tea, and to secure this at all times, it is the custom to keep the chatty or pot with water all day long on the fire ready to supply the needful liquid for infusion of the few leaves which they use at a time. In India the virtue of boiling the water used for drinking purposes is scarcely, if at all, known among the people, much less the infusion of tea, and as a consequence there is the forcible proverb of the British era: "Nothing more dangerous to drink in India than brandy, except *water*." Now the Indian authorities are trying to introduce the Chinese practice, or something allied to it, and if they only succeed to the extent of getting the 250 millions of people to use a quarter of a pound of tea per head per annum, or even half that, it will be seen what a special effect would ensue in reference to the consumption of the steadily increasing Indian tea-crops. Nothing has struck us more in glancing over some thirty to forty reports of Indian Tea Companies lately than the uniform way in which each speaks of an increase of bearing acreage and a larger crop estimated for "next year." The question of increasing the consumption of his product is therefore vital to the tea planter. Now in regard to our three millions of people in Ceylon, there is no reason why we should not encourage tea consumption and anticipate a rate equal to a pound a head at an early date, the main portion of the supply coming perhaps from native gardens, and the broken leaf and dust of plantations.

But all this is simply preliminary to our reference to Mr. Rutherford's letter in another column, and we desire now to press for acceptance on the Ceylon planting and mercantile community, the new scheme —or rather extension of the existing scheme —which is there so clearly formulated. Much as we prize the efforts made in the United Kingdom, in Australia, the Continent of Europe or India, there can be no doubt that all these fields sink into insignificance when compared with that presented in North America. At present the consumption of tea in the United States is only equal to 1¼ lb. per head; in Canada to 2½ lb.; while the United Kingdom takes 5 lb. and Australasia 6 lb. per head of population per annum. Now we are quite aware that a great portion of the States will ever be a coffee, rather than a tea, consuming country—the Southern States more especially. But at this moment, while there are as nearly as possible 60 millions of people within the United States, only one-third or about 20 millions will be found south of the line which we should make as denoting the boundary between the coffee and tea drinking divisions. Among the 40 millions of people in the Northern and Western States, precisely the same conditions obtain as in the United Kingdom, Australasia or Canada. The tea planters of India and Ceylon therefore should not rest content until the 45 millions of the United States and Canadian Dominion (a population, we need scarcely say, yearly increasing by leaps and bounds) are drinking tea at the rate of 5 to 6 lb. per head per annum. This will not be accomplished in a year or in several years, but clearly it is the goal to be aimed at in the campaign now opening. The planters of India have already taken steps to begin that campaign after a systematic fashion, and Mr. Rutherford's object now is to secure the assent of the Ceylon community to work "shoulder to shoulder" with their brethren of India. We feel sure that the response will be very generally, if not universally, one of approval, and there can be no better way of finding the "ways and means" than by a general though voluntary contribution, in proportion to "made" tea from each plantation. We do not see why the rate already fixed by Mr. Rutherford should not suffice, namely, of one rupee for each thousand lb. of tea. By the time the American scheme is fully developed, we may expect the crops of the two countries concerned and the consequent levy to be represented as follows:—

INDIA ..	90,000,000lb.	..	R90,000
CEYLON ..	30,000,000 „	..	30,000
			R120,000

The "sinews of war" for fighting such a campaign as would come home to every town and village, aye and station in the Northern, Western and Dominion territory might be properly sustained with R120,000 and upwards per annum from 1889 onwards for say five years. And when the American people found out that the article so vigorously canvassed was a really sound, pure, desirable product in itself, we may be sure there would be no difficulty in turning their taste in the direction required. Meantime let there be unanimity and enterprize shown at the very next meeting of the Planters' Association in accepting the proposal now formulated by Mr. Rutherford.

CHINA AND JAPAN TEA EXPORTS 1887-1888.

During the past two months there has not been any change worth noting in the China tea trade, and we have not therefore adverted to the subject. When we last wrote about it, the comparative decrease in the season's export to the United Kingdom was, as it is now, about 28 million pounds.

The season at all the treaty ports is over, and though the final returns will not be made up until next month, we know the result will not differ materially from that in the subjoined figures. The decrease in the exports to Great Britain

for 1887-8 as compared with season 1886-7, is made up as follows :—

	lb.
From Shanghai and Hankow ..	13,806,414
,, Foochow	14,273,669
,, Canton and Macao ..	172,424

On the other hand, there has been an increase from Amoy of 201,545lb., and from Japan of 170 1581b. America has taken 4,429,6071b. less this season, than in the last, 3½ millions being deficient in the Japan export and about a million from China. The Australian Colonies have received 3,8 9,8971b. more this season, and the Continent of Europe 1,790,9811b., the latter being chiefly to Russia. This does not account for the large and unaccountable falling-off in the export from England.

The export to Russia direct, exclusive of the quantity included in the export to the Continent, is 12 million pounds, against 11½ millions last year. Russian Manchuria has taken 7,211,224 lb. against 8,339,155, lb. last season ; but Russia, no doubt, draws supplies from China by other outlets, than through the treaty ports, and for which no returns are published. We notice that the North of China has taken from the Yangtse ports and Shanghai 51 millions, against the same quantity last year. Here are the total figures :—

Export from China and Japan		lb.
To England ...	1887-88	121,744,407
Do ...	1886-87	149,625,211
Do ...	1885-86	150,139,658
To United States	1887-88	66,065,147
Do ...	1886-87	70,494,754
Do ...	1885-86	63,965,379
To Australian Colonies	1887-88	23,791,511
Do ...	1886-87	19,961,614
Do ...	1885-86	21,769,305
To Continent of Europe	1887-88	13,245,016
Do ...	1886-87	8,534,035
Do ...	1885-86	8,660,926

In view of the large increase which is taking place in the production in India and Ceylon, the serious question for the British producer is whether the decrease in the export to Great Britain will be permanent, or only temporary ?. We hope as the production of tea in China does not as in other countries, depend on external consumption, the very low and unremunerative prices realized during the last two or three years, for a large portion of what is exported, will have the effect of curtailing, if not putting an end to, shipments of all teas which sell in England for only 3¾d to 4d per pound.

It will be impossible, however, to form any correct opinion on this point until we receive the first three months' returns of the new season's export, and these will, no doubt, be watched with great interest. Our mail news from China indicates a poor season before those interested in the tea of the Far East.

MR. R. E. PINEO AND CEYLON TEA IN AMERICA.

Mr. R. E. Pineo landed last evening from the P. & O. steamer "Ganges," having come back from America by way of Japan—where he has been visiting the tea districts—and has just come in the nick of time to give Mr. Rutherford and the Planters' Association the latest information in reference to the prospects of Ceylon tea in America. Mr. Pineo had to part company with Mr. MacCombie Murray, because the field in Philadelphia scarcely gave promise of a business sufficient for the two. But Mr. Pineo has now in view a much more likely way of creating a demand for our teas in the Western States through the co-operation of an enterprising New York capitalist not hitherto engaged in the tea trade, and who proposes to commence operations in Chicago and beyond, by the free distribution of 10,000 samples (each of 1 lb.) of Ceylon teas. Mr. Pineo's partner, however, naturally asks for some tangible evidence that the Ceylon planting community are interested in, and prepared to back up this new business—a departure from the line he has hitherto been engaged in. And for our part, we think there is a case to be taken into practical consideration by the Managers of the Ceylon Tea Distribution Fund, before whom, no doubt, Mr. Pineo will be prepared to give full particulars of the proposal, as also of his experience so far in promoting the acceptance of Ceylon teas in the States. We are glad to see Mr. Pineo looking well, and prepared to run through Uva to see the great change and the beginning of the Tea Enterprise in the Principality. Mr. Pineo agrees with us in anticipating that the rich valleys of Uva will be covered with native tea gardens ere-long, the leaf being sold to central factories. What with tea, tobacco, cotton, cacao, and other products, Uva will yet show a wonderful increase in production and, consequently, in heavy traffic for her railway.

THE HARVESTING OF CINCHONA.

The best method of working cinchona trees has been much discussed, particularly by the planters of Wynaad, but so far without any definite conclusion having been arrived at. Hitherto the area of yielding trees in that district has been comparatively small, and isolated planters have been content to try one system or another with varying results. But millions of plants have been put out within the last six or seven years, and will soon be fit to bark, so it is of great importance that the matter should be inquired into, and an authoritative decision if possible, be made on the question. There are three systems of taking the bark more or less in vogue, namely, stripping, shaving, and coppicing. The first of these has, we believe, not been generally found to answer. It consists in removing a long strip of bark down to the wood, and then covering up the part to allow it to renew ; but the bark very often refuses to renew under this treatment, and the tree is permanently damaged, if not entirely destroyed. Shaving is the process most usually adopted, and it has one advantage, at least, over coppicing, viz., that the proprietor gets a small revenue each year after the fourth, instead of having to wait till the seventh or eighth, and possibly losing his tree by canker in the interval. It may be done with the ordinary pruning knife, which many planters maintain is the best instrument for the purpose, or with specially made spokeshaves, or with a Ceylon invention called a boxscraper. This last answers very well for orignal bark, but, as at present made, will not remove the thick or renewed bark ; it is also rather expensive. After shaving, the tree is usually covered with grass. The rival methods of shaving and coppicing have both advocates who insist on the superiority of their own plan, and it is difficult to decide between them. A few years ago, when "druggists' quill" was worth four shillings a pound, a man who cut down a few thousand well grown trees made a small fortune. Unluckily there were very few who could do so. The demand for this variety—apparently only to be used as an ornament in druggists' shop windows—seems now almost to have died out, for while the enormous Ceylon export has lowered the price of every kind of bark, the fall in quill is the greatest of all. Shavings which were worth half a crown or three shillings a pound, are now down to eighteen pence, but the quotations for quill have sunk lower. While too, it is evident that the Ceylon supply of bark is gradually becoming exhausted, and that the market for ordinary kinds is improving, it seems questionable if quill will be again in great demand. Still, if we take the present market rates as a guide, the pecuniary advantages of the two processes appear to be pretty evenly balanced. The question as to whether the tree is checked in its growth or not by continued shaving may be left out of the present calculation; it seems agreed that, if the operation

is carefully performed at the proper season, not much harm is done. The following are approximately the respective revenues that would be derived from shaving or coppicing a fair specimen of cinchona succirubra by the seventh year, three annual shavings being about what an average tree will stand, though it is sometimes carried no longer. Shaving four years (original) 6d; five years (renewed) 10d; six years (renewed) 10d; seven years (cutting down) 4s—total 6s 3d. Coppicing at seven years, quill say 3 lb. 4s, sundry (branch &c.) 3 lb. at 9d, 2s 3d—total 6s 3d. The above estimates are, it will be understood, only such as can be made from data accessible to the ordinary cultivator, and are therefore open to correction. Only one establisment in India could, if it wished, give us full satistics on the subject. But useful as such statistics would be to the whole body of cinchona growers, the authorities at the Neddiwuttum Government Gardens prefer to keep them from the light of day. They go on flooding the market with bark, caring—and from all accounts knowing—little whether the sales show a profit or a loss, but they steadily withhold information. We would suggest that Mr. Lawson should furnish replies to the following as a sample of those questions about cinchona cultivation that urgently need applying to:—What is the relative mortality in trees shaved from, say their fourth year, and those left intact for coppicing? What are the relative profits of the same on a given area? What manures (if he has tried any) have increased the alkaloids and the growth of the trees? Has he discovered any prophylactic against canker, or any cure for it when once it has set in? We could increase the list considerably if we thought there was much prospect of any answers being elicited. [In copying the above from the *South of India Observer*, we confess we do not understand the charges against the Madras Government Botanical Department. Information is freely published.—ED]

THE INDIAN TEA SUPPLY COMPANY.

The Indian Tea Supply Company, which was started with considerable enthusiasm last year, has sent out many sample packets of tea to persons likely to take an interest in the movement. Some were received at the office of this paper a few weeks ago, and duly acknowledged. The enterprize, although entirely novel, is one to command the faith of every person who gives it careful consideration. It is nothing less than a scheme to convert Indian into a nation of tea-drinkers which may be more feasible than it seems, if proper measures be used to create a demand for the beverage. For one thing, there is a fascination in tea, which makes people take to it as they do to opium or intoxicating liquor; as we may see in England, where tea has become a necessary of life; and in China and Japan, where it is drunk all day long by all classes of the people. But we have in Calcutta positive evidence of the possibility of creating a taste for tea among the Natives, in the fact that a decoction not worth the name is sold at a pice a cup in the bazaars and streets, and that Natives buy it and drink it with relish. That is a clear indication of what we may look for in every town and village of India, if the taste for tea only be developed as it has developed itself in Calcutta. We do not mention the taste for tea which has sprung up among Natives of the upper classes, for these order what they want from the leading firms, and would not help the Indian Tea Supply Company except by taking shares in it. Nevertheless, it is a fact that a silver tea set has come to be an acceptable part of a "khillat" ordered for presentation to a Native Chief. So much for conservative old, caste-ridden India!

The chief thing is to devise means for introducing the little packets, and here is where the Company will succeed or fail. The peculiar "knack" which carries one man in a thousand to do some simple thing which other men cannot do, is not to be bought for money. A man must be born with it, or do without it. The thing to be done is to make tea-drinkers of the people of India, and the way which first suggests itself is to give the packets to petty shopkeepers on terms which will induce them to push the sale without being ruinous to the Company. As soon as a few men in a town begin to drink tea, others will follow their example, and the shopkeepers will need no further urging to supply the market. Natives are ready enough to take tea as a medicine, as most Europeans can tell from the constant applications for "cha" that are made to them by their servants and dependants. That being so, they need only to have the article placed within their reach, cheaply and conveniently, and the desire for the medicine will grow into a habit.

One or two remarks may be added about the packets as they have been put up and sent out by the Company. These packets are in neat yellow paper covers, and bear labels in English and three native languages. But the vernacular labels are simply translations, or rather transliterations, of the English, which reads thus:—"The Indian Tea Supply Company, Limited. Trade Mark Registered. 1 oz. Pure Indian Tea. Price 3 pice." Such a label could only suggest to the average Native some idea of European magic. "Supplaee," "Leemeetade," and even "Indeeyan," are simply turned into his own characters for him. Now we submit that unless the label be intended as a scare, every such word should be removed except from the English label, and the vernacular words confined to "cha" and "pice," with an assurance that the article is *bahut achcha* and *bahut susta*.

Another thing that seems important to the success of the scheme is that the packets, in the first instance, be sold at one pice each. At present the smallest packets are sold at three pice, and the larger ones at six pice and three annas—which are prohibitive prices. A pice is the Native's standard of value, and he will not look twice at a new thing for which he is asked to give more. Besides, a threepice packet makes nine cups of strong tea, or a dozen cups of such tea as Natives gladly drink; and it is quite contrary to a Native's ideas to give hostages to fortune in this way. In all matters of food he likes to pay for what he wants to eat, and to let the morrow take thought for itself. We do not forget that the packing of a small packet of tea costs more than the tea. Yet the commodity almost requires to be sold for a pice if it is to make way among the population at large; and there seems to be room for economy in the quality of the tea, which at present is distinctly superior to much of the article consumed by the poorer European and Eurasian families. These people too, I hear, are already purchasing from the new Company, which seems a clear proof that the tea is too good for natives, who are glad of the dried leaves from their master's tea-pots.—*Indian Tea Planters' Gazette*, March 17th.

PLANTING IN NORTH BORNEO.

The *British North Borneo Herald* for 1st March contains a very interesting review of the Sumatra Tobacco Trade for the year 1887, by Messrs. Binger and Herschel of Amsterdam, which we shall reprint in full in the *Tropical Agriculturist*. Meantime we quote a paragraph referring to Ceylon:—

"From Ceylon 107 bales arrived, of which 52 bales of excellent quality and colors and suitable for wrappers, fetched a high price. The last import of 55 bales, only fit for burners and fillers, remained unsold when offered by auction, and only partly found buyers when brought to auction a second time. The burn was satisfactory, the leaf rather thick, coarse and green."

Further Borneo items of news of interest are:—

The British Barque "Walter Sigfried" sailed on the 26th ultimo for London with a cargo of Borneo timber. This is the third vessel despatched by Messrs. E. E. Abrahamsen & Co. this year.

The Court of Directors has been pleased to sanction the purchase of 100lb of Tobacco from the Ranau

Estate, Marudu bay, to compete for the prize to be given by the London Chamber of Commerce in December next.

By the S. S. "Paknam" half a mile of heavy railway was imported by Messrs. E. E. Abrahamson & Co. The railway is especially designed to transport heavy timber from the forests, and if found practicable will be used on a large scale with steam cranes and motors.

The Sandakan Flower Show.—The most successful Meeting of the whole year, in Sandakan, is probably the Flower show, which was originally started by Mr. Pryer in old Sandakan, and has been held for the last ten years on Chinese New Year's day. In addition to exhibits of Flowers, a stimulus is annually given to gardeners to improve the quality and increase the number of their vegetables by prizes which are made as liberal as the funds will allow. Latterly, Fruits have taken a more and more important place in the exhibits as the trees have come into bearing. Last year, the "Manufactures and Products of British North Borneo" had a special place, which was increased this year by the offer of forty eight prizes for this department alone, to which about half the funds were devoted.

Messrs. Van der Hoeven, Van Gogh, and Merchistein were passengers to Sandakan by the S. S. "Paknam," arriving on the 19th February. Mr. Van der Hoeven as one of the Managers of the Deli Maatschappy has had the conduct of very extensive and successful tobacco plantations, and we are glad to welcome a gentleman of his experience to our territory. Mr. Van Gogh assisted by Mr. Merchistein of Deli is also on the look out for tobacco land of which there is doubtless plenty for all comers and which, thanks to our climate, is likely to be a most profitable undertaking.

Mr. W. A. Vos of Siak together with Mr. Schaper, visited Silam in January, and crossing over to the Segama found good land on the banks of that river. We now learn that the above gentlemen are so satisfied with the soil and climate of our territory, that each has decided to take up land for tobacco planting at various places,—on the Labuk, the Segaliud, and the Segama Rivers; and we hope to see tobacco planting commenced this year at each of these places, which, added to the tobacco plantations in Dravel Bay and Marudu Bay, will prove very decisively the position to be occupied by British North Borneo among the tobacco producing countries of the world.

Attention has already been attracted to the large percentage of sugar in the Borneo sugar-cane, and the Java planters are importing *beebit* from Borneo at high prices. The sugar-cane of Sandakan has already received a favourable analytical report and this adds interest to the immense size of the canes exhibited on the Chinese New year's day at Sandakan, which, as stated elsewhere, actually reached a height of 22' 6."

COCONUT PLANTING AND CULTIVATION.

MANURING.—There are few of our soils of such natural fertility, that they may not be profitably improved by the application of manure on an intelligent system, resting on the habits and capabilities of the cultivated plant. In the coconut we have to deal with a plant, that throws out a multitude of primary roots radiating in all directions from the vertical to the horizontal. In a uniform medium these roots always grow outwards in a straight line, only turning aside on meeting with some impenetrable impediment, such as a stone or a root of hardwood. These primary roots are of uniform thickness throughout their length, generally from one-fourth to one-third of an inch in diameter; they are closely studded with buds from which the secondaries are derived, and these again carry innumerable buds, and branch out indefinitely in all directions.

The rate at which the primary roots extend, is governed entirely by the mechanical condition of the soil; in a light loose soil they spread with great rapidity, and the more stiff and compact the soil, the slower the progress. The cultivator has only to deal with that part of the soil that is within one foot of the surface, and that happens to be the chief feeding space of the plant. In all newly opened land, a few inches of the surface are the richest in plant food, and as a rule more easily penetrated by the roots than that lower, thus the surface soil becomes matted with a load of interlaced roots, while the primaries at a greater depth and in a denser medium, make little or no progress till the upper soil is utterly denuded of fertility. In such cases, should cultivation be introduced, it must be done by destroying this whole mass of roots, to the depth of from six to eight inches, but if cultivation be begun with the beginning, all will be different. The operations necessary to consign the primary roots to a depth where they will not be interfered with in the future course of cultivation, is performed by trenching a circle six feet in diameter, and two mamoties deep, round each plant within the first year. The first mamoty on the surface should be reversed in the bottom of the trench, and the second placed above it, the surface soil will thus be placed at a depth of nine or ten inches, and no primary roots will seek to run in the poorer superincumbent soil. As the extremities of the roots approach the circumference of the trenched circle, an additional two feet all round should be treated in the same way, and repeated as often as required till the various circles meet across the spaces, or if the planter prefers it, he may trench the whole of the land at once, and have done with it, which will in the course of a few years, save in weeding the R20 per acre so expended.

It may be objected that this work will not pay, and it certainly would not if the trees struggled into bearing between the tenth and twentieth year, and afterwards only yielded annual crops of 2,000 nuts per acre, or less. The operation recommended above will, however, give such freedom to the extension of the roots, that the growth of the plants will be so very much more rapid, that the early trees will begin to bear in the sixth year, and the latest will bear by the tenth and bear very differently from trees that have to contend with an unbroken soils.

Besides the trenching, there is no work of importance during the first four or five years, except helping on lagging plants, with little nitrogenous manure, but when the stems begin to show above the surface, 56 lb of cattle-shed manure, or 15 lb. of poonac, or 21 lb of fish manure per tree, or any other nitrogenous equivalent will be of immense service in hastening maturity. A young coconut tree will generally begin to flower when it has a head of from 20 to 25 leaves, but it is generally admitted that our low-country soils are almost universally deficient in phosphate, the most important of all the elements to the abundance and perfection of all kinds of fruit and seed. It is no presumption to assume this deficiency as an established fact: therefore, the prudent planter will furnish his trees with a supply as soon as they arrive at the stage of making demands on the soil for this element. One pound of bone dust probably contains the phosphatic requirements of 30 medium-sized nuts. Thus, if the tree will naturally yield average annual crops of 30 nuts, 5 lb. of bone dust will carry it up to an annual yield of 80 for three years, if there is no deficiency of any other of its specific elements in the soil. The cost and application of 5 lb. of bone dust is from 25 to 30 cents, or say as an extreme figure R20 per acre against a return in three years of 10,000 nuts, but as to make this return, the tree, with all its parts and

tissues, must be kept in a healthy and vigorous state, it will take another sum of R20 per acre to supply in due proportion the other elements necessary to the plant.

It has been asserted that phosphate acts as a stimulant that causes temporary heavy bearing, which weakens the tree, and is followed by barrenness. I think this is to be accounted for otherwise than by the stimulating quality of the phosphate. There are other elements that enter into the composition of coconuts besides phosphates, the poonac is rich in nitrates, and as the barrenness complained of takes place, while there remains an abundant supply of the former in the soil, the cause of barrenness is more probably caused by the deficiency of nitrates than the excess of phosphates. I should, therefore say that the planter who is not prepared to keep up the due proportion of nitrates in the soil, has no business to meddle with phosphates, for it is only the tree rendered vigorous by the one that can avail of the other.

All organic matter in the course of decomposition, supplies plant food, but different substances yield it in different measure; the most universally approved article is the dung of herbivorous animals, which will convert, at least, its own weight of less tractable stuff into excellent manure. Unfortunately, however, the supply is very much less than the demand, and it is not a manufacture that can be extended at will. I once kept one hundred and odd head of cattle that grazed the estate, supplemented with poonac at will. I had the command of extensive deniyas that grew ferns and coarse grass, with which the cattle-sheds were fresh littered daily, and my turn-out of manure was under 450 cubic yards per annum, with which I was able to manure 1,200 trees. As there was over 16,000 trees on the estate, it required 13 years to go over them all, and the manure was wholly used up by the end of the sixth year, so that, however praiseworthy this manure may be, the quantity that can be produced gives but a poor chance for keeping up the fertility of an estate. For a further supply of nitrogenous manure, our resources are in coconut poonac, the natural manure of the tree, castor cake, fish manure, and some other substances available in special localities, but not worth the cost of transport to any considerable distance. Of manufactured manures, or the various salts of nitrogen, I can say nothing, as I have never used them. The other manurial resources locally available on a coconut field are scanty; the by-products of the trees are very bulky, but probably the poorest in fertilizing elements of all vegetable substances. If the leaves are piled in large heaps, they will, with time, rot down into manageable dimensions, but the husks are utterly intractable. So far as I can judge by numerous experiments, their manurial value will not pay for the labour of placing them; buried in the soil they take seven years to thoroughly rot, and they do not rot down into humus, but gradually wear thinner, and finally disappear without leaving a trace in the soil. Whatever the capacity of coir dust to absorb and retain moisture may be, its powers in this direction are not very striking when bound up with the fibre in its natural situation. All organic matters left to decompose on the surface pass away without in any way serving the cultivated plant, therefore the herdsman should carry a mamoty to turn in all the droppings of the cattle, all herbaceous weeds should be buried in shallow holes, and all ligneous ones buried and their ashes turned in, as the work goes on nothing that may serve the main purpose should be neglected, however trifling it may appear in detail.

When a coconut field is to be manured, whatever the quantity or quality of the material used, the most efficient mode of application is to spread it as equally as possible over the surface, omitting circles of 6 or 7 feet in diameter round the stems of the trees, which should never be touched, and turning it in with the mamoty. The plough would be a more economical instrument, if either trained cattle or trained ploughmen were to be obtained.

PETROLEUM.—The *Odessa Messenger* states that India is becoming one of the largest consumers of Russian petroleum in the world. In 1887 more than 2,000,000 poods were exported from Batoum for that destination, and in January alone, for the present year, as much as 400,000 poods were shipped at that port for the East Indies.—*Times of India*, April 3rd.

OUR COCONUT ESTATES.—The severe and prolonged drought is telling very much on vegetation in general, and on coconut trees in particular. Passing along the central road as far as Elephant Pass several times during the last two months, I noticed that the estates on either side are not in good bearing. Those who have seen more of these estates than a passer-by like myself are of the same opinion. The soil of the Pachchillapalli estates is very sandy, and it is generally during seasons of severe drought such as the present that the trees begin to wither and die. Some few estates are still in a good condition.—Cor., "Ceylon Patriot."

THE APPROACHING CHINA TEA SEASON.—The *Foochow Echo* says:—In the tea districts the usual preparations for the new leaf are rumoured to be very gloomy for the coming season. 'Doubts' seem to be the order of the day in all matters concerning the business. Last year was certainly a very salutary one, as a lesson to many of our enterprising but penniless celestial tea merchants, who we positively blame to be the cause of all the deterioration in quality and price, for they are the real inventors and sellers of the tremendous amount of rubbish that is placed on the market every year, and the result is that other respectable dealers who used to buy and place on the market pure leaf, are now compelled to give up any idea of fair dealing in order to remain in the trade at all. If a clean sweep of this grand class of tea dealers can be effected, China tea will be at once elevated to its old standard which the world so much appreciated.

"MINCINOLANISM": THE CINCHONA MARKET.—Some curious information respecting the doings of London and Amsterdam authorities on the Cinchona market will be found on page 721, from the latest *Chemist and Druggist*. The writer of the Amsterdam Report on Java Bark of December last, which created so much sensation, now comes forward in his own name, and to some extent defends the position he took up. But it is clear that he has no personal acquaintance with cinchona cultivation in Java, and writes on this part of his subject from "hearsay"—hearsay which the experience of the past three years shews us to be, in some respects, at least, untrustworthy. At the same time, there is some reason in his conclusion, that, if Messrs. Brookes & Green had, a good many years ago, sounded an alarm over their 15 per cent Java bark, they [illegible] possibly have done something to check shipments from Ceylon inducing a ruinous fall in price and so saved money to planters who [illegible] into the enterprise with inferior seed. The practical portion of Mr. [illegible] letter, however, is where he distinctly shows, that the analysis of Java bark sold in Amsterdam is steadily improving; the average being 4·2 per cent at the January and 4·7 at the February sales.

THE CONSUMPTION OF TEA is still increasing as compared with the last two years, the amount taken out of bond last month being 15,255,000 lb. against 14,318,000 lb. in February 1887. It is a pity that a distinction has not yet been made between China, Indian, and Ceylon teas as regards withdrawals from bond. That this ought to be done is evident from the fact that the annual imports from India alone are not much less than those from China. During the first two months of the present year, indeed, the Indian arrivals have been 3,000,000 lb. larger than the Chinese.—*H. & C. Mail*, March 9th.

TEA.—The example of Ceylon is being followed in South Africa and the West Indies, and even in Madagascar; and tea-growing is the planters' delight just now. The report upon some samples of Jamaica tea which appears in the Kew Bulletin of Miscellaneous Information for this month, accompanied as it is by notes on similar experimental efforts in Natal and Madagascar, shows that the products of India and China will soon be called upon to face the competition of numerous rivals. The Botanical Department of Jamaica has demonstrated the possibility of creating a very considerable tea trade, not only in Jamaica itself, but also with the outside world. The report from Messrs. Gow, Wilson, and Stanton speaks well of the first tea grown in the island, although all the specimens indicate a faulty manipulation of the leaf. The Natal tea is said also to be of good quality, and its cultivation is rapidly passing beyond the experimental stage. The first real field was only planted in 1880, but the cultivation has extended so widely that the output for last year has been estimated at something over 100,000lb.—*H. & C. Mail.*

TEA-PREPARING MACHINERY.—Mr. Dalgarno is about to leave for Calcutta *en route* to the several Indian tea districts. (He reports that the best of the Sylhet tea gardens of Messrs. Finlay & Co., Glasgow and Calcutta, are said to be yielding up to 20 maunds per acre!) Mr. Dalgarno has erected one of Jackson's latest improved Rolling machines —already referred to in our columns—on Peradeniya estate, and one of the improved "Driers" on Labookellie estate, Ramboda. We expect to publish accounts of the working of both machines after they have been tried a little longer. Meantime Mr. Ross of Peradeniya is much pleased with the Roller; while Mr. Corrie on Labookellie finds the new firebrick arrangement a great improvement, so much so that the heat is retained up to 150 degrees all through the night, and so the Drier is very quickly brought into work each morning. Mr. Jackson and his staff are now bent on solving the "withering" problem, and experiments on a varied scale are shortly to be made.

A GREEN BUG IN ENGLAND is thus noticed in a paper in the *Journal of the Society of Arts*, on diseases of plants:—

Of *Insects*, the *Hemiptera* require our attention for a moment. I believe that the injuries which *bugs* do to cultivated plants are not sufficiently recognised. As an example, I may cite a green bug, a kind of *Strachia* (sp.?), which annually destroys in my garden many buds and leaves of dahlias. Its presence is recognised by minute brown spots on the buds and earliest branches, the result of the stinging of the animal. Every stung part dies, and the leaf, therefore, becomes pierced like a sieve, and remains misshapen. I search for the animal (there being rarely more than one on a bush in high summer) by opening the young leaves. The animal then rushes out, and, like the bull before tossing, or the partridge after the first rise, stops for an instant. Then is the time to seize it. If it makes a second move it is generally lost to sight in an instant, and, once disturbed, never returns to the same dahlia plant. It has a distinct mint-like smell, less strong than the large coloured strachias on raspberry and other bushes.

