MDCCCLXXXVIII.

PRINTED AT THE "CEYLON OBSERVER" PRESS: COLOMBO, CEYLON: 1888.

TO OUR READERS.

In closing the Seventh Volume of the "**Tropical Agriculturist**," we have but to repeat what we have said on similar previous occasions, in directing attention to the large amount of useful information afforded, and to the great variety of topics treated in our pages. From month to month, we have endeavoured to lay before our readers the latest results of practical experience and scientific teaching in all that concerns tropical agriculture; and our ambition has been to make this periodical not only indispensable to the planter, but of service to business men and capitalists, never forgetting that agriculture trenches upon every department of human knowledge, besides being the basis of personal and communal wealth.

While directing our attention chiefly to the products prominently mentioned on our title-page, we have never omitted to notice minor industries likely to fit in with sub-tropical conditions; and our readers have an ample guarantee in the pages before them, that, in the future, no pains will be spared to bring together all available information both from the West and East, the same being examined in the light of the teachings of commonsense as well as of prolonged tropical experience in this, the leading Crown and Planting Colony of the British Empire.

The official Reports on the Royal Botanic and Economic Gardens in Ceylon are republished in full in the present volume, and throughout our pages will be found reviews of, and extracts from, the Reports of other Botanic Gardens situated in or near the tropics. We are ready to give copious extracts from, if not to reprint *in extenso*, the Reports of all other sub-tropical Public Botanic Gardens which may reach us. Most of these Reports we already receive and utilize as abovementioned for the benefit of our planting readers.

A full and accurate Index affords the means of ready reference to every subject treated in this, the seventh volume, which we now place in our subscribers' hands, in full confidence that it will be received with an amount of approval, at least equal to that which has been so kindly extended to its predecessors.

We are convinced that no more suitable or useful gift can be made to the tropical planter or agriculturist, whether he be about to enter on his career, or with many years of experience behind him, than the half-dozen volumes of our periodical which we have now made available. They are full of information bearing on every department and relating to nearly every product within the scope of sub-tropical industry.

In conclusion, we have to tender our thanks to readers and contributors, and our wish that all friends may continue to write instructively and to read with approval; for then, indeed, must the "**Tropical Agriculturist**" continue to do well.

A. M. & J. FERGUSON.

A CONSULAR REPORT ON CEYLON (PRODUCTS, &c.) FOR THE DUTCH GOVERNMENT.

"To see ourselves as others see us" has, since the days of Robert Burns, been fully recognised as a desirable thing by all reasonable men, and it is interesting to us all to see in what form this Colony is represented to the old masters of the island, the Dutch. We have had the opportunity of perusing the annual report from the Netherlands Consulate at Colombo for 1885, a report which doubtless has been seen and read by a large number of the Hollanders who are interested in the progress of the country. Although figures for exports, &c., are embodied in this report, we are pleased to find that instead of its being a dry document bristling with figures and statistics, the greater part of it takes the form of an agricultural report embracing all the principal products of the island under their respective headings and arguing a more extended acquaintance with its resources than might perhaps be expected under the circumstances. Under Coffee we find a short resume of its history and of the leaf-disease, and some allusion to the possible prospective destruction of coffee altogether threatened by the green bug which is now a subject of discussion in the local papers.

Under Tea a handsome compliment is paid to the spirit and energy with which Ceylon planters have been converting their old coffee estates into plantations of tea, and the statement is made that to rectify the difficulty arising from their own inexperience of tea manufacture, the services of experienced men were engaged—both for field and factory, as well as offices. The wonderful adaptation of the tea plant to all elevations and soils in the island is alluded to, and that time alone can show what will constitute paying concerns in the end.

Under Cinchona it is shown that the trees planted years ago, which have not been rooted out have assumed the proportions of forest trees, and produce individually pounds weight of bark, where ounces were hardly expected a few years ago, and this is supposed to account for the marvellous way in which exports have maintained their enormous amounts, and will probably do for some time in the future. Under Cocoa there is a short sketch of the curing operations and a reference to Blackman's air propeller as the American fruit drier.

Cardamoms, products of the cocoa palm, kittul and areca palms, rubber, rice, tobacco, cotton, sugarcane &c., have each a separate paragraph with remarks. The restoration of irrigation works by the Government is just touched upon with the suggestion that advantage might be taken of times of scarcity in India to introduce a sufficiency of population for the at present almost deserted country where the ancient tanks are situated. Ceylon is not credited with much in the way of manufacture, a fact which cannot be denied and which we should like to see amended.

The condition of the inhabitants of Ceylon is considered, and for this purpose they are divided into three classes: Europeans, natives and immigrants. In the condition of the first-named class, improvement was observable to some degree, more especially planters and land-owners, whilst the decay of the mercantile houses is rather forcibly pointed out, and we fear the remarks contain more of truth than we care to think of, though with the new tea industry fully established and more capital in circulation, it may be hoped that the merchants will get their share of its benefits. The "natives" included all who are neither European nor immigrants, and their condition in 1885 was decidedly worse than it had been previously and shewed no sign of improvement, and the distress and poverty consequent on the collapse of coffee was deplorable. The immigrant class on the other hand shewed more improvement than either of the abovementioned classes, and the demand for labour exceeded the supplies—with every prospect of this state of affairs continuing in the future.

Commerce between Ceylon and the Netherlands Possessions in India is of unimportant dimensions and since the export of machinery to Java has been discontinued, is restricted to seeds and plants on a very small scale. Even imports from Holland: beer, cheese, butter and cotton goods, have come by way of London.

The resucitation of the Oriental Bank is mentioned and under Navigation we quote:—"Most of the steamers flying the Netherlands flag, which call here on their way outwards have done so for the purpose of coaling and on their way home for the same purpose and to fill up with cargo generally for the Mediterranean ports.

The lines of mail Steamers:—

The	Stoomvaart	Maatschappij		Insulinde,
	do	do	do	Java,
	do	do	do	Nederland,
	do	do	do	Rotterdam,

have made Colombo almost a regular port of call on their way from Java to Marseilles and thence to Rotterdam, but no great efforts appear to be made to procure cargo and passengers."

One sailing vessel under this flag had filled up for New York.

Allusion to the completion of the Breakwater and proposed Fortifications closes the Report from which the good folk of Holland may learn that Ceylon has not gone to sleep over its misfortunes and they may possibly take a hint or two to help them to get over a similar deplorable state of affairs obtaining in Java to that which bade fair at one time to drive our planters from the hills of Ceylon.

GOW'S PATENT WITHERING AND FERMENTING MACHINE.

It will be remembered that after the trail of "Gow's Witherer" on Mariawatta, Mr. Jameson wound up his report to the *Observer* as follows:—

The great test that remains to complete the success of the machine is the London Market, and if teas made on this system pass muster favourably their, I think Mr. Gow may well be congratulated, and will deserve the thanks of tea planters for having conferred such a boon on them.

We and the planting public have been waiting for this London test not so much to see whether the machine turned out a tea superior to that ordinarliy manufactured, but one fairly approaching the standard. For, it will be at once acknowledged that the advantage of the "Witherer" is to enable planters—*especially at high elevations*—to get through work which otherwise could not probably be overtaken at all in certain weather, and also to save them in a great measure the necessity for night-work—a very important matter in Tea Factories as overworked planters well know. We are now favoured with the test of the teas in London—sent there under special private marks—and we think it will be owned that the result is extremely satisfactory, so that we are not surprised to learn that the

proprietors of Mariawatte have decided to keep the experimental machine erected in their Factory. This is in fact the best practical testimonial which could be paid to the machine. The London report is as follows :—

RESULTS OF THE WORKING OF THE MACHINE ON MARIAWATTE ESTATE.

Prices realised for Mariawatte Estate Teas. 12,320 lb. One-half made by Gow's "Monarch Witherer," one-half by the usual method of manufacture. The Teas were made with alternate days leaf pluckings.

	Gow's Witherer.	*Mariawatte Method.*
990 lb.	Bro. Pek. 1s 4½d	1s 5½d
600 „	Or. Pek. 1s 7d	1s 7d
3040 „	Pekoe 1s 1¾d	1s 1¾d
1530 „	Pek. Souc. 0s 11½d	0s 11½d
	Average 1s 2d	1s 2½d

Regarding the above the Secretary of the Ceylon Plantations Company writing to Mr. Rutherford says :—

"Messrs. Gow, Wilson and Stanton expressed their obligations to us not only for risking the experiment, but also for shipping the tea under another mark as it might have made a difference in the returns had not there been a strong demand for Ceylons at the time. Buyers prefer to follow up a well-known mark rather than buy stray ones like these. I think Mr. Gow was also pleased that we should have taken such precautions to avoid even the possibility of any one saying that he had anything to do with running the tea manufactured by the Witherer above its value."

We shall now await with great interest, a report on the "Witherer" erected in Carolina Factory to which (in respect of the accessories to the withering portion,) further improvements have been successfully applied.

INDIAN AND CEYLON TEA.

Our London Letter by this mail contains several references of much interest with regard to our new staple product, both in respect to the position it has now acquired with the home trade, as also as to the view taken by Indian tea-growers of the effect of the competition to which they are subjected by our own production of the article. The cause assigned by the *Economist*, the journal largely quoted by our correspondent, for the recent sudden leap into popularity that has been taken by Ceylon tea, may be, to some extent, a correct one, although it is to us comparatively novel. We are told that importers from China of the finer teas, have been so long used to a superior position in the home market, that, feeling secure in it, they held out for prices, for which those who dealt in Indian and Ceylon teas did not feel inclined to reserve their stocks. As a consequence, during that period of suspended sale of China teas, the retailers bought extensively of our own and Indian varieties. The wide distribution of these among their customers, to the comparatively total exclusion of China teas, gradually educated the public taste. The relative strength and resulting economy of the British grown varieties soon became acknowledged, and China lost—probably never to regain—the commanding position she may be said to have always hitherto occupied. To the cause quoted may, however, undoubtedly, be added the wide dispersion of Indian and Ceylon teas at the Indian and Colonial Exhibition, besides the very strenuous efforts made by special agents—ex-Ceylon planters especially—to bring their claims on the public taste well forward. We may, we think, conclude that as the joint imports from India and Ceylon must soon be on a parity as to quantity with those from China and Java, there is little prospect of the teas from the two latter countries ever again competing on the advantageous terms they had formerly enjoyed. There further appears to be every reason for concluding, according to the *Economist*, that China at all events will not be able to profitably compete with British growths at the scale of prices now ruling. If these could be forced up again, doubtless the produce of the Celestial Empire could be imported with profit to the merchants; but with the large annually increasing export to be expected from Ceylon and India such a rise is hardly to be counted upon. In fact, in the opinion of experts, there is little chance of any increase on present prices of an appreciable character.

We are therefore reduced, it may be said, to regard the chances of competition in the future to be divided mainly, between India and Ceylon. The gardens of the former are already beginning to feel the competition of those of the latter; and, as our exports must continue to increase, while at rates ruling there can be but scant inducement for any considerable extension of the cultivation in India there can be little doubt that the pinch is likely in every succeeding year, to be more and more severely felt by our neighbours. As to this point our London correspondent tells us of a conversation he has had with a gentleman of experience who but lately returned from a long residence among the tea estates of Darjiling. Even in that district, and on estates the most favourably situated both for profitable cultivation and for the production of the highest class teas, the effect of the competition of Ceylon is beginning to be felt. As we have seen by the report of the Darjiling Tea Company, it is but barely able to show a decent profit, although its teas have realised very considerably higher prices on the average than the bulk of those sent home from India generally. The gentleman referred to asserted, however, that the Indian tea-planters put a bold face upon the matter, and declared their capacity to outlive the competition of Ceylon, a competition to which they assign but a comparatively short life. Well, those that live longest will see most, and let those laugh that win!

Something like a boom in Indian and Ceylon tea and tea shares may be expected. Investors are at length beginning to realise the importance of the industry, and are looking very favourably upon investments in tea shares. The wonder is that they have been so slow to perceive the advantages which shares of this kind offer by comparison with many purely speculative undertakings in which they foolishly embark. We reproduce an article from the *Economist* which has an important bearing on the financial position of tea companies. The *Economist* is a paper of the highest class, and carries much weight. Its comments are therefore very valuable :—

The season now drawing to a close has been an eventful one for importers and producers of tea, as it has witnessed what is possibly the climax of the struggle between China and India, now, supplemented by Ceylon, for supremacy of the home market.

Early in the autumn, when it became known that the receipts from all sources would be little short of 230,000,000 lb., whereas the highest estimate of requirements was about 240,000,000 lb., it was evident that whenever the pressure to sell became heavy prices would give way, and the dealers consequently adopted a most cautious policy, endeavouring as far as possible to throw the onus of carrying stocks upon importers. The China shippers, encouraged by the prevailing opinion that their teas were of good average quality and

cheaply bought, were not disposed to meet the situation, but held out for their prices with more than usual tenacity. The Indian and Ceylon importers, on the other hand, followed their customary policy of selling rapidly on arrival, whereby early in the season a scale of price was established for all, but the finest descriptions much below the usual currencies, and sufficiently low to attract universal attention from the home trade —and even from exporters, who had hitherto been unable to push Indian tea in other markets on account of its price—with the result that an unprecedented increase in consumption followed at the expense of China tea. The change in the relative positions of the competitors for the favour of the trade is best illustrated by the following figures, showing the home consumption for the six months October-March during the past six years:—

Home Consumption. Oct.—Mar.	Indian and Ceylon. lb.	China and Java. lb.	Percentage of Indian and Ceylon.	Percentage of China and Java.
1886-7	43,500,000	48,500,000	47	53
1885-6	34,500,000	55,000,000	38½	61½
1884-5	36,500,000	59,000,000	38	62
1883-4	30,500,000	57,000,000	34¾	65¼
1882-3	29,500,000	59,000,000	33½	66½
1881-2	23,000,000	59,000,000	28	72

The natural result of this marked advance in the consumption of Indian and decline in that of China has been to effect a gradual readjustment of their respective values, Indian having risen while China has fallen; but the movement in either direction has been slow, and not yet sufficient to turn the scale in favour of China, as the percentage of Indian and Ceylon delivered during March reached the highest point yet attained. The reasons are that the retailers have become impressed with the superior value of Indian tea, and importers have continued to realise freely, notwithstanding the probability of higher prices resulting from depletion of stocks in the summer whereas the China merchants have been slow to face the position, and have not forced the market.

Importers have now to consider what action to take during the coming season, in view of a possible supply of 85,000,000 lb. from India and 15,000,000 lb. from Ceylon. Allowing for 5,000,000 lb. from Java, the total required from China, to meet a total requirement of 225,000,000 lb., will be 120,000,000 lb., and what this shrinkage of the China trade implies will be seen from the following figures showing the import from China during the past six months:—

	Total China Import.	Lb.
Season	1886-7	140,000,000
,,	1885-6	143,000,000
,,	1884-5	139,250,000
,,	1883-4	148,750,000
,,	1882-3	146,000,000
,,	1881-2	159,500,000

The questions which follow, and which will ultimately decide the matter, are—(1) Can Indian and Ceylon tea be produced to sell at the prices of the past season, or at even lower rates? (2) Can China tea be shipped at such a low cost as will enable it to recover its position, leaving comparisons of quality and relative value out of view? From all we can learn, there is still a fair profit upon the growth of Indian tea, even at present prices, and it will probably require many seasons less profitable than this one to restrict production. For some years past planters have been preparing for a crisis, and in the interval have found means for reducing expenditure in many ways, until it is now found practicable to lay down crops in London at a cost which was deemed to be impossible a few years ago. In many cases this has been effected by a system of cultivation which enables from 600 lb. to 800 lb. of tea to be harvested from each acre of plant, and although the system gives a crop not worth more than 9½d or 10d per lb. on the present basis of price, the cost being thereby reduced to 8d per lb., or less, it is clear that the point has not yet been reached which will check production. The alternative method pursued by planters whose estates are favourably situated with regard to soil, climate, and plant—of making a smaller quantity of much finer tea—has been so successful owing to the good prices still commanded by fine Indian tea, that some reaction in the direction of smaller crops and higher quality may be seen, but the risk attaching to such a policy will deter the majority from pursuing it. Few results of the past season's working have yet been published—and it is unnecessary to anticipate them—but it is pretty well known that those estates, which represent the system of making fine tea, such as the Jorehaut, Jhanzie, Borokai, Luckimpore, Scottish Assam, Tiphook, and many Darjeeling gardens, also some of those who adopt the opposite policy of making very heavy crops, have had a profitable year. The result of this will be to attract fresh capital to the industry, and to stimulate the energy of growers rather than to check it. Ceylon tea is another important factor of the future, for its merits have gained it so much favour from the trade, that, notwithstanding the supply has doubled, its average value for the season holds at about 1s. 2d. per lb., a price which leaves a considerable margin of profit, the cost of production being even less than that of Indian. China has, therefore, to face the certainty of increased supplies from Ceylon and India, and the probability of growers being able to hold their ground with still lower prices—for the means of reducing cost have not yet been exhausted. Those who know the Chinaman expect that they will not retire from the contest without making a great effort to recover their trade; and their anxiety to keep it has been proved by their consigning tea on their own account to the States and London through the Commission houses when buyers in China refuse to operate. Their experience, however, of this sort of business has not been encouraging, and they are probably astute enough to see that it will pay them better to reduce and regulate supplies instead of glutting the foreign markets. And when it is considered what an insignificant fraction of the total trade in China the quantity exported forms, 20,000,000 or 30,000,000 lb. more or less of foreign trade is not a great matter after all. Two courses seem open to them—the one, to find means of lowering their prices to the point at which they can sell Congou at 4d or 4½d per pound) which, so far, has not been practicable); the other, to improve the make and quality of their tea, and bring smaller supplies to the ports. There is no doubt that the average British consumer still appreciates good China tea, and that the trade would pay a fair price for it; but for a long series of years the character of China tea has been steadily deteriorating, until the bulk of the crop is now so far inferior to Indian and Ceylon that when prices come to about the same level, there is no question as to which the trade will give the preference. There is a third alternative—viz., such a growth of consumption as would enable us to absorb the increased crops while taking the same quantity of China as hitherto; but the figures of the past six years hardly justify such a hope. They are as follows:—

Home consumption United Kingdom,			
1886-7 (about)			183,500,000
,,	,,	,, 1885-6	160,000,000
,,	,,	,, 1884-5	*202,500,000
,,	,,	,, 1883-4	171,000,000
,,	,,	,, 1882-3	170,000,000
,,	,,	,, 1881-2	159,500,000

Allowing for growth of population, consumption seems to be increasing very slowly, but we believe that Mr. Goschen's opinion that this is not really the case is correct, and that the explanation is as he stated, that the 82,000,000 or 83,000,000 lb of Indian and Ceylon tea now consumed being stronger and therefore more economical, represent a much greater weight of China tea such as formed the bulk of the deliveries prior to 1881.

Notwithstanding that consumption makes only slow forward movement, the position of tea, from a market point of view, is much sounder than it was a few years ago; the speculative element has almost disappeared; the custom of "hand to mouth"

* Owing to heavy clearances when an increase in the duty was feared.

buying, now so general, has largely reduced the "invisible supplies" held out of bond by retailers; while, owing to the determination of importers and dealers not to carry heavy stocks over from one season to another, the stock in the bonded wharehouse is now 20,000,000 lb. less than it was six years ago, to meet the wants of a trade 2,000,000 lb. per month heavier. The effect of this is felt in the sensitiveness of prices whenever, from any reason, a general demand sets in.

A broad review of the position, then, is distinctly favourable to the Indian and Ceylon interest—in which, as a purely British industry, we are most concerned—and for the reasons above mentioned, especially the fact that cost of production has been so much lowered, and popularity with the home trade firmly established, the outlook is encouraging to those whose capital and energies are employed in these great industries of India and Ceylon.—*H. & C. Mail*, May 6th.

THE TEA TRADE AND PLANTING IN INDIA.

The Economist of last week published a very interesting review of the present position of the tea trade. It was especially so from the fullness of the comparison it drew between the relative trades of this country with China and with India and Ceylon. The two latter countries have been grouped in this comparison, so that it is difficult to extract from the article anything having sole and special relation to your island. It is stated by the writer of the article in question that, early in last autumn the receipts from all sources were not estimated to exceed 230 million lb., whereas the highest estimate of requirement was 240 million lb. Dealers feared a fall in prices, and threw the onus of keeping stocks upon the importers. The China shippers held back from selling, whereas the India and Ceylon teas were sold rapidly on arrival. This latter course established for all but the finest description a low scale of prices, and the Indian and Ceylon met a quick market, while China teas, when subsequently brought forward, had already suffered much from the competition then established, and whereas from October to March 1881-2 of the consumption of China and Java teas was 59 million lb. or against only 23 million lb. of India and Ceylon, in 1886-7 the figures were so received that the sale of the latter reached 43½ million lb. against 48½ million lb. of China and Java. The effect of this the writer states to have been a complete readjustment of prices, Indian having risen while China has fallen. But this has not yet brought a return of prosperity to the China growths, for the percentage of India and Ceylon deliveries during last week were the highest yet recorded, and this is assigned to the fact that the retailers have become impressed with the superior value of Indian teas. It is estimated that for the requirements of the coming season 225 million lb. will be wanted, and that of this there will be wanted 120 million lb. from China and Java. It is believed to be doubtful if at the low prices now obtainable the China tea can recover its position so as to make it worth the while of the importers to bring in this quantity. Space forbids my pursuing further extracting from the article referred to, but its full perusal may well be recommended to all your planters and others interested in the progress of the tea trade. The closing paragraph of the article may, however, well be quoted *in extenso*. "A broad review of the position then, is distinctly favourable to the Indian and Ceylon interest—in which, as a purely British industry, we are most concerned—and for the reason abovementioned, especially the fact that cost of production has been so much lowered and popularity with the home trade firmly established, the outlook is encouraging to those whose capital and energies are employed in these great industries of India and Ceylon."

A conversation had by me this week with an officer who has long resided in the tea districts of India enabled me to ascertain from him the views held by Indian tea planters as to the effect the competition of Ceylon is likely to produce upon them. He tells me that the planters of India say that they will contrive to live down all your island efforts. They argue, he says, that Ceylon has a very thin deposit of soil, and that tea being a very exhausting crop this will soon become worked out and the tea bushes will lose all vitality while they also contend that Ceylon does not possess the facilities for the large application of the manure which could alone stay the gradual extinction of the proper qualities in the soil needed for tea. I am quite unable to judge whether there can be any justification to be found for such a line of argument. If there be, all the stronger reason is then why all your planters should receive the greatest degree of aid possible in the means for transporting manure to their estates. My friend said the soil in the terai of India was that best suited for tea, that it was of great depth and almost virgin, while by degrees the fearful unhealthiness of the district has been overcome, and many Europeans and their families are now leading healthy lives there.—*London Cor.*

CEYLON ORCHIDS.

Not long back you published some remarks upon the orchids of Ceylon and the probability that if they were well searched for, the labour of doing so might be made to pay well. An enthusiast on the subject of orchids whom I met this week told me that he had just been to Bull's Show of those plants at Chelsea, and that there was not a specimen lower priced than five pounds. Another authority told me that a Mr. Lowe, a younger brother of Sir Hugh Lowe of Perak, had realized a fortune of £250,000 sterling by dealing in orchids alone. Of course he has a travelling staff of highly trained and correspondingly paid agents, who search all new countries such as Upper Burma, Borneo &c. It was told me that it was Mr. Lowe's own discoveries in the latter country which laid the foundation of his great fortune. In illustration of the procedure of these agents, my friend told me that one of these chanced to visit a Colonel—then resident somewhere in Burma. He saw an orchid perfectly new to him, and of magnificent form and colour. He eagerly asked where it was obtained and the Colonel told him he had come across it in some valley in Northern India and brought it with him to Burma. The energetic agent lost no time, but was off by the next steamer to Calcutta, and proceeding upcountry to the foot of the Himalayas searched the whole district till he came across the Valley described. It abounded in specimens of the orchid of which the adventurer had seen a single one in the house of his friend in Burmah. He collected a thousand of them, and shipped himself with them direct to Mr. Lowe in England. The plants sold for thirty guineas a piece! Their collector again returned to India and brought home another thousand plants, which he also sold well for Mr. Lowe in England; but after this second consignment was made the locality of the orchids got wind, and being very numerous there they were sent home in such numbers that the price soon dropped. This story seems to show that your contention that further searchin Ceylon might be remunerative was not at all far-fetched.—*London Cor.*

CEYLON TEA STATISTICS: PRICES AND GROUPING OF DISTRICTS.

To Messrs. Geo. White & Co., we are indebted for the very instructive statistics which we publish below and which cannot fail to reassure those amongst us who are liable to become faint-hearted and indulge in dismal prophecies of the immediate future of Ceylon tea. The increase in deliveries keeps pace with that of supply and the mere fact of the deliveries of Indian and Ceylon teas being within a trifle of the amount of China Congous and Souchongs shows the enormous hold the former have obtained on the home markets :—

London, 9th May.

A large percentage of the teas sold during the past month was thin and pointless and had the appearance of having been affected by the dry weather which has been so generally prevalent ; still there was a very marked improvement in some invoices, and they met with spirited competition. The advance in prices of nearly all kinds of Indian growths, especially in good medium and fine grades, has favourably influenced Ceylons, and the most recent sales show an advance of ¼d to 1d per lb. on fair to goood, while fine and finest are 2d to 3d per lb. dearer. The imports for April were slightly under those for the corresponding period of 1886, being 679,000 lb. against 705,000 lb. The deliveries were very satisfactory, being 657,000 lb. against 316,000 lb. last year. Taken together with Indian they amounted to 7,423,000 lb., while the deliveries of China Congou and Souchong for last month were 7,878,000 lb In addition to the figures given at foot, the following will show the movements of Ceylon tea for the past ten months :—

For the ten months from 1st July to 30th April :—

	1886-7 lb.	1885-6 lb.
Imports ...	6,549,000	4,044,000
Deliveries ...	6,395,000	3,263,000
Stock on 30th April	2,076,000	1,602,000

The total number of packages brought to auction during April was 13,108, against 5,024 for the same month in 1886.

The following quotations (which are only given where complete invoices have been sold) comprise 7,914 packages, with a general average of 1s 1¾d per lb., against 1s 1d realized for 2,779 packages in April, 1886. They are arranged in thirteen groups of districts, as under :—

Index No.	Outlet.	Grouping.
1	Nanoo Oya and Talawaakelle	Uda Pussilawa, Newera Eliya, Dimbula, Lindoola, and New Galway.
2	Hatton	Maskeliya, Dikoya and Bogawantalawa.
3	Wattewela	Ambegamua and Kotmale.
4	Navellapitya	Yakdessa and Dolosbagie.
5	Gampola and Kadugannawa	Kadugannawa, Pussilawa, Rambodde and Pundaloya.
6	Kandy	Hantane, Nikambe, Lower Hewahetta Upper Hewahetta, Maturatta, Dumbara, Rangala, Nitre Cave and Medamahanuwara.
7	Wattigama	Kalebokka, Kunckles, Hunasgeria and Panwila.
8	Matale	Matale, East and West.
9	Polgawela	Kurunegala and Polgawela.
10	Colombo, via Kelany Valley	Kelany Valley, Avisawella, Yattiantota, Lower Dolosbagie and Kitoolgalle.
11	Colombo, via Kaluganga and Ratnapuru Road	Kuruwitta, Ratnapura, Rakwana and Balangoda.
12	Colombo, via the Coast Railway	Kalutara and Bentota Districts.
13	Galle	Morowak Korle and Udagama.

The letters given refer to the different grades as follows :—" a " =Pekoe ; " b " = Broken Pekoe ; " c " =Pekoe Souchong ; " d " = Broken Tea ; "e " = Dust and "f " = Unassorted.

These figures, confined as they are to sales for the month of April only, though interesting to everyone connected with our tea industry, do not possess the absolute value they would have done had they related to the sales of a longer period, say six months or a year. One feature of the returns, however, is remarkable, that with a distinctly inferior market, and with more than double the number of packages on offer, the sales in April of this year shew an average increase in value of a half-penny a pound over that of the same month in 1886.

Taking the figures as they stand, Group No. 6 exhibits the highest average, viz. 1s 4d, and this may very easily be explained by its including the two favourite marks, Loolcondura and Rookwood realizing respectively 1s 10½d and 1s 6¾d. To those who feel anxious about the stability of the superiority of our teas—it must be reassuring to find the oldest estate in the island holding out in quality as it does, and though giving no very large yield per acre maintaining its quality so well. Leangapella does well for the average of this group at 1s 4¼d and Oodewella 1s 3¼d. The second place on this list is No. 11, Ratnapura and Kaluganga including Balangoda, and consequently Agarsland with a sale of 77 packages at 2s 1½d. There are sales from only four estates in this group, and with such a leader as this we should have expected the average would have been something over what it is, namely 1s 3¼d. Group No. 1 Nanuoya and Talawakelle including Nuwara Eliya comes next with an average of 1s 2¼d, Elbedde helps these figures considerably with the fine average of 1s 6¼d and Glassaugh makes a good second with 1s 4¼d, Mattakelly (the great centre of cinchona) 1s 3¼d. Fourth on the list is No. 10 Kelani stretching as it does into Dolosbage. The average of 940 packages from this group is 1s 1¾d, Ernan leading with 1s 3½, a rocky steep face with fine soil apparently doing as well for tea in the lowcountry as for coffee in the hills, Glenalla 1s 3d and Morton the same. Dunedin contributes 333 packages, and Levant 111 to the 940 from which the averages are calculated. Group No. 5, stands also the same figure in rate of average—1s 2d. This takes in Punduloya, Pussellawa and Gampola. Sogama leads with 1s 5¾d—most of it, we believe, is patana soil, but containing a good deal of limestone ; Dunsinane far up at the end of Punduloya follows at 1s 1¾d. We then find three groups averaging the same, namely, 1s 1¼d, Nos. 2, 3 and 7, Hatton, Wattewala, Wattegama. In the first of them Ovoca averages 1s 4¼d, Venture 1s 3½d, Castlereagh and Hardenhuish (with Lammermoor) 1s 3d; in No. 3, Goorookoya and Imbulpitiya each give 1s 2½d and K A W sent 366 packages (out of a total of 860) at 1s 2d, and in No. 7, Kallebokka gives 1s 5d, Nilloomally 1s 4¾d and Tunisgalla 1s 3½d. So that, some of the ancient well-known coffee estates seem to prosper as tea properties and assert themselves as no whit behind more modern plantations. Group No. 12, Kalutara comes next with only 351 packages averaging 1s 1d, of these Putupaula does best at 1s 2¼d. Of No. 8 group, there are sales but from two properties Brae and Poengalla and they average the same 1s 0¾d with 40 and 33 packages, respectively. There will soon be an improvement in this quarter, both in quantity and quality of tea, the Ratotte district is going to do well. Group No. 4, Nawalapitiya is but a farthing below this average. Gallamudune averages 1s 4¼d and Meanagalla 1s 3d, whilst Windsor Forest with 108 packages stands at 1s 2d. The last, with an average of the round shilling is Galle with sale of two marks only, Hayes 265 packages at 1s and Campden Hill 9 packages 1s 1d—the latter little lot being lost in the average of the larger sales of the former. There are no figures for group No. 9—Polgahawela and Kurunegala.

TEA AND THE EFFECT OF REDUCED TAXATION.

TO THE EDITOR OF THE " SPECTATOR."

SIR,—In your criticism of Mr. Goschen's Budget, in the *Spectator* of April 23rd, there is a sentence in relation to the consumption of tea which I think is a little misleading Will you allow me to point out in what way? You say :—" The consumption of tea, on the other hand, is nearly double in the thirty years since 1857 ; but though the consumption has doubled, the tea revenue has not doubled. Indian tea is so much stronger, and so much larger a proportion of the tea now imported is Indian than it was formerly, that, reckoned in relation to the increase of the population, the tea revenue shows signs of falling off."

Now, what are the facts ? In the year 1852, the total consumption was 55,092,000 lb. The duty then stood at 2s 2½d a pound, and the total product to the revenue was £6,025,687. In the early part of 1853, the then Chancellor of the Exchequer, Mr. Gladstone, in his ever-memorable Budget, began his great onslaught on the tariffs. He reduced the duty on tea at once to 1s 10d and provided for its further gradual reduction to 1s a pound. This reduction was interrupted in 1856 by Sir George Cornewall Lewis in consequence of the Russian war. The reduction to 1s was not reached till 1864 ; but in 1865 it was further reduced to 6d, where it now stands. I will not trouble you with all the figures, but in 1864, the gradual increase in the consumption of tea had reached a total of 91,296,000 lb, and in 1886 it had reached the enormous total of 181,488,122 lb., producing a revenue of £4,537,203, a sum very nearly equal to that produced when the duty stood at 2s 2½d. Think of what that means to the producer, to the distributor, and chiefly to the consumer ! Think what it means in the homes of the poor, where the great consumption of tea takes place ! It can now be bought at a fourth of its former cost, and all this with very little loss to the revenue,

The export deliveries amounted to rather over 40,000,000 lb.

It may be interesting to note that the distribution of this great total among the different growths of tea is as follows : —China tea, 146,823,504 lb. ; Indian, 68,419,878 lb. ; Ceylon, 6,244,740 lb. It was not until the year 1860 that Indian tea was known in this country, and the total product for that year was only 1,200,000 lb.

In regard to Mr. Gladstone's beneficent legislation in the reduction of duties on other articles, it would take pages of your space even to mention them. Sugar, for instance, now costs the consumer only the amount per pound paid as duty in 1864. The duty on soap, which at one time contributed over a million to the revenue, and the newspaper stamp duties also producing a million, have been swept away.

Now, one short sentence as to the effect of all this on the national prosperity, which can easily be tested. In 1853, an Income-tax of 7d. produced a total of £5,845,000, a penny in the pound producing less than a million. The Income-tax last year of 8d. produced a total or just £16,000,000 or £2,000,000 for every penny.

We are now celebrating the Jubilee year of her Majesty's prosperous reign; and as there can be no doubt that the legislation during that period has been beneficial, so there certainly can be no manner of doubt that there is one man above all others who, with clear vision and unerring instinct, has left his mark most deeply on that legislation, It is as well to recall this fact in these days, when we are constantly told by croakers that he has ruined the country.—I am, Sir, &c.,

HENRY BARTER.

16 Airlie Gardens, Campden Hill, W., April, 26th.

[We never heard any sensible man express anything but profound gratitude for Mr. Gladstone's economical and financial reforms. It is not in that direction that Mr. Gladstone has been underrated. As regards the Sugar-duty, however, the last great reduction of it should be ascribed to Sir Stafford Northcote.—ED. *Spectator*.]

NETHERLANDS AND INDIA HORTICULTURAL SOCIETY.

AMSTERDAM, May 4th.—A circular has been issued in which the establishment is announced of a Netherlands and Indian Horticultural Society at Zeist (Holland), with a capital of 150,000 guilders, of which 45,000 guilders have been taken up. The purpose of this society is to promote agricultural interests in Holland and Java by a mutual interchange of plants, &c., and this plan has met with much support. The Minister of Finance has published the terms of the new charter of the Netherlands Bank, and accompanies it with a statement of the probable profits to be expected. Under the existing charter the profit of the bank was about three million guilders per annum, or about 19 per cent. on the capital of sixteen million guilders. But in consequence of the depression generally prevailing in commerce, and the low rate of interest ruling of late, the profit was in 1884-85 500,000 guilders less, and in 1885-86 one million guilders less than the average of former years. Therefore, the total profit under the new charter cannot be estimated at more than about 4,400,000 guilders, the distribution of which will take place as follows: 5 per cent. to be paid to the bank as a dividend on the capital, which will be increased to twenty million guilders. Of the remaining profit 10 per cent. will be placed to the reserve fund. The balance of 2,160,000 guilders will be divided between the State and the bank, each receiving 2 per cent. of the capital, or 400,000 guilders, and of the remaining 1,360,000 guilders the State will receive two-thirds and the bank one-third. The total amount of profit to be earned by the State will be 1,306,667 guilders, whereas the bank receives 1,853,333 guilders and 240,000 guilders for its reserve fund. In the event of the reserve fund reaching the amount of 5,000,000 guilders the State is to receive 160,000 guilders and the bank 80,000 guilders more. There are some other stipulations in the new charter regarding the reserve fund and the increase of the capital. It is expected that the dividends will amount to about 7 per cent. It is also agreed between the State and the bank that the annual payment to the State of 100,000 guilders will be abolished, and that the bank will be authorised to invest half of the capital in public funds and to negotiate foreign bills of exchange. After the announcement of the terms of the new charter some transactions have taken place at the Stock Exchange in shares of the bank at a reduction of 12 per cent., and the closing quotation is 214 per cent.—*L. & C. Express.*

COFFEE, COCOA AND TEA.—In our mail intelligence it will be seen that the Brazil coffee crop was estimated as low as 3½ million bags—no wonder, though speculation then set in, and with an anticipated deficiency of this kind, there is some good basis for speculation to work on. At the same time, the cocoa market notwithstanding full stocks, is reported very strong: cocoa is, in fact, bound to profit by the scarcity of coffee, and to some extent this must also tend to the benefit of tea, for coffee-drinkers on the Continent of Europe as well as of America are already beginning to take to tea and will increasingly do so, when they find their old drink become so scarce and dear. In France, as in England, "five o'clock afternoon teas" have become all the fashion, and as one Ceylon authority remarks, when the French learn to drink tea of an evening, they will soon find it desirable to try it of a morning too.

WATER PIPES.—The reason for the opposition to the use of galvanized iron pipes for water conductors arises from the fact, "J" will find, that zinc dissolves in water, and that soft water, such as rain water, dissolves it more easily than hard, while that containing carbonic acid is specially able to dissolve it. This being the case, and the use of galvanized iron for pipes and tanks being so much on the increase, medical writers have recently called special attention to the importance of the subject, it being desirable to ascertain, as far as possible, to what extent solution of zinc coating takes place, and how far water contaminated by zinc is injurious to health. Investigations as to this point present evidence which is to some extent conflicting, but give a very decided balance on the side of the view that such water is considerably injurious, so much so. Indeed, that the French Government, some time ago, prohibited the use of galvanised iron tanks on board its men-of-war. Some analyses in this direction show, for example, that spring water, after it had travelled through half-a-mile of galvanized iron pipe, took up 6·41 grains of zinc carbonate per gallon. In another instance, spring water that passed through 200 yards of galvanized iron pipes to a house, took up 4·29 grains of zinc carbonate per gallon.—*American Cultivator*. [Boiling the water and afterwards filtering and cooling would, however, remove any risks.—ED.]

ECONOMIC BOTANY: THE NEED OF A TRAINING FOR INTENDING PLANTERS.—The following note appears in the *Gardeners' Chronicle*:—"In connection with economic botany from a visit I paid to Ceylon, and from a long residence in India, I have found that intending planters go to India and the colonies without any training whatever regarding the nature of the business they go out to manage and direct. They have no knowledge of the nature of the plants they will have to deal with; they know nothing about their physiology or mode of training them with a particular object, or of the probable result of denuding miles of country of their indigenous forest, the action of manures, the value of wind and storm screens, and a dozen other topics which would be of everyday advantage to the planter. If a training college for planters is not already a national institution, it is high time that one were set up in connection with agricultural colleges or schools of forestry. The planter's learning should be a combination of science and art, with the object of getting the best value out of his plants, with the least disadvantage to them, and of utilising all his surroundings to the best advantage for the same purpose. It is not impossible that the ruin of the Ceylon Coffee industry may have been hastened, not only by the planter's hurry to make a fortune, but also by ignorant mistakes, which by a sufficient training might have been avoided. In India it is thought a sufficient equipment for a planter's career for him to take out a battery of guns for sport. The result is disappointment, *ennui*, loss of money, debt, &c., and finally loafing about in search of some small Government appointment for one's bread and butter.—E. B., M. D.,

INDIAN GRASSES.

All who have read Mr. Symonds' articles on the grasses of the Madras Presidency, and on Army Animal Management, which appeared in the *Quarterly Journal of Veterinary Science in India*, will be glad to have them in the more complete and covenient form in which they are now published. In the present work the most important grasses of the whole Indian Peninsula are described, and figured with special reference to their use for fodder, and though, of course, a complete list of the Indian grasses cannot be expected, it will, we think, be found that all those known to be of value are included. Of course such a work must be in the main a compilation from other writers, but it needs a wide knowledge of the subject to make the compilation satisfactory, and we can congratulate Mr. Symonds on his success in this respect.

It appears that the most important of the fodder grassess of India is the *Cynodon Dactylon*, known in this part of India as hariali grass, and in the north as dhoob. It is the same as the couch grass of Australia and America, and grows well in all parts of India. This grass is treated of at considerable length, and many useful details are given regarding its cultivation. Perhaps the most interesting part is a quotation from a report made by Major-General Ottley upon some experiments which he made at Vellore on its cultivation on a fairly large scale. The soil was first very carefully prepared and manured, care being taken to remove all the roots of the corra (*Cyperus Rotundus*), a most troublesome weed, which is often found growing along with the hariali, and which can hardly be eradicated after the latter grass has been planted. In the ground thus prepared the hariali roots were planted in furrows, and the whole was then laid out in beds, so as to allow of irrigation from wells in the compound. At the end of about a month the first crop was ready for cutting, and by the judicious use of irrigation—once or twice a month—it was found that eight crops could be obtained in a year. Each crop yielded on an average two tons to the acre, so that it is well within the limits to say that 50 tons per annum can be obtained from 5 acres of ground properly attend to, and this yield is sufficient to render the crop a profitable one, even when we take into account the very heavy first cost of preparing the ground. On the produce of his five acres, General Ottley was able to keep eight or nine horses and sheep, and to supply hay for the racing studs and livery stables at Madras; while during the last Burmese war, at a time when there was not a blade of grass in the country, he supplied all the hay needed for the Horse Artillery sent to Rangoon. Experiments made at the Sydapet Farm on a plot of 3 acres in 1868, showed that a fair crop could be obtained even without irrigation, for from this plot 8 tons 13 cwt. of hay was obtained during the year. This hay sold for R360, while the cost of curing it was only R105. The hay made from hariali grass is of an excellent quality if care is taken to carry on the drying properly. The grass ought to be cut immediately after the flower appears and, according to Mr. Cameron of Bangalore, the cutting should be done in the cool hours of the day, so that the newly mown grass may not be exposed to the intense heat of the midday sun, and the drying should take place very slowly. But this is evidently a point on which "doctors differ," for Mr. Robertson, of Sydapet, gives advice which is very nearly the opposite of this, as he advises that the grass should be cut in the morning after the dew is off it, that it should then be left lying for an hour or two, and finally be turned and tossed about till sunset, for "it cannot," he adds, "be tossed too much during a hot sun." In dry weather two days of this treatment should fit the hay for being stacked. Our author does not attempt to decide between these diverse opinions, and neither will we, though we must admit Mr. Robertson's advice seems to agree with the best practice at home. A point which is not generally known with regard to hay is that it is decidedly advantageous that it should heat slightly after it is stacked, the fermentation that takes place in that case improving the quality of the hay as fodder, just as coarse grass is improved by fermentation in a silo. But of course care must be taken that this heating does not go too far. Mr. Robertson suggests the use of a single row of six inch drain pipes placed about the middle of the stack, and leading from the centre to the outside. But drain pipes are not things that are usually to be found in this country, and they can be replaced by hollow bamboos or split palmyra stems, or the stacks may be built round a "centre," as is so often done at home. Hay which has been well made, attains its maximum value from eight to twelve months, and after fifteen months begins to deteriorate, and by three years it is useless for fodder.

Another very valuable grass is the guinea grass (*Panicum Jumentorum*), a native of Guinea, but thoroughly acclimatized in this country. Not only does this grass yield a very large crop of a quality admirably suited for feeding horses and cattle, but it has the power of resisting the longest severest droughts. This was well shown on the Sydapet Farm during the last famine. A field of two acres was planted in September 1877, and in May 1878 it was perfect brown, and to all appearance lifeless, when the heavy rain which fell during the cyclone in that month led to its immediate revival. Before the third day of the rain was over, green shoots appeared all over the field, and in two months it yielded a crop weighing 5,566 lb., followed two months afterwards by a second cutting weighing about 12,000 lb. The popular idea that this grass requires to be irrigated, and that it should be taken up and replanted in fresh ground at the end of every two years or so, is situated to be quite erroneous. Of course irrigation will increase the yield, and any grass which grows so quickly requires an abundance of manure. The plants, too, soon become too large, and ought to be divided into four with a spade by two cuts at right angles through the centre, three of the parts may then be removed and the fourth left where it is. A subject on which Mr. Symonds has a very decided opinion is the present most unsatisfactory state of the system of obtaining grass for horses by means of grass-cutters. In Bengal the grass-cutters are men who are regularly enlisted and serve for a pension, but in Madras and Bombay in the army as well as in private stables, the grass-cutters are women who are generally the horsekeepeers' wives. All who keep horses know how difficult it is to have any real control over these women, and how badly they usually do their work, and that there is much need for an improved system. In connection with this we are glad to see that Mr. Symonds call prominent attention to very common error that the roots of grass are best for horses. If the the roots are young and small they certainly possess a considerable amount of nourishment, but old roots are always mixed with the young, and these are not only innutritious, but are actually hurtful. The following directions regarding grass seem worth quoting for the benefit of private horse owners. "The grass should be brought in dry, laid on a trellis frame, beaten to remove dust and dirt, and it is then fit for use. Perfectly dry grass is not always possible, of course in the rains it is impossible, then they should bring in 20 lb. extra, take every advantage of getting it dry keep it two or three days, then beat it and use it In very wet weather, when there is continuous rain, to keep it would only induce fermentation, but as soon as there is a break in the weather, the drying should be assiduously attended to, and it cannot be laid out too thin." The practice of grubbing up the grass with a mamoty is strongly condemned not only on account of the number of roots which are thus mixed with the grass, but also on account of the destruction of the grass; but this latter objection can hardly be maintained in view of the experiments recently made at Lucknow, where it was found that by scraping the surface, as practised by the natives, an advantage of 10,320 lb. per acre per annum was obtained over the plan of allowing it to grow, and then cutting it with a sickle. These experiments were made on hariali grass. In conclusion we may call attention to the sixty-two admirably executed lithographic plates of the various grasses described, which, taken along with the text, faciliate the identification of each grass, and greatly add to the value of the book.—*Madras Mail.*

Correspondence.

To the Editor of the "Ceylon Observer,"

ROSES ATTACKED BY FLIES.

Colombo, 17th May.

Sir,—I happen to be the happy possessor of a pretty good collection of choice rose plants. Since of late the plants are actually covered every evening with a swarm of our ordinary flies; and this causes the plants to put in a sickly growth. I have tried sulphur and ashes to drive them away, but without any success. I should feel greatly obliged if you or your numerous readers can tell me how I am to be rid of them. Thanking you in anticipation. D. J. C.

[A practical horticulturist answers:—"I have never heard of the ordinary flies (which I take to be the common house fly) doing any damage to plant life before I have no doubt they can be easily got rid of by syringing the plants occasionally with tobacco water in the evenings and with pure water the following mornings:—three or four ounces of tobacco to a gallon of water make a good wash and will kill or drive away any fly I have met with. To economise the mixture the leaves could be sponged or the shoots dipped in it. Newly slaked lime, mixed with a little snuff and dusted over the plants would, no doubt, also drive them away. The fumes of turpentine is another thing that all insects detest, but great care must be taken that it does not come in contact with the plants. It could easily be applied by placing a little in saucers or tins at the foot of the rose bushes."—Ed.]

COCONUT SEEDS.

21st May 1887.

Dear Sir,—The current number of the *Tropical Agriculturist* contains a very sensible communication on seed nuts. It is to be deplored that very little, if any attention is paid to this important subject by coconut planters. Considering that a coconut tree has not a limited lease of life, and that the financial success of a coconut plantation is greatly dependent on the bearing quality of its trees, it is to the manifest interest of planters to be extra careful in the selection of seed nuts. What do we actually find? Villages scoured for plants that have germinated in the coconut heaps, or nurseries made of nuts indiscriminately bought from bad and good trees.

In my neighbourhood is an estate planted from selected seed, which during the recent drought presented a striking contrast to the neighbouring estates. The former had very few trees with drooping branches, and displaced branches, while to the latter the lucid and poetical description of your ex-cinnamon and coconut-planter correspondent "S." of the trees in Veyangoda, Mirigama and Ambepusse applied:"The trees shed their branches and get them at the top, and at the age of 30 years the trees will hardly give any crop." I wonder where coconut trees in other districts get their branches?

I have before now recommended placing coconuts on their sides in the nursery, my principal reason for this being that the germs are continually kept moist by the "milk in the coconut," and the chances of successful growth are greater than if the nuts are placed in an upright position and the germs deprived of the moisture nature intended for them. Your correspndent inclines to an opposite view and in support of it makes the startling assertion that "the first event in germination is the conversion of the water into a light spongy substance that fills the whole cavity." Of what? Now this is in direct opposition to fact. In the process of germination all seeds make an upward and downward growth. The latter supports the former. Coconut is no exception to the rule. A sprout is thrown outside and a spongy mass grows from the germ inside the coconut. This absorbs the water inside the coconut which in its turn supports the sprout till such time as it developes roots. The roots occupy the space between the outer husk of the coconut and the shell inside, and feed on the husk till they reach "mother earth." It is surprising that a man of the evident experience of your correspondent has not observed that this spongy mass, which he so unhesitatingly asserts is formed by the water in the nut, is from its earliest growth attached to the germ, and cannot be detached from it without the application of some force. This ought to have taught him that it was the germ that gave birth to the spongy mass. While if his assertions were true, this substance will make its first appearance where the water is: if the coconut were placed in an upright position, at the bottom of the nut and it will also be a detached mass, which it is not.

I have heard it stated by natives that owing to the depredation done to a new coconut plantation by boys who wantonly root up and destroy the plants to feast on this toothsome spongy mass inside the coconut, it is scooped out before planting and the place it occupied filled with ashes or paddy husks, and that this treatment in no way affected the plants. This then supports my contention that this spongy substance supports the sprout only for a limited period.

A neighbour of mine recently had many of his coconut plants in his new plantation destroyed by boys for this spongy substance, while another gentleman finding a splendid nursery of his gradually die out, was curious to discover the cause. Taking up the sprouts he discovered that the nuts to which they were attached were missing. A watch was set and some coolie boys caught in the act of sticking the sprouts where they were and removing the nuts. I need hardly say that they gave up their little game after this discovery. It is curious that "W. B. L." who wrote a clear and elaborate essay for you on Coconut Planting did not include naughty boys amongst the enemies of the tree.—Truly yours, B.

CHEAP QUININE.

Dear Sir,—According to arrangement with the Government, the planters who are taxed in an unmerciful fashion under the Medical Ordinance, were to have quinine, &c., sold to them at cost price. Now Messrs. Mackwood & Co. have for a long time past been selling Howard's (white label, and black letters) pure Sulphate of Quinine at R2·40 per oz., and they will sell a single ounce at that rate—and no doubt they reap some small profit on the transaction. The Government charge is R2·50 or more per ounce—so I think it is sufficiently clear that the planters are not getting their quinine at cost price!

Colombo Chemists are advertising Howard's quinine at R2·50 per oz., but then will you be surprized to know this is Howard's second quality! It bears a black label and gold letters. The two labels are the only means taken by Messrs. Howard to denote the two qualities. If the black label quality is worth R2·50 per oz.—the advertized price—then the white label is worth about fifty per cent more—so all honour to the Hon. F. M. Mackwood who stands alone apparently in giving to Ceylon

CHEAP AND PURE QUININE.

CHEAP AND PURE QUININE: A CORRECTION.

Colombo, 24th May 1887.

Dear Sir,—"Cheap and Pure Quinine" asserts in his letter appearing in your yesterday's issue that "Colombo Chemists" are advertising Howard's Quinine at R2·50 per oz., but that "this is Howard's second quality" indicated by black label and gold letters; while the first quality is indicated by white label and black letters. Your correspondent proceeds to [illegible] authoritative tones, that "the two labels are the means taken by Messrs. Howard to [illegible] two qualities," and that "the white label is worth about 50 per cent more" than the [illegible]

Permit us to quote Messrs. Howards & Sons' reply, under date of 24th April 1885, to an enquiry from us as to the exact significance of the two labels in question :—

"Replying to your enquiry anent labelling of this article, the black and white label and red seal is the usual form for the home trade and the colonies, and the black and gold label and capsule is used, almost exclusively for the Indian market. *The quality of the quinine is in both cases identical.*"

We trust that we are incapable of trying to palm off on our customers and the public, an inferior for a superior quality of any article.

We leave you to reckon with your correspondent for his abuse of your columns by misrepresenting the leading quinologists of the world; by insulting by false and fulsome mention, the name of a respected merchant; and by his attempt to injure our humbleselves, who, we believe, are the only chemists in Ceylon who advertise "Howard's Quinine" at R2·50 per oz.—Yours obediently,

COLOMBO APOTHECARIES CO.,
FRANK E. BALLARD, Manager.

[From what we know of him, our correspondent is incapable of the conduct ascribed to him; he has simply been misinformed and made a blunder for which we have no doubt he will readily apologise. We are very pleased to give insertion to the information in respect of Howard's quinine packages.—ED.]

No. II.

Colombo, 24th May 1887.

SIR,—Your correspondent "Cheap and Pure Quinine" has evidently been misinformed. Allow me, as one who can speak with authority, to say that Messrs. Howards & Sons manufacture only one quality of quinine, viz. "Sulphate of Quinine pure."

That in bottles bearing a "black and gold" label, is identical with that in bottles bearing a "white and black" label, and Messrs. Howards & Sons' price is the same for both.

The "black and gold" label and metallic capsule is simply their style of putting up for India and the East.—I am, sir, yours &c.,

CHARLES W. WHITE,

Representing Messrs. Burgoyne, Burbidges, Cyriax & Farries, and Messrs. Burroughs, Wellcome & Co., of London.

CHEAP QUININE :—PURITY! THY NAME IS HOWARD.

DEAR SIR,—The very convincing letters published by you last evening prove that, like Cæsar's wife. Howard's quinine is above suspicion, no matter if bearing labels with white and black, or black and gold lettering, *the quality is uniformly the same and pure.* I therefore beg freely and unhesitatingly to apologise to all sellers of the black label in general, and to Messrs. Howard's in particular, for having made your columns the channel for circulating "an error" which certainly up till now was very prevalent, that the difference in label meant a decided difference in quality. All these doubts are now, however, set at rest, so I hope more good than harm has been done by my letter. Colombo chemists selling the white label ask for it today not R2·50 but R3, and R3·50 per ounce! So buyers will now know where is their cheapest market. That a special letter had to be written to Messrs. Howard on this very question and by one of the sellers of the black label, (their reply ought to be advertized occasionally) proves that some explanation was given by them, considered necessary. Now that we have all got that explanation, Messrs. Howard may decide upon adopting one uniform label.

In conclusion, I am still of opinion that but for the action of a certain estate firm, previously referred to by me, we should not today be enjoying the benefits of CHEAP AND PURE QUININE.

P. S.—The information, upon which unfortunately I trusted too implicitly and upon which my statements were based in all good faith, was of the very highest in my opinion, hence my writing so unreservedly C. AND P. Q.

[We think it a pity that Messrs. Howard & Sons should adopt the plan of having a different label for quinine for India from that for the rest of the world: it is sure to excite suspicion and lead to misconception.—ED.]

KINMOND AND RICHARDSON'S TEA ROLLERS.

SIR,—I have noticed several references lately to these rollers and having recently been engaged in erecting one of them on a well-known estate in the island, I am able to add my testimony to their efficiency. There are many who assert that Jackson's machines cannot be beaten as regards the quality of the work they turn out, but I believe all are agreed that his machines have one very serious draw-back, viz., the need for considerable driving-power, and when we consider what 2 or 3 H.-P., extra means in a factory where water is not available as a motor, it is easy to see what a serious drawback this really is. Now in the Kinmond roller, although the capacity of the machine equals if not exceeds, that of the "Excelsior," yet the action is so much simpler, that the driving power required for the former is reduced by 30 to 40 per cent, and motors which are useless for the one do all the necessary work for the other. Here at once is a very palpable advantage which cannot be overlooked where *fuel* is one of the burning questions of the day. In the Kinmond & Richardson machine the lower table, instead of having a lateral sliding motion as opposed to the upper, is simply a turn-table, operated by an adjustable ratchet, which moves at each stroke, in a circular direction opposite to that of the upper or "hopper" casing, in which the tea leaf is contained. The makers appear to have provided for considerably less weight on the upper rolling surface than the tea leaf actually requires for its proper manipulation, but fortunately the form of the machine is such that extra weights may be added without materially affecting the working or adding dangerously to the friction of the moving parts, and this is a great desideratum. I believe we shall hear more of these rollers, for their workmanship is perfect and the price for a machine taking a charge of 300 lb. of withered leaf at a fill, *cheap* when compared with some others,

CORRESPONDENT.

[This is from a gentleman in no way connected with the roller's makers, agents or advertisers. It is for the latter to keep the price and other favourable particulars well before the public in advertisements after recent repeated compliments.—ED.]

THE LITTLE CHINA LIME.

Colombo, 25th May 1887.

DEAR SIR,—I send you herewith a small branch from a fruit tree with a few fruits commonly known here as "Mekaunchi." It is said that jam or marmalade prepared from the fruit is very nutritious and that the effect is the same as Calfs'-foot jelly. Will you be so good as to tell me the botanical name of the plant, and if the fruits are really nutritious. Children are anxious to eat the ripe fruit.—Yours very faithfully,

B.

[The fruit is from a shrub popularly called "China Lime" here, and is quite safe when ripe to suck, though of rather peculiar a taste, the botanical name is *Triphasia trifoliata*, a native of China but naturalized in Ceylon and India, and most tropical countries.

It is called China Limboo at Bombay. The fruit is pleasant when ripe or preserved, but is often covered with white scale in Colombo.—ED.]

WHAT IS A "BREAK OF TEA"?—AND AUTHORITATIVE ANSWER.

SIR,—So much misconception seems to prevail in Ceylon as to the meaning of the term "Break of Tea" that I send you a few lines which I trust may throw a little light upon the subject.