LABOUR DIFFICULTIES IN INDIAN TEA DISTRICTS.—Says the *Pioneer*:—"The system of free emigration from Bengal to the tea-districts has lately been getting into some disrepute. There have been some cases of illegal recruitment in Chota-Nagpore, and a sentence of three months for assault in one of these cases was recently upheld by a Divisional Bench of the Calcutta High Court. There have, moreover, been one or two cases of wholesale kidnapping of coolies on the way: whether with or without the connivance of the recruiters in charge, it is at present impossible to say. The cases are being inquired into by a special police officer. The arrangements for feeding and lodging the coolies on the way are also defective. Large numbers have been recently despatched by the Eastern Bengal State Railway and an outbreak of cholera has followed at various halting stages on the route, and especially at Sara and Damookdeah." Our readers will thus see that the labour difficulties in Ceylon are slight when compared with those endured by some of the Indian tea planters.

THE OPPONENTS of the Produce Clearing House scheme are not strong enough to prevent the introduction of the new system, so that they must be content to record their protest against it. The meeting of gentlemen interested in coffee which was held last week, proves that on this, as on nearly every other subject, there is nothing approaching unanimity of opinion. On the one side it is argued that it is a mistake to make gambling in produce easy, while, on the other hand, it is contended that as gambling in produce is carried on to a great extent, it is absurd not to recognise the fact, and impart some system and method into the mode of conducting time bargains in produce. Many of the good old firms naturally object to a degenerate step, which will transform the whole system of business, but the weaker go to the wall in these and other matters, and we may look upon the Produce Clearing House as an accomplished fact. —*H. & C. Mail*, March 9th.

FORESTS AND FLOODS AND THE EFFECT OF CULTIVATION IN FLOOD PREVENTION are thus noticed by a writer in the *Pioneer*:—"I cannot give in my adherence to the apparently obvious dictum that forests prevent floods. So far as I can learn forests have no effect on this holding back water when it rains in excess. The water sweeps through a forest with the same vigour that it does over an unforested tract. I recollect very well we were saluted once with a sad record of the effects of deforesting the hills in North Italy—floods, devastation, loss of life and property, and so forth. Either the previous, or the following year, there were equally destructive floods in the Black Forest, the model in all forest operations; but never a word did we hear of the failure of the forest dogmas to prevent such floods! Ask the Engineer at Dowlaishweram whether the floods in the Godavery have been hindered by the forest operations in the Central Provinces. In point of fact, we have had in the last three or four years the very heaviest floods on record sweeping down the Godavery. I am constrained to say that the humble rice-growing ryot with his common bunds does more to prevent floods than all the efforts of Sir D. Brandis' disciples, and that what with the turning up the soil, thereby making it more porous, the levelling of high sides of water-worn courses in the operation of the agriculturists, the construction of channels and tanks, and, as aforesaid, the raising of innumerable bunds all over the country, the water is more diffused over a cultivated plain and held in better check than it is in a forest left by man just as God made it."

Correspondence.

To the Editor.

QUININE IN CHOLERA AND IN HEROIC DOSES.

Chittavurrai, Kannan Devan District, via Bodinayakanur, S. India, Friday, 19th March 1888.

DEAR SIR,—I enclose a newspaper cutting which contains interesting information for those connected with cinchona:—

The *Deccan Times*, on the authority of Dr. Lawrie, the Residency Surgeon, Hyderabad, says that a preventive for cholera has been found in quinine: "While the disease is about, every one ought to take from 3 to 5 grains of it before each meal. No one who does this, Dr. Lawrie is persuaded, will take the disease."

Has quinine ever been brought forward in this light before? With regard to the articles which have been appearing lately in the *T. A.* about "heroic doses" of quinine, I may mention that five years ago when about to leave home for this country, my brother, who was just then commencing to practice as a medical man, told me to disregard the advice of all men who told me to take 3 to 5 grain doses; the proper thing he said was to take as much as was possible without permanently injuring oneself, say 20 to 30 grains, and then retire to bed, making up one's mind for a couple of hours' splitting headache, and buzzing in the ears. When these symptoms subside, the fever is gone for good—at least that particular dose of fever. I have tried this treatment with success on myself and on coolies. Small doses are best taken as a preventive only.—Yours faithfully, AYLMER F. MARTIN.

COCONUT CULTIVATION.—No. II.

Siyana Korale, 15th March 1888.

SIR,—I was very much interested with "W. B. L.'s" review of coconut planting, that appears in your last night's issue. The result of droughts in coconut cultivation has a close bearing on Mr. Akbar's grand work of irrigation, and the figures your correspondent supplies as to the decrease in the weight of nuts resulting from the drought of 1886-87 offer something tangible to base calculations as to the financial success of irrigation for cocounts. "W. B. L.", when sending you an account of Mr. Akbar's irrigation works, mentioned that the annual droughts in the valley reduced the weight of copra per nut from 7 to 5 ounces=R7,800 on a million of nuts. Accepting the figures in the review under notice, I find that 1,500 nuts were necessary to make a candy of copra as against 1,200 under normal conditions. Taking 12 ounces to the lb., this will give 5·60 oz. per nut of copra under ordinary circumstances as against 4·48 oz. during a period of drought, or a difference of 1·12 oz. per nut. We have been told authoritatively that the yield of Mr. Akbar's estate is one million nuts per annum. If irrigation helps his trees, and of this there need not be a shadow of a doubt, to properly mature their nuts, the gain of 1·12 oz. on a million nuts will equal about 167 candies per annum, which at R30 = R5,000. This makes no allowance for an increase of yield which must, in the natural course of things, follow irrigation, and the rendering available all the year through the plant food existing in and applied to the soil, and for the nuts saved from dropping during these annual droughts from lack of moisture. I am not as sanguine as the correspondent who expects the yield to be trebled as a result of irrigation, but am more inclined to favour W. B. L.'s calculation of a 20 per cent. increase in the yield, and myself think that the average of 1,200 nuts for a candy of copra will be reduced to something near 1,000.

I think your correspondent is a "beetle" out when, in discussing the nature of phosphetic manures, he says that "a plant takes up no more than the due proportion its specific constitution requires to complete its tissues. Thus if you place a bushel of bone dust within reach of the roots of a coconut tree, it will take up exactly as much and no more than is necessary in its specific combination." As far as my knowledge goes, roots are not endowed with more than rational discrimination, but take up as much fertilizing matter as they are able to. Their powers of absorption are as limited as the capacity of a stomach. A human being or an animal, if an unlimited quantity of food be placed within reach, does not eat it all up, nor does it eat "exactly as much as is necessary in its specific combination," but as much as it is able to. I do not think I have ever denied that "Phosphate is an indispensable element to healthy fruitfulness," nor have I ever dared to differ from the general broad principles of agricultural science. Your correspondent and I are not agreed as to the applicability of these principles in particular cases. A definition is given of a stimulant, accepting even that definition it does not prove that phosphates are not used as a stimulant "to temporarily draw on the latent strength" of a young coconut tree in order to induce it to bear, because that is its precise action in this particular instance, and what is actually aimed at by its application. The experience of your correspondent must, I suppose, be the experience of everyone, that "the earliest tree is the best," but only if early bearing is not forced.

The experience of Mr. Kynaston, the Welsh gardener, who advanced certain theories on the function of certain roots, was given to the world in some agricultural paper, and taken over into the *Tropical Agriculturist*, somewhere about June or July 1884, I think. If this gardener were a young man and rash, I think it best both for himself and your correspondent, that he did not advance his theory in his presence, for the mere mention of it makes your correspondent lash himself into a rage; but my dear "W. B. L." it must strike you in your calm moments that your denial, however emphatic it may be, does not disprove Mr. Kynaston's theory. In this sceptical age a mere denial of anything, by however high an authority, is not accepted without being backed up by cogent reasons, and your denial of "any difference in the functions of roots" is not backed by what is an accepted and undoubted fact that the functions of lateral roots are not identical with those of tap roots, and yet both are roots.

The contention that "the most active foraging roots are near the extremities of the mains," is undoubtedly generally true, for the root hairs die on the older portions of the roots. Root hairs are generally at the extremities or tender portions of roots, and those on the older portions die off, as they become woody. But has "W. B. L." never seen a mass of rootlets at the foot of every tree, and is not the coconut tree constantly forming new roots, and observation will show that these have a large number of rootlets at their extremities, and not far removed from the trunk of the tree.

You question your correspondent's estimate of 20 nuts to a tree and say 30 nuts will be nearer the mark. Your correspondent's estimate is if anything too high. Have you forgotten the discussion that took place lately as to why Europeans retired from the field as coconut planters in Batticaloa? It was because the yield went down to somewhere about 5 nuts per tree, I think. B.

COCONUT CULTIVATION IN CEYLON: MANURING &c.

19th March 1888.

DEAR SIR,—During a casual discussion on manuring coconut trees with a friend quite recently, I objected to equal proportions of bones and poonac being used (3 lb. of each to each tree), and said that I thought a safe mixture would be one of bones to three of poonac, and that I would, by preference, use castor cake to coconut poonac. "Why?" inquired my friend, "Because castor cake has so much more of nitrogen and other valuable fertilizing matter than poonac," I answered. My friend insisted that Hughes

has laid down, that placing a certain value on the unit of nitrogen, the difference in the prices of the two manures was in just proportion to their intrinsic value, and offered rather warmly to produce Hughes tables of analyses in proof of his assertion. He further said that the difference in price between the two manures permitted of a proportionately larger quantity of cattle poonac being used. Now Hughes has said that taking 100 to represent the standard for purposes of comparison of white castor cake, coconut poonac, according to what was submitted to him for analysis, stood at 53, or a little more than half. Will my friend, who uses 3 lb. of bones to 3 lb. of poonac for each coconut tree, therefore, if he uses castor cake, reduce the quantity of it to 1½ lb. or one-half of the weight of bones? This is a proportion that no practical agriculturist will use, who has any regard for his trees. As to value, cocount poonac sells now at R45 the ton in the country. Is the price of castor cake twice as|high?

M. Hughes has, in a letter to the *Observer*, dated 10thrJuly 1886, supplemented his analysis of this most valuable cake, with an analysis of the inorganic matter or ash of the cake, as he says the previous analysis "does not afford information respecting the chemical composition of the mineral portion of the cake." In a note to his analysis he says that the cake has twice as much nitrogen as bone-dust, and five times as much as in 100 lb. of parchment coffee. Castor cake has 7·78 nitrogen as against 2·80 in coconut poonac, and 2·68 of phosphoric acid as against 1·45 in poonac. The actual fertilizing matter removed from the soil by coconuts is what is represented by the poonac. For oil, which, when burnt leaves no residue, removes nothing from the soil. The branches, which, when weaved, are used for estate buildings, are again returned to the soil in their decomposition, but unfortunately not to the exact spot on which they grew. The same with the husks, when not used for fibre. I am not aware whether an analysis has ever been made of the ashes of the husk, but they crystallize into a white salt which I believe is largely composed of potash, as shown by their cleansing power. But Mr. Hughes tells us that "castor cake yields an ash specially rich in phosphates of potash, lime and soda, and these exist in a form readily available as plant food." From the above it will be readily seen that coconut poonac cannot be compared with castor cake as a fertilizer for coconut trees; indeed, considering that it has more phosphoric acid than poonac, I think by its use we can dispense with the too stimulating bones. Certainly not to be used in too large quantities, for even its great advocate, Mr. Lamont, says the quantity used is calculated by the ounce rather than by the lb.

As to the wisdom of manuring trees not yet in bearing, every man is entitled to his opinion if it can be supported by science. Manuring, as I understand the term, is restoring to the soil the elements of fertility removed by cropping: coconut trees not in bearing have removed nothing from the soil; therefore manuring them is unnecessary, not to say positively harmful, especially with highly stimulating manures, which induce precocity in the first instance, and afterwards support a semi-artificial existence. Of course the practice has been suggested by so high an authority as Mr. Lamont, and it speaks volumes for him that he has found so ready an apostle in one, who, till very recently, held the opinion that manuring, or even disturbing the soil, was only to be resorted to when coconut trees showed signs of distress. As long as they bore well, it was not necessary to nourish them at all. The transition from one extreme to the other is rather rapid.—Truly yours,

B.

INFLUENCE OF FRESH WATER ON PEARL OYSTERS.

March 30th, 1888.

SIR,—The great success that has attended the pearl fishery this season will have made the panic at the prospect of the first great loss almost a forgotten incident of the past. I was one who, ha time permitted, intended to have advised the subsequent seeking that took place, believing they would find. Your correspondent "Nemo," in your issue of the 27th, wakes an echo that deserves a word or two of comment, to prevent a miscarriage of opinion on the subject of which he treats in fashion somewhat ex cathedra. No oysters can live in fresh water only: that everybody knows, but all oysters that are so to speak 'gregarious' of the 'bed' or 'bank' type, which the pearl oysters especially are, require for their food and sustenance the matters they assimilate brought down by the rivers discharging into the sea. In periods of drought these 'banks' or beds of oysters will (by whatever process they are migratory) hug up to the river deltæ, in search of food and modified salt water. Hence your able Master Attendant, Capt. Donnan, reported millions of oysters on bank at known shoals before the floods, all vanished after, the oysters having beaten a retreat before the heavy floods.

The principle of oyster growth and feeding has been studied, and is well-known in America and elsewhere, where oyster cultivation has assumed enormous proportions. Patents for catching the 'spat' are simply legion in the United States.

To give you an idea of the need of freshwater food and a modified salt water for the growth of the 'bank' oyster, coast lands in the New England States are constantly advertized for the joint cultivation of cranberries (!) and oysters—two orders of industry about as remote from each other as could reasonably be devised, one would naturally suppose; but not so,—the cranberries require 'bedwork' irrigation, and a large supply of water approaching to swamp land, which after drainage is carried out to seaward over the artificial oyster bank for the sustenance of the oysters, which, as I said, require fresh as well as salt water for their healthy production. So that whenever you hear of oysters having vanished, the fresh flood has been too much for their digestion, and they have only moved away to a suitable position where the delicate admixture of salt and fresh water is more to their liking. Oyster dredging over the pearl banks has hitherto proved a failure, at least so it appears I am convinced the right sort of machinery has not been employed. I think that if a single chain 'clam shell' with light 'tynes' on it—were used, depth of water would be no difficulty, and the problem would be solved. I say a *single chain* "clam shell" simply because a double chain takes up so much more room on the 'drum' where many fathoms have to be paid out. If this were to succeed, the Government haul would be three times as great as it is. Referring again to the 'cranbery,' I see no reason why it should not form a valuable industry here; their production in the United States yields sometimes 50 to 100 per cent: what they most want is water. The berry could surely be acclimatized,* and they are very little more trouble than the cultivation of ordinary grass, if you only have the water. The demand for the "canned" cranberry being in excess of the supply by any conceivable quantity; quite small farms yielding as much as £2,000 a year.—Yours,

ENGINEER.

[We have all along believed in the beneficial influence of the river water which enters the bay of Silavatturai, but we await Captain Donnan's deliverance on the deleterious effect of floods. It seems possible that even floods of fresh water would do no harm were they unaccompanied by currents?

* That is the question? Has it ever been known to grow in the tropics?—ED.

But, floods or currents or both, the puzzle in regard to this fishery is that the oysters were mourned over as lost, only to be found in greater abundance than usual!—ED.]

CURE FOR COFFEE LEAF DISEASE.

5th April 1888.

DEAR SIR,—I lose no time in sending you a translation of an editorial notice, appearing in the *Soerabaya Courant* of the 17th ult. The remedy proposed seems to me the most feasible that has yet been heard of. The issue of the same newspaper of the 19th ult. describes its perfect success in curing the potato disease, *Peronospora infestans*. I will send a translation of Heer Mak's letter as soon as possible. The experiment is so simple that it might be made at once before the rains begin.—Yours truly, J. D. Y.

It was our intention to insert in this issue an important communication sent by Heer Chamberlain Mak of the Hague, proposing a remedy for the coffee leaf-disease, but want of space compels us to postpone its publication; it will appear in our next number. At present we must be content to say that Heer C. M. prescribes sprinkling the ground under and around the coffee trees, with a solution composed of 1 kilogramme of Carbonate of Potash to 100 litres of water, which will suffice for 100 square metres of ground. The sprinkling to be repeated after an interval of 14 days. He hopes that all the spores of the *Hemileia Vastatrix* will thus be exterminated. The remedy is inexpensive, and of easy application, and therefore is preferable to the method of Dr. Burck.

Our planters will no doubt hasten to try this new remedy, and to ascertain if it will stand the test of experiment. But they will have to wait for favourable weather. The heavy rains we have had of late would probably dilute the mixture to be sprinkled on the soil to an unwished for extent.—*Translated from the "Soerabaya Courant" of the 17th March 1888 for the "Ceylon Observer."*

PUSHING CEYLON TEA:

PROPOSAL FROM MR. H. K. RUTHERFORD TO JOIN INDIA IN AN AMERICAN CRUSADE.

SIR,—Your tea-planting readers, no doubt, will have noticed that the Indian Tea Association in London has resolved to take measures for the pushing of Indian teas in America on a large scale, and that the scheme has met with influential support.

The interests of the Indian and Ceylon tea-grower being at the present moment identical, in so far as they are working with the common object of ousting China and Japan teas from the market; it has occurred to me, that were we to join our strength to that of India and unite in an American crusade, the results would be far more satisfactory to both countries than if each were to fight single-handed.

The introduction and pushing of Indian tea in America will undoubtedly help the sale of Ceylon tea forward in that country, and some may say that, if this be so, why should we offer to pay for what we can get India to do for nothing?

I would, however, point out that the American field being of such vast dimensions, and our efforts being required for the conquering of a Continent, our strength ought to be in proportion. It will tax the combined energy, finances, and perseverance of both India and Ceylon to drive China and Japan teas out of America, but I believe it can be done if carried out with an ample exchequer and the combined force of the two countries.

My proposal would roughly be as follows:—

1st. That subscribers to the "Ceylon Tea Fund" be asked if they would be willing (after the liabilities of the Glasgow, Melbourne, and Brussels Exhibitions are cleared) that their subscriptions, instead of being devoted to pushing Ceylon tea at Exhibitions, should be joined to the funds of the Indian Tea Association for pushing Indian and Ceylon teas in America?

2nd. That in the event of Ceylon subscribers agreeing to this, a proposal be laid before the Indian Tea Association, that the two countries do work conjointly in an American crusade for pushing their teas.

3rd. That the primary conditions of the joint working be

(*a*) That each country do subscribe funds in proportion to the crop yield of their respective countries, approximately this will be as 3 is to 9.

(*b*) That the London Committee be composed of an equal number of representatives of each country. The Ceylon members of Committee to be appointed by the Planters' Association of Ceylon.

(*c*) The London Committee to be entrusted with the working out of the whole scheme.

Ceylon planters are now so fully alive to the absolute necessity of finding new markets for their teas, that it is not necessary to say anything on that particular point of the subject. The question to solve is how we can best take advantage of our position, and utilize the funds which, will, in the future, be at our command from the tea scheme already at work? I bring the above proposal forward, trusting it may find favour with Ceylon and Indian tea growers, and in the belief that a joint effort, while being more economical in its working, would be overwhelming in its effects if liberally supported by all those interested in the growing of tea in India and Ceylon.

H. K. RUTHERFORD.

TEA IN DARJEELING.—Tea prices are looking up and it is quite time they did. When things get to the worst they always mend, and things could not have been worse than during the past two seasons; although some very satisfactory dividends have been declared. I hear of a good deal of blight of sorts on some gardens. Now-a-days these pests are always with us, and nobody seems to have hit on any way of getting rid of them so far. The Assam hybrid plant always seems to suffer most. It certainly is not nearly so robust as the China variety, and has consequently to be very much more carefully treated.—*Indian Planters' Gazette*, March 20th.

RUBBER IN ASSAM.—Says the *Pioneer*:—A curious instance of superstition standing in the way of trade and a people's advancement is mentioned in the report on the administration of Assam for last year. It was discovered some time ago that a magnificent forest of rubber trees existed in the vicinity of Borduk in the country of the Abors, a tribe on the extreme north-east frontier of Assam, which has given a good deal of trouble at times, but of late years has been kept fairly well in hand by the tact of our Political Officers at Sadya. It also happened that last year the price of rubber rose considerably; and when the fact of the existence of the Abor forest got abroad, traders from the more civilised Singphos and Khamptis immediately began to enter into negotiations with the Abors for permission to proceed up the Dihong and tap the trees. At this point, however, Mr. Needham, the Assistant Political Agent, had to interfere, and persuade the traders to return lest worse should befall them. The Abors, it appears, believe that the rubber tree is the abode of a great and powerful sylvan spirit, and Mr. Needham is convinced that all of them, except a few who are civilised enough to put a bribe above even a sylvan spirit, would resent any attempt at hacking it about. Until, therefore, this airy deity can be persuaded to remove his abode to some less valuable tree, the wealth of rubber among the Abors must remain untouched.

A FIBRE EXTRACTING MACHINE, presented to the Government of India by Sir Walter de Souza, has been despatched to the Andamans, where it will be tried on the fibre of the *musa texilis*, the cultivation of which has been successfully undertaken there.—*M. Mail*, April 2nd.

TEA IN THE KELANI VALLEY, we learn, is coming in at an unprecedented rate, the difficulty being to overtake the "flush" with the labour available. Our Kelani friends will have to get "pluckers" from the coast to help them, if the "flush" goes on at this rate.

SILKWORM DISEASE.—The proposal to bring out an expert from France to inquire into the spread of silkworm disease in Bengal, and to suggest measures for its eradication, having fallen through, it is now intended by the Government to depute the Cirencester graduate, who has up to this been conducting experiments in Bengal, to Paris, to undergo a course of study at M. Pasteur's laboratory, or at one of the silkworm breeding farms in France.—*Pioneer*.

CINCHONA.—A recent report calls attention to the fact that the proportion of really good Ceylon bark offered at the public auctions remains very limited. At the last bark sales only one parcel of Ceylon cinchona realized more than 1s. per lb., and many renewed barks now offered, by their woody and fibrous character, clearly show that the renewing process is being resorted to too often, viz., that the renewed barks are stripped too soon.—*Chemist and Druggist*.

TEA-GROWING.—The following is from a letter from Mr. J. Hulett, Kearsney Tea Estate, Natal:—"The tea plant is remarkably well adapted to this climate, and from information obtained from Indian and Ceylon people, we should do well. No estates in Ceylon are yielding better than this. I have an area of nearly 200 acres planted, and plucking area of 100 acres, but only partial on a portion; after five years' old no difficulty in obtaining 1,000 lb. of manufactured tea per acre. We are still in infancy, and the manufacture is still imperfect, though my teas have realised as high as 2s. 6d. in London; but we are not shipping, the colony at present taking all."—*H. & C. Mail*.

KUMAUN ORCHARDS.—Upwards of 4,000 grafted fruit trees were distributed, but the gardens could have supplied more, and Ranikhet was able to distribute upwards of 8,000. The establishment of the gardens was reduced some time ago for economy's sake, but economy has led to attenuated results, and the gain is not apparent. The Commissioner, who is giving the matter great personal attention, has submitted schemes for improving the Kumaun orchards and for organizing similar orchards in Garhwal.—*Agricultural Reports N. W. Provinces and Oudh, September* 1887.

GOLD IN CEYLON.—RECORDS OF THE GEOLOGICAL SURVEY OF INDIA, Vol. XXI, Part I, has reached us with contents as follows:—

Annual Report of the Geological Survey of India, and of the Geological Museum, Calcutta, for the year 1887. Crystalline and Metamorphic Rocks of the Lower Himalaya, Garhwal, and Kumaon, Section III. by C. S. Middlesmiss, B. A., Geological Survey of India.—(With 3 plates). The Birds-Nest or Elephant Island, Mergui Archipelago. By Commander Alfred Carpenter, R. N., H. M. I. M. S., S. S. "Investigator." Memorandum on the results of an Exploration of Jessalmer, with a view to the discovery of Coal, by R. D. Oldham, A. R. S. M., F. G. S., Deputy Superintendent, Geological Survey of India. A Facetted Pebble from the Boulder Bed ("Speckled Sandstone") of Mount Chel in the Salt-Range in the Punjab, by Dr. H. Warth. (With 2 plates) Examination of Nodular Stones obtained by trawling off Colombo, by E. J. Jones, A. R. S. M., Geological Survey of India.—The present Director is William King, B.A., D.SC., (*honoris causa*), Royal University (late Queen's), Ireland, Fellow of the Madras University, brother of Mr. Ælian King of the Ceylon Civil Service. We have marked the paper on the nodular stones found in deep water off Colombo for extract. The map of India shows that a large portion of the continent has been geologically examined and reported on, and as Ceylon is now joined to the Indian Trigonometrical system, we trust it will soon be similarly dealt with geologically. The following notice shews that Mr. Foote is the very man we want in Ceylon to report on the real value of our auriferous rocks:—

Mr. Foote has the Madras Presidency with its immense area of the crystalline rocks, or gneisses among which, however, he is still carrying out his latest distinction of a newer (Dharwar) series. At present the great interest attaching to this series of transition rocks is not so much that it may fall in with, or represent, some or all of the various transitional formations of Central India, which have been treated of by so many of us under the names of Bijawars, Aravalis, Champanirs, and Chilpis: but that it is the series in which auriferous reefs are more particularly developed in the Madras Presidency. I, myself, having had to work out the auriferous rocks of the Wainad region, which certainly appeared to me to occur among bands of the older gneisses, am unable to follow Mr. Foote throughout the whole of his generalizations, which would seem to tend towards an extension of the Dharwars into Wainad: but the fact still remains that he is perfectly clear as to the Mysore country to which his attention has been more thoroughly devoted. In this way he has become the best gold man we have: not an expert in the common acceptation of the term, which is properly a man capable of exploiting a region where gold is known to exist in greater or less quantity, but a geologist, experienced, *par excellence*, in the kind of rocks, or the particular formation likely to be auriferous in India.

A BOARD OF AGRICULTURE.—We see with great pleasure, that it is proposed to establish a Government department under a responsible Minister. The only drawback is, that in our system of government, the exigencies of party directly or indirectly predominate over public interests. It is very important at the present juncture, that horticulture should be recognised in the constitution of this new department, for it is obvious that while agricultural methods are no longer adequate to meet the circumstances of the times, the requirements of the case would be very largely met by the introduction of horticulture or of horticultural methods. We earnestly hope that the Royal Horticultural Society, in its reorganisation scheme, will not neglect its obvious duty in this matter. It is more than time that the gardener should be heard, and he could most effectively be heard through a gardeners' society. It is a splendid opportunity for the Society to prove to the public that it is concerned in something beyond the whims and fancies, however laudable, of those who find their recreation in horticulture, and with something more than the interests of those who cater for the supply of the requirements of the *dilettante*. Forestry, market gardening, and fruit culture will occur to every one as great, and, up to the present time, little worked departments; but it is to the adoption of horticultural methods, the increase of scientific knowledge of the conditions under which plants grow, of the diseases which affect them, and the enemies that prey on them particularly, that the farmer of the future must trust. When he tills his field as carefully as a gardener makes a Vine border, when he is as careful to secure the right strain of Wheat and Mangel, or what not, as a grower of Chinese Primroses for market—when he avails himself of every resource of the chemist, the botanist, and physiologist, by putting their discoveries to the test of practical experiment before adopting any—there will be hope for the farmer. In the meantime let the Royal Horticultural Society, as becomes its duty, bestir itself in the matter.—*Gardeners' Chronicle*.

SUMACH.*

The trade in one of the chief products of Sicily, sumach, styled *Rhus Coriaria* in botany, has increased in the course of the past year, and is receiving increased attention.

It appears in the markets in England and America in the form of a more or less coarse powder packed in bags of from 50 to 60 kilos., and produced by the grinding of the twigs and leaves when dried. To France the twigs and leaves are exported while in a dried state.

This powder serves both as a dye and as a mordant to fix other dyes, and for purposes of tanning. Good sumach contains from 30 to 40 per cent of the dyeing or tanning principle. The shrub is said to have been originally transplanted from Asia, and flourishes most in high and dry soils and requires little attention after first planting. The plants when once set out will last for a century or two. For the first three years the leaves have little value, but after that time they acquire their due proportion of their peculiar qualities. The plant is a low perennial shrub with long slender leaves. The harvest of the plant is made by cutting off the leaves every year, after which the plant throws forth feedshoots. Sicilian sumach, especially that about Palermo, enjoys a high reputation, as does also the sumach of Spain and Portugal. The soil of Dalmatia is also peculiarly fitted for this plant, and the cultivation of it is fostered by the Austrian Government. The largest and most luxuriant plants do not produce the greatest amount of tannin, and even in Sicily there is great difference in the quality of the powder produced from this plant.

The sumach powder produced in Sicily is of two sorts. The best is of a rich green colour and carefully sifted, it is soft to the touch, of a rather pleasant smell, and of a strong astringent taste. The second has these qualities in an inferior degree, while its colour degenerates and takes a reddish hue. The sumach grown in Continental Italy is much inferior to the Sicilian, and has a yellowish colour tending both to green and red. None of the inferior sorts are prepared with such care as the best Sicilian, and are known by the prevalence of unground fibres and minute chips, indicative of less pains taken in sifting. Various adulterations are practised in preparing sumach for the market; the most obvious, that of mixing it with mineral dust, can be discerned by steeping the suspected powder in water, when the mineral portions will fall to the bottom. When vegetable substances, however, are used, chemical analysis must be resorted to.—*Pharmaceutical Journal.*

EUCALYPTUS HONEY.

Mr. Holmes drew attention to a specimen of eucalyptus honey, of which mention had been made in several medical and pharmaceutical journals. Also to a new kind of strophanthus seeds which had recently come into the market, apparently resembling the *S. hispidus*, but he thought they were not identical. As there were several different varieties of strophanthus seeds now being imported, it seemed important that their physiological action should be known before they were employed in medicine as equivalent in value to the kind introduced by Professor Fraser. The seeds certainly belonged to different species, but would not necessarily be identical in therapeutic properties. There were several specimens presented by Dr. Ondaatje, a colonial surgeon of Ceylon, who came over to the Colonial Exhibition, and had remained here since. He brought a number of Ceylon products, but owing to ill-health had not been able to investigate them as he intended, and he had now presented the remainder to the Society. There was also a specimen of false chiretta, *Ophelia angustifolia*, which had recently come into the market. It was much paler than the official kind, and yielded a less bitter infusion, and the stem was more woody and contained no pith, whereas in the genuine there was a large pith with a thin woody portion. There were also some specimens of what the President objected to calling "false" ipecacuanha, but which had been offered in commerce as substitutes for it. One of them was generally attributed to *Psychotria emetica*, another to a species of *Richardsonia*, whilst of another one of more recent introduction the botanical source was at present unknown, but none of them possessed the physical characters of the true drug. There was a fine herbarium specimen of the asafœtida plant of Turkestan, presented to the Society by Mr. Carl Ferrein, of Moscow. The point of interest in this specimen was that although it was labelled *Ferula Scorodosma*, it differed from the figure of that plant given in Bentley and Trimen's 'Medicinal Plants' in having serrate leaves. The other species yielding asafœtida which had been presented at various times to the herbarium, were placed on the table for comparison. These were *Ferula alliacea*, yielding in Persia an asafœtida exported to India but not to this country; a specimen of *Ferula Narthex*, collected by Dr. Peters in West Afghanistan; a specimen of the leaf of the *F. Narthex*, from Regent's Park Botanical Gardens; and a specimen of *F. Scorodosma*, from Dr. Aitchison, collected in Afghanistan. Judging from the character of the leaf alone it would appear that there was in Turkestan yet another plant which produced asafœtida; that is, if the plant now sent as *F. Scorodosma* should prove to be distinct. Lastly, there were some fine specimens of fresh sugar-cane, which Mr. Martindale had brought from Malaga.—*Pharmaceutical Journal.*

* From a report by Mr. Consul Stigand on the trade and commerce of Sicily.

THE BOTANY AND VEGETABLE MATERIA MEDICA OF THE ISLAND OF PORTO-RICO.

BY ANTONIO JOSE AMADEO, M. D., M. R. C. S. E., L. R. C. P. E.

Flora of the interior.—This part of the island is very charming, with its multitude of rivulets, rivers, coffee plantations and hills, still covered in some places with the *Cedrela odorata*, *Dacryodes hexandra*, the *Mimusops*, the *Hedwigia balsamifera*, and many other valuable trees of the primitive flora, with a variety of ferns, orchideæ and graceful palms raising their crowns high above the dense underwood, which reveals the loveliest and brightest flowers in wild profusion, filling the air with their perfumes.

It is a source of pleasure to behold along the banks of rivulets the graceful *Jambosa vulgaris*, *Bambusa*, *Piper caudatum*, *Bixa orellana*, several varieties of *Citrus* and the *Helicona caribea*, the plant of the poets, showing its beautful racemose scarlet flowers, and inviting the traveller to rest. The *Hibiscus liliaceus* and the *Bromelia Ananas* grow side by side, protecting plantations of maize, rice, potatoes and pastures of several species of indigenous gramineæ, which never grow so luxuriously as the exotics, giving room for the intrusion of poppies, vervain, and other flowering plants, so that the landscape of the fields is more beautiful than that of the coasts, and resembles somewhat that of Southern Europe. On the hill slopes and ravines are the great plantations of *Coffea arabica*, protected by other taller forms of vegetation, among them the fruit-bearing tree *Mimosa Inga*. In the same formation the *Theobroma Cacao* is also cultivated, but not to the extent that it ought to be. The tree grows there quickly and the product is of the best quality. Several species of plantain and banana, potatoes, rice, corn, yams, mercuta, ginger, pigeat, oriental oily grain and other economic plants are cultivated all through this fertile zone, producing food sufficient for the consumption of its inhabitants. This explains in part the increase of the population, which is today about 800,000, the great majority white.

The *Caladium aquatile* and the *Arum arborescens*, growing wild, the first at the margin of the streams, are also eaten by the poorer people. In the hills bordering the southern coast towards Salinas and Coamo, the *Zamia intermedia* grows wild with its

feculent rhizome. This is another help for the poorer classes, who extract the starch by the same process as used for the manihot, eating the pulp the same as casabe.

Lately, it has been stated, that the leaves and buds of this plant when eaten by cattle produce a kind of paralysis of the extremities. I do not know to what extent this is truth, but I know positively that the rhizome is as poisonous as that of the "bitter cassava," and that the acrid principle is got rid of by repeatedly washing the pulp.

The cocoa-nut tree (*Cocos nucifera*) is met with all over the island, but it is more abundant on the marine zone, or litoral, where the fruit is collected and shipped. The oil is extracted, and it is of some economical importance. In moist places semi-aquatic plants will be seen growing, as the *Echinodorus cordifolius*, *Nymphæa crenata*, and other pretty ones. Besides the white native rose, the common rose, both red and white, has been long introduced, with many more exotic flowering plants now abundantly cultivated in gardens. Besides these almost all the garden stuff of colder climates grows or is cultivated wherever there is a plentiful supply of water. Several new species of handsome ferns are found on the highest ridges, as between Maunabo and Jabucoa on the Sierra of la Pandura, among granitic rock, forming a vegetation peculiar to these regions.

Scale insects, which produce troubles in nutrition and growth, are common on the bark of several species of *Citrus*, the cotton tree, the mountain mahoe, the papaw, the castor oil and bird pepper plants. Last year I made a collection of the coccidæ, some of them very interesting to science, and sent them to Mr. J. Henry Comstock, Professor of Entomology in Cornell University, Ithaca, New York, who will publish soon a description of them in his next paper on the coccidæ.—*Pharmaceutical Journal.*

BRITISH AND FOREIGN CONSULS' REPORTS.

SINGAPORE.

PEPPER CULTIVATION.—The unusually high pepper prices of recent years have caused a considerable extension in the cultivation of the plant in the Malay peninsula, especially by Chinese settlers. A few Europeans have also taken to pepper cultivation, but only experimentally, except on two plantations at Selangore, where the Chinese mode of cultivation is followed. Recently a company has been formed, most of the members being European residents of Singapore, to work a concession of 2,000 acres at Selangore, on which pepper is to be the staple cultivation. The company are trying to raise a capital of 20,000*l*. The Chinese mode of pepper planting consists in planting the pepper vines from six to eight feet apart. Along with the young plants poles are placed in the ground, round which the growing plants are twined and tied. After having grown for eight or nine months, the plants are taken down from the poles and buried in the earth, all except the tops. The buried part takes root and strengthens the plant. Calcined earth (earth burnt with leaves) and rotten fish are used for manure. A well-drained, sloping hillside is best for pepper growing. As a rule the berries, which grow in bunches, are first gathered when the plants are three or four years old. The Chinese calculate the yield of a pepper vine to average from 4 to 7 lbs. The cost of production cannot be ascertained, even approximately. The Chinese give widely varying estimates, and so far not one European plantation has attained maturity.

SPANIS COLONIES.

ANNATTO GROWING INH PORTO RICO.—The United States Consul at San Juan reports that annatto is disseminated throughout the island of Porto Rico, and is there of spontaneous growth, for there is no instance of any regular plantation being established. The country people plant near their homesteads two or three shrubs for the sake of the fruit, which they use as a condiment in place of saffron or red pepper.

A very small quantity of annatto is exported either to Spain or the United States, but no other preparation is given to the article than merely drying the pods in a current of air under shelter from the sun, and then packing them in bags or barrels. Of the two kinds known as "flag" and "roll," the former is the more generally used; the second is scarce, and commands the higher price.

The current value of the article in the crude state in which it is shipped is about 4*d*. per lb. As this plant is scattered and grows wild all over the Island, no true estimate can be given as to the cost of production. It is gathered mostly by women and children, and disposed of in small quantities at the shops in exchange for provisions and groceries.

STRAITS SETTLEMENTS.

GUM DAMAR.—This resin is sent to Singapore from Borneo, the Malay peninsula, Java, Celebes, Sumatra, other Malay islands, and Siam. The whiter, cleaner, and clearer it is (light amber) the more it fetches, though there is a flesh-coloured kind which finds much favour. The resin is abundant in the Malay forests, and if the natives applied themselves more to gathering it than they do it would soon become cheaper. The imports of damar into Singapore are given as follows:—

	Imported		Exported	
1884 ...	Pk. 8,694	$82,091	Pk. 8,365	$88,937
1885 ...	11,844	114,006	11,791	105,821

Of this were exported:—

	1884	1885
United States	$16.387	$25,082
France	25,365	8,160
The United Kingdom...	25,885	50,491

GAMBOGE.—The gamboge shipped from Singapore is exclusively the product of Cambodia and Siam proper—*i. e.*, the Menam Valley and its boundaries. The statistics relating to this article are as follows:—

	Imported		Exported	
1884	Pk. 826	$35,834	Pk. 708	$38,221
1885	315	18,624	313	18,658

ESSENTIAL OILS.—Essential oils of lemon grass, patchouli, nutmeg and other aromatic plants form fairly important items of export from Singapore. At present there are but two distilling works. The distillers are themselves cultivators of the plants they distil, among which lemon grass holds a prominent place. There are also factories of essential oils in Ceylon and India, and competition is pretty close. As per trade statistics, the exports of essential oils of all sorts, quantities not stated (they are sold per oz.), amounted in 1884 to $15,187, and in 1885 to $11,706. These amounts are probably incorrect, much more being both manufactured and exported, but probably not reported to the export office. There is such an abundance of aromatic leaves, flowers, roots, barks, and woods in Malaysia that it surprises one that the industry is not being more extended.—*Chemist and Druggist.*

ROYAL GARDENS, KEW.

Bulletin of Miscellaneous Information for January 1888.

COLONIAL FRUIT.

The prefatory matter states:—In *Bulletin* No. 11 for November 1887, attention was drawn to the subject of fruit growing in British Colonies, and a very comprehensive Report on the Fruits of Canada was given. In the present *Bulletin* it is intended to continue the subject and publish reports, which have been furnished by the Governments of other Colonies. These will add considerably to our knowledge of this comparatively new industry. It will be remembered that these reports have been prepared in response to a circular letter issued, at the instance of this establishment, by the Secretary of State for the Colonies. The list of questions to which answers are now furnished was published in the *Bulletin* for November last, pp. 2-4. This list, if consulted, will afford a key to the arrangement of the Reports, and furnish those interested with the points to which the enquiry has been directed. An important feature in the Reports

now published is the prominence given to the quantity of fruit actually available for export in each colony. To this is added the months during which the fruit is in season, and the prices usually paid for it locally.

Fruit-Growing in Victoria.

The Report received respecting the fruits of this Colony is of a very complete character. In forwarding the Report to the Government of Victoria, Mr. D. E. Martin, Secretary for Agriculture, summarizes the results as follows:—As regards the quantities of each kind of fruit available for export, I may state that so far it appears to me that the quantities produced are not in excess of local requirements, but there is reason to believe that shortly the production will exceed our wants. The whole of the fruits mentioned below are capable of being produced in much larger quantities than at present, and will be produced if sufficient inducement offers. As regards the enquiry as to what steps are necessary to start or develop a fruit trade, and what inducements local men desire to open or extend a trade in fresh or preserved fruits, I may state that cheaper rates of freight by railway, a reliable agent in England, extra care in shipping and unshipping, together with cool chambers in the vessels, are considered essential. In order to ascertain the views of the wholesale fruit dealers on the subject of exportation of fruit to England, I communicated with some of the dealers. By one I was informed that the experiment of exporting fruit had been tried and proved a failure. Another stated that the prices reported as having been realized at the Indian and Colonial Exhibition induced him to try a shipment of fruit as an experiment, and he found that owing to the cost of packing, freight, and the many charges imposed by the consignees for commission, wharfage, rates, &c., resulted with the prices realized for the fruit in a loss of 50*l*. He charges 7 per cent on his sales, and that covers everything, but at home they had no fixed scale. Fruit-growers here could not be relied upon for packing and placing a first-class fruit in boxes ready for exporting, owing to the fact that they could obtain prices here for the fruit, as they at present sent it to market, which, the prices they would obtain for the extra trouble and care would not recompense. Another thing is that there is not sufficient first-class fruit suitable for exporting grown here, and the want of material, such as cork sawdust for packing fruit, is another drawback. The dealer above-mentioned obtained 200 cases of lemons from Sydney in one shipment, and from indifferent packing and carelessness in handling the fruit, 50 per cent. of it was useless. He had also obtained fruit from Algiers, and owing to the difference in packing and handling, the quantity of the fruit unsuitable for disposal after its arrival here, was nil, although he had kept it without opening the boxes for a fortnight after its arrival. Foreign growers were educated to the manner of treating fruit which the growers here lacked. Here orchards were only an auxiliary means of livelihood. The ready sale which growers here can obtain, does not necessitate that carefulness in gathering, sorting, and packing, which fruit requires; and the jam factory furnishes as ready a receptacle for bruised or damaged as for sound fruit. He knew of men who had brought their fruit to market in bags. In a catalogue of one of the leading wholesale men in London, quoting prices obtained for oranges, the prices ranged from 4*s*. to 6*s*. 6*d*., and two lots were disposed of from 8*s*. to 10*s*. per case, the latter being of a superior class. The prices obtained here would compare favourably with the prices quoted, and while the fact remained, growers here would not be induced to try exporting. The lowest price obtained here for apples is about 1*s*. a case. To export them at that price, the case would cost about 10*s*. by the time it was disposed of at home, owing to freight, repacking, commission and other charges; and the case of apples would not realize that price. At present the colony is not in a position to dispose of its fruit in an export market. He stated the prices reported as having been obtained for fruit at the Indian and Colonial Exhibition were misleading, for the reason that such fruit as that which was disposed of at the Exhibition could not be procured here in sufficient quantity to export. He had obtained 160 cases of fruit from Tasmania to export, but owing to the lateness of the shipment in arriving here, only about 110 cases were transshipped, and the balance which remained here realized a better profit than the larger portion which was sent home. He could send fruit to New Zealand by repacking, and land and dispose of it there at a profitable price; but he did not think shipments could at present be sent to the English market to the same advantage. He had no doubt, however, but that ultimately as fruit-growing increased, and the better class of it was grown so as to meet the requirements of the home market, exportation would become a success.

South Australia.

The following Report on the fruits of South Australia has been prepared for the Government by Mr. John F. Pascoe:—

The order of importance is, to a certain extent, a matter of opinion, and varies slightly in periods of years. Until within the last four or five years, I considered the apple our most important fruit, but since that terrible pest, *Fusicladium*, commonly called "black spot," appeared in our orchards, and made such sad havoc, our apple crops have gradually decreased, and now they are of small commercial value; but I am hoping and believe this visitation is only temporary, and that it will disappear in time, as other pests have before, but it will take us many years to recover our former position. The fruits we grow are,—grapes, apples, apricots, pears, peaches, oranges, lemons, quinces, plums, cherries, loquats, raspberries, gooseberries, strawberries, currants, red and black, almonds, figs, walnuts, chestnuts, limes, nectarines, mulberries, pomegranates, olives, guavas, and hazelnuts. These are mostly grown in large quantities, and generally equal to fruits of the same kinds and varieties as can be grown in any part of the world. We also grow, in small quantities, citrons, shaddocks, blackberries, passion fruit, medlars, and white currants.

South Australia has always been noted for the excellent quality of its fruit, and taking it on the whole, I doubt if there is another country on the face of the globe that can produce in such abundance all those popular fruits needed by civilised communities. For a quarter of a century we have been exporting large quantities, but at present our orchards are under a cloud; they are terribly infested with pests, insect and fungoid, I believe, temporarily, but while they exist, a large portion of our population suffer great pecuniary loss. The kinds most afflicted are apples, pears, apricots, peaches, almonds, cherries, and oranges. Growers have tried all the remedies suggested with little or no good effect, what is wanted is a thorough scientific examination of our soils, &c. for the purpose of putting us on the right track for combating and annihilating our fruit growing enemies; private persons can only do this on a small scale; to be effectual it must be done by the Government or societies.

Western Australia.

The following is an extract from a dispatch from Sir F. Napier Broome to Sir H. Holland, dated Perth, Western Australia, 21st April, 1887, No. 8:—Numerous tracts of land in Western Australia are admirably suited for the cultivation of the grape. I believe it would be a very remunerative commercial speculation to make wine for the French market. A strong full-bodied and well-bodied and well-tasted wine of a Burgundy character, could be easily and cheaply produced in any quantity, and I feel sure it would command a ready market, not only for consumption, but, and perhaps chiefly, for mixing with French wines, for which purpose I am led to believe it would be most valuable and sought after. The vine disease of *Phylloxera* is unknown in Western Australia. If French wine growers or merchants could be made aware of the unlimited source of wine supply which might easily, quickly, and inexpensively be developed in Western Australia, I feel sure that the matter would have their attention. Were a company formed to start a large vineyard, I think the Government

would be able to give some assistance in procuring a suitable block of land.

TASMANIA.

The climate of Tasmania being cooler and less exciting than that of the neighbouring Colonies, is better fitted to bring out the good qualities of all ordinary English fruits, and hence Tasmania-grown apples and pears are better flavoured as a rule, and are endowed with better keeping qualities. Provided a payable market can be obtained, there is practically no limit to the quantity of fruit that could be produced in Tasmania. The cooler climate would give her an advantage in the production of fruit for export, as it would naturally possess better keeping qualities.

NEW ZEALAND.

The Vine is cultivated in many parts of the North Island, and at Nelson in the South Island. At Whangarei (North of Auckland) it is extensively grown in cold vineries: the produce realizes about one shilling (1s.) per lb. wholesale. The quality of the apples and pears grown here is unexceptional both with regard to appearance and flavour. It is fully equal to the best produce of the British Islands, and vastly superior to the American and Tasmanian fruit. The cultivation of these fruits is extending with great rapidity under the attractive prospect of exporting high-class qualities to Europe and the United States during the months when their markets are most bare. Much, however, has to be done in the way of learning the best method of packing for so long a voyage. The Government is desirous to afford every facility for the extension of the industry, and has sanctioned the inclusion of Pomology in the course of instruction to be given in the School of Forestry and Agriculture now being established in Whangarei. Another important subject, which in some districts is crippling the fruit industry, and reducing the yield to a point which affords no profit, is the prevalence of fungoid and insect pests. I need not insist here upon the extent of the injuries arising from these causes, but will direct attention to the advantage to be derived from a course of training that would enable the fruit-grower to recognize the different kinds when they make their first appearance, and teach him the lines upon which they can be most successfully encountered.

CAPE COLONY.

The abstracts of schedule returns showing kinds and prices of fruit grown in the several divisions of Cape Colony, are published with special reference to the export of fruit. It appears from the numerous suggestions made, that before a trade in fruit can be established with Great Britain, *cheap* and *speedy* transit to coast ports, and *low* freights thence must be secured. Information has been sought as to the stage of ripeness at which the different kinds of fruits should be picked, and as to the proper method of packing. It has also been proposed that inquiry should be made into the prevailing diseases of fruit trees. The principal fruits cultivated in Cape Colony, and likely to be suitable for export, are apples, apricots, bananas, figs, Cape gooseberries (Physalis), grapes, lemons, melons, nectarines, oranges, peaches, pears, pomegranates, plums, quinces, almonds, and walnuts. Most of these fruits could be grown in very large quantities in Cape Colony, if sufficient inducements were held out.

MAURITIUS

The following Report on the fruits of Mauritius has been prepared by Mr. John Horne, F. L. S., Director of the Botanical Gardens and of Woods and Forests:—The principal kinds of fruits grown in Mauritius, in order of merit, are:—The banana, "Banane," *Musa*, several varieties; the mango, "Mangue," *Mangifera indica*, many varieties; the pine apple, "Ananas," *Ananas sativa*, several varieties; the litchi, "Leechee," *Nephelium Litchi*; the longan, *Nephelium Longan*; the alligator or avocada pear, "Avocat," *Persea gratissima*; the strawberry, "Fraise," *Fragaria vesca*, a few varieties; the peach, "Peche," *Persica vulgaris*; the raspberry, "Framboise Maronne," *Rubus rosæfolius* (this plant is indigenous, it is not cultivated in Mauritius); the sweet sop, "Atti," *Anona squamosa*; the cherimolia "Chermoyer," *Anona Cherimolia*; the "Curossol," *Anona muricata*; the bullock's heart, "Cœur de bœuf," *Anona reticulata*; the fruit de Cythere," *Spondias dulcis*; the guava, "Goyave," *Psidium Pomiferum, pyriferum, chinensis* and *Cattleyanum*; the "Abricot de Pape," *Diospyros Kaki*. There are several other sorts of less importance than the above, as the Malay apple, carambole, mabola, &c. The banana is ripe throughout the year. Mangoes from October to April, but most abundant in January and February. Pine apples throughout the year, but most common in December, January, and February. The litchi, from the middle of November or beginning of December to the middle of January. The peach, from middle of November to the end of January. The other sorts follow at various times of the year. The quantity of fruit avilable for export from Mauritius on an average of seasons is very small indeed, It takes about all that is grown in the island to supply its inhabitants and the vessels in the harbour. The country enjoying a temperate climate nearest to Mauritius is the Cape of Good Hope. There tropical fruits do not grow, and there and the interior of South Africa, now opened up by railways, a large market might be obtained for fresh bananas, pine apples, &c. I have no doubt that the existing small trade in these fruits could be extended, particularly if the Colony enjoys in future regular and rapid steam communication with the ports of South Africa; and the steamship owners grant facilities to shippers, and airy places on board the steamers to store the fruits during the voyage.

SACCHARINE.—In reply to a letter addressed to him from this establishment in which it was stated that correspondents in the Colonies were anxious to learn the opinion of those best able to judge as to the future of saccharine, Sir Henry Roscoe expressed himself as follows:—

Sir Henry E. Roscoe, M. P., F. R. S., to Royal Gardens, Kew.

10, Bramham Gardens,
Wetherby Road, S. W.,
December 3, 1887,

My dear Sir,

In reply to yours of November 28, as to the probable influence of the discovery of saccharine on the growers and makers of sugar cane and cane sugar, I have to say that I do not believe that saccharine is ever likely to become an article of common use like sugar. In the first place, saccharine is not a food, whilst sugar is; and in the second place, I doubt whether saccharine can be prepared at a price likely to compete with sugar.

I think that this artificial sweetening agent will, however, become a useful material in cases in which sugar cannot be employed, as in diabetes and other diseases.

It seems to me beyond the bounds of possibility that the price or production of cane sugar can be materially affected by the introduction of saccharine.

I am,
Yours truly,
(Signed) HENRY E. ROSCOE.

D. Morris, Esq.

ADAPTATION OF PLANTS TO RAIN AND DEW.—Professor N. Wille records in Cohn's *Beiträge zur Biologie der Pflanzen*, 1887 the results of a series of experiments for the purpose of determining the extent to which plants can absorb moisture through their leaves or other aërial organs. The experiments were made on a number of different plants by placing on the leaves drops of a 1 per cent solution of lithium chlorate, and then examining, by means of the spectroscope, the extent to which the lithium was absorbed. The general results obtained were that water is absorbed so slowly, and in such small quantities, through these organs, in comparison to the amount taken up through the root, that it is without any physiological value to the plant. This applies equally to ordinary leaves, and to those which possess what have been regarded by some observers as organs specially constructed for the absorption of water.—*Pharmaceutical Journal.*

TEA ON OLD COFFEE LAND.

(By an ex-estate proprietor of 25 years' experience.)

What do I think of tea on old coffee land? Why I think it's a very wide question, and one that will take a lot of answering. There are many kinds of old coffee lands, there are many kinds of climate, and there are very many conditions under which tea can be planted to pay and not to pay. There is another point which bears upon the matter, and must not be lost sight of. On almost all old coffee estates there is often a large proportion of land which was planted comparatively a short while ago; some fields may be close on 50 years old, but the greater proportion may be 20 or under. Is all this to go under the denomination of old coffee land? If so there will be little difficulty in including properties not 20 years old, and a good deal of the abandoned coffee not more than ten years old. It would be easy to put one's finger upon coffee land planted 30 to 40 years ago, which will grow tea as well as any virgin forest in the island, and there are many localities where excellence of climate makes up a good deal for deficiency in soil. Again, there would be little difficulty in indicating old estates where there is no depth of soil, and what there is is not favorable for growth of tea, and the climate is equally unfavorable. In fact there is no end to the variations under which "old coffee land" could be discussed. Taking the aggregate of old coffee estates, I should say tea may advantageously be grown upon them, care being taken to plant them up according to circumstances of situation and climate, rejecting certain fields and ridges, and planting only what is best on each property. The great difficulty a few years ago was planters being urged by mortgagees to plant up everything:—good, bad, and indifferent land, gentle slopes and spaces steep as a house-wall and washed out years ago. All that was wanted was to "get so many acres under tea," and so put a value on the property. Anything in the shape of a tea plant, no matter what it was, was put out, and the result of it all is very naturally that it won't pay. It has always been the way in Ceylon, or at any rate during the last 30 years to "rush out" coffee plants, cinchona plants, tea plants, whatever the rage is, —run them out, and get so many acres under cultivation, and in the end failure is a not uncommon result. Whose the blame for doing this I needn't attempt to shew just now, suffice it to say that a long experience enables me to say that nine cases out of ten it is not the doing of the planter himself, who generally had to content himself with a protest more or less vigorous according to the position in which he was placed. There is another phase of the question "will it pay" which presents itself very prominently. When we inquire closely into it. What pays one man won't pay another in a different position. A man may have capital, he invests at a comparatively high price in a coffee estate, he puts it all into tea, and pays another man to do the work, he goes in for heavy expenditure in working the place and erecting factories, and he eventually gets perhaps 5% on an average in the course of years, and he naturally says it doesn't pay. Another man, who has nothing to live upon, gets an estate, opens it himself, does things as economically as he can, doesn't pay another person to work for him, but takes the pay himself, and in course of years finds he has been living comfortably, has brought up his family, and has 5% on his money laid by in the bank, and if you ask him "does it pay," he emphatically replies "of course it does." As a proof that good tea

95

can be made under difficulties with extreme economy (even as in ancient days we cured coffee well without power machinery, or cement barbacues), I have the pleasure of sending you a sample of tea* which was rolled by hand only, and fired on the end of an old nail drum over an ordinary garden flower pot, B. P. is valued @ 1/2 @ 1/3 per lb. pekoe @ /10. I don't mean to insinuate that any man should start a tea garden with the idea that he was going to cure all his tea in a flower-pot, but merely to show that it is not absolutely necessary, nor yet in many cases advisable, to commence with glass and iron factories, and a variety of expensive machinery. It is becoming pretty evident to a great many proprietors that an acre of tea costs more to bring into full bearing than an acre of coffee, one great reason being that it takes a much longer time to get the ground well covered with tea, and another great reason being the expensive nature of the factory and plant. That an old coffee estate, badly planted with inferior plants, is less likely to come into profitable bearing condition in a given time than new land well planted would, needs no demonstration, and yet this is the real reason why doubts are beginning to be thrown upon the paying qualities of old coffee land.

Start fair, plant well, work economically, and use commonsense and tea planting on ordinary old coffee estates will be a success as assured as is any other agricultural venture in existence.

As a planter of 20 years' experience and more, before I was instructed to put in tea, and having seen something of planting in other tropical countries, I protested strongly against running tea plants into miserable little holes where a man could not use a mammoty, or even put in his hand to arrange the roots of the plant, or find out whether or not there were stones in it, or in fact do anything he ought to do in a hole. I nearly got the sack for my pains, and now people are beginning to find out somebody was right.

MR. W. S. BENNET ON COFFEE AND TEA PROSPECTS.

After closing our Overland Summary last evening (April 11) we had a call from this gentleman and were much pleased to learn how satisfactory were the impressions he had formed during his present visit to the island. Mr. Bennet's own properties (Riverside and Nithsdale) are known to be exceptionally fine and promising. As showing his faith in old coffee land for tea growing, Mr. Bennet has just bought Glenloch estate, Pussellawa—formerly the property of Mr. John Tyndall—which is at once to be planted up with tea. In the Agras division of Dimbula, Mr. Bennet found coffee looking wonderfully vigorous, with, as he thinks, plenty of life to give good crops for many years under liberal cultivation unless "green bug" is going to excel itself by and bye. On Diagama, the Company's land both coffee and tea promise well and for the latter there has now been erected what Mr. Bennet considers one of the most complete Tea Factories in the island. The power is conveyed by a waterwheel some 30 by 5½ feet, he said, with a whole river of water available, so that eventually it is expected to drive eight rollers with the due proportion of dryers, sifters &c. The Factory is of iron roof and girders resting on chiselled stone pillars and is most substantial. No doubt we shall hear more about it from the active Manager. There can be little doubt that this new Dimbula Company is going to have good returns from their valuable property.

* And very good tea it is, we can say.—ED.

TEA IN INDIA.

(From the *Pioneer*.)

CALCUTTA, March 27th.

NEW MUTUAL TEA COMPANY.—The Report of the Managing Agents discloses a profit of R22,425 for season 1887, equal to 19 2-5th per cent on the capital, and with the sum brought forward from 1886, the amount at credit of profit and loss is R22,858, from which it is proposed to pay a sterling dividend of 7s 6d per share of R30. The outturn for the year was 4,021 maunds, against 3,899 maunds in 1886, and 3,320 maunds in 1885. The Revenue Account shows receipts R137,482 and expenditure R105,057. The estimates for 1888 are for a crop of 4,782 maunds at an outlay of R172,728. The area of the gardens under plant is 1,406 acres.

TUKVAR COMPANY.—The report of the directors discloses a profit on the season's working of R73,935 and an available balance at profit and loss of R73,097. An *ad interim* dividend of 5 per cent has exhausted R36,715, and it is now proposed to declare a final dividend of 4½ per cent and to carry forward R3,339. The outturn was 270,713lb., or some 116 maunds short of the estimate, owing to mosquito blight, but it realised the satisfactory gross average of As. 12-3½ per lb. as against As. 10-0¼ last year. The estimates for 1888 are for an outturn of 280,000lb. tea at an expenditure of R118,000lb. A small extension of 20 acres will be put in hand during this year, the present area under plant being 1,013 acres.

DESSAI AND PARBUTTIA COMPANY.—The report of the directors shows that the yield of tea during 1887 was 152,000 lb. against an estimate of 152,800 lb. and a crop in 1886 of 136,726 lb. The tea was sold in Calcutta and averaged As. 10-5 3-5ths per lb. against As. 9-3 16-25ths in 1886. The Revenue Account shows a profit of R17,721, and adding the balance from 1886, the amount at credit of profit and loss is R18,346. An *ad interim* dividend of 5 per cent has already been paid, exhausting R9,000, and it is now proposed to pay a final dividend of 3 per cent. and to carry R3,946 forward. The estimates for 1888 are for 164,000lb, at a cost in Assam at As. 6-1 per lb., which contrasts favourably with previous years. The area under cultivation is 572 acres.