The following example will best serve the purpose of demonstration:—

Per S. S. "Clan Scot," Jubilee estate:—

1-18	..	18	Boxes of orange pekoe
19-25	..	7½	Chests broken pekoe
26-37	..	12	Chests pekoe
38-67	..	30½	Chests pekoe souchong
68-72	..	5	Chests dust
73-97	..	25	Boxes broken mixed

97 packages tea.

Many men in Ceylon having sent off this quantity would state that they had just shipped off a "break" of 97 packages, a complete misnomer and one likely to confuse the home consignee very greatly.

These 97 packages can be referred to as "an invoice," a "shipment," a "consignment," but never correctly as a "break" except in the single instance of the whole having been packed as "unassorted" or all of one kind. The invoice will be seen to comprise six "breaks." These I have designedly arranged so as to exemplify the difference between sampling and non-sampling breaks 26-37, 38-67 and 73-97 are sampling breaks, because they exceed the limit fixed by the trade for such, namely 8 chests, 8½ chests and 20 boxes. 1-18, 19-25 and 68-72 are non-sampling breaks for the reason that all are below the limit fixed. Non-sampling breaks are never put on show at the docks or warehouses, and suffer as well from being in all cases sold at the termination of the regular auctions.—I am sir, yours, &c. A. H.

WHAT IS A BREAK OF TEA?—Our correspondent "A. H." whose signature above, will be widely recognised, has conferred an obligation on many Ceylon tea planters, by his clear exposition and illustration in our correspondence column, of what constitutes a "break of tea" and the difference between sampling and non-sampling breaks. There will be no excuse henceforward for falling into any mistake on these points.

A NEW TEA ROLLER is likely very soon to attract a good deal of attention, we hear. It is the invention of an old Uva planter on quite a novel principle; but in the opinion of an experienced tea-maker, it will not only do good work but with very moderate power, and the price will also probably be moderate. As "protection" has been secured, it may be mentioned that the principle is of one cylinder working inside another with the leaf between.

LINNEAN.—April 21st.—Mr. W. Carruthers, President, in the chair.—Mr. W. I. Spencer was elected a Fellow.—Mr. E. M. Holmes exhibited specimens of various species of *Shorea* from Borneo and Sumatra. Several species of *Dichopsis*, affording gutta-percha from the bark and fat from the seeds, were also shown. Mr. Holmes pointed out the importance of the cultivation of the more valuable of these trees, among others *D. oblongifolia* and *Ceratophorus leerii*, since they are being rapidly destroyed by the natives. Their cultivation has already been commenced by the Dutch.—*Athenæum.*

COFFEE.—No one can fail to be struck with the very material rise which has recently taken place in Java coffee. Since the close of last summer the quotations have very steadily advanced, and are now higher than they have touched for a very long time. The real reason is the scarcity of South American yield, though, of course, the decreased quantity of Java has likewise helped. It is cause for much regret that with all the signs of a good market to arrive at the quantity of Java seems to get reported shorter and shorter by each succeeding telegram.—*L. & C. Express*, April 29th.

CHINA TEA EXPORTS.—The following table, which has been kindly furnished to the *N.-C. D. News*, will be of interest to tea-shippers:—

EXPORT OF TEA FROM HANKOW AND SHANGHAI TO ENGLAND.—SEASON 1886-87.

	Black—lb.	Green—lb.	Total—lb.
Glens ...	13,088,581	1,055,872	14,144,453
Holts ..	11,137,654	2,340,356	13,478,010
P. & O. S. ...	10,600,405	2,632,264	13,232,669
Mutuals ...	7,892,477	604,101	8,496,578
Bens ...	7,627,642	298,715	7,926,357
Shires ...	7,107,940	231,963	7,339,903
Castles ...	3,888,885	38,123	3,927,008
'Aberdeen' ...	3,160,342	10,687	3,171,029
Messageries ...	1,049,586	198,022	1,247,608
	65,553,512	7,410,103	72,963,615

—*China Mail*, May 27th.

VANILLA.—The large crop of 1885—when about 135,000lb. were gathered in Bourbon, and about 58,000lb. in Mauritius—caused the price to rule low until August last, when large American orders suddenly caused an advance in the price of 20 per cent. It was said that the 1886 crop had been greatly damaged, and the decreased shipments from Bourbon (which thus far show a falling-off of 27,000lb.) have further influenced the market. But the increased value seems to be maintainable with difficulty, and it seems also scarcely probable that the whole of the old stock should have been disposed of before the arrival of the new crop. It must, however, be kept in view that very small quantities only will be received from Mexico this year, the Mexican crop having been cleared by firms in the United States, at an advance of 75 per cent. over last year's prices. The Seychelles islands now also produce vanilla, and last year small consignments from Tahiti were received at Hamburg; but the latter variety is probably of little importance.—*Chemist and Druggist*, May 7th.

A PUFF FOR CHINA TEA.—The opinion seems to gain ground amongst medical men that China tea is less injurious to the system than the more pungent Indian, which, though apparently given more value to the consumer, as it brews stronger, and a smaller quantity is required, is attained at the expense of the partial destruction of the gastronomical organs. There is no doubt that many minor diseases are now met with—especially amongst women—which the doctors attribute to the fact that so much more tea is drunk than formerly, and the results of inquiries show that the Indian classes are more injurious than the China ones. Whether this is due to climatic causes in the countries where they are respectively grown, or to methods of preparation, we are not prepared to state. If this fact becomes generally disseminated, and gets a hold on the ordinary consumer—who as a rule only looks to see how strong the liquor will turn out—the boom that is so much desired in the China trade will soon be brought about, and we shall hear no more of the gloomy prognostications which have been so rife of late.—*L. & C. Express*, April 29th.

ROYAL GARDENS, KEW.

(*From the Bulletin of Miscellaneous Information.*)

VII.—*Manila Hemp* (*Musa textilis, Nees.*)—This is one of the most important of cordage fibres, and the whole supply comes from the Philippine Islands. The imports of Manila hemp to Great Britain amount to about 170,000 bales, and to the United States about 160,000 bales, equal to about 50,000 tons per annum. The fibre is yielded by a member of the banana or plantain family known locally as Abaca (*Musa textilis*), the apparent stem of which is made up of sheathing leaf stalks. The habit of growth and treatment of the plant under cultivation are identical with those so well known in the case of the common banana. The fruit of *Musa textilis* is green and hard and useless as food.

From a report by Consul Honey, dated Manila, 10th April 1879, we gather that this plant thrives best in soils largely composed of decayed vegetable matter. Hence, freshly cleared forest land is essential. Hilly land, about 200 feet to 500 feet elevation, is considered more suitable than low-lying land, probably on account of drainage. The Manila hemp plantations are situated where there is a rich volcanic soil,* and where the climate is hot and humid with a heavy rainfall. The plants suffer severely during drought. Although seed is produced plantations are usually established by means of suckers put out when about 3 feet high, and about 8 to 9 feet apart. These form a root-stock, from which numerous stems are successively produced. The land is cleaned of weeds about twice a year. The first crop is reaped at the end of the second year after planting; a full crop is not obtained until the fourth year. The yield is then continued for 15 to 20 years, after which the plantation is exhausted. The stems are fit to be treated for fibre just before they begin to flower. In stems that have been allowed to flower the fibre is said to be weaker and of less value. They are cut about a foot from the ground and the leaves removed. Each stem is then stripped or resolved into its component layers, and these are again divided into strips or ribbons about 3 inches wide. Usually each layer or leaf-sheath is divided into three strips. The outer layers contain a coarser and stronger fibre than the inner, while fibre from near the middle is of a fine silky texture, and capable of being utilised without spinning or weaving and made into articles of dress and ornament.

The method of preparing the fibre is very simple but effective. Each strip, in a fresh succulent condition, is taken up by hand and drawn deftly "between a blunt knife and a hard smooth board," which are attached to a light portable frame. This process, repeated several times if necessary, removes all the watery particles and pulp, and there remains in the hand of the operator a beautifully white and lustrous fibre. The fibre is thoroughly dried in the sun and afterwards packed in bales for shipment. Hemp not properly dried or exposed to rain becomes discoloured and loses strength. On the other hand, hemp from the outer layer of the stem is of a reddish colour, but is quite sound. It is a characteristic of Manila hemp that it readily absorbs moisture, and in an ordinary dry condition it contains 12 per cent. of water. In a damp climate it has been known to contain not less than 40 per cent. of water.

Cordage, ropes, and indeed everything made from Manila hemp can be easily converted into paper of excellent quality.

The cost of establishing a Manila hemp plantation in the Philippines, including cutting down forest, cleaning and planting, is about 5*l.* to 8*l.* per acre. This does not include the cost of the land. After this the yearly expense of weeding and maintaining the plantation in full bearing is at the rate of 30*s.* to 35*s.* per acre. The yield during the fourth and subsequent years is at the rate of 400 to 700 pounds of dry hemp per acre. "A labourer working under pressure can clean nearly 20 pounds of hemp per diem; but as a rule the quantity cleaned by one man working steadily, day by day, averages about 12 pounds." Usually two men work together, one cutting down the stems and splitting them while the other cleans the fibre. "At the current value of hemp in 1879 one labourer's earnings were 7½*d.* to 8*d.* per diem." Several attempts have been made to introduce machinery, but so far nothing has been so successful as the primitive method above described.* It is essential that any machinery introduced should be of a light and portable character, and that it should clean the fibre at a cheap rate, without breaking it.

From these particulars it will be seen that the Manila hemp industry is, to a large extent, supported by special circumstances which happen to be favourably combined in the Philippines, and hence there is produced an exceptional article in large demand at a comparatively cheap rate. The conditions of soil nad climate may possibly be found elsewhere, but, as a necessary adjunct to these, there must be an abundant and cheap supply of labour adapted to a rural industry.

A plant of Manila hemp (*Musa textilis*) may be seen in the Palm House at Kew. For the purpose of illustrating the industry there are very complete sets of exhibits in the Kew Museum, No. 2. These include the raw fibre, cables, ropes, twine, fine muslin fabrics, "half stuff," and paper of all kinds, the latter being made from old Manila ropes.

The valuable character of the fibre yielded by *Musa textilis* has naturally drawn attention to it as a valuable industrial plant, and during the last 60 years it has been introduced to India and elsewhere for experimental culture. Plants of *Musa textilis* were cultivated at Calcutta in 1822; specimens were introduced to the Madras Presidency direct from the Philippines in 1858; while at the Andaman Islands this fibre plant has been thoroughly established.

Experiments in India so far have shown that plants of *Musa textilis* can be successfully grown in many districts; but it is not yet clearly shown that the fibre can be cleaned so expeditiously and so cheaply as to compete successfully with fibre from the Philippines.

After a systematic series of trials made by the Glenrock Company at Madras in 1885, it is stated that plants put out in 1864 grew well and yielded numerous shoots. 179 stems, weighing about 60 pounds each were cut down for experimental purposes and passed through Death & Ellwood machines. These produce 159 pounds of clean fibre, or 1·49 per cent. of the green stem. The cost of cleaning the fibre was at the rate of 6*l.* per ton, while the fibre itself, described as "poor, weak, and flaggy, with some clean fibre of good colour," was valued in London at 10*l.* per ton; the best alone was valued at 25*l.* per ton. The minute upon this of the Government of Madras is that "unless much improvement both in the method and cost of production of this fibre can be made, the cultivation cannot be made remunerative."

Manila hemp plants have been introduced from Kew, to Jamaica, and to other portions of the West Indies. In favourable situations they grow well; but not so readily as the ordinary bananas and plantains. As the fruit is valueless they can only be grown for the sake of the fibre and this alone does not appear to offer sufficient inducement to plant up large areas. Usually the return from a fruiting stem of the common banana or plantain would be from 6*d.* to 2*s.*, depending upon the size of the bunch. The return from the Manila hemp plant would according to experience in the Philippines be about one pound of fibre, the local value of which would be only 2*d.* to 3*d.*

NOTE ADDED.—In the Kew Bulletin, No. 3, pp. 5 and 6, the prices there given for Sisal hemp, as indicated in the context, are not the present prices. The price current in the London market in December 1886 is given on p. 8 of the Bulletin quoted. As

* Which does not exist in Ceylon.—ED.

* For which, we suspect, labour is too expensive in Ceylon.—ED.

showing the avrage price per ton of Sisal hemp in London for the years 1879-1886 inclusive, we are enabled, by the courtesy of Messrs. Ide and Christie, to give the following:—1879, 24*l.*; 1880, 27*l.*; 1881, 28*l.*; 1882, 28*l.*; 1883, 27*l.*; 1884, 21*l.*; 1885, 19*l.*; 1886, 21*l.* The average price for the three months ending March 31st 1887, is 28*l.* per ton.

VIII.—Plantain and Banana Fibre.
(*Musa Sapientum, R. Br.*)

In connection with Manila hemp some reference may be made to fibres produced by other species of the genus *Musa*. The late Director of the Botanical Department, Jamaica, discusses the subject as follows:—

"It would appear that the fibre of the ordinary plan-"tain and of the banana is valued at about 12*l.* or "15*l.* per ton. This it will be noticed is only one-"third the value of the best qualities of Manila "hemp. There are in both the East Indies and West "Indies numerous wild species of *Musa* which might "yield good fibre, but so far none appears to have "been found equal to the plant-yielding Manila hemp. "The following facts have been elicted by recent ex-"periments. A banana stem just after fruiting, cut "as is usual with the country people, about 2 feet "above ground, and denuded of its foliage weighed "108 pounds; this being divided into three lengths "of 2½ feet each and split longitudinally into several "pieces was prepared by beating and washing by "hand, and yielded 25 ounces of clean marketable "fibre, which is at the rate of 1·44 per cent. of the "gross weight. The fibre of the lower portion of the "stem, as also the fibre in the petioles of the leaves "was not extracted.

"A smaller banana, cut under similar circumstances, "that is, 2 feet from the ground, and denuded of "its foliage, weighed 41 pounds. This was divided "into two lengths of 2½ feet each, and after being "split longitudinally into several pieces was prepared "by hand, and yielded 6¾ ounces of good clean fibre "or at the rate of 1·02 per cent. on the gross weight.

"At the Hope Plantation similar experiments were "conducted with banana stems which yielded very much "the same results. Two banana stems cut after fruit-"ing, at two feet from the ground, and denuded of "their leaves, weighed 147 pounds. These yielded 33 "ounces of clean fibre, or at the rate of 1·44 per cent "on the gross weight.

"From ordinary stems of banana, cut after fruiting "at about 1½ to 2 feet above ground, a settler might "easily prepare about 1½ pounds of clear fibre, but if "the stems are large, and if the whole length is "used as well as the petioles of the leaves the amount "of fibre might be increased to 2½ pounds if not 3 pounds "per stem.

"With plantain stems* the results are more satis-"factory than with the banana, both as regards the yield "and the quality of the fibre.

"At the Castleton Gardens, a plantain stem weigh-"ing, when cut and dressed, 25 pounds, was pre-"pared in exactly the same manner as the banana "stems above described and yielded 7¼ ounces of clean "fibre or at the rate of 1·81 per cent on the gross "weight. At the Hope Plantation a plantain stem "weighing exactly the same, viz, 25 pounds, yielded "9 ounces of clean fibre or at the rate of 2·25 per "cent on the gross weight. The plantain fibre is "whiter and finer than the banana fibre, and it ap-"proaches more nearly to the fine glossy character of "the fibre of the Manila plantain.

"For purposes of comparison I had the fibre of a "small stem of the Manila plantain, which, cut at 6 "inches above ground and trimmed, weighed 10 pounds, "prepared in the same manner as the banana and "plantain fibre, and the result was 3 ounces of a "beautifully fine and glossy fibre. This is at the rate "of 1·87 per cent on the gross weight.

"In Jamaica another plantain s known as the Abys-"sinian plantain, *Musa ensete*, which is the largest "species of this genus. It was discovered by the "traveller Bruce in Abyssinia, and is remarkable as "being represented on ancient Egyptian sculptures. "Specimens of this plantain growing at the Govern-"ment Cinchona Plantations at 5,000 feet have often "leaves 20 feet long, the stem is about 8 feet in cir-"cumference at the base, rises to a height of 25 "feet and weighs probably about a quarter of a ton.*

"Specimens of fibre prepared from this plantain "are of excellent quality. Taking a portion of the "central stem about 4 feet long and weighing 73 "pounds, clean fibre, weighing 13 ounces, was obtained "by beating and washing by hand. This is at the rate "of 1·16 per cent. on the gross weight.

"This plant might be grown extensively for its "fibre, and it should prove valuable, but of course "not equal to *M. textilis*, which is unapproachable "as a fibre plant."

It may be metioned that samples of all the banana and plantain fibres noticed above are to be seen in the Kew Museum, No. 2.

From the same source we find that about 2,000,000 banana stems, after the fruit is gathered, are cut down every year in Jamaica, which are allowed to rot on the land without any attempt being made to utilise the fibre they contain. It is suggested that the merchants who purchase the fruit from the negroes should offer a small sum for clean and well-dried fibre, and take it in small lots as it comes to hand. The merchant might afterwards sort and pack the fibre and put it up in tightly compressed bales for shipment. Some such plan as this, suited to local circumstances, evidently offers the best means of starting a banana-fibre industry in the West indies.

In the course of the energetic efforts made by Governor Sir William Robinson, K.C.M.G., to develop what are called "minor industries" at Trinidad, attention has naturally been directed to the utilisation of fibre from both the cultivated and wild species of *Musa*.

A "red banana," very commonly cultivated as a shade and fruit plant, and the supply of which is said to be almost inexhaustible, has been brought forward as a possible source of commercial fibre.

A sample of fibre prepared from this red banana was recently sent to Kew, and the opinion of Messrs. Ide and Christie obtained upon it. Their report, dated 29th October 1886, is as follows:—

"We think highly of this fibre, for which we "consider there might be a considerable demand, pro-"vided it could be produced of a better colour. We "are inclined to think its dull hue is probably the "result of inexperience in its treatment, either by "allowing it to steep too long in rather foul water "or from the leaves being too old and discoloured "before treatment. The attention of preparers should "be directed to the production of a fibre of the bright "natural colour of the enclosed specimen of Manila "hemp, and were quantities of the new fibre produced "of this appearance we think they would command "24*l.* or 25*l.* per ton to-day in the London market. "Colour is of great consequence when fibres are used "for the production of 'white hemp' ropes. Of course, "in the manufacture of tarred rope colour is of no "moment, but the white 'hemp,' Manila, Sisal, and "New Zealand are seldom tarred."

It is quite possible that, in spite of many years of experimental trial, the fibres of the banana and plantain may not assume great commercial importance. In that case attention might be turned in another direction, and they might be partly prepared on the spot and utilised for paper-making. But to compete successfully with esparto and wood-pulp the fibre or "half-stuff" of banana and plantain should be delivered in Europe at a cost not exceeding 4*l.* to 6*l.* per ton, depending on condition. For paper-making it might be sufficient to cut the stems into short pieces, and then divide them longitudinally

* It is to be understood that in these notes the plantain is what is used as a vegetable, while the banana is the soft sweet fruit seen on tables for dessert. In India the name plantain appears to be applied indifferently to both of these. So in Ceylon. —Ed.]

* There are a few specimens of this gigantic plan at Hakgala.—Ed.

into numerous narrow strips. These, after being passed between rollers to get rid of the water and mucilage, might be dried in the sun, and afterwards put up in compressed bales for shipment.

The whole subject resolves itself into a question of cost, and it can only be practically solved in countries like Demerara, Trinidad, and Jamaica, where several thousand acres are occupied by banana plantations, and where sufficient material lies close at hand to maintain a moderately large industry.

For some years considerable interest has been taken by the Government of Bengal in the subject of the utilisation of plantain stems for the manufacture of paper. In a Report presented by Dr. King, Superintendent of the Royal Botanical Gardens at Calcutta, he mentions:—"Since receiving these papers "I have gone into the whole matter with some care, "and I now give you the results. Before proceeding "further, I wish to explain that in the following "remarks the term *plantain fibre* is used to designate the fibres of the various kinds of plantain found "wild and cultivated within the Indian Empire, but "does not include the fibre of the Manila plantain "(*Musa textilis*), which is a fibre of an altogether "exceptional kind. The fibre of the Manila plantain, "usually known as Manila hemp, is one of the most "valuable fibres known, and is worth in London "from 30*l.* to 40*l.* a ton, a price that takes it quite "out of the range of raw materials for paper.

"I have ascertained by reference to a large English "paper-maker, that if it can be delivered cheap "enough, plantain fibre would be readily bought in "England for paper-making. Quotations as to the "exact value of the fibre can hardly be given until "a trial shipment has been put on the home market. "Esparto is the fibre against which plantain fibre "would be pitted as a raw material for the paper-"maker, and the price of the best Spanish esparto "now (1883) stands in London at about 10*l.* per "ton. It is not likely that plantain fibre would be "so valuable as esparto, but it might bring as much "as 7*l.* to 8*l.* per ton."*

It appears that the Bally Mills Company, near Calcutta, has for some time utilised the stem of the cultivated plantain for paper-making, and the results are said to be satisfactory. The company purchase the roughly dried stems from contractors who collect them from villages in the neighbourhood. The price paid by the mill is 3*s.* 6*d.* to 4*s.* per cwt., according to quality. In this instance the preparation of the fibre is very simple. The plantain stem is cut down after fruiting, and the outer sheathing portions are cut into strips and thoroughly dried in the sun. The leaves and central core being useless only about two pounds of rough fibre are obtained from each stem. By this rough mode of preparation the fibre is not freed from the cellular tissue, and although it can be utilised on the spot it is doubtful whether it could be exported in this state.

An attempt was made in the latter part of 1883 to utilise the thousands of acres of wild plantains growing in the Chittagong Hill tracts which it was thought might yield large quantities of fibre at cheap rates. It was found, however, that any attempt at crushing the stems in a fresh state entailed heavier machinery than could be easily moved from place to place, and the idea was ultimately abandoned without any practical results being achieved. In spite of this, however, Dr. King is of opinion that plantain stems in India will eventually become available as paper material, and considering the immense number grown for shelter, shade, and food purposes, the subject is of considerable importance both to the people of India and to paper-makers.

* Spanish and Algerian espartos are quoted in London (Dec. 1886) at 70*s.* to 110*s.* per ton. The estimated value of plantain fibre must therefore be reduced to one half of the above. [At which price it cannot possibly pay to prepare it, and the stems had better be left to rot on the land.—ED.]

IX.—PINE-APPLE FIBRE.
(*Ananas sativa.*)

A note may be added here on the fibre yielded by the leaves of the pine-apple plant. Although not at present in commercial use, this fibre has a future of considerable importance before it. It is finer and stronger than that yielded by any other plant and in the Philippines, where the West Indian Ananas has become thoroughly naturalized, a beautiful fabric known as "pina cloth" is made from it. A rope of pine-apple fibre 3¼ inches in circumference bore a strain, at Calcutta, of 57 cwt.

There are several samples of fibre of a wild pine-apple (*Bromelia sylvestris*, Willd.) from the West Indies and Central America at Kew, but there is no record of their commercial value. A sample supposed to be from this plant was lately sent from Trinidad, upon which the brokers reported as follows:—"Not "yet in commercial use, but destined, we think, to "a successful future; fine, soft, supple fibre, strong "and good colour, ample length; say 30*l.* per ton "and upwards."

The fibre of the Jamaica pinquin (*Bromelia Pinguin* L.) would appear not to be of high value. The plant covers hundreds of acres in the plains and lowlands of Jamaica, and an effort was made some time ago to prepare the fibre for commercial purposes. The report of brokers upon a sample of 90 pounds was as follows:—"A long towzelled weak fibre, of "bad colour, coarse, no strength, and only fit for break-"ing up. Similar to St. Helena hemp tow, but not "so good. We should think 12*l.* to 10*l.* per ton the "utmost value." Several samples of this pinguin fibre from Jamaica and elsewhere, cleaned both by hand and by machine, are to be seen in the Kew Museum, No. 2.

If the leaves of this plant were cut up, roughly dried, and placed in compressed bales, they might prove of value for paper-making. To establish this point it would be necessary to forward to England about half a ton of dried leaves in compressed bales, in order that paper-makers might be able to test them on a sufficiently large scale.

D. M.

[We have frequently expressed the opinion, that, of all the fibre plants in Ceylon, pineapples grown native fashion in shade and producing very long leaves offer the best chances of success.—ED.]

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

DAIRY STOCK EXPERIMENTS IN BELGIUM: DUTCH VERSUS DURHAM COWS—ANIMAL DIET—MANURE AND MANURING.

PARIS, May 14.

In Belgium, the attention of the Agricultural community is kept fixed by the Government on two points: improving the national race of horses, so as to compete directly with the Percherons; and, secondly, in the case of dairy stock, selecting races best suited to the resources of each region and the ends in view whether the production of meat or of milk.

Since twenty years the controversy exists respecting the comparative merits of the Durham and the Dutch cows for dairy purposes. The conclusions arrived at in 1869 by Drs. Lehmann and Petermann, at the experimental farm station of Pommritz, in Saxony, are as true and as applicable today as then. In dairy industries two interests are in play, the production of butter and cheese, and the selling of the milk fresh. These necessarily involve the question of the composition of milk. The latter is now accurately known.

The Pommritz experiment was made upon nine Dutch and nine Durham cows selected out of a herd of sixty head of cattle. The animals were respectively aged 6 to 8 years, and which had calves at different periods. The eighteen experimented upon cows were lodged in the same shed, and fed on identically the same conditions. The winter dietary

extended over 227 days, and consisted of 44 lb. of mangolds, 2¾ lb. of oil cake, the same quantity of bran, 5½ lb. of hay, and 10 lb. of chaffed straw. In summer, cut clover and 3¾ lb. of bran. As in German cow sheds, the supply of salt and water was unlimited.

Pending the 365 days, the average total yield of milk per Durham was 657 gallons, per Dutch 778. In other words, the proportion was 110 to 118. Respecting the composition of the milk, one litre (1¾ pint) of that of the Durham contained 40 grammes (1¼ oz.) of fatty matter, 36 gr. of caseine, and 51 gr. of sugar, whilst the proportions of these matters in the same quantity of the milk of the Dutch cows was 33, 34 and 48 grammes respectively. Conclusion: when the object is to sell the milk fresh, the Dutch cow is incontestably to be preferred—that which practice confirms. The difference may not be so pecuniarily great when the plan spreads of purchasing milk by analysis.

The Durham yields a higher quality and the Dutch a superior quantity of milk. Now the difference would be only apparent, when in both cases the milk was to be converted into butter and cheese. Estimating, according to the relative analytical richness of the milks of both races, and keeping in mind the superior quantity of milk produced by the Dutch cow, the latter will be found in the course of the twelvemonth to be in round numbers absolutely the same as the Durham. In the butter and cheese point of view, the relative richness of the milk should occupy less attention than those other factors which affect the value of stock-precocity and aptitude for fattening.

Some confusion apparently exists respecting the rôle of water in nutrition. The animal tissues could not fulfil their functions were they not imbibed with a certain quantity of water, which is the necessary dissolvent as well as vehicle of all the matters which penetrate into the economy. Water thus permits the absorption of the aliments and prepares them for assimilation. M. Boussingault who was amongst the earliest to point out that weighing an animal before and after a certain dietary was the test to determine the nutritive value of a forage, &c., by revealing if the animal throve or fell away, developed muscle or fat, &c. It is at the same time not a little strange, that in the researches of Liebig, Boussingault, Payen, Dumas, &c., on fattening, they have never taken into account the water drunk by animals.

In all Boussingault's writings there is not a single trace of any direct experiment where the connection between the water absorbed and the process of fattening is dealt with.

The body of an adult man consists of 60 to 70 per cent of water. By secretion, respiration and cutaneous transpiration—varying of course following age, exercise, temperature, humidity of the air, &c.—a man loses in twenty-four hours from 5½ to 6½ lb. of water. The loss by the lungs is more uniform, about 15 ounces daily. Now in man, as in animals, this loss must be repaired, and is so not directly by water, but by the food forming during the combustion of the aliments in the animal economy, water, as well as carbonic acid and urea. Dr. Callamand, one of the best authorities on the rôle of water in animal life, concludes it is only the medium for the acts of nutrition, that water promotes neither obesity nor leanness, and does not modify the equilibrium of the functions.

Complaints still continue of the prevalence of abortion among cows, even where the sheds fulfil all sanitary conditions. In such cases the cause must be sought for in the food and the quantity given. The total mean capacity of the stomachs of a cow is 55 gals.; and by the way, the volume of the stomach of a horse is 12 to 15 quarts; of a pig, 6 to 7; a dog, 2 to 3 quarts, and a rabbit, ½ to ¾ of a pint. Food, if given too warm, will produce abortion in cows by irritating the uterus; so will frozen roots, or fodder, beet leaves, cabbage, rape &c., covered with rime or hear-frost. Cold drink is also a promoting cause; trough-water should not have a lower temperature than 40 degrees Fahr. An excess of chaffed straw imbibed with water in rations can also act injuriously by producing pressure against the matrix, especially if the animal lie on the right side—that which often kills the fœtus. The same remark applies to other swelling rations.

When rape cake contains mustard seeds, and is blended with water, it engenders a pungent essence which acts detrimentally on the abdominal organs. Pure rape cake should not be given in larger morsels than the size of a pea. Of course ergoted fodder will be eschewed, ergot being a specific for provoking abortion; happily, the parasite generally selects rye for its home. But ergot is also found on many weeds peculiar to meadows, and notoriously on foxglove. As many as 110 ergots have been counted on that dangerous pest. Ergot is more common on the first cut of a meadow, than in aftermaths. Maize is liable to charbon, or smut-rust, another parasite nearly as dangerous for cows in calf as ergot. The fungus which frequently white-spots the under part of the leaf of tares and peas makes the haulm often a dangerous fodder.

One ton of hay is estimated to produce two tons of farmyard manure. A French proverb says, "The meadow is the mother of the fields." If the hay be inferior by the predominance of rushes, weeds &c., so will be the manure, and the soil receiving the latter must suffer in its fertility. Now the soil is not so insensible as many cursory observers might be inclined to conclude, to the maintenance of the conditions of its richness, though scientists are still somewhat at sea, respecting the nature of these conditions. Unlike the raw material in other industries, we do not know "all about the soil." It presents perplexities which baffle science. We are aware at present, what plants require, thanks to the analysis of their ashes. Some dozen of simple bodies—potash, soda, lime, iron &c. borrowed from the soil and oxygen, carbon and perhaps nitrogen taken from the atmosphere are the building materials of plants. And we can estimate in advance like a contractor how much of each material a crop will demand from the soil and the air.

The composition of the atmosphere is the same in every part of the world. But soils vary in composition; we know their ingredients, but are not at all fixed as to the processes by which the plant draws up its sustenance from the soil. For example, here are two fields equally well cultivated; they are sown with the same seed, situated alike as to climate and position; the ploughings, harrowings, and other mechanical operations, have been carefully made, and at suitable epochs. Yet when harvest arrives, one field will yield double the produce of the other. Why this great difference? Due to inequality in the natural richness of the soils? No; for when both soils are analysed they will reveal not only the presence in sufficient quantity of phosphoric acid, lime, potash &c., but absolutely in like proportions.

Plants resemble animals in their manner—chemically and physically—of grouping the simple bodies, which, in their assemblage, form the elements of their mutual nutrition. But they differ in their mode of obtaining their food, that is of seizing it. An animal is endowed with locomotion, can go in search of what will supply its hunger-wants. A plant on the other hand is fixed and must be content in the matter of food-getting with what its rootlets can octopus-like grasp and draw up. The comparison will explain the dissimilarity in the fertility of the two fields, containing equal quantities of phosphorus, lime, nitrogen, &c. Take the latter raw material, it is indispensable for the development of all living beings. The animal can only assimilate the nitrogen which it requires by specially grouping with the other raw materials—carbon, oxygen, and hydrogen—so as to produce those nitrogenous compounds, albumen, fibrine and caseine, which are the bases of eggs, flesh, and milk. But if an animal was supplied with nitrogen in the form of gelatine for instance, and in the absence of other elements it would succumb from hunger.

It is precisely the same with the plant which can only nourish itself on nitrogen in the form of nitric acid and ammonia. Nitrogen in any other state however rich would no more keep it alive that could gelatine the animal. The plant lives on phosphorus, potash, &c., but it depends not on the absolute quantity of these matters contained in the soil, so much as on the chemical condition or assimilable state in which the soil presents them to the roots. In a word, plants and animals alike must be allowed to prepare their own pap, and according to their own culinary and mysterious processes. It is in the manner the ingredients of that pap are presented to the roots that the primary condition of soil-fertility depends, and which explains the unequal harvests from two seemingly identical fields.

Flowing from these principles is the important necessity for securing the minute, the physical dissemination of plant-food in the soil, so that it can be conveniently within reach of the rootlets, those unlocomotive stationary mouths always open like the bills of nestling birds. It is not the mass of mineral food in the soil which influences the yield, but in its fineness and its appropriate dissemination. All food not within seizure of the root is of no use to that root: all food not within reach of the mouth of an animal is of no use to that animal. Hence, in case of soils these cannot be made too friable nor the fertilizing agents, natural or artificial, cannot be rendered too assimilable or ready for being worked up. Then the cupboard of feeding property of the soil will be utilized. Make the mineral food assimilable: next ensure its judicious physical distribution in the soil. So far analysis has not yet been able to group and measure these two conditions on which soil-fertility and plant-development depend. Science, however, is on the track of the solution and patience is the forerunner of success.

In a few of the co-operative dairy farms in Switzerland some dissensions have arisen. Complaints were made by consumers that neither the milk, nor the butter, nor the cheese had the flavor desired. The cause was laid to the charge of the farmers employing commercial fertilizers and feeding the cattle too much on cake. The charges have not been borne out by test-experiment. Only more care has been recommended to be observed in the storing of the cake to keep away fungus, and to secure absolute cleanliness in the feeding troughs.

Dr. Petersen has concluded his experiments on the comparative richness of meat from cattle fattened on grass land and in shed. He attests that all fat stock as a rule have the lean uniformly impregnated with fatty matter. The more lean meat is relatively rich in fat, the less water it will contain, and *vice versa*. Finally, the flesh of pasture fatted oxen is richer in nitrogen, that is, albuminous matters than those fattened under cover, and consequently more nutritious.

Dr. Grasmann, as the result of his trials with the germination of beet seeds, recommends that between one-half and under one inch, is sufficient covering depth for sowings.

Professor Welstein continues his crusade in favor of keeping cows clean. Those so cared enjoy better health, fatten quickest, and yield more milk. After a winter of shed-residence, the professor laments that the animals very often have more filth on their hides than flesh on their bones. This neglect, he adds, is one of the chief causes of cattle-plagues.

Hennerbeg recommends that every stable and cow-shed ought to be provided with a thermometer and the normal temperature of the buildings maintained at 60 to 64 degrees Fah. Too high a temperature will irritate and weaken the animals, while too low a heat 50 degrees will exact more good without a corresponding benefit. Thus cold like fire consumes.

AT San Francisco the *Cupressus macrocarpa* is most successfully used for converting seaside sand dunes into forests.—*Queenslander.*

COCONUT-PLANTING, SUGAR, CASTOR-OIL PLANT AND LIFE GENERALLY IN JAMAICA.—From a bright letter in the *Christian World* by Samuel James Capper who is on a visit to his brother, who is Inspector of Schools in Jamaica, we take the following paragraphs of special local interest:—

With us in the carriage was a young man, who was a fairly good representative of the modern Jamaica planter, in contradistinction to the typical West Indian proprietor of fifty years ago. He has the management of two or three estates belonging to his father or family, and also superintends a store in Mandeville, which was the original source of the family prosperity. I said he must have his hands pretty full. He replied, "They ought to be," but seemed rather glad of our two hours' delay at the railway station, as it helped in the war constantly being waged, even more unremittingly in Jamaica than at home in England, against the arch enemy—time. This fortunate young man had only taken to his Jamaica life after three years at school at Stuttgart, two at Neuchatel, and three at the University of Cambridge. As coconuts are fast becoming, in the decadence of the sugar industry, one of the staple products of the island, it may be interesting to notice how differently their value may be estimated. Our host at Spring Garden considered that when in full bearing you might calculate upon a net return from each tree of 4s per annum, and he considered the capital value of the tree, the land being thrown in, at £3. Our present friend said he had an estate with 12,000 coconut palms upon it, of which it would be safe to reckon that 8,000 are in full bearing; that about 2s each is all he ventures to calculate the annual yield at, and that if any one were to offer him £8,000 for the estate, with the 12,000 trees upon it, he would jump at the offer.* As a matter of fact, as a result of the general depression, large estates, if sold at all, seem to go for nominal prices. Within the past week three large sugar estates, comprising more than 3,000 acres, much of which acreage is in cane, were sold, with all buildings, machinery, and stock upon them, for £13,000. The fortunate purchaser, it is estimated, has received as part of his bargain oxen and cattle to the value of £8,000. It is, indeed, not an uncommon thing to hear of estates being sold for less than the value of the stock upon them, the land, houses, and machinery thus going for absolutely nothing. * * *

At last our train got under way, taking us first through swampy ground covered by dense tropical bush mangrove, and other trees. This swamp, which covers many square miles, was fertile and cultivated land until a great hurricane in 1,726 which reduced it to its present condition. Leaving this dismal swamp we pass through what looks like a noble park on the grass of which graze many cattle, who are protected from the sun's too ardent rays by magnificent umbrageous trees. Beyond the park we come upon the bright green of the sugar cane, and among the canes is working a gang of negroes, whose black skins and brilliant handkerchiefs and other clothing look very picturesque against the bright verdure. The park, as well as the sugar estate, is the property of Mr. Verley, a gentleman of colour now credibly reputed to be worth a quarter of a million sterling, who began his career as a working mechanic earning 1s 6d. a day. This huge fortune he owes to his own industry and perseverance in establishing steam-mills and a bakery in Kingston, which shows that enterprise, when wisely directed, does not go without its reward even in Jamaica. * * *

A weed which is much encouraged on the cuttings and embankments of the railway, as its roots bind the earth together, is the castor-oil plant; yet I believe there is no export whatever of the oil from Jamaica, and the bulk of what is used in the island is imported from England

---

* We certainly agree that 2s per tree per annum is a very good return: at 80 trees that would be £8 to the acre, a result above anything got save from the very best estates in Ceylon. R50 per acre is considered a good average return in Ceylon although in rich soil with careful cultivation and manure, this may be doubled (*vide* "Planting Molesworth"). Jamaica has a good market for its nuts in America, but there is little done in expressing oil or making copperah as yet.—ED.

TURTLE: A NEW MINOR INDUSTRY.

It seems to us to be most desirable that in the midst of larger questions for discussion we should never wholly lose sight of those many minor industries, the successful prosecution of which goes so far towards increasing the sense of the happiness and prosperity of the native races among whom, we Europeans, are dwellers. While it must be admitted that, primarily, the Ceylonese are, to a very great extent, dependent for both the qualities referred to, upon the successful results to European enterprize, there is no doubt that they may be largely added to by the endeavour to point out new fields for the exercise of such industries as are particularly fitted for the labour of individual natives. We have on many occasions endeavoured to fulfil this—as we deem it to be—important obligation. The result to our having done so has sometimes no doubt been failure; but that fact need not, and should not, restrain us from further endeavour.

That the commencement of new undertakings among the natives of Ceylon is always attended with many difficulties must be fully recognized by all those acquainted with their character and with their conservatism. By the latter term we characterize that indisposition to move out of settled grooves which is, of course, but the outcome of centuries of habit and in many cases of centuries of prejudice. Still, in spite of the many failures that must certainly appear on the record, we believe that we can in many directions recognize the result of that leavening which the infusion of European energy and of improved education has introduced. There seems to have been no want of desire and no absence of enterprize in respect of the recent failure to establish Fish-curing on a wider scale and on a sounder basis than the desultory methods which have been customary among our seaside population for ages almost immemorial. Circumstances have been adverse, and some years must probably yet pass before they can become so changed as to admit of success where hitherto there has been nothing but non-success. We should not, however, suffer such present results to altogether discourage us. If we fail of achievement of our purpose and desire in one direction, it still behoves us to draw attention to other sources whence it appears to us that our native population may yet draw contributions towards that improvement in their industurial condition which we are sure every European co onist desires to see established.

A correspondent who from long experience with such a subject is well qualified to inform us on the matter, expresses his regret that so little harvest is reaped by what he terms the "turtle crop" of this island. He points out to us that, whereas the islets which fringe the Jaffna Peninsula absolutely team with these savoury reptilia while the market of the chief town of that peninsula is at all times almost glutted with fine specimens of them, it is extremely rare to see one in the markets or bazaars of Colombo or of our southern towns generally. He is inclined to attribute much of the physical superiority of the Tamil race over that possessed by the southern Sinhalese to the stimulating and nourishing diet thus freely, and at an extraordinarily cheap rate, placed at their command, and he holds that were a system established and well carried out—probably under some Government supervision—by which the turtle during their breeding season were protected from disturbance, they would soon so increase in numbers as to be compelled to seek feeding ground farther to the south, and so bring to the doors, as it were, of our North-western, Western and Southern Provinces, a food supply of a most valuable character which is now, comparatively, wanting to their people.

Why it is that up to the present time the turtle have not migrated to the southward it is rather difficult to say. Perhaps on our western coast the barrier of Adam's Bridge greatly hampers that migration; while the eastern coast of the island presents first the disability of very rough seas, and, secondly, it possesses but few of those islets which afford the quiet breeding-grounds in which the turtle delights. But both at Kalpitiya and Negombo, as well as at the entrance to the Mutwal river, there are, we should say, many spots which if carefully watched and protected might furnish the quiet and security for which the female turtle seeks when about to incubate. The oyster has been made to accustom itself to *habitats* which it is not naturally inclined to, and with most profitable results. Why should not the turtle be made to be equally docile? We must recollect that for its flesh there is not only a wide local market, but that it might be possible for us to become successful competitors with the West Indies in the supply to European markets of that dried material which furnishes the basis of the nourishing soups so dear to *gourmets* and so restoring to invalids. Much we think might be accomplished by a Society established for the express purpose of forwarding minor Native Industries. To its members might be read papers embodying the experience of those whose residence in certain localities might have made it of value over a wider field. In the direction we have named, as in many others, we feel sure there is much that might be usefully done.

LONDON TEA COMPANIES.

Darjeeling Company, Limited; paid up capital, £135,420, in 6,771 shares of £20 each; area under cultivation 1,735 acres. Directors—Messrs. Henry Smith (chairman), William Sangster, James Percy Leith, and Sir George Macleay, K. C. M. G. The twenty-second annual general meeting of the shareholders of this Company was held on the 4th inst., when the following interesting report was presented to them by the directors:—

The crop of tea gathered in 1886 amounted to 517,316 lb., being an increase of 6,279 lb. over the previous season, but the average price obtained for it was only 1s. 3·18d per lb. showing a decrease of 2·54d per lb. as compared with the average price of the 1885 crop. The proceeds of the sales amounted to £32,411 19s 5d., or £4,835 12s 2d. below those realised in 885. On the other hand, the rates of exchange between Calcutta and London were lower in 1886 than in the previous year, so that the required amount in rupees was provided in India at a saving of £5,465 19s 6d, against £1,330 0s 10d in 1885, although the amount of drafts issued on the Company in London was only £15,500 against £17,000 in 1885.

The items to the credit of the profit and loss statement are as follows:—

By Tea Account	...	£32,411	19	5
" Exchange Account	...	5,465	19	6
" Sales of Tea, 1885	...	18	19	0
" Interest Account	...	20	2	2
Total	...	£37,917	0	1

The expenditure in Darjeeling amounted to £17,33[illegible] 15s 7d, showing a considerable saving of £1,469 10s 4d, over that in 1885, and Mr. Harcourt, the manager, deserves great praise for having succeeded in reduc-

ing the outlay, particularly at a time when there was a large crop of tea to be manufactured, and when an additional acreage of young tea plantations had to be cultivated.

The general expenditure, including insurance and charges on tea amounted to £7,968 12s 4d, being £572 1s 4d below that in 1885.

Thus the several charges to the debit of the profit and loss statement are:—

Expenditure in Darjeeling	£17,338	15	7
General expenditure	3,145	2	11
Insurance and charges on tea	4,823	9	5
Total	£25,307	7	11
Leaving a gross profit of	12,609	12	2
	£37,917	0	1

The gross profit in 1885 was £14,293 5s 3d, so that the profit in 1886 shows a falling off of £1,683 12s 1d. But under the circumstances this may be considered a satisfactory result, particularly when it is remembered that the prices for Indian teas in 1886 were the lowest on record, and that unfavourable weather at the plantations during the season proved detrimental to the production of teas of the finest quality.

It is proposed to distribute the profit as follows:—

Commissions to staff ...	£1,513	4	0
Directors' extra fees ...	75	0	0
Income-tax	380	16	8
Dividend at 7½ per cent ...	10,156	10	0
Reserve fund	484	1	6
	£12,609	12	2

The following comparative statements show the operations of the Company during the past three years:—

TOTAL OUTTURN OF TEA AND COST AT PLANTATIONS.

	Acres	lb.		lb.		R.
In 1884,	1,586	473,206	at	298	per acre,	174,932
,, 1885,	1,661	511,037	at	307	,, ,,	188,082
,, 1886,	1,735	517,316	at	297	,, ,,	173,387

GROSS EXPENDITURE AND COST PER LB. OF TEA, AFTER DEDUCTING THE DIFFERENCE IN THE RATES OF EXCHANGE.

In 1884,	£23,856 ...	cost per lb.	1s.	0·18d.
,, 1885,	£25,022 ...	,,	0s.	11·90d.
,, 1886,	£21,811 ...	,,	0s.	10·11d.

ACCOUNT SALES WEIGHT OF TEA, AVERAGE PRICES, AND PROCEEDS.

In 1884,	468,239lb.	at	1s. 5·41d.,	£33,975
,, 1885,	504,311 ,,	at	1s. 5·72d.,	£37,247
,, 1886,	512,173 ,,	at	1s. 3·18d.,	£32,411

DIVIDEND.

The directors recommend the declaration of a dividend at the rate of 7½ per cent., clear of income-tax, to be made payable on and after May 4th and the members will be asked to sanction this by resolution.

From 1884 crop of tea, the dividend was 7 per cent.
,, 1885 ,, ,, 8 ,,
,, 1886 ,, ,, 7½ ,,

RESERVED PROFITS.

On the 31st December, 1885, the amount to the credit of this fund was	£3,965	3	3
From profit and loss account, 1885	1,459	5	4
	£5,424	14	0
From profit and loss account, 1886	484	1	6
Total undivided profits	£5,908	15	6

A portion of this amount has been invested in the purchase of £5,000 in New South Wales at 3½ per cent. inscribed stock, at a cost of £4,850.

TEA SEASON, 1887.

The usual estimates have been prepared by the manager at Darjeeling, giving in detail the probable expenditure at the plantations and amount of tea likely to be manufactured, should fair, ordinary weather be experienced, of which the following is an abstract:—

ESTIMATED EXPENDITURE AND CROP OF TEA.

		R.	Lb.
Sudder charges	...	11,498	....
Ambotia Plantation	...	53,309	200,000
Ging do	...	47,827	142 000
Tukdah do	...	41,828	124,000
Phoobsering do	...	23,632	72,000
		178,094	538,000

These estimates exhibit a probable increase in the outlay of R4,714, and an increase in the crop of 20,684lb. of tea, as compared with 1886.

Moderate extensions have been made in the tea plantations during the past cold season. These new tea-drying machines have been supplied, and the maintenance of the plantations in a high state of efficiency has been provided for.—*H. & C. Mail.*

TEA CULTURE AND THE NATIVES OF UVA.

(From a Correspondent.)

31st May 1887.

I have been a long time answering your queries about the villagers. Much of my time has been spent in travelling lately, leaving little for correspondence. They (the villagers) have not taken yet to tea-cultivation, but many of them, especially from Paranagama, have gone to work on estates where tea is grown—compelled to work by their poverty, and I have no doubt that one result of this departure will, by and bye, be village tea-gardens, superseding the abandoned coffee. There are 80 or 90 Kandyans working on Warwick estate, I believe. I saw about 40 gathered at muster on an Uva estate some few weeks ago. The poor things were a painful contrast, in regard to condition, to the Tamils mustered on the same barbecue.

In some places, when I ask the people why they do not take to tea, the reply is, "We have not got the money needed to begin, and we have not the strength for the work." There is no doubt that large numbers of them are in a very sorry physical condition and are perhaps not strong enough for such work as tea cultivation requires, and there is no doubt also that with many there is very little inclination for work.

It would be well worth while on the part of the Government to try the experiment and distribute tea seed. Great poverty prevails in the villages and much sickness resulting from poverty.

AGRICULTURAL CHEMISTRY.

BY DR. J. E. TAYLOR, F. L. S., F. G. S., &C., EDITOR OF "SCIENCE GOSSIP."

Recent experiments demonstrate that copperas or green vitriol (sulphate of iron) is a capital dressing for a variety of crops. A plot of ground measuring one-eighth of an acre, treated with 14lb. of the above salt, yielded 5,287lb. of potatoes, showing an increase of 400lb. against the same size of a plot which was purposely left untreated. In another experiment the sulphate was applied to a field of turnips, and the yield was as good as a similar-sized field on which guano and dissolved bones had been used. In an experiment on two fields of hay, one was manured with the salt and the other not; the yield of hay by the former was nearly double that of the latter. Other crops were equally benefited by it.

Mr. R. Warrington has just published the results of the experiments he carried on at Rothamstead last autumn on the distribution of the nitrifying organism in the soil. He shows that the conditions which favour nitrification in the subsoil are such as enable the air to pe etrate it. Artificial drainage, a dry season, or the growth of a luxuriant crop causing much evaporation of the water of the soil—all, by removing the water from the soil, cause air to penetrate more or less deeply, and thus render nitrification possible. Mr. Warrington concludes that the

nitrogenous matter of a clay subsoil is nitrifiable. The quantity of nitrates produced in the subsoil is smaller in every case than in the surface soils, but the proportion of the original nitrogen of the soil which was nitrified is on the whole quite as large in the case of the subsoils as in that of the surface soils.

Another new "food for cattle" has been discovered, as if the world were not just now suffering from an excess of food materials. But such a food. It consists of sawdust mixed with certain chemicals by way of spice, and "other matter." The composition is said to form a very wholesome and nourishing food for pigs, horses, and cattle.—*Australasian*, April 9th.

PLANTING COMPANIES IN JAVA.

THE DELI-BATAVIA COMPANY.

De Indische Mercuur learns that on a meeting of shareholders of the Deli-Batavia Company, held at Batavia on April 18th, it was agreed to fix, according to a proposal of the Dutch shareholders, a sum amounting to f.1,000,000, and to discuss later on the emission of bonds. Likely there will be afforded to the shareholders in the run of the year another share of f.250 for any share of 1,000 guilders, at 125 per cent.

THE WEST JAVA CINCHONA AGRICULTURAL COMPANY.

We (*Indische Mercuur*) are enabled to record respecting this company the following particulars. The company intend to bring about three very effective raising plantations, viz., Panjaran, large, 638 bouws; Tjiseureuh, large, 741 bouws; and Bajabang, large, 579 bouws; respectively situated in the Assistant Residence and Tjandjoer of the Preanger Districts. We are informed that all the above plantations are producing both coffee and cinchona, and the crops of 1887 are, moreover, estimated yet at 92,970 kilo. cinchona-barks and 200 piculs of coffee; of 1888 at 114,500 kilo. cinchona-barks and 300 piculs of coffee; and of 1889 at 107,000 cinchona barks and 250 piculs of coffee. Estimation of the next year's was considered to be not advisable. The cultivation of the plantations was, at January 1st, viz., 2,624,525 cinchona trees and 330,000 coffee trees, with a view to increase the number of cinchona trees with another 1,300,000 trees by extending the cultivation, seeds and cuttings being in store. The social capital of the company is fixed at f.1,000,000. The plantations are bought at f.850,000. From the capital a sum of f.725,000 has been negotiated, and the remainder will be offered in sale *a pari* in a few days. The directors will be composed, viz., Director, M. T. Boissevain, Esq; Commissioners, E. Bunge, Esq., manager of the firm Bunge and Co., H. M. van Eghen, Esq., manager of the firm Orommelin and Co., and Mr. T. Krol, late chief director of the Deli Company at Deli; Agents in India are Messrs. W. Rudolph and H. Gyselman; the Committee of Superintendence in India, the Jhr. J. W. E. de Sturler, Esq., and Messrs. S.T. Dunlop and J. Dingertoz.

A LONDON BOTANICAL COLLECTOR IN JAVA.

As recorded by Mr. P. J. Wigman in the April issue of the Dutch *Agricultural Horticultural and Forest Culture Journal* in Netherlands India, Mr. Curnow was landing at Buitenzorg in March, intending to get a collection of orchidees. He has in view to collect 10,000 phalœnopsis grandiflora in the South Preanger Districts, at the same time another 5,000 orchidees, viz., vanda tricolor, renanthera coccinea, &c., will be received with pleasure. He told Mr. W. that the former way f. i. packing and despatching to London at once, after having collected a certain quantity of orchidees, was not more of use. Now a certain quantity is collected and transferred by the collector himself. By this way he is enabled to unpack and examine the plants, and there is a good chance more to have same alive at home. The *Orchidees* says Mr. W. f. i. a large deal of dendrobiums vanda's and renantheras may be despatched very well, but the phalœnopsis grandiflora, known in India under the name of Angrek Boelan, are suffering very much on the passage. There are already ten years that Mr Curnow has been travelling for Messrs. Hugh Low and Co. During that time he was working in South and Central America, Madagascar, British India and Burmah.

THE PAGOTTAN AGRICULTURAL COMPANY.

According to the *Indische Mercuur* the Pagottan Agricultural Company is established at Batavia, having in view to purchase the sugar manufactory Oeteran, situated in the Residence of Madioen. When the acquisition does not succeed the company will be considered as never having existed. The capital of the company is fixed at f.200,000.—*L. & C. Express.*

(*Translated from the Netherlands-Indian papers.*)

We learn from the *Bataviaasch Nieusblad* that the Soekabomi Association has petitioned the Netherlands-Indian Government te protect insect-eating birds, to introduce a tax on firearms and *soempitans* (blowpipes) and to prohibit the disturbance of nests and destruction of eggs. The Government, however, has replied that it does not see the use of such protection as suggested. This reminds us of our Ordinance for the Protection of Wil Birds, which, from what we see, seems to be a dead letter.

Several prosecutions have recently been instituted by the Netherlands-Indian Government against European Managers of estates in East Sumatra for the treatment of coolies, the last one being against Mr. E. W. F. Kearns, Manager of Ludwigsburg estate, Langkat. It is gratifying to see the Netherlands Indian Government using its utmost endeavours to secure the good treatment of coolies on the tobacco estates in East Sumatra, and we would direct the attention of those who are only too ready to spread false reports regarding the condition of labourers there to this fact. —*Singapore Free Press*, May 21st.

(*Translated for the Straits Times*, May 25th.)

In the district of Natal on the West Coast of Sumatra the Controller has discovered coal fields stretching over wide areas. The coal has been found by experiment to be of superior quality.

At Samarang, so says the *Locomotief*, a soap factory is now in full swing, every preparation has been made, and all the raw materials for the purpose are at hand. It is well-known that of all animal and vegetable fats, coconut oil is the best for manufacturing certain kinds of soap in great demand in Europe. Mr. Steenberg who has started this particular enterprise is confident that he can turn out soaps equal in every way to the imported article, at moderate but remunerative rates. It is indeed absurd that coconut oil must first travel to Europe to return to Java in the form of soap.

Telegrams intimating improved sugar quotations in Europe have given a much needed impetus to transactions in that article at Sourabaya, prices at one time reaching 9 guilders a picul. Coffee too has been dealt in at very high rates indeed. Offers for whole crops of parchment coffee at forty-five guilders a picul have been rejected. Planters in Java are confident of still brighter prospects. No wonder need be felt at this. News has come of short crops and disease among coffee especially in Brazil. In Java, however, leaf disease is prevalent which in the end must lead to lessened yields and a further rise of prices. The island has one advantage over Ceylon in this respect. Leaf disease has so far not wrought such havoc as in the latter country.

It is intended to hold at Batavia in September next, in the Botanical and Zoological Garden there, an exhibition of articles manufactured in Netherlands India from wood, rattan, horn, fibres, leaves, and feathers.

Sugar growing in Java which proved so prosperous in bygone years, that, in 1884, the yield totalled nearly six-and-a-half million of piculs offers no prospect of extension within the next few years, now that quotations rule so low. Growers there are in a bad way indeed.

There seems to be some prospect of a railway being constructed on the West Coast of Sumatra, to tap extensive coalfields in the valley of the Ombilin [illegible]. A Bill has been brought into the Netherlands States

General authorising its construction by Government. In Sumatra so far, the only railway in operation is a private line in Deli. The Ombilien fields have long been famed for the quantity and good quality of the coals found there. For years, private enterprise has vainly sought to move the Government to take some action for the development of that productive region.

DELI NEWS.

(Translated for the *Straits Times*, May 25th.)

In Deli, several planters have taken to growing paddy on fields too exhausted for tobacco cultivation, through coolies on the estates. Natives too have been carrying on paddy growing on similar land. But, for all this, the yield of rice there so falls far below requirements that, in 1885, no less than 240,000 piculs of that article had to be imported. Pepper growing is steadily extending, save in the district of Assahan. There the cultivation of that product has considerably decreased in consequence of the exactions and squeezes of the holders of the plantations. In a neighbouring district, many new pepper estates have been started. In the island of Bengkalis, experiments in growing that article have been made without satisfactory results worth mentioning.

Planters in Deli have become keenly alive to the disadvantage of trusting to only one product. Tobacco, at present their mainstay, may at any time fail them. Other kinds of cultivation have been tried energetically without encouraging success. On Mariendal estate, coffee trees have been planted by the hundred thousand in all. At bearing time, wet weather interfered with the ripening of the berries. Drying operations, too, were attended by difficulties partly overcome by improved driers. The outturn shipped off to Europe as parchment coffee, realised low prices. Tae cultivation of Liberian coffee on this estate had to be abandoned from the results proving bad indeed. This variety seems to take more kindly to the environment of the Tanah-Abang estate in Serdang, where the yield, 150 piculs in 1885, was almost doubled last year. Coffee has also been planted on two other estates in Deli. Cocoa growing has so far failed to answer expectations. Indiarubber and Guttapercha planting, do not offer a more promising outlook. Near Medan, rameh growing yielded a fair crop. Trials with newly invented machinery for preparing the fibre, resulted unsatisfactorily. At Sungei Agul, indigo cultivation with seeds from Guatemala has been tried with some success. The experiment fully came up to expectations. The quality of the article turned out, though prepared in a primitive way, proved very good. Gold prospecting in Bila only led to disappointment.

COFFEE IN BRAZIL.

The *Rio News* of April 6th states :—

The recent spurt in our coffee market is but another proof of what we have sustained, that Rio must prepare to hold much larger stocks than has heretofore been the practice, and that consuming markets will be more and more disinclined to pile up large quantities of coffee when their necessities can be so rapidly and readily supplied from this. The recent movement here undoubtedly arose because our market was the cheapest at the moment, and as prices here have been advanced sharply, the demand may become less urgent and is, we think, likely to be more moderate pending another accumulation of stock and a consequent modification in prices. While advices from abroad are undoubtedly stimulating, we incline to believe that the movement in consuming markets has been purely speculative. There is no absolute explanation of the small average receipts in March. Opinions vary as interests are concerned and unfavourable weather, or the absolute scarcity of the bean, are in turn ascribed as reasons for our small supply. We incline to believe that a third hypothesis might be added, viz, that factors here have advised planters to restrict their shipments, pending the movement that has occurred in our market. Absolute scarcity as yet we do not credit, and either, or both, of the remaining reasons must be considered temporary. Unfavourable weather cannot always continue, and the advance in prices here will modify the counsels of factors relative to shipments from the interior. Therefore we look to not more than a moderate business, until prices again reach such a range as will again attract the attention of consuming markets. There is very little said at present about the 1886-87 crop. A significant remark is made by a writer in our principal journal, in which he disclaims a belief in no crop, and estimates for 1886-87 one-half a crop, to be supplemented by the produce of new plantations in Minas, S. Paulo and Espirito Santo. Here is the very factor that leads to miscalculation in coffee crop estimates, and subsequent disappointment and loss. It matters very little to the consumer whether coffee be produced in the Parahyba valley, or in the provinces above mentioned, provided it be exposed for sale in the Rio market, and it would almost seem that some modification of the earliest crop estimates is possible. There is one feature in the trade that at no distant date is likely to be of importance. We allude to the increasing coffee shipments from the port of Victoria, Espirito Santo, to direct consuming markets. This coffee was formerly a part of the Rio crop, and its shipment direct will ultimately tell on our export figures. Whether an increase in the production of Minas and in such parts of S. Paulo as are tributary to Rio will suffice to meet the reduction in the supply of our market from Espirito Santo is a question that only time can solve. We may close our remarks by confessing that we see little probability of our supply for the six months, January-June, of this year, reaching 2,000,000 bags as we estimated it would in January 1st. We do not doubt that the coffee could be produced, but for this purpose so high a range of prices in our market would be requisite, upon which it seems to us injudicious to calculate, that we consider a modification in our estimate of the supply for the last half of the present crop necessary.

CHEAP QUININE.

(*Straits Times*, May 30th.)

The Planters' Association at Bandong in Java has appointed a permanent committee to start a movement which should command every support and aid in this part of the world. Its object is to cheapen the retail price of quinine, and bring it within the reach of almost every one. That remedy, so indispensable in tropical countries, has of late risen considerably in retail value, notwithstanding the circumstance that its wholesale price within the last few years has fallen sixty per cent. The association in question has taken steps to remedy the evil by strenuous efforts to supply the article not only in Netherlands India, but also in adjacent foreign colonies at rates which would admit of the poorest people laying in adequate stocks of it. This class of society forming the bulk of the population, suffers most from the high rates ruling. Only well-to-do persons can freely supply themselves with the article. As may be expected, this untoward state of things has taken effect detrimentally upon the sale of quinine, and upon cinchona cultivation as well, especially in Java. To bring about a change for the better in this respect, the permanent committee of the abovementioned association took counsel with some of the leading quinine manufacturers in Europe. Their object in view

was not only to bring the price of quinine as low as was consistent with fair profits, but also to secure it in the handiest and readiest form admitting of meeting adequately the demands of consumers. The managers of a quinine manufactory in Brunswick came to terms with the committee. They made arrangements for supplying Java consumers first of all with quinine in bottles containing 80 gelatine capsuled pills, at rates 70 per cent cheaper than those generally charged by apothecaries. Powdered quinine they undertake to supply at one-third the prevailing quotations. When once business enterprise on these lines has fairly come into play, prices may be expected to fall still more, to the material advantage of all classes especially the poorer ones. As mentioned above, the committee when a fair start has been given to the undertaking, intend to extend the sphere of their operations to neighbouring countries and colonies. It has already made enquiries on the subject, with the result of showing that matters there in this respect are as bad as in Java. In British India, for instance, the Government has long been fully alive to the fact, that in the interest both of the common people and of cinchona cultivation, there was urgent need of lessening as much as possible the retail price of quinine. For establishing branches of the committee in neighbouring colonies, there is every encouragement. Facilities may be counted upon and taken advantage of. The measures to be taken are said to admit of the wants of consumers being satisfactorily met. When other quinine manufacturers take the hint and do likewise, competition will arise. The committee have not overlooked this contingency. Arrangements have been made to test new brands of quinine coming into the market. The late Dr. Moens, an eminent quinologist, certified favourably as to the quinine of the Brunswick manufactory aforesaid, after testing it at the request of the committee. The latter have secured capital sufficient for present requirements by means of donations and subscriptions. The managers are however fully aware that efficient working and abiding advantage demand more systematised organisation on a permanent footing. To extend its sphere of operations and to further the good work of cheapening quinine in Java as well as in the adjoining European colonial possessions, they have set to work floating a company in shares to conduct a trade in that article. The profit aimed at, will be moderate but sufficient to ensure the shareholders a good investment for their capital. The committee set no store by large profits, but intend merely to act as intermediary between the manufacturers and consumers of quinine. The primary object in fact is to further the consumption of quinine, and thereby to give as great an impetus as possible to the cultivation of cinchona. They will be quite content with a 5 per cent return on the capital required for the purpose. The committee certainly are entitled to the countenance and assistance of all philanthropic and right-thinking persons. Strenuous effort to generalise and push on the use of quinine in tropical lands by lowering its price, deserves every success.

TEA.—The *Hupto* says that since the 23rd ult., nearly 100 piculs of tea have arrived at Foochow from Pei-ling, and the price, per picul, averaged from 16,000-17,000 cash to 22,000-23,000 cash, being cheaper than last year, by five or six thousand cash per picul. The value of copper cash is, however, higher than last year, and the prices vary accordingly. On account of frequent rain during the picking of the leaves, the taste and colour of the teas are not good; experienced tea dealers predict that the tea business this year is not likely to be profitable.

TOBACCO, CINCHONA AND COFFEE IN NETHERLANDS INDIA.

(Translated for the *Straits Times*.)

Attention continues to be drawn in Java to British North Borneo, as a field for tobacco planting. Dealers at Rotterdam have not failed to sound a note of alarm in this respect. They have the acuteness to perceive that the competition arising in North Borneo, bids fair to prove dangerous to planters in Java and Deli. One Netherlands trade journal admits that the good quality of the article grown in that land of promise, shows that experienced planters will find there a profitable field for the exercise of energy and industry. It deems, however, that planters in the neighbouring Dutch Colonies need not make themselves uneasy at present, owing to the planting community in North Borneo being sparse, and from uncertainty as to the actual extent of suitable land. It advises them, should the country be really fertile, to lose no time in taking advantage of the new opening, and settling down themselves there.

During the first quarter of the present year, the Government cinchona plantations in Java have suffered severely from hurricanes which wrought great havoc in many localities. On one estate, no less than 1,500 cinchona trees were uprooted. The bark crop last year reached 525,698 half kilogrammes, a heavy increase over 1885. There is every prospect of this year's crop far exceeding expectation.

The Surabaya *Courant*, on the authority of a correspondent in Mid Java, says that coffee leaf-disease, prevalent enough there in certain places, does not seem to spread apace. The signs of its presence are manifest enough, readily to catch the eye. Few of the diseased trees ever ripen the berries they happen to bear. The crop looks dismally small as it is. Blossoms, however promising at bearing time, very seldom come to anything. Leaf disease sometimes relaxes its hold for a while, only to return with fatal results to trees over wide areas. It has made such destructive progress in that part of the island, that coffee cultivation seems ruined past recovery. Even with high prices it has no chance of becoming sufficiently remunerative to admit of adequate business enterprise in that particular line. Continuous short crops and the death of whilom productive and vigorous trees, prove a sore discouragement. Hopes arising from disease apparently losing ground, have also invariably come to nought, by its recurrence with increased virulence and strength. Meanwhile, at Surabaya, the price of coffee has been rising rather wildly. At one time it shot up amazingly high only to fall shortly to 50 guilder cents per catty. A further rise to 60 cents was confidently expected. The available quantity of coffee in the market happens, unfortunately, to be small there. Sugar on the contrary continues to decline in price after a fitful rise. At present, a waiting policy suits Java growers best. By last advices, crushing operations had not yet set in. The canes are deficient in juice of the required strength, owing to rainy weather. The sun must reassert itself before matters mend. In that part of Java, the cane in the fields looks splendid and unusually tall with no signs of disease. In East Cheribon and Tegal, disease among cane has done much mischief. Plant cane from other districts cannot stand against it. During the rainy season the disease in question in spite of every safeguard, has made considerable progress. It has gained in virulence, and has spread over still wider areas. The roots of the plant are first attacked. The cane soon withers, and the juice wholly dries up or becomes deteriorated.

The *Batavia Nieuwsblad* draws attention to the circumstance that, with capital supplied by Deli planters, one of the Penang hills has been secured for the purpose of starting a Netherlands British sanitarium called the "Crag" chiefly for Europeans from the East Coast of Sumatra. It stands at a height of 2,300 feet above sea level in a cool climate, and is said to be especially suitable for the diseases arising from malarious surroundings The establishment is said to be under the business management of a Netherlander, and to be under the superintendence of the Consul-General for the Netherlands.

THE INDIAN DUTY ON RICE.

English rice millers and merchants have a grievance which is very strongly felt. Discussing the matter from a free-trade point of view, they urged that rice, far from enjoying any such boon has to struggle against a repressive impost that is of ruinous effect. There was up to 1873 an export duty upon wheat sent out of India, but in that year it was repealed, and since then the Indian wheat trade has multiplied tenfold. But the export duty of 6d per cwt. on rice sent out of India and Burmah has been maintained, and since 1873 the rice trade of the United Kingdom has decreased 27 per cent. These two matters have a direct bearing upon each other. The uncleaned rice that is brought to this country is manufactured into white rice, rice flour, and rice meal, and there is direct competition between the two latter products and similar wheat products. Hence the 6d per cwt. export tax upon rice places the English rice merchants and millers at a direct disadvantage in competing with wheat millers and corn merchants. Nor is this all. The export duty is the same upon both cleaned and rough rice, and this practically gives the miller in Burmah an advantage of about 5s per ton in shipping cleaned rice to the Continent. Th n, when the rice from Burmah reaches France it is admitted duty free, whereas if it be sent to France from Englnad, an import duty is levied of 30s 6½d per ton, and this differential treatment has simply ruined the English rice trade with the Continent. When to these grievances is added the fact that in some Crown colonies a duty is levied upon rice that renders business impossible, it is not surprising that the rice trade is endeavoring to bring their troubles under the notice of Parliament. They have enlisted the services of Mr. Baden Powell in the matter, and when opportunity offers, the Honorable Member will have little difficulty in showing that the policy that has been pursued has had a disastrous effect both upon invested capital and the employment of labour in rice mills.—*Grocer*. [The Indian Government offers no defence for the one export duty retained in their tariff except that in present circumstances the revenue derived from the sixpence (it does not seem much) on each cwt. cannot be sacrificed.—ED.]

THE MAY ISSUE of the Kew *Bulletin* contains a useful summary of facts, now for the first time brought together, respecting Bowstring hemp. This valuable fibre, which is valued in London at 30*l*. per ton, it yielded by some ten or twelve species of Sansevieria, a liliaceous genus of plants, very abundant on both the east and west coasts of tropical Africa, but extending also to Ceylon and India. They are described as essentially tropical plants, with mottled leaves; they prefer a rich moist soil, and a comparatively humid climate. The fibre is very firm and elastic, hair-like, and silky; it takes dye very readily, and the refuse material, or tow, can be converted into excellent paper. One species, described as *Sansevieria longiflora*, sent by Sir John Kirk from Zanzibar, has leaves 9 feet long, and the fibre is described by experts as "very bright, clean, strong fibre, and in every way a most desirable commercial article." The opinion is expressed that this will doubtless prove a new fibre-plant of great value. We would mention that these *Bulletins* are published by Messrs. Eyre & Spottiswoode, London, and can be obtained either directly or through any bookseller.

TOBACCO AND SUGAR IN MANILA.

(Translated for the *Straits Times*)

A correspondent assures the *Comercio* that the current tobacco crop in the island of Luzon looks flourishing, but that there is every prospect of the crop proving short of last year's. This falling off is ascribable to many cultivators having given up growing it. They grudge the toil and trouble attending the cultivation of an article requ'ring so much care and attention, and fetching now-a-days such unremunerative prices. This is especially the case in the province of Isabela. There, growers display such indifference and heedlessness in bringing tobacco of inferior quality to market, that the article in question has steadily fallen into discredit. Many cultivators instead of remedying the evil by paying more attention to securing a product of superior quality become discouraged, and make hardly an effort to carry on an industry, formerly so profitable but now fast declining.

The sugar growing interest in the islands has been favoured by Government, which bids fair to help them materially in facing the sea of troubles menacing them. The Home authorities have sanctioned the reduction of the export duty on sugar in Philippine ports by twenty per cent. The sugar planters in sore straits indeed in the islands, welcome this slight relief with joy. Little as the reduction looks, it is something to be thankful for.

CEYLON UPCOUNTRY PLANTING REPORT.

THE MONSOON—DEMAND FOR TEA PLANTS—INDIAN TEA SEED A FAILURE—THE LIFE OF THE TEA TREE—INCREASE IN NUMBER OF TEA FACTORIES—THE MACINNES TEA ROLLER—COOLIES AND HARDROLLING.

6th June 1887.

The monsoon so far has been mild, without much high wind, and there has been splendid planting weather. There is a considerable demand for tea plants, and although a little while ago those who had gone in for nurseries as a spec did not see their way out of them very profitably, still this is pretty much changed now. Orders are coming in somewhat freely, and several with plants for sale are booked up to their full extent, and deliveries are large.

There is a considerable amount of discontent at the results of Indian seed. It is, if true, a fraud and a failure than ought else, and those who have dealt most largely in it, have least faith in it, and incline to have their wants for seed supplied for the future from local gardens of approved jâts.

In regard to the longevity of the tea tree, one has to go pretty far afield to settle this. How long it will last in Ceylon may perhaps be known by some future generation, but not likely to be a burning question for a considerable time to anyone else than Indian tea planters. But as a contribution to what it can do in Japan, there was a visitor in this district lately from that part of the world, and he spoke of tea gardens which he had seen, the leaf from which was reserved for the Mikado and had been so all along. There were in those gardens vigorous trees, which were said to be three hundred years old. A good deal less than that would satisfy the present Ceylon planter.

Factories keep going up, on all sides, and what before would have had a newspaper notice, is now allowed to pass unchronicled. It is not everyone, however, who goes in for a three-storied iron store from home, such as is at present being erected on New Peradeniya estate. The work is being done by an engineer imported from home, who will see to its erection, and the removal of the machinery already in the place.

Although the Badulla side of the country is not yet very forward with its tea, still they have their own roller, that designed by Mr. John McInnes. I saw

some samples of leaf rolled by this hand-machine, and it was all that could be desired, wiry and with a fine twist. One who has been using the roller for some time speaks very favourably of it. He says: "One great advantage it has is its simplicity, and coolies soon understand it. If hard-rolling is wanted, any amount of pressure can be put on without any trouble—with power it ought to be perfection." As long as the cooly has to be depended on for tea rolling there is always a difficulty and will always be, whatever may be the machine. To depend on Ramasami in this kind of thing is a constant worry: he does not like hard-rolling, and so you always find a sigh for power, to get rid of the constant driving which is wanted to keep him up to the mark. I fancy he finds it especially when the weights are put on to be "a horrid grind."

PEPPERCORN.

PETROLEUM AND ITS PRODUCTS.

BY BOVERTON REDWOOD, F.I.C., F.C.S.

From a Cantor Lecture so entitled, we take a few interesting extracts:—

Probably the earliest descriptive mention of petroleum was made by Herodotus who about, 450 B.C. gave an account of the pitch lakes of the Island of Zante, and referred to the use of bitumen which had been brought down by the waters of the Is into those of the Euphrates, in the building of the walls of Babylon. This writer describes a well at Arderrika, thirty-five miles from Susa, which produced asphalt, salt, and oil, the mixture being drawn from the well in half a wine skin, and poured into a receptacle, when the asphalt and salt became solid, and the oil, which was black and emitted a strong odour, separated. A distinct reference to the use of petroleum occurs in the account of the building of the tower of Babel in the Book of Genesis, for the word "slime" in the English version is *asphaltos* in the Septuagint and *bitumen* in the Vulgate. Sir Lyon Playfair is of opinion that some form of petroleum is more than once referred to in the Old Testament, under the generic name of salt, and he hazards the conjecture that Lot's wife was converted into a pillar of asphalt, as this would constitute an enduring monument which might have been seen by Josephus, and his contemporary, Clement of Rome, both of whom declared that they saw it, while a pillar of common salt would have been washed away by the first shower of rain. Travellers to Persia and India, before the discovery of the Cape of Good Hope route, speak of the pitch fountain of Oyun Hit, on the Euphrates, and the people of the locality have a tradition that the bitumen for the building of the tower of Babel was collected there. The use by the Egyptians, for embalming, of the bitumen found in the valley of the Indus, is mentioned by Strabo and Diodorus of Sicily, and the former also relates how this substance rose to the surface of the Dead Sea during or after earthquakes. The existence of the petroleum deposits of the Apsheron Peninsula has probably been known for at least 2,500 years, for it is believed that the Persian fire-worshippers frequented Surakhani from the time of Zoroaster, who lived not later than 600 B.C. The so-called "eternal fires" at Surakhani result from the burning of the natural gas which issues from the ground in considerable quantity, and a temple still exists which, until recently, was frequented by fire-worshippers.

There are at present about 20,000 more or less productive wells in the oil-fields of the United States.

Then follow figures showing that the production rose from 5,000 barrels in 1859 to 31,000,000 in 1882, the culminating year. In 1885 it went down to 21,600,000.

In 1885 the production of Russian crude petroleum at Baku was no less than 1,371,000 tons.

When I visited Baku in the autumn of 1884, there were about 400 drilled wells in the neighbourhood, but I was informed that only about 100 of these were, at the time of my visit, producing. Of the 100 wells only some 20 were flowing wells. The producing territory on which all the wells supplying the requirements of the Baku refiners are situated is not more than three and a half miles square. Some of the wells are, however, enormously productive. I saw one throwing up a stream of oil at the rate of more than one million gallons per twenty-four hours, and others have yielded at the rate of more than double that quantity. * We shall presently see that this small tract of land bears a very small proportion to the total area of the petroleum lands of Southern Russia, and when we came to consider the geograpical aspect of our subject, we shall have to deal with other regions in this country, in which more or less oil has been obtained.—*Journal of the Society of Arts.*

THE SUGAR CANE AND SUGAR INDUSTRY AT MAURITIUS.

(*Translated from the "Revue Agricole," Port-Louis, February* 1887, *for the "Tropical Agriculturist."*)

(*Continued from page* 791.)

CHAPTER III.

During a considerable time, the sugar industry of Mauritius had only to compete with other inter-tropical colonies, and found its if placed in such conditions of equality as permitted it to maintain this competition without disadvantage. In all cases, the climates in the competing countries were similar, the soil was of equal fertility and the processes of cultivation and manufacture were the same. The development which has taken place in Europe during the last fifteen years in the cultivation of beet root, and in the manufacture of sugar therefrom, has changed this state of things. The price of sugar has fallen to such an extent that the colonial sugar industry, taken in the aggregate, has ceased to be remunerative, and the planters in the Colonies see themselves under the necessity of finding some means of producing the article at a cheaper rate.

For the solution of this problem there are two conditions to be fulfilled: reduce the expenditure which has already been done, and increase the produce which remains to be accomplished.

The augmentation of production raises two problems of different orders. On one part the increase in the agricultural produce, which is a question of agronomy. On the other hand, the increase in quantity obtained in the manufacture, which divides itself again into two distinct sections, the extraction of the juice contained in the cane, which is a question in mechanics and physics, and the extraction of sugar from the juice which comes under the domain of chemistry.

As to what concerns the agricultural production, we have before us this fact, that whilst the mean produce on well cultivated land does not exceed 4,000 lb. an acre, it has frequently been established that in particular instances the production has been as much as 12,000 and even 15,000 lb. an acre; from which it is evident that the average production hardly reaches to one-third of what it might be. In the face of such disproportion, it seems reasonable to assume that the mean production might be considerably increased by more judicious methods of cultivation and a more suitable use of fertilizing agents. In localities sufficiently watered by the rainfall, it is not difficult to increase production by a more liberal application of manure and by more minute care in the cultivation, but such a mode of operation of necessity involves increase of expenditure which goes directly against the object in view. The question is thus evaded, and to prevent useless outlay on manure which increases the cost of production without any corresponding advantage, we have still to find out a certain soil being given, the relative

* The Armstrong No. 2 well, in Butler County, Pennsylvania, one of the most productive known in the United States, yielded only 260,000 gallons per twenty-four hours.

proportions of the different fertitizers to be employed, so as to produce the greatest quantity of sugar at the lowest possible cost.

This is a problem, for the solution of which, the primary data are almost entirely wanting. We know as a general rule, that we have to supply the plants with azote, phosphoric acid, lime and potash, but we are still ignorant of the nature of the action of these different elements on vegetation, or what the effect is, which each of them exercises on the sugar contained in the cane. Nor are we any better informed as to the form in which each is most advantageously presented to the plant, nor are opinions fixed even as to the best method of application. Is it better to place them on the surface leaving the rain to cause them to penetrate into the soil? Or is it preferable to incorporate them with the soil by a systematic digging, or ought we rather to concentrate them at the foot of each plant?

Again, what are we to think as regards renovating the soil by means of cultivation more or less unproductive, such as peas, the embrevatte, &c., which cultivation improves the soil in a certain measure, but which has the disadvantage of leaving capital idle for a longer or shorter period on which interest has to be paid? May it be possible by the employment of manure to do without the rotation of unproductive crops?

Such are the principal questions raised by the problem for increased production, questions which can only be solved by numerous and minute experiments, carried on methodically on establishments especially devoted to such researches. If we turn from cultivtion to manufacture, we find before us questions fully as important and equally complex.

The first point is the separation of the cane juice from the woody fibre of the plant. Hitherto this operation has been effected by the crushing power of cylinders turned by machinery.

But, although we seem to have attained the maximum crushing power which is mechanically possible, this separation is accomplished in a very imperfect way, the best mills still leaving in the "bagasse" or cane refuse from 20 to 25 per cent of the total juice contained in the cane, which represents 25 to 33 per 100 of the juice obtained. Amongst the numerous methods which have been proposed for the purpose of reducing this loss to the minimum that which seems to present the best chances of success is "la diffusion," or extraction of the succharine matter by boiling the cane. But the application of this method to the sugar cane presents difficulties which do not appear to have been as yet overcome.

Besides the modifications of the apparatus used in the case of beet root, in order to adapt it to the manipulation of sugar cane, which modifications in some respects are at the present time subjects of experimental investigation, there are other difficulties of a grave nature which must be kept in mind. First, the increased quantity of fluid to be evaporated, increasing the quantity more or less considerable of coal which is rendered necessary.

Secondly, the difficulty of drying the husk of the cane when removed from the boilers (diffuseurs) or digesters, so as to render it fit for fuel, as is now done with the "bagasse" (cane trash or "ampas" as it is called in Java).

The idea has been suggested of abandoning the use of the refuse of the cane as fuel, and the opinion has been put forward that by digging it into the fields as manure, it would represent a value equivalent to the cost of replacing it as fuel by coal, but this is an opinon that has not yet been confirmed by experience.

The loss of sugar consequent on the incomplete extraction of juice from the cane is not the only results of the imperfection in our processes of manufacture; we must also bear in mind the quantity of sugar retained in the molasses and which may be estimated as a tenth of the quantity of sugar contained in the cane juice. This is caused by the presence in the juice of glucose, mucilage and different salts, all of which substances have the effect of opposing the crystallisation of the sugar.

And this loss of quantity is not the only result of the presence of such mollasses forming matter, we must remember that the loss in quality in the 2nd, 3rd and 4th boilings caused by the discoloring produced by these same matters may be calculated at from 3 to 10 per cent of the value of the whole crop.

Let us now add the sugar which remains in the skimmings that which is dispersed in evaporation in the triple effects, and lastly the unavoidable waste which takes place in some proportion, and we shall arrive at the conclusion that the loss incurred in manipulation of the juice is equal to that arising from its imperfect extraction from the cane, and that each of these losses represents fully 20 per cent of the sugar produced. There is thus a total loss of 43 per cent resulting from imperfect manufacture.

Thus it will be seen that there is a wide field open to the researches of scientific men, and it is greatly to be desired that agreeably to the request addressed to Government by the Chamber of Agriculture, substantial rewards should be offered for the discovery of the means of reducing this loss to a minimum.

To sum up the result of the imperfection of our process of manipulation as well as of our system of cultivation is, that our soil produces hardly the half of what it ought to yield, and that there is room for the hope that important improvements might be effected in these matters, if a plan of serious studies could be organized, systematically conducted and pursued with that perseverance which can alone lead to success. C. B.

EXHIBITION AT CONEGLIANO.—An important exhibition of apparatus and implements for the prevention of the diseases of the vine, and for destroying insects that infest it, was held last month at Conegliano. The exhibitors, who were not limited to Italians, were 197 in number, and of the 524 different machines, apparatus, and implements shown, 450 were connected with application of milk of lime, the most effectual remedy for the disease called *peronospora*, the proportion being from 8 to 10 of slaked lime to 100 of water. The experiments, made before a jury composed of the most eminent viticulturists and scientific men, which lasted five days, will be described in a report to the Minister of Agriculture, and will contain a variety of useful information and plates. Three gold medals, three silver with money prize of 150 francs, seven silver ones, and four bronze ones were awarded, and besides these, three special premiums were given by the local agricultural committee.—*Journal of the Society of Arts.*

MR. GOW'S TEA WITHERER AND ITS WORK.—I have this morning seen and tasted samples of tea made by Mr. Gow's witherer, sold at the same time and by the same broker as a break of tea from the same estate, but made by the ordinary process during the same week and in similar weather: the one tea was finished off in two hours, the other in twenty-four hours. The broker who sold them knew nothing of these conditions, and it is worthy of note that the two parcels sold for the same price within a farthing, a difference not worth considering. So far as I was able to judge, there was really nothing to choose between the two lots, a fact which proved beyond doubt that the new withering process is absolutely successful, although these teas were made in favourable weather, and, therefore, did not show as might otherwise have been done, the advantages of Mr. Gow's system in unfavourable weather. For special reasons this tea from the Mariwatte estate was sold under a different mark—a plain "M."—and there is an opinion that had it gone forward under its proper mark, more money might have been obtained for it, as buyers as a rule pay little attention to teas with unknown marks.—Home Cor., Local "Times."

COLONIAL AND INDIAN EXHIBITION: LONDON, 1886; REPORT ON FRUITS.

BY D. MORRIS, M.A., F.L.S.

Amongst the objects of productive industry displayed at the Colonial and Indian Exhibition, there are few that have awakened so much interest as the array of fruits brought together in a fresh and preserved state from all parts of Her Majesty's Dominions. Fresh tropical and sub-tropical fruits were exhibited and regularly sold during the course of the Exhibition in the Colonial Market, and hundreds of thousands of stay-at-home English people realised for the first time what boundless stores of delicious fruits were capable of being supplied by our Colonies.

The limits prescribed for this Report entirely prevent anything like a detailed account of the exhibits. Wherever practicable, a brief statement of the general capabilities of each Colony in the way of fruits is given, and the more promising fruits for commercial export purposes are noted. More than this could not be attempted.

CANADA.

The best fruit produced in Canada is no doubt the apple. The magnificent trophy in the Canadian Court, wherein not only apples, but numerous other fruits of the several provinces were shown, was a striking proof of the vast capabilities of the Dominion. The Canadian summer is a short but marvellous developing period, which is succeeded by a long and severe winter. In spite of this, however, the Canadian fruit-growers have made wonderful progress in the number and character of their productions, and have developed fruit-growing on a scientific basis with the best results. In the trophy above mentioned, fruits of all kinds grown in Canada and preserved in fluid were shown from the Provinces of Ontario, Quebec, and Prince Edward Island. These fruits were collected and arranged by Mr. William Saunders, to whom great credit is due for the complete and representative character of the exhibits. Among these fruits were apples, pears, plums, cranberries, quinces, the quaint but useless Osage orange, gooseberries, grapes, strawberries, currants, thorn-apples, raspberries, barberries, egg-fruit, crab-apples, blue-berries, native grapes, buffalo-berries (*Shepherdia argentea*). Apples were arranged altogether in eighty named varieties. Late keeping apples were shown at the beginning of the Exhibition, and up to the month of June, while early varieties of the season of 1886 were shipped from Canada, and on view at the end of August. Besides these, there were shown plums, peaches, and pears of exceptional quality.

During the month of October an Exhibition of Canadian apples was held in the Conservatory of the Royal Horticultural Society, which attracted considerable attention. The Canadian apple best known in England is the Newtown Pippin, which as a dessert fruit is in season from January to March. The tree of this variety is invariably grafted, and is an uncertain producer. Hence its cultivation is not largely extended, and indeed is restricted to a few localities. The Canadians themselves do not appear to prize the Newtown Pippin as highly as Europeans do; the latter either from fancy, or from its attractive character in late winter, have placed its fruit first in the market. Of early apples, there are the Gravenstein, Alexander, Duchess of Oldenburg and St. Lawrence, in season from September to December; while of late apples there are Golden Russet, Gloria Mundi, Nonpareil, and many others, which are in season as late as May or June. The Gloria Mundi, in exceptional specimens, has been known to reach 18 ounces in weight. During the course of the Exhibition various plants were adopted to pack and ship Canadian fruits, and some of the experiments were of an interesting and suggestive character. The experiment made with a packing of infusorial earth between the double boarding of cases were found not to yield such satisfactory results as were at first anticipated. In fact, nothing was on the whole so satisfactory as a careful wrapping of fruit in tissue paper to prevent bruising, and giving them as much air as possible in a cool storage. Soft fruit, such as plums, peaches and grapes, when packed in compartments, arrived in fair order; but during such an abundant fruit harvest as the last in England, foreign fruit of this character could not pay expenses. Now that the merits of late keeping Canadian apples are better known, there is no doubt that the demand for them will steadily increase. At present, owing to the round-about way of reaching the consumer, a barrel (three bushels) of apples, which in Canada is worth about 5*s.* or 6*s.*, is sold in England at something like 26*s.* or 28*s.* per barrel. Hence the greater part of the profit at present goes to the middle men.

As indicating the enormous proportions which the Canadian apple-trade has assumed, it is stated that the Province of Ontario alone has exported this year half a million barrels. All these do not come to England, a considerable quantity going direct to Norway and Denmark. British Columbia, as might be expected, is destined to become the competitor of California in choice fruits, especially in pears, which are magnificent both in size and quality.

In preserved, canned, and evaporated fruits, a large display was made by the Aylmer Canning Company of Ontario, and of those examined the pears, blackberries, peaches, cherries, plums, and apricots were excellent.

NEW SOUTH WALES.

As the apple is the fruit of Canada, the pine-apple, the fruit of the Bahamas, and the banana, the fruit of Jamaica, so the orange is destined, I believe, to be the commercial fruit of New South Wales.* The samples of Sydney oranges shown in the Colonial Market, although evidently not selected and graded according to the experienced style characteristic of Mediterranean oranges, sufficiently indicated the inherent good quality of the fruit. New South Wales oranges are expected to arrive in England in June, July and August, a time when no oranges can be produced in northern countries. This will naturally cause a change in the characteristics of the English fruit trade; but there is a manifest opening for good Colonial fruit during the early summer months, and Australian (and for the matter of that, Cape of Good Hope and Natal) fruit-growers would do well to follow up their experimental shipments of the present year, and establish a market for their produce. So far, reference has been chiefly made to oranges from New South Wales. It is not to be supposed, however, that this is the only fruit that can be grown there. Excellent lemons, quinces, guavas, apples, apricots, peaches, nectarines, plums, figs, loquats and melons are also produced, and these in a preserved state formed a special feature in the New South Wales Court.

VICTORIA.

This, the richest and most prosperous of England's Colonies in the southern hemisphere, possesses wealth in her vegetable productions no less than in her mines and gold-fields. While importing a large quantity of fresh fruit, and what is called "fruit-pulp" from Tasmania, which latter is the orchard of Australasia, Victoria is able to produce, at certain seasons, large quantities of fruit, some of which, shown in London, has been of excellent quality. The canned or tinned fruits of Victoria indicated a near approach to the best fruit of California, which hitherto have monopolized European markets. In a special Report on fruits exhibited by the Red Cross Preserving Company, it is stated that "the quality is equal to many of the Californian fruits in the trade, and as soon as the prejudice is dispersed, arising from the introduction of Australian packs in English markets (it being quite a recent step), there will doubtless be a large trade done between the mother country and the dependency of Victoria."

* The trees suffer considerably from blights.—Ed.

The apple is the most esteemed of Victorian fruits, and thrives in all parts of the Colony. * The apricot prefers the warmer districts, where its produce is both large and fine. Cherries are largely grown, and appear to thrive in the strong volcanic loams that exist in various parts of the Colony.

The fig grows exceptionally well in the warm northern districts, and fig-drying is being taken up as a local industry. The grape, both for wine-making and for a dessert fruit, flourishes in all but the coldest climates. In suitable localities the bunches and berries are described as of enormous size, fine colour, and excellent flavour. Melons are in great demand in local markets, and "a cross-bred variety of sugar melon" is much used for jam. The peach, often grafted on almond stocks, is one of the most delicious fruits grown in the Colony. The persimmon (Kaki) is becoming popular on account of its rich flavour and fine colour. Plums are abundant, and are obtained in the markets at a low rate. The raspberry, grown in the rich valleys of the Yarra, is sent to Melbourne to the value of £150,000 annually; while of the strawberry, two, and even three, crops are not unusually borne in the year.

SOUTH AUSTRALIA.

This Colony, next to New South Wales, made a very successful show of fresh fruits. Its grapes, apples, and pears were of special interest, not so much for what they were in themselves, as for the possibilities which they foreshadowed, and the promise which they held out of an extensive and prosperous fruit trade between the Australian Colonies and the mother country. The resources of civilization in this instance are evidently being directed to a comparatively unworked field; and there is no reason why this trade in fruit should not grow into permanent benefit alike to producer and consumer. The special points wherein some shipments failed have already been pointed out by Mr. D. Tallerman, who had charge of the Colonial Market, and it is unnecessary to repeat them here. The knowledge, so far gained, will be of great benefit in arranging for future consignments. In packing fruit, it is suggested that "the cases for fruits should be of the ordinary flat shape, with one or two partitions." "I find," says Mr. Tallerman, "that the fruit from Adelaide, in the old-fashioned cheap Tasmanian cases, with the apples papered, has arrived in good condition. Some South Australian shippers simply line the cases with paper, and pack their apples loose, and they have arrived equally well; but I recommend that all large and choice fruits be papered."

The dessert raisins, Zante currants, and Sultana raisins, shown in the South Australian Court, were of a most interesting character, and compared very favourably with the best qualities usually imported into England. It is evident that South Australia, no less than the Cape of Good Hope, can supply both the European and American markets to a large extent with these dried fruits, and they have done well to display in so enterprising a manner their special capabilities.

QUEENSLAND.

At least one-half of the vast territory of Queensland lies within the tropics; hence, in a classification of its fruits, they may very conveniently be divided into tropical and sub-tropical. Belonging to the latter class, there are the fruits of the orange family, Chinese and Japanese fruits, and the more delicate of English-grown fruits, such as apricot, almond and peach. Of tropical fruits grown in, or suitable for, the climate of Northern Queensland, there are the banana, pine-apple, and mango, for which there is a very large local and Colonial demand,† and it is said that "growers have for years past been accumulating wealth by growing and marketing them." An export fruit-trade exists between Queensland and Sydney, and having regard to the vast extent of rich lands suitable for fruit culture, there is scope for almost unlimited development.

Queensland scarcely did herself justice at the Colonial and Indian Exhibition in the matter of fruits; and indeed, judging by the specimens shown under Class 67 (fruits, fresh and preserved), it would be impossible to express an opinion respecting them. It is evident that it is not sufficient to grow good and choice fruits; but for external trade, the most approved and skilful methods must be studied for selecting, packing and shipping such fruits expressly for long voyages.

WESTERN AUSTRALIA.

The representation of fruits in the Western Australian Court comprised one magnificent pear weighing 3 lb. and 3 oz., some dried apricots and figs, dried peaches, several boxes of raisins, and a selection of preserves of Cape gooseberry, melons and gooseberry, and melon and limes.

There were exhibits of candied fruits, and one lot of preserved olives.

Judging by the specimens here shown, it is evident that both raisins and currants can be grown in Western Australia, equal to any in the English market. The stalk, or dessert raisins, prepared by C. W. Ferguson and C. C. Fauntleroy, were in excellent condition, and deserve special mention. Practically an undeveloped country, Western Australia cannot be expected to show advance in cultural operations equal to her sister-colonies. What she has done already, is good earnest of what she is capable of doing; and it is evident that choice and delicious fruits are to be numbered amongst the stores of her prosperous future.

NEW ZEALAND.

The best and most successful fruits for export purposes in New Zealand appear to be the apple, pear and quince. Excellent apples of a most attractive colour and size were shown in the New Zealand Court for three weeks after arrival, proving that they possess excellent keeping qualities.

Besides apples, there were received from New Zealand, during the course of the Exhibition, such fruits as pears, lemons, limes, walnuts, all of which arrived in fairly good condition. As the success of sending fruit such a long distance, assuming it was first carefully selected and graded, depended on the mode of packing, it may be useful to place on record the method which appears to have given the best results. In a Report kindly placed at my disposal by the Executive Commissioner, Sir Julius von Haast, K.C.M.G., it is stated that of New Zealand fresh fruit:—

"In all, about thirty consignments were received. The first that came to hand, was in a case brought by Mr. John Bowman of Green Lanes, Auckland, in the "Sutlej" *via* the Suez Canal: his mode of packing seems to have resulted satisfactorily. Mr. Bowman's apples were packed in a close case of Kauri pine, with no holes for ventilation. Each apple was wrapped in tissue paper, and completely surrounded with chaff, so tightly packed that the fruit could not shake about. The apples were from one-and-a-half to two inches apart at the nearest point. Each layer of apples was separated by a wooden shelf. The chaff was not dried artificially before packing. On opening the case, from 10 to 13 per cent. only were found unfit for use, the rest of them being in perfect condition, and still retaining their bloom. The apples had not sweated at all, nor had the dampness from the bad fruit affected the good ones near them. The fruit being large and fine attracted great attention from visitors, and when placed in a glass case in a prominent part of the Court, was generally taken for models similar to those shown by the Australian Colonies.

"Although packed in the Colony three weeks before subsequent arrivals, some of these apples were still good in the case after three weeks' exposure here. Mr. Bowman's apples are stated to have been packed in the last week in March, or more than three weeks

* The "codlin moth" is a great enemy to apples and pears; so are sparrows to cherries, while the peach has been almost killed out in some districts by disease. Victoria has a wonderful variety of climates, however.—ED.

† Especially in Melbourne.—ED.

before those of other exhibitors. A small barrel had been packed nearly twelve weeks when it was opened, and from the apples being wrapped in tissue paper and closely packed in chaff, only 14 per cent. of the contents were damaged."

After describing in detail the condition of fruit received, variously packed in twenty-nine other consignments, but not in such good order as the above, the Report concludes with the following remarks:—

"Judging from the result of this experimental venture, and from the high prices, fine specimens of apples realised, viz., 6*d.* to 1*s.* each; there appears to be a good prospect of a paying business resulting from shipments made to arrive during the few months before European fruit comes to maturity.

"Fancy prices cannot of course be expected, as at a great International Exhibition, where novelty and curiosity lead to purchase, but rumenerative returns from shipments arriving in good condition may be depended on."

Of fruits preserved in syrup, the only successful exhibit was that shown by Mrs. H. D. Knight, of New Plymouth, which consisted of an assortment of thirty-six New Zealand fruits in excellent order.

Of jams, the best exhibits were those of Messrs. Holland Brothers, Wellington; and Messrs. Kirkpatrick & Co., Nelson. All these were put up in attractive well-made tins, and consisted of strawberry, cherry, plum, black-currant, peach, raspberry, gooseberry, nectarine, tomato, green-gage, apple, Orlean plum, apricot and damson:

FIJI.

This Colony consists of a group of islands, variously stated at from 200 to 300 in number, situated in the Pacific Ocean, between Lat. 15° and 22° S. It is distant about 1,900 miles from Sidney in New South Wales, and 1,200 miles from Auckland in New Zealand. As giving an idea of the extent of this comparatively new British Colony it may be mentioned that "Viti Levu, one only of the eighty inhabited islands, is about as large as Jamaica, and considerably larger than Cyprus; that a second (Vanua Levu) would contain Mauritius three times over, and Barbados ten times: and that the aggregate area of the whole is greater than all the British West India Islands including Trinidad."

The fruit trade of Fiji, as might naturally be expected, has been developed by its geographical position in relation to the Australasian Colonies. It was started in the year 1877, on the occasion of a monthly line of steamers being subsidized to run between Levuka, the capital of the group, and Sydney. The progress made since then is shown by the following summary:—

	£	s.	d.
Value of fruit exported in 1877...	507	10	0
" " " 1885...23,994	17	6	

The green fruit exported consists chiefly of pine-apples and bananas, but hopes are expressed that oranges, limes, citrons, lemons, guavas, and mangoes will soon be added to the list, and the trade considerably increased. At present, fruit ranks third on the list of exports. The samples of fruits in the Fiji Court consist wholly of preserved fruits prepared by J. H. Marrinon and the Fiji Fruit Preserving Company. The latter were in neat attractive-looking tins, and both lots indicate the resources of the Colony in this particular branch of industry in a favourable manner. They also lead to the conclusion that Fiji is fully capable of becoming the tropical fruit garden of the Australasian Colonies.

CAPE OF GOOD HOPE.

The excitement incidental to diamond-fields and other speculative undertakings no doubt tends to the neglect of purely agricultural and horticultural pursuits, and hence it is not a matter of surprise that the capabilities of the Cape of Good Hope in the matter of fruit should be practically an unworked field of commercial enterprise. The export of dried fruits in some years (1885) has reached a value of £11,000, while in other years (1881) it has fallen so low as £761. It is possible that the recent action of the Legislature, in granting a rebate of duty on sugar used wholesale for the manufacture of jams and preserves, may encourage the establishment of factories. The chief fruits preserved are Cape gooseberry, orange, lime, guava, quince, melon, citron, peach, fig, apricot; and Cape of Good Hope preserves are claimed "to surpass any of the English manufactured fruits." Raisins are made from the Haanepot grape, and a small thin-skinned raisin (currants) from what is known as the currant grape. Artificial drying is recommended for both. Fresh grapes have been successfully shipped to Europe, and as they arrive in the early summer when the price of grapes is highest, there is an undisputed market ready, which the viticulturists of the Cape should duly utilize.

Returning to raisins, it is stated that about 200,000 pounds are produced annually, and if sufficient demand arose fully 500,000 pounds "could easily be produced." The fine samples of raisins exhibited in the Cape of Good Hope Court were of excellent quality. But it would appear that not much has been done yet, as compared with the possibilities of the Colony, to supply European markets. Strenuous efforts are being made, and this Exhibition will doubtless enable the producer of Cape raisins to have a larger trial than he has yet received. There are two kinds of raisins produced—stalk raisins for dessert, which are in demand all the year round, except during the short English fruit season; and loose raisins, which are used chiefly during the three winter months when British house-wives are concerned with plum-puddings.

The Cape of Good Hope, in the production of fresh fruit, especially grapes; in the manufacture on a large scale of preserves, jams, and jellies; and in the preparation of raisins and currants, has an extensive field for developing its fruit industries; and as it can place these in the European markets just at a time when they realise the highest prices, its future in this respect cannot be over-estimated.

NATAL.

This Colony contributed oranges in a fresh state to the Colonial Market which, although small, were of bright colour and fine flavour. The dried and preserved fruits in the Natal Court were throughout of a high class of excellence, and proved one of the most interesting in the Exhibition. Messrs. Jameson and Co., Durban, had a large assortment of preserves consisting of Granadilla (West Indian Sweet-cup) *Passiflora edulis*, loquat, quince, guava, peach, papaw, Cape gooseberry, pine-apple, green limes, and the native Amatungulu. Messrs. Baker and Cautherly, Estcourt, had an attractive exhibit of dried fruits, such as apple, pear, quince, yellow peach, and pine-apple. Mr. Thos. Proctor, Pietermaritzburg, illustrated the fruits of Natal by a collection consisting of seventeen large jars of whole fruits in syrup, which deserved special notice. Among these the most striking and interesting were the Amatungulu or Natal plum (*Carissa grandiflora*), of the natural order Apocynaceæ, which ripens with a white milky juice and has a pleasant refreshing flavour; and the Cape gooseberry (*Physalis pubescens*), of the natural order Solanaceæ. It is somewhat remarkable that both these wholesome and refreshing fruits belong to natural orders which usually produce fruits of a more or less poisonous character. The yellow peach of Natal, or St. Helena peach, as it is sometimes called, is a cling-stone peach, which is so abundant in the Colony that it is often used for feeding pigs; and the ground under the trees of deserted Dutch orchards is almost paved with the stones of the fallen fruit. Sun-dried peaches and apples were exhibited by Mr. William Judson, Ladysmith, which might be supplied to the English market in large quantities and at cheap rates.

It is evident from the above brief review of the capabilities of Natal as regards tropical and sub-tropical fruits, that after supplying all local requirements, as well as those of the neighbouring Cape Colony, it should be able to supply European markets in large quantities. In some of the preserves there was evidence of the sugar used being of too low a quality,

giving a slight molassed flavour; while again the syrup in which whole fruits were preserved was too thick, and of a cloying sweetness. If these defects were removed there is no dout that Natal preserves would possess special advantages, and their general use in European countries would be assured.

CEYLON.

Among the Ceylon Exhibits no fresh fruits were shown, neither were there any specimens in spirits or solutions, to illustrate the productions of the island in this particular section. Owing probably to the general dampness of the climate, the best fruits of Ceylon are certainly wanting in flavour as compared with the choice fruits of the West Indies; but having said this much it is to be noted that Ceylon is by no means so deficient as India of fruits either in quality or quantity. If the coconut were used and regarded simply as a fruit, Ceylon would rank as the largest fruit-growing Colony in the Empire. The luscious mangosteen has been successfully grown in special localities for some years; the durian is also grown but very sparingly; pine-apples attain large size and do well, though they are somewhat insipid as compared with the pine-apples of the Bahamas, Pernambuco, and Jamaica. Oranges are fairly plentiful and easily grown, although, on account either of the special variety established in the island or of circumstances of climate, probably the former, they remain green even when ripe, and are wanting in the rich colour, juice, and aroma of the fruits as generally seen in England. Limes and citrons are cultivated to a small extent. The Pumelow or Shaddock is a choice fruit in the best varieties, and is capable, in as much it requires damp moist heat, of being grown more largely in Ceylon than any other of the Citron fruits. Excellent preserve is capable of being made from the Pumelow, which in the West Indies is highly esteemed. It also makes "candied peel" scarcely inferior to citron.

Mangoes are plentiful, and are generally of the Bombay sorts. The Rambutan (*Nephelium lappaceum*) allied to the Litchi is a refreshing fruit, which, if produced in large quantities, might be dried and exported. The Mora (*N. Longanum*) is sometimes produced in large quantities, but is seldom seen on the tables of Europeans *. What are known as Bananas in the West Indies are called in Ceylon Plantains. They are evidently identical, and are used in exactly the same manner, viz., as a dessert fruit. In the rich alluvial soil of the plains of Ceylon "plantains" might be grown on a large scale, but unfortunately there is no external market for the fruit, and only enough is grown to meet local demands or supply mail steamers at Colombo.

Having thus indicated very briefly the general character of the fruits of Ceylon as known in the island, it only remains to refer to the preserves, fruits and pickles shown in the Ceylon Court, which were exhibited by the Government. These consisted of pickles made of lemon, papaw, coconut, cabbage and nutmeg, and of preserves made from mango, arecanut, Lovi-lovi *(Flacourtia inermis)*, Kamaranga (*Averrhoa carambola*), and nutmeg. In the excellent Official Handbook and Catalogue of the Ceylon Court, there is given, what is wanting in every other Court in the Exhibition, exact particulars as regards the origin and mode of preparation of the exhibits. As likely to be of general interest to persons residing in the tropics, the following description under preserves and pickles is given in full:—

Grape Jam is made from Jaffna-grown grapes boiled in syrup, the seeds being removed during the boiling; two pounds of grapes to one pound of sugar in a pint of pure water in the proportion in which it is prepared. The jam keeps a long time if preserved in air-tight bottles. The average price of a pound of grapes is thirty cents.

* The jungles towards the north-central portions of the island are full of the trees which give names, such as Mora-gala, to many places.—ED.

Mango Jam is prepared by boiling the mango in syrup after removing the skins and stones, and the sour juice squeezed out by the use of forks, and soaking in fresh water; two pounds of mango to one pound of sugar is the proportion in which it is prepared. The average price of a pound of mango is three cents.

Bilimbi Jam.—This jam is made by removing nearly three-fourths of the juice of the fruits of *Averrhoa Bilimbi*, by the use of forks, and soaking in fresh water, squeezing the fruit, and boiling them in syrup. The cost of 100 fruits is about three cents, and the proportion of sugar used is similar to that used with mangoes.

Nelli Jam.—This jam is prepared by soaking the fruit of *Phyllanthus Emblica* in pure water, and boiling the juice in syrup; the proportion of sugar and fruit is the same as that with mangoes. The cost of 100 fruits is about six cents.

Citron and Lime Pickles.—Citrons and limes in both the Northern and Western Provinces are first cut into four parts, with one end kept to hold them together, and salt inserted, and dried for some time. The Brahmins use curry stuffs and the sediment of the lime-juice for preserving it, whilst others use vinegar.

Mango Pickle.—Well-matured, but not ripe mangoes are cut lengthwise in halves, and the kernel of the seed is removed. The pieces being washed and salted for a day or two, the space occupied by the kernel is filled up with a preparation of well-chopped papaw fruit, garlic, onion, chilli mixed with ground mustard and vinegar, and the two halves are brought together, and tied up and put into a large-mouthed bottle or jar filled with vinegar; after remaining so for a week the pickle is fit for use.

MAURITIUS.

With the exception of one or two samples of preserves, Mauritius made no display of its fruits, although it is well-known that the island in lat. 19° S. produces most tropical fruits, such as pine-apples, bananas, litchis, and guavas, in considerable quantities. The natural outlet for fresh fruit from the Mauritius, especially in the winter months, is evidently the Cape, and possibly South Australia, and with suitable and regular shipping facilities, a business in fruit should assume some importance. The island produces first-class sugars suitable for preserving and canning fruits, and the depression in sugar should lead to attention being directed to the cultivation of fruit and to its export in quantities to any market offering remunerative results. Oranges appear to be comparatively scarce, but pine-apples and bananas alone should prove of sufficient importance to be placed among the exports of this fertile island.

The peach grows and bears good crops in most parts, and its fruit is an article in local commerce. The demand for the Alligator or Avocado pear is greater than the supply. Strange to say, the bread-fruit is not, according to Mr. Horne, so highly esteemed in Mauritius as the Indian jâk fruit. The strawberry grows well in the high lands, and the "Colonial" raspberry (*Rubus rosæfolius*) yields an abundance of fruit in a wild state. The Cythère (*Spondias dulcis*) is one of the choice fruits of Mauritius, and its cultivation deserves attention. Jams and jellies are made, for local consumption, from the cherry-tomato, which is evidently suited to the climate. The impression which a careful consideration of the circumstances of Mauritius, as regards fruit, leaves on the mind is, that its capabilities in this respect are not fully realised, and the people lose large sums of money which might do something to alleviate its present depressed condition.

STRAITS SETTLEMENTS.

In the notes on Perak it is stated that tropical fruits are supposed by the great majority of English people to be far finer, richer and better in every way than those grown in colder climates; but

according to the writer of the notes, such is not really the case. Malayan fruits are admitted to exceed English fruits in size and often in strength of flavour and odour, but it is claimed that the English strawberry, pear or peach (or a green-house pine) is quite unequalled by anything grown in tropical countries. This after all is purely a matter of opinion; and the fact cited that Europeans in the tropics ignore local fruits and fall back on tinned and bottled English fruits, is merely another way of saying that Europeans have certain set habits and tastes, and a love of "home" things, which they will not or cannot give up. It must be remembered, however, that tropical fruits have not, as a rule, received that careful and scientific culture which has been expended on European fruits: in fact that they are practically wild fruits, more or less indigenous to the country, and suited to be used only under the special circumstances in which they are found. A pine-apple grown in a tropical country and costing only a few pence may not be equal in size and flavour to a pine-apple grown in an English hot-house, and costing twice as many shillings. But what English fruit is so refreshing and so suitable for the composition of a really well-cooked dish in the tropics as the lime? *

Opinions may differ as regards the special merits of the mangosteen, "fig" banana, mango, cherimoya, freshly-gathered date, the litchi, a really good orange, or a dozen other tropical fruits that may be named; but if we take each one on its merits, and use it according to the circumstances and habits of the country in which it is found, there are few, if any, English fruits that are so well adapted to refresh and revive flagging physical energies, as those we meet in the tropics.

Having said this much by way of defence of tropical fruits, I turned to the varied and interesting collections shown in the Court of the Straits Settlements.

The chief place is taken by the pine-apples of Singapore, which, preserved whole in syrup, have entered into commerce, and are now regularly supplied by London stores. The pine-apple is canned and shipped in a similar manner from the Bahamas, Fiji, and Natal; but owing probably to the greater enterprise shown by Singapore firms such as Bastiani, Tye Seng Bee, and Nethersole & Co., each of whom have London agents, the Singapore pine-apple has established itself as one of the best in the market. There were stalls with a tasting-bar maintained at the Exhibition, which no doubt greatly contributed to make the Singapore fruit widely known. The Singapore Preserving Company, the Chasseriau Land Planting Company, C. Favre & Co., J. Graham, and others, exhibited an excellent series of tropical fruits, which attracted considerable attention. Many of these fruits, unfortunately, had only the native names both on samples and in the Catalogue, and hence were difficult to recognise. But the mangosteen, durian, mango, papaw, guava, pumelow, rambutan, banana, lemon and bread-fruit were easily recognised.

BRITISH GUIANA.

Owing to the enterprise of Messrs. Scruton & Sons in fitting up one of their steamers with a cool-chamber, fresh tropical fruits from British Guiana were among the most interesting features of the Colonial Market. It is now clearly demonstrated that by careful and judicious treatment and storage in a cool-chamber, numerous tropical fruits from the West Indies can be brought to England in a perfectly sound condition. Bananas arrived from British Guiana on several occasions which were sold for the first time in the London market, while such perishable fruits as papaw, sapodilla or naseberry, bread-fruit, mango, and the Avocado pear were received from the West Indies in excellent condition, and utilized as dessert fruit at English dinner tables. As an experiment the enterprise has been thoroughly successful. There remain, however, many details to be arranged before a regular trade in tropical fruits is established, but of ultimate success there would appear to be little doubt.

In the rich alluvial soils of British Guiana, all tropical fruits are capable of being cultivated: and the dried and preserved articles shown in the British Guiana Court, no less than the models of fruits produced in the Colony, would indicate that a large and undeveloped field of industry is connected with them.

JAMAICA.

The fruit industry at Jamaica is one of the most important of any tropical Colony. The value of fruit exported from this island, chiefly to the United States, is nearly £200,000 annually. The principal fruit so exported is the banana, which, in 1885, reached a total value of £129,917. Next comes the orange, of the value, in 1885, of £31,660. The development of the fruit trade in Jamaica has been very rapid, and, as in British Honduras, was chiefly due to the establishment of subsidized steamer communication, whereby regular and rapid sailings were secured and loss of fruit in transit reduced as much as possible. In 1867 the value of the fruit exported from Jamaica was only £728. Two years later an agency was established at Port Antonio (which was then a decaying port) for certain fruit houses in the United States, and seven schooners were loaded with bananas. In the following year coconuts and oranges were added, and since then the trade has gone on progressively, and has extended itself throughout the island. Several steamers are now engaged in this profitable business, the greater part of the fruit being conveyed to New York, Philadelphia, Baltimore and New Orleans.

The Jamaica fruit consisting chiefly, as noted above, of bananas and oranges, is packed in the hold of ordinary steamers, with no special appliances or cold storage. Every effort is made to give the fruit as much air as possible; but there is much room yet for improvement both in the selection and packing of the fruit, as well as in the arrangements for carefully stowing it on board ship.

Jamaica produces numerous choice and luscious fruits, which are, however, too delicate to bear a long sea-voyage, and hence are comparatively unknown in Northern latitudes. Amongst the samples of fruits preserved in spirit, and shown at the Jamaica Court of the Colonial and Indian Exhibition, there were Cherimoya (*Anona cherimoyer*), Sweet Sop (*Anona squamosa*), Alligator Pear (*Persea gratissima*), Ginep (*Melicocca bijuga*), Tamarind (*Tamarindus officinalis*), Jew Plum (*Spondias dulcis*), Mango (*Mangifera indica*), Papaw (*Carica papaya*), Guava (*Psidium guaiava*), Chinese Guava (*Psidium cattleyanum*), Blimbing (*Averrhoa bilimbi*), Coco Plum (*Chrysobalanus icaco*), Akee (*Blighia sapida*), Sweet Cup (*Passiflora edulis*), Pomegranate (*Punica granatum*), Naseberry or Sapodilla Plum (*Achras sapota*), Tree Tomato (*Cyphomandra betacea*).