ELLENBARRIE TEA COMPANY.—The report of the Managing Agents discloses a net profit of R21,012, and adding the balance from 1886, the amount at credit of profit and loss totals up R24,825. An *ad interim* dividend of 5 per cent has already been declared, and it is now proposed to pay a final dividend of 10 per cent; making 15 per cent for the year, and to carry R2,325 forward. The outturn was 1,892 maunds against an estimate of 1,800 maunds and nearly all the tea was sold in London, the net average price being As. 9⅓ against As. 7 last year, The estimate for the current year is for 2,100 maunds at an expenditure of R64,921, and the total area under plant is now 408 acres, while 38 acres will be cleared this year.

AMLUCKIE TEA COMPANY.—The report of the Managing Agents shows that the outturn was only 2,65¾ maunds against an estimate of 3,000 maunds consequent on deficient rainfall; but the quality made up for the quantity, the average gross being 11 annas per pound. The accounts show a profit of R44,651, and with the balance from last year, the sum of R68,263 at credit of profit and loss. An *ad interim* dividend of 5 per cent has exhausted R22,285, and the Managing Agents recommend a final dividend of 3 per cent, making 8 per cent for the season; that R6,000 be taken to Reserve Account and R26,607 be carried forward. The estimate for the current season is for a crop of 3,000 maunds at an expenditure of R99,129, which includes some machinery and an engine.

MIM TEA COMPANY.—The report of the agents for the year 1887 discloses a profit of R19,466, and a credit balance at profit and loss of R20,536. An *ad interim* dividend of 5 per cent was paid in November, and it is now proposed to pay a final dividend of 7 per cent, making 12 per cent for the year, and carry R1,456 forward. The outturn for 1887 was 123,643 lb. against an estimate of 114,400 lb. and an outturn in 1886 of 112,661 lb. The gross average price realised was 10¾d. per lb. or barely 9 annas, against 11⅝d per lb. last year. The estimates for the current season are for a crop of 124,000 lb. tea at a cost of R52,100; the expenditure last season was R46,205. The area of the gardens is 385 acres.

EASTERN CACHAR TEA COMPANY.—The report of the directors shows that the outturn was 4,946 maund against an estimate of 5,140 maunds and a crop in 1886 of 4,835 maunds. Some of the gardens were badly cut up with hail in the early part of the season which accounts for the deficiency. The average price realised was As. 7-9 against As. 7-5 last year. The area of the gardens is 1,486 acres. The receipts amounted to R1,93,314 and the expenditure to R1,64,417, leaving a profit of R28,897. A sum of R20,000 was transferred from last year's profit and loss account to block, and after payment of the debenture interest, the amount at credit of profit and loss is R37,290 It is proposed to write off R29,607 from block, machinery, &c., and to carry R7,683 forward. The estimates for 1888 are for a crop of 5,500 maunds at an expenditure of R1,72,394. The capital of the Company is seven lakhs.

CHENGA TEA COMPANY.—The report of the managing Agents discloses a loss on the season's working of R6,072 and a debit balance at profit and loss of R5,570. The outturn was the smallest on record, 733½ maunds against an estimate of 950 maunds and a crop in 1886 of 851 maunds. The quality also was most indifferent, the average price realised being As. 7-3·81 per lb. Blight and drought have much to answer for. The estimates for 1888 are for a crop of 900 maunds at a local cost of R24,500. The managing agents fear that if their manager cannot show better results, they will be reluctantly compelled to advise his dismissal. Debentures for R25,000 have been issued.

DEHING COMPANY.—The report of the directors discloses a profit of R33,538, and including the amount brought forward from last year a credit balance at profit and loss of R36,738. A dividend of 4 per cent will exhaust R35,744, leaving R994 to be carried forward. The dividend last year was 3 per cent. The outturn for the season was 5,009 maunds against an estimate of 5,175 maunds and a crop in 1886 of 5,1196 maunds. The average price realised was As. 9-4½ gross against As. 7-11 per lb. last year. About 44 acres of new land have been opened, and in addition about 33 acres of old nurseries have been staked out, making the area under plant 1,184 acres. The estimate for 1888 is for a crop of 5,250 maunds of tea.

BENGAL TEA COMPANY.—The report of the managing agents discloses a profit on the season's working of R13,716, and adding the balance from 1886 a credit at profit and loss of R19,212. A dividend of 2 per cent will exhaust R18,970, leaving R241 to be carried forward. The outturn for the season was 4,318 maunds against an estimate of 4,400 maunds and a crop in 1886 of 3,605 maunds; and the average price obtained was As. 8-7 per lb. for fine and As. 4-8 for coarse tea, against As. 8-6 and As. 5-5 respectively in 1886. The estimates for 1888 are for a crop of 5,000 maunds at an outlay of R161,352. The area of the gardens under plant is 1,431 acres. The new flat gardens will be extended to 750 acres by the next cold weather, and thereafter 50 acres will be added annually.

MOTHOLA TEA COMPANY.—The report of the directors discloses an estimated profit of R9,606 on the season's working and a credit balance at profit and loss of R11,795. An *ad interim* dividend of 7½ per cent in December last exhausted R10,359, leaving R1,445 to be distributed in a final dividend of 1 per cent, and a balance of R65 to be carried forward. The crop weighed out 1,488½ maunds against an estimate of 1,500 maunds, and a crop in 1886 of 1,470 maunds. The gardens suffered a good deal from blight during the year. The whole of the crop was sold in Calcutta and realised a net average price of 11 annas per lb., against As. 10-0¾ in 1886. The estimates for 1888 are for 1,550 maunds. The area under plant is 309 acres.

GOMTEE TEA COMPANY.—The report of the managing agents discloses a balance of profit of R7 803 and a credit balance at profit and loss of R7,587 A dividend of 7 per cent exhausts R5,600, leaving R1,987 to be carried forward. The total outturn was 67,012 lb. against an estimate of 60,000 lb and an outturn in 1886 of 69,000 lb. The average price realised was As.8-10.23 per lb. against As.8-0 last year. The estimates for 1888 provide for a crop of 800 maunds at a local cost of R22,700. An extension of 20 acres is contemplated, which will bring the area under tea to 292½ acres. The block account stands at R72,000.

KALACHERRA TEA COMPANY.—The report of the directors discloses a net profit on the season's working of R2,189, which reduces the debit balance at profit and loss to R9,512 The outturn was 146,595lb. against an estimate of 128,000 lb. and a crop in 1886 of 119,515 lb. The average price realised was As.7 per lb. against As. 7-6½ in 1886. The estimates for the current season are for a crop of 1,900 maunds at an expenditure of R62,388. It is proposed to open out 80 acres on the Yow Bheel this season at an expense of R7,700. It is first class land and will be planted with pure indigenous seedlings. The area under plant at present is 605 acres

HOLTA TEA COMPANY.—The report of the directors discloses a profit of R8,073 and a balance at credit of profit and loss of R8,726 which it is proposed to carry forward. The outturn for the season was 104,908 lb. against an estimate of 120,000 lb. and a crop in 1886 of 121,000 lb. The average price realised was As. 12-1½ against As. 11-1½ in 1886. The retail trade has been steadily increasing and now reaches 60,000 lb. annually. The Manager, Mr. Compton, has left the Company's service, consequent on some misunderstanding, and the directors place on record their high appreciation of his services. They consider that in the development of the local sales he has been particularly indefatigable and that the garden owes much to him.

RAJABAREE TEA COMPANY.—The report of the Directors for the year just ended discloses a profit of R12,851 and a credit balance at profit and loss of R14,803. A dividend of 7 per cent will exhaust R14,000, leaving R803 to be carried forward. The outturn for the season was 98,023 lb. against an estimate of 120,000 lb. and a crop in 1886 of 126,520 lb. The gross average price realised was As. 11½, against As. 8 for 1886. The estimates for the current season are for a crop of 1,450 maunds at an expenditure of R54,050. The area under plant is 368 acres.

KHOBONG TEA COMPANY.—The report of the managing agents discloses a profit of R31,526, and after paying a dividend of 10 per cent on the 1,610 A shares, a credit balance at profit and loss of R35,543. After payment of a dividend of 4 per cent on the B shares, there remains a sum of R30,223 which will admit of 277 A shares being drawn and paid off in terms of the Articles of Association, The total crop was 1,234½ maunds against an estimate of 3,800 maunds and an outturn in 1886 of 3,647 maunds. The tea realised an average of As. 10-3·11 per lb. net against As. 9-1·92 last year. The estimates for 1888 are for a crop of 4,300 maunds at a local outlay of R90,060. The area under plant is 576 acres, and an extension of 20 acres is proposed during this year.

SCOTTISH ASSAM TEA COMPANY.—A circular report has been just issued by Mr J F Moffat, C.A., Edinburgh, Secretary of the Scottish Assam Tea Company, Limited, which contains the following :—

"The total quantity of tea made during season 1887 amounted per monthly statements to 240016 lb., and the quantity available, after deducting red and coarse leaf, loss by firing, packing, &c., will be about 233,000 lb, being 31,000 lb. more than the previous year, and 2,000 lb in excess of the manager's estimate. Up to this date about 205,250 lb. of the season's teas have been sold, producing a gross sum of £12,700, or an average price of fully 1s 2·4 per lb. Two invoices yet remain to be sold. Judging from past experience it would not be safe to calculate upon those producing the same average, but taking them at 1s per lb., the general average for the season would be about 1s 2¼d per lb., as against 1s 4·1 per lb. for the preceding year. Complete accounts have not yet been received from India, but so far as can be seen at present the expenditure will exceed that of the previous year by about £1 000, the excess arising chiefly under the heads of cultivation, manufacture, and importation of coolies. On the other hand, rates having again been exceptionally favourable, considerable additional profit will arise under the head of 'Exchange,' Mr. Denton's report of the gardens, dated December 27th, 1887, states that he has been carefully over the three gardens belonging to this company and finds a general improvement since the date of his last visit. He has been very much pleased with the steady improvement generally noticeable throughout the Company's property under the careful management of Mr. Edwards. Mr. Edwards proposes estimating for a crop of 244,000 lb. good tea. Mr. Denton considers the estimate a reasonable one, and with fair weather this outturn should be exceeded. More plucking hands are required, and a liberal supply of labour will lead to further outturn."

MAJAGRAM TEA COMPANY.—The report of the directors discloses a loss on the seasons' working of R7,179, the expenditure having been R31,141 against a revenue of R26,662; the amount at debit of profit and loss is now R16,775. The season's crop was only 59,340 lb. against an estimate of 84,000 lb. and an outturn in 1886 of 76,693 lb. Severe blight in July accounts for this. The great bulk of the tea was sold in Calcutta, and averaged net As. 7-1⅞ per lb against As. 6-7 last year. The estimates for the current season are for 1,100 maunds of tea at an expenditure of R43 400, and prospects are encouraging. Debentures for R25,000 at 8 per cent. have been raised. The area of the gardens under plant 339 acres.

"MAZAWATTEE TEA."

The packet of tea samples promised by Messrs. Densham and Sons, as sold under the above mark, duly reached us some days ago, and we referred the same to Messrs. Somerville & Co. for report *pro bono publico* :—

(*To the Editor, 'Ceylon Observer.'*)

Colombo, 12th April 1888.

Dear Sir,—Having examined and tasted the following Teas, we now beg to hand you our report and valuations, as under, viz. :—MAZAWATTE TEA.

Box No. Sample	Marks.	Description.	Present London Value.	REMARKS.
1	Mazawatte...	Grade 1...	11¼d to 1s	Blackish, brownish choppy Pekoe and Souchong leaf, with ends, rather dusty and broken, dark, malty liquor, fair strength, little flavour and quality.
2	do.	...Grade 2...	10d to 10½d	Blackish even choppy Pekoe Souchong leaf, rather broken & dusty, few ends plain dark liquor, fair strength.
3	do.	...Blend 3..	8¾d to 9d	Greyish blackish choppy Souchong and broken tea mixed, thin light China flavour.

—We are, dear sir, yours faithfully,

p. p. SOMERVILLE & Co.—A. H. THOMPSON.

No. 1 and 2 are good ordinary drinking teas of Ceylon growth. No. 3 (Blend) has a distinct China flavour and in our opinion contains about 50 per cent of China growth.

p. p. S. & Co.—A. H. T.

But what guarantee have we that the above are not special samples of the tea sold as "Mazawattee" (a name that no philological explanation can make us believe was not first thought of in connection with Mariawatte.) On the contrary, the

packets bought under that mark many months ago by reliable correspondents—Ceylon planters and others—showed how trashy were some of the teas sold. Here is the report on some of them furnished in September 1886 :—

We have been favoured with the following report on one of the samples sent us by Mr. John R. Hood of tea bought by him at Brighton as Ceylon tea, and this we give here to show how much need there is for establishments where pure Ceylon tea can be guaranteed :—

To the Editor of the "Ceylon Observer,"
Colombo, 24th Sept. 1886.

Dear Sir,—Having examined and tasted the following Tea, we now beg to hand you our Report and Valuations, as under, viz. :—

MAZAWATTEE BLEND : SAMPLE.

Mazawattee Blend: Description, Broken Pekoe Souchong; London value 8d. Blackish, reddish, mixed, broken souchong and siftings very dusty, dull common liquor wanting point and character.

This tea has a peculiar China "*moning*" flavor and contains, in our opinion, a very small percentage of Ceylon tea.—We are, dear sir, yours faithfully,

pp. SOMERVILLE & Co.,
A. H. THOMPSON.

It is right to say that the packets now before us are made up with extreme neatness, and that "blend" is clearly marked on the poorest.

THE GREAT TEA COMPETITION.

Not a moment too soon has the Pekin Government taken action for the improvement of Chinese tea. The policy of "masterly inactivity" which was previously adhered to by the mandarins in this matter was steadily destroying the industry. It appears from the annual circular of Messrs. G. White and Co. that during the last three years, China tea has lost ground at an accelerated speed. In 1885, the total deliveries into the United Kingdom amounted to 123,842,000 lb ; the year following, the quantity diminished a little more than 5,000,000 lb ; last year witnesses a further shrinkage of over 21,000,000 lb. Has the taste for tea drinking diminished in the British Isles? By no means ; Great Britain still remains the greatest tea consuming country in the world, in proportion to population, with the exception of her Australasian colonies, which absorb about 1½ lb per head more than their English kinsfolk. Our consumption last year was, we learn, 3½ million pounds in excess of the previous year. How, then, was the deficiency of the Chinese supply made good? By the augmentation of imports from India and Ceylon. In the course of three years these increased from 68,896,000 lb to 93,054,000 lb. a prodigious growth to occur in so short a period. But now that the Chinese Government has awakened to the perils of the situation, we may expect a steady improvement in Celestial teas. There is no question whatever that the Chinese can, if they like, produce an excellent article, quite capable of holding its own against any competitor, and now that they see the unprofitableness of sacrificing quality to quantity, their shrewdness will soon influence them to reverse the process.—London *Globe*.

ANNUAL REPORT ON TEA.

INDIA, CEYLON, AVA.

(From *Geo. White & Co.'s Annual Indian, Ceylon, and Java Tea Report.*)

LONDON, 31, FENCHURCH ST., E. C., March 19th.

In reviewing the course of the Indian tea market for the past twelve months, we find that from March until the arrival of the new crop, there was a depressed tone for all the lower grades, which for the better descriptions prices improved, especially after Easter, and, up to Whitsuntide, showed a marked advance. Subsequently, however, business became dull and continued more or less so until August. Prices during the current season have not fluctuated so much as in former years, although they have varied from time to time according to the amount brought forward. The most noticeable features have been the large increare in the imports, that the demand has kept pace with them, and that there is every probability that by the end of June the deliveries will more than absorb the extra supplies, which owing to the abrupt close of the season, will fall below the original estimates, telegrams from Calcutta, just received, giving shipments thence as 83 million pounds.

Ceylons have followed very much the market for Indians during the greater part of the year, except the last three months of 1887, when all descriptions under 1s 3d per lb., owing to limited arrivals, sold at enbanced rates, and were much above those ruling for similar grades of Indian. With heavy sales after the turn of the year there was a gradual decline until the fine grades showed better value than Indians, while the lower descriptions were more nearly assimilated.

Javas have not been in over supply, partly in consequence of the shortness of the crop. Some very good teas have been received, and these have met with steady support from home and export buyers, but there has been a considerable quantity, thin and pointless in the cup, which have realised very poor averages, the unprecedentedly low prices ruling for China Congous having affected values. Rather more business than usual has been done for London in Holland, some of the purchases having given very satisfactory results to buyers. There is also a large and increasing demand in Java for Teas especially prepared for direct shipment to Constantinople and Persia.

The London Bonded Stock on 30th June, 1887, was as follows :—Indian, 18,803,000 lb.; Ceylon, 2,737,000 lb. Java, 1,154,000 lb against 16,426,000 lb. 1,919,000 lb. 1,016,000 lb. respectively, at the same date in 1886.

The average prices for this season have been—say, Ceylon 1s 1d., Indian about 11d per lb ; China 8d per lb as compared with 1s 1½d 11d and 8¼d per lb during 1886-7, and 1s 3½d 1s 1½d and 10½d per lb for the previous year.

The total home consumption of all tea for the year 1887 was 180½ million lb., against 177 million lb. in 1886, an increase of 3½ million lb. ; whilst our export for the same period, chiefly on account of larger direct shipments from China to Russia, decreased 9 million lb, being 35 million lb. against 44 million lb. in 1886. The falling-off in the home consumption of China tea was, however, no less than 13¾ million lb., but the increased deliveries of Indian and Ceylon have more than covered this deficiency, and made up the excess in the total home consumption. This proves that British-grown tea has gained in favour rapidly at the expense of Chinese, as the monthly deliveries of the former have at times rather in excess of Congou.

It has been fortunate for the market generally, that total shipments for the season, as telegraphed from China, are about 28 million lb. less to Great Britain, otherwise there would have been an excess to deal with but with the probable increased yields from India and Ceylon, another shrinkage of 20 to 35 million lb. is necessary in the exports from China during the coming season.

	lb.
Supposing our Home Consumption to be increased to...	185,000,000
And Export Trade to be reduced to	30,000,000
The total requirements will be...	215,000,000
India will probably send ..	92,000,000
Ceylon and Java	33,000,000
The balance required from China will be	90,000,900
	215,000,000

From which it will be seen that only 60 million lb. of China Tea will be wanted for home consumption.

INDIAN 1887 CROP.—The Indian season opened in June with small quantities, chiefly of unattractive quality, whilst most of that offered in July was below the average; the few finest lots from Darjeeling, Terai, and Dooars realizing extravagantly high figures. With few exceptions, however, there has not been so much fluctuation in prices as in former years, and as there was no budget scare to displace figures, a fairly steady trade has been carried on throughout. One notable feature has been that, owing to more rapid despatch, teas came to hand quicker, and the heaviest sales were held in September, whereas they used generally to occur in November. The quality was on the whole good, though there was a preponderance of well made tea, especially Pekoes with light cup and consequently dark liquoring teas have been much wanted and sold well. Although the yield has been larger and the crop better, there has been a smaller proportion of common to fair broken teas, which is an advantage, as this class is less used than formerly, and is not saleable if in full supply, except at very low rates. On the whole, though in some instances the average price has been less, results have probably been better to many garden owners, as with increased facilities for manufacture and despatch, lower freights and reduced warehouse charges, the tea has been laid down in London cheaper, and in some cases as low as 7¼d per lb.

CEYLON.—Ceylon teas have been in favour throughout the season, except when the quality fell off temporarily, and have sold well. The demand for these, originally fostered to a large extent by those interested in their production, has become thoroughly established, and owing to the continued energy displayed in keeping them well before the public, they now hold a prominent position, as they have special merit of their own and a taking flavour which induces those who have once acquired the taste, to continue to use them. It is evident that more care is usually taken in plucking, as well as in manufacture, than formerly, as the leaves are on the whole more even in appearance with a very small proportion of broken tea, and freer from stalks and pieces of stick than Indian. Many dealers will not buy stalky tea, unless at reduced rates, because grocers do not like the expense and trouble of picking it over, and if left in, their customers complain that it is adulterated.

An analysis has recently been made by Dr. Paul to determine the proportion of Theine in tea grown at different elevations in Ceylon. The result attained is interesting, as it tends to show that altitude has an effect on the growth and properties of tea, the produce of high elevations containing less Theine and Tannin than that of lower; and consequently, though both may be equally valuable, the one will be most appreciated by connoisseurs who prefer flavour, and the other will commend itself to those who desire strength, and will be useful for blending purposes.

JAVA.—The quantity of Java tea shipped to this country has been less than usual, but the way in which all good and useful parcels have been taken up, shows how they are gradually gaining favour with the different buyers, and not being dependent on one market can take advantage of both home and export demand.

NEW MARKETS.—There is a growing feeling amongst those interested in tea gardens, that with larger supplies it will be necessary to open up new outlets for their produce in the shape of fresh markets, and to facilitate this, a meeting was recently held in London, at the offices of the Indian Tea District Association, with the object of selling Indian teas in Canada and the United States. Something of this sort would no doubt be of use, for, although home consumption increases, and export to the Continent slowly advances, still some further impetus will be required to carry off the yield of the large tracts in Ceylon now coming into bearing, as well as of extensions in India. Up to the present, the drinking of tea as an ordinary beverage has been, to a great extent, confined to Great Britain and her Australasian Colonies, the average annual consumption per head for the former being about 4¾ lb, while in the latter it varies from about 5¼ to 7½ lb. when, therefore, we see that Canada takes, rather more than 3½ lb. per head, the United States barely 1½ lb, and Russia a little over ½ lb per head, while the other continental nations use only a very small quantity, it is evident that if these latter could be persuaded to take to tea drinking on the same scale as the British public, an enormous development would follow.

PROSPECTS.—Although the news from India recently received points to a rather late opening of the season, and advices from Ceylon state that very dry weather had been experienced, which would temporarily curtail the outturn, still there should be full supplies in this market by August, and it is to be hoped that managers will endeavour to send good quality, as fine teas will then be much wanted. Calcutta and Colombo buyers will no doubt be alive to this, but should not attach, as they have done this season, too much importance to the possible curtailment of shipments from China, as so much teas Congou will be required for home use.

SIZE OF BREAKS.—During this season there have been many complaints from buyers, of duplicate breaks of the same grade of tea in a factory-bulked invoice, and they have refused to buy them unless bulked together here. Two and even three invoices from one garden have also been shipped in the same vessel, and as this happened frequently (although also factory-bulked) they had to be rebulked here. The recurrence of this should be avoided, as with the very large number of samples to taste each day, every endeavour must be made to minimise the labour and economise the time of buyers who often, even now, are unable to give proper attention to the whole of the large daily sales. Some specially full-sized breaks, sent lately, consisting of 200 chests each, have been much appreciated, and sold well. A reduction in the number might often be effected if managers, for instance, instead of sending say 40 chests of Pekoe Souchong, which sell at 7¾d per lb. and 40 chests of Souchong at 7½d per lb., would make a break of 80 chests, so that one sample would suffice.

BULKING.—Speaking generally, the work of bulking (especially in Ceylon) has been better done than formerly. In some cases, however, the tea, although well blended, has had to be re-bulked here owing to the irregularity in appearance caused by crushing the leaf into the chest so as to alter its colour, or by the end of the pile, which is usually dusty, being placed on the tops of some of the packages. Some Ceylon teas, lately to hand, packed by David Fairweather's packer, were very regular in appearance, the leaf being much less crushed than by the old method of treading in the tea, and something of this kind would be a valuable adjunct to the machinery of an estate. In these days of competition and cutting down of the London warehouse charges, the tendency is to bestow less time and care on the work than it should receive, which renders it the more desirable that the tea should arrive here in a merchantable condition, so that no time need be lost in bringing it forward for sale on arrival. Some parcels, especially from Assam, though carefully blended, have had a peculiar fusty, almost approaching to mouldy smell, more noticeable on some packages than others. This has probably arisen from the Tea being passed too quickly through the dryer at a very high temperature, so that the outside of the leaf is crisp, but the middle is not thoroughly desiccated. The moisture thus left behind causes a reaction to set in after the tea is packed, and the musty flavour is thus acquired. On the other hand, many parcels, notably leaf kinds, doubtless owing to over-firing at a very high temperature, appeared to have had all the sap and flavour dried out and on infusion drew pale pointless liquors. These defects might be obviated by slower and more efficient drying at a lower temperature, especially in the case of Pekoes and Souchongs.

Some planters store their tea, when manufactured, temporarily in lead-lined chests until they have a lot of each sort to bulk into a break, and they find it keeps fresher than in bins which they have pre-

carded. The patent metal packages would be very useful for this purpose; considerable quantities of these have been sent, especially from Ceylon, lately and they arrived in good condition, and appear to be liked by the trade.

MANUFACTURE, &c.—Although much of this season's crop from India and Ceylon has been of good quality, a large proportion, especially from India, has been poor, and has therefore come into competition with China Congou, which has been selling at unprecedentedly low rates, thus holding out much inducement to retailers to reduce their prices; and, owing to the prevailing competition, "*the shilling canister*" has been adopted, which is much to be regretted. The serious falling off in their trade has been forced on the notice of the Chinese authorities and growers, and they are becoming alive to the fact that something must be done, as it is evident that considering their tea has to bear an export duty and Lekin tax of about 2d per lb., they cannot continue to lay it down in London to sell at 3½d to 4d per lb., which prices were current last month for common Congou. Managers should therefore use every endeavour to keep up the reputation of their marks, as there is no reason why China should not send quality equal to that of former years. Although, owing to labour-saving machinery, tea is now landed here at a low cost, the utmost economy must still be practised, as with increasing supplies, present averages may not be maintained, besides which the low freights and warehouse charges ruling this season will probably be raised.

Expenses may be reduced by careful bulking so as to avoid the need for it in London, and by packing an equal quantity in each chest, so that the Teas may be net-weighed here, care being taken to give an overweight of about 2 oz. in every package to turn the scale. A saving may also often be effected by making the gross weights to come within the warehouse rates, as a package weighing 129 lb. is charged no more than one of 90 lb. Boxes of flavoury Pekoe or Pekoe Souchong, which are often very saleable here, should weigh under 28 lb. gross to avoid the 1 lb. draft which is allowed over that weight.

Sorting into too many grades should be avoided, as it tends to make the Teas dusty, which is objectionable, and often brings them within the category of small breaks, which are sold after the ordinary sales and meet with limited competition.

The present limits for full-sized breaks are:—
12 chests. 18 half-chests. 30 boxes.

COMPARATIVE QUALITY OF THE OUTTURN OF THE DIFFERENT DISTRICTS FOR THE PAST THREE SEASONS.

ASSAM.

1887 Crop.—The quality generally has been fully up to the average, but a large proportion being thin in liquor sold badly. Several marks have, however, been well to the front throughout the season.

1886 Crop.—On the average under an ordinary crop, a few gardens having sent desirable tea throughout, some others good and bad alternately, whilst the produce of many has all been poor.

1885 Crop.—Quality on the whole good, though crop in some districts very short. Teas received during August and September very fine, and even better than those of the previous season.

CACHAR AND SYLHET.

1887 Crop.—The former district has not been well represented as regards quality, some managers having preferred to go in for quantity. From the latter, some very useful teas have been received, with dark liquors, which have sold well.

1886 Crop.—Large supplies of undesirable quality have come to hand, as it quantity had been aimed at. Only a few really choice liquoring invoices realized comparatively high rates.

1885 Crop.—Outturn large, but the crop as a rule poor. A few exceptions, however, which prove that fine teas can be made if proper attention be paid to manufacture.

DARJEELING, KURSIONG AND TERAI.

1887 Crop.—The crop has been very varied, some exceptionally choice parcels having been received which commanded high prices. A large proportion, however, was poor, with thin liquor, which sold with difficulty at exceptionally low rates. Planters should endeavour to make good teas, as they are required for flavouring purposes.

1886 Crop.—On the whole disappointing, and in some cases the worst seen for many years. A few really fine flavoured parcels received during September and October, also January and February, realized extreme rates, proving that this district's teas when fine are much appreciated.

1885 Crop.—The quality generally was poor, many of the invoices being dry and sapless. The few fine Teas consequently commanded very full prices.

DOOARS.

1887 Crop.—Similarly to the 1886 crop, some fine teas were received at first, but quality fell off later on. Towards the close, some fairly thick full flavoured invoices came to hand for which much better averages were obtained,

1886 Crop.—The season opened well, but the teas fell off shortly after. Sufficient useful quality was sent to prove what might have been done under more favourable circumstances. Late arrivals showed every sign of excessive flushes, and lack of care in manufacture.

1885 Crop.—As usual, there has been much irregularity shown in the outturn. With a few exceptions the teas lacked quality, though for a time they were good, being full in the cup and drawing thick liquors.

KANGRA VALLEY, KUMAON, AND DEHRA DOON.

1887 Crop.—A few choice invoice from the former district, were much in favour with the trade, and commanded high figures. The bulk of the crop was light in cup and devoid of flavour, so that only low averages were given; Kangras will not sell well unless of first-rate quality. The two last-named districts, as usual have utilized most of their produce for local consumption.

1886 Crop.—With a few exceptions, the former has sent thin pointless teas, unsuitable for this market. Rich flavoured lots always sell well, and the few received were eagerly bought up at 6d to 1s per lb. advance on similar grades, with poor quality. From Kumaon and Dehra Doon only limited supplies have been received, and chiefly of low class.

1885 Crop.—A few choice parcels were received from the former which commanded high rates, but the produce of the other districts has been poor and in comparatively short supply in this market, a considerable quantity being sold locally.

CHITTAGONG.

1887 Crop.—A fairly good yield, as compared with other districts, but below what used to be received from here, the proportion of thick juicy teas being small.

1886 Crop.—Like other districts, the proportion of useful to fine has been small. For a time some good prices were paid, but the general average must be a bad one.

1885 Crop.—Some useful teas received, but a large proportion has been below the average and therefore realized low prices.

NEILGHERRIES AND TRAVANCORE.

1887 Crop.—Most of the shipments from the former have been of the inferior makes, and it is evident that the best teas are stil lused locally.

From Travancore, however, some choice flavoured parcels have again been received, and this comparatively new district promises well.

1886 Crop.—Only a limited quantity has been received, and this generally of the worst description. It is said that most of the best tea in the former district is used for local requirements. From the latter some very desirable parcels have come to hand, similar in flavour to Ceylons.

1885 Crop.—Supplies only moderate, and as a rule of undesirable quality, far behind that sent some five or six years ago. A good portion of the crop sold locally.

CEYLON.

1887 Crop.—The demand for these growths has kept wonderfully steady when they have possessed the full aromatic flavour for which they appeared to be so much appreciated for self-drinking purposes. The results of thin and undesirable invoices, manufactured under unfavourable conditions, prove that poor quality is not saleable, except at a low figure.

1886 Crop.—On the whole the quality has been good, and full prices have been realized. The average being about 2½d. per lb. above that of Indian growth, proves the estimation in which these are held. Thin and undesirable shipments have sold badly, and should discourage garden owners from going in for *quantity*.

1885 Crop.—Still in favour with consumers, and whenever supplies have fallen off, there has been a strong demand and full rates obtained. These teas have made a great name for themselves which will probably be maintained if the quality is kept up.

JAVA.

1887 Crop.—The supplies have been limited, and quality on the whole fair, with perhaps less full teas than last season. There has, however, been a steady enquiry for home use and export, with indications of a further development in consumption, whenever they have been of a desirable character.

1886 Crop.—Some really useful teas have come to hand and they are gradually gaining favour with home and export buyers, especially where attention has been paid to manufacture. The quality, however, must be kept up and in some cases improved, if they are to take further hold on consumers.

1885 Crop.—Since the introduction of seed from India, an English machinery for manufacture, there has been a marked improvement in quality, many of the teas having full rich flavour.

GEO. WHITE & Co., Tea Brokers.

PLANTING NOTES FROM UVA.

RAIN—TEA—TOBACCO—COTTON AND THE NEW COMPANY—THIEVES.

Haputale, 3rd April.

The rainfall during the last month was copious, and towards the end of March accompanied by lightning and thunder, and for a few days it looked very like an early setting-in of the S. W. monsoon; but since the 1st of this month it has again cleared up and set fine. Since 1st January the total rainfall at the Haldummulla end of the district has been close on 24 inches to date.

January 3·91 inches, February 0·07 inches, March 19·81 inches—total 23·82 inches. Tea, which is flourishing wherever planted, must, in future, be the mainstay of the Province of Uva, as I am sorry to say many acres of coffee land on the other side of the Pass are looking very "shuck," and succumbing to the effects of green bug, leaf-disease, and periodical gales of wind, against which latter no "wind-belts" were reserved in times past. These if reserved, and a more liberal system of cultivation by manuring had been adopted at first, the ill-effects of the above pests might have been modified, or counteracted to a great extent. It is to be hoped that the planters of the present day, who are now converting their acres of coffee into tea, will bear this in mind, and go in for extensive belts of timber, not only to protect their tea flushes from wind, but for timber for fuel, which is almost entirely wanting from one end of the district to the other. Now that the Railway Extension is sanctioned, there is some chance of all the good coffee being kept up by manuring which was prohibitory hitherto owing to the enormous cost of transport. Besides tea, there are other products which are engaging the attention of some of our planters at the present moment, such as tobacco and cotton, both of these products were years ago grown in Uva, for which the climate is excellently adapted. I remember the late Mr. G. A. Crowell telling me that on his first arrival in the island of his putting out a nursery of tobacco somewhere near Bordadde or Wilson's Bungalow, on the Baron Delmar's account. I think he said. I also remember seeing a tobacco store (as it was called) at the Mahgakanda Mills then the property of the Baron Delmar, where cigars were manufactured for export; perhaps Mr. F. R. Sabonadiere or Mr. J. P. Green will be able to say whether these cigars were manufactured from tobacco grown in Uva. Mr. Bertlin of Oodawerra and Kotagodde estates, in Badulla, used to grow tobacco amongst his coffee, prepare tobacco, and manufacture cigars in the "fifties." Badulla cigars were noted for being of excellent quality, and preferred by smokers to the best Jaffna cigars. About the year 1870 I imported from Australia, some parts of the Colonies then growing and manufacturing tobacco largely, some seeds of Virginia, Kentucky, and Havana tobacco which I planted on the property of my late lamented friend, G. Wharton Brown, in the Passara Bulatwatta valley, and without manure grew some excellent tobacco and manufactured cigars, which my smoking acquaintances considered very good. Tobacco grows like a weed everywhere in Uva, and does not require irrigating as it does in other parts of the island, such as Jaffna and Batticaloa. Cotton was grown in many parts of Wellassa and round the base of the Monoragala range, from where it was sent to the hand-looms at Batticaloa to be made into cloth, cambayas, table cloths, and napkins. One variety known as the silk cotton is almost indigenous in the district, and grows everywhere. I have some plants in my garden here which have been bearing pods of very good cotton every season for the last five years, and though I have cut them down yearly, they grow up again, and don't seem to get exhausted or tired of bearing pods (by this post I send you a simple of some of the cotton).* That is a grand scheme of the promoters of "The Ceylon Spinning and Weaving Company," prospectus of which has just reached me; it is sure to be a great success and inestimable blessing to the poor natives of the country. What have those wealthy members of the Agricultural Association been about that they did not think of schemes like the above to benefit their countrymen, instead of idling their time away in snarling at Railway Extension to Uva? These gentlemen (except yourself and Mr. Weeracoddy) must feel like puppy dogs with their tails just cut off, going round in a circle howling!

"WHAT THE PLANTING ENTERPRISE HAS DONE FOR CEYLON."

Volumes might be written on the subject; and if we treated of the matter fully we should only be going over ground travelled over so often, that our readers would be inclined to cry "hold, enough." But if there is one department of public improvements and works more than another that has been considered ever since its introduction to have been originated, fostered, and paid for by the planting enterprise, it is our Railways. Never before has a question been raised as to the identity of the Railway to Kandy, to Matale, to Uva, with the planters. Why the accusation cast in the teeth of the Government and of ourselves, again and again has been embodied in the terse designation of a policy indicated by "Planters' Railways. But our contemporary of the "Examiner" has suddenly awakened to an idea that the Ceylonese community should be credited with a large share of the credit due to the construction and payment of our upcountry Railways, and, as we expected, he is not content with the exposure of his weak case already presented by us, but endeavours to make a great show by figures apart from the point at issue. We expressly left out of consideration, the extension line, as not coming into the discussion originally raised as to the pay-

* A true cotton, but too short stapled to be of much use. We will have to get better seed before Uva can turn out the proper article.—ED.

ment of the cost of the main line. We further kept to the case before us by considering the railway traffic and profits between 1867 and 1883, the year in which the last debentures for the Kandy line were paid off. We made one omission: in saying that the coaching receipts were insignificant as compared with the goods traffic, we should have made it equally clear that we referred to the years in which the great profits from the main line were accruing. This might well have been inferred. Not so with our contemporaries original statement which he has not yet withdrawn, namely, that "the export duty did not repay a tythe of the sum expended on the Kandy railway." We have shown that the export duty paid as nearly as possible one-third of the total cost and certainly over three times the proportion the "Examiner" alleged Good care is also taken not to notice the fact that the vast proportion of "coaching receipts" is due to the planting enterprise. How many people would travel from Colombo to Kandy, Matale, Nawalapitiya and onwards save for that enterprise? It will be worth the while perhaps—and we shall get the return made as time permits—to show the proportions of receipts under "coffee," "rice," "other goods" and "coaching" from 1867 to 1873 when only the main line existed; from 1874 to 1877 before the seaside line was added; and since then, separating the little lowcountry line. But our contemporary will not be satisfied without widening the area of the discussion so as to cover the whole island, bringing in the rice fields of Batticaloa and the palm gardens of the East and North as well as of the West, and quoting our own figures for such cultivation as if they had a bearing on the Railway payments. No doubt, it might be instructive to compare the total area cultivated in 1837 with that for 1887, and ask to what the great change is due. A readier means however of showing how the material improvement of the island in the fifty years has been mainly effected can be found through the history of our export trade. In 1837—at the beginning of the planting enterprise—the total value of the Exp rt trade was £326,860, of which planting (European) products made up about one-third. The figures since then are nearly as follows:—

Year	Total value of exports.	Approximate value of Plantation Products.
1837	£ 326,000	£ 105,000
1847	961,117	£ 560,000
1857	2,558,460	£ 1,600,000
1867	3,530,224	£ 2,500,000
1877	5,730,051	£ 4,600,000
1887	4,001,836	£ 2,300,000

The great falling-off in coffee of course explains the difference, latterly; but every year now will see tea working up to the old proportion of coffee. This year for instance, plantation products will probably give a value approximating to £3,000,000. We need not refer to the effect the local wealth caused by "coffee" between 1857 and 1877 had in developing the cocoanut planting industry. Indeed on the general question as to the planting enterprise having simply "made" Ceylon, its railways, its roads, its public buildings and institutions, we have evidence outside that of editorial circles altogether. We can quote Sir Henry Ward, Sir Hercules Robinson and Sir Wm. Gregory; while as to the Railway, we should be willing to leave a jury of intelligent Ceylonese to decide on the point as to whether if there had been no European Planting Enterprise in Ceylon, there would in this year 1888 have been 74 miles of railway made to Kandy, much less 90 additional miles to Matale and Nanuoya

---

LARGE GOVERNMENT ORDER FOR FOREST TREES.—We note in the *Dumfries and Galloway Standard* that the firm of Messrs. T. KENNEDY & Co., nurserymen, Dumfries, were recently invited by Her Majesty's Commissioners of Woods and Forests to tender an offer to supply 600,000 young forest trees of specified varieties for planting on the Crown lands in the Isle of Man. Their offer has been accepted for over a quarter of a million plants, which have to be straightforth delivered to the Crown Receiver at Douglas. The order consists of Birch trees, Beech, Sycamore, Alder, Silver Fir, Corsican Pine, Austrian Pine, Douglas Spruce, Scotch Firs.—*Gardeners' Chronicle.*

A NEW REMEDY FOR DIABETES.—A new drug of apparently great value has recently been introduced into the market. It consists of powdered Jambul seeds—the seeds of a plant *Syzygium Jambolanum* or *Eugenia Jambolana* found in various parts of India, the Mauritius, Ceylon, and the United States of Columbia. It has been well tested by the medical faculty in England, Germany and the United States, and is said to be a promising remedy in all cases of diabetes. The action of the drug is to prevent formation of sugar in the system, and so to stay waste; and cases are on record showing that under its influence the special restrictive diet—so obnoxious to diabetes patients—can be dispensed with.—*Cassel's Magazine of January 1888.*

MYROBALANS FRUIT AS A MEDICINE.—At a recent meeting of the Société de Thérapeutique, a letter was read from M. P. Apéry, of Constantinople, on the subject of myrobalans fruits as a medicine, drawing attention to the undeserved neglect into which they have fallen, since from the middle ages to the beginning of the present century they were highly esteemed for their cholagogue, purgative, and astringent uses. They are still extensively used in Turkey and Persia at the present day as a laxative, possessing, like rhubarb, a subsequent astringent action. M. Apéry, however, appears to labour under a misapprehension with regard to the commercial varieties of the drug, since he regards chebulic, citrine, belleric and black myrobalans as four stages of the same fruit gathered at different degrees of maturity. This probably arises from the fact that Sanscrit writers on medicine recognize several kinds of chebulic myrobalans, dependent on size and age, very young fruit about the size of cummin seed being known as Halileh-i-zira, when of the size of a grain of barley as Halileh-i-jawi, when of the size of a raisin as Halileh-i-hindi, when half arrived at maturity and yellowish as Halileh-i-chini, when still further advanced Halileh-i-asfar, and when quite mature as Halileh-i-kabuli. Of these, however, the first, third and sixth only are in general use in India. The third when drid are the black myrobalans of M. Apéry, and are known in Turkey as kara-halileh (*i. e.*, black myrobalans), and are commouly carried by the pilgrims to Mecca for use in dysentery and diarrhœa, and are taken in powder in the dose of 1 drachm twice a day. The sixth, or mature fruits, are said by Dr. Waring to form an efficient purgative without griping or other ill-effects, the dose varying from one to six fruits. The citrine myrobalans are, however, the produce of *Terminalia citrina* and the belleric of *Terminalia bellerica*. These are largely exported to this country for tanning and dyeing purposes. M. Apéry remarks that water and dilute alcohol extract from myrobalans a considerable quantity of tannin, precipitating the persalts of iron bluish black, and afford also a greenish oleoresinous matter soluble in alcohol, ether, petroleum spirit and oil of turpentine; to this oleoresin M. Apéry gives the name of myrobalanin. He believes that an extract of the fruits would be found very useful in chronic diarrhœa. *Journ. de Pharm. et Chem.*, p., 140.

ROOT DROUGHT IN WINTER.

As soon as the great importance of through drainage dawned on cultivators, not a few of them rushed into the opposite extreme of keeping their plants too dry, especially throughout the winter months. This was only a natural, though doubtless in not a few cases it has proved a most mischievous reaction.

Possibly, more plants have suffered and perished through having an impossible dormancy forced upon them through drought, than through excessive supplies of water; while as to fruit crops, it is more than probable, far more have been dried than flooded off. Besides, the flooding off is more or less problematic, while the drying off is absolute matter of demonstration to all cultivators of experience. The *contretemps* of fruit-bud drooping is most common among stove fruits. I firmly believe, that it mostly orginates in dryness at the roots. No doubt, at times it is atmospheric or severe depressions of temperature chill the buds to such a degree as to lower their vitality and loosen their hold of the branchlets, or the frost or winds may be so severe or strong, as to virtually destroy or wither up the more vital portion or substance of the blooms on embryo fruit. But fruit-buds are mostly safe from such catastrophes or contingencies under glass. On the other hand, very few fruit blossoms in the open air succumb to drought. The natural rainfall in our climate, unless shed off by artificial means, suffices to prevent such losses. But the case is widely different with internal fruit borders or plants in tubs and pots. On or in these, water is given or withheld at will. Often it is withheld too soon, and too long to enforce early and higher maturity of growth in the autumn. When to this is added a long spell of drought throughout the winter, a very arid condition of roots results. When this is carried to excess either in degree or duration, there can hardly be a doubt that this unnatural dryness becomes one of the most fruitful sources of bud-drooping.

Possibly, the buds are virtually starved off for lack of food and moisture. The sap may become too thick and dense to move or flow freely to supply their urgent wants in time. Before such temporary failures can be made good, the connection between bud and plant may be irrevocably severed. This is the more likely; as, notwithstanding all the nonsense that has been written on the rest, sleep, and dormancy of plants, it seems certain that nothing analogous to the obvious meaning of these words occurs among them; on the contrary, it seems possible, that root-force is abnormally active during the so-called dormant season, and certain that the fluids of plants are never at absolute rest unless inspissated or frozen into solids. The former process may de accelerated, if not caused by, the forcible method of water. Against such fearful risks of excessive drought, there are no corresponding advantages to the plants. It is even doubtful how far drought at the root hastens or lengthens the maturity of the wood and buds; that it favours the growth of fungus among and on the roots is admited by every experienced cultivator. It also favours the growth of warts and canker, as well as hardens the bark and lessens the size of the roots. All this either fetters the fruit function or favours disease, therefore, excessive root drought ought to be avoided. So far as is known, moisture at the roots of our fruit trees is good, not evil—it neither injures nor kills. On the contrary, it keeps the fruit buds fully supplied with food and water, and so strengthens their hold on the plant when it passes through the critical setting period in safety. Fruit buds flooded off, probably a hundred are starved off. Our natural water supply is not excessive. It is not water at the roots, but stagnant water, that is to be warred against; and the art of thorough draining consists in setting and keeping the water in motion among the roots, not in shedding it off the surface of the land, or in leading it by the shortest cut, away from its natural ministry of aid for the roots, into the nearest ditch or river.—D. T. Fish.—*Gardeners' Chronicle.*

90

CEYLON AS A BARLEY-PRODUCING COUNTRY.

Nothing at the recent Nuwara Eliya Show was in itself more interesting, than the many exhibits of Ceylon-grown barley which the Murree Brewery Prize produced, and a few words as to the cultivation may be interesting. Many years ago, an attempt was made to grow wheat at Baker's Farm, but though wheat undoubtedly *grew* there, it was a failure as a crop. The climate of the Nuwara Eliya plain was found to be far too wet and windy for corn of any description, and the attempt was abandoned. Similar results have attended other fitful experiments in various parts of the country until quite recently, when Mr. J. W. Howard took over the management of the Murree Brewery in Nuwara Eliya. The equable climate of Uva, and the fertility of much of its soil, early attracted his attention, and suggested to him the possibility that barley might be grown there as successfully as on the plains of India. Seed was given to Dambewinne Ratamahatmeya, who interested himself in the experiment, and he distributed it amongst various cultivators in Udakinde, sowing a fair extent himself with the grain. The result has exceeded expectations, for, not only is the barley grown in Uva equal in weight and fullness to the home-grown article, but it is found to be very much more prolific and profitable than paddy. Those who attended the Nuwara Eliya Show, could not fail to be struck with the very fine samples of barley which were then exhibited. In the opinion of experts, they were generally inferior in color to English barley, but, tested by weight, they showed very well, Hy. Dambewinne's sample, which took the first prize, running up to 56½ lb. the bushel—a very good weight indeed, seeing that 54 lb. is considered an average at home. The success of the experiment initiated by Mr. Howard—so far, at all events, as proof that barley of good quality can be successsully grown in Ceylon is concerned—is complete. It is also placedb eyond doubt, that it is a more profitable cultivation than paddy, and we see no reason why the Murree Brewery in time should not obtain all their supply of barley from Uva, instead of importing it from Bombay. The imports of barley from India during the past two years have been as follows:—

	Bushels.	Duty 13 cts. R.	Value. R.
1886 ...	20,892 ...	2,716·04 ...	31,339·31
1887 ...	14,525 ...	1,889·11 ...	21,788·29

We take it, that the whole of this was imported on account of the Murree Brewery Company, who must be contributing very largely indeed to the revenue, for the whole of the goods they require have first to be carried over our costly line to Nuwara Eliya and then to be conveyed, very much increased in bulk, all the way back to the coast again. Of course, if these heavy transport charges can be avoided in the case of barley, it will pay the Brewery to encourage its local cultivation, and will enable them to offer a very much higher price than it would cost laid down in Colombo. We understand, that all the last crop has been taken over by Mr. Howard at the rate of R3 per bushel—about three times the value of village paddy—so that the cultivators have done extremely well with their first venture, and there is little doubt that their example will be followed by numbers of others. The field before local cultivators is not large, for it is unlikely that the grain will ever be grown so cheaply as to render it possible to export it at a profit; but the requirements of the local brewery are not small, and it, as we are informed, they use about 15,000 bushels annually, 700 acres of land now lying idle might be very profitably employed in producing this quantity of barley. The locality where the cultivation has been so successful, is in the vicinity of Welamadde, on the Nuwara Eliya-Badulla road. Hollows are selected where rich soil is good, and the rough growth is cleared and cleared, and as far as possible ploughed and sown. The best time for this is proved to be November, when the worst of the north-east monsoon rains are over and the soil is soft and workable. The young grain gets the last showers of the monsoon when it is green and

short, and by January the ears have appeared. In March it ripens and is reaped, and the land can either lie fallow till the end of the year, or crops of yams and other roots can be raised upon it; though whether a regular rotation of crops will be necessary we do not know. We think it is a great thing that native cultivators have taken so readily to the cultivation. In former years, the villages between Wilson's Bungalow and Wellamadde were all surrounded by native coffee trees and coffee gardens, but of late disease has played sad havoc with them. Many are abandoned, and those that remain are not very remunerative. The decline of coffee has in reality been as severely felt in the villages of Uva as in any part of the Central Province, and, once convinced that it is a paying crop, we feel persuaded many natives would gladly cultivate barley in small patches. Messrs. K. M. and D. A. Fernando, who took the second prize for barley at the Show, sowed less than 5 bushels, over 8 acres, and obtained 150 bushels, equivalent to about 33-fold. Considering that paddy cultivated in the ordinary fashion in Ceylon does not yield more than 14-fold, this result must be considered highly satisfactory, more especially if as much as R3 per bushel is paid for the crop! Of course, Mr. Howard is desirous of fostering the cultivation as much as possible in its initiatory stages, but, even if only R1·50 or R2 per bushel were paid, it would still be very remunerative to growers if anything like such satisfactory results can be obtained in the future, as have already been done. Mr. Howard, in what he has done, has doubtless been chiefly guided by a desire to work in the interests of his Brewery, but nevertheless, the greatest credit is due to him for what he has done and for the liberal manner in which he has given seed away *gratis* to cultivators and encouraged them with advice and assistance to persevere. We hope that in time the Brewery at Nuwara Eliya may cease importing barley at great cost from Bombay, and that the beer that is brewed there may all be made from Ceylon-grown grain, thereby allowing the Brewery in all probability to extend its operations and providing a number of cultivators with something over and above their crops of paddy whereon to live and prosper.—"Times of Ceylon."

THE PUBLIC GARDENS OF BRITISH INDIA, ESPECIALLY THE BOTANIC GARDENS.*

The appearance of the hundredth Annual Report of the Royal Botanic Garden, Calcutta, is an event of no little interest in the botanical world, not alone for what it contains, but also for the evidence it affords of the vitality and vigour of the institution, the primary object of which was to disseminate useful information respecting the vegetable products of the possessions of the "Company," and to introduce exotic plants of economic value.

Dr. George King, F.R.S., the present able Superintendent, gives a concise history of the foundation and progress of the Garden down to the present time; and the appendices show that the establishment was never conducted with greater activity. We might make some interesting extracts from the present Report; but our object now is to give a foreigner's view of the principal horticultural establishments in India.

Mr. Warburg roughly classes the gardens under three heads, according to their degree of scientific and practical utility, as distinguished from purely pleasure-gardens, though no hard and fast line can be drawn, because some of the gardens are maintained partly for pleasure and partly for profit. There are only three real botanic gardens in India—we let Mr. Warburg speak for himself—namely, Calcutta, Madras,† and Saharunpore, unless we count the garden at Gunesh Khind, near Poona, which is often erroneously called a botanic garden. Besides these, there is the botanic garden at Peradeniya in Ceylon, which, however, comes under the Colonial Office. Of the officially so-called botanical gardens, two were originally founded as such by far-seeing officials: Calcutta by General Kyd in 1786, and the Ceylon Garden by Sir Joseph Banks in 1810; the latter having been established at Peradeniya ever since 1821. The origin of the Sarahunpore garden in the North-West Provinces I did not ascertain [it was originally a pleasure garden of the native princes, and when Lord Moira conquered the Mahrattas, he caused it to be transformed into a botanic garden; and the first Superintendent was Dr. Govan (1816–23), who was succeeded by the better-known Dr. Royle, Dr. Falconer, and Dr. Jameson]; and the gardens of Ootacamund and Singapore have passed through various stages before attaining their present condition. Of agricultural experimental gardens, I am acquainted with those of Kandesh (Bombay Presidency), Saidapet (near Madras), Nagpore (Central Provinces), and Hyderabed (in the Deccan).

There is also a horticultural garden in Lucknow, an agri-horticultural garden in Lahore (Punjab), and the beautiful garden at Madras belonging to an Agri-horticultural Society. Similar Societies exist in Calcutta, Rangoon, and probably in other places; the first publishing a special Journal.*

In almost every town where there is a considerable European population or garrison, there are ornamental gardens or parks, called into existence by the demand, and almost necessity, for some such place for social recreation—riding, driving, and walking—in a tropical country, where many of the pleasures and amusements of our Europeans towns cannot be enjoyed. Then there are numerous extensive and costly gardens belonging to the native princes and nobles †.

Respecting the gardens having a practical aim, we may be very concise, as their objects are much the same, subject only to the climatal differences of the various provinces, and consequently the kinds of plants that may be profitably cultivated within their several radiuses of activity. The manner in which these practical ends are attained, consists on the one hand of experiments and trials in the acclimatization of useful and ornamental exotic plants; and on the other hand, of raising new and improved varieties of native plants, and when successful results follow, propagation on a large scale is practised for free distribution or sale. Thus, for instance, during the year 1884-85, the Calcutta Garden sent out 23,500 living plants to various places in India, and forty-two Wardian cases of plants to foreign countries. Further, some 3,000 packets of seeds were distributed; yet the proceeds amounted to only 1,075 rupees, because one of the principal functions of the Calcutta Garden is to provide the public gardens and pleasure-grounds with plants.

In the same year, the Saharumpore Garden distributed as many as 42,000 plants and 21,300 packets of seeds: whereof 31,400 plants and 14,000 packets to private persons; the amount received being 8,500 rupees. But ornamental plants, both as living plants and seeds, occupy the first position, while fruit-trees, timber-trees, and seeds of vegetables take a secondary place.

The Singapore Garden sent out the large number of 163,000 living plants in 1884. These figures, however, are merely extracted as examples of what is done by the different establishments, and afford no idea of their relative importance, inasmuch as the number of plants distributed by each one is subject to the greatest fluctuations; in illustration of which it may be

* Chiefly from an article by O. Warburg in vol. xliv. of the *Botanische Zeitung*.

† Mr. Warburg refers here, doubtless, to the Madras Presidency, as the botanic garden is at Ootacamund in the Nilgherries, and not at Madras. It should be understood that we are only extracting passages from a rather long article.

* And we may add that there is an experimental garden in the mountains at Mussoorie in connection with Saharunpore; another at Darjeeling, partly pleasure and partly practical; and an important experimental garden at Mongpo (Sikkim), under Mr. J. Gammie: the two last offshoots of Calcutta.

† We must pass on to what Mr. Warburg has to say concerning the conditions and functions of the botanical gardens and their adjuncts.

mentioned that the Saharunpore Garden distributed 116,000 plants in 1882-83, against 42,000 in 1883-84; the difference being almost made up by 100,000 plants of agave. Similarly in 1884 the Horticultural Gardens in Madras sold 100,000 plants of the "Mauritius hemp," *Fourcroya gigantea*.

As already observed, the nature of the work of the different gardens varies according to the requirements of each district. In many parts, especially in Ceylon, the Nilgherries, British Sikkim, the interest of European planters have to be considered first; in the rice-growing district of the Ganges, Malabar, and Ceylon, the things cultivated in the gardens and plantations engage special attention. In Bengal, jute, indigo, and to some extent opium, and in Central and Nothern India improvements in the cultivation of cereals, are of primary consideration; while in the Bombay Presidency and some parts of Ceylon, cotton is added thereto; often associated with the latter the sugar-yielding palm, *Borassus flabelliformis*. For the dry regions of the Punjab, it is a question of finding suitable woody plants for afforestation, as well as for the saline soil of the North-West Provinces, in order to provide fuel for the agricultural districts, and thereby gain the dung of cattle for purposes of manuring. And among other things of vast importance is the conservation and renewal of the rapidly disappearing caoutchouc forests of Malaca.

The Singapore Garden has only been a scientific establishment since 1882, when it was placed under the direction of Mr. Cantley; but much has been done in these few years without destroying the natural beauties of the old garden. A small herbarium has been formed, and the most necessary buildings erected. The new plantations are, as far as possible, systematically grouped. A special charm of this Garden is a remnant of the original forest, traversed only by a few paths, where one can enjoy, in a small way, the delights of tropical vegetation without the fatigue attending excursions in pathless forests. The fern garden and the palmetum promise to be very rich and attractive; but a larger income is necessary to carry out the functions of a botanic garden fully and expeditiously. It is perhaps superfluous to add that the Director has to superintend the gardens and promenades of the town; but in order to understand the whole of the circumstance, it is important to bear in mind that he has also been placed at the head of the newly created Forest Department for the whole of the Strait Settlements—an arrangement which of course causes him no inconsiderable amount of additional labour.

Seeds and plants are continuously being distributed from Kew, where all new things are reported and presented, and where competent authorities are consulted on the merits of the samples sent in. At this centre advice is sought, and there is a constant interchange of ideas and experience between it and the Indian establishments, the advantages of which are so evident that it is unnecessary to enumerate them.

With the exception of rice, tropical cultivation generally is so uncertain and subject to fluctuation, owing to the conditions of labour, communication, and credit, that improvements are very slow; and the experimental work is not so systematically conducted as with us. There are too few officers, and everybody has too much to do; nevertheless, many of the reports exhibit an amount of zeal and industry, deserving of all the more recognition on account of the difficulties under which much of the work is done.

From this point, Mr. Warburg explains and describes in some detail, what has been effected by the combined action of Kew and the Indian botanic gardens in the introduction, resulting in the extensive cultivation of economic plants of the first importance, such as the cinchona, tea, and coffee, the cultivation and manufacture of which have developed into industries of incalculable value. He further alludes to the cultivation of rubber-trees, gum-yielding plants, &c., which is, in many instances, still in a more or less experimental stage. He also enters into particulars and comparisons of the climate of different districts in its relations to cultivation, and altogether his Report is an interesting and instructive one, containing much information new to the English public. He specially mentions the great interest taken in the Madras gardens by Sir Mountstuart Grant-Duff, and the material assistance he extended to Prof. Lawson. And he concludes with a brief review of the literature directly or indirectly connected with the botanic gardens of India, culminating in Sir Joseph Hooker's gigantic undertaking, "The Flora of British India." With regard to the intimate connection between Kew and the Colonial and India gardens, Mr. Warburg thinks it is at present most beneficial, though he looks forward to the time when they shall have developed so far as to be less dependent on a central institution.—*Nature*.

REVIEW OF SUMATRA TOBACCO.

Regarding the U. S. Tariff question, already so often treated, we have very little to say this time, as the past year offered no new points of view worthy of any discussion. The uniform duty, so long desired by every one in the Sumatra leaf trade, is still wanted, and the only change which has taken place, was in in the mode of application. At present the Appraiser opens one bale out of ten and "ten hands" are taken out of this, by which the percentage is determined for the duty of 25 and 75 cts., which is in so far an improvement, that the Tobacco in the bales is not so much destroyed as formerly, when the appraising was not confined to so small a number of "hands". According to our opinion, a uniform Tariff is not likely to be introduced, unless the enormous surplus accumulated at the Treasury, according to the speech of the President at the opening of Congress, should also bring profit to our Sumatra Tobaccos, either by the reduction or abolition of the duty, which in all cases is an unjust tax towards our Sumatra Produce. But, as stated above, we have no doubt, that the Protectionists will take care by their manoeuvres to retain the majority. How badly the present rules work, and in how different a manner they are applied by the appraisers, is sufficiently illustrated by the candid words of an American Manufacturer, published in the "U. S. Tobacco Journal," of Nov. 12th. He said, a. o.