This, although a fairly representative list of West Indian fruits well known and largely produced at various elevations in Jamaica, is by no means an exhaustive one. With cool storage and refrigerating chambers fitted up in rapid-going steamers, a large number of other fruits might be utilized and exported. Of fruits not mentioned above, there are the Sour Sop (*Anona muricata*), Custard or Sugar-apple (*Anona reticulata*), Granadilla (*Passiflora quadrangularis*), Pomme d'Or or Water Lemon (*Passiflora laurifolia*), Calabash Sweet-cup (*Passiflora maliformis*), Caramba (*Averrhoa carambola*), Bread-fruit (*Artocarpus incisa*), Anchovy Pear (*Grias cauliflora*), Locuat (*Eriobotrya japonica*), Rose-apple (*Jambosa vulgaris*), Mammee apple (*Mammea Americana*).

The particular variety of banana exported from Jamaica is the large yellow kind, sometimes known as the Martinique banana, but now generally known in the United States as the Jamaica banana, to distinguish it from the large red banana formerly ex-

* Lime juice is refreshing and is used in Ceylon cookery to give tenderness to newly killed fowls. Lime pickle is also nice, but we do not understand what is meant by the fruit entering into the composition of a well-cooked dish.—ED.

ported from Cuba. The Cuba banana has now been almost entirely replaced by the brighter and more attractive as well as the more luscious fruit from Jamaica. The banana generally seen in England is the Chinese banana (*Musa Cavendishii*), which has a smaller fruit than the variety of *Musa sapientum* above described. The choice and small bananas known in the West Indies as Fig bananas are seldom exported: the attention of traders being evidently directed to the larger and more bulky, though less delicate varieties, which make a greater show in the market.

The oranges exported from Jamaica are a sweet well-flavoured kind, with a fairly thick rind and a bright colour when ripe. They approach very nearly to the once noted St. Michael's oranges, from which they were, no doubt, once derived. The trees yielding the bulk of the present oranges in Jamaica are self-sown seedlings growing in cattle pastures—although several well-kept plantations in the neighbourhood of railways and shipping ports are springing up.

Limes are abundantly produced, and while some (809 barrels) are exported in the green state, or pickled in brine (to suit the special taste of the people in the States), the larger quantity is utilized in the preparation of lime-juice, which is exported to be converted into citric acid to the extent of 55,000 gals. annually. Sicily lemons and the true citron are being cultivated on a small scale, while a choice pink-fleshed pumelow is also planted.

Pine-apples are exported in the green state only. The choicer sorts, like the Ripley pine, which have been known for the last hundred years as the most acceptable of Jamaica fruits, are seldom able to bear the rough treatment at present accorded to them. The Madeira and Canary pines, which reach England in such excellent order, are packed in light boxes with a separate compartment for each fruit. The Jamaica fruit, on the other hand, is badly selected in the first place; and is generally packed in bulk two or three dozen together, in an ordinary flour barrel.

The mango is completely naturalized in the island, and thousands of tons of this fruit are produced, of which probably only one-fourth is at present utilized. The crop comes in from May to September, when, unfortunately, there is little demand for tropical fruits in the northern markets. The best varieties might be canned or preserved: and, in my Report on the Botanical Gardens of Jamaica for the year 1884, p. 45, I have there suggested that the commoner sorts might be utilized in the production of a useful spirit, or for the manufacture of glucose.

BAHAMAS.

These islands, from their proximity to the United States, and the rapid means of communication, were the first to establish an export trade in tropical fruit, which, in the one item of pine-apples is possibly the largest of any in the world. The particulars of fruit exported in 1885 are as follows:—

	Quantity.	Value.
Pine-apples	455,965 doz.	... £50,847
Shaddocks	34,000 No.	... 64
Avocado Pears ...	2,950 ,,	... 8
Bananas	15,358 ,,	... 618
Coconuts	26,170 ,,	... 193
Oranges	1,900,000 ,,	... 1,753
Sapodillas	102,550 ,,	... 26
	Total value ...	53,509

The tinned pine-apples of the Bahamas, as also the bulk of the fresh fruit, form a large trade; but, under a more careful and enterprising system of cultivation, it is possible to extend and improve this industry, which in many respects is the best suited of any to the circumstances of these islands. The pines generally cultivated are the Cuban and Scarlet varieties, which evidently thrive well in hot shallow soils. The Bahamas Factory exhibited a series of preserved fruits, as also pine-apples preserved whole in a similar manner to the Singapore fruit. The guava jelley from the Bahamas was excellent. Models of tropical fruits were well shown. The general character of Bahamas plants was illustrated by water-colour drawings made by Mrs. Blake, wife of the Governor, and among these were accurate and life-like delineations of many West Indian fruits.

BRITISH HONDURAS.

Since British Honduras was connected with New Orleans, the great commercial port of the Southern United States, by a regular mail service, the fruit industry has assumed some importance. The exports for the year 1884 consisted of: bananas, 88,538 bunches, of the value of £7869; coconuts, to the United Kingdom, 796,172, of the value of £2688, and to the United States, 757,977, of the value of £2,833; limes, 6½ barrels, of the value of £3; mangoes, 47 barrels, of the value of £24; oranges, 12 barrels, of the value of £6; Avocado pears, 6 barrels, of the value of £4; pine-apples, 8,496 barrels, of the value of £1,017; and tamarinds, 6 barrels, of the value of £3. The total value of fruit exported in 1884 was £14,464. The coconuts of Central America and British Honduras are of large size, very heavy, and generally command the highest prices. The whole seaboard of British Honduras should in time be covered, as in Ceylon, by extensive groves of this valuable palm. Bananas are being extended in the alluvial soils of the Southern districts, and find a ready market. Oranges, limes and lemons are hardly yet established, although in the drier and more rocky portions of the colony they would do well. Pine-apples are grown in light loamy soils; and although the exports at present are small, they are gradually increasing.

There is in this Colony an unlimited field for fruit-growing; but it is right to mention that only those who have had previous experience in the tropics and possess some capital are suitable for pioneering work in a comparatively unopened country. British Honduras was too remote to exhibit fresh fruit at the Exhibition; the dry coconuts were, however, a conspicuous feature in the decorations. The preserved fruits consisted of preserved citron, preserved papaw and a wild fruit known as "Craboo," preserved in rum, very much resembling cherries. Tamarinds preserved in sugar were shown by two exhibitors.

TRINIDAD.

This island so far exports only coconuts under the category of fruits, but it is capable of growing and exporting immense quantities of all kinds of tropical fruits if a suitable market were available. In the Trinidad Court were numerous samples of preserved fruits of an attractive character.

GRENADA.

The fruits of Grenada were excellently shown in large glass jars by Colonel Duncan, to whose enterprise the island owes much in the introduction of new objects of culture. Amongst the fruits exhibited were granadilla, pine-apple, nutmeg, tamarind, shaddock, custard apple, *pois doux*, lime, sapodilla, mammee sopote, sour sop, mammee apple, papaw, bread-fruit, forbidden fruit, jack fruit. Preserved oranges, nutmeg jelly, guava jelly and shaddock peel were also shown. The exports of fruit from Grenada at present consist of coconuts of the value of £49, pine-apples, &c., £52, and plantains, £285.

TOBAGO.

This island made an excellent show of preserved fruits and jellies too numerous to mention. A canning establishment would appear to have a good field for starting operations here: and as land is cheap and labour abundant, "capital and well-directed energy" are the only requisites to success. In quality and general representative character the preserved fruits of Tobago, consisting of above 200 exhibits, were the most complete of any in the tropical section.

ST. LUCIA.

The Agricultural Society of St. Lucia exhibited the fruits of this island in a preserved state, consisting of about twenty specimens, such as shaddock, orange,

tamarind, pine-apple, lime, mango, papaw, pinguin, granadilla, tomato, guava. A small trade in fruit exists between St. Lucia and Barbados of the value of £400, but this fertile island is capable of great development in almost every department of tropical culture.

DOMINICA.

This island resembles Jamaica in its physical conformation as also in its productions. Limes are cultivated for the sake of the expressed juice: but oranges, bananas, coconuts, and indeed all choice tropical fruits are capable of being produced, and an industry in fruit, which at present is of the value of £3,444, is gradually increasing.

ANTIGUA.

The pine-apples of Antigua in a fresh state were on sale at the Colonial market throughout the Exhibition. They are smaller and not so delicate in flavour as the fruits which come to England from the Azores, but there is a large demand for pine-apples in the early summer months which Antigua is well able to supply.

MONTSERRAT.

This small island has become the head-quarters of the lime industry in the West Indies, and there were exported in 1884:—Lime- juice of the value of £10,300, green limes of the value of £325, tamarinds of the value of £254, and general fruit of the value of £93.

BARBADOS.

As a large sugar-producing Colony, Barbados draws supplies in fruit from the neighbouring islands: but it exports preserved tamarinds to the value of £1,305.

CYPRUS.

This island is not only noted for its abundance of oranges and lemons, melons, apricots, cherries, almonds, and fine pomegranates, but also for grapes of exceptional good quality. Such being the case, it is a matter of regret that a large collection of the characteristic fruits of the Eastern Mediterranean region was not shown. The exhibits consisted only of hazel-nuts, almonds, walnuts, caroubs, and two jars of raisins. The walnuts were large and bright looking; the raisins were of exceptional size and quality. Figs are most abundant in Cyprus, but it is said that they are inferior to those of Smyrna.

The chief trade in fresh fruit, after satisfying local demands, is with Egypt. Pomegranates appear to be the chief article of export, and these are in great demand at Port Said, 250 miles distant, and Alexandria, 300 miles distant. Although not a fruit in the general acceptance of the term, the Caroub, or Algaroba bean, the produce of a large tree, *Ceratonia siliqua*, is an important article of export from Cyprus. This bean contains much saccharine matter, and is very nutritious. Although sometimes eaten, its chief use is in the manufacture of food for cattle. A "black honey made from Caroubs" was not honey in the general acceptance of the term, but evidently a pulpy saccharine matter extracted from the Caroub beans.

Royal Gardens, Kew, 22nd April, 1887.

REPORTS ON THE COLONIAL SECTIONS OF THE COLONIAL AND INDIAN EXHIBITION, 1886.

Issued under the Supervision of the Council of the Society of Arts, and edited by H. Trueman Wood, M.A., Secretary to the Society. (London: William Clowes & Sons, 1887.)

These long-looked-for reports, which form a volume of some 500 pages, are, we presume, the final official records of last year's Exhibition. The contents of the Exhibition have been treated of in twenty-three separate reports, each by a different writer, the names of some having been scarcely heard of before. Though the book will be useful as a record, in one handy volume, of the raw products of the British colonies, it is nevertheless disappointing, consisting as it does for a great part of extracts from the catalogues of each colony. After the issue of such descriptive catalogues and handbooks as most of the colonies prepared during the period of the Exhibition, the necessity for a repetition of much of the matter, though stamped with the names of certain gentlemen whom the Prince of Wales was "pleased to nominate," is not apparent. What would have been a useful permanent record of the show would have been the writer's own opinions upon the value or utility of the products based upon his own experience or upon that of experts who might have been associated with him, or upon practical experiments or examination, such, for instance, as that of Mr. Cross on "Miscellaneous Fibres," or the second report on "Timbers," by Mr. Allen Ransome.

Several of the reports are remarkably weak, notably those on "Drugs, Chemical and Pharmaceutical Products," "Gums, Resins, and Analogous Substances." Here is a paragraph from the former report:—"Myrica cordifolia yields an excellent wax, which is used for candles;" this occurs on p. 255, while twenty pages further on, in the report on oils and fats, and under the head of "Myrtle Wax," this substance is stated to be "yielded by several species of Myrica (Cerifera, serrata, quercifolia, &c.). The reputed source of this product is said to be North America, but in this instance the exhibitors were Messrs. Hall & Zinn, of the Cape of Good Hope." Why Myrica wax should be included in a report on drugs it is difficult to understand, and the reporter on oils and fats seems to be unaware that these plants are found both in America and South Africa. A better joke, however, is to follow. Here is an extract from the same report on oils and fats, p. 265:—"A fat closely allied to Palm oil is Shea butter, also known as Galam or Bambouk butter, the produce of several varieties of Palms in the Niger districts, chiefly the Bassia Parkii." This is evidently a new discovery, the classifying of a Sapotaceous plant in the order Palmaceæ.

Leaving "oils and fats," with its other blunders, and the misspelling of botanical names, we find a goods,start on the first page of the report on "Gums, resin &c.," for we are there told, under the head of New South Wales, that "the hard brittle resin of the Xanthorrhœa hastilis, a *Tree Fern* of the colony, is known ordinarily as grass-tree gum or green maccroides." It is needless to say that the italics are our own. Referring to the Xanthorrhœa resins further on, however, under Western Australia, the writer alludes to the interesting nature of these resins, and hopes that they may be more thoroughly investigated.

Timbers are treated of in two separate reports, but as they are arranged alphabetically, each under its own country, it follows that the same wood, where the tree is widely distributed, is described in each colony. In the consideration of Queensland woods the following paragraph occurs:—"Cedrela australis, F. Muell., the Red Cedar or Toon tree, native name Mamin and Woota. A very large tree, yielding a beautifully grained, red-coloured wood, easy to work, and said to be very durable. This will be found a valuable wood for cabinet purposes, and would be useful in many ways. It is in general use in the colony."

This individual paragraph would have been much more valuable had the information been attached to it that the tree, known now as the Cedrela Toona of Roxburgh is the same species that yields the Toon wood of India, where the tree is found, as well as in Burmah. But why the same woods should be treated of separately in the two timber reports it is difficult to understand. This is what the writer of report No. 2 says:—"Red Cedar (Cedrela Toona). This resembles the wood last-mentioned (Dysoxylon Fraserianum), but it is somewhat inferior. It is softer and lighter, and considerably coarser in grain. It planes and works very well, however, and would do for common cabinet-work. It is already known in the English market as Moulmein Cedar."

If the two reporters on timber had worked together and combined their matter, such information would have been more easily available. We are bound, however, to say that the second report, being the result of actual practical experiments, will be found very useful.—*Gardeners' Chronicle.*

THE CAMPHOR TRADE IN FORMOSA, which had almost become extinct, has recently been taken under the protection of the Chinese authorities as a government monopoly. Mr. Consul Giles states that for some years the collection has been so scattered that it has been impossible to obtain camphor in Formosa in remunerative quantities; the Government has therefore now undertaken to establish fixed depôts for receiving the scattered supplies, which will be paid for at a certain rate and resold at a fair profit for export.—*Pharmaceutical Journal.*

COCA LEAVES.—With respect to coca leaves Professor Schrenk remarks that the lines on the under surface of the leaf are formed by a narrow band of tissue consisting of several rows of elongated oblong cells, which contrast very much with the polygonal cells of the epidermis bordering these lines. A cross section through one of these lines shows that it is a ridge consisting of a subepidermal strand of collenchymatous cells. There is no connection, as has been stated, between the lines and the veins of the leaf. He believes that the lines serve as an elastic stiffening of the blade of the leaf.—*Pharmaceutical Journal.*

WONDERFUL PLANTS.—I recently came across the mention of two of these in an Arabic book (with an English version of the text as well as the original), printed in 1801, in which the following occurs:—1. A singular work by Ebu Tophail says:—Our pious forefathers (may God reward them !) relate that there is an island among the islands of India which is under the equinoctial line; and this is an island in which there are born men without father and mother, and in which a tree bears women as fruit! 2. The fourth magician made a tree having branches of iron with hooks; and when a bad man approached it, these hooks seized him, and would not dismiss him till he confessed his crime.—I give you the English translation; the original is at your service for perusal.—N. E. D.—*Gardeners' Chronicle.*

MARRAM GRASS.—In our issue of last week allusion was made to what is termed the Marram Grass which our Government Botanist introduced to Australia, and sent seeds to Belfast and elsewhere for use in binding the drift sands of the sea coast. The grass has several synonyms both English and scientific, being popularly known as Morrem, Marrem or Bent Grass, and to scientists as Psamma arenaria (Roemer and Schultes) P. littoralis (Beauvois), Calamagrostis arenaria (Roth), and Arundo arenarius (Linnæus). It is found wild on the coasts of Europe, North Africa and middle North America. It is one of the most important, says Baron von Mueller, of reedy grasses, with long descending roots, for binding moving drift sands, for the consolidation of which, in Europe chiefly, this tall grass and Elymus arenarius are employed. It delights in the worst of drift sands, and for its full development gradual accumulation of fresh sand around it becomes necessary (Wesseley), hence it never gets suffocated. The plant will by gradual upgrowth finally form stems and roots sanded into a depth of fully a 100 feet. It can be also used as a paper material, for tying and for mats, but cattle will not touch it. It collects the sand drifts at the top of the ridges, while the Elymus fastens their sides.—*Leader.*

SUMMER DRINKS FROM HONEY.—There seems to be very little doubt that in the near future honey will be used for many things, as in primitive times, and nothing is more wholesome. The rustic, when he spoke of the clergyman and his bees, said "he have edecated them," meaning he had great power over them, so I suppose the public taste must be a little more "educated" before it can appreciate the various articles made from honey. I have before me a very exhaustive list emanating from the honey depôt at Reading, which I believe owes its existence to the Rev. V. H. Moyle. Commencing with the healing art not only were there medicines for the human race, but honey drinks for horses and calves, dog soap, &c. Then there were drinks innumerable; and, valuable as honey is as an article of food, it is still more so in drinks. It is needless to mention all the drinks sold at the honey depôt. Some people make a specialty of them. I mention these things to cheer the beekeeper, and to show him (or her) that there will no doubt shortly be a revival of business in the honey trade, and a sale for all the honey which can be gathered. While on this subject, I do not consider it a good thing to mix honey and lime-juice; at any rate, it would not suit some stomachs. The musty taste of most kinds of lime-juice mixed with honey does not seem the right thing. It may not be generally known, however, that there is a lime-juice which is not musty at all, the name of the manufacturer of which, as well as that of the fabricator of the varied honey drinks mentioned above, I would supply to any person desirous of having either. He has various kinds, which are not only very pleasant to drink, mixed with aërated or common water, but also medicinal, antiscorbutic, &c.—WALTER CHITTY, Pewsey, Wilts.—*Gardeners' Chronicle.*

RED-SPIDER ON VINES.—Mr. Douglas inquires if any correspondent can suggest a safe plan to destroy red-spider. In my opinion the sponging of the leaves with soft-soap and water is the most effectual and the safest way. The sponging should be carefully and thoroughly done, sponging the upper and lower surfaces of every Vine leaf in the vinery. All Beans and Strawberry plants should be removed from the vineries when such are grown there, as the dry atmosphere maintained whilst the Vines are flowering is almost certain to lead to the spread of spider from these to the Vines. The sponging process is somewhat tedious, but the result amply repays the labour thereby incurred. With regard to the practice of sulphuring the hot-water pipes Mr. Douglas says:—"It should be done when the temperature has been raised in the afternoon to 90°, and that the house ought to be shut up with this temperature, and that the pipes must be sufficiently heated to cause a slight mist in the house from the fumes." Is not afternoon a misprint for evening? I notice this because I fear that disastrous results would follow the action of the sun on the leaves and Grapes while in such an atmospheric temperature as that indicated above. Sulphur should be supplied to the hot-water pipes in the evening only. No moisture should be distributed in the house that afternoon. The fire should be started early, so as to get the pipes well heated by the time the sun had gone completely off the houses leaving air on till then, when the flowers of sulphur, at the thickness of paint, should be put on the heated pipes with a brush, keeping the temperature at between 85° and 90° for about three hours, at which time a little top air should be given, and the fire banked up. The house should be ventilated more freely than usual for two or three days afterwards. However I have a great objection to the red-spider "remedy" of painting the highly-heated hot-water pipes with flowers of sulphur, inasmuch as the fumes arising therefrom, in my opinion, destroys the freshness of both leaves and Grapes, and also leaves a musty, ungenial smell in the house for several weeks afterwards.—H. W. WARD.

——Your correspondent, Mr. Douglas, asks for remedies found serviceable in preventing the ravages of red-spider infesting Vines. I have found passing a soft dusting brush on the under side of the leaves with a little flower of sulphur and water to be efficacious—syringing the under sides of the leaves with clean, cold, soft water, taking care not to wet the Grapes, which can be easily done by a practised person using a syringe with a nozzle. The operation should be done about 6 o'clock in the evening, when it will act as a cold bath to the red-spider for the remainder of the night—a treatment which they dislike. When red-spider infest Vines badly it is the result of a dry ungenial atmosphere in the vinery. —R. MAHER, Tattendon Court.—*Gardeners' Chronicle.*

NOTES ON TEAS.

(*Home & Colonial Mail*, May 20th.)

Commending on the prospects of the Canadian tea trade this season, the Montreal *Trade Bulletin* observes:—"It was expected that the market for new-crop Japan teas would open today (April 29), and consequently news was anxiously looked for to know the result of the first sales. Large orders have gone out from Canada, against which credits have already been placed at Yokohama; but it will depend a great deal upon prices as to whether they will be filled or not. If the market opens at reasonable rates a large business will be done; but if prices rule high, very few Montreal orders will be executed. A leading feature in the trade, and one to which we have recently referred, is the increasing demand for black teas. These goods have grown in such favour with Canadian Consumers that it is estimated that more than double the quantity is now sold than was the case three years ago."

The *Grocer* of last Saturday (14th May) takes up the theme of some of its correspondents, who lament that the tea trade is degenerating. The *Grocer* thinks that the decay of the taste for fine teas has had much to do with this, and it therefore enlarges unnecessarily upon the roughness of Indian and Ceylon teas, as compared with those from China. It says:—"With this indifference to and neglect of, the choicer qualities, side by side has been the increasing competition of Indian teas, the bulk of which have abounded in strength rather than in delicacy of flavour; and as the populace have fancied that teas, because they are strong must be the best, the greater run of the demand upon these has left China and other fine teas more and more in the background, chiefly on account of the greater number of 'brewings' which could be obtained from one pound of Assam growth as compared with a similar quantity of China tea at the same figure; or, as Mr. Goschen tersely explained the matter in his recent Budget speech —'Indian teas are stronger than the Chinese teas, and therefore go somewhat further in making the same number of cups.' This, we believe, is the real secret of the whole question, 'Why should the great socialising beverage be made the target for catch-price adventurers?' Indian and Ceylon teas of late years have been more constantly paraded before the eyes of the public than China solely because of their roughness and 'point,' and while nothing virtually has been done to keep the finer grades of China teas well to the front in general estimation, every device that could be hit upon has been zealously tried to 'educate' the palates of consumers in favour of the rougher kinds of tea, and stimulate their use in this country as much as possible."

The *Grocer* goes on to admit that after all, the public have some choice in the matter. It continues:—"It has also happened that, at the same time the 'palates' of the millions of tea-drinkers have been trained and accustomed to prefer teas giving strength and colour, their pockets have been appealed to in a practical way, by proving that a much stronger quality of Indian tea at a lower price can be had than is always to be found in China descriptions for more money; and with thousands of consumers in all ranks of the population, the love of economy when it saves the 'pocket' is as powerful an element in calculating the object of their choice as the gratification of the palate. The people, after all that may be said and done, are the final judges of what tea really suits them, and the more they are dictated to as to the qualities which they should choose, the less likely are they to be free users of the sorts recommended."

It concludes:—"Individual tastes, everyone is aware, differ very much, and we do not think it advisable, even if it were possible, to lay down a hard and fast rule, and declare that one description of tea is more desirable than another, beyond the broad fact that good tea is always preferable to bad. When Indian tea first came to be noticed it was because it had an entirely distinctive quality, such as was rarely met with in China growths, and it supplied a want which had long been felt for the peculiar raspiness which many old-fashioned tea-drinkers liked in the cup, and before then could only be furnished by an admixture of so-called "green" tea of Chinese manufacture—a class of tea that is going out of consumption more and more every year. It may be said that the "Sale of Food and Drugs Act," passed years ago, nearly killed the trade in green teas, as they were supposed to be heavily adulterated with turmeric, plumbago, &c.; and to take their place, as well as to satisfy the ever-expanding requirements of eager buyers, the astringent and highly flavoured teas of India were drawn upon to an unheard-of extent. Popular instinct, more than special education on this point, has helped to make the trade what it is at present, and we see no reason for believing that it will deviate much from the course already marked out by long experience in the customs and habits of the average tea-drinkers. Wishy-washy stuff no one likes, and the greatest consumers of tea are those who buy the roughest kinds. This is how Indian teas have been so rushed after since their wonderful qualities became known." Precisely, Indian and Ceylon teas have materially helped to popularise tea drinking in this country.

DIRECT TEA SHIPMENTS FROM CALCUTTA TO GLASGOW.

As the following paragraph has been going the rounds of the provincial press, we insert it as an evidence of the manner in which Indian tea is rapidly gaining the attention of the trade:—

THE DIRECT IMPORTATION OF TEA TO GLASGOW.—"An attempt is being made by certain tea dealers in Glasgow to break down the monopoly of the Indian tea trade at present held by the London brokers. Several shipments on a small scale have been brought direct to Glasgow, and the experiment has proved that this method is practicable. When it is stated that the freight alone from London to Glasgow is greater than that paid from Calcutta to Glasgow, and that the Glasgow importers can buy on equal terms with London in the Calcutta market, it seems evident that the new enterprise ought to succeed. We understand that the importers are so well satisfied with the results achieved that they are now making arrangements to develop the business, their idea being to give the city a tea market, and to make it independent of London for Indian tea. With this view they are approaching the tea growers in India, and hope to arrange that lots of tea will be sent to Glasgow direct from the garden."

On the face of it there is something attractive in the idea of breaking down monopolies, but in our judgment there is no monopoly in the case whatever. There is now nothing to hinder anyone in London setting up in business as a tea broker; the only trouble is to find clients to operate for, and we have not the slightest doubt but that any buyer of tea in Glasgow or elsewhere who can buy an entire break of any kind of tea, and pay cash before delivery as all the London dealers have to do, will have no difficulty in finding scores of London tea brokers only too willing to operate for him.

It is a well understood fact in Mincing Lane that the qualities of Indian tea suitable for one part of the United Kingdom are not readily saleable in another.

Hence one of the greatest difficulties of a tea blender is to find the quality that suits the peculiar tastes of the district in which it is to be consumed. Some descriptions draw a dark infusion in one town, but are pale and undesirable in another. It will naturally follow, therefore, that an invoice of tea from any particular garden of peculiar or distinctive quality, shipped to a small market, would suffer considerably in value if it did not exactly suit the fancy. Besides, it is not very likely that English buyers would take the trouble to compete in the Glasgow market, whilst in London the whole kingdom competes. Such experiments have been tried in the past, and been found impracticable. It is quite within the recollection of the present generation of Mincing Lane tea brokers, that the import of tea

into Liverpool was once as great as the import into London. Steadily it gravitated to the Metropolis, one or another of the Liverpool dealers removed to London till at present the annual import of tea to Liverpool is of the most trifling quantity. We are always pleased to see new markets opened for Indian tea, but we do not regard this as at all a new market, for the Glasgow buyers buy now in London; and if they buy in future at their own doors it practically amounts to this, that whatever the planters may gain in the provinces they will lose in London. The carriage from London to Glasgow by rail, which is made so much of, is of course equal to a farthing a pound, and we can believe that Glasgow buyers would be prepared to give the extra farthing for such lots as suited their tastes, but one or two breaks of unsuitable quality which might have to be cleared up twopence per lb. under London rates would probably equalise the net results.

BROOK TROUT IN CEYLON.

Early in the present year, Mr. Le Mesurier, of the Ceylon Civil Service, undertook to import the ova of the brook trout, *salmo fario*, into Ceylon, with a view of stocking some of the mountain streams. The rivers of Ceylon seem peculiarly adapted to the requirements of brook trout, on account of their perennial streams, and there is every probability of the experiment proving successful. The ova were imported in two batches of 15,000, and out of one lot only 500 fry were obtained, whilst the other was more fortunate, and produced as many as 7,000 of the young fish. Under the most favourable circumstances a large percentage of the ova of fish fail to hatch, Mr. Le Mesurier may therefore be congratulated upon having secured so many fish under the circumstances. The cost of the importation was £150, half of which sum Mr. Le Mesurier provided himself. The other half was subscribed by Ceylon gentlemen who are interested in the experiment. The ova, which resemble delicate pink peas, were packed with the greatest care, in alternate layers, between moss, and were protected with a covering of muslin which prevented the eggs from escaping or being crushed. They were then placed on zinc trays, which were enclosed in a box. This box was put inside a larger box, and was surrounded by charcoal. Ice was kept constantly on the package, and the temperature was never allowed to rise above 40°. The hatching progress was thus retarded, or suspended, during the journey. As soon as the ova arrived at Nuwara Eliya they were placed in hatching tanks, and immediately the little fish began to appear, all eyes and tail, and none the worse for their travels in the embryo state. When about two months old they were considered capable of beginning life on their own account, and little colonies have been turned down at Nuwara Eliya, and in the surrounding neighbourhood. Two hundred of the little fish were intended for Madras, but Mr. H. S. Thomas has already described the death of the fry on the journey down to Colombo. The failure is much to be regretted, as all experiments in pisciculture take time, trouble, and money.

The last batch of Mr. Le Mesurier's fry was turned down a few day ago in a beautiful stream running through Bopatalawa, commonly called the Bopatanas —a lovely mountain district near Dimbula. The little fish were carried from their nursery in Nuwara Eliya in old kerosene tins, slung on a pole, and borne by two coolies. Every twenty minutes the water was aerated by means of a syringe, a process which the fry enjoyed immensely, if one may judge by the way in which they clustered under the jet of air. Fresh water was not necessary very often, and when it was given, the greatest care was observed in the choice of a stream. Any water showing traces of iron was avoided, and, if possible, a spring was chosen from which drinking water was usually taken. Progress was naturally very slow, and, in spite of an early start the first half of the day only brought the fry as far as Dimbula, a journey of fifteen miles. The afternoon saw the little fish on the Agra patanas, which adjoin the Bopatanas. The hills stretch away in grassy undulations, crowned with jungle, and through the meadow-like patanas a clear stream winds its way now tumbling over rocks and now stretching out into glassy reaches of quiet water. The first place selected for a colony was one of these still spots, a few yards up a tributary of the main stream. The bottom of the creek was well furnished with healthy-looking weeds which, in their capacity for harbouring poochees, gave promise of good feeding ground for the young strangers, and excellent cover and protection in the rush of freshets and floods. As the fry were transferred one by one from their tin to the stream, they showed every sign of taking willingly and happily to their new home. They struck off into the weeds in good style, without a moment's hesitation or misgiving, and disappeared in a minute or so amongst the weeds. About twenty-five were put down here, and the rest were carried higher up towards a gorge. The next place chosen was another tributary stream, that drew its source from the heights of one of Ceylon's loftiest hills, a stream which is probably the actual fountain head of the beautiful Mahaweliganga, the largest river in Ceylon. This spot was selected on account of the low temperature of the water which, coming from such a height and flowing through forest, would probably be especially suitable for fish of a temperate climate. The bottom of the stream was clear and gravelly, and the current of the water slow, so that the fish would have two or three hundred yards of cold still water if they desired it. The third colony was turned off just below the gorge where the river winds through high banks, overgrown with jungle, a cool shady place suggestive of flies and caterpillars. The last two score were started on life's journey in a weedy little stream above the rapids of the gorge.

Brook trout are active fish, and in their native streams they run to about 4 lb. in weight, though in the south of England they sometimes attain 7 lb. or 8 lb. Like most other creatures they have their enemies to contend with, and the little fish will not find themselves exempt from danger in the streams of the Bopatanas. The otter will prove one of the trout's most formidable foes, whilst in the water itself a carnivorous looking fish, something like the stone loach of our English streams, will probably be anything but neighbourly in its conduct. The young fry will be fortunate if they escape the water scorpion, a pest which infests the streams of some of our Indian hills. The greatest enemy of fish is however man and if the trout escape the fangs of the otter they will yet have to run the gauntlet of the piscatorial Singhalese.—*Madras Mail*, June 6th.

COFFEE (ARABIAN AND LIBERIAN), CACAO, AND TEA ENTERPRISE: OFFICIAL REPORT FOR THE CENTRAL PROVINCE OF CEYLON.

(From Administration Report for 1886, by Hon. W. E. T. Sharpe, Government Agent, Central Province.)

The rapid conversion of abandoned coffee estates into tea gardens is a notable fact in every part of the hill country. Vast expanses of tea now meet the eye in every direction. The crop was last year, perhaps, less than was expected, owing to an exceptionally wet and prolonged south-west monsoon. Factories are being rapidly erected everywhere, giving remunerative employment to large numbers of sawyers, carpenters, and masons. New bazaars are springing up along the lines of roads, and there is every appearance of returning prosperity. The yield of tea throughout the province, and the high prices realised in the London market, have been most encouraging.

A gentleman in Madulkele writes:—"In three years' time the number of tons of produce sent from these districts will probably equal that of coffee in former times. Of cinchona, there is probably 600,000 lb. of bark, which will be harvested during the next three years."

A gentleman in Maturata writes:—"It may be anticipated that a year or two hence will see all the opened acreage under tea."

Of Maskeliya, a well-known resident writes:—"Of the total uncultivated acreage of this district about four-fifths is now under tea, which has everywhere so far done well."

A planter of Pussellawa writes:—"With regard to tea cultivation, on which the future prosperity of this district must depend (*i.e.*, from a planting point of view). In the immediate neighbourhood of the Peacock, including Hellebodde estate on the one side to Sanquhar on the other, there will probably be, by the middle of this year, upwards of 4,000 acres planted land. This is not inclusive of the Nilambe district and estate. Two large factories—viz., Helbodde and Sogamma—have for some time past been manufacturing tea, but the bulk of the land above mentioned will not yield any appreciable quantity of tea for another year at least. When all is bearing, the exports from these estates might be estimated at one million pounds yearly."

Of Matale, a resident superintendent writes:—"Coffee.—There is now little coffee left in this district, and on only one or two estates does it receive systematic cultivation; in these instances it has responded to the care bestowed upon it, and a good paying crop has been gathered.

"As a rule, coffee is merely tolerated where it does not interfere with other products, and cannot be said to be cultivated; it receives no pruning worthy of the name, and suckers are often allowed to grow. Even under these circumstances it has borne fairly well, and wherever it is at all in heart there have been fair blossoms for the current year. This general abandonment of coffee is due to the attacks of black bug, which in places has quite wiped out hundreds of acres. It appears now, however, to have done its worst, and leaf-disease is also less virulent.

"*Liberian Coffee* hardly receives that attention it deserves. Plants from carefully-selected seed grow vigorously, and when in bearing yield four to five hundredweight an acre. This variety of coffee has recently sold in London for sixty shillings, and is sought for by Moor traders for use in the northern provinces. The growth on poor soils is generally good, but the possibility of black bug and leaf-disease proving too much for even Liberian partially prevents its cultivation being seriously undertaken.

"TEA.—The acreage under cultivation has been greatly increased; there are now few estates in the district that have not a portion of their acreages in tea.

"Matale East may be said to be entirely given over to tea (although there is a good deal of cinchona still growing there). In Matale West and the centre of the valley, tea has been planted where elevation and soil are unsuitable for cacao. Speaking generally, the growth is favourable; and when the soil has not been exhausted by previous cultivation, there is a fair prospect of success. The low-lying estates, such as Wariyapola and Hapugahalanda, perhaps make the best show for their age.

"The Vicarton group of estates in Matale West have recently changed hands, with a view to cultivation in this product. Land has been purchased from natives, and Crownland applied for with, I believe, the same object.

"*Cinchona* does not receive much attention, owing to the low prices ruling at present. Succirubra grows extremely well in almost all parts of Matale East, but there will be no extension to speak of while prices remain as they are.

"*Cardamoms* do well wherever they have been carefully planted all over the district, and even at present prices pay moderately well. A rise in prices would probably cause an extension in the acreage under this product.

"CACAO.—The cultivation of this product has not been much extended, but confidence, which was shaken by the drought of 1884, and attacks of *Helopeltis*, has entirely revived. Crops as a rule, have exceeded estimates, and there is now no doubt as to the success of cacao in the rich soil in the centre and north of Matale.

"It ought always to be borne in mind, however, that no crop to speak of can be looked for before the fifth year, and nothing large enough to give a profit before the seventh. Attention ought, therefore, to be devoted to products suitable for cultivation with the cacao, which gives an earlier return.

"If Sinhalese could only be brought to give care to the cultivation of cacao, it would more than supply the place of coffee with them; but I fear that the natural apathy of the Sinhalese villagers will always be an insuperable objection to the introduction of this product as a plant to be grown round their houses. Cacao to be successful must be protected from cattle and kept from suckers and weeds, and this amount of attention is more than the villagers will bestow.

"It is worth notice that villagers now offer their services on estates, and in one case that I know of a gang of Sinhalese are now resident in lines, and are treated in every way as Tamil coolies are. At some works they are quite able to compete with the Tamil; but they are not to be relied on in bad weather, and lack the power of adapting themselves to circumstances which a cooly has. In time, however, they may prove a valuable addition to the labour force of the district, an event much to be desired for all parties."

A visiting agent of great experience in the Kandy district writes:—

"COFFEE.—Planters have rightly turned their chief attention away from the cultivation of the old staple of the Colony. Years of continued disappointment in resisting leaf-disease have been followed by the attacks of green bug, so well described by Mr. Green, of Pundalu-oya, in his able pamphlet, added to which they have had to contend with low prices. Now there are rifts in the cloud of depression that has assailed the old favourite. The harvesting of a fairly good crop in Dumbara in 1886, followed now by one of the best blossoms that have been seen in the district for many years, and the likelihood of good prices for coffee for some time to come, have influenced planters to stay their hands in eradicating coffee, and they will probably carefully cultivate what bushes are now left. In this connection I may instance what was done by the late Mr. R. B. Tytler, the well-known pioneer of planting in Ceylon. In 1856, he bought the Deegalle and Pallekelle estates, which were then abandoned, and cleared out a hundred acres of what he knew had been previously fine coffee. He cultivated the suckers growing on the stems, as there were no primaries, and as they yielded crop cut them off, allowing fresh suckers to take their place. He, in fact, secured good, continuous crops from suckers instead of primaries. This, I believe, is now being done in the higher districts where primaries have been cut off, to allow the growth of tea, and where planters are now induced to let both products grow together for a little longer.

"CACAO.—Dumbara, one of the leading Kandy districts, is the home of this product. No estate has come up to Pallekelle for extensive and productive cultivation. I must leave the Matale and Kurunegala planters to deal with cacao in their respective districts. It is also profitably cultivated in Wattegama and Peradeniya.

"The first attack of *Helopeltis*, accompanied by an unusually dry hot season for two years, threw cold water, if I may so express it, on the cacao enterprise. Wise men shook their heads, and prophesied failure; 1886 has, I am glad to report, dissipated this pessimist view, and the success of cacao, materially assisted by the growth of shade and shelter belts, may now be looked on as a well-established fact.

"On one estate I know 700 acres of bearing cacao will give 3,500 cwt. (1886-87); and as that cultivation is one that requires but a very moderate annual outlay (say, R50 or R60 per acre), the capitalist may thus reckon what returns he may expect from a well-chosen cacao property. At first starting other products should be continued, say, coffee raised from Mysore seed, tobacco, Liberian coffee, and (as a shade) rubber, which in many instances has served the purpose and will be subsequently a source of revenue.

"TOBACCO.—This product is now receiving the close attention of careful and skilled planters in the Dumbara district. The exports of tobacco in 1887 will, I hope effectively prove that this is one of the rising industries in the Island. The year 1886 has to these gentlemen been one of education, but they are now, I believe, reaping

ing the benefit of their attention. If the annual exprots of Dumbara tobacco can be raised to 100,000 lb. in the course of two or three years, that means no small addition to the prosperity of the districts near Kandy.

"TEA.—It is quite cheering to see the way the fine old estates of Uduwella, Hantana, Hunasgeria, Peradeniya, Mount Pleasant, Hopewell, &c., are being turned into productive tea gardens. The rainfall is sufficient and the climate forcing. On Sundays the bazaars of Kandy are again well frequented by the coolies, spending their money freely. I firmly believe we shall see the trade of Kandy in a year or two fairly prosperous, and, what is of so much importance, a good deal of the money required in the cultivation of estates will be earned by Kandyans instead of Malabar coolies, who take the bulk of their savings out of the Island.

"Kadugannawa, Galagedara, &c., all share in the revival of prosperity created by the cultivation of tea, and what must be gratifying to the Government of Ceylon is the determination of planters not to have all their eggs in one basket, but also to cultivate other products that will bring grist to the mill in seasons prejudicial to the successful flushing of tea.

"CINCHONA.—These districts have not been much benefited by this cultivation. It has no doubt helped to pay for the transition of coffee into tea properties.

"Liberian coffee, cardamoms, vanilla, and kapok, have all helped the planters in Kandy to tide over the years of scarcity. In Rangalla, I understand, cardamoms have done exceedingly well."

QUININE IN ENGLAND.—A resident in Hertfordshire writes in reference to enquiries in the *Observer*:—"In enquiring at my druggist's I found that the retail price of quinine is now about 4s 6d an ounce. He is a considerable holder, and probably bought some time ago anticipating a rise, which may result, if your planters—finding the market price will not pay them—cease to grow the bark!"

COFFEE.—The *Diario de Santos* gives the receipts of coffee at Santos in March as 192,445 bags, making a total of 2,071,424 bags since the beginning of the crop-year against 1,479,311 in 1885-86. The March clearances were 235,765 bags (including 81 coastwise), making a total of 1,943,620 bags since 1st July, against 1,347,645 bags in the same period of the preceding year.—*Rio News.* [Coffee in Santos, therefore, shows not a decrease but a considerable increase.—ED.]

TREES AND CASTE.—At a meeting of the Anthropological Society of Bombay recently, Dr. W. Dymock read a paper on the "Anthropogonic trees of the Hindoo castes." He began by mentioning that it was a general custom among the Hindoos to bring into the house, the branch of a tree, as an object of worship in the marriage ceremony. The same tree is not used by all castes, the Udunbara (*Ficus glomerata*) being used among the Brahmans, Asupala or Ashoka (*Saraca Indica*), among the Vaishas, Dhataki or Agnijavala (*Woodfordia Floribunda*) among the Shenvis, and so on. The author also pointed out that some of the ancient customs in European countries were very like the Indian, and briefly summed up, that in every Aryan country at least owing to the analogy between trees and men, popular superstition supposes the first men to have sprung from trees.—*Indian Agriculturist.*

TEA.—The *Produce Markets' Review* says of last week's tea sales:—The market for Indian tea continues active, and nearly the whole of the heavy supplies brought forward at the public sales were sold. Prices remain very firm for all good descriptions, and in some cases a further advance of ½d to 1d per lb. has been established. The most active enquiry has been for good souchongs and pekoe souchongs, and as the quantity of these grades is gradually becoming more restricted, values have risen about ½d per lb. as compared with the prices paid a week ago. For medium whole and broke pekoes there has also been a brisk demand, especially for broken pekoes with a good appearance and infusion, which show an advance of from ½d to 1d on previous rates; the finest sorts have also been in steady request, at slightly improved values. Common broken teas and the less desirable whole leaf sorts show no important alteration in value, the poor quality of most of the parcels checking any upward movement. The general quality of Ceylon teas has not improved, but smaller supplies, coupled with the firmer prices paid for Indian teas, have lent them steadiness, and rather higher prices were realised at the sales. Java growths met with a moderately good enquiry, and are also rather firmer in value."

TEA.—The *Grocer*, discussing the tea sales, says:—"There has been a quiet but steady business doing throughout the week at previous rates, with a shade firmer tendency here and there. The remaining supply in importers' hands is small, but dealers are able to supply most of their moderate wants at auction. There is absolutely no export demand for Russia (and has not been all this year), consequently our home market has had to take those extra millions that generally go to Russia. If Russia had only taken our extra supply of fine Moning this spring, as she did last year, prices would now be on a very different basis. Two or three of our large London firms have bought the bulk of the fine Monings that have been slaughtered of late, and we hear from them that it has proved a great success, as the value they have been able to offer to the retailers has been so remarkable, that they are now taken freely in the place of Indian Pekoes. A small proportion of good Indian or Ceylon tea, used as a blend to make up the deficiency in strength and flavour of the China tea, is very necessary; but it is generally used half-and-half, and often pure and simple. Do not let us have this refreshing beverage blown upon by the Faculty because the public ask for strength and colour; but let us rather train them to understand and appreciate what a cup of pure and good tea really is." This exhortation to the trade to educate the public taste in tea is a new departure.

LIFE OF CULTIVATED TEA.—It is rather strange how little this subject has been touched on by successive writers on tea. The majority ignore it, no doubt from want of the necessary data; but, writers on Assam at least, ought with very little difficulty to have acquired useful information on the subject. In Balfour's "Cyclopædia" we find the following reference which is rather inconclusive in its deduction:—

The tea plant does not yield leaves fit for the manufacture of tea until the third year; it increases yearly its produce until the eighth or tenth year, at which time it attains its maximum. It has been found indigenous in Assam and Cachar, aged, it is averred, sixty and seventy years, and still producing leaves of an excellent quality. A tea plantation may be compared to an English orchard,—a property producing an income during the life-time of the planter and passing to his descendants.

Simmonds quoting some old writer on China tea has an equally unsatisfactory, not to say enigmatical, piece of information;—

The plants live from twenty to thirty years, and when old, are frequently cut down, and a young shrub grafted into the old stock. Quicker returns are thus obtained, but the plant does not last so long.

One would like to know how long the tree would last if not cut down and a young graft applied, and also how much the latter increases the crop and for how many years. We are reminded by a critic that in pruning of tea, "stripping off the leaves is condemned by all good planters. The cinnamon bush is coppiced, tea pruned, result much the same and much of tea in colder climate. I have no doubt bushes 50 years old are in existence. *Ours being many stemmed* in Ceylon are likely to last longer. Even if original stems die, others succeed."

Correspondence.

To the Editor of the "Ceylon Observer."

THE CROPPING AND LIFE OF TEA BUSHES.

26th May.

DEAR SIR,—As an answer to Mr. Anstruther's enquiry, to quote the age of tea bushes in India, is to answer the question generally. Much more to our particular purpose is it to be informed of the oldest bushes under cultivation here. The cultivation of the bushes in India and in Ceylon is not analagous. The natural conditions are not identical. In India the bushes are said to have a natural rest of nearly 6 months' duration. In Ceylon the bushes are cropped all the year through, and if during the dry weather the bushes cease to flush for 6 weeks, long and loud are the cries of the planters. I was the first in the island to denounce the barbarous treatment bushes receive annually and euphoniously termed pruning. I said that continous picking and annual hacking are not likely to favour longevity. Mr. Armstrong in his last essay is evidently of the same opinion, for he says that annual topping and pruning once in 2 years, I believe, is the best treatment for tea bushes. But the mischief has already been done. The constitution of the bushes has been undermined by early topping, early picking and annual hacking. Careful and considerate treatment is necessary to overcome the evil already done. The "wonderfully recuperative" character of our climate cannot lessen the evil that has been done to young and immature tea bushes.

The treatment cinnamon bushes receive is in no one particular similar to that tea bushes receive. Tea bushes are topped and their growth stunted in direct violation of natural laws. Cinnamon is not similarly treated. Tea bushes are stimulated to continuously throw out new flushes, which are as continuously picked. This is very exhausting to the bushes, for scientists have told us during the enquiry into leaf disease in coffee, that a crop of leaves was as exhausting as a crop of berries. Cinnamon receives no such treatment. Tea bushes are annually cut down and deprived of all foliage * in the responsive action between leaves and roots temporarily checked. Cinnamon receives no such barbarous and unnatural treatment. In cropping cinnamon no natural law is violated. The bushes are simply thinned out by the removal of mature sticks. And see the cultivation cinnamon receives. All the weeds, leaves and pruning from shade trees are buried twice a year, and on a carefully cultivated estate, the holes of the previous year are not disturbed in the year following. Of course the soil is minus the constituents which the cut sticks represent, for a cinnamon property is never manured, but these constituents have not been determined by analysis and cannot be very much; for properties nearly a hundred years old are still cropping famously. No sir, the age of cinnamon bushes can by no means determine the age of tea bushes, for the treatment each receives is widely dissimilar,—Yours truly. B.

[There is no topping of the cinnamon and no constant removal of the leaves, but there is a continual removal of coppiced stems and a continual renewal. So that there is some, indeed considerable, analogy. Tea must no doubt, sooner or later be manured, and if abundance of manure can be afforded the longevity of the plants can doubtless be largely extended. At the same time, unlike berries and bark, the material for leaves comes to a large extent, from the atmosphere and Mr. Hughes bears testimony to the fact that our rains in Ceylon are specially rich in ammonia.—ED.]

* There are some cases where as a part of the process of pruning, the bushes are deprived of all foliage, every leaf being carefully stripped off. But we have never heard other than condemnation of such a proceeding.—ED.

CHINESE TEA CHESTS.

SIR,—Do the Chinese tea exporters invariably line their cases with lead, or sometimes only with glazed paper inside? The Moormen here, are now purchasing freely the inferior teas of our factories for exportation to the Coast. They make their own boxes, and line them with paper only. I should fancy a good proportion of the tea gets musty before it could reach the consumer. But the Chinese themselves, as well as the European merchants in China, do things more thoroughly. I remember, when at home, having got hold of an old China tea chest, and, then as it was, I found it almost impossible to break it up. Could we not import some veritable China tea chests? They are covered externally with glazed paper, but is the trade at home already accustomed to paper linings made water-tight? ENQUIRER.

[For several years back we have expressed our conviction that tea might be safely packed and carried in papier mâché boxes, properly made (subjected to the greatest pressure) and well glazed with some substance capable of resisting damp. We are surprised that the invention has been so long delayed, while everything else, including barrels and even bottles, are made of paper.—ED.]

Colombo, 3rd June 1887.

DEAR SIR,—In reply to "Enquirer," China tea packages are *always* lined with lead, the outer wood cases and edges being papered and glazed. "Enquirer" is quite correct in supposing tea would get musty * being packed without lead.

The Home trade would be very chary of buying tea packed in wood without lead and no one conversant with tea and the requirements of the trade would think of shipping tea without a lead lining to the packages. —Yours faithfully, FRANCIS F. STREET.

THE COFFEE MARKET AND PLANTERS.

DEAR SIR,—An advance—again *corroborated* by Reuter—in Fair Rio at New York of no less than 33½ per cent, in as many consecutive days, landing the price at 22 cents on 3rd June as compared with 16½ cents on 30th April last, has now to be chronicled. Considering that the prices wired by Reuter in May 1885 and May 1886 were 7⅞ and 9 cents, respectively, this rapid and truly astonishing change of front, after so many years of deep depression, is, I suppose, unprecedented in the annals of the fragrant berry. Some are of opinion that the advance cannot be maintained let alone continued. On this view of the question Messrs. Rucker & Bencraft in their circular of the 18th Nov. last, after hinting at unheard of prices as likely to be seen later on, wrote as follows:—

"The 'Bears' have had happy experiences during the past four or five years, and don't seem to take to their new quarters. From an argumentative point of view they seem to have little to advance beyond the statement that all estimates are nonsense, most especially, moderate or small ones, and that every man will now drink hot soup and water, instead of coffee at current ruinous prices."

The above remarks are premised in the same circular:—"Indeed, it is no exaggeration to say, that if the information current prove fairly correct, we are practically jumping from an epoch of over-production to one of under-production."

Has not the time now arrived for Ceylon coffee proprietors to bestir themselves and attempt

* Or very flat and out of condition.—T.T.S.

to save their remaining trees, if possible, from the ravages of the green bug. An effort should be made to tempt some *leading* European scientist to visit our island with this object. A guarantee fund should be at once started and an offer made to pay the scientist's travelling expenses and *in addition* the further sum of two thousand pounds if he could show us how to conquer our latest and deadliest enemy without injuring our trees. If a cure could not be found, the proportion to be paid by each proprietor would be so small as not to be worth consideration. Even if five thousand pounds were offered for a cure it would be a good investment. A pound an acre would, I suppose, cover even this seemingly large sum. On these lines I am prepared to guarantee TWO HUNDRED POUNDS.

P.S.—The price of Ceylon coffee must surely shortly further advance and very considerably. The latest quotation wired from London is reported to be 104/, against in May 1885 61/; against in May 1886 63/. This is simply ridiculous! Even Java coffee has, in the past twelve months, risen from 25 cents to 57 cents, and *during the past two years Rio coffee has about trebled itself in value.* After writing the above I hear that Rio coffee has made a still further advance at New York.

Further extract from R. & B.'s Circular 18th November 1886.

"Coffee (the circular commenced thus):—" It has been truly remarked that during the past ten to fifteen years, three different epochs in the history of coffee, stand out far from the other in an exceptionally plain manner

" 1st. The epoch of underproduction, when good average Santos ranged from 100 to 148 francs.

" 2nd. The epoch of balanced production and consumption, when good average Santos ranged from 70 to 100 francs.'

" 3rd. The epoch of overproduction, when good average Santos ranged from 40 to 60 francs.

Well, as regards the above, we are a long way yet from 148 francs.

COFFEE: ABOUT GREEN BUG: PRACTICAL SUGGESTIONS.

Upcountry.

DEAR SIR,—Green bug is a familiar name in the ears of most of us planters now, but I am afraid that few of us can speak of this pest with that amount of authority we should like.

Discussion generally gives some of us new ideas, and I feel sure that your columns will be open to me that I may set the ball rolling with a few observations:—

1. In Harris's "Insects Injurious to Vegetation" we get a few remarks on the life history of the family Coccadæ, to which I believe our green bug belongs:—

"Early in the spring the barklice are found apparently torpid.....sticking by their flattened inferior surface closely to the bark.....A little later on the body is more swelled, and on carefully raising it with a knife, numerous oblong eggs will be discovered beneath it and the insect appears dried up and dead, and only its outer skin remains, which forms a convex cover to its future progeny. Under this protecting shield the young are hatched and on the approach of warm weather, make their escape at the lower end of the shield which is either slightly elevated or notched at this part. They then move with considerable activity and disperse themselves over the young shoots or leaves."

I will not take up your space further with quotations from Dr. Harris than to say that according to him the female having once taken up her position remains stationary, that these pests sometime breed two or three times a year, and that it is probable that the insects of the last brood pair in the autumn after which the males die but the females survive and lay their eggs in the following spring.

Now I consider these remarks of the very greatest interest to us, for I consider that they apply very closely to our green bug.

For the last 15 months I have been watching green bug, and I would like to give you my experiences. Green bug first made its appearance here, or at least was first seen here, last March, a year ago. It spread a little but did not do much harm till July and August when it showed itself all over the place.

In September and October it decreased and did not make its appearance in an active form till this February-March: it has gone on steadily since.

Now from these premises I would draw the following conclusions, that it was brought here last March either by wind, coolies' clothes, or perhaps even on transport sacks. That it bred slightly for 3 months afterwards until in July when the second brood came out and nothing having been done to check it, it had increased and multiplied. Our cold weather begins in October, so that this last brood of August did not breed till February and March this year, and as the cold weather kills off numbers of them, we are not having it so badly as we shall have it in July when the second brood commence work.

Now for a few suggestions in the way of fighting the enemy:

Firstly.—The more coolies work in affected parts, and go to the unaffected parts afterwards, the more the disease will spread, as I have no doubt it can be easily carried from one tree to another.

Secondly.—I have very little faith in applying remedies now, as the insects swarm all over the tree, and it is impossible to apply any remedy so as to kill every insect. Of course you can check them but you cannot exterminate them.

Thirdly.—There is no doubt that the right time to attack them is when there are fewest of them. This is in winter. If we prune all affected trees heavily during the wet weather, there is no doubt that numbers of females would be killed and so vast numbers of future generations destroyed.

If this were first done and a careful inspection held at the beginning of the fine weather and remedies applied, I have little doubt that green bug could be very largely kept under.

Lime and kerosine do undoubtedly kill off the pest. The only piece of coffee I have alright this year which was badly affected last year, is a field under our "Gap." The monsoon mist was constantly going over the gap and I have no doubt that it was too much for Mrs. Green-bug. Trusting you will think this worthy of an insertion in your paper, I am, dear sir, yours truly,

A. K. U.

PLANTS AND GRUBS.

Watagama, 28th May 1887.

DEAR SIR,—Under separate cover I am sending you portions of the root and stem of a tea plant, and shall be obliged if you will find out whether the grub that has hollowed out the root and stem so neatly is something new or something already well-known to you, though now turning its attention to tea. I could not find any outlet or hole by which the grub had got into the plant.

—Yours very truly, N.

[Dr. Trimen, to whom we referred, writes:—" Peradeniya, 4th June.—Without examining the borer, and your correspondent sends no specimen, it is of course quite impossible to say if it be new or old. But the tunnel in the wood is quite like the work of the larva of the moth (*Zeuzera*) which attacks coffee and many other shrubs."—ED.]

RATS DESTROYING TEA PLANTS.

DEAR SIR,—Can you, or any of your correspondents, tell me how to get rid of Bandicoot rats, which are doing much damage to my two and three years old tea?

They cut right through half inch thick roots, and in many cases pull the plants right out of the ground.

They stick pretty well to one patch in a rocky field, and I can find no trace of them in the daytime, neither do my dogs scent them, and there are no holes. I have tried poisoning, tom-toms, reward for tails, but all to no effect and the damage is serious. Any advice will be gratefully received by—Yours faithfully, PROPRIETOR.

[On an estate in the Nanuoya district, about a score of the very finest plants were destroyed about six months ago, by bandicoots, in the manner described. This was in a corner quite close to a belt of jungle. Nothing that we are aware of was done, except to put the coolies on the scent of this game. The damage soon ceased. We scarcely understand the failure of good dogs to trace the bandicoots by sight or scent.—ED.]

COFFEE AND TEA IN OOTACAMUND.—The retail price of coffee in Ootacamund is just now 30 rupees a maund. The sudden rise has affected consumption among the poorer classes of natives to such an extent that its use is almost abandoned by hundreds who regularly drank coffee before. This is the opportunity for those who believe in the introduction of a cheap tea into the bazaar. Put up in convenient little packets or sold by the ounce, a large demand for cheap tea cannot fail to spring up, of which local dealers should not be slow to take advantage.—*Nilgiri Express*, 1st June.

PLANTING IN CEYLON.—A correspondent in one of the Ceylon planting districts writes:—"Tea has advanced much since I was here three or four years ago. There are tea factories in all directions, any men who have not factories, and cannot afford to build, are selling their leaf, contracting to supply a certain amount regularly for a certain time. The tea factories are furnished with better machinery than formerly, and the rolling is no longer done by hand. Coffee has done better this last season than it has done for years, but there is much less coffee than formerly, as it has given place to tea. Labour is scarce."—*Madras Standard*, May 18th.

BRAZIL COFFEE.—The following are the objections to the export of coffee in the hull, as presented by a correspondent of the *Jornal* on the 31st. The shipping of coffee in the hull will lead to adulteration, for the Germans mix roasted hull with the roasted bean; it will render useless the considerable expense incurred by planters in mounting cleaning machines; it will cause loss to the country through reduced freights on the railways, and the reduction on export duties; it will attract rats on board ship, and the hulls being an excellent manure, the export will tend to the depauperizing of the plantations.—*Rio News*, April 5th.

A NEW ASPARAGUS.—Some little interest has been excited by the announcement of the discovery of a new and remarkable variety of asparagus on the steppes of Akhal-Tekiz. It has not been botanically indentified, but it is represented as growing perfectly wild, the stalks being nearly as thick as a man's arm and attaining a height of five or six feet, so that one of them is said to suffice ten Russian soldiers for a meal. If the preference of experts for wild asparagus finds justification in this variety, and its flavour is described as equal to that of the best European kinds, asparagus lovers may have a good time before them.—*Pharmaceutical Journal*.

INDIAN TEA.—The latest reports from the tea districts are that the weather in Assam has been, on the whole, very favourable, but in the Kachar and Terai districts blight has become prevalent, and in Darjeeling complaints were made of the coldness of the weather which stopped rapid flushing.—*Pioneer*.

COFFEE.—A correspondent at Calicut writing to the *Madras Times* says:—The price of Coffee which is daily going up, has risen to R1,500 per ton owing to the very deficient crop. As an instance, it may be mentioned that one estate in the Wynaad, of over 600 acres under plants, has only turned out this season 64 bushels, the worst result known for some years. The owners, preferring to dispose of it locally to sending so small a quantity to England, have sold the crop outright to Messrs. Hinde & Co. in its uncured state —a proceeding which has been followed by many others. Coffee, which was sold in the local bazaars a month ago at 14-0 per viss, is now securing R2-0-0 and promises to go much higher. This state of things is attributed to a deficient rainfall, and to an absence of rain at the time it was wanted.

CULTIVATION IN TUNIS.—A recent report by Sir R. L. Playfair of a tour along the coast of Tunis gives the following notes on the cultivation of desert land. At Gabes, he says, a great improvement has taken place in one year. Only two stone houses existed twelve months since, and now there is quite a small town. Oued el Melah, 8 miles from Gabes, is where Colonel Rondaire proposed to make a cutting which should inundate the Sahara. Artesian wells have been sunk, and Consul Playfair says:—"It is not more than six months since any attempt was made to bring the land around under cultivation, and already the most surprising results are apparent. The ground is perfectly flat and sandy; it was covered more or less with sparse scrub, which by decomposition during centuries had added a certain amount of vegetable matter to the soil; indeed, in years of unusual rain the Arabs had been in the habit of cultivating small patches here and there; but for all practical purposes the land was desert and absolutely valueless. Now 150 hectares (375 acres) have been cleared, arranged for irrigation, and sown with cereals and Lucerne; a vegetable garden has been made, and a nursery of young trees planted. Everything is looking flourishing and hopeful. Wide roads have been laid out in all directions, and marked out by rows of Date Palms; even the commencement of a village has been made. Two other artesian wells are being sunk, one on either side, and when all are completed it will be possible to irrigate 3000 hectares (7500 acres) of land."—*Gardeners' Chronicle*.

INDIAN AND CEYLON TEAS.—The supply of Indian Tea placed upon the market has been much smaller, and as the demand continues active, prices on the whole remain very firm. The medium descriptions, owing chiefly to the limited selection obtainable, have been largely competed for, and as the recent arrivals appear to have brought but a comparatively small proportion of these grades, it is not improbable that a strong market will continue for the present. Values for the commoner teas have also shown a hardening tendency, while the Whole Leaf descriptions, especially good-class souchongs, are from ¼d to ½d. dearer. Common low-priced broken teas have shared in the increased firmness, but the finest sorts have been in less request, and show no change of importance. Judging from the continuous expansion in the consumption of Indian teas, there appears for the present every probability of a strong market, as, at the present rate of deliveries, the stock bids fair to be considerably reduced before there is any material addition to the supplies by the arrival of the new crop. The Ceylon teas brought forward this week have shown some improvement in quality, and as there has been a good general demand, they have on the whole fetched firmer prices. The small quantity of Java tea sold steadily at about late rates. At the public sales 14,779 packages were offered, including 12,062 Indian, 2,528 Ceylon, and 189 Java teas. The inquiries generally were active, and nearly the whole sold at firm to advanced rates.—*Produce Markets' Review*, May 14th.

THE MADRAS GOVERNMENT CINCHONA PLANTATIONS.

Correspondence is published in the *Madras Mail* in which the Madras Chamber of Commerce complain that contrary to a pledge given the Government cinchona plantations were being extended while, in view of the profit they had yielded they ought to be sold. It was also made ground of complaint that the Government Analyst was not instructed to make analyses at cost price of specially interesting specimens of bark submitted by planters. The reply was that the gardens were not and would not be extended, that they were only being filled up where they had fallen into decay; that the bark sent into the market from them was about 100,000lb., against some 30,000,000lb. produced in the world, and that the gardens would be retained until the results of experiments with various manures were ascertained, as also of experiments to obtain preparations of the bark of the cheapest possible nature, so as to place febrifuges within reach of the poor, and finally of experiments in the interest of planters, for obtaining cheaply in this country the crude alkaloids, so as to save the cost of carriage of the bark. As regards analyses it was pointed out that Mr. Hooper by his agreement with the Secretary of State was allowed to charge for private analyses.

It seems that as yet cow dung, horse dung and poudrette seem only to increase the quantity of bark but not the proportion of alkaloids, a result different to that formerly obtained.

CHINA TEA.—I have seen myself in the London Warehouses, China Teas in small packages with *paper lining only*, but whether this was only common sorts or an exception. I could not say.—*Cor.*

COFFEE.—In Brazil kinds a very large business has been done, influenced mainly by the American and French markets, where the advance has been more marked than in London. The loss of the "Ville de Rio de Janeiro" on Monday, with 23,000 bags from the Brazils, stimulated the excitement, and helped the upward movement.—*Produce Markets' Review*, May 14th.

HOW TO POISON RATS.—Our planter correspondent who wrote about bandicoots may find "something to his advantage" in the following extract from the *Indian Agriculturist*:—

Captain Fred. Pogson, of Kotegurh, recommends the following speedy and effectual methods for the destruction of rats:—"To exterminate rats is by no means a difficult operation, and may be most successfully done by—1st, a simple substance which is a deadly poison only to rats, who partake of it; and 2nd, by introducing "sulphuretted hydrogen gas," into their holes. Cats, as we all know, are attracted by "Valerian," and rats by the oil of "rhodium." By means of a few drops of this oil, numbers of rats can be drawn to any particular locality, where the tasty poison being placed, they eat and die on the spot. To make this Rat Poison, take of squill, in powder, 2 ounces; of cheese of any sort, powdered, 8 ounces; mix the two intimately together, and the result is the Rat poison, and is said to kill rats instanter. The "Squilla Maritima," is the variety recommended, though perhaps Indian squill might answer as well. The cheese can be made by curdling fresh milk, with or without rennet. As regards the sulphuretted hydrogen gas, its preparation is given in all chemical works, and it can be filled into bottles or bladders, and the gas on being poured into a rat hole will instantly pervade space, and kill every rat in the hole. The cost of preparation is a mere trifle. This plan will kill rabbits as well, and has been placed before the Governments of Australia for trial, as likely to be more effectual than wire fencing one hundred miles long, to keep the rabbits of one State from migrating into another. See map of Australia for such boundaries."

COFFEE.—An Ootacamund correspondent writes that coffee is becoming rather scarce in Ooty markets. At present it cannot be had for less than R16 per maund of 25 lb. It was sold at the rate of 15 annas per viss about two months ago, but suddenly there was a rise in the price which has been increasing week after week.—*Madras Mail*, June 7th.

TEA.—There are now (says the *Shunpao* of the 14th May) on the Hankow market 165 chops of Hu-Kwang teas, amounting to about 133,000 chests, including last year's and new season's teas; 395 chops of Ningchow and Keemen teas, amounting to about 161,000 chests. Nearly one-half of Ningchow and Keemen, and one quarter of Hu-Kwang new season's teas have already arrived at Hankow.

CINCHONA-PLANTING IN RUSSIA.—We hear from a Continental source that the Russian Ministry of the Imperial Domains is about to try cinchona-planting on an extensive scale in the neighbourhood of Tiflis (Caucasus). Experiments are said to have demonstrated that the soil and climate of that part of the Caucasus are very suitable for cinchona-growing, and it is claimed that cinchonas have actually been grown in the Caucasus, and yielded a bark suitable for quinine manufacture. We are not in a position to judge of the accuracy of the report, which, it should be said, emanates from the same journal which announced the impending appointment of "Dr." Ritchie as British "Minister of Public Health."—*Chemist & Druggist*, May 7th.

CEYLON TEA AND INDIAN TEA.—Although the Indian tea planters have again and again asserted that tea will not last long in Ceylon, they are evidently fully alive to the fact of the progress we are making. We read in the *Madras Times* of the 6th:—

A meeting of gentlemen interested in the tea trade was held at Calcutta on Thursday, to consider the best means of popularising tea with the native community throughout India. Mr. Lyall, of the firm of Messrs. Lyall and Marshall, who was in the chair, pointed out, in view of the largely increasing production of tea in Ceylon, that the Indian producers must look to every possible outlet for their production. The market at their very doors had been hitherto neglected. After some discussion the meeting appointed a committee to work out the details of a scheme which they promised heartily to support. It was proposed to raise the required capital in shares of ten rupees, no shareholder to hold more than 100. The experiment is to be first tried in Bengal and Upper India. The smallest village where shops exist will be made the seat of an agency. The tea will be sold in one, two and four ounce packets, at three, six and twelve pice respectively.

DECLINE OF PLANTING IN FIJI.—The following, from the *Fiji Times* of April 23rd, gives a gloomy picture of the planting industry in Taviuni:—One of the oldest of the Taviuni planters has furnished the following:—"It will no doubt be surprising to the early pioneers of Fiji who reside abroad, to learn that there are now only sixteen plantations occupied and even in partial work on the whole island. Some few other holdings are occupied, but all cultivation has been abandoned. Of the original cultivation on others which have been totally abandoned no sign remains, and the lands which were cleared at such an immense expenditure of money and labour have relapsed into the old state of scrub and forest. The European population has dwindled to about 80 people all told, and the island from being the garden of Fiji, has except in a few spots, degenerated into a wilderness. Of the few plantations occupied seven are *vakatawa'd*, the owners being absentees, and other departures will follow almost immediately, still further reducing the population.

INDIAN, CEYLON AND CHINA TEAS: PRACTICAL SUGGESTIONS.

A gentleman engaged in the wholesale tea trade at home has sent us some interesting notes suggested by an article that recently appeared in our columns on the subject of Indian tea. He points out the distinctive properties of China, Indian and Ceylon teas, and gives his opinion, as an expert in tea-tasting, that under favourable conditions for infusion no tea has yet been grown out of China that equals in elegance of flavour and refreshing properties the really good Chinese article. He adds, however, that the water in which China tea is infused must be soft and pure. In hard or limy or irony water its properties are not drawn out, and the liquor is pale and tasteless. This throws an important light on the somewhat remarkable circumstance drawn attention to in our leader that English tea dealers recognize and cater for local tastes, one class of tea finding a ready sale in one district that would fail to meet with favour in another. Our correspondent points out that this is not merely due to special tastes acquired by habit, but is more to be accounted for by the different waters in which the tea is infused, which vary in every locality and have an important effect on the infusion, the precise chemical nature of which is not yet understood but which is quite apparent to the senses of the tea taster. Hence in localities where the water is hard or impregnated with lime or iron, under which circumstances China tea becomes insipid, Indian tea has a distinct advantage, giving by its superior strength and barky, grippy taste a full and rich liquor which, however, has to be modified with cream and sugar before it becomes agreeable to the palate. This beverage, in our correspondent's opinion, is never so finely flavoured or so refreshing as fine China tea under favourable infusion. But as the supremely favourable conditions under which China tea is to be had in perfection are comparatively rare, there is a large field in England peculiarly favourable as a new market for Indian tea. The tea, however, must be supplied of the best possible qualities. The great desideratum to be aimed at is to combine as far as possible the strength of the Indian tea with the fragrance of the China leaf. In our former leader we quoted a statement made by Captain Temple that a native tea grower in the Kangra district has made his estate pay large profits by supplying a quality of tea for which the natives of the Punjab have shown a liking This preference, our correspondent says, is solely due to the fact that in the Darjeeling and Kangra districts the tea plant most closely resembles the China variety, being a hybrid, not the native indigenous Indian plant of Assam. So, in England, the increased consumption of Indian tea has been largely brought about by the extended cultivation of the more delicately flavoured kinds, and especially those which combine depth of liquor and flavour. It is a matter of great nicety in the manufacture to secure this combination, as flavour alone and sharp liquor means under-fermentation, and great depth of liquor means over-fermentation with want of flavour or deadness of taste. The exact point between the two requires to be taken, and will vary according to the condition of the leaves and local circumstances, which only an experienced and observant manager will be able by close assiduity and intelligence to cope with.

Our correspondent says that much of the Indian tea that reached the English market during the past season was beautifully made, better than ever before, but withal of lower quality of liquor than in any previous year. This may have been partly due to unfavourable climatic conditions, but our correspondent gives it as his opinion that another factor has to be taken into account, namely that as the gardens grow older the tendency is for the tea to deteriorate, becoming less fresh flavoury and with less point and character. Thus, the bulk of the Indian tea sold last year in England was of dry, woody medium and low qualities, and, in our correspondent's opinion, it had deservedly low prices. Its cheapness, however, led to a greatly increased consumption, as the retail price was two shillings and under, a figure at which the home consumption of tea now largely runs. But it is at the same time important to note that parcels with any pretensions to point (fresh flavour) or distinctive qualities fetched relatively very high prices, in many instances bringing 2s to 2s 4d per lb. wholesale on the London market though only just a little better than the kinds fetching 6d or 8d per lb. Last year, writes our correspondent, the Indian growers seem to have gone in for quantity more than for quality. The above figures show that the reverse policy will be far and away the better paying. The increased consumption last year was more marked in the case of Ceylon tea than of Indian tea, the extra 4½ millions of the former that reached the London market being very quickly taken off in preference to the Indian growths. This is accounted for by our correspondent simply on the ground that Ceylon tea combines the thickness of Indian with a sweet flavour almost approaching to China tea. The Ceylon teas, when true in character, give a soft, luscious, sweet liquoring, suitable for drinking alone. When burnt, or peculiar in flavour, it is against their use for mixing. "As long," adds our correspondent, "as Ceylon can produce as thick fresh teas as the new gardens do now, they will be popular. What effect time will have on the gardens remains to be seen."

One great and undoubted advantage, our authority points out, that the Indian tea trade has over China is the fact that growers here are in close and intelligent touch with the consumers at home, and are quick to ascertain exactly what is wanted. In China the actual growers of the tea are in absolute ignorance of its fate, and they go on year after year turning out the article in a haphazard and unintelligent way. They go in for cheapness instead of quality, and now grow comparatively little of the superior article they sent over twenty years ago, and which fetched from 2s to 3s per lb. on the London market. Hence the China tea of today is for the most part thin and watery, and if flavoury at the beginning of the season loses its freshness month by month, and is therefore considered by the trade in England dangerous to hold in large quantities. If the Chinese were thoroughly abreast of the times they would at once procure Indian seed and hybridise. Our correspondent points out the danger that Indian tea will come to this state also if the tendency continues of growing for quantity rather than for quality. He concludes by giving the Indian planter a brush up: "A peculiarity of Indian planters," he writes, "is that each thinks the produce of his own garden the best, and that he should get the highest price going. If he does not obtain this, he considers himself robbed by the dealers here. It is a mistake. Tea from all parts of the world is in one focus in the London market, and its true value is compared and ascertained to a nicety according to its deserts by keen and intelligent competition." To sum up, the more important points brought out by this interesting communication are (1) that Indian tea has an advantage in competing with China tea in localities where the water is hard or impregnated with lime or iron; (2) that it has a further advantage from the fact that the Indian tea grower is more in touch with the home market than his Chinese rival; (3) that the continued advancement in the consumption of Indian tea will depend mainly on good kinds being placed on the market; and (4) that, as a really fine tea possessed of distinctive properties commands a price from three to four times greater than that given for the ordinary article, it will pay the Indian grower to go in for quality rather than for quantity.—*Times of India*, June 3rd.

CEYLON TEA IN AMERICA.

Open Secrets About the People We Meet and What They Are Doing.

For twenty years prior to yesterday I had not tasted tea. At the beginning of that period I had become tired of the adulterated stuff that so many people find pleasure in sipping, and I never expected to touch it again. I was yesterday induced to [illegible]

determination, however, by the persuasive eloquence of R. E. Pineo and J. McCombie Murray, two leading tea-growers of Ceylon, who have recently located themselves in this city with a view of educating young folks in the matter of tea, concerning which you are in a lamentable state of ignorance. They drew such an alluring picture of the delights of the beverage made from the Ceylon shrub that I reluctantly consented to drink, and now I can truthfully say that never before had I known what tea tasted like and had never before, as you never have, touched the pure, unadulterated article. The story of the introduction of Ceylon tea which these gentlemen have told me is most interesting. * * *

Did the people of America thoroughly understand the difference between the tea of Ceylon and that of China or Japan, it is certain that those who could get the pure, clean, machine-prepared leaf which is turned out from the planters' factory would never touch the far from pure articles prepared by the hands and feet of the unwashed Mongolian. In China and Japan tea is mostly cultivated in small patches by the peasantry, who gather the leaves and prepare the tea in their huts in a very unfastidious manner. The tea, either in a half manufactured or finished state, is sold to petty dealers, who in turn sell to larger dealers. The large dealer mixes and manipulates the teas, packs and sells them to the European merchants for shipment to England, Australia or America. The manipulation of tea is an art in which the Chinaman excels, and in many of the inferior kinds the quality is infinitely deteriorated: thus, the dust of the tea is mixed with clay and manipulated into the form of the ordinary leaf. This is with appropriate philological coincidence termed "lie" tea. Tea leaves which have already been used are again manipulated and rolled into shape and sold as genuine tea. The teas of Japan, which are almost entirely consumed by Americans, are frequently and admittedly "faced" with a mixture of Prussian blue and soapstone.

It occurred to me while in the office of the two Ceylon gentlemen at 9, North Thirteenth street, that I would obtain for my lady listeners a tea grower's method of making "the cups that cheer but not inebriate." This is what they said to me:

Some people swear by their old opinions and customs; the older, the more they swear. To such people we would say, you have never before seen or tasted Kootee or Ceylon tea, and you are not acquainted with its peculiar properties. It is not the same as other teas, and there is only one proper way to make it. The method which ought to be used in making other tea is absolutely necessary in making Kootee tea.

FIRST.—Boil your water. Steaming water is not necessarily boiling. When water boils, the kettle is alive, and you are made aware of the fact that it is boiling by the noise and commotion. Second. Warm the teapot just before measuring in the tea. Third. Calculate one teaspoonful of tea for three to four strong cups of tea. The tea will turn out a rich amber colour, not black, as is the case with tea faced with black lead and indigo to make them appear strong. Fourth. Don't put your tea put on the stove at all, but on your dining table, where you can allow it to rest for seven minutes to infuse. Stir up the tea a little before pouring off, as the strength remains at the bottom. Use a cozy if you have one.

It appears to me that if you have listened to me today you have learned something worth knowing.

BYSTANDER.

Philadelphia *Daily News*, April 30th.

CINCHONA GROWING AND THE MADRAS GOVERNMENT.

The following letters in connection with the Government Cinchona Plantations have been published:—

Letter from the Hon. S. R. Turnbull, Chairman, Chamber of Commerce, Madras, to the Secretary to Government, Revenue Department:—

The report of the Director of Government Cinchona Plantations for 1885-86 and the order of Government thereon, 15th November 1886, No. 988, Revenue, are of particular interest to the Chamber in connection with the correspondence between the Chamber and the Government which was recorded on the 15th June 1886 (No. 486, Revenue). In the order of the latter date the Government was pleased to inform the Chamber that the increase in the number of trees in the Government Cinchona Plantations was more apparent than real, and that no new land had been planted in recent years. The Chamber had noticed, with regret, that in the year 1884-85 the number of trees had advanced from 1,122,766 to 1,620,744, and it now gathers from the report before it that at the end of 1885-86, the number was 1,950,345. It was remarked by the Chamber in its letter of the 4th Feb. last that the surplus of revenue over expenditure up to 1884-85 was R5,51,743, and that the Government possessed an estate that would realize a large sum of money were it offered for sale. From the appendix to the report of 1885-86 it now appears that the surplus is set down at R4,95,539 after allowance had been made for 4½ per cent simple interest on outlay to the end of that period. The Chamber begs to be permitted to say once again that it is unable to see the necessity for further extension. The investment has proved a conspicuous financial success, and the Government, it seems to the Chamber, can now safely relieve itself of the trouble, expense and possible loss connected with extensions, and confine its attention to securing the bark already grown or in growth, and to the conduct of experiment and investigations in the cultivations of cinchona. The Chamber is informed that in November of 1885 the Wynaad Planters' Association addressed the Director of the Government Cinchona Plantations requesting that the Government would allow the Association to have analyses of cinchona bark made at cost price if they were likely to prove of practical utility. The Association pointed out that experiments might be made with different kinds of manure, and that Government might give the results of experience in matters connected with the harvesting of Ledgerina bark in which the Wynaad is largely interested. The Director, in reply, declared his inability to help the Association in the matter. The Chamber agrees with the Association in thinking that the conduct of investigations is essentially what the Government declares to be its raison dêtre as a cinchona planter, and that its refusal to help the outside planting community in the matter is a contradiction of its apology for continuing its connection with the industry.

This letter having been referred to the Director of Government Cinchona Plantations for such remarks as he may have to offer, Mr. M. A. Lawson, Government Botanist and Director of Cinchona Plantations, Nilgiris, wrote to the Secretary to Government, Revenue Department:—

With reference to letter (undated) from Mr. S. R. Turnbull, Chairman of the Chamber of Commerce which has been forwarded to me for remarks under your endorsement No. 551, of the 26th January 1887, I have the honor to inform you that I have little new to add to what I wrote in my former letter No. 1, dated the 2nd April 1886, upon the subject, as the comments of the present Chairman of the Chamber of Commerce on my report are precisely the same as those which were made by his predecessor Mr. MacFadyen on my report of the year before. The so-called extensions of the Government Cinchona Estates are restorations of portion of the plantations, which in past years had been allowed to go to decay, and if these restorations were not made, the Chairman's aspirations that Government whenever they sell the estates "would realise a large sum of money" would not be accomplished. Experiments upon the value of different kinds of manure are being carried on, and, when completed, the result will be communicated to you. Such experiments as these, however, must be spread over a long period, if they are to be of any real value. The question of fees to be paid to Mr. Hooper for private work done by him was settled by Government in their G. O. No. 186, of 12th March 1886, Revenue, and it seems to me that it would be unfair by this gentleman if the Chairman's

proposal should be adopted, and Mr. Hooper be compelled to perform analyses for private persons without his receiving any remuneration. Indeed, I believe it will be found that such a proceeding would be in direct opposition to the terms of his agreement with the Secretary of State, who evidently intended that he should be allowed to add to his official income by means of private practice, so long as this did not interfere with the interests of his employers. The total output of bark in the world per annum is not, I believe, accurately known; but I suppose that about 30,000,000 lb. per annum will not be far from the mark. Of this amount, the Government estates will furnish this year from 90,000 to 100,000 lb., a proportion so small that it cannot have any perceptible bad effect upon the planting interest. The Government are just acquiring a disintegrator and other apparatus for determining if some very cheap method cannot be discovered of producing a large amount of a good febrifuge from bark grown in this country for the use of the poorer classes of the natives in this Presidency who, it is known, die annually of fever alone by hundreds of thousands. Another object of Government in getting out this apparatus is to endeavour to discover some means by which the crude alkaloids of the bark may be extracted in this country so as to avoid the great expense which all planters have to incur in sending their bark in bulk to the European markets, and Government may reasonably hope that both of these objects will be achieved seeing that they possess in Mr. Hooper, one of the most skilled quinologists of the day.

The Director of Cinchona Plantations was then requested to submit, for the information of Government, copies of the correspondence that took place between himself and the Wynaad Planters' Association on the subject of analysis of cinchona bark referred to in the letter from the Chairman, Chamber of Commerce, dated 4th February 1887.

The following are the letters referred to:—

From G. Romilly, Esq., Honorary Secretary, Wynaad Planters' Association, to the Director of Revenue Settlement and Agriculture, dated Vayitri, 9th November 1885.

Under instructions from this Association, I have the honour to request that we may be favoured with a copy of Mr. Lawson's annual report on the Government Cinchona Plantations. I am further instructed to petition Government to allow their analyst, Mr. Hooper, to report at cost price on samples of cinchona barks if such samples are forwarded by this Association, and recommended as likely to show by their analyses results of practical utility. This concession on the part of Government would be a great boon to the general community of planters, inasmuch as it would keep them informed of the progress that can be made in the matter of cultivating cinchonas and of harvesting their bark.

Forwarded to M. A. Lawson, Esq., Director of Government Cinchona Plantations, &c., for disposal.

From M. A. Lawson, Esq., Director of Government Cinchona Plantations, &c., to the Honorary Secretary, Wynaad Planters' Association, Vayitri, dated Ootacamund, 20th November 1885, No. 1882.

With reference to your letter, dated the 9th November 1885, to the address of the Director of Revenue Settlement and Agriculture, Madras, transfered to me by him for disposal, I have the honour to inform you that I have addressed Government to furnish me with 25 spare copies of my annual reports of which I will send you one, when received. Mr. Hooper, the Government Quinologist at Ootacamund, is already authorized to analyse private barks. I enclose a table of his charges for such, and am sure that you can arrange to have any barks you wish analysed by him by placing yourself in communication with him. It will afford me much pleasure to give you any information which you may at any time desire.

From G. Romilly, Esq., Honorary Secretary, Wynaad Planters' Association, to the Director of Government Cinchona Plantations, dated Neppadi, 28th November 1885.

I have the honour to acknowledge the receipt of your letter of 20th November and its enclosure, giving the Government Quinologist's charges for private analyses. If you will refer to our letter of the 9th November, you will read that we petition Government to allow analyses to be made at cost price of samples forwarded and recommend by this Association as likely to show results of practical utility. By this we mean samples from trees treated experimentally in different ways. In your interesting report on Government Cinchona Plantations you do not mention what manures have been tried, and in a letter communicated by you to the Collector of Malabar (of which I have been favoured with a copy) you say that manure increases the yield of bark per tree, but not the yield of alkaloids per lb. of bark. Perhaps if different manures were applied different results might be arrived at. It is for the sake of making useful experiments of this sort that we have requested the assistance of Government in letting us have analyses from their quinologist at cheaper rates. You are good enough to offer to give us any information we may at any time desire, and I hope after our next meeting to send you a few questions on matters connected with cinchona.

From M. A. Lawson, Esq., Director of Government Cinchona Plantations, &c., Nilgiris, to the Secretary, Planters' Association, Wynaad, dated Ootacamund, 4th December, 1885, No. 955.

I had not overlooked the remarks in your letter of 9th November relating to analyses being made by the Government Quinologist at cost price, but it seems I did make it sufficiently clear to you that Government have no voice in the matter. Mr. Hooper is paid so much for analysing such things only as Government may require for their own purposes, while in the matter of analysing products for private persons, he is, by his agreement with the Secretary of State, allowed to do this for his own profit. Any arrangement, therefore, which the Association may wish to make regarding the analysis of their barks or other commodities must be made direct with Mr. Hooper himself. With respect to the effect of manures on cinchona, I have as yet tried only horse dung, cow dung and poudrette, and from these I get similar results. No doubt it is very desirable to try other kinds as well, and this I hope to do during the present season. I shall be very glad to have any question put to me by your Association, as it is only by accumulation of different experience that accurate information can be arrived at.

Government has passed the following Order on the correspondence:—"The increase in the number of trees in the Government Cinchona Plantations, during the years 1885-86, to which the Chamber of Commerce takes exception, was entirely due to renewals and there were no extensions, as the Chamber supposes. His Excellency the Governor in Council considers that, so long as the plantations remain the property of the State, they should be worked and cultivated according to the most approved methods. In G. O., No. 486, Revenue Department, dated 15th June 1886, the Government stated the grounds upon which it was determined to retain and work their cinchona plantations. These grounds have not ceased to exist. Since the date of the Order, mentioned, trials of the febrifuge, manufactured by Mr. Hooper, have been extended, and preparations for turning it out, on a large scale, are in an advanced stage. An interesting and valuable report on experiments with regard to subjects of the nature of those alluded to in paragraph 4 of the G. O. quoted above, has also been laid before the public, and experiments, the results of which will be published in due course, are being continued. It is anticipated that on the establishment of the cheap febrifuge, which it is one of the chief objects of Government to produce, the whole of the bark realized from the Government plantations will be required for its manufacture. The Chamber need, therefore, be under no apprehension of an increase in the very small percent-

age of bark, as compared with the total exports of this product from the Madras Presidency, which has hitherto been placed in the market by Government. It would, however, be premature to engage that none shall be sold. Until the experiment of producing a febrifuge, which will be effective as well as so cheap as to be within the means of the poor, has had a full trial, the question of selling or reducing the Government Cinchona Plantations, cannot be entertained. The only assurance that Government can give is that they will not be extended. As regards the complaint made on behalf of the Wynaad Planters' Association, a perusal of the correspondence forwarded by the Director, Government Cinchona Plantations, will probably convince the Chamber that it was based on very insufficient grounds."—*Madras Mail*, May 20th.

THE TEA TRADE IN INDIA.

CALCUTTA, 2nd June.—A meeting of gentlemen interested in the tea-trade was held this afternoon to consider measures for developing the taste of tea amongst the Indian population. Mr. R. Lyall, of Messrs. Marshall, Lyall and Co., was in the chair, and the meeting was largely attended.

It is proposed to form a company to raise the required capital in shares of R10 each, no shareholder being authorized to hold more than 100 shares. Experiments are first to be tried in Bengal and Upper India, and within that limit it is proposed to establish agencies in every village where a shop exists, and where tea is to be sold in packets of one, two and four ounces at three, six and twelve pice respectively. The shopkeepers will be paid by a commission on the number of packets sold, so as to give no inducement to sell large packets. The prices of the packets will be printed on them in English, Urdu, Nagri and Bengali. Tea of the required quality can be bought at eight annas a pound, and, if the selling price be computed at twelve annas a pound, the margin of four annas will, it is thought, cover working expenses and a liberal commission to agents.

Mr. Lyall said that the meeting had been called to learn if the tea traders approved of the scheme, and if they were prepared to support it; and, further, to obtain the views and suggestions of those interested in the matter. He thought they must find a new outlet for their tea, and that they had hitherto neglected the large market at their very doors. He had received a letter from the Tea Association asking him to push on the scheme, and stating that they were prepared to support it. Mr. Lyall quoted a Ceylon paper showing the progress of tea in that island, which in another five years will probably export eighty millions of pounds, and said that competition in the future was likely to be severe.

The meeting passed a vote heartily approving and supporting the scheme, and subsequently appointed a Committee to work out the details and draw up a prospectus. A number of shares were taken up before the meeting separated.—*Pioneer.*

THE CHINA TEA CROP

is said to be "a woeful one—the worst ever known"—see *China Mail* news. Since writing this, we have come on the *North-China Herald*'s correspondence on the subject, which is so important that we give it in full:—

TEA AT HANKOW.

(*From our own Correspondent.*)

The market was opened on the 9th by Russians. The crop both of Hankow and Kiukiang teas is the worst ever known, there being absolutely no fine tea. Business is almost entirely confined to the Russians, only 17 chops of Hankow tea having been bought for London, purchases for that market being mainly confined to Ningchows and Keemens; but the total business thus far is quite insignificant and not enough to fill one ship.

Prices paid by buyers for Russia are fully five taels above the limits generally sent from London. It has naturally happened that settlements have been small and, taking the intrinsic quality of the leaf into account, the prices are little less than those paid last season. Arrivals are very heavy, the estimated unsold stock being 350,000 half-chests. The "Moyune" began to take in a little tea today and is the only vessel that has so far commenced to load,—so that she will probably be the first to sail.

The crisis that has been so long impending in the China tea trade seems at last to have arrived, and the native tea packers who have been living on upon the prestige acquired before India and Ceylon had shewn how tea should be picked and packed, will at last have to succumb or be compelled to reform their ways. Against the bright uniform infusions of Indian teas, the China teas exhibit a mixture of dark decayed leaves throughout. The natives attribute this to want of rain previous to the picking time and to excessive rains after the picking had begun. Be this as it may, the fact remains that worthless leaf has been fired and packed *en masse*, upon which heavy charges and duties have to be paid which the buyers, for London at least, decline so far to make good. For Russia and America, whither Indian teas have not yet made their way, shippers take what they can get, and in doing so are paying prices which, judged by intrinsic quality, are often positively higher than last season's. The only teas with any flavour at all are the Keemens and these have been taken to some extent for London at 2d. to 3d. per lb. over present values in that market.

Chinamen acknowledge that the first crop will be 10 per cent larger than last year's, but assert that they are now entering into a binding combination to pack no second crop tea. They also talk of storing their present stock under advance and withholding it from the market until the proposed combination has had its effect. It remains to be seen in how far the credulous Western will be influenced by the report of these crucial measures. Thus far London buyers are practically holding aloof, it being the unanimous opinion that a further decline here of at least 2d per lb. must be patiently awaited.

STATISTICS TO DATE ARE, IN HALF-CHESTS.

	Arrivals.	Settlements.	Stock.
Hankow Teas ...	273,039	97,053	175,986
Kiukiang „ ...	252,448	116,771	135,677
Total ...	525,487	213,824	311,663

Of the above about 40,000 half-chests only are estimated to have been bought for London, chiefly Keemens at Tls. 24 to 33, and Lylings at Tls. 11½ to 13½=(at £4 freight) 1s 1½d to 1s 7½d, and 8d to 9d, laid down with all charges respectively.

16th May.

NOTES UPON THE NEW TEAS AT HANKOW.

The situation in Hankow has, as regards Teas, at all times been curious in the eyes of the spectator. Today (17th) it is simply unique.

Last written advices from the great river port per *Kiang-yung* today are to the effect:

a That the crop is a woful one, the exceptions being Kiangsi Teas: Keemens which are *decidedly* better and Hohows which are *doubtfully* better than last year.

b That Hankow Teas are on the average worth perhaps 10d for the very best grades, and that teamen are under the fond delusion of expecting to obtain Tls. 22 for "not the very best."

c That the losses to natives, though a "kind of cruel," are much deserved.

d That the Shansi bankers are beginning to look bluer as their chits in the hands of the foreign banks approach maturity.

e That foreign banks will only part with their sycee against *Bills of Lading* and not against *Godown Orders*. Rough this upon the "*dear Chinese.*"

f That the rate *of* mortality amongst the native "teaman" element promises to be abnormally high.

Telegrams to hand this morning confirm, in a measure, these anticipations. The Tea Guild, in response to the tearful and fearful solicitations of its weary and heavy laden members has issued an ukase "withdrawing all samples from the market until a little light breaks the present darkness."

Here is an opportunity for the bold foreigner to play his trump card: and apart altogether from inclination, he must *entre nous* play "brag," for it is a fact, alas! but too well known, that he is suffering from very "limited orders" and materially *shortened* credit.

The "Moyune" was to be the first steamer away, with a solid freight list running close on £20,000 sterling, and likely to clear on the 18th instant.

The Tea settlements were only 70,000 half-chests for England and 90,000 half-chests for Russia. Total arrivals 600,000 half-chests.—*N.-C. Herald*, May 20th.

THE FOOCHOW TEA TRADE.

(*Consular Trade Reports.*)

Acting-Consul Ford writes on the trade of Foochow for 1886 to the Marquis of Salisbury as follows:—Twenty-six steamers, all British, loaded tea for the Australian colonies against 18 in 1885. Seventy-three British steamers and six sailing ships, of which four were British, took tea to London during the year as compared with fifty-two steamers, of which one was German, and five sailing ships, of which three were British, in the previous year. One sailing vessel, under the German flag, loaded for the Cape of Good Hope. The employment of sailing vessels for the London trade, noticed by Mr. Sinclair as the special feature of the shipping trade of the port in 1885, continued, and even slightly increased, as will be seen from the figures given above. The competition evidently began to tell upon steam shipping, seeing that "the Conference" offered, towards the end of the year, to allow such returns on all freight given to their steamers at such times as there might be a sailing vessel in port loading for London as would reduce the rate to about forty shillings a ton, and to warehouse in London teas shipped under these circumstances for two months after arrival free of cost to the shipper. The object of this offer was, of course, to discourage shipments by sailing ship, by placing it at the shipper's option to obtain the chief advantage derived therefrom—delay in putting the tea on the London market. All the steamers that loaded for London belonged to one or other of the "Conference" lines, the raising of the return on freights from 5 per cent. to 10 per cent. having effectually prevented any outsiders being placed on the berth. The import trade remains unchanged in its character, being, with the exception of the two articles of opium and lead, almost entirely in the hands of Chinese traders. The total export of tea for 1886 (including re-exports) amounted, according to the Customs return, to 775,216·47 piculs (equal to 103,362,196 lb.), valued at H.T. 9,317,367, being an increase of 40,031 piculs (5,337,466 lb.) in quantity, and H. T. 840,214 in value on the export of 1885. Of this total—

	Piculs.	Lb.
To Great Britain and Continent	411,833 (equal to	54,911,000)
To Australia and New Zealand	149,671 („	19,956,000)
To America ...	44,753 („	5,967,000)
To South America	4,316 („	575,500)

The following remarks are taken from a brief review of the tea season of 1886-87, which one of the resident British merchants, largely interested in the trade, has been kind enough to draw up for me for the purposes of this report:—"Owing to a favourable season in 1885-86, in which both native teamen and Europeans made money, cash was plentiful and cheap at the beginning of the year, money was lent at a low rate of interest by the foreign and Chinese banks, and, as credit was good, a large amount was sent up-country for the purchase of the new crop.

"The great drawback to Foochow teas has always been the large amount of 'dust' in them. It is hoped that this year the climax may have been reached in this respect, as the lowest grades had as much as 20 per cent. to 26 per cent. of dust in them. An attempt made by the Chamber of Commerce to reduce the proportion of dust had no effect, but the loss that the Chinese have suffered may cause them to look into the matter in their own interests. On the other hand, Foochow teas have never been much adulterated with spurious leaf, and this season they have been particularly free from the admixture of old and useless leaf; this has been most noticeable in the Foochow packs and scented orange Pekoes. This result may be attributed to the prompt action of the customs in London last year in stopping the sale of spurious teas.

It is worthy of notice, as bearing on my friend's remarks regarding the adulteration of Foochow teas, that at the beginning of the season a large quantity of what is known here as "lie tea" was offered for sale. The fraud was clumsily carried out and soon discovered in consequence, and a considerable portion of the spurious leaf was seized by the authorities and afterwards burned. Proclamations were also issued by the lekin authorities here, warning the people of the consequences of continuing to make counterfeit tea and to place it on the market.

Attention has again to be drawn to the great development in the manufacture of brick tea from dust and broken leaf by the Russian merchants. The export increased from 71,912 piculs (9,588,300lb) in 1885 to 105,850, piculs (14,113,300 lb) in 1886, that is, that brick tea has to be credited with more than four-fifths of the total increase in the export of tea of all kinds during the year.

COFFEE, TEA AND CINCHONA PLANTING AND TRADE IN JAVA.

Consul McNeill reports to the Marquis of Salisbury on the trade, commerce, &c., relating to the island of Java for the year 1886 as follows:—

The past year has neither been an eventful nor a prosperous one for the island. The crops were on the whole satisfactory, both as regards quantity and quality, the rice harvest especially having been a very plentiful one; but except in the case of coffee, where an improvement took place towards the end of the year, prices for the staple products have remained on a most unremunerative level.

As regards Java produce, the export duty on tea has been abolished, whilst that on sugar was reduced in July from 18 to 9c. per picul. At the close of the year this diminished duty was abolished for a term of five years, while considerable modifications of the taxes payable on estates working in contract with Government, to the benefit of the planters, were voted. The prosperity of the island greatly depending on sugar, the great fall which has of late years taken place in the value of this article has been severely felt in nearly all circles of the community. The question as to the price at which sugar can be produced here is a very vexed one, in view of the varying circumstances under which mills work in the different districts of the island. Mr. Vanden Berg, the President of the Java Bank, who has a wide reputation for the interest he takes in the welfare of this and other industries in the colony, lately collected statistics bearing on this point from all the districts of the island, and came to the conclusion that the crop of 1885 cost on an average 8fl. per picul of 136 English lb., or about the equivalent of 11s 6d per cwt. f.o.b. for No. 14. The present crop will, it is said, cost less owing to further economies having been introduced in the manufacture of the sugar. Turning from the average cost of production over the whole island to that of some individual mills, I may mention that in several well-authenticated instances this does not exceed 6fl. per picul, or about 8s 9d per cwt. f.o.b., while a cost of 7fl. per picul=10s 6d per cwt. f.o.b., is by no means rare. A marked development in the export of sugar to China has to be noticed, over 1,000,000 piculs out of the 1886 crop having gone to that quarter. The serah-sickness in the canes, to which allusion has been made in my last reports has not entirely disappeared, but the damage done during the year under review was trifling.

Leaf disease has again been prevalent in some parts of the island, especially in Middle Java, and some coffee estates have entirely succumbed to it, and have been abandoned. The yield has nevertheless been a very good one, compared with the preceding year, the production of the Government gardens having reached 816,932 piculs against 449,907 piculs, while the private

estates have also shown in many instances an important increase.

Exports of tea for the year, show a fair increase, the figures being 3,247,319 kilos, against 2,568,675 in 1885, but the industry generally remains very stationary. The importation of seeds from Assam has continued.

The area of land planted with cinchona on private account is estimated at 21,000 acres, and the number of trees at 30,000,000, of which about 14,000,000 are of the C. Succirubra species. The crop for 1887 is estimated at 1,433,250 lb. The average proportion of sulphate extracted from the bark is estimated to be about 3 per cent.

The export of Banca (Government) tin in 1886 was 3,235 tons.

IMPORTS.—Emigration of coolies engaged to work on the tobacco estates in Deli, Sumatra, has continued regularly throughout the year. For the first time gangs of labourers also left for Queensland, engaged under contract for the sugar plantations there. It looked at one time as if this traffic might assume considerable dimensions, but both the Governments of Queensland and of Netherlands-India appear to have regarded it with disfavour, and the latter have finally put a stop to it by publishing a decree in Jany. 1887, rendering criminal the engagement of natives for labour purposes outside Netherlands-India. I am not aware whether the labourers imported into Queensland from here have given satisfaction, but I should be inclined to doubt it. The resident peasantry who work on sugar estates here are still too well off to think of emigrating, and I fancy the coolies shipped to Queensland were not of a class to take kindly to the work.—*L. & C. Express*, May 27th.

WAVES UTILISED TO PUMP WATER.

S. B. Palmer writes to the *Scientific American*:—"I send herewith a description of a wave-operated force pump I constructed last summer, to supply my cottage with water, at Thousand Island Park, St. Lawrence River, N.Y. The water was delivered through a three-quarter-inch pipe, 200 feet, with 40 feet elevation to tank. The power was obtained from the momentum of the waves, which proved ample. The first method by which I endeavoured to obtain the power was by a float upon the water, which operated beautifully when detached, but when required to work very little power was developed. I then hung a shaft about six feet long, from supports anchored in cribwork as shown in the sketch, and from shaft suspended three arms, three feet long. Suspended from the end arms was a plank trough, six inches wide. Practically, the apparatus represented a six-foot wheel, like the paddle wheel of a steamer, with barely one bucket, and that having a trough-like section. A cross arm at right angles projected from the central arm, to which was attached the pump. The incoming wave would impart its force or momentum to the swinging pendulum, carrying it much or little, according to the size. It was a surprise to see how small waves could do work; that is, little swells, which would swing the bucket but a few inches, would deliver a corresponding amount of water, frequently in drops, rather than in a stream. Another lesson was learned by constructing the bucket 11 inches wide. At first, when a stream came sufficient to fill the bucket, there was not only a large waste of power, but great danger of destruction of the machine. Six inches proved to be the best width. For increase of power, increase in length is preferable. I am well aware that such apparatus might not be as practical as a wind-mill where heavy seas are liable to occur, as the construction of the piece to stand the shocks would be expensive. In this experiment the cost was not one-quarter that of a windmill, while the apparatus was out of sight."—*Sydney Mail.*

NEW ZEALAND WOODS FOR TEA BOXES.

Planters' Association of Ceylon,
Kandy, 16th June 1887.

To the Editor "Ceylon Observer."

SIR,—I beg to enclose for publication copy of a letter received from Mr. Haldane on the subject of New Zealand woods suitable for tea chests.—I am, sir, yours faithfully, A. PHILIP,
Secretary.

P.S.—With regard to the date of Mr. Haldane's letter I should explain that it only reached my hand a few days before the Committee meeting on the 10th instant, having been forwarded through a third party. A. P.

24, 25 and 27, Rood Lane London E. C., Feb. 1887.

To the Ceylon Planters' Association. Gentlemen,—I believe you experience considerable difficulty in obtaining suitable wood for tea chests. Since I left Ceylon I spent about two years in New Zealand and paid considerable attention to the timbers of that colony, many of which are very valuable, and some of them are well fitted for tea chests. To enable you to judge of the suitability of these woods, I send you a few small samples of some of the common timbers used in New Zealand.

The colonists are cutting down the fine native forests with a recklessness which is to be regretted, as in about twenty years more Kauri will be a tree of the past. The country has steam saw-mills wherever there is sufficient "bush" to keep one going, competition is keen and prices low. Most of the saw-mills are near the coast. I fancy Ceylon planters would get timber as cheaply from New Zealand as from any other part of the world, as the mills are large and powerful and will cut up logs seven feet in diameter; freight is the chief obstacle that I foresee.

There are two ways in which you could obtain timber from New Zealand. To charter one of the numerous Auckland schooners to run to Brisbane and discharge her cargo into the British India steamers—or from the South Island to Melbourne, and ship by the P. and O. steamers.

The following timbers are worthy of your attention:—

DAMMARA AUSTRALIS.—Kauri—the finest general timber in the Southern hemisphere. The wood is free from knots, straight, and works as easily as deal. The trees grow to an immense size, planks 12 feet in diameter being procurable. The present value of first-class boards and scantlings at the mills f. o. b. is 9s to 10s per 100 feet, and second-class boards 6s per 100 feet. Now the last are more sap wood than the former, and I think quite good enough for your purpose, and for 1 sper 100 feet extra, the mills would rip them up into lengths to the size of your boxes which would reduce the cost of freight. I send a sample of an ordinary kauri plank, cut out of a packing case. Kauri only grows north of latitude 38° s; weight 35 to 40 lb. a cubic foot.

DACRYDIUM CUPRESSINUM.—Rimu or red pine-grows to a height of 130 feet and 6 feet in diameter. The timber is clear, grained and solid. A handsome wood, of much value, and exceedingly valuable for many many purposes,—very plentiful in New Zealand. Grows in both the North and South Islands. Perhaps the best is obtainable about Wellington, where Mr. John Duncan could make shipments. I enclose a sample, if not too resinous this would be an excellent timber for your purpose. Good planks could be got for about 7s to 8s per 100 feet f. o. b.; weight 40 lb. per cubic foot.

PODOCARPUS DACRYDIORDES.—Kahikatea or white pine—very plentiful in both islands, grows to 150 ft. high with a diametor of 4 ft. or more. Timber white, tough and soft. It does not last well when exposed to wet, but is a good in door timber, well adapted for tea-chests; value of planks at the mills 5s 6d per 100 ft. f.o.b. Colonists use this wood for packing cases for their cheeses, &c. It warps little—is soft to work and weighs 30 lb. a cubic foot.—It grows abundantly on the Waikato River, where there are mills belonging to a Mr. Gibbon.

KNIGHTIA EXCELSA: REWAREWA (pronounced Rivirivi).—Grows to 100 ft., wood handsome and curiously flowered, splits easily and is used for shingles. Common about Auckland, would make good boxes or chests—weight of timber about the same as Rimu—a sample is sent.

PODOCARPUS TOTARA.—Totara—grows to 120 feet, with a diameter of 4 to 10 feet, wood durable with a clean grain, red in colour, resembling cedar and works very freely. Grows in both islands and is fairly abundant about Auckland, weight 40 lb. a cubic foot, value about 8s per 100 feet. I regret I cannot send a sample, but it is well suited for your chests as it is less thought of than Kauri.

LIBOCEDRUS DONIANA, KAWAKA.—Libocedrus Bidwillii Pahanted, known as "N. Zealand cedar." I send a sample, but am not sure of which variety. It is a free working wood of fine grain, the second variety being more brittle than the first. This is well-adapted for your chests, but I cannot quote the price.

DACRYDIUM COLENSOI.—Manvao, yellow pine—very durable, used for furniture. Grows in both islands.

PODOCARPUS SPICATA.—Black pine—common in the South Island, wood yellow, of close grain, weight 40 lb. a cubic foot. Is not so common in the North Island.

I think I have given the names of the most common woods, easily procurable which are suited for tea chests. Should you think of ordering a trial shipment I would advise you to have them all cut in lengths of one size for chests and half-chests. Your native carpenters would then only have to nail them together. This is such a simple matter, when French nails of drawn wire are used, that there would be no difficulty. If you want the sides and bottoms to be extra strong drive the nails diagonally. This increases the holding power of the nails very much. It is a good plan to do what I have noticed in Indian chests and have a triangular slip of wood nailed into the corners of each chest: this preserves the lead.

Mr. A. T. Anderson, late of Ceylon, is now a commission agent in Melbourne (his address is care of Gibbs, Bright & Co.). He could find out the cost of shipments *via* Melbourne both of New Zealand and Tasmanian timbers. Mr. Arthur Horsburgh Parnell, Auckland, New Zealand, would be able to help you about shipments from Auckland *via* Brisbane.

Should any order be sent for planks, I would advise the exact sizes being given, so that the sides and ends of the chests would be made of one piece of board. I do think this would increase the cost and it would facilitate putting them together on the estate and make a stronger chest, more waterproof than when two boards are used, and less likely to oxidize the lead by damp.

Of the New Zealand timbers I have mentioned, I think the following most likely to suit your purpose:

1. Kauri—Dummara Australis,
2. Kahikatea—Podocarpus dacrydioides,
3. Rimu—Dacrydium cupressinum,
4. Totara—Podocarpus Totara,

all of which could be got at Auckland and shipped from there to Brisbane.—I am, gentlemen, your obedient servant, (Signed) R. C. HALDANE.

THE FLORENTINE STRAW INDUSTRY.

An account is given in the report just issued by Consul-General Colnaghi, of the Florentine straw industry. It is stated that this industry was originally confined to the *Contado* of Florence, where it existed in the 16th century. From this district it gradually spread into other parts of Tuscany and of Italy. The industry appears, however, to have become of importance only at the beginning of the 18th century, when Domenico Michelacci introduced or perfected the culture of spring wheat (*grano marzuolo*), sown thickly, from which an excellent straw is obtained. The first experiments were made on the hills round Signa, and their success caused this culture to be quickly extended to the neighbouring districts. The industry now is so generally extended throughout the Florentine district, that there is scarcely a family in which some of the members are not engaged in this work. Children begin to plait at five and six years of age, while the mothers of families, in addition to their domestic occupations, and females of all ages and almost of all conditions, who do not follow the business as a means of livelihood, employ their leisure time in it. Formerly when the production was carried on by persons connected with agricultural labour only, the work was not constant, but now it goes on all the year round. In the cultivation and preparation of the straw, the seed used is carefully selected with regard to the nature of the soil in which it is to be sown. The quality employed is always a variety of spring wheat (*Triticum æstivum*). As the object of the cultivator is to produce a fine long straw, and not a full crop of wheat, all the usual conditions are reversed. Thus a spring wheat is sown in winter, a mountain variety on low lands; the seed is thickly instead of thinly sown &c. The thicker the seed is sown the finer the straw comes out. Straw is largely grown about Campi, Sesto, and Prato, in the plain between Florence and Pistoia, diminishing in quantity in the neighbourhood of the latter city. The cultivation is important between Florence and Empoli, principally on the south-west side of the Arno, on the plain, and on the hills commencing in the vicinity of Signa. In the principal centres of cultivation straw is grown on nearly every farm. Plots of land are also hired at a money rent for this culture. The seed is sown very thickly towards the end of November, or the beginning of December. The ground is dug up and manured in May, and generally sown with spring beans and the like, which are often dug in. About October the ground is ploughed for sowing, and at the end of May, or the beginning of June following, when the ear is beginning to swell, the straw is pulled up by hand, a sunny day being chosen for the operation. The straw is then made up into bundles containing as much straw as can be easily held in the hand, and these bundles are tied up with broom. The gross produce of a hectare of land, the hectare being equivalent to about 2·47 acres, is calculated, approximately, at from 19,000 to 20,000 *manate* or bundles. The next operation which the straw undergoes is that of being bleached, which is effected by exposure to the sun by day and to the dews by night. The bundles are spread in fan shape on a bare river bank of other open space, which must be entirely devoid of vegetation. After four or five days' exposure the straw will have acquired a light yellow colour. The bundles are then turned over, and the under part exposed in its turn for three or four days more, when the straw, after being well dried, is gathered in. When the dews are light, the process is slower but more perfect. In case of rain, the straw is at once heaped together and covered over to prevent it becoming spotted. The straw is now ready for manufacture, the first operation of which is the *spilatura* or unsheathing the ends, leaving only the inner portion to be worked up, this is generally done by children. When unsheathed, the straw is carried to the factories, and after having been slightly wetted it is first exposed to the fumes of sulphur in a tightly-closed room. The straw has next to be sorted according to its different thicknesses. This is done by means of an apparatus which consists of a series of vertical metal cones placed on a stand in a double row, and provided with movable copper plates perforated at their lower ends. The holes in each succeeding plate are a size larger than those in the preceding one. The numbers generally range from 0 to 13, but sometimes they run up to 20, 0 represents the finest stems. A bundle of straw being placed in the first tube of the series, a saltatory movement is given to the machine by means of a combination of cog-wheels, generally worked by hand. The finest straws pass through the holes of the plate, where they are suspended by the ear. The larger straws are then put into the next tube, and so on until the whole is assorted, a constant supply being maintained. The sorted straws which have passed into the holes up to the ends, by which they are suspended and prevented from falling through, are then drawn out by the ears and placed in separate receptacles. The first thing after assorting the straw is to cut off the ears, an operation termed *spuntatura*, which is done

by a special machine. Then follows the *spilatura*, or assortment into lengths, which is effected by placing on a table a small cylindrical tin case, open at both ends, and about eight inches in height, and eight inches in diameter, into which a loose bundle of the prepared straw is placed vertically. The operator sweeps his hand over the bundle, and draws up from it the longest straws which project above the rest. These he deposits in the first compartment of a table furnished with different divisions. He then draws from the bundle the next longest straws, and so on until he comes to the shortest. The straw is usually divided into five or six lengths for the finer kinds. The straw is of a better colour, more consistent and finer as it approaches the ear, the lower part, which is protected by an outer covering, being whiter and softer. Formerly this end was not used, but now it is employed for making all the articles that go under the name of pedal hats or pedal plaits. The sorted straw is next made up into small bundles, which are bound together in a large packet, the point or upper ends being placed upwards in two bundles, and downwards in the other two. The united packet is now laid under a cutter, and being divided through the centre yields four smaller packets, two of point and two of pedal straw, which are ready for the plaiter. The straw is given out to the plaiters either directly from the factory or through a factor, in bundles either sufficient to make a length of fifty yards of plait, or a hat as the case may be. Before being plaited, the straw is slightly wetted to render it more flexible. The hats are sewn either with waxed thread or with the fibre of a rush which grows on the marsh lands near Signa, and which is prepared for the purpose. On the plaits being returned to the factory, they are measured. The length being found correct, they are washed in potash water in order to whiten them, and occasionally they are cylindered to give them a polish. They are next wound upon a circular toothed frame of one yard in circumference, the teeth being to keep the strands of the plait evenly one over the other. They are then made up into packets of six or twelve pieces, or sometimes of twenty-four pieces, after which they are packed in cases for export. On the hats being brought to the factory, the loose straws are first cut from the brims, and any defects in the plaiting are made good by insertion, after which they are piled up on one another, and placed in large troughs full of potash water, in which they are pressed down by planks. They are then dried in the sun when the weather is fine, or in hot rooms when it is wet. The hats are then ready to be moulded into shape, which is effected by their being placed in heavy zinc moulds, and forced into shape by hydraulic pressure. They are next powdered with sulphur and polished with a small wooden instrument, and packed in cardboard boxes in dozens, and subsequently in wooden cases ready for export. According to the official trade returns, 1,000 cwt. of plaits and 3,399,000 straw hats were exported from Italy during the year 1885, chiefly to the United Kingdom, Switzerland, Germany, Austria, France, and North and South America.—*Journal of the Society of Arts.*

CEYLON TEA IN AMERICA.