"The present arbitrary scale was the cause of endless confusion and annoyance. It tended to unsettle the market price of imported tobacco, and left a wide range for fraud, such fraud as was always observable, sometimes directly and sometimes only circumstantially, whenever the rate of duties was optional. With all those with whom he has conversed in any way connected with the trade, he had heard the same complaints. It was not for him to say, whether there was bribery or collusion. He did not know whether there was, or not, and therefore, would not attempt to pass a judgment. But it was, however, a fact that two and sometimes three different prices were being asked for the same quality of tobacco in the market to-day."

This season again was a very favorable one for Sumatra Tobacco. With an increased Import, prices not only held their ground, but thanks to the want of competitive tobaccos suitable for wrappers, they advanced considerably above those of last year. Whereas, formerly, the export to the U. S. commenced with the shipment of small parcels, to judge the quality of the crop, and be able to act accordingly in the subsequent subscriptions, this year the first sale was already a foreboding of the large demand to be expected from the U. S. At the first sale a "running-lot" was brought for American account, and the marks thereof not suitable for the U. S., resold to the European trade. This was sufficient proof, that the new crop would be well received, which was promptly confirmed by the fact that all "Firsts" out of superior parcels, whether of the required weight or not, were taken at high prices. The stock of good parcels being soon exhausted, whilst there remained a very little on hand of inferior ones, some fatty "Seconds" were also taken

for the U. S. Although the market opened high, prices continued to rise regularly, and the highest figure was attained in the September subscription, when, for instance, series of "Firsts" weight and no weight, out of the best parcels brought together 350 c. D. crey per ½ Ko. Taking into consideration, that a certain quantity of these were not at all faultless, it can be reckoned that the best marks among these series brought 380 and 396 cts. for some "Seconds" also nearly 300 cts, was paid. These high prices were carried over through the October and November sales without any perceptible rise.

The good demand for "Firsts" at the duty of 35 cts. as well as 75 cts. for fine qualities, prevailed throughout the entire season. The consequence was, that the figure realized for this crop considerably over-reached that of its predecessor, notwithstanding the quality being inferior. Considering the outturn of the crop, we have met with many faulty colored tobaccos. Where the color was often not motley, it showed fallow and greenish. Of course with such a number of parcels as we received this year, there were many which in this respect made a very favourable exception. In some parcels, the leaf are somewhat tender, in others the nature of the tobacco was too dry, and the leaf therefore lacked the desired elasticity and stretch. On the other hand, this crop possessed the good quality of being light in weight, compared with that of 1885, and with less holes in the leaves, thus working more economically, and allowing the importation at the 75 cts. duty to become remunerative on account of the large number of leaves going to an Amer. pound. The burn of the tobaccos from Deli and Lankat was good; that of the other districts, of Serdang, Bedagei and Batoe Barah was again less efficient, which was all the more to be regretted, because the greater part of these tobaccos contained the finest colors combined with sound leaf. All conditions of colors, leafiness, and even burr, cannot be put down to any fault of the planters, as being too closely connected with the quantity of rain falling during the growth, or the special situation of the grounds. But we do find fault with the assorting by the planters, which in only too many parcels showed a want of such care, as, with such high prices ruling, buyers are more or less entitled to. It is with pleasure, however, that we noticed the improvement in this respect in some marks, for instance, the parcels of the Deli-Batavia-Maatschappij, imported by the Dutch Trading Company, were much better assorted and especially better packed, which no doubt greatly influenced the prices realized. If planters will follow the matter up, experience will show them, that, with continued careful treatment, assorting and packing of their tobaccos, even should the production increase considerably, their goods will readily find buyers. As a proof, we mention that the Tobaccos of Deli Maatschappij's and Amsterdam Deli Compagnie's plantations are always most readily sold.

The first question asked by the important buyers from across the Atlantic invariably is: How is the Tobacco packed, are the bales square and firm? During the season, all our old American friends put in appearance, with many others visiting our market for the first time. With varying results, the large buyers competed for the different parcels, so that the shipments to the U. S. came up the considerable figure of about 36,000 bales. The 1886 Crop produced about 15,000 bales more than that of 1885; the proportion of "broken leaf" being pretty much the same, viz., 25 per cent against 28 per cent for the former crop.

The average sale price of this crop was 56 cts. U. S. Crcy., or 4⅝ cts, equal to 10 per cent advance over the former. The parcels were readily realized by subscription or by private sale with the exception of a few lots sold in auction, chiefly consisting of Tobaccos of deficient burn. The total unsold amounts to 771 bales, not for want of buyers, but an account of careless treatment or other serious faults. From Assahan, for the first time, some small parcels came to our market, and also to Bremen: color and nature were very good, but the burn was not desirable.

Reviewing the imports of Tobaccos, competing (?) as Wrappers with Sumatra, we can name the following:—

From Borneo, a few small parcels, of fine leaf, and good color, which fetched a high figure. Burn and flavour this year were very satisfactory and compared with the crop sold last year, a considerable improvement is observable, as far as it is possible to judge by such small quantities. Only with larger receipts it will become possible to determine, whether this produce can count as a competitor of Sumatra. From Ceylon 170 bales arrived, of which 52 bales of excellent quality and colors and suitable for wrappers fetched a high price. The last import of 55 bales, only fit for binders and fillers, remained unsold when offered by subscription, and only partly found buyers when brought to auction afterwards. The burn was satisfactory, the leaf rather thick, coarse and green.

At Rotterdam 53 bales were imported from Menado (Island of Celebes). The leaf was good, but the tobacco seemed to have been hardly or not fermented; hence unripe and green colors and bad taste. If the planters wish their undertaking to be successful, their first duty is to treat the tobaccos in conformity with the requirements for attaining a useful produce. From Malacca 301 bales were imported of very inferior quality, only finding buyers at a very low price.

The American papers brought us the news, that a Company has been founded at New York, to recommence the culture of the formerly well-known Florida tobacco. The new Company seems to have a very sanguine opinion of the success of this undertaking.

We, for our part, do not think Sumatra has anything to fear from it, because the ground is not so suitable as in Sumatra, and, as far as we know, the experiments with Sumatra seed under different climates have never given satisfaction.

The soil in Florida is at a disadvantage, inasmuch as it is too poor to produce without fertilizers being added, moreover, the climate promotes the growth too quickly, whilst in Sumatra, Tobacco matures gradually, and with a normal growth, the leaves attain regular proportions. The former Florida Tobacco always showed wild, large and irregular leaves, which is not an advantage in manufacturing. This year several new Companies were again founded for the cultivation of Tobacco in Sumatra, in districts not yet under culture, and if they succeed, a much larger import can consequently be looked for.

The record of this year, so favourable for Sumatra Tobacco, finishes with a great disaster. The Steamer "W. A. Scholten," which left Rotterdam on Nov. 19th bound for New York, with a costly cargo of Tobacco, consisting of the most select marks of the subscription of Nov. 4th, was run down near Dover, causing the loss of 1,617 bales Sumatra Tobacco amongst which the well-known marks:

DELI MAATSCHAPPIJ/A, TR/DELI,
——,,——/E,DELI Ba. MIJ/ TL
/DELI,
——,,——/H,

valued at about $ 280,000.

The fine Tobaccos lying in America will no doubt profit by this loss. The reports concerning the new Crop are not unfavorable, the quantity however is inferior; but at present it is impossible to give any definite prediction of the outturn.

S/d. BINGER & HERCHEL.—*British North Borneo Herald.*

CEYLON.—Dr. Trimen has rendered good serviceby the publication of a classified list of the plants, both native and exotic, growing in the Royal Botanic Gardens, Peradeniya, Ceylon, the two categories of plants being carefully distinguished. The catalogue is arranged after the sequence adopted by Bentham and

Hooker. Very few synonyms are added, but the Sinhalese and other vernacular names are appended. An alphadetical index of genera is also supplied. No numerical lists are given, but the catalogue comprises no fewer than 120 pages, with, at a rough computation, twenty species in each at least, so that not far short of 3000 species must be comprised in the garden record.—*Gardeners' Chronicle.*

THE SUNFLOWER AND MALARIA.—It is stated that since the sunflower has been cultivated on certain swamps of the Potomac, malarial fever has decreased. At the mouth of the Scheldt, in Holland, it is stated that similar results have been obtained. The sunflower emits large volumes of water in the form of vapour, and its aromatic, as well as the oxygen it exhales, may have to do with the sanitary influence in question.—*Cassel's Magazine.*

ORANGE PUDDING.—Peel and pick to pieces four or five oranges (according to size), put into a pudding dish. Sprinkle sugar between each layer. Be careful to take out all of the seeds, as they give a bitter taste. Take the yolks of three eggs, one tablespoonful of cornstarch, one cup of sugar, and one pint of sweet milk. Boil this custard. When it is done and still hot, pour over the oranges. Beat the whites of the eggs to a stiff froth, add two tablespoonfuls of sugar, and put it over the pudding, and place in the oven until it is a delicate brown color.—*Rural Californian.*

TEA CULTIVATION.—Indian Tea now forms 50 per cent. of all the Tea used in this country, whereas no longer ago than 1865, China furnished 97 per cent. According to an article in *Nature*, the Australians consume 81 oz. per head of the population, English people 73 oz., while the inhabitants of the United States come next with 21 oz., those of Russia, Belgium, Holland, and Denmark consume only from 7—8 oz. per head of the population. Unfavourable contrasts are sometimes drawn between the services rendered by botany and botanists to the State, and those rendered by chemists and engineers. The botanists, however, can show a good record—Indian Tea, Chinchona, Cotton, India-rubber, Guttapercha are all substances, the development, and, in some cases, the discovery of which was due to botanists, and their culture to horticulturists.—*Gardeners' Chronicle.*

THE SECRETION FROM ROOTS.—Recent investigations on this subject undertaken by Dr. Hans Molisch have shown that the acid secretion from the roots of plants attacks organic even more powerfully than inorganic substances, not merely dissolving them, but causing in them important chemical changes. It exercises both a reducing and an oxidizing power. It stains guaiacum blue. It oxidizes tannin and humin substances, and hence, greatly promotes the decomposition of humus in the soil. It transforms cane-sugar into reducing sugar, and has a slight diastatic action. Plates of ivory are corroded by it. The root behaves in many respects like a fungus, especially in the fact that the fungus alters the organic constituents of the soil by definite excretions, and causes their more rapid decomposition. This root secretion does not merely impregnate the epidermis, as has been generally supposed, but is often excreted over its surface in the form of drops.—*Pharmaceutical Journal.*

GRAINS OF PARADISE IN PEPPER.—A new adulteration of pepper has just been noticed by M. Fabri, a student at the Nancy College of Pharmacy. Grains of paradise is the substance employed. As the prices of the two substances are not very different, there seems to be no reason for a fraud of the sort, were it not that the grains being about twice as pungent as pepper, every pound of these added will enable the sophisticator to introduce one pound of some inert substance. The most usual mixture is said to be made with equal weight of pepper, grains of paradise, and starch, which gives powdered pepper of very fair appearance. But the fraud is easily detected, because true pepper contains no tannin, while the adulterant does in notable proportion. The test may be applied by macerating the suspected powder with a mixture of two parts of alcohol and one of ether, and adding to the filtered liquor one drop of ferric chloride solution. Pure pepper affords no colouration, while a deep greenish brown will indicate the presence of grains of paradise. Other common adulterant of pepper, such as date or olive seed, strike a slight green colour with the ferric solution; but it is so different from the other that no possible doubt can be entertained.—*Chemist and Druggist.*

LONDON: CINCHONA.—South American Bank: Only slightly over 100 packages sold, old *Cuprea* at the low price of 1¾d per lb., and some fine *Calisaya* quills from the Bolivian plantations at 10½d to 11d per lb. West African Bank: The supply consisted of 79 bales and 2 cases, imported via Lisbon from the island of St. Thomas. The quality was not very good, and the whole lot sold at 4½d to 5d for fair *Ledgeriana* chips and weak small quills, and 3d to 3½d for weak young ditto. From a private letter which we received this week from a Ceylon planter (who is not personally interested in cinchona) we abstract the following:—"There are still large quantities of bark, both growing and stored, throughout the island, and shipments will largely depend upon the obtainable price. The bottom, however, has been touched, and very little cinchona is being freshly planted. Harvesting early means the extinction of the tree, as shaving leads to renewal, and coppicing to fresh shoots. Still, from ill-health arising from various causes, a very large percentage of the trees dies out every year, and when a tree is thus seen to be dying, it is at once taken out and fully harvested—root, stem, and branch. Any considerable rise in price would at once increase the yield of bark beyond what it otherwise would be; but the total available supply, or, say, the number of growing trees, is long past the maximum, and must continue steadily to fall, with little probability of any future increase. Much unsuitable land was once planted with cinchona that never will be so again. There is little available land left, and most of that would be preferred for tea."—*Chemist and Druggist*, Feb. 18th.

ANTS AND PLANTS.—In the last volume of the *Nova Acta Regiæ Societatis Scientiarum Upsaliensis*, Professor Lundström publishes some remarkable information on the relation between ants and plants. Studying the nectar produced on the leaves of the Cow-Wheat (Melampyrum) he found that ants were attracted by the nectar on the leaves, and that some while walking over the leaf bore the seeds of the Cow-Wheat in their mouths down towards the ground. Professor Lundström was astonished by the great resemblance of these seeds to the "ant-eggs" (the cocoons of the ants), and he found that the ants took these seeds for cocoons; for when he strewed some seeds on the ground the ants saved them as they did their cocoons. Lundström afterwards found that the thin membrane which surrounds the seed and causes it to resemble an ant egg so closely, falls off soon after the seed is brought by the ants to the soil, and that it remains there untouched by the ants. Another observation of the same author, noteworthy for aboriculturists, is the following. At Christineberg, near Hudiksvall, the soil in an avenue of Populus tremula was dug and the ants, which were formerly very numerous, disappeared in consequence. In the next year Professor Lundström found that the leaves of these Poplars were destroyed by insects in a short time, whilst those of the other Poplars, where the soil had not been dug up, were quite intact. Careful observation showed that the first leaves of the trembling Poplar have short round petioles with nectar glands, whilst the petioles of the older leaves are much longer, flat, and without these glands, as Professor showed in the *Botanical Gazette*, vi. (1881). Lundström's notion is, that the ants are attracted by these glands, and preserve the tree from the attacks of caterpillars, &c., for the first time. At a later season, the leaves with the long, flat petioles are so much disturbed by the movements of the leaves, that no caterpillar can go on them. The author found ants in every situation where the trembling Poplar grew.—*Gardeners' Chronicle.*

PLANTING IN NETHERLANDS INDIA:

CHINESE SWARMING INTO JAVA.

TERMS FOR LEASING LAND IN NORTH BORNEO.

(*Translated for the "Straits Times."*)

In the district of Charingin in Java which had been laid waste and depopulated by the volcanic outburst at Krakatau five years ago, jungle has been overspreading the land. Tigers have in consequence increased and multiplied, notwithstanding the high rewards set upon them by Government. They have struck such terror among the people, that the latter have forsaken several districts, and removed elsewhere. It is expected that the tigers will follow them up.

The Batavia *Nieuwsblad* says that all the buildings at the petroleum springs in Langkat, now worked under a concession from the native authorities, have been burned down. The resulting pecuniary losses are something serious. The Government has spent a large amount on plant and machinery for testing the wells. A mining engineer has since gone to the spot to inquire into the matter, and see what can be done. Hitherto the enterprise had been mostly carried on at Government expense, the concessionary having had little to say. It remains to be seen whether the Government will feel inclined to go on with the undertaking. The presence of petroleum in the district has been proved beyond question. But it has not yet been determined whether the quantity available will pay for working the deposits.

The States General have passed the Bill for transferring the mail contract in the India Archipelago from the N. I. S. N. Company to a Dutch syndicate. The Java *Bode* says that the news has been hailed with some satisfaction by the mercantile community at Batavia, from hope that the change may prove an improvement upon the existing order of things. The virtual monopoly exercised by the N. I. S. N. Company has not been relished by them.

The planting community in Java are growing restive under the load of taxation weighing upon them. Appeals to the Government to lighten the burden have invariably come to nothing. Petitions for redress found their way into official pigeonholes for good. The lessees of Crown Land not only complain of the heavy incidence of the taxes, but also resent uncalled for hindrances and obstacles in the way of their lines of business enterprise. The Home authorities talk glibly enough of reform and improvement, but seldom go beyond a flow of words. The planters looking for deeds not words, become discouraged and long for a change. Many of them have in consequence turned their gaze upon British North Borneo. Those who ventured there, found the prospects so attractive, that they took to the country, and sent word to their fellows, announcing it to be veritable land of promise. Others came back with nothing but praise of the fertility of the country, and the liberality of the Government in land matters. The managers of the Batavia *Nieuwsblad* fancying that the accounts they brought were too glowing, wrote to the Government of British North Borneo to inquire how, and on what terms, land was leased there. The reply ran as follows:—

Land and Survey Department, Sandakan,
9th Feb. 1888.

Sir,—I am requested by His Excellency the Governor to acknowledge your letter of the 17th January and to give you in reply all information respecting Land in British North Borneo.

The price of country lands over 100 acres in extent in British North Borneo is $1 per acre, in return for which a Lease is granted free from Rent for 999 years, or, should the buyer prefer it, he may pay 50 cent per acre and ten cent per acre rent per annum, with the option of redeeming the Rent charge at any time by paying $1 per acre. One-third of the purchase money must be paid at the time of selection and the balance within twelve months or on the signing of the Lease. The land will be surveyed by the Government at the expense of the Lessee on the printed scale of Fees (vide Land Registrations.)

All land is sold subject to improvement, viz.:—planting must commence within 18 months and one third of the acreage should be opened within twelve years.

There are no export duties on estate produce at present, and in the case of tobacco it has been specially provided that there shall be no export duty before the 1st January 1892, and that for 20 years after that date the duty, if charged, shall not exceed one dollar cent per English pound.

The import duties apply chiefly to Liquor, Opium, and Tobacco, and the export duties are chiefly on jungle produce. Tools etc. are free of duty.

Labour is fairly plentiful. The last steamer from Singapore brought 320 Chinese for the Tobacco estates. In Sandakan, Chinese labourers are obtainable at $9: and Malays at $8: to $9: per month. There is a strong desire to obtain direct communication with China. It will shortly be a necessity, and, once commenced, labour will be easily obtainable at low rates, as the distance is only five days steam from Hongkong.

There are three European Firms in Sandakan who would arrange for estate requirements in the way of Tools etc: and would buy produce. The Treasury does the banking business, but it is understood that a Banking Company are about to establish themselves at Sandakan with branches at the outports.

The chief products of British North Borneo are tobacco, pepper, sago, and coffee. The three first have been cultivated for some hundreds of years, and latterly attenion has been drawn to the high quality of the Estate Tobacco while the high price of pepper is stimulating that planting industry. Liberian Coffee appears to be well suited to the climate and the Experimental Garden at Silam and Mr. Christian's Estate at Kudat afford valuable evidence that it will be a profitable cultivation.

The rapid development of the Timber Trade and the facility thereby afforded to landowners to sell their timber to wood-cutters should decrease the cost of estate opening, if near the water frontage. How much capital is required is a question I do not feel able to go into, in the limits of this letter. I will merely say that a planter can begin opening his land the day his selection is approved of by His Excellency the Governor. The Government wish to see the land cultivated and afford all reasonable facility for prospecting, and the Land Office (and officials generally) afford all information in their power.

Communication with Singapore is maintained by four regular trading steamer, these are supplemented by occasional steamers,—and from Sandakan Bay two timber ships have already, this year, left for China ports and two others are now loading.

I send you a map of the Territory whereon I have marked the principal stations by a red flag.

I also send you copies of the Land Regulations in Dutch and English, and shall be glad to supply you at any future time with further information which you may also obtain from our Agents, Messrs. A. L. Johnston & Co., Singapore, who have a supply of maps etc. for sale.—Your obedient servant, HENRY WALKER, Commissioner of Lands.

In Java, the land is leased out on obstructive conditions. A lease from Government may run for no longer than 75 years. There is no chance whatever of securing ownership rights. Payment of the price in one lump-sum is out of the question. Lands are either offered or applied for, and granted on lease at a yearly rent fixed from time to time. The present minimum rate is 2.86 per acre yearly. In British North Borneo, for that amount, the same area of land may be obtained on lease for 999 years without any risk of the rent being raised. The planter in Java is excused from payment of land-tax during the first six months of occupancy. But he has to bear fiscal burdens, notwithstanding. He has to meet outlay on a coolie poll-tax, and a license tax. His produce has to pay toll. High railway charges and export duties form a grievous drain on his finances. A horse tax and other levies remind him unpleasantly that the Government has not done with squeezing yet. Year after year the fiscal screw gets a few more turns, simply because he happens to be a lessee. In British North Borneo, after

paying once for all the price of the land selected, he becomes exempt from the Collector's call. It need hence excite no wonder that British North Borneo has proved a powerful magnet in drawing away people from Netherlands India,

The Sourabaya "Courant" lays stress on the circumstance that the Chinese element has latterly been increasing in Java, to an undesirable extent. Of late, swarms of immigrants from the Celestial Empire have settled down in Java. Many of them ply the calling of hawkers, and as such find their way into the interior more and more. Their presence in the interior will not lead to disturbance, but they are likely to do harm when the Java-born Chinese combine with them. The newcomers settle down in the inland districts, usually without asking leave of the officials. When they once effect a lodgment in any place, the natives soon feel the evil consequences. Their weak points soon become manifest to their Celestial neighbours who do not fail to profit by the knowlege. Their vices are artfully encouraged and turned to account in the direction of usury, opium smoking, and gambling. The Chinese, when a footing has been gained inland owing to the heedlessness of the authorities, soon develop their powers of mischief. They always manage to take an ell when given an inch.

CEYLON UPCOUNTRY PLANTING REPORT.

16th April, 1888.

GENERAL RAIN AND GENERAL ACTIVITY—COOLIES, ADVANCES AND DEBT—TOBACCO—CACAO AND DROUGHT.

Now that the rains have been general, and of a liberal nature, the enforced inactivity which the late dry weather rendered necessary has come to an end. The cry everywhere is for coolies to keep up with the rush of flush, and as is usual when a squeeze comes, there is a good deal of wild talk regarding advances. I heard of one man who wrote to his agents in Colombo to sanction R20 a head, and got the sanction! It is to be hoped that there are not many who will follow this foolish example. If men on the ground are to be subsidized in this way, we will never have coolies enough do what we like. It certainly won't be their interest to import labour, and if they are to do so, what kind of coast advances would satisfy? Ramasami dearly loves to be in debt, but this weakness of his should not be fostered overmuch, if we are to have the full labour supply which the tea enterprise demands.

The big Tobacco Company is felling 100 acres in Kurunegala for the cultivation of that plant. Other clearings are being opened, and there should be a demand very soon for a Tobacco Manual. Indeed the demand is on now, for several men have been importing seed from the best centres, and they are feeling about for information. Everyone seems wiser than his neighbour, and if you got a wrinkle it is given, and expected to be received with bated breath.* The tobacco manual would be sure to find a good many readers, and put a stop to this exciting style of communication. There is abroad a sort of undercurrent of belief that to go into tobacco is the next thing to having a fortune left you, and when a man tells you anything about it, he places you at a disadvantage, and expects to see lovely gratitude on your part.

The manner in which CACAO has stood the late drought, is the admiration of all who have taken an interest in it. I suppose the trees being older and the roots deeper may be part of the reason, for whereas the hardy tea has had a bad times, the cacao has had a very good one. And now that the rain has come, the hatfuls of blossom which are clustering on stem and branch are full of promise. This alone was wanting to make the ideal cacao tree complete. If the blossom should set well, and the weather is certainly favourable for this, there should be a fair crop to be gathered, albeit it will be two months late. Although the drought did not seem to affect the full-grown tree except in a favourable way, the supplies which were coming up have been rather tried by it. A considerable percentage of those have died. How constantly supplying is wanted in cacao, is known best to those who cultivate much of it. Only when you do get it thoroughly established there is then, with any kind of decent care, a promise of long life and prosperity.

PEPPERCORN.

* See an immense amount of information in the *T. A.* volumes.—ED.

PLANTING REPORTS FROM THE HILL COUNTRY OF CEYLON.

THE WEATHER AND RAINFALL—A RARE "STICK INSECT."

NANUOYA, April 16th.

When I wrote to you on Friday the 13th, the heavy rain of that day led me to believe that "the little monsoon" was fully upon us. This I still believe, although after the 76 cents of rain on Friday there came an interval of fine weather, Saturday the 14th and Sunday the 15th were types of glorious summer days "at home." Today also rose fine and continued bright until about 2 p.m. The thunder which then commenced and the smart shower of rain which then fell, did not surprise us in view of the oppressive and sultry heat which previously prevailed. We shall see tomorrow morning what the record of the 24 hours will be. As yet for the 3½ months of this year ended yesterday, our total rainfall has been only 6·07 inches, as per enclosed memorandum. Largely, no doubt, owing to the thorough saturation of the soil in the last quarter of 1887, the tea, and I may add all other cultivated plants, are flushing splendidly. All looks beautiful and fresh.

RAINFALL AT UPPER ABBOTSFORD:—

					Average for 5 years.
1 APRIL	·05	Jan....	·18	Jan...	2·69
5 ..	·01	Feb..	·12	Feb...	2·45
6 ...	·01	Mar...	3·13	Mar...	3·27
7 ...	·01	April	1·32		
10 ...	·43				8·41
12 ...	·05		4·75		
13 ...	·76			April (whole month)...	4·73
up:	1·32				

Today I have come upon "a stick insect" such as I never saw before. It has no legs, like the mantis about which I recently wrote, unless what looks like a nodule in the middle of what seems a bit of twig about 3 inches long, contains the rudiments of legs, or serves some purpose of locomotion. The mouth of this anomalous creature resembles exactly undeveloped buds. The opposite extremity is blunt. But what has surprised me most is that this species or variety of mantis (?) seems to be provided with a *spinneret* and able to let itself down by a long thread like a spider. When the creature appeared at the end of a thread suspended from the bough of a tree, I never doubted it was a broken bit of twig which had got entangled in the thread of a true spider. But when the thread got caught by a bunch of flowers in my hand the supposed twig hauled itself rapidly up by the cable and fixed itself to the leaves, on which it actively used its strange mouth. The imitation of a bit of dried twig is perfect. But will any entomological reader tell me if the provision of a spinneret is well known in the case of the mantis tribe?

April 17th.

The short but heavy thunder-shower of yesterday, resulted in only 60 cents of rain here, but there must have been quite a rain-storm on the Nuwara Eliya ranges, for the rivers came down in full flood and the waters were loaded with earthy particles. Today rises beautifully fine and fresh, but the atmosphere indicates saturation with moisture. As yet "the little monsoon" has been distinguished by the mildness of the winds, even when they have blown markedly from the South West.

UDUGAMA IN 1847 AND 1888.
COFFEE *Vs.* TEA.

I visited Udagama in 1847, in order to see the abandoned estate of Oodellamatta, and to report upon the land thereabout. The estate paths having grown over with jungle, interlaced with the vines of the pitcher plant, the last two or three miles of the journey cost me a very severe struggle, and the estate itself, when I emerged, was a ghastly sight. The remains of the bungalow, from which the doors and windows had been taken, skeleton-like, a symbol of death dominated over a desolation which seemed irredeemable. Even the indigenous vegetation seemed to be scared from the spot, where only a reddish yellow surface of baked clay was visible, with here and there a vain attempt of some undergrowth to establish itself. A glance was enough to satisfy anyone that the estate had been wisely abandoned, for there was not a single coffee plant remaining. Eve y one had succumbed, and all trace of there having been any coffee there had been obliterated by white-ants or decay. The forest around was heavy, but all the best timber had been stolen and floated down the river. I therefore quitted the spot with the conviction that the land was practically worthless. I never expected to see it again.

When I heard, some years ago, of the new enterprize of the Udagama Company, and that it was undertaken by men of such experience and skill as the Directors undoubtedly are, I presumed I had seen only the worst of the land, and that the new Company had discovered some of much better quality. Still, failure seemed to me to be, even in their hands, more probable than success in such a locality. From time to time, in passing through Galle since the Company commenced its operations, I have often intended to revisit the district, but have never been able till now to carry out the intention.

This time I was able to drive into the very heart of the district, and, in doing so, had the opportunity of noticing, by the cuttings in the road-sides, the nature and depth of the soils. But *now* these soils, which in the old days of Ambegamuwa we planters associated with the terrible failure of coffee, have assumed a new character for tea. My first impression, therefore, as I entered the district, was that of the incalculable change the introduction of tea has made upon the condition and prospects of the country. It seemed as if the failure of coffee had proved a blessing, in turning attention from a product which at least was cultivable only within a circumscribed range of elevation and on virgin lands, to one suitable to a much larger area and to an infinitely wider range of soil including much that would not grow coffee. Sympathy for the prodigious losses and heart-breaking disappointments the Ceylon coffee planters have suffered, must erelong give place to congratulations on their having at length hit upon the *true staple* of the island, an enterprize which will reward the toil of the cultivator at all elevations, for which there exists an almost inexhaustible supply of land. It seemed, when the decline of coffee commenced, that we had already exceeded the limits of profitable area; but for tea cultivation there still remains ample scope for extension in many directions.

Udugama under the new conditions has come to the front. The district which was so hopeless for coffee is now flourishing in tea. The pioneers, it seems, did not at first recognize the true policy, but wasted their skill and energies on new products, which failed and forced them, *nolens volens*, to acknowledge their best friend. Already a fair start has been made in the right direction, and there are flourishing fields of tea yielding good results and giving excellent promise. It is a pity the pioneers were so hard to convince, but they are now making amends for past loss of time. Some of their tea is the finest jât I have ever seen.

There is in many parts of the district a good depth of every suitable soil, far better in every point of view than that I first saw at Oodelamatta, though of a character which in those remote byegone times, would have been discarded as hopeless for the staple, and only staple, of that period. There remains but little trace of any of the new products, which therefore have left a clear field for our grand and new staple tea. There are, however, a number of thriving belts of areka palms, and also some fairly good sappan, which, except as a fence, were better discarded. There is a good time coming for old Udugama, and ere long it will outlive the curse of a bad name which is probably one of the most enduring and oppressive of all curses.—G. W.