(*From a Correspondent.*)

I send you a part of McCombie Murray's letter which he asks me to send on to you, and a specimen of his poetic advertisement. I also send you a paper with the letter regarding Ceylon Pure Tea and Coffee Company's teas &c. Pineo and Murray seem to be doing their level best and deserve encouragement :—

Philadelphia, 11th May 1887.

We are going ahead with Ceylon teas here as best we can with such a limited capital. The fine teas are much appreciated by some, but the souchongs are considered fit only to be thrown out. No one will drink them and we have to cater to the class of people that are willing to pay a good price for a really fine tea. We sent President Cleveland some tea the other day and had a very nice note of acknowledgmen from him in which he says, "We have tasted the tea and coffee, and we think the flavour of both very good." I send you by this mail the first evening paper of Philadelphia, which contains a letter regarding our teas. This letter has done much to further the sale of our goods, and people are getting interested slowly, but we hope *surely*. We have taken an office, and pack and sell in packets of 1 lb. and ½ lb. from the office. We have also some agents three in the city, one special agent in Tarrytown and one in Whitehall.

The trade generally will not handle Ceylon tea at all. It doesn't pay them to do so in any way whatever, and if Ceylon tea is ever introduced into America it must be through such an agency as ourselves, who are fighting for the one interest with the hopes of getting a monopoly until the tea becomes well enough known to *force* the general dealer to handle it. People who talk in Ceylon papers about introducing it through the regular trade talk *absolute nonsense*. If it had paid any New York firm to handle it, the Yankees are quite wide awake enough to grasp the great idea of introducing our teas through the regular trade. Strange that when Ceylon or Indian teas *are* put up in New York there is scarcely a bid for them, and that they are invariably sold at miserable prices. We have tried all the big houses of Philadelphia and they will scarcely give us a hearing. I wish some enterprizing correspondent would write to some American house on the subject, or better still, show how the thing can be done, by sending his tea here to some disinterested house on consignment! Let it be a man who is not very careful about seeing his money again and doesn't mind seeing his tea. [It is in Chicago and the West, where tea firms are not so wedded to the China trade, that a trial should be made.—ED.]

THE PRICE OF COFFEE.—The price of coffee has risen very considerably of late in Madras. About a fortnight ago, excellent coffee could be purchased in the bazaars at the rate of one rupee and eight annas a viss, but the price has risen so rapidly that a viss of coffee cannot be purchased at the present time for less than two rupees and ten annas. The bazaar men declare that the price will continue to rise till it reaches one pagoda (R3½) per viss, or R100 per maund! This rise in the price is said to be due to the large exportation of coffee to Burma.—*Madras Mail*, 9th June.

CEYLON TEA AT HOME—Having to stop an hour at Luton, yesterday afternoon, I strolled through the town and found a shop devoted solely to the sale of Ceylon tea, coffee and cocoa. I wondered whether your friends had any interest in the agency, otherwise than in the encouragement of Ceylon products, so I brought away some of their advertisements. I also bought quarter lb. of the tea which we have tried and found delicious, but I am not sufficient of a judge to say whether it is superior to China tea at the same price. I thought you might be interested to hear of the affair.—*Home Cor.*

DARJEELING.—This season has been rather one for flushes. We have had no lack of moisture, but so far there has been little heat. The winter was moist and cold, favourable for nurseries, young plants in extensions, and ought to be for checking the Red Spider (were that pest not indestructible), but unfavourable for burning of charcoal and brick-making; and at one time was so wet and cold as to delay the pruning. So far, the Spider shows less than in recent years but this is simply because we have had little of the weather needed to develope it,—bright hot sun, with showers. When the pest comes on late in the season, it is worse than coming early. Hail has been very severe, and has done much damage on several Gardens widely apart throughout the district, many between and near having entirely escaped, or almost so.—*Indian Tea Gazette.*

PRODUCTION OF PITA FIBRE IN HONDURAS.

Consul Burchard, of Ruatan, says that the pita plant called "silk grass," belongs to the same order as the pine-apple. It has never been cultivated, but is found growing spontaneously in the vicinity of the sea coast, on the margins of rivers and lagoons, and also on the highlands, below an altitude of 2,000 feet. It is very abundant and prolific, and it grows in patches of various dimensions, some of which contain not less than a hundred acres. When it takes possession of the soil it spreads rapidly, and kills all other vegetables except large trees. Each plant or sucker has from thirty to fifty stalks, which measure from five to twelve feet each in height, and from two to three inches in breadth. The fibre is contained in the centre of the stalk, in filaments running through its entire length. The outside bark covering the fibre is very hard and tenacious. The following is the method employed in extracting the fibre. The Indians place each stalk upon an oval slab, and scrape off the bark which covers the filaments with the sharp edge of a split bamboo. This is a slow and laborious process, which yields on an average not more than one pound of clean fibre a day to each man or woman. The Caribs keep the stalks in water until the bark becomes partially decomposed, when it can be rubbed off quite easily, but the process is said to injure the strength of the fibre. In recent years many attempts have been made by foreigners to extract the pita fibre mechanically, variety of machines having been invented for that purpose. Grants of territory and exclusive privileges have been obtained from the Government of Honduras to work the pita fields, and large sums have been expended in erecting machinery and other preparatory works. In every instance such attempts have failed, owing entirely to the fact that no machine or process has yet been invented that will extract the fibre from the pita plant on a scale sufficiently large to make it profitable. In Honduras the pita fibre is in general use for thread, especially for sewing boots and shoes, for nets, fish-lines, halters, and the best quality of cordage. Samples of this fibre, Consul Burchard says, have been sent to the United States and to Europe, which have been manufactured into a variety of articles such as handkerchiefs, laces, ribbons, wigs, false hair, &c. It is claimed that it can be successfully employed as a substitute for either silk or linen. The fibre is sold by the Indians in the backwoods, prepared in rolls or skeins of about twelve inches each, at a cost of about one shilling the roll. In the cities and towns of the interior it is sold in small quantities to shoemakers and others for about four shillings per pound. Consul Burchard, in conclusion, says :—"The cost of preparing pita fibre for market by the native system is too great, and the quantity prepared too small for it to become an article of export. With suitable machinery thousands of tons could be extracted from the wild pita fields of Honduras, and when these are exhausted, it could be cultivated with the greatest facility. There can be no doubt that this valuable fibre is destined to become a very important element in the future commerce and industry of this country."—*Journal of the Society of Arts.*

CARE OF BOILERS.

[*Compiled from Rules issued by various Boiler Companies.*]

1. SAFETY VALVES.—See these are ample in size, and in working order. *Overloading or neglect* may lead to disastrous results. Examine every day to see that they act freely.

2. PRESSURE GAUGE.—Should be at zero when pressure is off, and should shew same pressure as the safety valve when that is blowing off. If not, then gauge should be tested by one known to be correct.

3. WATER LEVEL.—See that water is at proper height. Do not rely on gauge glasses, floats or water alarms, but try the cocks. If they do not agree with water gauge, learn cause, and correct it.

4. GAUGE CORKS AND WATER GAUGES.—Keep clean. Blow off water gague frequently; glasses and passages to gauge should be kept clean. There are more accidents attributable to inattention to water gauges than all other causes put together.

5. FEED PUMP OR INJECTOR.—Keep in perfect order; no pump is continuously reliable without regular and careful attention. Safe to have two means of feeding boiler. Check valves, self-acting feed valves, examine and clean frequently. See frequently that the valve is acting when feed pump is at work.

6. LOW WATER.—Immdiately cover fire with ashes (wet if possible) or earth. Draw fires as soon as can be done without increasing heat. Neither turn on the feed, start, or stop the engine, or lift safety valve *until* fires are out, and the boiler cooled down.

7. BLISTERS AND CRACKS.—When first indication appears, there must be no delay in having boiler examined.

8. FUSIBLE PLUGS must be examined when boiler is cleaned, carefully scraped clean on both water and fire sides, or they are liable not to act.

9. FIRING.—Fire evenly and regularly, little at a time. Moderately thick fires are most economical; this firing must be used where draught is poor. Do not "clean" fires oftener than necessary.

10. CLEANING.—All heating surfaces must be kept clean outside and in, or there will be waste of fuel. Hand holes should be frequently removed and surfaces examined.

11. HOT FEED WATER.—Cold water should never be fed into any boiler if it can be avoided. When necessary mix it with the heated water before coming in contact with any portion of boiler.

12. FOAMING.—Check outflow of steam. If caused by dirty water blowing down and pumping up will generally cure it. In cases of violent foaming, check draught and cover the fire.

13. AIR LEAKS.—All these to boilers or flues, except through the fire, should be carefully stopped.

14. BLOWING OFF.—If water be muddy or salt, blow off a portion frequently; empty boiler every week or two, and refill. When surface blow cocks are used, often open for a few minutes. Make sure no water is escaping from blow-off cock when it is supposed to be closed. Examine cocks whenever boiler is cleaned. Never empty the boiler when brickwork is hot.

15. LEAKS.—When discovered, repair at once.

16. RAPID FIRING.—In boilers with thick plates or seams exposed to the fire, steam should be raised slowly, rapid and intense firing avoided.

17. STANDING UNUSED.—Empty and dry thoroughly, or fill quite full of water and put in quantity of common washing soda.

18. GENERAL CLEANLINESS.—Everything about boiler room should be kept thoroughly clean and in good order.—*Indian Tea Gazette.*

FIBRES:—ROYAL GARDENS, KEW.

(From the *Bulletin of Miscellaneous Information*)

BOWSTRING HEMP.—This at present is not an article in commercial use; but attention may well be directed to the capabilities of numerous species of *Sansevieria* for producing fibre of great value. Plants of *Sansevieria*, of which there are 10 or 12 species, are very abundant on both the east and west coasts of tropical Africa, which, indeed, may be looked upon as the head-quarters, of the genus. One well-known species (*S. zeylanica*) is indigenous to Ceylon; and this and others are found along the Bay of Bengal, extending thence to Java and to the coasts of China. The leaves of these plants are more or less succulent and abound in a very valuable fibre, remarkable [illegible] for fineness, elasticity, and for strength.

Usually the leaves are not more than 1½ to 2 [illegible] long; in some species, such as *S. guineensis* [illegible] *cylindrica* the leaves attain a length of 3 or 4 feet; while in one species, native of tropical Africa, the leaves under favourable circumstances attain a length of 9 feet. In this species, for particulars of which and for samples of its fibre, we are indebted to [illegible] John Kirk, G.C.M.G., Consul-General at [illegible].

the quality of the fibre is exceptionally good. We have doubtless here a new fibre plant of great value.*

In the treatment of the leaves of *Sansevieria* by machinery, the great drawback hitherto experienced has been their comparatively small size, and the difficulty of cleaning the fibre contained in them in an expeditious and remunerative manner. These circumstances would not obtain in the case of the plant brought into notice by Sir John Kirk. Indeed, for moist tropical climates, as opposed to the dry, hot, and arid districts of Yucatan where the Sisal Hemp is grown, this and *S. longiflora* if they are really distinct would be likely to prove of exceptional value as fibre plants.

It may be mentioned that all species of *Sansevieria* prefer a rich moist soil and a comparatively humid climate. They are essentially tropical plants and do not thrive in a temperature less than 60° Fahr. Under such conditions they grow rapidly and establish themselves permanently by means of large spreading fleshy rhizomes or underground stems. It is true they will grow in comparatively dry districts, and even in soils strongly impregnated with salt; but their growth under such circumstances is very slow and the leaves are seldom large enough to produce marketable fibre.

Dr. Roxburgh proposed that the fibres of Sansevierias might be called *Bowstring hemp*, because the natives of the Circars make their best bowstrings of them. On the other hand, small samples of fibre from *S. guineensis*, which have appeared in the London market, have been called African bowstring hemp. These fibres are very firm, hair-like and silky, and closely resemble those of the pine-apple; they are said to take dyes very readily; and the tow is mentioned by Royle to have been converted into good paper at Trichinopoly.

Plants of *Sansevieria* are already abundant in a wild or semi-cultivated state in most tropical countries. They are capable of being propagated very readily. Usually the underground stem or rhizome is divided and planted; but plants may also be raised from seed, or from the leaves, which latter, planted whole or cut into small pieces, readily take root in moist situations.

A full botanical description of the several species of Sansevieria may be found in a monograph of the ASPARAGACEÆ, in the fourteenth volume of the *Journal of the Linnean Society*, pp. 546-550, by Mr. J. G. Baker, F. R. S. The description given in the following notes are contributed by Mr. Baker. The species are restricted to those which are now under cultivation at Kew, and of which specimens of fibre have been prepared and examined. The plants may be seen in the West Transept of the Palm House at Kew, while the specimens of fibres are in Kew Museum, No. 2.

The species or well-marked sub-species, of *Sansevieria*,† of which we have living plants at Kew are seven in number, and they may be readily classified according to their leaves in three groups, as follows:—

I.—Leaves comparatively thin and flat:—

1. *S. guineensis.* 2. *S. longiflora.*
3. *S. Kirkii.* 4. *S. thyrsiflora.*

II.—Leaves semi circular in transverse section at the middle, deeply hollowed down the face:—

5. *S. zeylanica.*

III.—Leaves club-shaped, more like stems than proper leaves:—

6. *S. cylindrica.* 7. *S. sulcata.*

1. Sansevieria guineensis, Willd., is one of the two oldest and best known species. It was first figured and described, long before the days of Linnæus, in the year 1701, by Commelinus in his "Horti Medici Amstelodamensis Rariorum Plantarum Descriptio" (tab. 20), under the name of "Aloe guineensis radice geniculata foliis ex viridi et atro undulatim variegatis." Linnæus classified it under the genus *Aletris* and so did Jacquin, who figured and carefully described it in 1770 in his Hortus Vindobonensis, vol. 1., p. 67, t. 84. It has horny, erect, lanceolate leaves, 3 or 4 feet long, 3 inches broad at the middle, narrowed gradually to an acute apex, not distinctly bordered with red, copiously mottled on both surfaces with broad irregular bands of white. The flowers are in a lax, simple spike, which rises to the same height as the leaves, in clusters of three to six, with a whitish perianth about 2 inches long, of which the six segments are about as long as the cylindrical tube. It is a native of Guinea, from which we have wild specimens gathered by Barter and others. We have it also from Central Africa, collected by Schweinfurth and Grant, and Abyssinia by Beccari, and what is most likely the same from the Zambesi country, gathered by Sir John Kirk in 1860; the latter accompanied by a sketch made on the spot, when he was botanist to the Livingstone Expedition.

On the Zambesi *S. guineensis* appears to be called "Konje," and Sir John Kirk speaks of it as "yielding a valuable fibre similar to Manila hemp." It is described as "growing in great abundance in many places keeping to the shade of woods."

Mr. Horne, Director of the Royal Botanic Garden, Pamplemousses, mentions that—

"This plant thrives well in Mauritius in damp "marshy places in the lowlands. I have no doubt "that it would thrive well in the wet up-"lands."

It is widely distributed in the West Indies, and has been grown experimentally for the sake of its fibre at St. Thomas, Jamaica, and Trinidad.

As regards cultural treatment, the following information is taken from notes prepared by the late Director of the Botanical Department, Jamaica, on this and *S. zeylanica*:—

"In the first instance plants may be put out at "3 feet by 3 feet, which, allowing for roads and "paths, would give about 3,000 to the acre. If the "soil is kept well broken and moist, these plants, "by the extension of root suckers, will spread in "all directions, so that ultimateley the whole ground, "with the exception of certain paths, which should "be kept permanently open, will be covered with "plants. As regards the time which must elapse "between planting out and the first yield of leaves "suitable for fibre, there would appear to be a "great difference of opinion. Plants which I saw "at St. Thomas at three years old were only just "ready to be cut; and Baron Eggers, who had "planted them and kept them under close observ-"ation during the whole of that time, was of opnion "that Sansevieria plants could not be depended "upon to yield a crop before three or three and "a half years.

"My own experience coincides with this, but "necessarily much must depend upon the nature of "the plants when first put out, the character of "the soil, the amount of moisture received, as well "as on the system of cultivation pursued.

"From actual trial tests in India, where one-third "of an acre was cultivated with *Sansevieria* "*zeylanica*, it appears that full grown leaves of "three to three and a half feet long (their actual "age is not mentioned) yielded about 1 lb. of clean "fibre for every 40 lb. of fresh leaves. That is, the "weight of clean dry fibre was at the rate of 2½ "per cent. of the fresh leaves. Dr. Roxburgh calc-"ulated that one acre would yield 1,613 pounds "of clean fibre at a gathering, two of whcih may

* As to the identification of this plant Mr. Baker remarks as follows:—

"We have a specimen in flower from Buchanan, 'Shire highlands, Zambesia. Yields a most excellent fibre.' So far as can be judged by a rough sketch Sir John Kirk's is the same plant; and there seems no reason why it should not be identical with *S. longiflora*, Sims, in Bot. Mag. t. 2634, of which we have specimens from Guinea, Angola, &c."

† As regards the spelling, following the Genara Plantarum, we have adopted Sansevieria, instead of Sanseviera as being the oldest name. Thunberg had it Sansevieria; Willdenow altered it to Sanseviera, and Kunth followed. Bentham in Genera Plantarum reverted to Sansevieria.

"be reckoned on yearly, 'in a good soil and a favour-
"able season, after the plants are of a proper
"age.'

"This would be at the rate of 1½ tons of fibre per
"acre per annum at the end of three or three and a
"half years, of the gross value (at the rate of 30*l.* per
"ton) of 45*l.* Whether this return can be depended
"upon for the West Indies on an extensive area I am
"unable to say."

In an experimental trial carried on at Jamaica, 1,185 pounds of green leaves of *S. guineensis* yielded 29 pounds, 10 ounces of dry fibre. This was cleaned by machine. The reports of brokers were as follows :—(*a*) "Value, 18*l.* per ton, mixed fibre partly uncleaned ;"(*b.*) "Poorly cleaned a good deal of mixture in it, "not so strong, value about 25*l.* per ton ;" "(*c.*) No good in the state sent; it has a lot of bark "in it, and requires more dressing; both ends are "clean, but the centre is dirty. Price if dressed "properly, would be as good as *S. zeylanica*, viz., 30*l.* "per ton."

In September last, His Excellency Sir William Robinson, Governor of Trinidad, forwarded to Kew samples of fibre of this species, which he stated had been prepared "at the convict depôt at Chaguanas without the aid of machinery of any kind." The report of Messrs. Ide and Christie on the Trinidad sample was as follows :—

"In point of cleanness and softness of fibre it seems "well prepared; but to compete successfully with "Manila hemp it would require to be of a better "colour and of equal if not superior strength. We "value it for rope-making purposes at 20*l.* "per ton in London. The small piece of "Manila fibre which we enclose has a value to-day "(Sept. 24, 1886), of 31*l.* per ton."

A few leaves taken from plants grown at Kew were recently passed through Death's fibre machine, but the result, owing to the smallness of the quantity and the necessity of adjusting the machine to the size of each leaf, was not satisfactory, but it is not devoid of interest. The report of Messrs. Ide and Christie on the sample of fibre submitted to them was as follows :—"Short and only moderate strength. "Value 23*l.* per ton. We reported on fibre from "this plant from Trinidad in September last, when "we valued the sample at 20*l.* per ton. The difference "now is due solely to the advance in the price of "Sisal hemp."

Of samples of fibre of *S. guineensis*, the Kew Museums contain one specimen machine-cleaned from Jamaica, sent by Mr. D. Morris, 1884 with the following note :— "Leaves 3½ to 4 feet long, broader than *S. zeylanica*, "mottled, unarmed, common and easily propagated." A specimen from Trinidad, cleaned by hand, forwarded by Governor Sir William Robinson, and valued by Messrs. Ide and Christie at 20*l.* per ton. Also a leaf, rope, and fibre from S. E. Africa, sent by Mr. T. Baines. A specimen of leaf and fibre from Sir. John Kirk appears under the following label, "Maculated Sansevieria, called 'Konje,' near Lupata, 1860." This is probably identical with *S. guineensis*.

2. Sansevieria longiflora, Sims, a native of equatorial Africa, was first figured and described by Dr. Sims in 1826 at tab. 2,634 of the Botanical Magazine. The leaves are very like those of *S. guineensis*, but as grown with us, they are larger, flatter, not so firm in texture, and not invariably blotched with green. The best character by which it may be known from *S. guineensis* is the flower, which is 3½ or 4 inches long, instead of 2 inches. We have specimens in the Herbarium with flowers as large as this from Guinea gathered by Barter and Mann; from the Congo by Prof. C. Smith; from the Zambesi country by Mr. Buchanan; from Angola by the late Mr. Monteiro; from Niam-niam land by Dr. Schweinfurth. Whether all these are the same species it is impossible to say at present. There is also a large flowered species, called *Sansevieria bracteata*, which was gathered by Dr. Welwitsch in Angola.

In 1879 Sir John Kirk forwarded through the Foreign Office a specimen of fibre from the leaf of a species of *Sansevieria* found growing on the mainland opposite the island of Zanzibar. The specimen sent was the produce of a single leaf, the length of which was 9 feet. The report of Messrs. Noble on this specimen was as follows:—"We have carefully examined the "fire from East Africa; it is worth as a hemp 22*l.* "per ton at the present time" (1879).

Recently Sir John Kirk has been good enough to furnish more detailed information as regards the plant yielding this fibre, which leads us to conclude that it is probably *S. longiflora*, Sims. [*See* footnote, p. 50.] In a letter dated 2nd Dec. 1886 he mentions:—

"It grows abundantly near Pangane on the main-
"land opposite the island of Zanzibar and in the
"district between that and Mombasa, and is used
"by the natives to yield a long and useful fibre of
"which I sent specimens to Kew some years ago.

"The plant has flowered with me at Mbwéni in
"the island of Zanzibar, but the soil being too dry
"and sandy it did not succeed very well.

"The flowers are on a stalk crowded in a head,
"not racemose, or in a spike, as in another species
"common in the island. Unfortunately my flowering
"specimens rotted in drying, so that I have never been
"able to send home the inflorescence for identification.
"The leaves which yield the fibre are at first flat
"and clouded, but after a time the lower part be-
"comes much elongated, round and grooved on the
"upper side, the end only remaining flattened and
"not so mottled.

"It is a plant worth being introduced to our tropical
"colonies."

Several plants of this species are growing in the Palm House at Kew, from which it would appear that it is a very free growing and robust species. Some leaves from these plants were lately tested for fibre by means of Death's fibre machine, which yielded at the rate of 1·69 per cent. of clean dry fibre. The report of Messrs. Ide and Christie on specimens thus prepared was as follows:—"A very "bright, clean, strong fibre and in every way a most "desirable commercial article. It would compete with "the best Sisal hemp for rope-making purposes. "Value 30*l.* per ton."

There is little doubt that from the robust habit and size which this species is capable of attaining, that it is a most valuable fibre plant. As reported by Sir John Kirk, a single leaf of what we take to be the same species under favourable circumstances attains a height of 9 feet; and from one such leaf excellent fibre weighing ¾ oz. has been produced. This and other examples of fibre are in the Kew Museum, No. 2.

3. Of Sansevieria Kirkii, Baker MS., we know the leaves only, but it is evidently a distinct species. It was sent to Kew by Sir John Kirk in October 1881 as a native of the east coast of Africa. We have had it in cultivation at Kew since that time, but so far it has not flowered. The leaf is oblanceolate in shape, and very horny in texture. We have only grown it to a length of 2 feet, with a breadth in the middle of 3 inches. The leaf is dull green, with a distinct brown edge, and is much mottled on both sides. The base is much thicker, and its edges are more incurved than in either of the three other comparatively flat-leaved kinds, and down the back of the lower part of a leaf run about five distinct grooves, a character which distinguishes it readily from *S. guineensis* and *S. longiflora*.

Specimens of fibre prepared from *S. Kirkii*, yielded at the rate of 1·69 per cent. by weight of the green leaf. They were described by Messrs. Ide and Christie as follows:—"Rather stout, but very clean "and good colour: the strength fair. Value 27*l.* per ton."

4. Sansevieria thyrsiflora, Thunb., is the species on which the genus Sansevieria was first constituted by Thunberg, in the year 1794. The leaf is nearly flat and does not reach above a foot or a foot and a half in length, and is an inch and a half or two inches broad at the middle, with abundant mottling and a distinct red edge. The flower does not differ from that of *S. guineensis*. It is a native of the eastern parts of Cape Colony. Zeyher

gives the place of growth as "Uitenhage, in woods "of Zwartkops and many other places in the east "of the colony; *Kei* of the Hottentots; a decoction "of the root used for dysentery."

The leaves of this species, growing at Kew, were too small to be tested for fibre.

5. Sansevieria zeylanica, Willd., is a very well known and well-marked plant. It is a native of Ceylon, and, long before Linnæus, was figured and described by Royen, Commelinus, and Pluknet. There are 8 or 10 leaves in a tuft and they are semi-circular in transverse section, 1 or 2 feet long, rounded on the back, deeply channelled down the face, ½ or ½ inch thick in the middle, in colour dull-green, copiously banded with white, with a distinct red margin. The peduncle and flower spike are each about a foot long, the flowers being rather smaller than in *S. guineensis*, but quite similar in structure. It is well figured in Rédoute's Liliaceæ tab. 290, and in the Botanical Register, tab. 160, in the year 1816.

In Ceylon this species is known under the Sinhalese name of *Neyanda*. It is indigenous to the hotter parts of the island, and the fibre yielded by it is used in numerous ways, such as strings, ropes, mats, and of coarse kind of cloth. In India the plant is known as *Moorva*, *Moorga*, or *Marool*. Sir William Jones, in the Asiatic Researches, Vol. IV., p. 271, mentions *S. zeylanica* under its ancient Sanscrit name of *Moorva*, and he says that: "From the leaves "of this plant the ancient Hindoos obtained a very "tough elastic thread called Maurvi, of which they "made bowstrings; and which, for that reason, was "ordained by Menu to form the sacrificial zone of "the military class." Dr. Roxburgh describes the plant as common on the jungly salt soils along the coasts, growing under the bushes, and easily propagated on almost every soil, from the slips which issue in great abundance from the roots, requiring little or no care, and not requiring to be renewed often, if at all, as the plant is perennial. The leaves, when thus cultivated, are from 3 to 4 feet long.

Mr. Horne makes the following note on this plant at Mauritius:—

"Several species of Sansevieria are common here in "waste lands, near the sites of old gardens, and by "the road sides. They are not so readily nor so "cheaply established on land as the *aloes vert.* "But they yield a good fibre, which is used for "cordage &c. It has the reputation of being one of "the strongest of fibres. It is known by the name of "*Bowstring hemp* and *Moorva*."

Generally in Ceylon and India the natives prepare fibre from this plant by retting or by simple beating and scraping. Full grown leaves yield at the rate of 7·87 per cent. by weight of the green leaves. Owing to the smallness of the individual leaves they are difficult to clean by machinery, but if it were possible to separate the fibre by a chemical process, this plant would become of great commercial value.

Of samples of *S. zeylanica* fibre the Kew Museums contain one specimen from Ceylon, sent by Dr. G. H. K. Thwaites, under the name of Neyanda fibre; one labelled Moorga or Bowstring hemp, from Jamaica, from Mr. D. Morris, 1884, with the following note attached:—"Longest leaves 3½ to 4 feet long, narrow, "mottled, unarmed, very common, and very easily "propagated either by root, suckers, portions of the "leaf, or seed." There are also samples from the Botanic Garden, Mauritius, sent by Mr. Duncan; from Mysore, obtained from the India Museum, besides rope and twine from Balasore and twine from Cuttack, likewise from the India Museum; a Sinhalese whip and nose strings for harnessed bullocks from Kandy, sent by Mr. J. A. Ferdinandus; a sample of paper half stuff from the India Museum; and some fibre, dyed in two colours (red and blue), from Madras by Dr. Hunter.

Samples of fibre of *S. zeylanica* prepared at Jamaica by machinery in 1884, were described as follows by London brokers:—(*a*) "Beautiful fibre, rather heavy "and hard, might be whiter, value very uncertain, "20*l.* to 30*l.* per ton;" (*b*) "Rather dull in colour "and short in growth, fairly well cleaned. Value "about 30*l.* per ton;" (*c*) "Might be whiter. It is "almost too good for roping purposes. Worth about "30*l.* per ton."

6. Of Sansevieria cylindrica, Bojer, an excellent figure and a full account by Sir William Hooker will be found at tab. 5,093 of the Botanical Magazine. It is a most distinct and curious looking plant. The leaves are cylindrical, round in horizontal section, faintly sulcate all round, especially in the young state, obtuse at the end, arching, reaching when fully developed a length of 3 or 4 feet and a thickness of about an inch. The peduncle is about a foot long; the raceme much longer, with clustered cylindrical flowers just like those of *guineensis* in structure, but only about an inch long. It is spread across South Africa from Zanzibar to Angola. Our Kew plants were received by the Foreign Office from Angola in 1859 under the name of Ifé, and an abundant supply of its fibre and ship's cables and other ropes manufactured from it were shown in the Portuguese Department of the Paris Exhibition in 1858.

In the description attached to the figure of the plant in the Botanical Magazine mentioned above, Sir William Hooker adds the following particulars:—

"About three years ago (that is in 1857) there "were received at the Foreign Office, and transferred "to the Admiralty, samples of a peculiar fibre and "cordage under the name of Ifé, said to be derived "from a new plant at the Portuguese Settlement, "Angola, west coast of Africa. These were accom-"panied by some apparently living plants, which "were placed in the cellars of the Foreign Office, "and by the kindness of our valued friend, G. "Lenox-Coningham, Esq., forwarded to Kew, where "they soon recovered, and have since flowered. The "habit of the plant was that of *Sansevieria*, but the "leaves very dark-coloured, and quite terete and solid "in the interior, very unlike any known species of "that genus. My duties at the Paris Exhibition of "1855 led me to the careful investigation of the "vegetable products, and I was there agreeably sur-"prised to find most extensive samples, in the Portu-"guese Department, of the raw material fibre, and "manufactured articles, ship-cables, rope, beautiful "cordage, &c., of the same material, and amongst "'The Products of Angola,' it is thus stated in my "'Report':—'*Fibre* marked, from *Sansevieria ango-*"*'lensis*, this latter being a MS. name of Dr. Wel-"'witsch for a remarkable species of *Sansevieria*, "'with long, stout, terete leaves, which is in cult-"'ivation at Kew. The cordage and rope made of "'this plant appear to the eye of excellent quality, "'whatever experience may prove them to be.' Ex-"periments recently made with this cordage have "shown it to be the strongest and best fitted for "deep-sea sounding of any fibre known; indeed this "is the less surprising, seeing that other species of "*Sansevieria* (the well-known *S. zeylanica* and *guineensis*, "for example) are cultivated in almost all tropical "countries on account of the strength and durability "of the fibre, under the name of *Bowstring Hemp*."

Of samples of *S. cylindrica* fibre in the Kew Museums there is one specimen from Mauritius, sent by Mr. Duncan; fibre of the Probo and rope and cordage made from it, probably *S. cylindrica*, Sierra Leone, Commodore A. Eardley Wilmot, H.M.S. "Rattlesnake." The following note accompanies this specimen:—"Grows abundantly, can be easily pro-"pagated." There is also a specimen labelled Mokhosi fibre and leaf, probably *S. cylindrica*, used for making cordage, &c., marked S. E. Africa, T. Baines, Esq.

Specimens of fibre prepared from plants growing at Kew, by Death's fibre machine, were described by Messrs. Ide and Christie as follows:—"This is the "second best fibre amongst the samples sent, and except "that it does not appear as strong, it is almost equal "to *S. longiflora*. Value 28*l.* per ton."

7. We have at Kew a dried specimen, as well as living plants, of S. sulcata, which appears to be an unpublished name of Boger's. The plants, probably from East Africa, have never flowered, but in leaf character they are very similar to *S. cylindrica*,

Under cultivation they are shorter and more slender, with rather deeper vertical grooves, but no bands or markings. A small sample of the fibre of *S. sulcata* was prepared, and the broker's report upon it was as follows:—"Similar to fibre of *Furcræa cubensis* "and of about equal strength. It is, however, cleaner, "and would also compare with Mauritius hemp. Value "26*l.* per ton."

It is quite possible that other species of *Sansevieria* may be found in tropical Africa, whilst some more or less distinct may be under cultivation in colonial gardens. The illustrations given on page 3 of this Bulletin will assist in the determination of the species mentioned here. Specimens of any others will be gladly accepted for the Kew collections.

In his synopsis of succulent plants, Haworth described briefly a number of additional species of *Sansevieria*, which are now lost to cultivation, so far as we are aware, and of which no figures or dried specimens are known. It is not improbable that there are many more types in existence than we possess materials for individualising or recognising at present. Of plants once in cultivation which Haworth briefly notices, we should be glad of information or specimens of the following: *S. lætevirens*, *S. ensifolia*, *S. glauca*, *S. polyphylla*, *S. grandicuspis*, *S. pumila*, and *S. fulvocincta*.

As regards machinery for the extraction of fibre from these plants, the subject is one which lies outside the scope of the *Bulletin*. Machinery is in use in Yucatan and Mauritius for the extraction of fibre from *Agave* and *Furcræa* leaves, and machines are said to be made suitable for the treatment of leaves, of *Sansevieria* and others. We cannot do better, however, than refer to the literature given on this subject in Spon's Encyclopædia, Div. iii., pp. 923-930.

In the chemical extraction of fibres from plants there are several methods under experimental trial, some of which may prove ultimately successful.

CLIMATE AND CULTIVATION IN TEXAS.

In a report on the trade and commerce of Texas during the year 1886, the British Consul refers to the present state of the trade in cotton seed as follows:—"Cotton-seed oil is a great export staple of Texas and other cotton-growing States, from which it is sent to Europe, chiefly to Italy, where it is refined, bottled, and sold all over the world as olive-oil, for which it really forms a wholesome substitute. Cotton seed was, therefore, not long ago a profitable article to the cotton farmers, but a syndicate has recently been formed under the name of the American Oil Mill Company, which has bought up nearly every oil mill in the Southern States. They have, in consequence, already run down the price of seed from 7 dols. 50 cents, the normal figure, to 5 dols. per ton, while they have run up the price of oil from 28½ cents (1*s.* 2½*d.*) to 40 cents, or 1*s.* 7½*d.* Having purchased the mills, they close down such of them as are not convenient for their operations, and thereby lessen the rates of labour and expenditure, while they contrive to break down such opposition mills as hold out for a time by paying high prices for oil-seed."

In a description of the climate and soil of Texas the following interesting notes occur:—Northern and Central Texas contain the best farming and orchard land in the State, with a good rainfall, in consequence of the proximity of the hills and forests of the Indian territory; there are also numerous creeks and rivers. Eastern Texas is in great part covered with Pine forests; there is a fair rainfall, and the soil though sandy, is fertile, the drawback to farming more or less throughout the State, but especially in South-western Texas is the prevalence of long spells of dry weather, which, since the felling and clearing of large tracts of forest in the interior, are undoubtedly on the increase. Texas is in the same dgree of latitude as Algeria, Syria, Southern Persia, &c., and the climate will, no doubt, eventually become, at any rate in the South and west, much what it at present is in the above countries—afflicted with dry, hot summers, little or no rainfall, and agriculture entirely dependent on artificial irrigation. Irrigation has hardly been attempted as yet in Texas, though at least half its area is practically unfit for cultivation without it. Another climatic defect is the "northers"—cold piercing winds of the nature of the *mistral*, which suddenly descend during the cold months from the Rocky Mountains, often causing serious destruction both to vegetation and to live-stock. These "northers" will kill off all but the very hardiest subtropical vegetation, so that although the mean temperature of the climate for the year round is very much higher than that of European and Asiatic countries where the Orange, Lemon, Date, Pomegranate, Fig, Citron, &c., perennially flourish, these fruits can hardly be grown in Texas, the trees being continuously killed off by frosts. On the other hand the heat is too great for the fruits of temperate climates (except far to the north) such as the Vine, Apple, Pear, &c.

In January, 1886, a "norther" set in which in a few hours sank the temperature 45°. Galveston bay long before morning was a sheet of solid ice for many miles. Fishermen were frostbitten in their boats, and in two or three instances actually frozen to death. This frost killed every subtropical tree or shrub, Orange, Lemon, Oleander, Date, &c., in and around Galveston, and temporarily ruined the entire Orange industry in Florida for 4° or 5° to the southward. Cattle died of cold in thousands all over the country. Southern and Eastern Texas have this year (February, 1887) suffered from a prolonged drought, no rain to speak of having fallen for nearly two months; and were it not for heavy dews, fogs, and mists which have set in occasionally, every blade of grass would have been burnt up. The climate of Texas is perpetually in extremes either of heat or cold, damp or dryness.—J. R. JACKSON.—*Gardeners' Chronicle.*

COCA.—It is reported that Coca leaves (Erythroxylon Coca) are becoming a recognised article of export from Peru, a demand having "sprung up for them for the manufacture of Cocaine, now so much used in surgical operations for killing pain." The quantity exported from Mollindo during the year amounted to 705 quintals, valued at 17,625 dollars.—*Gardeners' Chronicle.*

COFFEE CULTURE IN RIO JANEIRO.—Reporting on the general state of the province of Rio Janeiro, the British Consul thus speaks of the Coffee crops. The tree, he says, is found growing in almost every part of the province—in the plains as well as in the highlands. The principal plantations are situated in the Cantagallo range, in the lands in the vicinity of the Parahyba River, the bed of which is from about 900 to 1,050 feet above the level of the sea, at Commercio, Uba, Vassouras, and other places. The trees are there planted on the sides of steep hills. The Coffee blossoms from August to October according to locality, and is picked in March and April. A hectare of land is supposed to contain some 918 Coffee trees, which yield from 675 to 2,000 kilos, according to the fertility of the soil. In the districts of Cantagallo, S. Fidelis, and other parts, for some years past, the Coffee trees have been subject to a disease manifested firstly in the yellowness of the upper leaves, and afterwards in the shoots, the trees soon drying up. In this way about one-tenth part of the trees in the above-named districts have perished. This disease is supposed to be propagated by an insect which lives in, and feeds on the, roots. It deposits its eggs in the knots of the roots causing the fibres of the same to rot. On this the eggs are seen, having the shape of Mushrooms. This generally takes place in the heaps of weeds or grass which rot at the foot of the trees, forming a fine soil for the new root fibres. As a remedy against this evil it is recommended by Dr. Glazio that the weeds and grass should never be heaped up to rot near the roots, but should be left to be dried by the sun and afterwards brought together and burned. The Orange trees are also subject to be attacked by the same plague. Dr. Glaziou is convinced if this rule be attended to that in two years' time the Coffee estates will return to what they were formerly.—*Gardeners' Chronicle.*

LONDON TEA COMPANIES.

Wilton Tea Company of Assam, Limited; capital (paid up), £28,000; area under cultivation, 735 acres. The crop of tea was 3,499 maunds 10 seers, or 279,940 lb., and was made at a cost of 9½d per lb., and sold at an average of 1s 0⅝d per lb., giving a profit of 2⅛d per lb. Seeing that the average price of tea was in 1886 fully 2d per lb. lower than in 1885, the result of the year's working may be considered satisfactory, and reflects credit on the management of the superintendent, Mr. Hannay. The estimated out-turn for the present year is 3,757 maunds or 300,560 lb. of tea, at a garden cost of 4 annas 6 pies per lb., or slightly under that of last year. The following figures are interesting, as showing the gradual improvement in the working of the company's property:—

Season	Cost of Manufacturing Per lb. s. d.	Price realised Per lb. s. d.	Loss Per lb. s. d.	Profit Per lb s. d
1883 ...	1 1⅝ ...	1 0½ ...	1⅛ ...	—
1884 ...	0 11½ ...	1 0 11-16th	— ...	1 3-16
1885 ...	0 10 2-5	1 1-3 ...	— ...	2 14-15
1886 ...	0 9½ ...	1 0⅛ ...	— ...	2⅝

Total Loss, Season 1883	...	£1,119	8 0
„ Profit, „ 1884	...	1,159	1 0
„ „ „ 1885	...	3,162	12 8
„ „ „ 1886	...	3,082	16 8

During the past two years the drainage of the gardens has been undertaken on an extensive scale, the old gardens at Wilton needing it most. The drains are connected with the neighbouring river, and the work is being carefully carried out, and the superintendent states that when the whole of the drainage is completed he hopes to reach an average yield of six maunds per acre from the plants in full bearing, and if this is realised it will still further reduce the cost of manufacture. The number of coolies now on the gardens is 428 men, 334 women, and 95 children, equivalent to 809 statute adults.—The Jokai (Assam) Tea Company, Limited; capital, £120,000, in 12,000 shares of £10 each. Out-turn.—The crop estimates and actuals for the past season were:—

	Estimated lb.	Actual Out-turn. lb.
Bokel Division ...	264,000	269,065
Jokai „ ...	100,000	80,327
Muttuck „ ...	144,000	165,208
Jamira „ ...	172,000	193,380
Total...	680,000	707,980

Being an increase of 27,980 lb. over the estimate, and of 57,662 lb. over the yield of the previous year.

The entire crop, less 520 lb. lost in taring, &c., being 707,460 lb. was sold in London, reaziling, with the sale of seed, a gross sum of £35,044 12s 6d. or an average per lb. of 11·89d, showing a decrease on last year's average of a penny per lb.

The gross average price per lb. with cost of production and the profit realized in each division is shown in the subjoined tabular statement:—

	1886. s. d.	1885. s. d.	1884. s. d.	1883. s. d.	1882. s. d.
* Bokel Division	1 1·06	1 0·27	0 11·55	1 0·58	1 0·58
Jokai „	0 10·87				
Muttuck „	0 11·23	1 0·81	1 0·80	No returns, teas being sold at Calcutta.	
Jamira „	0 11·27	1 1·90	1 2·73	1 1·04	1 0·04
Average of the whole	0 11·89	1 0·91	1 0·76	1 1·02	1 0·20
Cost of production	0 9·23	0 10·56	0 10·53	0 11·95	0 11·00
Profit per lb.	0 2·66	0 2·35	0 2·23	0 1·07	0 1·20

The large sum of £5,975 0s 11d was expended during the year in importing labourers and in the supply of additional or improved machinery. The board believes that there are no other estates in Assam better found with labour, machinery, buildings and appliances of every kind, than the properties of this company.

* This division, it should be borne in mind, was formerly known as the Jokai, but was divided last year, the smaller portion retaining the original name.

Estimates.—The abstract of the detailed revenue estimates for the current year indicate a crop 720,000 lb of tea, for an expenditure of R252,625 in India, or £18,947, at 1s 6d rate of exchange, and of £7,353 for English charges, making together a total of £26,300, or an average cost of 8·76d per lb. for laying down the tea in London, including administration, sale charges, &c. Market.—As anticipated by the Board in last year's report, a considerable fall took place in the general value of Indian tea. The consumption having, however, lately outgrown even the enormously increased production, the fall has been checked, and the value of the article during the ensuing season is not likely to be materially less than in 1886-7.

Dooars Tea Company, Limited; capital, paid up, £106,000; area under cultivation, 3,080 acres.

There were in 1886, 690 acres of tea in full bearing, and 2,190 acres of younger plant; and, as the permanent value of the company's shares must depend mainly upon the young tea, every effort has been made, with success, to maintain and develop this cultivation. The capacity of the company's gardens to yield eight to ten maunds an acre, and to deliver tea in Calcutta at less than 6d. per lb, has been proved. These results guarantee future prosperity. Cholera appearing with terrible severity at the main garden, in the height of the manufacturing season, reduced and disorganised labour, so as to greatly diminish the out-turn, and spoil the quality of much of the tea. Fortunately, such outbreaks are rare. Further, the tea market was unusully depressed, and the season of excessive rain and deficient sunshine was unfavourable for manufacture. Thus through exceptional circumstances, the company has had to meet a short out-turn, combined with low prices. But though the out-turn was shorter than anticipated it was 140,253lb, more than in 1885. The expenditure of 1886, has been well within the sanctioned estimate. Turning to 1887, the general superintendent's estimate contemplates an expenditure on revenue account of R253,080 for an out-turn of 760,000 lb., or more than 200,000lb. increase for the year.

From these figures it is further apparent that 2,880 acres now under plant, will be five years old and upwards in 1891, and taking an average of only seven maunds, will yield 1,612,800 lb of tea. The latest report for the current season are reassuring. The weather and other conditions have proved propitious, and the out-turn of tea is well in excess of that for the corresponding period of 1886. —*H. & C. Mail*, May 27th.

NOTES ON PRODUCE.

The position of the Indian tea industry, at least those concerns which are judiciously managed, has never been brighter than now, and shareholders as well as directors and managers of gardens have reason to congratulate themselves. With but few exceptions good dividends are anticipated, and it is surprising that in view of the handsome returns made by economically managed concerns, the shares of some companies are not quoted higher. When the investing public begin to realise the prospect, something like a rush for tea shares will take place.

As an illustration of the wild theories which respecting the manufacture of tea, possess the minds of some grocers, the following letter, which was printed in the *Grocer* of last week, is some indication. The correspondent asks, why does Ceylon tea deteriorate, and he then embarks on the following: "In the interests of our trade I wish to call attention to this question. Now, I hold that it is not so much the production or growth of tea but in the method of curing that the fault lies. The method most generally used in Ceylon is most diametrically opposed to those in other parts of India and China, where they almost universally adopt the method of firing tea by means of atmospheric air passing through glowing charcoal, thus forming what is called 'carbon dioxide,' and we never hear of tea cured in this way losing strength and flavour after the packages have been opened as we

do in the case of Ceylon teas. Now, it is admitted that Ceylon tea does deteriorate when opened. And why? Because I believe the method of curing is wrong. They cure principally by pure (not atmospheric) air in machines made for the purpose. Another way, I believe is largely adopted that is, by passing atmospheric air through machines and cast-iron pipes heated to redness in a furnace, thereby impregnating the tea with fumes of sulphur, phosphorus, and other impurities which are to be met with in red-hot cast-iron, producing an inferior quality of tea, dangerous to the public health. Now, sir, if these statements are worth anything I feel sure that some of our connoisseurs of tea will not hesitate to express their opinions on this matter, and I invite their criticisms upon the different methods of tea-curing. I contend that the charcoal system is the right way, and if it can be made clear that such is the case, I believe we should very soon have as good quality teas imported from Ceylon as from China and Assam."

Now that China teas at the movement are beginning to claim attention, says the *Grocer*, it may be worth while to point out that, the time was when nothing but feverish excitement marked the commencement of the new crop season in China, and almost fabulous prices were paid to make sure of getting the earliest "settlements" away by the first ship for London, but when the teas arrived here the result of the sales in Mincing Lane was more or less disappointing; and the depression experienced on this side, it also, at last, felt in China. Teas from that quarter are now exceedingly cheap—in fact, some authorities say that they never were so low in prices as they are at present, for, although there was a material rise in Jannary last, it has since disappeared, and existing rates are down again to the extremely reduced point at which they stood in December last. In the ensuing season, China teas will be less able to compete with Indian makes than before, and instead of occupying their old position as the premier teas of the world, they will probably have to make room, more clearly than hitherto for the attractive productions of India and Ceylon.—*H. and C. Mail* May 27th.

ON THE PREPARATION OF "PHOSPHATE OF QUININE,"

(*From Mr. John Hughes.*)

It must be most disheartening to planters to notice the continued fall in the value of Cinchona Bark in the home market which has been going on steadily for some time, and with but small hope of any substantial rise.

The only possible way in which a remunerative return for the lower qualities of Bark can be hoped for, is by setting up a local factory in Ceylon for the extraction of the valuable alkaloids on the spot by a simple and economical process.

From some experiments that have been made on a small scale under my own personal inspection, I believe it could be done without any great expense. Hitherto it has always been considered necessary to employ either Sulphuric or Muriatic Acid for the extraction, but according to my experiments concentrated Superphosphate made by dissolving pure Mineral Phosphate of Lime with Sulphuric Acid, will answer equally well and, moreover would yield a much more valuable material than the ordinary Sulphate of Quinine.

Phosphates are extremely recommended by the medical profession as specially useful in many cases of nervous weakness and debility, and is, consequently, frequently used in conjunction with Quinine Sulphate, so that if we had the two important constituents combined in one preparation, it would not only be a great advantage but would really furnish a new medicinal preparation for which there would be a special demand.

The process of extraction would consist in treating the finely ground Bark with hot water in which a small quantity of the concentrated Super. had already been dissolved. The whole mass which would become quite a paste upon concentration, must then be pressed in bags (as Linseed and Cotton seed are treated) and the liquid extract refined, as may be considered necessary and further experience might suggest. The Indian Government are making a medicinal preparation with the ordinary acid which is of course a dangerous material to transport from place to place, and the freight of it is as a consequence very high.

But concentrated Super., could be sent in double bags at a low freight by sailing vessel and without any risk of damage to other goods.

The matter is well worth the consideration of local merchants and planters who will really understand that the first advance in the direction of a local factory for Quinine preparation, must come from themselves as the interests at home are naturally quite opposed to such a development of Colonial enterprise. I am not aware that Superphosphate has ever been recommended for the extraction of Quinine and have much pleasure in bringing every proposal before your readers. —JOHN HUGHES, F.C.S., Analytical Laboratory, 79, Mark Lane, London E. C., May 13th, 1887.

[We commend this suggestion to the serious consideration of the several Planters' Associations in the island.—ED.]

CEYLON UPCOUNTRY PLANTING REPORT.

TEA IN THE LOWCOUNTRY—A NEW TEA COMPANY—A PROOF OF THE STABILITY OF TEA IN CEYLON—MALABAR AND MYSORE CARDAMOMS—BLACK BUG DESTROYING COFFEE.

20th June, 1887.

The Southern Province is evidently determined not to be behind any of the other districts in regard to tea growing. Whatever wiseacres may say relative to the possible want of lasting qualities in lowcountry tea, or however dilate on the poverty of the soil, there are always to be found other wiseacres who dispute the conclusions. "Why should n't it last?" is their reply; "the thing grows in the air, and is bound to grow with all that heat and moisture. Did *you* ever see good soil in the lowcountry? *I* never, and yet we know what it has already done." The question is, who is to decide? The man who does not believe in tea in the lowcountry won't plant it, the man who does will. As to whether the tea will last, or how long the soil will support a regularly cropped tea bush, are matters which will in time settle themselves. A man may look wise and give his opinion, but what is it worth? When I hear of unfavourable forecasts regarding an untried or partially completed tea experiment, my mind will revert to one who had to do with the opening of "Mariawatte" as a tea garden, and who declared that the owners were simply burying their money in a sandhole!

There is a block of land some 3,000 or 4,000 acres in extent in the Udagama district near Galle, owned by Messrs. S. Agar and Baker & Hall, and of this 500 acres are about to be opened at once in tea and the proprietors purpose starting a new Company in connection with it. I understand the concern is to be called "The Tea Company of Ceylon, Limited," and the shares are to be R100 each. The proprietors are prepared to part with their whole property at R25 an acre, and as usual take part payment in shares. There is said to be lots of good timber about,

and plentiful water carriage. It is not quite decided as to whether the Company will be floated here, or in London, but as there are already several applicants for shares on the ground, and more may be expected when the prospectuses are issued, very likely there will be sufficient local capital found, without going further afield.

By the way, as an indication of how other tropical planters regard tea as an investment, I hear that a wealthy tobacco-grower who paid a visit to Ceylon the other day and saw what was being done was so favourably impressed, that he purposes investing largely in tea property.

Cardamoms of the Malabar variety have proved so uncertain, that acres of them are being dug out in the northern districts to be replaced by the upstanding Mysore. Over the Malabars in many places there has come a blight, and as the other variety seems hardier and less liable to insect attacks it is fast driving out the weaker kind, and the growers are more sure of a steadier return. What coffee has come to in Ceylon is manifest from the fact that one family I heard of who has connections in Southern India found the procuring of coffee in Ceylon for bungalow use so difficult that it has taken to import it from the Indian estates.

Black bug still lies in wait, and depresses and destroys. Men who were hopeful a little while ago of doing well with their coffee speak less hopefully today. It is surprising how quickly and quietly black bug causes a crop to disappear. The bug seems to be decreasing, and if you have not been observant you may fancy that what was set at the beginning of the attack is there still. But alas: a large portion of the promise is gone, and what is left is much deteriorated. I see every now and again in your columns a cry, "Can't something be done?" This has gone up from every district through which the pest has past, and there is something pathetic to find it still echoing on. Those who have been smitten have succumbed or recovered; they are now busy with the newer products, but they feel how hopeless all help is to combat this plague, and that to fold the hands and wait seems about all that can be done.

PEPPERCORN.

CEYLON TEA IN AUSTRALIA.—Mr. D. W. Campbell, formerly of Ceylon, writes to us from Sydney, N. S. W., under date 31st May:—"Ceylon Tea pure and unmixed with China stuff is beginning to be appreciated here, and in time, I believe, a good trade will be established here, as once they get a liking for it people will drink *no other tea*. New South Wales is having a very hard time of it just now, but with the fine seasons we are having, no doubt, trade will revive again. I would very much like to see the country going in for agriculture more than they do as I thoroughly believe it to be the backbone of success in all countries and N. S. W. will not be an exception."

COFFEE AND GREEN BUG: THE NEED FOR UNITED EFFORT.—A planter writes:—"I am glad to see such constant references to green bug in your paper. It must do some good and rouse planters from their callous state at last. If you could only urge on them the importance of forking up and so burying the leaves, combined with a good dressing of caustic lime, they might perhaps combine and do something. Specifics are put down as too costly, but digging and liming is not expensive and the benefits are certain, the soil is sure to be improved. Those who are experimenting here are losing heart because their neighbours are doing nothing; and they say, not without reason, what is the use of exterminating bug here when So-and-so is encouraging its growth over the boundary?"

INDIAN GOLD MINE RETURNS.—The following are the returns of crushing on the Mysore and Nundydroog Mines:—Mysore Mine for May:—526 tons crushed produced 608¾ oz. of gold. Nundydroog, during April and May 63 tons of quartz crushed produced 54½ oz of gold,—*Madras Mail*, 10th June.

COFFEE AND BANANA CULTURE IN COSTA RICA.—Coffee and Bananas are said to be the two chief articles that are now attracting attention in Costa Rica—the former for the better prices ruling in Europe, and the probable failure or short Brazilian crop for the next year or two, and the latter for the quick and ready returns the cultivation of Bananas gives. For instance forest land, say of 200 acres can be cleared, sown, and be yielding a fair crop in eighteen months, whilst Coffee, Cocoa, and Rubber require four to five years before any return can be made.—*Gardeners' Chronicle.*

WHEAT, BARLEY AND GRAM.—Experiments made with the object of ascertaining whether flour made from wheat, barley or gram is the most nutritious, have shown that parched gram is highly nutritious, being rich in starches, nitrogen and fat. Cakes made from the flour of parched gram are very nourishing and also palatable, and promise to be a useful and economical ration for native troops in the field. Great care in preparation of the flour is, however, necessary as unless the husk is carefully separated from the grain before the flour is made, dysenteric symptoms are induced in some constitutions.—*Madras Mail*, 8th June.

DOLOSBAGE, 11th June.—Beautiful planting weather which is being taken advantage of. We want a little more sun to make the bushes flush more freely. The last tea sales show how foolish it is not to be prepared with the necessary appliances to make good tea during the dry season. Fancy only having a Jackson and a No. 3 Sirocco and small supply of water to take in something like 100,000 lb. tea. Why, such a place ought to have at least 2 Jackson's, 2 or 3 T Siroccos and if short of water a steam-engine, then things would show different results. However, pennywise and pound-foolish appears to be seen on lots of gardens. We all learn by experience.

TEA IN CEYLON.—I see it stated that such and such Ceylon estate placed all its tea on board-ship last year for 30 cents, but this is not the case. Proprietors of estates deceive themselves. They look at the accounts and say, "Let us omit the cost of new clearings, let us take a little off superintendence on that account, a little off contingencies. Then there is the new machinery—not absolutely necessary—let us omit that, and the result is 30 cents a lb." That is all very fine, but year follows year and there is always expenditure of this sort, and if matters were fairly treated it would be found that the cost of producing 1 lb. of tea here is about 45 cents a lb., that is about 7½ annas. Even this leaves a fine margin of profit.—*Cor., Indian Planters' Gazette.*

CEYLON CHOCOLATE AND COCOA.—Messrs. Shand, Haldane & Co. write to us under date London, 25th May, as follows:—

"We have the pleasure of sending you a new Ceylon industry which we have recently started:—I.—Pure Ceylon chocolate, retailed in England (in 3 lb. card-board boxes) at 2s per lb. II.—Pure Ceylon cocoa which we find competes successfully against Van Houten's or Tulloch's: price retail in England 2s 10d per lb.; packed in ¼ lb. tins three dozen in a wooden case. We have great pleasure in bringing the above to your notice, as they will show you to what perfection Ceylon cocoa is capable of being brought, and we hope to improve upon it still."

The design adopted for the wrappers is a view of Adam's Peak with a border of coconut palms. We have tried the chocolate and the cocoa and find them both excellent. We wish Messrs. Shand, Haldane & Co, every success in this new industry.

Correspondence.

To the Editor of the "Ceylon Observer."

COFFEE-PLANTING IN CENTRAL AFRICA: A CHANCE FOR PIONEERS WITH THE OLD STAPLE.

Edinburgh, 18th May 1887.

DEAR SIR,—I enclose you a newspaper cutting on coffee planting in Central Africa, from which is would seem that the world is not used up yet at pessimists affirm it to be. From all we have heard and read of the interior of the dark continent, land to any extent with suitable climate is there in perfection for the cultivation of all tropical products; labour also must be plentiful, the only question being: Are life and property safe? I suspect not, until some civilized nation occupies a supreme position. All this will doubtless come in time, probably not in our days.

In the meantime, however, it is well worth consideration by our young, strong, and healthy planters with some capital at command, whether it would not be better to proceed to Central Africa than to struggle on where they are with exhausted soil worn out, and, in many cases, diseased coffee trees.

It will be there, as it was in Ceylon, the first at it will get the best land in the best localities, with this difference in their favour, that they will have experience and so avoid the errors by which so many were originally ruined in Ceylon.—Yours truly,

P. D. MILLIE.

COFFEE PLANTING IN CENTRAL AFRICA.