A RAILWAY THROUGH A PLANTATION OF PALMS.—A railway through a Palm grove is a novelty to most gardeners, we therefore avail ourselves of Mr. C. B. Clarke's kindness by giving an illustration taken from a photograph made by that botanist, who also kindly furnishes the following particulars:—This view is from a photograph of the railway near Theria Ghat, in the Khasi Terai, in East Bengal. The Palm is Areca Catechu, which is largely cultivated at the foot of the Khasi Hills, where it grows as luxuriantly as in the islands at the mouth of the Megna, and attains 80 feet in height. It is the Palm which supplies the Betel-nut chewed throughout South-East Asia and Malaya; and from its exact erectness is likened by the Sanskrit writers to an arrow shot down from heaven. The railway depicted is worked, at the foot of the hill, by a locomotive; it ascends the face of the Khasi Hills 3000 feet at an angle varying from 3° to 45°, and is there worked by a wire rope. This route through Theria Ghat has always been the chief approach from the plains to Khasia; and it was this route which Sir J. D. Hooker traversed and described in the second volume of his *Himalayan Journal*.—*Gardeners' Chronicle*

CINCHONA.—The usual assortment of South American barks was offered for sale today, and a few lots here and there were disposed of, *Lima* at a fresh decline; 2d. to 2½d. for broken slightly mossy quill. The limit of 2d per lb. for the remainder of the parcel seemed unobtainable. A parcel of cultivated Bolivian Calisaya bark, thick, flat and unsightly pieces, stated to contain 4·70 per cent. qunine sulphate and 2·12 per cent. other alkaloids, was shown, but not sold. Some other lots sold, fair but thin sound, 1s 9d.; damaged, 1s 2d to 1s 3d.; ordinary broken quill 1s per lb. Maracaibo sold at from 2½d to 7½d. per lb.; and 5 cases Ledgeriana (Java) damaged quills, at 7½d. per lb. The exports from British India (Chiefly Madras) have been as follows:—Season 1886-7, 1,286,900 lb.; 1885-6, 857,040 lb.; 1884-5, 745,730 lb.; 1883-4, 306,419 lb. The exports of cinchona from Java in the periods between July 1st (commencement of the season) and January 31st have been as follows:—

	Private Pl. ½ kilos.	Govt. Pl. ½ kilos.	Total. ½ kilos.
1887-8	1,808,880	467,511	2,276,391
1886-7	1,063,221	399,391	1,462,612
1885-6	567,516	297,082	864,598
1884-5	618,672	261,172	879,844
1883-4	393,082	359,027	752,109

COCA LEAVES.—Only a few parcels were offered at today's auctions; one of these, of five cases, together about 140lb., small and dark-coloured leaves, was bought in at 1s. per lb. nominally, from 1d. to 2½d. per lb. being offered. These cases were imported per East Indian steamer, and bear a mark which would seem to indicate that they were shipped from Java. Three cwts. good green but slightly stalky Truxillo leaves sold at 1s 3d per lb.—*Chemist and Druggist*, March 24th.

COCONUT LAND IN THE NORTH-WESTERN PROVINCE.

The striking development of coconut cultivation, during the past ten years, in the Puttalam revenue district, is as deserving of notice as the rise of a new tea or cacao planting district out of a wilderness of forest or waste land. Under Mr. Lushington's administration more especially, the industry has received a special impetus, and now, we suppose, in few parts of the island are there such prosperous and promising coconut gardens and plantations. We have been making enquiries on the subject of local cultivation with reference to our "Handbook and Directory," and the result has been to obtain some very interesting information, part of which we lay before our readers as follows :—

I recently saw a discussion regarding the produce of coconuts, when the figures given were ridiculed; but I can assure you that in parts of this district the crops, with little or no cultivation, are enormous. In the Puttalam district as it *now* stands, *i.e.* since the recent division, the average throughout is 36 nuts per tree per annum. 75 trees to the acre=2,700 nuts per acre, and we calculate the price at 2½ cents per nut which gives a yield of R67·50 per acre; but the average here is much reduced by some of the old badly planted gardens of Akkarai Pattu. At Chena kudirippu and Arachchivillu (suburbs of Puttalam) the average yield is 60 nuts per tree, *i.e.* 4,500 per acre, and the same applies to the well-planted lands of Akkarai Pattu, and a few gardens near Kalpitiya and Karaitivu. This makes the yield equal to R112·50, but as most of the owners of gardens have numerous dependants who work in return for food, they convert the nuts into copra, getting thereby 50 per cent increase in their returns. The average (good and bad together) throughout the Pitigal Korale south is calculated at 60 nuts per tree, while in the villages along the road from Madampe via Marawila to Vennappuwa and Nainamadama, the yield is as high as 100 nuts per tree, and in some gardens even higher. This brings the yield to 7,500 nuts per acre, and the value R187·50. In these parts the land is valued at over R1,000 per acre. Now in this Pitigal Korale south there are no less than 17,339 acres of coconuts *in full bearing*, and it is easy to work out what is the quantity of coppra produced. Of land planted between 1876 and 1883, *i. e.* just coming on into bearing, there are 5,578 acres, and since 1884 (the date of Mr. Lushington's coming to Puttalam) no less than 10,241 acres have been planted. These figures are for Pitigal Korale south alone, and give a total of 23,158 acres. In the Pitigal Korale north (Chilaw and its neighbourhood), the figures show a great drop. There are only 1,678 acres in full bearing, and 300 acres between 8 and 4 years old; but the progress made since 1884 here has been proportionately greater than in Pitigal Korale south as it amounts to 2,950 acres, or nearly double the extent in bearing. In Kalpitiya and Akkarai Pattus, the figures available are not quite so reliable; but the returns show 8,430 acres of 10 years and upwards, 4,135 acres from 4 to 10 years, and 7,575 acres planted from 1884 to present time, giving a total of 20,000 acres approximately. This extent is being daily increased. Old Mr. W. Hall once gave you very misleading information regarding coconuts north of Chilaw, because he thought only of the main road, forgetting the peninsula and the Akkarai Pattu, &c., land west of the canal. The whole of this from Udappu to Dutch Bay is one long line of coconut gardens, originally only a fringe extending along the sea shore and the lake shore; but now gradually extending until the two meet. On the "main land" too, cultivation is now spreading along the main road, and where there was a vast stretch of jungle in 1884, now one sees flourishing gardens with only rare intervals of jungle. The change is marvellous, and will be still more so 10 years hence.

Certainly, after this picture of the marvellous advance made in a staple planting industry—apart from the heavy salt traffic altogether—no one can think Mr. Lushington's proposal for a Chilaw Railway to be far-fetched or unjustified by the industries and wealth of his district. But, as regards what is said by the correspondent whom we have quoted above in reference to the yield of nuts, an experienced coconut planter of many years' standing (though not W. B. L.), gives us the other side after reading the figures :—

I still, however, am sceptical of any extent of land yielding 90 to 100 coconuts per tree—small extents no doubt do bear at this rate; and with manure trees in good soil may be made to do so over a large acreage. I have found that in most districts where the yield in nuts is large, the kernels are small, and instead of taking only 1,100 nuts to the candy of copra, from 1,400 to 1,500 are required. Digging and ploughing, to improve the mechanical condition of the soil, and manuring with bones would, I should say, tend to increase the size of the nuts. How your Chilaw correspondent makes out that by converting the nuts into copra 50 per cent increase in returns is obtained, I don't understand. I know, that the margin of profit to men who make a living by purchasing coconuts and converting them into copra is small; rarely more than 15 per cent; usually less.

Nevertheless, there is margin enough to make coconut planting a profitable and popular industry, and we have now to call attention to the fact, that, a few days hence, there is a series of blocks of Crown land to be sold at the Chilaw Kachcheri suitable for coconuts. These blocks are situated near Rajukadaluwa, about 6 miles north of Chilaw, and a correspondent reports that,—

Mr. G. D. Miller, who owns Rajakaduluwa, returned to the island a few days ago. I saw him yesterday, and he appeared to be delighted with the appearance of his estate even after our long drought.

There ought, therefore, to be good competition for the 13 blocks of land from 36 to 94 acres each to be sold at Chilaw Kachcheri, on the 30th instant.

A COTTON MANUFACTURING INDUSTRY FOR CEYLON:

THE DUTY OF NATIVES, COLONISTS, AND GOVERNMENT TOWARDS THE NEW ENTERPRISE.

CEYLON SPINNING AND WEAVING COMPANY.

(From a Leading Stakeholder Paper.)

After texture goods were begun to be imported from foreign countries, the growing and weaving of cotton in this island were almost abandoned. Yet still hand-weaving is carried on in the Chilaw and Batticaloa districts, where cloths and napkins of sorts are produced, which are very valuable owing to their durability and strength. But it will be apparent that this work cannot be done so cheaply—at the same time making the fabrics of a finer twist—as when machinery is applied.

It is said that as the cotton grown in Ceylon possesses a short staple that spinning by machinery is impracticable. But we do not think that we will be unable to introduce to our island cotton of a good variety from other parts of the world. There are many districts in Ceylon where tea, coffee, or coconuts cannot be grown to pay. If these could be planted with cotton, we believe, poor people will probably earn a means of livelihood. However, raw cotton can be got from Egypt, Tuticorin etc., for

purposes of weaving. England, France, and Germany import raw material from these countries, and the manufactures are brought back and sold to us at high prices. But Ceylon being nearer to these markets, goods can be made at a comparatively cheap rate if weaving is accomplished by machinery * * *. In India similar Companies are known to earn from 10 to 12 per cent profit per annum, after deducting all expenditure. But we are inclined to say that 10 per cent profit is quite sufficient for those who can easily afford to invest money. Besides, they will have the advantage of buying their clothes cheap. The people will find employment, and dyeing materials will find a ready sale. The large sums of money given to India and other countries would be saved and circulated in the colony itself. We are surprised to find that no other Sinhalese gentleman than Mr. Proctor de Saram is appointed as a Director of this Company. Why leave out Messrs. Soysa, Peris, and like millionaires? We hope that the natives of this country will give every support in their power to make this Company a success.—The "Dinakaraprakasa" of April 11th.

The above is a translation of an editorial in a leading Sinhalese paper on the new Company, and we think the editor does well to point out that a number of the leading and wealthy natives in the community have not as yet come forward and done what would seem to be a duty specially devolving upon them. Under ordinary circumstances the native population might fairly be expected to look up to such men and to follow their example, but when the natural leaders of the people hold back, it clearly becomes necessary to rouse them to a sense of the obligations which they owe in the positions in which Providence has placed them.

With all new industries there is, in the introduction of them, a certain amount of uphill work to be performed, and doubtless in the case of the Cotton Mills industry, it will be found that there is no exception. We are glad to learn, however, that with respect to the scheme now before the public, applications for shares continue to come in steadily. The natives, other than those above referred to, are doing their part, and even the planters are coming forward and contributing substantial support, but other Europeans in the country seem slow to make up their minds to subscribe and to take part in so commendable an undertaking. Why, it is difficult to assign a reason, when it is remembered that the objects to be attained are such that only good can accrue to the island generally.

In years gone by, men used to combine and bear a hand in all that was devised for the benefit of the Colony. Public posts, men readily made sacrifices to fill, and there used to be little difficulty in finding competent persons to give their time and services for the work, say, of the Legislative Council, the Chamber of Commerce, the Friend-in-Need Society, the Committees of Missionary, and other Societies we could mention. But now-a-days, many of our Colonists seem to be of a different stamp, and in some instances at least, there prevails a selfish indifference to all, but what affects the individual directly, and unfortunately, while the high motive of old days is wanting, the material benefit of "number one" appears to be a first mainspring of action. Critics of course only live to criticise, but some there are who seem to wish that anything in which there is any good, may not prosper, but rather the reverse. Others there are who, whilst expressing their best wishes that you may succeed, never think of putting their hand in their pocket, or of lifting a finger to help in making progress easier or more assured. They indulge in gloomy prognostications, deluded all the while with the idea that such may be taken for wisdom. Others forget that they,—all but drones in the colonial hive,—only study how easy they can make their life here, and spend their days in striving to minister to their own personal comfort. The true Colonist on the other hand, will welcome all that is for the good of his adopted country, and exert himself to the utmost in assisting the development of everything that is industrial and elevating, which will contribute to the moral and material welfare of the people.

The cotton industry, that is now being set on foot, is essentially one in which nearly all may take part. Those who have money may give material help, and those who have got little, can do something towards promoting and extending the growth of cotton. The boon that this would be to the natives throughout the length and breadth of the land, is very great. Something is wanted to take the place of the defunct native coffee tree. Something that would give as little trouble in the growth and preparation for the market as did coffee. The cotton plant is eminently adapted for this. It is merely necessary that the ground, cleared of jungle and weeds, should be ploughed or hoed. The seed is then sown broadcast and covered, and in a few months the plant grows up to maturity. In due time the cotton pods form, the bolls open, and the cotton is picked. The next process is the "ginning," and this is done in Southern India by the native "Churka," consisting of two revolving rollers worked by hand, by which the seed is separated from the fibre. In Tinnevelly every household is provided with a number of these, and in the cotton season all the members of the family are employed,—men, women, and children, in preparing the staple for the market. The seed, as is well known, is valuable as food for cattle, and in course of time, oil might be extracted from it, as is done from Egyptian and American seed. When once the seed is introduced and cotton growing is started, there will be a supply of the seed for the annual planting for all time, but the introduction will require initiatory effort, and some degree of perseverance In this we think it would be the duty of the Government to help to the utmost of its power. If this is done there cannot fail to be some good return to the native population of Ceylon.

As to the practical cultivation of cotton here, we may have a good deal to say by-and-bye. What has been done by way of experiment in times past will be found summarized in our "Agricultural Review" prepared for our "Handbook and Directory" of 1877-78. The Administration Reports for certain districts—notably Hambantota—may also be consulted with advantage. Anything that can be done must be through native agency, and no better beginning can be devised than for Government to import good seed for distribution under the auspices of their Director of Public Instruction and "Agriculture," and through the Assistant Agents of Hambantota, Trincomalee, Puttalam and Manaar and the Agents for the Uva, Eastern, Northern and North-Central Provinces. One fact which we found established even in the Southern States of America—the greatest cotton-growing country in the world—must be even more emphasized in Ceylon. It was put by an American friend of ours in Richmond, Virginia, as follows:—

"Cotton, in one sense, is the most valuable crop that is grown. It furnishes laborers with employment from the day it is planted until it finally ends its career in the paper mills, and printing offices: but cotton will bankrupt and ruin any man or country that attempts to make it pay for the horses, mules, hay, meat, bread, molasses, and almost every other article of daily consumption, from the profits of an 'all cotton crop.'"

In other words, cotton is not a crop like tea, coconuts, grain, to be depended on by itself, and the cultivator in Ceylon must have his fruit and vegetable garden or rice field as well.

COCONUT PLANTING IN THE WESTERN PROVINCE.

Hapitigam Korale, 16th April.

Two months of rainless weather must be a sore trial to the tillers of the ground anywhere, but here it is an annual infliction. We have to bear it as best we can. The dry season on the last occasion began on the 9th December, and lasted till the first March, during which we had rain more or less heavy on six days, with eight to ten days dry between each break, and since April began we have had alternations of cloudy and showery weather. The fall of unripe leaves has hardly been so great this as in some past seasons, but the four or five last opened flowers are almost entirely denuded of fruit, which will tell sadly on the crop, but as it is an annually recurring fact, we have no right to complain. I am not by any means certain, however, that we lose much in the number of our nuts by the dry weather. The loss, I am inclined to think, is in the size, and not in the number. Even when the dry season is broken by frequent showers, it is still between March and November that the bulk of the year's crop is gathered and the flowers opening between November and March, still drop the bulk of their germs; I therefore think it probable that irrigation during the dry season will do more in the way of enlarging the crop already on the trees than in adding materially to the number. My desiderated annual crop has always been limited to an average of one hundred nuts per tree, but I have lately seen a patch of four or five acres that must give double this return. It is a level spot close to the river, and about ten feet higher than its bed. Whenever it is in flood this piece is overflowed, and on the subsidence of the water about a quarter of an inch of soil is added to the surface of the very richest quality. As this process has been going on from immemorial time, the fertility is inexhaustible and nothing to be done for it but to keep it clean and gather the crop.—I should like to meet with a more recent analysis of bones than that of Forcroy and Vanquellin which gives 51 per cent of easily decomposable matter, chiefly albuminous, 37·7 phosphate of lime, carbonate of lime 10, and phosphate of magnesia 3·7 = 100.* What I would like to know is, how much nitrogen there is in the 51 per cent of decomposable animal matter?—I observe by a note in the *T. A.* that the coleopterous enemies of the coconut so well known here have made their appearance in the Straits, and that the people there are groping in the dark for a way of dealing with them. The large black beetle so destructive to the leaves, the *kurumenia* of the Sinhalese, deposits its eggs in dung heaps or any other mass of decomposing organic matter. The best way of dealing with them is to turn over all such deposits in the neighbourhood from time to time, and kill the grubs. The red beetle *kandapanuwa* that eats into the stem, and finally destroys the tree is to be met by negative rather than positive treatment. The dangerous time for the trees is between the first appearance of the stem till the flowering begins. At this period the old leaves cling tenaciously to the stem, and remain till they rot and fall off. This is Nature's provision for the protection of the tender stem till its surface is properly ripened and hardened. If the leaves are left untouched till they drop of themselves, the insect can make nothing of the stem; but if by their removal, however carefully the stem is too early exposed to the weather, cracks open and the insect has its chance. And again the slightest wound in the stem is its opportunity. In a plantation where the leaves are left to nature, a few accidents may occur during the dangerous period, but with trimming they will be multiplied indefinitely. Whenever the presence of the grub is detected in a tree, the best thing is to root it out, chop it up, and burn it, else in a few months there will be thousands instead of tens seeking weak spots.—*Cor.*

PRIVATE *V.* GOVERNMENT CINCHONA-GROWING IN JAVA.

[How Java cinchona exports are increasing may be seen from the figures given in our planting column yesterday: and here is further evidence of progress in extracts from the *Chemist and Druggist*, while we call further attention to the letter of Mr. Anton Kessler in another column, the gentleman who frightened us all a year ago. Altogether the outlook is not encouraging for Ceylon bark owners.—ED.]

The Java cinchona-planters consider themselves aggrieved by the action of the Dutch Indian Government, which is vigorously extending its cinchona plantations in different parts of the island and sending the bark for sale to Europe in competition with the, private growers. A number of the latter, therefore have now presented an address to the Governor General of the Dutch Indies, in which they call attention to what they allege to be the unfair Government competition, and request that the Director of the Government cinchona plantations may be instructed not to lay out any new gardens, or to renew planting where trees are cut down. The memoralists point out that originally the Government plantations were commenced solely for the purpose of ascertaining whether cinchona cultivation was practicable in the Dutch colonies, and of encouraging and assisting private planters in raising trees, while the commercial aspect of the Government undertaking was limited to the sale of a sufficient quantity of bark to defray the working expenses of the gardens. It is further asserted that the private planters are heavily taxed, while many of them also work with borrowed capital, and are otherwise hampered in their undertakings, and it is pointed outthat the cultivation of cinchona is still extending very largely, while the estimated consumption of quinine only increases by about 10 per cent. per annum, and that, moreover, at the present market prices of the bark, the Government gardens, so far from being a source of profit, are worked at an absolute loss. In 1885, for instance, the last year of which complete official figures have been published, the Government bark, which averaged 3·15 per cent. quinine sulphate, cost 37½ cents per half-kilo., or 6⅜d. per lb., to produce, so that it must have left a loss of about 2d. per lb. at the unit figures then ruling in Europe. The case of the Java planters certainly appears to be a strong one, but it is doubtful whether the Government will accede to their request, and difficult to see how they could do so except by selling their cinchona gardens outright to the highest bidder. It may here be mentioned that, although the shipments of Government bark have risen from 432,718 half-kilos. in 1885 to 525,698 half-kilos. in 1886, and are estimated at 700,000 half-kilos for 1887, yet the exports of bark by private planters have increased in very much larger proportions, and are now four times as heavy as those of the Government, whereas in 1884 they barely equalled the latter.—*Chemist and Druggist*, March 23rd.

PLANTING AND LABOUR IN NATAL:

A BRIGHT PICTURE OF CHEAP WORK, AND TEA YIELDS UP TO 1,200 lb. PER ACRE!

An ex-Ceylon planter, writing to a Colombo correspondent, says:—

I notice the *Observer* editors are a little at sea as to cost of "labor" here. You may tell them from me that employing an average of 100 hands, one-third coolies, two-thirds kaffirs, my average daily rate which includes all native overseers, ploughmen, domestics, &c., varies from 6½d to 8d., and has not in two years exceeded the latter, moreover I employ no women. Of course this rate includes all food and every charge of every description.

Further, from the constant fine weather and long summer days, 11 working hours nearly, I am able to work 300 acres of cultivated land with about 100 hands,

(more often 80), inclusive of coffee, of which I have just taken and prepared 26 tons clean coffee, and have opened, I should say am in course of opening, (only 100 acres actually planted with tea,) 200 acres of forest clearings in tea and coffee, fruit trees, (in belts). Off these clearings I am about to gather a catch crop of 200 tons of maize.

There is the undoubted fact that *Kaffirs* are unreliable, and with a plethora of them at one season of the year; at others they are hardly obtainable. I believe this will come right in time, At 8s. to 10s. a month and their food, another 2s. they are wonderful cheap labor, much stronger than coolies, but much lazier. Still they average up a good day's work, and knock 'spots' out of coolies at any hard work, such as holing, clearing, &c.

Our Indian coolies are *better than* in Ceylon, and no wonder with the rations they get, and do more work. They cost about 1s per diem inclusive of everything.

Mr. Hulett must be highly amused at the idea that he and his family do *all* the work of his tea estate. Mr. Hulett manages, and his sons assist in the management, in addition to which they are capable of carpentry work, building, repairing engines, &c., but on the garden over 100 coolies are employed, and this season they are making 90,000 lb. tea off 110 acres plucking area, of which 2-3rds is under 4 years old, and a large proportion not 2.

Their tea *over* 5 years old has never given less than 1,200 lb. per acre. I have had 14 years' experience of Ceylon; *and I know* that *if* the Kaffirs can be persuaded to work *quite* freely, *if* the cooly immigration is not interfered with, and *if* a little of the capital at present poured into Ceylon and elsewhere can be diverted here, Natal is the *rival* in tea that Ceylon may most fear. There are half-a-million acres of land, with soil such as is only seen in small patches in Ceylon on which the plant would thrive to admiration. At present you have these three *ifs* to keep us in embryo. In my garden here overlooking the sea I have mangos, pineapples, oranges, &c., apples, pears, strawberries, &c., &c., every vegetable imaginable; in fact everything that will grow in the temperate zone, and nearly everything in the tropic ditto does well here, but then, where I am we never have any frost.

I hope to pay Ceylon a visit in not many months, when the *Observer* will be welcome to my information about Natal, gained by practical experience and garnered from a Ceylon point of view.

It is marvellous with all the advantages mentioned that hitherto, Natal should have been so backward with sub-tropical culture: coffee for instance, we know, ruined a good many men before the leaf-fungus days; but perhaps the hardier tea-plant suits better. As to production we shall not grudge Natal supplying all the requirements of South Africa and getting the whole population there to drink tea up to 4 or 5 lb. per head per annum, which would absorb Natal crops for a good many years to come!

TEA ON OLD COFFEE LAND.

In your issue of 7th February there is a letter headed "The Tea Industry of Ceylon," in which some of the statements are misleading and erroneous, though evidently given in good faith. I refer to old coffee land being taken up for tea planting, and the reason given for its turning out so well, *viz.*, owing to the tea bush having a long tap root and drawing nourishment where its sister plant, with a shorter root, was unable to do so; and this being the cause of such good results on the little Island. It has been generally admitted by all who have studied the tea plant in India, that it is most assuredly a surface feeder, and not a tap root feeder, and this theory has pretty sound facts to back it. It will now be my object to try and prove this to your satisfaction. There is a practice, though I don't say largely carried on, of cutting the tap roots of young seedlings to half their original length when they are being transplanted, if the plants have been longer than eighteen months or two years in a nursery, owing to the difficulty in lifting them with the tap root uninjured. I have known such plants do remarkably well, which, if the plant were pure and simple tap root feeder, they could not have done. Don't imagine I recommend this cutting system. It is only allowable in very peculiar cases, which I will explain further on. Again, it is allowed by men at home, that to grow a fruit crop the surface roots should be pruned; and you will invariably find, with any estate that has been systematically deep double hoed, and all the surface roots cut in so hoeing, that there is a tendency on the part of the plant to grow seed, and less incliuation to flush freely. To prove this statement would be easy, if anyone would be at the trouble and cultivate a patch in this manner, and so see for themselves, that without surface roots the tea plant was by no means capable of the flushing functions required of it.

The tap root of a tea plant is the sucker from which the plant gains its liquid nourishment, so to speak, and the surface roots feed it with the vegetable matter requisite for its existence. To grow seed or a fruit crop, more mineral matter is required than vegetable, and *vice versâ* for a leaf crop; as the two crops exhaust the soil in two quite different ways. It will thus be seen that many old *teelah* gardens out here are unable to turn out leaf in large quantity, simply owing to the exhaustion of all the requisite matter which goes to form leaf, which is more or less on the surface, and only the mineral properties remaining. Of this there can be no doubt, as, if at the end of a season any Ceylon planters like to pay a visit to our tea districts, they will see for themselves. Our bushes are then covered with a beautiful flower, though not so beautiful as that of the coffee tree. Almost in every instance this flower is a cause of much anxiety to us, as it goes to show the soil has lost its leaf-producing qualities, and that only the fruit-bearing ones remain. As so many of our old gardens were planted with the China plant, the seed crop would in no way benefit us; nor even if we had a better *jât* (class), could we expect a seed crop to benefit us, as our market would be glutted with seed.

The reason, I hold, why the tea plant has done so well on all coffee land, is in a great measure due to two causes. One is that coffee estates have only been weeded, and not hoed like our tea estates: consequently, less wash of surface soil has taken place. The other reason is that the coffee plant is a mineral feeder, and has not exhausted the vegetable matter so essential to a leaf crop. Now as to the tap root. It is, as I have already stated, the liquid sucker, and it is only of use to the plant as such. On high table land, rolling land, or *teelah* land, it is essential to see that a plant, when put out, has its tap root in no way injured, for it is through its means that, during our long cold weather, extending over about five months, when we have little or no rain, this tap root supplies the plant with all the liquid so necessary to keep it in a robust state. Again, in low lands (*bhils*) the tap root draws up the moisture, and with what result is but two well known now to all who have invested their capital in these *bhils*. Owing to an excessive run of sap caused by the tap root drawing all the liquid matter of these *bhils*, a thin weak liquor is the result of all teas manufactured from *bhil* garden leaf. These teas fetch, owing to their weakness, but a poor price in the market. These *bhils* are like a sponge, and in time, when the vegetable matter has been exhausted, both by filtration and as food to the plants, little or nothing will remain to feed the plant; and though some human beings live by suction, I have my doubts as to a tea plant surviving on suction alone. That *bhil* lands are inclined to be exhausted sooner that other lands, is well enough known; and some of the earlier *bhil* gardens have deteriorated very much lately.

Now, as to cutting the tap root when plantin in *bhils*, it is advisable if the seedlings to be plante are large ones, and if from any cause the land

not sufficiently drained, leaving sufficient tap root to steady the plant in the ground; and the surface roots will do all that is necessary in the feeding line for a plant, and owing to a short tap root it is just possible less moisture may be absorbed, and stronger liquor obtained. It will be noticed that whenever the land contains excessive moisture, if it is not throughly drained, the land becomes sour, and the tap root in sour land blackens, rots, and dies off, and in other ways injures the plant above ground, which becomes sickly, and does not yield well, and often enough dies off; and so I say, in any land of this kind cut the tap root prior to planting. With half its length it will do quite as good service as a long, fully developed tap root will do on high ground. That the coffee plant requires higher land to grow in than the tea plant is too well-known, it having a shorter tap root at its call for liquid matter to form. It is not therefore so requisite for me to detain you longer with a description than to say that it has been proved out in India, that in a low flat, which sometimes may get flooded, where tea will grow, coffee has died out. I think that it will be seen pretty clearly by what I have written, that the tap root is not the means by which a tea plant derives its food, but that it is from its lateral surface roots that it is fed.

In conclusion, I may say that if Ceylon planters or others doubt the theory I have just expounded, I shall be glad to have their views on the subject; and if they can prove satisfactorily to me that I am in the wrong, I am open to be convinced of my mistake, though it will take a good deal to convince me that a tea plant is a tap rood feeder. If such be the case, and the coffee plant a surface feeder, let some of the Ceylon planters come over here and plant out coffee on some of our old abandoned tea gardens, similar to the way they have planted out tea on their coffee estates. It is, by the theory expounded by the author of the "Tea Industry of Ceylon," a surface feeder, and should do well both by his showing and by mine, as I have said that the mineral matter which goes to form a seed crop still exists, and by his theory our tea plants have not exhausted the pure soil with the tap root.—ACHARI.—*Indian Planters' Gazette.*

THE BIRDS' NEST INDUSTRY.

Travellers going from Hongkong to Bangkok or Singapore by steamer pass along the coast off Annam and near a group of islands that are at once picturesque and curious. Behind them is Tourane, an ancient French Settlement, the stopping place of steamers bound for Bue and Haiphong, and destined to be an important commercial port in a not very distant future.