The *New York Sun* says:—"For several years two little stunted coffee-plants led a wretched existence in the Botanical Gardens, Edinburgh. They would not thrive in spite of all that the gardener could do. One day a happy thought struck the curator. He heard that the African Lakes Company had put three steamboats on Lake Nyassa and the river Shiré, and was about to start some coffee plantations in Africa. The curator asked the Company to give his poor little plants a chance to live in the highlands of the Shiré. So they were taken away, and transplanted to the deep rich soil of Mount Zomba. Too much happiness or something or other killed one of the little plants. The other took on a new lease of life. It struck its roots deep into the red earth. Its leaves drank in the congenial air of the African highlands, and at last it burst into berries. The fruit was fine, and it was all carefully saved for seed. A while ago photographs were exhibited in Edinburgh of plantations filled with heavy-laden coffee trees. They were the gardens of the Buchanan Brothers, of Mount Zomba, and samples of their coffee have been priced at a high figure in the London markets. Every coffee tree on this plantation is directly traceable to the puny little plant that could hardly keep life in Edinburgh. It is said that 100,000 trees claim direct descent from this little shrub." It appears that there are some grains of fact in the foregoing statement of the Yankee journalist. About seven years ago Mr. Lindsay, curator of the Edinburgh Botanic Gardens, gave a case of different kinds of plants, including one or two coffee plants, all thriving and healthy, to Mr. John Duncan, who was connected with the Church of Scotland Mission to Central Africa. It was found that the coffee plant throve in the mission in an extraordinary fashion, and there was not the slightest appearance of the disease which in the shape of a fungus attacked the coffee plant in Ceylon, and practically stopped its cultivation there. Ultimately the coffee planting in Central Africa passed into the hands of the African Lakes Company, who have repeatedly brought quantities of coffee, said to be of very high quality, into the British market. From the case of plants given to these missionaries by the curator of Edinburgh Botanic Gardens there may yet spring important results, and the "Dark Continent" may become a great coffee-producing field.

TEA FOR GLASGOW.

Glasgow, June 2nd, 1887.

DEAR SIR,—I enclose you some papers and marked paragraph of a scheme which I am the organizer. Perhaps, as it interests your port and island, you will re-insert the paragraph.—Yours truly,

A. E. MUIRHEAD.

The Importation of Tea to Glasgow. A New Shiping Industry.—The general public will no doubt be surprised to learn that hitherto there has been no direct importation of tea to Glasgow from tea-growing countries. It seems that the three lines of steamers which are owned and loaded at Glasgow, and which run to Calcutta, mostly load in Calcutta for London, almost nothing coming direct to Glasgow. The London monopoly in tea at least is, we believe, likely to be soon a thing of the past, a new venture in the shape of the shipment of tea direct from Calcutta to Glasgow having just been made on a small scale. The success of the venture was at once assured, but the chief difficulty in the way is the formation of a large market. A practical effort has been made by the importers to overcome this difficulty, for a firm of merchants have opened a warehouse in Charlotte Lane, whereby tea can be brought at once into the consumers' hands from the Customs' bonds. The saving this will effect is of course, apparent. At the present moment the rates of freight between London and Glasgow are almost as great as between Glasgow and Calcutta, so that by the direct importation of tea from Calcutta the additional freightage rate from the Metropolis will be saved. Under the present system the tea trade is done through London, where all the tea is landed, warehoused in bond, &c., and then sold in lots to Glasgow where it is forwarded from bond. Under the new system, not only will freightage from London to Glasgow be saved, but also the charges of middlemen, such, as London merchants, brokers, and so on. The undertaking deserves the full support of the public.—*Glasgow Evening News*, 4th May 1887.

COMMERCIAL NEWS ON 'CHANGE.—We understand that arrangements have been made under which Indian Tea is now being shipped from Calcutta to Glasgow on through Bill of Lading. Several lots have already arrived in the "Asia," "Britannia," "Nubia,'. and "Hesperia," and others are *en route*. Hitherto, as is well known, Tea for Glasgow has been first landed in London and filtered through the hands of the London brokers. By the new arrangement Tea is landed in Glasgow at 50s per ton over the Calcutta price, which is about ¼d per lb.—*Glasgow Herald*, 22nd April 1887.

AN ENEMY IN THE GARDEN.

Kattiaratan, Pallai, 5th June 1887.

DEAR SIR,—In the accompanying match-box you will find a curious-looking little insect which has lately been proving very destructive to some of the ornamental crotons belonging to one of my neighbours.

His *modus operandi* is to make a clean, deep incision round the stem, causing it to break off in the course of a day or two, when it has almost the appearance of having been cut with a knife.

Oleanders, bullock's-heart and custard-apple plants are also subject to similar visitations from this ruthless little destroyer, and I have put into the box containing the insect a small portion of the stem of a bullock's-heart plant on which he has been at work.

Can your entomological referee kindly tell me the name of the little "varmint," and suggest some means whereby his ravages in the flower-garden might be checked?—Yours faithfully,

H. G. MADDOCK.

[Mr. A. P. Green has favoured us with the following report on the insect :—"*Oncideres*, a species of beetle belonging to the family of Longicorns, *Cerambycidæ*, and known in the United States as the Girdler. The habits of the American insect, *Oncideres cingulatus*, are described by Packard: "The female makes perforations in the branches of the tree upon which she lives (which are from half-an-inch to less than a quarter-of-an-inch thick), in which she deposits her eggs; she then proceeds to gnaw a groove of about a tenth of an inch wide and deep around the branch, and below the place where the eggs are deposited, so that the exterior portion dies, and the larva feeds upon the dead wood and food which is essential to many insects, although but few have the means of providing it for themselves or their progeny by an instinct so remarkable. The effect of girdling is unknown to the insect, whose life is too short to foresee the necessities of its progeny during the succeeding season."]

CINNAMON AND TEA CULTURE.—No. I.

7th June 1887.

DEAR SIR,—In a foot-note to my last letter insisting that there is no analogy between the treatment a cinnamon and tea bush receives in cultivation, and that it is unsafe to draw conclusions as to the age a tea bush will attain from the known age of cinnamon bushes, you say that though "there is no topping of the cinnamon bush, and no constant renewal of the leaves, yet there is a continual removal of coppiced stems and a continual renewal." This is not so: cinnamon crops are harvested twice a year, therefore the coppiced stems are not continually removed but only twice a year. I again repeat that there is no analogy whatever between the two in cultivation, because nature's laws are not violated by cinnamon being topped and made to assume an artificial existence, by an unnatural growth being induced and checked very frequently, and by an annual hacking.

The majority of the estates I passed through on my way to Nuwara Eliya last September had no leaves on the pruned bushes. Even if not wilfully stripped, no leaves that will serve their purpose are left on a tea bush in the process of pruning. Only old attenuated leaves remain. It is only the climate of the hills that saves tea from total extermination if pruned during dry weather. So great is the shock to the bush from this unscientific treatment, that a whole field of pruned tea was nearly killed out in the lowcountry during a dry season.

I lay no claim to an intimate knowledge of agricultural chemistry, but I have an idea you are mistaken when you say that "the material for leaves comes to a great extent from the atmosphere." I believe you are confusing one of the functions of leaves, to draw supplies of food from the atmosphere for the building up of the tree as a whole, to that function being of use only for the growth of leaves. The authority you quote says, no doubt, that there is much ammonia in rain and water, but rain-water is absorbed mostly by the roots. As regards coffee, Mr. Hughes has proved by analysis that leaves are a more exhausting crop than the beans, and his recently suggesting that white castor cake and bones be applied to tea suggests the possibility that tea leaves are as exhausting a crop as coffee leaves, for the manure he recommends is composed principally of phosporous, potash and nitrogen.—Yours truly, B.

No. II.

10th June 1887.

DEAR SIR,—In my opinion there is very little in common between tea and cinnamon; cinnamon is known to have yielded its special product for a century year by year on soil where tea would not even take root. In the one case the crop is wood and bark, in the other leaf alone; the one crop leaves the leaves on the land and with no other aid from manure maintains its rate of average crops from generation to generation, the other may possibly do the same on suitable soil and climate, but no such fact has yet been proved in Ceylon. My private opinion is that on the deep clay loams of the mountain zone tea will be as enduring as cinnamon on the sands of the lowcountry; I am more doubtful about the poor gravels either high or low. The crop of cinnamon probably makes much lighter demands on the soil than that of tea: indeed, it must needs be so else the soil of the old fields must have been exhausted long ago, but it looks as if the natural rate of decomposition in the material of the soil was quite equal to the necessary supply of soluble bases for the annual crops. It is generally held that leaves contain a larger proportion of the soluble bases than any other part of the plant and the newly developed and immature leaf more than the older and harder growth. It is also said to be the same case in respect to nitric acid, and if this be true, tea must be a very exhausting crop. As to thwarting the natural law, cinnamon and tea are on all fours: nature in both cases rears a forest tree which the cultivator reduces to a bush and keeps it so.

I believe the theory is pretty firmly established that plants derive their carbon and oxygen from the atmosphere through their leaves; that they derive any part of their nitrogen from the same source is a disputed point, but the evidence so far favours the negative. I therefore conclude that with the exception of carbon and oxygen all the elements that are found in the parts of plants are derived from the soil either as mineral bases or as acids that each plant requires in definite proportions according to its species and the deficiency of any one of which gives unsatisfactory results to the cultivator.—Yours truly, HERMIT.

BATS' GUANO.

June 11th, 1887.

DEAR SIR,—I should be glad if you could inform me whether the above is suitable for manure and whether it is ever used; as I am sure a large supply could be taken from various caves about where there is a large deposit. Any information would greatly oblige, Yours &c., INQUIRER.

[Most certainly, bats' guano, which abounds in caves in several districts of Ceylon, is a very valuable fertilizer. The natives have long used it in certain parts of the lowcountry for their paddy fields, and only the other day we heard of an Uva estate which was regularly manured with cave guano.—ED.]

A PROTEST FROM AN ANGLO-CEYLON PROPRIETOR IN ENGLAND AGAINST INTRODUCING RABBITS INTO CEYLON.

DEAR SIR,—Your valuable journal reaching us regularly in England, we are concerned to find in the last number (April 19th) some correspondents seriously advocating the introduction of rabbits into Ceylon.

Having given the subject a place in your columns and reserving judgment until arguments on both sides have been submitted, we have a strong hope that you may see fit to use your influence in urging recourse to that "discretion which is the better part of valour" in a matter where issues so momentous are involved.

Some considerations at once present themselves of an opposite character to those of "Uva Zoozoo," whose observations, interesting as they are

from a naturalist's point of view, create a most lively apprehension from a planter's.

Sending for our headkeeper, a most intelligent man, we gave him the *Observer* to read, and asked his experience of the habits of the rabbit tribe, desiring him to put it down in writing, and cannot do better than enclose the result.

The same peculiarity as to growth of teeth mentioned by the keeper in rabbits applies to rats, lock-jaw having been known to supervene with them when debarred by confinement or other causes from filing down their teeth by gnawing.

On many estates at present hares are a serious pest, yet they possess no powers of multiplying, nor habits of gnawing, to compare with rabbits. As to nursing the latter into existence, once established, no human power can limit them to a special district, and the theory of your correspondent is that they will find so much jungle food as to leave estates alone. But does he not overlook the leech question? Compared with many countries, Ceylon is singularly devoid of ground vermin, most things take to living in the trees; perhaps this is a clue. Leeches may or may not be plentiful in Uva, but elsewhere we have scarcely heard of a jungle or "patana" in which they do not swarm. May it not safely be concluded that such haunts would be rendered as unbearable to rabbits, as they now are to cattle trying to graze; and where else would the maddened rabbit run, but to the peaceful shelter of a cultivated estate? Follow them to this estate: imagine the existing trouble of "wash" trebled by burrows all over the place, perhaps under the roots of the trees; their young shoots nipped; their stems probably barked; and let us enquire do we not already suffer enough from squirrels, hares, "borers," helopeltis, &c., &c., to risk to add the last straw?

And for what compensating equivalent? Ramasamy *might* like his curry strengthened; but if he had previously found his paddy-field devastated as English wheat and oats are by this interesting animal, his blessings might be read backwards.

It may be that the satyr in the fields might frighten the rabbit from depredations; it may be that snakes &c., would keep down his numbers (thereby adding to their own); it may be that he might not take to the climate—but duplicating almost as it does in places both that of England and Australia, this is hardly to be relied on; it may be that he would prove a blessing in disguise: but the chances are so slender, that, knowing his ravages too well at home, we cannot too earnestly and emphatically implore the planters to leave a problem of natural history blank, rather than their own coffers. ENGLAND.

RABBITS FOR UVA.

The letter of "Uva Zoo-zoo" in your issue of April 19th *re* the importationof rabbits into Uva (or indeed any part of Ceylon) is a subject that should have careful thought and attention before being acted upon. Rabbits being rodents must have some exercise for their front or cutting teeth besides that caused by mere mastication, or they will soon grow to an abnormal length even to the extraordinary one of one-and-a-half inches, and curved backwards after the manner of the tushes of the wild boar which I have frequently seen when through accident or otherwise the grinding action provided by a beneficent nature has been interfered with, consequently no matter how good or how rich their pasture may be they will, if young trees are within their reach, nip off the young shoots for mischief if not for food. I do not say they would ring or bark the stem in Ceylon the same as they would do in a hard winter in England, but I fancy the loss to a young tree, of its leader, would nearly be if not equally as bad. Then again let them once get firmly established and from their well-known fecundity, that would only be the question of a few years, you have a repetition of the New Zealand pest carrying devastation in its course and spreading year by year until it has acquired such magnitude that their destruction would be regarded as a blessing. Having been from childhood familiar with rabbits and their habits, prompts me to reply in this strain to "Uva Zoo-zoo," to whom great credit must be given for his praiseworthy endeavour to introduce an animal that would be an acquisition to the food-producing animals of the island, if its acclimatization could be carried out without a risk of its being a curse instead of a blessing. I think that of late years the planters have had sufficient drawbacks to contend with, without introducing another that might in all probability prove worse than any of its predecessors. THO. HARROD, *Head Keeper.*

[Anyone who has visited Australia and witnessed the incalculable damage and widespread ruin effected by burrowing rabbits would certainly not readily think of trying the experiment of introducing the burrowing creatures into Ceylon. Even in the case of the pet domestic variety there is danger. A few days ago, on an estate near Nanuoya, the renewal of the floor of a rabbit shed had to be stopped, because it was found that the rabbits had burrowed into the earth and had families of young in the holes.—But the idea of the observant naturalist who started the discussion was that as there is no valuable cultivation on the wide stretch of Uva patanas, while, unlike Australia, our native population is very numerous, there would be no risk of rabbits getting the upper hand. Still, after reading the above, we daresay "Zoo-zoo" and other planters will agree it is wisest not to make the attempt at introduction, though we heard the other day that application had already been made about the matter to the P. & O. Agent.—ED.]

CINNAMON CULTURE.—Veyangoda, 14th June—Cinnamon peeling operations are in full swing, but there seems to be a general paucity of peelers. Some account for it as the outcome of the sickly season; others say that there has been a general migration to the small Native Gardens, where the lines of the peelers are more pleasant, owing to their being able to get through more work, as quality in make is not insisted on (and this means more pay), and where Coconuts, Jak, and vegetables are allowed gratis. Neither the one nor the other cause can operate for long, and we hope in time to have sufficient peelers for our wants. In the meantime, the sticks that could not be harvested last year owing to the failure of the N. E. monsoon, are, with the weather we are now having, growing apace—not much to be regretted though in the face of the result of the last sales, when there was a rise in the price of the coarse qualities and a corresponding decline in the price of the fine qualities. If such a thing as unanimity is attainable amongst Cinnamon Planters, a reversion may be possible to the old style of quilling Cinnamon to suit the present requirements of the trade, and the making of fine Cinnamon, which had reached ridiculous lengths, abandoned. As formerly, only coarse sticks can be cut and the Cinnamon quilled to the size of the present 3rds and 4ths—payment accordingly. This will benefit the peeler, as he will be able to get through more work; and the Planter, as he can harvest his crop during the season, and not as now all through the year, giving the bush no time for development. If the trade has had a surfeit of dainty dishes of superfine Cinnamon, and wants as a corrective plain, coarse Cinnamon, suit their healthy tastes, I say, with plenty of coarse Cinnamon and—I say it with fear—chips."—Local "Examiner."

* This would mean a larger outturn, and as spice is not an article the demand for which grows apace there would be a further fall in price, growers only being strong holders.—ED. "T.A."

COFFEE IN MYSORE.

By "Aberdonensis."

Ah! But there 's more, my dears, than Volunteering to rouse us and cheer us. Grand prices in retrospect and grand crops in prospect is cheering:

Oh! let them go on, those men in Ceylon
They 'll choke all the markets and countries with Tea.
With hope and with trust, we 'll keep to our crust,
Or rather our coffee; and joy to be free!

It is very cheering to have good prices and good crops. It puts the past, the present and the future in a good light and makes a man enjoy his work. You have all left your old love. I have followed her to a far country; and there her soft whispering caresses as I pass along the estate paths; her ropes of green swelling pearls; her sweet breath untainted by blight or deadly spores of *Hemileia*; her willing response to care and trouble; these all as in the laughing days of my youth, now console my more sedate spirit. "Coffee, when it pays, is the best thing going for any man." How often has that been said? Is it not true? Your tea does n't pay so well and gives you a lot of bother. The trim tidy bushes of coffee—contrast them with the hideous pruned tea field. I saw some when I was last in Ceylon. I compared a pruned tea bush and a pruned coffee bush. The latter is a maid with her tresses trimmed and braided, her dress arranged tidy and neat. The former a ghastly corpse half devoured by some unholy creature, its bones pointing to the sky.

The sweet smell of the cherries as they merrily drop through the machinery, the scent of the dry parchment: how does that compare to the sickly heat and trying sour atmosphere of crushed and fermented and fired leaves mingled with the dust and the noise? Then instead of the clean gunny you have the solder, the lead, the stencil plates, &c.

NOTES ON POPULAR SCIENCE.

BY DR. J. E. TAYLOR, F. L. S., F. G. S., &c.,

EDITOR OF "SCIENCE GOSSIP."

There are few subjects which possess a greater fascination for agricultural chemists than the immense stores of nitrogen in the atmosphere around us. If they could only tap them! The dream of doing so is to them what the possibility of converting the base metals into gold was to the mediæval alchemist. And to none has the possibility of somehow being able to make use of this atmospheric store appeared more sanguine than to the French chemists. The Emperor Napoleon took intense interest in scientific agriculture, and one of the best chemists of the day, Professor Ville, superintended his experimental farm at Vincennes. Professor Ville was very sanguine about chemists being able to cheaply use the nitrogen of the atmosphere. Certain kinds of plants, such as the order Leguminosæ, had learned to do so, he said, and why should not men. He wanted the French Academy to offer a prize of £10,000, and throw it open to the world, for the lucky person who discovered an easy method of utilising the nitrogen of the air.

M. Berthelot, a distinguished French chemist, is the apostolical successor of the late Professor Ville in this matter. He is constantly experimenting in the direction that Ville suggested. Last week he read a paper before the Academy of Sciences on "The Direct Fixation of the Gaseous Nitrogen of the Atmosphere by Vegetable Soils with the Aid of Vegetation." If agriculturists could only manage to grow crops which would enrich their soils instead of pauperising them, it is manifest that there would be some hope for agriculture. M. Berthelot evidently thinks he has partly succeeded on argillaceous, or clayey soils, in fixing atmospheric nitrogen—but not with the aid of vegetation. His experiments have been carried on at Meudon, one patch with vegetation on it and the other without. He found that the amount of nitrogen fixed by the former was 12·7, and as much as 23·15, whilst that fixed by the aid of vegetation was only 4·67, and the utmost 7·58 grammes.

The Colonial College and Training Farms at Hallesley Bay, in Suffolk, have started, the principal being the Rev. Dr. Ross, who had 16 years' experience at Graham's Town, South Africa. It is intended to train youths who have left school, and who intend being colonists, in such practical yet scientific details as will make them all the better colonists. The farms include nearly 1,400 acres of all sorts. This is a tolerably large farm in England. There are flocks and herds on it, and the lads are not only being taught husbandry, but something of veterinary surgery, practical chemistry, geology, and botany as well as sheep shearing and slaughtering, a little of blacksmithing and carpentery, and indeed everything likely to make a young fellow handy in every way. So our young "new chums" may be able to give you a few wrinkles by and by. They are not instructed in the art of tea making, but they will soon learn that when they get over to your side, and find how bad the water is.

In a paper on the subject just read before the Paris Academy of Sciences, by M. Andouard, the writer shows that it is a great mistake to mix nitrates and superphosphates together as artificial manures.—*Australasian.*

COMPANIES AND SOCIETIES IN JAVA: THE AMSTERDAM QUININE FACTORY.

Our readers (says the *Indische Mercuur*) know perhaps that for various reasons it was decided to liquidate the Amsterdam Quinine Factory. An endeavour is to be made to reorganise the establishment. With a view to this the factory has been purchased by one of the former directors, Mr. W. Sieger, who wishes to form a company with a capital amounting to 250,000 guilders, of which already 150,000 guilders have been taken by the following gentlemen, viz., A. L. Fransen van de Putte, J. J. van Santem, B. R. G. Bouricius, Dr. A. S. Wanstart, G. M. Boissevain, W. Dull, W. A. van Dorp, A. Koch, Paul van Rath, J. T. Cremer, J. E. Tegelberg, F. A. Vriese, the Netherland Trade Company, W. H. Bloaun, J. R. Wuste, S. B. Leveryn, T. C. Brandt, junr., G. T. de Clercq, and T. Pryce. Mr. W. Sieger has also succeeded in securing the co-operation of the well-known quinine manufacturers, C. F. Boehringer and Sohne, of Mannheim (Germany), and the technical management and superintendence will be carried on by that firm. The factory and accessions have been purchased for the low sum of 101,285·75 guilders, for which amount the factory has also been admitted to the Company. The usual expenses of sale and the intended extensions, which increase the power of production from 3,600 kilos. to 8,000 kilos. sulfas quinine, bring the costs of the factory to about 135,000 guilders. Considering that the factory will be obtained by the Company for a very small sum, and that numerous well-known commercial men are among the directors we may safely predict the success of the undertaking.

THE "NGOEPIT" AGRICULTURAL COMPANY.

The Agricultural Company "Ngoepit" (says the *Indische Mercuur*), which will be erected at Amsterdam, has in view to continue the cultivation of that plantation, situated in the District Soeracarta, large 1,911 Government "bouws" (one bouw is equal 1,7537 acres) with about 1,300 working hands, and planted with indigo, tobacco, coffee, and cocoa. The capital has been fixed at 430,000 guilders, divided into 430 shares at 1,000 guilders each, and has been wholly furnished. As a complete payment of the 330 shares, in association with the proprietors, will be admitted the plantation, including the inventory. The Company is erected for 40 years. From the net profits fitted by the

general meeting will be disbursed to the shareholders 6 per cent of the amount of their shares, and 29 per cent to the reserve fund. The remainder will be distributed as follows:—10 per cent to the managers and clerks; 5 per cent to the directors; 10 per cent to the commissioners; and 75 per cent to the shareholders. Mr. H. G. Th. Crone has been appointed director, and Messrs. G. L. Bosch, of Arnhens, C. P. Lohr, the late chief manager of the factory of the Netherland Trade Company, and F. C. A. Hauschild, partner in the firm of Firsch and Hauschild, of this city, are engaged as commissioners.—*L. & C. Epress.*

PEPPER AND PADDY IN NETHERLANDS INDIA.

(Translated for the *Straits Times*, 15th June.)

The Batavia *Nieuwsblad* states that the pepper plantation in the Lampong districts in the Sumatra, have suffered so much from disease that experts, consulted as to the best course to follow under the circumstances, have advised the rooting out of all the diseased plants. The result is the more regrettable, from the officials in that quarter having made strenuous exertions to push on this branch of cultivation in the interest of the people.

Black coloured paddy is becoming extensively grown in the province of Malang in Java. It is said to differ widely in taste and smell from the ordinary kind.

Some important experiments have been set on foot by a gentleman in Java with a view to testing the capabilities of native silkworms. He has got permission from the Government to continue experimenting with them in a practical fashion in the Botanical Gardens at Buitenzorg. To facilitate matters, a Government grant-in-aid has been placed at his disposal. In his opinion the silkworm industry will never pay Europeans to take in hand. It will prove only remunerative among those natives who can utilise the services of women and children for the purpose. Inquiries made in France have shown that the silk produced by the Javanese worm which, by the bye, is suffered to run wild, answers manufacturing requirements. This branch of industry, even if it yields only one guilder profit yearly for each family carrying on silkworm rearing, would diffuse prosperity and well-being far and wide in Java. The Javanese only require judicious leading to benefit by these experiments.

TROPICAL PRODUCTS IN THE SOUDAN.

The task of opening up the Soudan to trade should be undertaken by a company, and that a sufficient number of ports or factories should be established on the coast of the Red Sea, both north and south of Suakin, to allow the inhabitants of different regions to resort each to the one which may be most convenient to them, and, at the same time, to avoid the collisions between tribes at feud with one another which would be almost inevitable if the transactions were confined to any single centre of operations. The power of the Soudanese to avail themselves of the opportunities offered by the projected company would depend, of course, upon the possible productiveness of the country; and on this point the statements of Mr. Fox are exceedingly encouraging. Prior to the late rebellion, the united export and import trade of the Soudan amounted to a total of two and a half millions sterling; and it is probable that this was practically limited to the most accessible fringe of the population. The larger proportion of the land is described as being "most fertile, offering great capabilities of development, abounding in agricultural resources, and, it is believed, in mineral wealth." Even the desert portions yield an abundance of gum, ostrich feathers, and raw hides; and the quantities of these would no doubt be much increased by a proper organization of the industry supplying them. Emin Bey asserts that in the equatorial provinces he has cultivated cotton, indigo, sugar cane, and rice, and that ostrich farms have been started; while the Sennaar is described as being of almost unlimited corn-growing capacity, and fit also for the production of coffee and tobacco. With these natural advantages there is every reason to believe that the inhabitants, when in constant contact with the products and resources of civilization, would speedily develop a taste for things which at present are unknown to them, or are known only as almost inaccessible luxuries; and so the old sequence of events would once more be set on foot. Wants would create industry, before which tribal feuds and foreign wars would of necessity die out, and industry would soon produce a demand for education. The dismal trade of slave-hunting, with the precarious profits and heavy risks attending its prosecution, would be replaced by pursuits calculated to offer a shorter and more easy road to wealth; and thus man's natural love of comfort and luxury would once more become a powerful agency in the elevation alike of his material and of his moral condition. —*The Times.*

British North Borneo.—I have good news: a Tobacco Company has been started in Darvel Bay and a Trading and Planting Company in Sandakan—both of which promise well. Province Dent doing well and is becoming an important exporter of pepper by its own people. Governor Weld is now there, engaged in a special Commission to examine into and settle matters connected with Brunei, Sarawak and British North Borneo.—*Cor.*

The effects of what we doubt not are *symplocos* stumps is thus stated:—

"A destructive kind of blight, or fungus, has been attacking the tea plant in the Dooars with fatal results. Messrs. Jardine, Skinner & Co. have forwarded to the local Agri-Horticultural Society some roots of tea bushes thus attacked, with the accompanying letter:—'We send herewith roots of tea bushes that have died of on forest land in the Dooars. The bushes thrive well for a time, then suddenly wither, and it is noticeable that in every, or nearly every instance, the bushes that die are adjacent to decaying stumps of trees, felled when the land was cleared of forest. The bushes are from 2 to 3 years old, and as a rule, do well in the soil of the garden. Perhaps Dr. King, or Mr. Wood-Mason, would kindly favour us with their views as to the probable cause of the bushes dying. Can it be fungus from the decaying stumps and roots of the forest trees?' The roots were sent to Dr. King who reports upon them as follows:—'I have carefully examined the diseased tea bushes sent to me, and I have submitted them to Dr. D. D. Cunningham, who makes vegetable blights a special study. The result of Dr. Cunningham's examination of the specimens is, that the root bark has in them all been completely destroyed by a minute fungus. It is extremely likely that this fungus originated in the dead and decaying stumps, which your correspondents say abound in the garden from where the bushes come. But whatever may have been the origin of the blight, it is infectious; and all tea bushes affected by it should be rooted up and carefully burnt. Beyond this precaution I can suggest no remedy.' Tea planters in the Dooars will thus have a new pest to contend against."

A VISIT TO KEW GARDENS.

A visit to these world-renowned gardens cannot fail, at any season of the year, of being a source of the deepest pleasure and gratification to all lovers of plants and those interested in their cultivation; but it is more particularly so in the spring time, I think, when not only can the tens of thousands of exotics, from all corners of the earth, be viewed with comfort under the shelter of the numerous glass structures, but when the enjoyment is enhanced by a ramble in the extensive and beautifully kept grounds, which at this season assume a most attractive and captivating appearance. The deciduous trees and shrubs collected from many lands and arranged with due scientific care and order are now budding into leaf and flower; the noble evergreens are secretly dropping their seer and yellow leaves, under cover of the new ones which the present warm weather is rapidly developing, the lawns have already put out their carpets of richest green, thrushes, black birds and other birds may be seen hopping about amongst the grass and under the trees, and singing in the branches above; the mysterious voice of the cuckoo comes floating on the still and balmy air, and when bird and plant life alike seem to have settled down to a time of deep enjoyment, at least so it appeared to me on my recent visit to the gardens. It was a day perhaps the more to be enjoyed as being among the very few really warm spring days we have yet enjoyed, since the termination of the miserable north easters we have been experiencing ever since the month of February. It was one of nature's holidays in fact, which had the effect of keeping me on my legs in the gardens for eight consecutive hours in rare enjoyment of its treasures both indoors and out.

In years gone by, when the weather of the earlier months of the year in England was not quite so fickle as it is now-a-days, what is called amongst horticulturists "bedding out," that is, replanting the beds of the flower garden with their summer and autumn flowering occupants was usually commenced not later than the 1st of May, but in these latter days, when spring time is so delayed, and when east winds and frosts are so loath to bid us farewell, no one dreams of filling up the beds of the flower garden with plants which produce such glorious annual displays, till the month of May has quite ended, so that the period of leave, as it were, has been extended to the spring flowers proper for displaying their fresh and delicate beauty, by one month.

At the date of my visit numerous spring flowers and alpines were in the hey-day of their beauty in the flower beds, borders, lawns, and rockeries. On entering by the Cumberland gate, the first thing that caught the attention of the visitor was a charming group of various coloured polyanthus, springing from the lawn on the left of the walk and backed by a row of primula denticulata; in front the grass was dotted with plants, in full flower, of a pink tinged variety of the wood anemone (*anemone nemerosa*), the beautiful blue squill (*scilla liberica*), and one or two other dwarf spring flowers, which had a most pleasing effect. The flowers of the polyanthus were large and of the most varied and beautiful colours, and with the setting of the velvety lawn, where not a suspicion of soil was to be seen and the other flowers made a group which at once arrested the attention on entering the garden and made it hard to believe that its arrangement was merely the result of accident and not the outcome of careful study on the part of some student of nature. Be that as it may, I think a useful hint might be taken with reference to the grouping of many flowers on lawns instead of on beds and borders as a better means of exhibiting their beauties. Not far from this group might be seen in all their freshness and rare beauty, such spring flowers as *Caltha pulustrus*, or the March marigold, *Primula rosea*, a most lovely Indian species producing quantities of deep rose coloured flowers from a stem 4 inches high. *Muscaria*, or the grape hyacinth in great variety, some of the flowers of the most intense violet. *Anemone appendua*, with its delicate pale-blue flowers. *Anemone fulgens*, that glaring and brilliant flower from South Europe. Christmas rose, in great variety and many curious forms, many kinds of *Symphylum caucasicum*, or comfrey with its different shades of blue, *Gentian verna*, Crown Imperial lily, *Primula Japonica*.

Hyacinths and tulips too were in the height of their beauty, both in beds of separate colours and mixed, but after seeing the entrance group on the lawn one could not help thinking that both hyacinths and tulips might be similarly treated in their cultivation with a very happy effect. Beds and borders of brown earth be they kept ever so tidy and clear of weeds detract from the beauty of flowers generally. Flowers in a purely natural state of growth are rarely to be seen without the assistance of other plants to hide from view mother earth "and give a setting to their floral conpanions," and I suppose after all we cannot do better than imitate nature in the arrangement and cultivation of the flower garden. I am tempted to give the names of a few hyacinths as seen at Kew in beds of the ordinary kind which were very beautiful indeed, but what they would have appeared like if similarly treated on lawns I leave to the imagination of your readers. There were several beds of Charles Dickens' single blue with a noble spike and wonderfully regular in size and shape. Grand Silas,—pale blue, also a grand spike. Baron Von Thuyl, dark blue, a fine flower, Madam Hodson, single red beautiful spike, Grand vanquier, single white, beautifully pure, and noble flower, and giganta another grand white. There were other mixed beds of the abovenamed kinds, and the sight of these beds was one of rare beauty and the rich scent of the thousands of blooms filling the air. For the benefit of the cultivators of this flower on the Nilgiris, I would mention that the bulbs are cultivated in Holland, from which country they are yearly imported into England in a soil composed mostly of pure sand, mixed with a large proportion of completely decayed cow manure, and I should think that success in their cultivation, after the bulbs leave Holland, will depend greatly upon as near as possible an approach to a similar mode of treatment and cultivation.

Amongst other plants in flower of which I made a note at the time as likely to be suitable for cultivation in the climate of the Nilgherry Hills,* I would take leave to make particular mention of one which I came upon in the large conservatory or old Palm house, near the Chinese Pagoda, and one which if not already introduced would be likely to do well, and I venture to think would be a great acquisition if included amongst the garden plants of Ooty. It is named *viburnum plicatum*, and is a native of Japan, it is an evergreen shrub with handsome bronze-coloured leaves and flowers of the purest white, the shoots are long and slender and assume a pendent or drooping habit of growth, the clusters or globes of flowers are produced at short intervals in regular pairs along these shoots, forming long wreaths, giving the whole plant a most charming and striking appearance. The old Guilder rose—*viburnum opulus*—is a hardy plant in England, and is well known for its white balls of flower so profusely produced in the spring, but the viburnum under notice is much superior in gracefulness of habit and purity of colour as well as size, and has few equals I think as a flowering shrub. A writer in describing the Queen's Drawing room a few days ago says "Cherry blossom and white Rhododendron appeard to be the newest floral garnature for white millinery. Guelder roses are always pretty, but when carried straight down each side of a skirt and then brought upwards to a point in the centre they are particularly charming," and if this be so with regard to the common guelder rose, how much more so would it be if flowers of the plant under notice were used. Japanese plants do well in the climate of Ooty, as instance the Camellia, hydrangia, and many others. Amongst Rhododendrons in flower in the same house I noticed that grand

* And consequently in Nuwara Eliya and the surrounding hills.—Ed.

and magnificent species from the Hymalayas *Rhododendron Auklandi*, the flowers were of huge size and of the purest white, a truly noble flower which with its clear pale brown stem and branches and long leaves give the tree a very beautiful appearance. This would also be a grand plant for the hills. Growing beside it was a large tree of the Neilgherry Rhododendron, large and well shaped and crowded with trusses of its bright scarlet flowers. Another Hymalayan species was also in flower *Rhododendron Nuttalli*, flowers very large trumpet-shaped white, yellow inside, a striking and splendid flower but not so pure in colour as *Rhododendron Auklandi*. Also in the same house I noticed several plants of a creeper Hibbertia dentata from south-east Australia, with very dark shining leaves and single yellow flowers, it struck me as a particularly handsome climbing plant for walls or bowers, and no doubt would thrive well in the climate of Ooty as most Australian plants do. The three species of Araucaria from the same quarter of the globe, viz., *A. excelsa*, *A. Bidwilli*, and *A. Cunninghami* were all represented by tall and superbly graceful specimens; these are all easily raised from seed and should be extensively grown on the hills as ornamental plants for lawns, &c., than which there are none finer. In one of the hotter houses I saw a cluster of Impatiens Sultani, fine plants in pots drowned in scarlet blooms. This plant is familiar enough at Ooty with you, I have no doubt, but I saw another new species of Impatiens also in flower, which perhaps may not be so well known, *Impatiens Hookeri* from the South Sea Isles a stronger and stiffer plant with black polished stem and side shoots and large scarlet flowers a most striking and lovely plant. For hanging baskets let me recommend *Begonia glaucophyllia splendens* as a veritable gem. It is plentifully seen at Kew and also in all the London nurseries, and everywhere it is a beautiful object, when well grown and in full leaf. Covering the sides and top of the wire baskets it might, I think, be grown to advantage mixed with a few roots of a devallia fern of which you have such an abundance growing on the trees in any shola. Another fine plant for covering a pillar is *Begonia lucida*; and for growing in pots or out of doors as a companion to *Begonia fuchsioides*, which used to grow so plentifully in the Government gardens—its scarlet flowers making a grand display—is *B. odorata*, flowers white and exquisitely scented, the plant grows to about the same size as *B. fuchsioides*. Another evergreen green house shrub which in all likelihood would thrive in the climate of the Neilgherries is *Euchium callythæsum*, it is rather a tall growing shrub with light green leaves and long spikes of splendid blue flowers. In the houses devoted to Orchids I saw many fine examples in flower, and was very much struck with the freshness and clean appearance of the structures, every plant looking the picture of health and vigour. Amongst those Orchids *not* in bloom I may mention *Cœlogyne corrugata*, a dwarf growing plant common on the Neilgherries, flowers white with yellow lip striped with orange and forming huge masses growing on sheet rocks on many parts of the hills; the plant at Kew is grown in a large pot and looks healthy, but with leaves much longer than those produced in its native habitat. I was told by the person in charge that the plant had not flowered during the three years he had been employed at Kew, the result, I would venture to suggest (and I do it with all due deference to the Kew authorities) of wrong treatment, the plant being subjected to stronger heat than is necessary and being kept too far removed from the glass. A thorough knowledge of the true position in which these plants are found in a wild state and the nature of the climate to which they are exposed would, I imagine, be often of considerable advantage to English cultivators.

At the entrance to the orchid house for species from hot climates was conspicuously placed a splendid plant of *Dendrobium alboluteum* from India, with four long spikes of rich yellow flowers, each spike composed of from 50 to 60 individual flowers, it was truly a splendid plant. Many well flowered plants of *Dendrobium Nobile* from Assam, helped to augment the fine display in this house, whilst in the cooler house, a number of plants growing on blocks suspended from the roof added not only beauty to the general group but exquisite and powerful scent besides. These consisted of plants of an orchid from South America, *Cattleya citrina*, bearing golden yellow flowers of large size singly on a stem scenting the whole house, numerous plants and varieties of *Odontoglossom Alexandræ*, also from South America were also in full flower in this house adding greatly to the show, with their splendid spikes of delicate white pink and creamy flowers, and which are such great favourites in the making up of choice and expensive bouquets. Cypripediums or our lady's slipper in numerous and curious species were also in bloom, many of these plants are natives of India and are very curious and interesting. One species, *C. caudatum*, a species from Panama being amongst the most curious of orchids, the long tail-like petals are the most extraordinary part of the plant often reaching, when fully developed to the length of thirty inches, giving the plant a most wonderful appearance. Many other species were also in bloom but too numerous to mention. These plants are becoming more and more popular every day in England, and as many species come from cool climates and in large quantities, orchid growing is getting to be quite common even amongst people with limited means, as plants can frequently be picked up at sales at a remarkably cheap rate, and with regard to orchids from temperate or cool climates there is as little trouble required for their proper cultivation as there is for an ordinary geranium or fuchsia, so that the cultivation of this truely aristocratic tribe of plants is likely, ere long, to be developed to a yet greater extent in England. Firms exist in London and its suburbs that employ a regular army of collectors all over the world, whose duty it is to rob the jungles of their natural treasures, establish them in glass cases, or pack them in dry moss, and transmit them to England for the decoration of the glasshouses and drawing rooms of the wealthy. The climate of Ooty and other parts of the Hills would admirably suit such kinds as Odontaglossoms, Oncidiums, and many others from temperate regions, and others from hotter parts could be grown and flowered with success under the shelter of glass structures, I imagine, with only a tithe of the trouble required for the cultivation of such plants in England. There are many grand species to be found in the Wynaad and other districts surrounding the Neilgherries, such as *Succolabium guttatum*, *Dendrobium album*, and others which could be collected with but little trouble and would amply repay any time spent on their cultivation. The two abovenamed kinds could be transported with the branches of the trees they are found clinging to, thus obviating the ill-effects produced by detachment from the trees and re-establishment on blocks of wood or baskets afterwards.

The palm house at Kew on the day of my visit was patronised as usual by crowds of admiring visitors, and certainly the bringing together of such a vast collection of palms, cyclads, tree ferns and other splendid tropical plants from all parts of the world has produced a wonder exciting spectacle, and one not easily effaced from the memory. The Indian palms—and no doubt those from other countries also—look every bit as healthy and as much at home as in their native clime, and the house is so splendidly arranged and furnished and kept, in such beautiful condition withal, that a visit to it is a treat of no mean order. I saw the two tall coffee trees near one of the entrances to the building as usual in excellent health, and carrying some withered "Cherries" and many clusters of recently withered flowers. The leaves and general appearance of the plants differed very little from those to be seen on the Neilgherries or in the Wynaad, setting the mind to work in wondering if coffee cultivation in England under glass would be likely to "pay!"

Although the arrangement of the plants in the palm house, the general appearance of the building, and the splendid growth and health of the various

orders of plants left little to be desired, such can hardly be said of the collection of plants representing the flora of Australia, New Zeland, and Tasmania. But the fault does not lie with the officials of Kew, but rather with the nature of the English climate and the almost insuperable difficulty of growing so many specimens of plants and trees, many of which grow to an immense size in pots, with any hope of maintaining or developing their true character. Take the Eucalyptus family for instance: true, we have the various species represented but few are in true character, and give but a very faint idea of what the trees are in their native country. It is quite different with most of the palms and other plants to be found in the palm house; these thrive and grow to their full natural size in comparatively confined and cramped root spaces; but to exhibit, the family of Eucalyptus in anything approaching their natural conditions would, of course, be a hopeless task in England, and while looking over the collection at Kew I could not help thinking how differently examples of nearly all the Australian flora could be grown and exhibited at Ootacamund, and what a splendid Botanical Garden could be established and upheld at a comparatively small cost in such a climate. Thousands of plants from such countries as China, Japan, Australia, New Zealand, &c., which in England require the protection of glass could be brought to their fullest development in such a climate as Ooty, without any such protection, and thousands of others from warmer climes could be equally well grown with simply glass protection without the addition of fire heat which is such a heavy item of expenditure in England.

Kew gardens are not open to the public till twelve noon on week days and 1 o'clock on Sundays; and no bag or parcel of any kind is allowed to be taken beyond the lodge gates, so that there is not the slightest chance of any one desirous of taking an early summer morning walk in the extensive grounds or enjoying anything resembling a picnic having his or her wishes gratified. These restrictions, to my mind, are very absurd. I would not of course have cricket nor such like games played on the velvety lawns of Kew gardens, but as matters stand now visitors are allowed to walk on these lawns and to rest under the grateful shade of the many wide spreading trees to be found all over the grounds, and what harm could possibly result from the public, if they chose partaking of tiffin while so resting, it is difficult to conceive; true, there might be a few bare bones and pieces of paper left behind at first, but this difficulty might be overcome by adopting certain rules and rigidly enforcing them, and the comfort and pleasure to the tens of thousands of people who annually visit the grounds would be very greatly enhanced by some such concession. As matters stand now, no one can have any refreshment within the grounds, save and except what he can smuggle it in his pockets, and it is quite impossible for anyone to inspect the gardens to any purpose under a good many hours, so that the rules of the garden as they at present stand are undoubtedly productive of much discomfort to the public. Another rule is that no one shall enter the gardens unless "decently dressed." I wonder who are our judges in such matters, and on what grounds their decisions are based? Dear old Ooty, "with all thy faults I love thee still"! Well do I remember thy charming gardens free to every one, from earliest dawn till dark night; where one could enter either in the garb of a West-End exquisite or dressed in shikaree garb of rubicund jail cloth and bettered helmet or mushroom hat and be welcome all the same, and where no fault was found if a following of coolies accompanied his steps to thy picnic ground on the hillside, laden with heavy baskets of various requisites for the inner man. But in Rome, I suppose we must do as Rome does and put up with these discomforts at Kew, of carefully dressing before entering the gates and refraining from ringing with us anything in the shape of refreshments till such time as an agitator or two with equal unity and energy to Messrs. Parnell and Co., bring about the repeal of these rules in the House of Commons.

The institution was started in the first place, and subsequently maintained by large Government grants mainly for the purpose, as I imagine, of instructing the public, and that being so, every inducement should be held out for the largest number of people visiting and inspecting the gardens, instead of such rigid restrictions as at present obtain. Visitors from a distance anxious to make the most of their time cannot be expected to leave the gardens in the midst of their ramble, and just perhaps when their interest in all they see is becoming greater and greater, for the sake of adjourning to a refreshment house for a dinner or a much needed cup of tea. Kew gardens are of great extent, and it takes a long time to see everything, so that is absolutely necessary that these restrictions should be reversed if anything like a comfortable holiday is to be spent there. The Londoners too, who do so much to make up the annual total of visitors feel the effect of these rules perhaps more than anybody else, for a Londoner bent on holiday making is nothing without his tiffin basket, and one effect of these rules is undoubtedly to keep away many thousands that would be otherwise glad to spend a day at Kew gardens occasionally very greatly to their benefit.

Kew is doubtless a glorious place, a garden of beauty and of wonders, but many months in the year one can only find enjoyment under the shelter of the glass roofs owing to this fickle climate of ours. Imagination can picture what kind of garden could be brought into existence in a climate like Ootacamund if equal encouragement and support were accorded it as at Kew.

India with all its wealth and great advantages can boast of nothing like Kew, her so-called Botanical gardens are many of them, unworthy of the name and of a great and mighty—empire. Let us hope that the Madras Presidency will soon take the initiative in striving to transform by every means in its power, the Government Botanical Gardens at Ooty, from their present embryo state to a condition worthy of their name and the magnificent district in which they are situated.—HORTUS.—*Nilgiri Express.*

QUININE.—We learn from the *Indische Mercuur* that the quiuine factory in Amsterdam, which stopped working some months ago, has been purchased by one of the late Board of Directors with a view to reorganization of the business, in the carrying out of which Messrs. Böhringer and Son, of Mannheim, will take an active part.—*Pharmaceutical Journal.*

CAFFEINE AND THEINE.—Considered chemically, the base obtained from coffee and from tea has hitherto been regarded as one and the same substance, though the names of caffeine and theine have been applied to it according to the source from which it is obtained. It is, moreover, probable that as a commercial article it is chiefly, if not entirely, produced from tea. There have been statements that the base obtained from coffee has a physiological action different from that of the base obtained from tea, but they have not met with much acceptance, though it is a common opinion that there is a decided difference between the effects of tea and coffee when used as beverages. This question has recently been studied by Dr. Lauder Brunton and Dr. Cash, and in a paper read before the Royal Society they have described a difference in the action of caffeine and theine upon the voluntary muscles which is sometimes exceedingly well marked, though variable. According to these authorities theine seems to be more powerful in its action than caffeine, and there is a qualitative difference between them, inasmuch as theine tends to produce rhythmical contractions in the muscle. The study of such differences in the physiological action of substances differing in composition has already given a number of interesting facts, and it appears likely to be a means of throwing still further light upon the constitution of substances which appear to be chemically indentical.—*Pharmaceutical Journal.*

CULTIVATION OF RAMIE, OR CHINA GRASS IN SPAIN.

In a recently issued Consular report on the trade and industry of the district of Barcelona during the year 1886, it is stated that agriculturists in the Gerona district have lately been turning their attention seriously to the cultivation of the Ramie, or China grass plant (Bœhmeria nivea, H. and A.). For some years past, in consequence of the destructive inroads of the Phylloxera and other pests among the vineyards, and of the increasing importations of cereals from America and elsewhere, the cultivation of the Vine and cereals has ceased to be as profitable as formerly in that part of Gerona, and finding that the climate and soil are in every way suited to the cultivation of this plant, and that the few essays that have been made have resulted in success, a factory for decortication has been erected near the plantation, its inauguration, although created and carried out under foreign (French) auspices, having been attended by the notables of Cataluna. Hitherto the roads from the above district have been dry beds of torrents, which prevented conveyance of produce to any distant market; now it appears the roads are to be levelled and made passable. It is said that this plant is destined to replace, not only the Hemp and Flax which are imported from France for the manufacture of textiles in Barcelona, but even that of Cotton. The plant grows to a height of 60 to 90 inches. It is essentially a textile plant, and two cuttings may be made in the year, and cultivated under good conditions a hectare would grow from 3,000 to 10,000 kilos. of stalks. At present there are few or no reaping machines in that part of Spain, but as labour is cheap, the loading and pulling of the crop is done without much expense. The plantations at Torroella de Montgui, the district of Gerona in question, have an extent of 130 hectares, but there is land disposable for the culture extending over 3,000 hectares. The present price of Ramie is 10 pesetas (8s.) the 100 kilos. There are three decorticating machines at work, moved by a steam-engine of 15-horse power. They decorticate 215 kilos. of stems in twelve hours, from which are obtained 43 kilos. of thread, requiring but two workmen to manage each machine—one to introduce the stalks and the other to recieve the fibre; and the expense is 12 pesetas 50 c. per 150 kilos. of thread per diem. The society to whom the plantations and factories belong is the Société de la Ramie C. Française, founded in 1882, with a capital of 3,360,000 francs.

The advantage of the Ramie over other textiles rests in its great resistance to wear, three times greater than that of Hemp, and from its greater length is more flexible, and has the property of colour, assimilating itself to silk.

The thread produce can be manufactured into blinds, white cloth, mixed cloths for curtains and hangings, the *punto* cloth, the finest blankets and flannels equal to those manufactured from Sariss wool.—J. R. J.—*Gardeners' Chronicle*.

PROCEEDINGS OF THE AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA. FOR MAY 1887.

COMMUNICATIONS.

Cassia fistula.—From G. F. Checcacci, Esq., Calcutta, making some enquiries regarding Cassia fistula seeds for an experiment which a correspondent of his in Italy wishes to make. At present only the pulp in the seed-pod is commercially utilized, the seed itself being thrown away, Mr. Checcacci's correspondent wishes to utilize this waste seed by extracting the same product from them. The information required was supplied.

Teff; *Eragrostis abyssinica*.—Some of the seed of this Abyssinian cereal, received from Kew, and noticed in the last proceedings, was sent to Dera Ghazi Khan for trial at Fort Munro; this has been received by Mr. Lowis in the absence of Dr. Jukes and sent on to Fort Munro for trial.

Some of the seed was also sent to Mr. C. C. Stevens, Commissioner of Ranchi, who has sent it on to the Raja of Jushpore for a careful trail. A third portion was sent to Mr. Flamsteed of Syook Tea Estate, Darjeeling, who will sow in June at the season the millets are sown there. In reference to this grain the following remarks of Dr. Schomburgk, Director of the Adelaide Botanic Garden, in a letter addressed to the National Agricultural Society of Victoria, will be read with interest: "I do not believe that Teff flour "would be used in South Australia, but the grass "may turn out excellent hay. The plant is only an "annual." Even should Teff not produce grain to compete with the different millets cultivated in India or with wheat, should it make a really good hay it would probably find a place in Indian Farming, particularly if it can be cultivated at a season to follow tobacco or precede paddy.

Araucaria Cookii.—Babu Pratapa Chandra Ghosha presented a small section of the stem, taken at 25 feet from the ground, of an Araucaria Cookii 59 feet high, which grew in his garden at Belgharria, and which was blown down in a storm during the early part of May. He says:—"On examining its trunk I observed that "about four feet of it had been severely attacked "by white ants which had almost perforated it. "It is remarkable that a tree, with resin resembling "turpentine should, while alive and in a healthy "condition, be so seriously attacked by these insects." It seems probable the stem had been injured before the white ants attacked the dying wood.

FUNGI ON TEA ROOTS.

The following letter from Mr. Grant, Manager New Cinnatolliah Tea Co., Limited, North Lakhimpore, Assam, in reference to a notice which appeared in the Proceedings of the Society for March, will be read with interest by Tea planters:—I have noted in the Proceedings of the Agri. and Horticultural Society of 23rd March last, some remarks about fungi on roots of tea-bushes. Finding no allusion to certain kinds of tree roots killing the tea-bushes round them, I take the liberty to inform you for the benefit of others that the roots of the *Soom* (on the leaves of which the Assam Mooga Silk-worm is fed) and *Bookain*, a kind of pariah Neem unless removed when a clearance is made for planting tea, always destroys the tea planted round the stumps, and unless the root is *entirely* (including laterals) removed, it will be difficult to get tea to grow near it for years. I myself have seen numbers of instances; in some places the tea-bushes were destroyed within a radius of 15 feet from the stump. Though there are other tree roots that have the same effect, the above two hardly ever fail when the tree is cut and the root left in the ground to decay, otherwise if left growing, they do not seem to effect the tea-bushes. The only way is to remove the stump entirely and replant the spot, sacrificing even a few bushes, as they will invariably die in time if the roots are not entirely dug out.

The subject being of some importance to Tea planters, Dr. King was consulted, and the following is his reply:—An analysis of the two trees you mention would not, in my opinion, be of any use. If experience shows that the wood of these is especially affected by this dangerous fungus, all stumps of these species should be up-rooted. But I do not think that by an analysis of their wood, we should learn the cause why the fungus prefers them. If the dead stump cannot be actually dug out from gardens where they have been left, they might be isolated by digging a trench round them, so as to prevent the spread of the fungus from them to the surrounding tea-bushes.

TOBACCO.

A paper was submitted from Mr. Reinhold, together with his correspondence with Government on the subject.

In his paper Mr. Reinhold advocates the fostering by Government of the cultivation and manufacture of a superior class of Tobacco in India, as a means of restoring the balance, and largely increasing the export trade of India. Mr. Reinhold thinks that the present depression in the rates of exchange give an

exceptional opportunity of developing a trade which would compete on advantageous terms against other exporting countries, having mainly gold currencies. As an inducement to capitalists Mr. Reinhold shows that Government might advantageously move in the matter, and by associating itself with a Syndicate of Merchants and Zemindars, and making exhaustive* demonstrative experiments on a commercial scale, prove the adaptability of the Indian soil and climate for producing a first rate tobacco equal to competing with the best in the markets of the world. Mr. Reinhold gives statistics to show how the price of tobacco has been maintained in the face of the shrinkage in value of Coffee, Sugar, Tea, Wheat, Cotton, Silk, Flax, Wool, and Indigo: and bases on this some portion of his argument on the commercial advantages which would follow the development of a trade in this product.

In an appendix a carefully compiled estimate is given, taken principally from the reports of District Officers written when Government was making inquiries on the subject of Tobacco cultivation. The estimate shows the expenditure which would be incurred in cultivating and curing the tobacco off 2,000 acres of land, under European supervision. The paper will be discussed at the next meeting.

THE INDIAN TEA INDUSTRY.

There are probably few British Industries of equal magnitude to that of which this article treats which attract so little attention from the public, and the reasons are not far to seek. Its operations have been conducted at a distance, and mainly by private enterprize. Few large concerns have come to the public for capital, and of these some have had a career which has not favorably impressed the public with tea companies: while, owing to the small number of shares floating in the market, and the wide margin made for them in the Stock Exchange quotations, buyers and sellers have been hindered from operating. The time is possibly at hand when this class of investment will receive more general attention (1) on account of the present prosperity of the industry, and the growing popularity of Indian and Ceylon tea with the home trade; (2) from the recuperative power shown by estates whose future at one time seemed doubtful; through the high return upon the capital yielded, which will be shown by many companies whose reports will shortly be published, and this, too, in a year when the price of tea in the London market has fallen to a lower level than has hitherto been touched.

A few figures illustrate the growth of the industry: In 1876 the import was 29,5000,000 lbs., in 1881 it was 45.750,000 lbs., and in 1886 it reached 76,500,000 lbs. The consumption for the corresponding years was 26,750,000 lbs., 48,750,000 lbs., and 68,500,000 lbs., while during the current season ending May 31 the import will reach 78,000,000 lbs., and the consumption from 75,000,000 lbs. to 76,000,000 lbs. The feature, however, which arrests attention is the proportion of Indian and Ceylon tea taken from home consumption which during the past four months has risen to 50 per cent. of the whole as against 30 per cent. in 1881 and 17 per cent. in 1876. Indian tea, as a matter of fact, is slowly but surely ousting its rival and obtaining command of the market. This has not been achieved without a lowering of price to compete with the cheaper rates at which China tea sells; but the reduction has been slow, the average value of Indian tea in London being about 1s. 1½d. per lb. This, however, has been anticipated, and has been met by a considerable reduction of the cost of production effected (1) by consolidation of estates; (2) increased use of machinery; (3) by more scientific methods of cultivation and manufacture, through which finer and larger yields are secured. India, indeed, having always beaten China in quality, now competes in price, most estates laying down their crops well under 1s. per lb. in London, and some under 8d. per lb., while it is admitted that a further reduction in cost is practicable.

Among the companies known to the London market the largest is the Assam Company, which has 7,710 acres under plant, an annual yield of 2,500,000 lbs. to 2,750,000 lbs., and which has paid dividends averaging over 16 per cent. during the last 10 years of its working. The next in extent is the Land Mortgage Bank of India, owning about 7,600 acres of bearing plant, with an annual production of about 2,000,000 lbs., upon which a profit of £28,000 was made last season ending May 1886, and which will be a valuable property to the shareholders. The Jorehaut Company follows with 4,360 acres, known as producing some of the finest tea grown in Assam, and with a dividend record of 12½ per cent. in 1884, 15 per cent. in 1885, and 15 per cent. in 1886, while for the current season a very satisfactory financial statement will shortly be issued. Among other successful companies accessible to the investor are the Darjeeling, the Borelli, the Lebong, the Jhanzie Association, and the Scottish Assam Company; while as a specimen of the recuperative power alluded to we may mention the Luckimpore Company, respecting which a good report is shortly expected, and the Upper Assam Company, now, through careful management, earning large annual profits on its crop.