Several of these islands produce an important article of commerce, that is, the edible birds' nests, which have caused considerable learned discussion among scientists. They are as dear to the Chinese palate as to the Chinese purse. It is a singular fact that Annam is the only country that produces them.* Why the swallows select this locality as a habitation, and no other, when there are islands apparently as eligible scattered all along the Asiatic coast from Sumatra to Korea, is a mystery that the scientists who have given the subject so much attention have never attempted to elucidate. Had Banquo lived in these times he might have given an explanation as poetic and reasonable as that which he gave to Duncan for the preference manifested by the Scotch martins for the pure and delicate air that bathed Macbeth's castle. The swallows' nests are a source of riches to the region. Their value is said to have been discovered some hundreds of years ago during the reign of Gia Long, who promised a liberal reward to any one who would discover a new and profitable article of export within his realm. The nests discovered in the island of Nam Ngai were presented to the sovereign, who, faithful to his promise, offered a patent of nobility to the finder. This was respectfully declined, and instead a monopoly of the harvest was accepted by the discoverer for himself and his descendants. This privileged family was to pay yearly eighty pounds of the nests to the Emperor as royalty. On the other hand they were to be exempt from personal taxes, from military service, and from contributions of personal labour, such as are common in Oriental countries. They formed a family league of forty or fifty men, elected two of their number as leaders, under the title of *gnan* and *doi*, and founded a village convenient for their commerce, which still exists under the name of Yen Xa—"Village of the Swallow's Nest." The nests are the product of a salivary secretion of the birds. As to their mercantile value they are divided into three distinct categories. The most valuable are those into which there enters a certain proportion of blood. These are called *yen huyet*. Singularly enough, they can only be produced by the birds affected with a malady which resembles consumption, and which is attended by copious hemorrhage. Nests of this kind are in great demand. They are rare, and are gathered only in the spring. Local tradition says that these birds died of exhaustion, or of the consumption in its advanced stages, before the end of the second winter. Scientists being scarce among the Annamese and the French colonists not having yet had sufficient time for observation, it is not known whether this disease is peculiar only to a part of the birds or whether the salivary secretion that causes the malady causes the death of all of them after a year or two of existence. The smallness of the quantity of these nests annually gathered—which is only three or four pounds—would seem to indicate that the disease is only partial and peculiar to those possessed of the weakest lungs. All other nests (*yan soo*) are classed as second quality. Nothing but the saliva of the birds enters into their construction. They are gathered in the spring, summer, and autumn. The spring harvest is the most valuable because it includes the two qualities. Two nests of the first quality weigh one ounce and are worth at the place of production five Mexican dollars at current value in Annam. Those of the second quality are worth little more than half as much. The summer gathering is entirely of nests of the second quality. They are smaller and less compact. It requires four of these to make an ounce, which is worth two Mexican dollars. The autumn harvest is still less valuable. The nests are scarce and not highly esteemed. It requires seven to make an ounce, which is not worth more than $ 1. 20 to $ 1. 40. Experts express the opinion that this third gathering should be dispensed with, since it is worth so little and there is danger of destroying the eggs. Nearly all the nests are sold to the Chinese living in the cities of Annam and Tonquin or sent to Chinese ports. Only the Chinese and some high mandarins of the Court of Hue who prefer the Chinese *cuisine* can afford the luxury. They are eaten by the Chinese cooked with flesh or with sugar, having first been cleaned of all extraneous substances by a liberal application of hot water. When cooked with fowl or game, fruit of the water-lily is added. Chinese physicians prescribe them as a sovereign remedy for diseases of the lungs, asthma, disordered digestion and most other maladies. If they have curative qualities of the kind mentioned they probably share them with other alimentary substances containing more or less gelatine. The good qualities of the nests are estimated no doubt in proportion to the price. It is certain that, as an article of diet, they have made little impression on Western nations.

The harvest is made in a manner simple and picturesque. Sections of bamboo are thrust into the holes in the side all the way up the precipice. Ascending an immense ladder by whose rounds the coolies ascend, detaching with a knife as they go the nests glued to the walls. One of the family which monopolises the industry watches meanwhile anxiously below to see that the labourer does not in gathering

* This is not quite correct.—ED. *T. A.*

detatch some portion of the precious nest and secrete it about his person. The operation is full of danger, and annually costs several lives. The monopoly is at this moment in danger of passing into other hands. A rich Chinese company of Hongkong, which is building a handsome European hotel at Tourane, and which has branch houses in the principal cities of Annam and Tonquin, is offering the Hue Government a handsome bonus for the privilege of gathering the nests. The monopolists are greatly excited at the prospect of losing it, and in support of their claim are offering in evidence the very document given to their ancestors by the Emperor Gia Long. Money is needed at the court of Hue, and the ancient manuscript will be critically scrutinized by Annamese officials to discover if it is indeed a grant in perpetuity or whether there is not a chance to make a good round sum by the transfer. In the meantime the swallows, instead of seeking haunts free from invasion, come back punctually with every recurring season, regardless of their health and this increasing spoliation. Other swallows in other countries can return peacefully to their last year's nests in the ensuing spring. These swallows of Annam must keep on pandering to an aristocratic desire, building and rebuilding their homes and giving their life's blood forever to satisfy a diseased appetite.—*Shanghai Courier.*

TEA ESTIMATES.—The *Produce Market Review* has the following:—"Indian and Ceylon, &c.—It is expected that England will receive during the present season from India alone about 93 million lb of Tea, and as the estimated supply from Ceylon and Java together amounts to another 33 million lb, it is clear that unless an enormous increase takes place in the general Tea trade, both for export and home consumption, the quantity required from China will be smaller and smaller. It may be noted that the 126 million lb of Tea expected from India, Ceylon, and Java this year exceeds the entire deliveries for home consumption in the United Kingdom during so recent a year as 1871."

EXPORT DUTY ON SOUTH AMERICAN CINCHONA.—In our issue of March 15th we mentioned a report current here that an export duty would shortly be imposed upon all cinchona exported from Bolivia, and expressed a doubt whether this rumour could be correct. This doubt was well justified, for it now transpires that, so far from an export duty being placed on bark, the now existing duty will he removed at the end of June. This will probably have the effect of increasing the shipments of bark from Bolivia,, as we understand that all dealers there, except one, are holding back their shipments in anticipation of the removal of the duty. The one firm who still export cinchone do not suffer from the duty, as they are themselves the contractors from the Bolivian Government, and therefore in paying duty merely pay from one pocket into the other. —*Chemist and Druggist.*

CINCHONA.—The supply of bark, offered at Tuesday's auctions was rather in excess of that offered at the preceding sales. It included 1,401 packages from South America (of which two-thirds were Cuprea), 1583, from Ceylon, 783 from British India, the largest quantity offered for many months, and only 22 packets from Java. It was generally anticipated that prices would show some improvement upon the last auctions, but this hope was destined to be disappointed, for notwithstanding the diminished exports from Ceylon and the more favourable statistical position of cinchona in London, buyers held off and the bulk of the Ceylon bark was bought in by the owners, who, if they had pressed it upon the market would have had to submit to a decided reduction Indian barks were not so firmly held, and the bulk of these, including a large proportion of good parcels, sold with rather better spirit than was manifested for Ceylon bark. Altogether about 200 packages South American, 700 Ceylon, 600 East Indian, and 22 Java bark sold at a unit which certainly did no average over 2½d., the principal buyers being the agents for the Mannheim quinine works and English manufacturers.—*Ibid*, March 30th.

INDIAN PRODUCTS.—The late Colonial and Indian Exhibition appears to have led to some interest being taken in the exportation of Indian drugs of various kinds on trial. One of these articles received during the past month was a sample of white musli, the root of *Asparagus ascendens*. It has an ivory-white colour and is hard and twisted, the pieces being about an inch long and two lines in thickness. It has a sweetish taste, and forms, according to Dr. Dymock, an excellent substitute for salep, than which it is nicer and is more relished by Europeans. At the present time, when salep is dear, it would form an excellent substitute for it as food for invalids. Large quantities of different varieties of gum arabic are also now being sent from India. Some of these, however, are imperfect'y soluble in water and very dirty, being evidently collected without much care. Nevertheless, those that have been examined possess a considerable amount of adhesiveness, and appeared to contain mere traces of tanning matter. A valerian root, apparently that of *V. Wallichii*, and costus root (*Aplotaxis auriculata*), are also among Indian drugs that have been sent to this country on speculation recently from India.—*Pharmaceutical Journal.*

THE COMING TEA SEASON, says the *L. and C. Express* of March 25th:—The time is now rapidly approaching when operations will commence for the Tea season 1888-9, many buyers having already left, and others being about to start for China. It does not, therefore, seem out of place to offer a few remarks which, we hope, may prove of service to those about to embark on the campaign. The enormous import of Indian and Ceylon teas during the season, now drawing towards its end, estimated at over one hundred million pounds, together with their comparative cheapness, has had a marked influence on the sale of China tea, the transactions throughout being of a most retail character except when forced at auction. It seems probable also that this state of things will continue unless shipments from China are materially different to what they have been this season. The best authorities anticipate an import from India and Ceylon during 1888-9 at over one hundred and twenty million pounds—possibly nearer one hundred and twenty-five millions. With such supplies from these countries, and several millions from Java, &c., and placing our requirements for twelve months roughly at two hundred and twenty millions total, it is evident that if China sends us more than a total of all kinds of ninety-five millions, it must result in dull markets, with an absence of healthy competition. The question for consideration appears to be how the necessary reduction from the present season's total is to be brought about. We think this can only be done by buyers in toto refusing to ship the low grades, such as the market has recently been inundated with—rubbish that does the China trade an immense deal of harm, and from the low range of prices at which it is realised, can scarcely be beneficial to anyone concerned. There is another matter that should not be lost sight of—viz., the decrease in the export demand here; this has for some years past kept prices fairly steady for good teas, but from several causes it would appear that in future we must expect a continual falling off in this respect. If the Chinese wish to retain even a moderate portion of this gigantic trade they must cultivate their trees so as to produce leaf with something of the fragrance for which their growths were noted some thirty years since, and at prices sufficiently reasonable to compete with those from India and elsewhere; that they can do this the experience of the last proves. With a little attention to the firing, we do not see why China should not continue to command a fair share of the trade, for we can scarcely believe that the Chinese have anything to learn from India as to the preparation of the leaf, if they only pay the attention they formerly bestowed on it. The trade have naturally been looked also to the Chinese Government as to what their action will be in the matter of duties.

TOBACCO CULTIVATION, I am afraid will be a failure in the Western and North-Western Provinces. I have seen it repeatedly tried by a very persevering coconut planter in the first-named Province, but it could not be made to pay.—*Cor.*

DARJEELING.—Regarding tea prospects, I have little to say just now. There is a good deal of blight about, and more rain is badly wanted in many parts of the district. In the meantime, I think planters are looking up a good bit, after their long time of depression, and it is becoming apparent that hill tea will pay in the long run, if the property is only fairly well managed. The latter is the important point.—*Indian Planters' Gazette*, April 10th.

INDIAN TEA NOTES.—Tea making has begun at Dehra Doon. The Gardens are looking well, as they have had very good winter rains. On the 30th Lallamook had an earthquake—two small shocks. The weather is favourable. "All the squalls come at night. One iron rod has been carried away. Nearly all the gardens have started their machinery." A heavy hailstorm passed over Cachar last Tuesday and Wednesday (3rd and 4th instant), and is reported to have done very serious damage on some of the tea estates. One Manager telegraphs that his garden is "cut up" by the hail, and that the manufacture "is stopped indefinitely." Another planter with facetious sadness wired that he had iced pegs with his dinner which cost him R10,000!—*Indian Planters' Gazette*, April 10th.

TEA DRYING is thus noticed in the London Letter of the *Indian Planters' Gazette*:—A friend who has recently been down to Chingford to see some more experiments tried with Mr. Gibbs' new filter stove, took with him some specially selected delicate, lightly fermented Jhanzie tea, after having had the same sampled by two leading brokers. This tea he slightly moistened for the purposes of the experiment; thereby not only giving the dryer some work to do, but rendering the tea more liable to absorb any foreign flavour which might be applied to it though exposure to the direct products of combustion. Some Assam coal had been procured from the office of the Assam Railways and Trading Co., Lmtd., in order to test the actual fuel of that province. Some teakwood had also been obtained as giving out a powerful aroma, in order to put wood fuel to a severe test. The delicate Jhanzie tea operated upon was dived; part was dried by the direct products from the coal, and part from those from the teak. Previous to operating upon the tea, the fan was stopped, and immediately the densest possible volume of smoke were emitted from the feed hopper. The instant the fan was turned again the emission of all smoke ceased and—not a trace of it, or of any odours, was to be discovered at the hot air exit! The tea was brought back to town and tested by the same brokers who had originally sampled it, and they could find no trace of injury from *foreign flavour*, though the quality and appearance had of course, been affected by the damping. My friend also told me that Mr. Gibbs is about to erect a full-sized filter stove in order to complete the thorough testing of the invention before launching it upon the world. Drying tea direct from a coal fire would have been laughed at a few months ago. We may have it dried by gas yet; indeed, thought is already being directed.

PURE SULPHATE OF QUININE is now made by Mr. Gammie in Northern India, and an official paper has been published giving a full account of the process. Dr. King and Mr. Gammie are specially thanked by the Government of India. We shall quote the whole paper, together with the description of the method of extraction, into our *Tropical Agriculturist*. But meantime, we quote the following passages:—

During a visit which he paid to Holland in 1881, Dr. King acquired some hints as to a process of extraction by means of oil. And now benefitting by the advice of some chemical friends, Mr. Gammie has been able to perfect this process with the result that the whole of the quinine in yellow bark can be extracted in a form undistinguishable either chemically or physically from the best brands of European manufacture. This can be done so cheaply, that as long as the supply of bark is kept up quinine need never cost Government much above twenty-five rupees per pound. It is true that at the present moment quinine is obtainable in the open market at rates not very different from this; but that is due to entirely exceptional causes. For some time back the Ceylon planters, have been uprooting their cinchona trees both to save them from disease, and to make way for tea planting which appears now to be becoming the principal industry of that colony; and cinchona bark has actually been sold in London below the cost of its production in Ceylon. Indeed, so far has the fall in price gone, that South American bark has been practically driven out of the market. This is a state of matters, which cannot continue very long, and which is not likely to recur. In the ordinary course, therefore, quinine might be expected soon to rise to what may be considered its normal price. The object of making public the process now discovered is to check this rise in the price of a drug of such general utility.

"COCO-NUT OR COCOA-NUT."—We call special attention to the following editorial note from the *Pharmaceutical Journal* of London. We have for several years back with the concurrence and approval of the highest authority in the island (the Director of the Royal Botanic Gardens) adopted "coconut" in all our publications. The difficulty usually is to get people at home to aid in a change of the kind, but now that the step has been taken by so good an authority in England, we trust all writers, printers and publishers out here will follow suit and do what they can to make the convenient and indubitable form of "coconut" universal. We would especially appeal to our contemporaries, to the Department of Public Instruction (and Agriculture?), and last not least, to the Government Printer to adopt what is so clearly and scientifically shewn to be the correct form. If we could only convince "Mincing Lane" we should like next to see "cacao" adopted for the produce as well as the tree; but this is more difficult, "cocoa" as pronounced being a universal household as well as "market" word for this food product and drink, in England. Still if "coco" is kept for the nut, there will be much less risk of "cocoa" beans, nibs, or paste being supposed to come from the palmtree. Here is the paragraph:—

COCO-NUT OR COCOA-NUT.—A discussion as to whether this should be spelled c-o-c-o or c-o-c-o-a has recently been published. The palm yielding the coconut and the tree which furnishes the substance used as a beverage and called cocoa, are known by botanists, and hence by pharmacists, to have no connection. Nevertheless, many persons outside that intelligent circle have an idea that the products of the same tree, or are connected in some way, and even botanists do not agree as to the correct spelling of the word coco in coconut. The evidence on the subject is briefly this:—In early botanical works and books of travel coco-nuts are mentioned, the word "coco" being derived from an Indian word coc or cocus, used to indicate the fruit of *Cocos nucifera*, on account of a fancied resemblance of the base of the endocarp, with the three circular impressions, to the face of a monkey whose conversational powers were limited to uttering a sound like coco or cocus. According to another authority the word "coco" in Portuguese means anything which frightens children, the monkey-like expression on the endocarp being perhaps used for that purpose. Linnæus in forming the genus [illegible] probably founded the name on these variations, and how it came to be known as cocoa (c-o-c-o-a) nut is not quite clear, but there is nothing to warrant such a method of spelling. Now that the leaves of [illegible] are also articles of commerce and known as coca (c-o-c-a), it becomes a matter of much importance to discriminate carefully between the three substances of similar names but widely different nature.—*[illegible]*, March 31st.

IMPORTANT MEETING OF THE COFFEE TRADE.

A special meeting of those interested in the coffee trade, convened by the coffee and cocoa trades section, of the London Chamber of Commerce, was held at the office of the Chamber East Cheap, E. C., on 26th February "to consider the proposed creation of a bank and *caisse* for settlement of time bargains in London, with special regard to the effect of such an institution on the coffee trade." There was a numerous attendance. Mr. H. Pasteur (Patry & Pasteur) presided.

THE CHAIRMAN said: Gentlemen, this is the adjourned annual general meeting of the coffee and cocoa section of the London Chamber of Commerce. At the previous meeting, on the 20th instant, I thought it my duty to bring under notice the projected creation of a bank and clearing-house for time bargains in coffee and sugars, which I considered a subject of the highest importance to all interested in those trades. Some discussion took place, but, as the question had not been mentioned amongst the agenda, it was felt and very rightly so, that a further opportunity should be given, with due notice, for discussion, and also for the passing of any resolution which the meeting might think fit to adopt. On Friday last the prospectus of the London Produce Clearing-House was issued, and we are now informed that the "*Caisse de Liquidation*" in Havre, and a similar institution recently established in Hamburgh, are to be the models on which the business of the new clearing-house is to be established. This makes it clear, therefore, that the business is to be in time bargains, or paper coffee and paper sugar, although the words "time bargains" do not not appear in the prospectus. This to say the least, introduces a new style of business in colonial produce in London, which may have very serious consequences for the trade, and on that account I think it is a question which should be examined and discussed calmly and impartially by those interested in the various branches of the coffee trade. (Applause.) It is not a question affecting banks, or financial houses, or brokers only, but also growers and importers of coffee, and those who buy, deal, and distribute the article throughout the United Kingdom and abroad. (Applause.) Will the new kind of business which it is proposed to introduce under the auspices of the London Produce Clearing-House lead, in the terms of the prospectus, to an extension of business as well as to an actual increase in imports, and thereby benefit the trading and shipping and dock interests of London? Or will it, as others fear, have a detrimental effect on the coffee trade of London, by inviting and encouraging purely speculative transactions, entailing constant fluctuations in prices, and a state of uncertainty which is paralysing to the dealers in the real article, without, on the other hand, encouraging importation, which is attracted in the long run to the countries where coffee is consumed, and not by transactions in paper representing coffee, and settled by differences in price, instead of by the delivery of produce? Those, gentlemen, are questions of great moment; and I trust that those who may wish to address this meeting have duly weighed the various aspects of the great changes which it is desired to introduce into the mode of conducting business, and that they will be guided in the views they advocate by a sincere desire to uphold the best and truest interests of the London coffee trade. (Applause.)

MR. S. FIGGIS said that at half an hour's notice he had been asked to propose the following resolution:—"That this meeting of merchants, brokers, dealers, and others interested in the coffee trade, deprecate the establishment in London of a bank and *caisse de liquidation*, intended, under the name of the London Produce Clearing-House, principally for the settlement of time bargains in coffee, which, in their opinion, will be detrimental to the interests of the trade, and by unduly encouraging the speculative transactions with constant fluctuations, in paper coffee, will render business in the real article uncertain and precarious, to the injury of growers, importers, dealers, and distributors of coffee." Mr. Figgis said that the compliment had been paid to his firm of bringing strong pressure to bear upon them in order to induce them to join in founding the new company; but they felt that it was their duty—he would not say their interest—using their intelligence and experience that his senior partner especially had acquired in Mincing Lane in the course of half a century—they felt it was their duty not to promote the movement. Perhaps, therefore, he would be allowed to say a few words as to the attitude that his firm and other brokers had taken in regard to the company. A business like theirs had only been made by real, constant hard work such as Englishmen, as a rule, had been proud of, and it was felt that business of the new style would not be productive of the wholesome results which had been the glory of Old England. (Hear, hear.) There had been a little wonder—he would not say anger—expressed at the attitude some of them had taken in venturing to express their conscientious opinion on the subject; but every Englishman was entitled to hold and express his own opinion, whatever others might think. The gentlemen who had promoted this company—no doubt with the best intentions in the world—were few in number. Having looked at the names of the founders, he did not believe that those gentlemen, eminent as they were in the entire commercial world, really knew, and understood, and upheld the intentions of the actual founders of the company. (Hear, hear.) No doubt, this clearing-house having been once established, they, as brokers, and therefore as agents, would be compelled to take part in the transactions of the company, but it would only be by orders of their clients. To promote and foster and push a thing, and to do everything one could to make it a success, was very different from realising the fact as a practical man that one was bound to take some part in it, however unwillingly and without doing all one could to further its objects. They would probably be taunted with the fact that they would be compelled to join the company; but that would not deter him from saying that the system proposed was foreign to English habits and thoughts. (No, no, and Hear, hear.) Whilst some such organisation might have become a necessity, owing to what was being done in America, France and Germany, and the great number of foreigners trading in England, it was gambling pure, and simple. (No, no, and Yes, yes.) It was betting on time bargains. (No, no and yes, yes.) It was doing paper business. In most cases the intention of the "operators" would be that no article of produce should pass. That would be destructive of habits of business and industry, and detrimental to commerce, and would unfit men for their regular trade and work. (Hear, hear.) The system was producing, and had produced a restless frame of mind in our younger men, leading to their betting in many ways, and to a large extent. It might injure regular trade permanently; his firm believed it would, and it was for that reason that they opposed it. Centuries had been occupied in building up the trade of England and there had been only three or five years' experience of the new trade in paper produce to go by. Surely that experience was not very favourable either as to the profits or the morals of the business! (Hear, hear.)

MR. W. J. THOMPSON, sen. (W. J. & H. THOMPSON), in seconding the resolution, said that the object of the *caisse* did not interfere with his special business; but he was urged to join in the scheme, and he would have done so if he had thought that it would be for the advantage of Mincing Lane. He felt very strongly, however, that the scheme would ultimately work infinite evil in the general business of Mincing Lane, and he declined the honour that was offered, though he was much pressed, and though representations were made that the scheme would be a commercial success and that great advantages would follow upon it. Certainly, with regard to the commercial success of the thing, there had been a great demand for the shares, but he remained unconvinced, and was glad to have the opportunity of seconding the resolution, and of supporting the views so ably put forward by Mr. Figgis. (Applause.)

Mr. ROUSE said this question had been before Mincing Lane for many years. Two years ago he attempted to bring it forward, in order to get an association for the settlement of contracts, as they had in Liverpool. At that time the same old arguments that were now heard were advanced in opposition to the proposal, and the thing fell into abeyance. It had been revived because of the success that had attended settlement contracts in Havre, Hamburg, New York, and other places. Much had been said in opposition to the scheme, and if there were no Suez Canal and no electric telegraphs, and if 999 out of every thousand contracts in this country were not made for forward delivery, he could understand the opposition. (Applause.) But there was the actual experience that the business of the country was done for forward delivery. The man who bought goods from countries that it would take two or three months to bring them from was doing a time bargain, and that question must be settled. This year coffee had reached a very high point. Rio coffee had reached about 80s., and Messrs. Johnson's telegram came in, estimating the crop at eight and a half millions. He had the figures of all the estimates, and the lowest was about six and a half millions for export this year. What was the consequence? People, being perfectly solvent at the time, who had bought coffee, were suddenly faced with a drop of about 20s. The whole of the business of this country would be conducted by the purchase and sale of produce which was still on the ground in India and America, or which had just been harvested, and, seeing that that produce was all sold for forward delivery or shipment, was the present state of things safe?

MR. FIGGIS explained that his firm did not object to forward contracts, and they had provided selling forward deliveries of real produce and the articles they dealt in. But they objected to time bargains in which it was not intended that produce should pass.

MR ROUSE remarked that he was coming to that point He had no hesitation in saying that the bulk of the business of this country, with the exception perhaps of tea and wool contracts, was conducted on the principle of selling forward produce. It must be and would be so, because the stuff was bought from England in the producing markets instead of being bought here. He apprehended that it was desired by means of the Clearing-House to introduce the principle of settlement, and he supposed that articles would be tendered on forward contracts. That was done in Havre, Hamburg, and New York; five days before the close of the time specified in the contract, notice could be given that there would be a tender of the goods. He supported the Clearing-House because he thought brokers and merchants and dealers ought to be protected in their transactions. At present they were face to face with this difficulty, that they might have bought an article in which a sudden telegram from the other side might cause an immense fall, and yet they had no means of selling the article in consuming countries except at a ruinous loss. (Hear, hear.) Let them not be hypocrites. (Applause.) He believed they all desired to join with him in making business in Mincing Lane as safe as possible—(hear, hear)—and to cause things to go on easily. That was why the Clearing-House had been established. When the telegrams to which he had referred came in from the States, the English people wired off to Havre Hamburg, and New York, and sold against the contracts. What it was desired to do was to introduce into this market a contract on which Rio coffee could be sold. A man who held Rio coffee would be able to go into the market and sell against it, because there would always be buyers in a terminal market.

SIR HENRY PEEK said, he had been much surprised by Mr. Rouse's statement that 999 contracts out of every thousand were made for future delivery. He had made transactions to thousands of contracts, and he did not suppose he had ever made a forward contract in his life. The Clearing House did not at present affect the wholesale dealers so much as some others, but he supposed it was to be made to apply in the future to tea and everything else, and he could not help thinking that it would introduce an element of difficulty for the wholesale trade such as they had never before had to face. He could see no advantage in the scheme. A broker was usually as wide awake as most people, and, if he had to deal with a shady man who wanted to speculate, it almost served him right if he did not make a margin himself. (Hear, hear).

MR. WALES (Moffat & Co.,) challenged Mr. Rouse on this point, that a very large portion of the transactions in the Havre Clearing-House were in respect of coffee, the delivery of which was not sought for. (Applause.) It was that element which concerned the London brokers and merchants. He opposed this scheme, not because it was new, but because it violated the principle of business upon which the whole fabric rested—(hear, hear),—and sought to introduce that element of gambling, which in business had always been a canker eating the life out of it, and which in time might destroy it altogether. He feared they were nowadays seeking these new methods of conducting business as a short road to making money, and he was quite sure that in the long run they would not answer, because they would drive out of the trade the enormous capital now embarked in it—(hear, hear)—and would render it a business absolutely unsafe to follow. Every day of the week they received quotations from Havre ten or twelve times, and probably the values varied during that short period. Was it possible to conduct business in the ordinary course of things when a man was liable, not only from day to day but from hour to hour, to fluctuations in the value of the article in which he was dealing? Nothing could explain that constant variation except that it was the effect of gambling. As a member of the trade he had the strongest objection to seeing this system brought into Mincing Lane. In getting the margin paid into this bank, a certain sum would be secured; it might be a sum belonging to the person himself or to his creditors, and if the man should come to grief, the bank would hold the money as against all his other creditors. (Hear, hear.) An exporter of coffee in London, he would suppose, ships £5,000 or £10,000 worth of coffee to the Continent, and is paid by bill. In the meantime he finds that the man to whom he has shipped the goods is speculating in a terminal market, where he has to pay a margin, and where, when the price goes against him, he has to pay certain further sums, till the total possibly reaches thousands. Well, the man receives the goods from London, and turns them into cash in order to pay further deposits into the Clearing-House, and when he goes to the wall, all his ready cash is in this bank as against every other creditor. (Applause.) This security to the bank was one of the dangerous elements of the thing. Gambling never could be made safe. Every attempt towards that end must fail, and it would be far better to keep to the old methods. If they followed the new plan they would be killing the legitimate trade in an article for the purpose of securing large incomes without the trouble which pertained to all proper businesses. Therefore he supported the resolution and he trusted that the good sense of the meeting and of the Chamber of Commerce would support those who protested against the evils which it was proposed to introduce into Mincing Lane. (Applause.)

Mr. W. VON GLEHN observed that this was not a question of morals. They wanted to do the best they could for the trade of London, and they wanted to get as much coffee as they could to London. Would coffee be brought to London by this terminal business? ("Yes") Could Brazil coffee be diverted to this market? He believed that produce would always find the shortest and cheapest way from the producer to the consumer and no terminal market would divert it. (Hear, hear.) The intention, he apprehended, of those engaged in the coffee trade of London was, as far as they could, to distribute Brazil coffee over the markets of Europe, and he did not think that object would be served in the slightest degree by transactions for delivery

within twelve months. The distribution of Brazil coffee was a matter of hard work; they had to distribute various kinds of coffee, and they would not assist the operation by undertaking transactions for the delivery of one special quality within the next twelve months. They did not see that coffee had been diverted from the ordinary course: it went from the country of production to the country of consumption, without reference to terminal markets. A share of the Brazil coffee might be obtained in London, but only a share, and they would get more if they turned their attention to the proper method of distributing it. Havre merchants were occupying all their time and money in gambling transactions; last week, he believed, the transactions represented three times the amount of coffee there. The real intention in the case of one of these contracts was not to make delivery, and if they in London would turn their attention to doing the real trade, they would get the best of it. (Hear, hear.)

Mr. Walton said the Clearing-House was a *fait accompli*, and he would move as an amendment that this discussion be adjourned for six months. It was very difficult for one broker to talk about what other people did, or, for the matter of that, about what he did himself; but it certainly seemed a pity that orders for 100,000 bags of coffee—200,000, he believed, had been known—should be sent from London to New York, Hamburg, or Havre, when it might be done here. (Applause.) The stock of coffee at Havre was now many times larger than it was before the Clearing-House there was established. (Hear, hear.)

After considerable animated discussion, Mr. Walton drew up his amendment in the following terms:—"That this discussion be adjourned for six months, to enable the Section to see how the establishment of the Clearing-House will work during that time." That was then carried by thirty-six votes against twenty-two.—*Indian Planters' Gazette*, April 3rd.

GOLD IN CEYLON.

(*From our Galle Correspondent.*)

Galle, 21st April.

Mr. A. D. Dominico informs me that he was the first to draw the attention of Government to the existence of gold in Morawak Korale. In the course of a visit, which he paid to Akuressa last month, he saw two nuggets above one ounce each, besides several smaller ones in the possession of the Constable Arachchi, which had been obtained while gem-digging at Deurangalla. Other gem-diggers had also secured gold, but not in such quantities. According to Mr. Dominico, the precious metal is quite loose and free from quartz, showing that gold exists in decomposed quartz on the surface of the primitive soil, so that the presence of a solid reef may be expected at not a great depth. The name "Deurangalla," or burnt gold stone, is derived from the circumstance that gold was obtained by calcinating the stone, and there is a tradition amongst the villagers, that in olden times gold-digging was under the patronage of royalty. The existence of abandoned pits is pointed out in support of this.

On arriving at Matara, Mr. Dominico reported the circumstance to Mr. H. P. Baumgartner, the Assistant Government Agent, who despatched Mr. Perera Mudaliyar of Gangaboda Pattu to Akuressa, and obtained specimens of the metal from the Constable Arachchi. On the 30th March, Mr. Dominico presented a petition to Mr. E. Elliott, the Government Agent of the Province, in which, after stating these facts, he added that "as there is no doubt that gold in paying quantities can be obtained in this Province, your humble petitioner begs that you will be pleased to report the matter to Government, and to recommend that he may be assisted to carry on operations, with a view to develop the resources of the country. Should the Government be sceptical on this point, your humble petitioner would further ask that some person of experience and scientific attainments be selected to personally visit the spot, with the object of ascertaining the truth of his statement."