It is difficult to estimate the average return upon the 40,000,000 or 50,000,000 sterling invested, owing to the large proportion of estates in private hands, but the best proof that it is a substantial one is that of late years only one company of any size has come for capital to the London market. The following table, prepared from the latest published accounts, gives a fair index to the general position of the industry. The figures selected, as affording the best guide to investors, are the capital per acre, yield per acre, average of prices obtained for the tea during the past three or four seasons, and the cost of production during the last year (1885-6) for which accounts have been issued:—

Company.	Capital per acre.	Yield per acre lbs.	Price realized average of past Seasons.	Cost of production per lb.
	about	about	s. d.	s. d.
Assam Co. ...	£ 24	340	1 0 9/16	0 10
Land Mortgage Bk. ...	43	262	1 2 11/16	0 10½
Jorehaut Co. ...	23	291	1 2 7/8	1 0
Brahmapootra Co. ...	49	463	1 2⅜	0 9¾
British Indian Co. ...	116	286	1 0 1/12	0 9¾
Doom Dooma Co. ...	69	700	1 0	0 8¾
Darjeeling Co. ...	81	307	1 5½	0 11 9/16
Jhanzie Assn. ...	37	312	1 2⅜	1 0½
Lebong Co. ...	65	345	1 4	0 11
Borelli Co. ...	80	417	1 2¼	0 11½
Luckimpore Co. ...	79	265	1 3 7/16	1 2¾
Borokai Co. ...	46	273	1 7½	0 10¼
Tiphook Co. ...	32	318	1 0 15/16	0 10 1/10
Scottish Assam Co. ...	111	281	1 4 1/16	0 11½

From these figures it appears that those companies with a low capital per acre of plant, or those noted for the high character of their produce, are in a strong position, and should prosper even if the competition with other producing countries should still further reduce the price of tea. In the annual reports, due in June, some will show a higher price obtained, many of them a lower cost of production, and the majority of them a return of from 6 per cent. to 9 per cent. to the investor at present share values. We have spoken of a possible lowering of the price of tea by competition of producing countries, of which Ceylon and China are the chief. As regards Ceylon its increased consumption is probably effected at the

* That the experiments would be *exhaustive*—(of the soil)—there can be no doubt. Immense areas which would grow grain and roots for human food are ruined by tobacco culture.—ED.

expense of China tea, which it easily displaces, owing to its superiority; while as regards China tea it can now only injure Indian by being imported at such a low cost as to undersell its rival, and this we understand, is not addmitted by the China merchants to be possible.—*Indian Planters' Gazette.*

FATS DERIVED FROM SAPOTACEOUS PLANTS IN SUMATRA AND THE NEIGHBOURING ISLANDS.

Among the specimens recently presented to the Museum of the Society are a series of the Sapotaceous plants yielding vegetable fats in Sumatra and Borneo, etc. Although the produce of several of these trees is well known in the East, and finds a ready market at Singapore, they are still almost unknown in this country. Several of the trees also yield guttapercha. Dr. Burck has given descriptions of the plants in his 'Mededeelingen uit 'slands Plantentuin' (No. III., pp. 36-43), from which the following account is taken. The majority of them are species new to science. They are as follows:—

1. *Palaquium Pisang*, Burck.—"Foliis obovatis ellipticis, subtus aureo-nitentibus, costulis 12–14; petiolis 1·5 to 2 per cent. aureo-pubescentibus."

This tree grows to a height of 60 to 80 feet, and yields an inferior guttapercha which was formerly used to mix with gutta-soentei, but is not now collected. The seed is sub-globose, 1½ centimetres long, with a polished testa. It yields the fat called "Balam."

2. *Palaquium oleosum*, Burck.—"Foliis obovato-ellipticis vel elliptico-lanceolatis subtus aureo-pubescentibus; costulis 20-22 teneris prominulis."

The fat is distinguished by the name of Soentei fat. It is a somewhat smaller tree than the last, attaining a height of only 50 to 60 feet, but it yields a valuable timber of a reddish colour, that of *P. Pisang* being white and not durable. The seed is 3 centimetres long, and two broad, with a large hilum covering the greater part of the seed. Both the trees grow in Sumatra in damp bushy places near the coast, at an elevation very little above the level of the sea.

The seeds of both species are sometimes eaten in times of scarcity, but the greatest part is exported to Singapore, the collection forming no inconsiderable source of income to the natives, as may be gathered from the fact that between November 1884, and March 1885, no less than 600 kojangs* of Balam and Soentei kernels were exported from Sumatra, the former being valued at 80 to 100 dollars per kojang, and the latter 60 to 73 dollars, the price sometimes rising to 120 and 100 dollars respectively. The Balam fat is of a yellowish colour, and has a slightly bitter taste; it is as pliable as wax. It is used in sugar refining, artificial flower making and in the preparation of tapioca, being employed to grease the pans (heated to 300°) in which the tapioca is dried. By far the greatest quantity, however, is exported to Europe *via* Singapore.

The Soentei fat is of a pure white-colour, has a sweetish taste, and is used by the natives for cooking purposes. By the rough process of extraction used a good deal of the fat is left behind, so that 34 to 36 per cent. only of Balam, and 28 to 30 of Soentei fat is obtained. By the European method employed at Singapore, probably 45 per cent. could be obtained from the balam, and 37 from the soentei fruits. The price varies from 7 to 15 dollars per picul in the European market. The industry is probably capable of considerable extension, since the trees will most likely be found in districts where the value of the fat is not known at present. Both the Balam and Soentei fats are known at Singapore as the vegetable tallow of Siak.

3. *Palaquium oblongifolium*, Burck † (*Dichopsis oblongifolia*, Burck, 'Rapport Gutta Percha,' 1884, p. 21).—"Folia petiolata oblonga v. lanceolata oblonga, longe acuminata, nervis lateralibus 20-30 utrinque in folii substantiam immersis."

The tree is found in Borneo, Sumatra, Riouw and Malacca. According to Mynheer Toorop the fat is prized in the Sambas province more than any other fat for cooking purposes, and is even used as butter. It is prepared almost exclusively for home use, and consequently is not quoted in the Singapore trade reports.

This tree is considered by Dr. Burck to be distinct in the form of the leaves and the size and form of the flowers from *P. Gutta*, the species from which guttapercha was originally obtained, and which, with the exception of a tree cultivated at Singapore, and those cultivated in Java, is believed by Dr. Burck to be now extinct, at least in a wild state (*Annales, l. c.*, p. 69).

According to Dr. D. de Loos,* it is a hard white fat consisting principally of stearin and olein, and should be very valuable for the preparation of stearin candles. This tree in Borneo, Sumatra and Riouw is the source of the best gutta-percha, and is now planted by the Dutch Government on this account in the Tjitjoeroeg district. It should receive attention at the hands of the British Government, since not only does it yield the best known guttapercha and a valuable fat from the seeds, but also useful timber.

4. *Payena lancifolia*, Burck.—"Foliis longiter petiolatis e basi acuto-lanceolatis acuminatis, 1-1½ pedaliis, supra glabris, subtus aureo-nitentibus."

The tree grows in marshy land, especially on the banks of the smaller rivers, and the fat is used in the Sintang province of N. Borneo in the same manner as that of *P. oblongifolium* in the Sambas district. The fat at the ordinary temperature of the tropics is a clear fluid, and for kitchen purposes it is not so much esteemed as the Tangkawang fat. It is called by the natives "Kelakki" fat; it is not as yet exported. The wood of the tree is used for making oars.

5. *Payena* (?) *multilineata*, Burck.—"Foliis lanceolatis longiter-acuminatis glabris, subtus pallidis costulis subtilibus densissimis plusquam 60."

This tree grows in the same district as the last, and yields an inferior fat, which is only used for lighting purposes. Neither flowers nor fruit have yet been seen, and the tree is therefore referred doubtfully to the genus *Payena*. The native name for the tree is "*Belaban*" or "*Melaban*."

6. *Payena Bankensis*, Burck.—"Folia e basi acuta v. subacuta lanceolata, acute acuminata vel apice rotundata glabra, subtus pallida fuscescentia, nervis secundariis circiter 30 utrinque prope marginem arcuatim unitis pertensa ('Ann. du Jardin Bot. de Buitenzorg,' vol. v., p. 54).

The fat of this tree is at the usual temperature in Java a thick fluid; according to Dr. D. de Loos (*loc. cit.*, p. 9) it agrees in colour and purity with almond oil, and is usually soft, and light green in colour. In Sambas province the fat is known as "Tengkawang sangai," but in Banka as "Ketiauw" oil. It does not appear to be exported. The tree affords a guttapercha of inferior quality, known as gutta katijau or ketiauw.

7. *Payena latifolia*, Burck (*l.c.*, p. 58, t. ix).—"Folia e basi acuta ovalia acuminata, nervis secundariis prominulis circiter 20 utrinque. Florum fasciculi axillares multiflori."

This tree is a native of Billiton and Riouw; it yields an oil called *Minjak Bengkoe*." The oil, according to Dr. D. de Loos, is clear, of a yellow colour and a pleasant taste. It has an odour of bitter almonds, and at 4° is perfectly solid. It is insoluble in alcohol, but miscible with fats; is soluble in benzol, and is not a drying oil. In Riouw Archipelago it is used in the preparation of pastry (*Natuurkundig Tijdschrift v. Nederlandisch Indie*, 1862, pt. xxiv., p. 481).

* At Singapore a kojang consists of 40 piculs (of 133⅓ lbs.), and in various parts of the Dutch East Indies from 27 to 30 piculs.

† See "Sapotacées des Indes Néerlandaises," in Ann. du Jard. Bot. de Buitenzorg,' vol. v., p. 25, tab. 5

* 'Beschrijvende Catalogus van het Kolonial Museum te Haarlem,' vol. ii., pt. i., p. 10, 1884

8. *Payena macrophylla*, Burck (*Kakosmanthus macrophyllus*, Hassk).—"Folia breviter petiolata e basi rotundata vel subcordata oblongo-obovata apice rotundato-obtusa vel breviter acuminata, 1¾ pedalia supra glabra lucida, subtus argenteo-sericea. Stipulæ triangulares acuminatæ pubescentes 5 mill. longæ deciduæ."

This tree is a native of the province of Bantam; the oil of the seeds is used for various purposes, W. H. de Vriese, 'Tuinbouwflora' (iii., p. 229, and *l. c.*, p. 51).

9. *Diploknema sebifera*, Pierre (*Archives Néerlandaises*, tom xix., p. 104, pl. iv.).—"Ramuli crassi folia ad apices ramulorum conferta, alterna. Flores polygamo-dioici numerosi ad axillas defoliatas vetustioresque umbellati pedunculi breves ferruginei tomentosi."

The tree was collected at Barabay in Borneo. The fat is obtained by boiling the seeds. It forms the Minjak Tangkawang of Bandjermassing. Dr. Pierre thinks the tree worth cultivating. The genus *Diploknema* was erected by Dr. Pierre on account of certain differences in the structures of the flowers of the present species, by which it is separated both from *Bassia* and *Payena*. From the former it differs in the short corolla tube, in the stamens being in an undistinct series or scattered, in the hypogynous pulfinate disk, and in the style not being elongated, and from *Payena* in the venation of the leaves, inflorescence, style, and ovary; and from both in the number of sepals and the polygamous flowers, which are of rare occurrence in the Sapotaceæ.

Of all the above Sapotaceæ the Balam and Soentei trees of the east coast of Sumatra seem the most worthy of attention as objects of culture, more especially as the fats have already found uses in European industries. While it is possible some of the other Sapotaceous fats may possess equally valuable properties, there is always great difficulty in introducing unknown and untried products. Thus the Bengkoe oil of Riouw and Billiton, and the Minjak Tangkallah * (*Cylicodaphne sebifera*) of West Java and Banka, have as yet found no entrance into commerce, in spite of strong recommendations.—*Pharmaceutical Journal.*

FLOWERS IN PARIS.—On January 1 there were sold in Paris, between 4 and 5 A.M., 150,000 dozens of cut Roses from Nice; 15,000 trusses (*bottes*) of Roses, 10,000 dozens of Camellias, 15,000 trusses of Lilacs. We take the figures from the *Bulletin d' Arboriculture.*—*Gardeners' Chronicle.*

PLANT DISEASES.—The United States Government allots a sum of 9,400 dols annually to the Department of Agriculture at Washington for investigations into the nature and treatment of plant diseases. Other 6,000 dols. are appropriated to other departments of botany.—*Gardeners' Chronicle.*

A METHOD OF CLARIFYING WATER has been devised by Professor Dobroslavine of St. Petersburg. He uses first a solution of perchloride of iron, and follows that with a solution of carbonate of soda. The quantities are said to be three grains of the perchloride of iron, and four grains of the soda crystals per gallon of water.—*Nilgiri Express.*

TEA AT HIGH ELEVATIONS.—A gentleman who has been through our chief tea districts in the Central Province says he has seen nothing (in tea) finer than the top of Hethersett, Udapussellawa, at over 7,000 feet elevation! How tea responds to good planting and careful work is well seen in the fields here running up to 7,200 feet. One advantage possessed however is that the estate faces the Uva lowcountry giving it more heat than is usual at the elevation.

THE FIGS OF ASIA.—Fig trees form such a prominent feature in tropical vegetation generally, and in the vegetation of tropical Asia more especially, that a fully illustrated monograph of the Asiatic species of so difficult a genus will be hailed with delight by botanists, and prove useful to horticulturists. We have seen the first part of Dr. G. King's monograph, on which he has been engaged for some years, and a cursory glance at it is sufficient to convince us that it embodies much honest labour. This part contains nearly one hundred plates, and we hope to give a fuller notice of it very shortly.—*Gardeners Chronicle.*

TEA: INDIAN AND CEYLON.—Although the public sales of Indian tea have been rather smaller, the tendency of values has been towards greater cheapness, as compared with the firmness observable last week. Many of the teas brought forward, however, were of poor quality, especially some of old import, which appear to have considerably deteriorated since their arrival. The buoyant tone of the market during the last few weeks was hardly likely to increase on the near approach of the Whitsun holidays, and the slackening of the demand for the descriptions that have shown such a considerable rise in values from the lowest point seems chiefly due to that cause.—*Produce Markets' Review*, May 28th.

TEA FOR INDIAN CONSUMERS.—The meeting on the 2nd June at Fairlie Place to discuss a scheme for the wider consumption of Indian tea among the Indian people was fairly well attended by representatives of the tea trade. A committee has been appointed. A correspondent says:—"I confess that I am not very sanguine as to the results. Our Aryan brothers and their female relatives will drink tea if it can be had for nothing; but when it comes to be a case of parting with pice to obtain it, that is a different matter. Tea is a luxury which the bulk of the populace of India are not yet prepared to indulge in to any large extent.—*M. Mail*, 15th June.

CINCHONA NEWS FROM JAVA is rather "mixed" (see our extracts); great damage has been sustained in some of the plantations from hurricanes, but yet the outturn of bark this year was likely far to exceed expectations; on the other hand, the crop of last year which was reported large is only given at about 600,000 lb.! have received a telegram reporting "London Tea market very firm for common qualities, and firm for the finest qualities."—In fact, a good market all round, no doubt owing to the bad accounts of the China teas, and also that the sales in Calcutta so far have been of poor teas. As regards the stock in London, it also principally consists of poor quality teas, we understand.

SOUTH AMERICAN STATES.—Mr. Lames, of the Paris *Revue Sud Americaine*, has published a most instructive book on the financial and economic status of Central and Southern America, from which many valuable statistics are taken. It appears that the Argentine Republic and Chili are exceptional from other South American countries in the character of their population, as shown by the following table:—

POPULATION OF SOUTH AMERICAN STATES.

Countries.	Caucasian.	Indian.	Hf-breeds.
Brazil	3,500,000	3,500,000	4.500,000
Mexico	1,200,000	4,086,000	4,400,000
Argentine Republic	3,200,000	100,000	200,000
Chili	2,000,000	50,000	300.000
Venezuela	300,000	800,000	1,000,000

—*American Grocer.*

ARTESIAN WELLS have been utilised with great success for fertilising the African desert. Sir R. Lambert Playfair, in the course of a consular tour in Tunis, has visited the ground where the first well was sunk, and reports most favourably as to the success of the project. A space of 375 acres has been cleared, and sown with cereals and lucerne, a vegetable garden been made, and a nursery of young trees planted. Two other wells are being sunk, which on completion will irrigate 7,500 acres of land. The Bay of Tunis has conceded to the Artesian Wells Company 25,000 acres of land, which they can select themselves from districts which are at present of no value.—*Indian Agriculturist*, June 4th.

* See *Pharm. Journ.*, [3], xiv., p. 481.

The Glasgow Tea Market.—This market has been instituted with the special object of bringing Indian and Ceylon teas more prominently before the Glasgow public, and for enabling buyers to obtain their supplies directly from the importer's stores. During 1886 the consumption of Indian tea in Glasgow and the neighbourhood exceeded 10,000,000 pounds and there seems to be every prospect of an increased demand. Moreover, seeing that Glasgow has cheap and regular communication with the North of England and Ireland, it may be confidently assumed that there are openings in those quarters for considerable further development of the trade. For 20 lb. to 40 lb. boxes, direct from the gardens, it seems certain that there will be a large and regular demand. Through Bills of Lading from Calcutta and Colombo to Glasgow can now be obtained at about the same rates of freight as to London, by steamers of the highest class. Charges are as follows:—

Clyde Dues, ...	.. 2s per ton weight
Cartage to Warehouse	.. 2s 6d ,, ,,
Storage per chest of 1 Maund ..	.. ½d per week
Receiving each chest ..	.. ¾d
Weighing ,, ,, ..	.. 1d
Delivery ,, ,, ..	.. ¾d
Fire Insurance ..	.. Nominal

Perfumes.—The following table will afford some idea of the value of the agricultural productions from which perfumes are manufactured:—

		Will produce		£
One acre of Jasmin plants,	80,000,	500 lb. of flowers	@ 1s. =	250
Rose trees	10,000,	2,000 ,, ,,	,, 9d. =	75
Orange trees (at ten years old)	100,	2,000 ,, ,,	,, 6d. =	50
Violets		1,600 ,, ,,	,, 2s. =	160
Cassia trees *acacia farnesiana* (at three years old)	302,	900 ,, ,,	,, 2s. =	90
Geranium plants	16,000,	40,000 ,, ,, leaves producing 2 oz of distilled otto per cwt.,	,, 5s. =	200
Lavender		3,547 giving flowers for distillation, value		=30

The Rosemary, per cwt., will yield 24 ounces of *otto* oil; ani-seed, 35 ounces; carraway, from 3 to 4 lb., 12 ounces; fennel seed, 2 lb.; patchouli, 28 ounces. The other plants which yield perfumes are mignonette, verbena, heliotrope, peppermint, wall-flowers, laurel; Australian wattle, and myall wood, &c. The perfume stills for the finer qualities are best with a capacity of about 8 to 10 gallons.—*Indian Agriculturist.*

A New Machine.—The *Financial and Mining Record* of New York describes a new machine for pulverising, or grinding, of the hardest substances by the action of air set in motion, resembling that of a cyclone. The air is confined in an iron chamber not larger than an ordinary house furnace. At a test given in the paint factory of McDougall, Logie & Co., where the machine has been in operation for six months past, nails, iron, slag, and flint rock were reduced to an impalpable powder, while the operation was equally effective with phosphates, mica, asbestos, rice hulls, and other pulpy and soft substances. The device is very inexpensive, and so far as the investigation showed, accomplishes results so important, as to point to a revolution in pulverising and grinding operations in numerous departments of trade. [What "a numerous department of trade" may be, we need not stop to enquire, but if the machine in question can cheaply effect the grinding of rocks, such as our felspathic gneiss, it will confer an immense benefit on agriculture, by rendering the fertile matter in rocks easily soluble, and assimilable by the feeding rootlets of plants.—Ed.]

Tea.—At the last meeting of the Indian Section of the Society of Arts, under the presidency of Sir Roper Lethbridge, M.P., Mr. J. Berry White, late of the Bengal Medical Service, read a paper on "Indian Tea." The lecturer said: The suitability of the soil and climate of some parts of India for the culture of the tea-plant was a frequent subject for discussion and report as early as the latter part of last century, but until 1834 these investigations and reports never got beyond a scientific or academic character. In that year the honourable court in Leadenhall-street losing the monopoly of the China tea trade which they had hitherto enjoyed, sanctioned the appointment of a committee to consider and submit plans for the introduction of tea culture in India, and for the superintendence of such plans if approved. Mr. White then described the circumstances which attended the discovery of the plant in Assam, which ultimately resulted in the importation of the China tea-plant into the province, which he said was, in its way, as disastrous to Assam as the potato fungus had been in Ireland, or the black bug to Ceylon. The tea-plant of China was a shrub with small leaves, in size and appearance somewhat resembling the finest of our hedge-rows. That of Assam was a tree growing from 25ft. to 35ft. high, with leaves six times larger than the China variety. Under like conditions the yield of leaf from an acre of Assam tea would be not less than double that of the China plant. Mr. White having referred to the progress in tea cultivation in some parts of Bengal, the North-West Provinces, the Punjab, and Madras, said that it was, however, in Assam alone that it possessed any real commercial importance. During the four years following 1858 cultivation extended rapidly in every district of the province excepting Goalpara. Many companies were formed, and the inevitable reaction and collapse followed rapidly, the climax of the panic being reached in 1866, when most of the companies formed during the mania disappeared. Since this time the tea industry in India had made steady and generally healthy progress. It had had, of course like all other enterprises, its periods of depression and moderate inflation, due to the fluctuations in the market value of the staple; but there had been no undue excitement upon the one hand or panic on the other. This great industry employed over 500,000 of our Indian fellow-subjects, over twelve lakhs of rupees being paid to them in monthly wages. About 275,000 acres were under cultivation at the close of last year, a considerable portion of this area being immature plants; the whole when in full bearing, it was estimated, would yield 120,000,000lb. of tea. About £19,000,000 sterling was invested in the enterprise. The market value of the current year's crops might be roughly estimated at £4,500,000. The consumption of tea of all sorts in the United Kingdom since 1870 had been an advance from 117,000,000lb. in that year to 187,000,000lb. in 1878, showing an average annual increase of four and two-third millions. The command of the tea supply not only of the United Kingdom but of the world finally rested with whatever country could produce it at least cost, and this country, taking every factor into consideration, was undoubtedly India. (Cheers.) A brief discussion having taken place, the proceedings closed in the customary manner.—*L. & C. Express.*

MIXING MANURES.—In the "Science Gossip" at the Melbourne Leader it is stated:—"M. Audouard has thrown some light on the proper use of manures. It is a common practice to mix nitrates and superphosphates, but this he shows to be a mistake, reactions being set up which destroy the very qualities for which the respective manures are valued and recommended. Used separately they react upon the constituents of the soil, which is what is wanted. The toper's maxim—'never mix'—is applicable in this case, although with most other manures, especially the organiced, mixtures are found to be beneficial."

TO HASTEN THE GERMINATION OF HARDSHELLED SEEDS.—A correspondent of the "Indian Agriculturist" writes :—

Some years ago I undertook the raising of many varieties of the beautiful Australian acacias, the seeds of which I had imported. My object was to ascertain whether these could be naturalised in this country. Knowing full well that to get a crop of seedlings at an early date, the outer shell of the seeds must be softened, I steeped the entire lot in a mixture of fresh cow-dung and water—previously heated—for 24 hours. Having prepared my beds, I sowed the seeds (in the beginning of July) and fully 90 per cent germinated within three weeks. I have since raised hundreds of acacia seedlings—the common *babool* among them,—and never found any difficulty about the matter. This is the native method of sowing the seed, and is as good as any that I know of.

GOW'S WITHERER AND ITS WORK.—The following memorandum from Mr. Jameson should we think settle the question as to the enormous advantages to be gained by using this machine :—

MEMORANDUM, GOW'S SYSTEM OF TEA MANUFACTURE.—Wet leaf put on the Withering Tats at 12 noon and 5 p. m., will be ready for commencing manufacture on the following morning at 6 o'clock, when a charge of 450 lb. to 600 lb. leaf may be put into the "Monarch" (2nd size) and, after being worked in the machine at about 170° for ¾ hour to an hour (according to the state of the wither) will be ready for rolling, the leaf being then in a gummy state, of a darkish colour, and fermentation being well advanced. The fermentation goes on during the heavy rolling, and at the end of an hour the roll will be ready for firing, though I think the colour is improved in the time occupied in breking up and sifting the roll, previous to firing. When the leaf is very much underwithered, the large leaf of the roll is much improved in twist, and somewhat in colour, by a second rolling of half an hour or so.

	hours
Time of leaf on Tats	18
,, of charge in "Monarch" ...	1
,, Rolling	1
,, Breaking up and sifting ...	0¾
,, 2nd Rolling ...	0½
,, Firing in "Victoria" ...	1½
,, lost moving leaf to and from machines	0¾
,, from arrival of leaf in factory till made into Tea	23½

4,000 lb. wet leaf put on Tats at 12 noon and 5 p. m. can be made into tea by 4-30 p. m., the following afternoon.

ORDINARY SYSTEM OF TEA MANUFACTURE.—The same kind of leaf would not be sufficiently withered for rolling till the evening after it was put on the tats (possibly not then). Manufacture therefore would begin about the time the tea was finished by Gow's system.

	hours
Time of leaf on Tats	29
,, of Rolling	1
,, Breaking up, re-rolling, fermenting	3
,, Firing	1½
,, lost moving leaf from and to machines	0½
,, from arrival of leaf in factory till made into tea... ...	35

4,000 lb. leaf put on tats at 12 noon and 5 p. m. can be made into tea by 4 a. m. on the second morning after.

(Signed) GEO. D. JAMESON.

Mariawatte, May 24th, 1887.

STOCK SEED.—The bed in which plants are grown for stock seed is the soul of the garden ; it may not attract strangers, but its owner sees in it some promise of reward, in the splendor which his garden shall possess in future years ; and, as a business matter, there is no good return surer than from the introduction of a flower which presents new and unusual beauties. But there is in true floriculture a nobler object than mere money-making; the question is not only what can one make of the flower, but what can the flower make of us. In elevating its character, the cultivator's character is ennobled ; improvement does not go singlehanded ; what man does for the plant, in making it more beautiful or useful, the plant returns him ten-fold—not alone commercially, but in dividends of beauty and worth, and in the satisfaction with which success crowns a well-directed effected.—*Nilgiri Express.*

NOTES OF A NATURALIST IN SOUTH AMERICA.—Several ports on the rainless coast were touched, and Mr. Ball landed at Tocopilla, situated about 17° south of Payta, and about 22° south of the equator. "Here," says the writer, "I found what I had often heard of, but in whose existence I had almost ceased to believe—a land absolutely without a trace of vegetable life. . . . . Not only was there no green thing; not even a speck of a lichen could I detect, though I looked at the rock through a lens. Even more than by the absence of life, I was impressed by the appearance of the surface, which showed no token that water had ever flowed over it. . . . . I saw no insect and no lizard, no living thing, with the strange exception that on the rocks nearest the houses there were several small birds, which appeared to be rather shy and which I was not able to approach. I was afterwards told that these birds live on the grain which they are able to steal or pick out from the manure in the stables where a few horses and mules are kept for the needs of the place." Most of the water required at these desolate ports is obtained by distillation from sea-water, but some is conveyed to them by steamers.—*Gardeners' Chronicle.*

A LARGE "PEARL BLISTER" is thus noticed in the *Singapore Free Press* :—"There is just now on view at Sayle & Co.'s store, an interesting natural curiosity, which has just been brought by Mr. Neil Galbraith from Western Australia. It consists of a pearl oyster shell with a remarkable growth of nacre adherent to its internal surface, being what we are told is generally termed a "blister." It is about 2¼ inches long, by 1 inch broad, and stands up in relief to a height of nearly five-eighths of an inch. It is of the exact appearance of pearl and is the very largest example of the kind that has ever been met with in the experience of the pearlers of West Australia. Mr. Galbraith intends to send it home by the next mail. We have heard that a high value has been put upon it, but it is doubtful whether it will fetch the price named."

FORESTRY IN CEYLON is thus noticed in a review of a work on the Edinburgh Forestry exhibition by M. Reuss, which appears in *Indian Forestry*. As our readers are aware most of the land "denuded for the now useless cultivation of coffee" will be devoted not to forest trees but to tea bushes. There is plenty land for forest operations, however :—

"CEYLON.—Returning to Asia, our author notices the state of the Ceylon forests, which he says cover 39 per cent. of the total territory of the island. Here also the services of the Indian Forest Department were called into requisition, and a forest administration has been established on the report of Mr. F. Vincent, sent on a special mission in 1883. The principal object of this new department will be to reafforest the tracts denuded for the now useless cultivation of coffee, and to introduce, where possible, plantations of teak, which has been grown from seed imported from India, with considerable success." We believe Mr. Alexander wrote a report on the Edinburgh Exhibition for a home periodical,

CAMPHOR.

The mountains in the interior of Formosa, especially in the Northern part of the island, are still covered with camphor trees, but these are ruthlessly destroyed as the Chinese invasion progresses, and their place is taken by other cultures, such as tea and indigo, which yield a much quicker return. The total extinction of the camphor-laurels in Formosa is therefore, to all appearances, a question of, perhaps, not more than twelve or fifteen years, at the end of which period the Chinese camphor of our markets may have become a thing of the past.

Statistical information concerning the exportation of camphor from Formosa is published occasionally, but the figures given in different reports seldom agree. The average yearly shipments from the island may, however, be set down at about 11,300 piculs. In 1882 and 1883 the exports fell to one-half of the usual quantity, and in 1884 and 1885, partly on account of the political differences between France and China, and partly because of the increased restlessness of the aborigines, they ceased almost entirely. Last year the shipments again assumed normal proportions.

The probable future of the camphor industry in Japan is to some extent a matter of conjecture, as it is difficult to obtain entirely reliable data; but a careful comparison of the information vouchsafed by the most trustworthy sources favours the assumption that in this country also the destruction of camphor laurels has, for some time at least, been proceeding at a much faster pace than the raising of new trees.

Japanese camphor, the variety most esteemed of those known to European commerce, has a peculiar sassafras odour, is larger grained and of a paler or more pinkish tint than Formosa camphor, and it now occupies the leading position on our markets. It arrives here in wooden tubs weighing about 1 cwt., and is principally imported *via* Hiogo, smaller quantities reaching us *via* Osaka, Yokohama, and Nagasaki. The same discrepancy in the export figures occurs in the different Japanese statistics as is the case with Formosa.

The following figures (expressing number of piculs) are derived from a source generally considered reliable, but we are inclined to believe that in some cases the Hiogo exports alone are made to do duty for those from all the Japanese ports together:—

1879	1880	1881	1882	1883	1884	1885	1886
25,044	18,861	23,714	33,994	33,241	30,365	21,199	36,632

It will thus be seen that Japan now yields about three or four times as much camphor as Formosa. The Japanese provinces of Tosa and Satsuma are the centres of the camphor industry. The product distilled there is taken to the capital of Tosa and shipped to Osaka, where it passes into the hands of European dealers, who export it *via* Hiogo. Large quantities are also obtained in Kiu Sin, the southernmost island of Japan, and brought into commerce partly *via* Nagasaki, the only port on that island, and partly *via* Shanghai and Hong Kong, to which ports the camphor is conveyed by native craft.

The process of distilling camphor as carried on in Japan is of an extremely simple character. The collectors choose the oldest trees, which are generally the richest, and having cut one down, proceed to lop off the branches. The whole is then cut into chips and put in a wooden tub with a false bottom, placed over an iron pan filled with water and heated by means of a stove. The vapour of the boiling water passes through the tub, carrying with it the camphor from the chips through a bamboo tube to the cooling apparatus, where, upon being passed in a zig-zag direction through vertical layers of rice straw, it condenses, along with its by-product, the camphor oil. This oil is generally put through a further process of distillation, whereby more camphor is obtained and exported to Europe, but large quantities of it are also consumed in the country, principally in the preparation of varnishes.

In Japan the camphor trees are mostly owned by the Government, who, employ the wood in shipbuilding. Formerly there were also extensive plantations in the hands of private owners, but at present these plantations are almost extinct. It is said that at one time the Japanese law required a new camphor tree to be planted wherever an old one was destroyed, but that this practice has now become obsolete. Reports have obtained currency lately that large tracts of trees owned by the Japanese Government had been cut down, and perhaps the anxiety to strengthen the maritime resources of the country may account for the largely increased production of camphor during the last five or six years. Speculative movements apart, there is, perhaps, no reason to expect any important advance in the price of camphor for some years to come; in fact, it seems quite within the range of possibility that the over-production of the crude product at present existing, is destined to assume still larger proportions in the near future; but it is not unreasonable to suppose that this period of abundant supply will be followed by one of extreme and continued scarcity, unless steps are taken to propagate the camphor trees on an extensive scale in countries other than those which now supply our requirements.

The camphor laurel thrives best in certain tropical and semi-tropical districts, possessing a dry soil and a moist atmosphere, such as is found on many mountain-slopes. In Japan the tree is able to bear the hardest winters, during which occassionally as many as eighty or ninety frost-nights occur, the temperature sometimes falling to 90° Cent. below zero. The propagation of the tree is very easy. The seeds can be planted in garden soil after the manner of peas, and by next season will have attained a height of about 2 feet. They may then be permanently transplanted with the care required by evergreen trees. In California and the Southern States of America camphor trees flourish very well, but they have not hitherto been cultivated there for commercial purposes. In Europe the tree flourishes in certain parts of Italy.

The position of camphor at the present moment may be summed up as follows:—A comparatively favourable statistical position, coupled with an absence of demand on the part of the refiners, who appear well supplied. A firm tone rules for the refined product, which is comparatively cheap, but there is less demand on the part of consumers that might have been expected at the present time of the year. There are prospects of considerable shipments from the producing countries for some time to come, but of a dearth in the exports at no very distant date.

There seems very little chance that the consumption of camphor, either for medicinal purposes or as a preservative of clothes, will at all diminish, no efficient substitutes for the drug having hitherto been discovered. Napthalin has indeed been named as a probable competitor of camphor in some departments, but it does not seem likely ever to become a dangerous rival.—*Chemist and Druggist.*

PRESERVING WOOD.—A very simple method of preserving wood effectively is as follows, which is applied in Norway to telegraphic poles:—After the poles are set in place a man goes from one to another with an auger, with which he bores a hole in each post, beginning at a point about two feet above the ground and boring obliquely downward at as small an angle as possible with the axis of the post, until the point of the auger reaches the centre of the stick. The auger hole should be an inch in diameter, and in telegraph poles of the ordinary size will hold easily four or five ounces of sulphate of copper, which is put into it in the form of coarsely powdered crystals, and the opening then stopped with a plug, the end of which is left projecting as a handle, so that it can be pulled out and replaced. Just what action goes on in the interior of the stick no one pretends to say, but it is found that the crystals of copper sulphate disappear slowly, so that every three or four months the charge must be renewed, while the wood both above and below the auger hole, even to the very top of the pole, gradually assumes the greenish tint due to the presence of copper in the pores.—*American Cultivator.*

THROUGH THE TEA DISTRICTS.

FROM NUWARA ELIYA *via* WATAWALA AND GINIGATHENA GAP TO YATIYANTOTA, AND BACK *via* AMBEPUSSA AND KANDY.

[The following account of a trip through Tea districts has been lying in type for some time, waiting a fitting opportunity to appear, which seemed as if it would never come.]

It has been remarked in connection with the interesting analysis of Ceylon tea sales in Mincing Lane for 1886, presented by Messrs. Wilson, Smithett & Co., that the average price realised for Kelani Valley and Nuwara Eliya teas was the same. Considering that the altitude of the two districts differs by from 5,000 to over 6,000 feet, this result is doubtless rather surprising. But it is in reality far too early in the history of our tea districts to make comparisons which can be of any practical value. In both the districts named, for instance, there are so many clearings which last year gave their first crops of tea, and tea prepared after a primitive fashion, or at least without the aid of machinery, that it would be premature to rank the average quality of the teas by last year's prices. Flavour and delicacy in teas are associated with high elevation, but so many other contingencies operate, that we may often find low elevation compensated for even in these respects by countervailing advantages. The character of the "jât" of the tea grown has always been deemed an important factor; but it is now generally believed that too much may be made of "jât," especially in the case of high districts where a hardy Assam hybrid and in some cases a good China seem to prosper best all the year round. From these, of course, may come teas of delicate flavour, and, I believe, Mr. A. H. Thompson, of the well-known firm of London Tea Brokers, on his visit to Ceylon some time ago, congratulated Mr. Rossiter on the quality of his Fairyland and Hazelwood (Nuwara Eliya) garden teas approaching closely to that of Darjiling teas. Perhaps such ought to be marked "Darjiling-Ceylon," in order to be classed separately and receive due attention. Practically, the factor which most planters at present deem of importance to secure due preparation and due quality in their teas, is "plenty of power" to secure thoroughly adequate not to say hard "rolling." Mr. Gow used to dwell much on the "fermentation" or rather the chemical change in the leaf, as the most important process with reference to the quality and price of Ceylon and Indian teas; but I suspect most of our planters would say:—"Give me power and good machinery for a thoroughly satisfactory roll and I'm not afraid in any of the other processes,—with due means and attention, of course,—of failing to do full justice to my tea."

These reflections would, however, perhaps better follow, rather than precede, a short account of the trip described in my heading. To begin with the Nuwara Eliya district, there can be no doubt of the successful growth of tea at these, the highest elevations in Ceylon. Apart from Mr. Rossiter's older fields, there can be seen on Portswood and Pedro—both Mr. Grinlinton and Capt. Bayley having taken special pains—as promising tea as could be desired. The only risk may be found, as I said before, in the very goodness of the jat of tea planted; but the soil is exceptionally fine and the plantations well sheltered. Further on in Udapussellawa there is tea flushing and bearing satisfactorily at as high an elevation as any in Nuwara Eliya, except it be Oliphant. I refer to a portion of St. Margaret's and Goatfell estates. The top fields of Abbotsford too—reaching as they do to 6,000 feet—may be taken as encouragement, the appearance and yield of tea there surprising even Assam visitors. It would be interesting to know how the yield of leaf from Mr. Rossiter's field of 'China' compares, acre for acre, with that from his 'Assam hybrid' garden, and also how both compare in resisting frost. Several flushes have been lost on fields in the neighbourhood of Nuwara Eliya, during the recent season, but this visitation, for February, is declared by old residents to be quite exceptional. In connection with "Baker's Farm" Margastotte, there are some very fine tea clearings, and one or two little gardens on the wayside to Hakgala are but the precursors of many such which we may anticipate in this neighbourhood and on to Wilson's Bungalow as well as throughout Upper Uva—tea gardens probably taking the place of the once famous coffee 'watties' and even, higher up, of the no longer successful potato planting. It is strange how, of recent years, neither change of seed, nor site, nor the utmost attention in manuring and tillage, can secure a successful potato field in the neighbourhood of Nuwara Eliya.

The first, or last, tea appertaining to the Nuwara Eliya district on the way to the railway, is that of "The Scrubs" on the side of "One Tree Hill," and very promising is the growth and appearance. The new tea store is a prominent object not far from the roadside, while on the opposite and farther side of the lake, the smaller Naseby store for a little tea totum running up and over the hill sides may be noticed. Here tea has prospered in the open as well as under cinchona, though on flat pieces frost has touched up the bushes this year, especially those of the finer jât. In one rather marshy corner, after the sharp attack of one night (February 5th), the display of colour—from bright yellow to the deepest bronze—over a cluster of tea bushes was as varied and attractive as on the tops of the adjacent jungle! There is only a short period of the year when such liability is incurred up here, and that period may, we suppose, be usually regarded as the time for resting—wintering—the tea bushes. Seeing that the fine basin of forestland from the boundary of "The Scrubs" nearly to Messrs. Cross and Pallardie's property at Nanuoya station is claimed by the representatives of Sir Edward Barnes, we may any day see it cleared and planted for tea and cinchona—a great loss to the "amenities" of the drive between the Sanatorium and the railway Station to which this forest so largely contributes. There will always, however, be a considerable fringe, we should suppose, of the forest too high or too important for shelter to be felled, and that will be of interest to the visitors by way of contrast to the cultivated vegetation below, while the Nanuoya itself in its rapid descent over rocky cascades, by fernclad glade and anon through deep, black pools, will always be "a thing of beauty and a joy for ever." And yet, this stream in its upper reaches may be shorn of some of its proportions; for, with the consent of the Government, the proprietors and manager of Abbotsford are even now endeavouring to secure a share of the water from a point below the "Lady's Waterfall." The levels are being tested, and it shows the importance attached to plenty of motive power (especially water) for driving tea-preparing machinery when it should be proposed to incur the very considerable expense of cutting a channel for six miles between the estate and the point named along, at some points, rocky and precipitous mountain sides. The fear is however that the levels will not permit of the diversion of the water. The condition attached by Government is that the water, after

doing duty at Abbotsford factory, should be returned to the same stream lower down.

As already mentioned, I made the journey of over 5 miles from Nuwara Eliya to Nanuoya station in 40 minutes, more comfortably than in any coach. Nothing could be better or more uniform than the jat of tea in this neighbourhood so far as I had an opportunity of observing: on Edinburgh and Inverness particularly so; on Clarendon and Loxa tea is doing well, while it is refreshing to see good coffee well kept up both on the first-mentioned estates and on Dessford and Lorne, where, however, preparations are being made by extensive nurseries for planting of tea on a big scale. Higher up tea prevails on Maha Eliya and especially on Calsay with its turbine-worked factory, while farther round it is very promising on Lippakelle and on other places in the neighbourhood. The Agrapatana division of Dimbula together with the middle and lower Bogawantalawa sections of Dikoya are regarded as among the few remaining strongholds of coffee on this side of the country, and very opportunely have the good prices and brighter prospects come to encourage continued attention to the old staple. Nevertheless, we may be sure that neither here nor in Uva will efforts be wanting to prepare against the necessity of a change, especially if "green bug" continues. This pest I hear is still prevalent on the other side and does not confine its attention to coffee, being freely seen in the jungle. "Down the line" from Nanuoya, coffee on each side is slowly but steadily giving way to its more vigorous leafy successor. But as yet there are not many fully-equipped factories at work in this region. What a large demand on our tea-machine makers, and on iron-work in great variety, must be made before all Dimbula even is equipped with the rollers, driers, sifters, cutters, &c., &c., requisite in the present day to a well and economically arranged factory. If cooly labour continues scarce, we may be sure of all the greater rush after labour-saving appliances, and in all departments of the tea-planter's work, both in field and factory, there is ample scope for the application of ingenuity.

Erroll estate, above Hatton, where I made a short halt, is in the midst of a tea district pure and simple. Coffee is nowhere to be seen, save far up the valley; but there are very fine covers of tea visible, notably on plantations which never took high rank, even in the palmy days, for their yield of the old staple. Erroll is a model little tea estate, and there are many very fine shows of tea on the hillsides and flats visible from it in the lower division of Dikoya district, as well as in Lower Dikoya proper. Farther away, towards Norwood and Bogawantalawa, a good deal of coffee is still carefully looked after, although tea is getting a fair share of attention. Maskeliya, on the other hand, is to be a tea district *par excellence* almost immediately. Coffee on Kintyre, Avoca and Brownlow, and one or two other places, is still to the fore, yielding well this season; but the one hope of the future in this favoured region as regards rainfall is in tea. The large extent of forest still visible from any eminence in both Bogawantalawa and Maskeliya is reassuring, when we recall the large demand which must be made on the wood-fuel of the country, where all the tea now growing is in bearing, unless some cheaper or equally accessible fuel is provided. Even with its splendid water-power for driving machinery, the Carolina or K A W Factory for drying alone requires the produce of several acres of timber for its annual outturn. Where a steam-engine as well as driers have to be fed, the demand will be larger, and when we think of the many plantations in the middle of the young districts without a stick on them, or in reserve, unless it be the old coffee, the question of firewood is indeed likely to be a troublesome one. K A W factory does at present the largest amount of work in the country, buying leaf far and near, as many as a couple of tons a day of freshly-gathered leaf coming down the line in basket to be delivered at Watawala station at times. This is a great convenience to young estates, but factories are more rapidly multiplying. That of Darawella is now going ahead and leaf being bought for it in mid Dimbula; but few sites have the natural advantage of K A W with the water from the river to drive its turbine up to 30, 40 or more horsepower if required. There need be no hesitation here to make the "roll" heavy or fully-charged.

(To be continued.)

CEYLON UPCOUNTRY PLANTING REPORT.

PLANTING WEATHER—WHERE THE PLANTS GO TO—GREEN BUG STILL GOING ON—BRAVE EFFORTS TO COMBAT THE ENEMY—CANKER IN CINCHONA.

5th July 1887.

Since the Jubilee festivities the rain has been on in proper style, and with it there has been a good deal of wind. This of course is what is to be expected at this season of the year, and when one gets up to one's expectations there is not much room to grumble. All the same, we could do with less wind. Plants are very much in demand, and the prices keep pretty steady. I understand that those who put out extensive nurseries on 'spec' have had fair orders, and where the *jat* is really good, many of them are sold out, and could have disposed of considerable quantities more if they had had them. And yet before the planting season began, there was a kind of idea abroad that nurseries for the season were rather overdone, and that to sell, some sacrifies would have to be made. But it is pretty much always this way. The sellers have a harder time of it with the buyer who buys in advance than the man who comes in when the rains are on. He does not ask many quustions as to price, if at all like the thing, and an extra rupee a thousand is not thought so much of when times are propitious, and plants must be got.

Where all the plants go to is the mystery, and yet those who have had experience of bad bits, and have seen how the hope of yesterday which looked so promising when planted out has come in a short time to resemble those Arabs, which folded their tents "and silently stole away," can at least account for some of them albeit not in a very satisfactory way. Nothing tickles a man up so much as these sore bits that *won't* grow, and the capacity they have for putting away plants is harrowing. Round after round of supplying still find them wanting, and the unhappy possessor is at last driven to his wits' end to give a reason for the failure. He only attains unto the wisdom of the wise when he ceases his speculations, and keeps "pegging on."

Is it the case that tea planted on old estates is proving somewhat of a disappointment? I have heard this said. Of course there is a wonderful difference between one district and another, new land and old, and those who have planted old places must necessarily exercise more patience, and wait longer for results. The London Director who explained the cause of the tardiness of the returns of his Company from the fact that the taproot of the tea had not yet penetrated into

the virgin sub-soil is evidently the man to give comfort to those who are induced to regard the future of old properties with distrust. That there will be disappointments are what are to be expected, and that the thing is being talked of now in a quiet way is indicative of some anxiety present, by those who are watching the results. But that tea grown on old places should in the majority of cases be unremunerative and disappointing has yet to be proved. No doubt we hear of the successes much more readily than of the failures, but for all that the other way of it will force itself into public notice, although perhaps not with such celerity.

The bug still goes on. I heard of an estimated crop of coffee—10 cwt. an acre—which has already been reduced by half. The rest has disappeared. Even if the 5 cwt be got it would be good in these degenerate days, but if the promise of ten has already been reduced to five and the bug still there "what will the harvest be"?

Brave souls still go on battling the plague. I have been told of kerosine and water being tried successfully; but when you begin to enquire as to the extent of area experimented on, or how any considerable number of trees can be practically subjected to the cure, the thing breaks down. In fact these abortive efforts are simply expressions of that energy possessed by our race. To see a fine field of coffee attacked with bug and do nothing for it, is too much to expect. "Something must be done, you can't stand by and do nothing to try and save it" is how they put it, and so every now and again a rush is made, and a bold effort to stop the enemy's advance—with the usual unsatisfactory results. I supposed there is a kind of satisfaction in having spent some money and made some effort, but it must be after all a satisfaction of a melancholy kind, like following the remains of a friend to their last resting place.

Since the rains have come cinchona seems to be going in for dying out. Canker is the plague, and when one would rather not harvest, to have to do it, is somewhat trying. And then the price you get for the stuff! To continue such a subject is surely too much to expect.

PEPPERCORN.

SUN FLOWER; BARLEY CULTURE IN CEYLON.

C. J. R. LeMesurier, Esq., Assistant Government Agent, Nuwara Eliya, Central Province.

NEW AREAS OF CULTIVATION OPENED.—There has, of course, been a great extension of the area under tea during the year in every part of the district. I notice that the sun-flower plant is being cultivated to some extent on De Soyza's places at Hanguranketa, and by natives in the vicinity. I have not been able to discover that it has any particular commercial value, though I wrote home for information on the subject to some London brokers. The oil appears to be used for mixing purposes, and the oil-cake as a cattle food; but there is little demand for it in the London markets, and it would not appear so far to be a remunerative product. It would grow very well, I believe, throughout Walapane and Uda Hewaheta, and as its cultivation is very simple and it gives a quick return, it is eminently suitable for natives; and if a local use and market could be found for it, its cultivation would soon be largely extended.

INTRODUCTION OF BARLEY.—There was a fairly successful attempt made by the Ratemahatmaya of Uda Hewaheta to cultivate barley during the year. Mr. Howard, the manager of the Nuwara Eliya brewery, provided the seed; the Ratemahatmaya grew it on some land at Hanguranketa, and obtained a crop of 100 bushels, the seed yielding about twelve fold. There is a large demand by the Murree Brewery Company here for the product, and the manager has agreed to supply seed free of cost and to take any quantity at R2 a bushel up to 10,000 bushels per annum. There is thus the making of a considerable industry in this if villagers can only be persuaded to take it up.

FLIES IN PADDY.—Some experiments were tried in various parts of the district with kerosine oil mixed with ashes as a remedy for flies, and where these experiments were carefully conducted the insects disappeared.

PLANTING IN NETHERLANDS INDIA.

(Translated from the *Straits Times*, June 22nd.)

In Java, too, bright points begin to appear on the horizon so sombre and lowering of late. The price of coffee has been rising so amazingly high, that its continuance, of which there is every prospect, bids fair to make good the losses in sugar. So encouraging has the outlook become, that, in different parts of Java, waste land never hitherto turned to account from dread of loss has been largely put under cultivation. This revival of plantation enterprise will not benefit one whit the twelve sugar estates there, which have suspended operations, or the one hundred and seventy one whose outturn, estimated at six millions of piculs, can only find customers at ruinously low rates. The depression of trade has limited the circulation of money among the native cultivating class, and diminished their purchasing power. It will be long yet before import merchants can profit by the improvement in the financial position of the natives brought about by the high quotations ruling for coffee. The Javanese of late have not invested heavily in imported articles. The tax gatherers of late have bled them too freely.

Java tea is steadily coming into favour in the London market. The quotations for the article stood higher than those for Indian kinds last season, with but slight fluctuations. Owing to manifest improvement in quality, Java tea may be expected to stand high in the estimation of dealers in that city. They generally do not anticipate that prices will go on rising for an indefinite period. The public has got so accustomed to tea of ordinary kinds, that the only way to raise quotations must be sought in betteing the quality. In sorting, it has been found desirable to limit as much as possible the number of sorts. Tea planters in Java evidently have every reason for contemplating the future with greater confidence than ever.

The planters in the district of Sukabumie have found to their cost that insect eating birds need protection. To gain this end, they have petitioned the Government to tax the possessors of fire arms to forbid the use of sumpitans or blowing tubes, and to prohibit birds nesting. The Government declined, in reply, to legislate in that direction, on the plea of the needlessness of the protection sought. In Europe, legislation of the kind suggested by these planters has been enforced with decidedly beneficial results.

Kapok or silk cotton is at present attracting attention in Java as a source of wealth likely to be of highly profitable account in the near future. In Europe, it is steadily coming into prominence for manufacturing purposes. The kapok has in its favour the advantage of rapid and ready growth. It is not particular as to soil, and thrives luxuriantly on hill sides at altitudes up to even 5,000 feet above sea level. It begins to bear in the third year of growth. A full grown tree yields from 1,000 to 1,500 fruit. Evidently the kapok has a promising future before it.

The Batavia *Nieuwsblad* points out that coal tar seems to yield no end of useful articles. Already it has produced several serviceable dyes, a very good disinfectant, a couple of glorious perfumes, and prussic acid. Saccharine too has been extracted from it. This is not all. A Dr. Fischer has also succeeded in adding to the number of these useful products from coal tar, a substance which possesses all the qualities of the best quinine. Should this discovery prove paying, the Java cinchona growers will find their difficulties thicken around them.

The Batavia *Nieuwsblad*, on the authority of a correspondent on the spot, states that a gentleman

named Harrison has started a tobacco estate in Palembang at a place called Tanjong Buah. He relies on Chinese coolies imported from Singapore, who come under engagement to work in the plantation at a wage of 20 guilders a month each. Within the last two months or so, twenty of these coolies have absconded. Most of them, thinking better of it, returned, and underwent punishment for their perverseness. The remainder tried their luck in marauding. They turned to and started in business as robbers by forming themselves into a regular band. These fellows have made the whole neighbourhood unsafe. Quite recently, they murdered a native forest ranger. After the murder, the whole gang seems to have become panic stricken, and hastily took to flight, leaving sundry articles behind them, including a portrait found near the corpse. This discovery is expected to facilitate their detection.

To alleviate the poverty and distress now rife among European descendants in Java, an agricultural company has been started there for the purpose of affording them facilities for earning a livelihood by planting or cultivation. Planting prospects are now so looking up in that Island, that a newspaper has just been started in the interest of plantation enterprise. The practical nature of the views predominent among the planting class of the community, comes out from the readiness with which tobacco growing is taken up in Java now, owing to the high price it fetches. By last advices from Batavia to the 11th June, unseasonable rains have fallen. However beneficial they may be to the public health, the standing crops are the worse for them. Tobacco suffers therefrom. On several sugar estates in East Java, crushing operations have had to be stopped in consequence. The ripe cane in the fields will not be the better for remaining longer uncut. These estates are in no condition to stand further blows from adverse fate. The Cinchona planters are at a loss how to meet Ceylon competition which they foresee will affect their ventures detrimentally, but a heavy output of bark which threatens erelong to make the price of that product unremunerative, unless the consumption of quinine increases.

DELI NEWS.

(*Translated for the Straits Times.*)

It is said that by consigning tobacco to Europe by the North German Lloyd steamers, instead of by those of Holt's line, the Deli planters have benefitted by the difference in freight charges to the extent of an additional 2% in dividends.

TEA AND ITS PROSPECTS.

"A. B.," writing to the *Indian Financial Review*, says :—The estimated crop for 1887 is not yet authentically issued by the Indian Tea Association, but sufficient has leaked out to show that the crop will probably exceed 1886 in even a greater ratio than that year did the previous. This of necessity points to an enormous supply of common broken teas, and, as prices in London are as low as 5d per lb. for that quality, it is not a matter of much difficulty to decide what can be expended in the cost of manufacture to produce tea that can sell at such a figure, and show a profit. It stands to reason the entire crop is not low class tea, but it may safely be estimated that 50 per cent. of this year's crop will be; and taking the other half of the crop at an all round price of 8d, which is certainly a handsome allowance, this gives an average of 6½d, which, turned into rupees, about equals 6½ annas. Carrying the calculation still further, to work at a profit, tea on the garden must be made for 4 annas per lb., and allowing one anna per lb. for Calcutta charges, including brokerage, &c., this would still allow of a return of 1½ annas per lb. or R7-8 per maund.

The annual statement of a private concern situated in the Dooars supplies the following facts :— 350 acres under plant gave 2,900 maunds of tea, the average price realised at auction was very nearly 7 annas per lb.; granting it was worked on the basis given above, this shows R20 per maund, or a profit of R58,000. Now to make this garden, including machinery, and interest whilst coming into bearing, the actual cost was R120,000—therefore in what was considered an indifferent year, 1886, a return of nearly 50 per cent. was realised. This is not a solitary instance. It is the result of economical working, and the result of a large outturn reducing the cost of production. There is, however, a large margin between working at a profit or a loss on the basis of such figures, and surely admits of some method being found of so reducing the cost of production in gardens that can only turn out their five maunds per acre, that a profit will ensue. An expert will tell you, and with some force, that the same labour is required for both gardens, whether growing eight or five maunds per acre. Allowing for the sake of argument this contention, yet it seems monstrous if eight maunds can give at seven annas such a large return, a garden that only yields five maunds cannot be worked to a small profit. The investor fixes the value of the five maunds garden, if a limited company, and all the late auction shares were sold at one quarter of their actual value, companies paying three per cent yielding at that figure twelve per cent on the price paid. Allowing that your native establishment cannot be much less on the five maund garden that on the eight maund garden, surely the work of the European establishment cannot be compared on the one to the other, and there arises again the question of amalgamation of small estates and the cost of European supervision. The annual reports are conclusive on this point. Without giving names, one lately issued shows that the Company's establishment, and bonus to Manager and Commission to agents on a garden in Assam, amounted to within 30 per cent of the sum paid in daily wages to the coolies, the average just over 300 and the outturn 1,900 maunds. Within less than a mile of this same estate is a garden of 400 acres, with a European establishment, equally large for a similar outturn; added together they return 4 per cent on the present capital, and both at the time of being converted into limited Companies were sweatened to the extent of 200 per cent. Will any one contend if these gardens had remained private property, and been worked for the benefit of the original proprietors, such an enormous sum would have been spent on the European establishment of either? How often have efforts been made to amalgamate tea properties for the very purpose of making a saving in this respect, and utilizing the labour in a more general way, and invariably failed what with petty jealousy in the district, as to the planter likely to be sacrificed by the amalgamation, and the same unfortunately in Calcutta with regard to agents supposing as is often the case, they are under different agents in Calcutta. Are these obstacles to stand in the way because they exist and continue until perforce the gardens are abandoned?

The apathy shewn by shareholders in the present state of affairs generally has much to answer for. If they would only rouse themselves and insist on both ends being made to meet, and not accept estimates based on prices being realized for tea that are faliacious, there would now be less of the terrible future, that can only end in lakhs of rupees being sunk and lost for ever. Too much is taken for granted by the complacent shareholders, as long as a return for his money comes in annually, but, even with the more fortunate concerns, any care-

ful shareholder has only to look back old files, and he will find gardens now producing tea at 6 annas that formerly spent 10 annas, and the same old excuse against any reduction. "The Manager advises us the reduction proposed would simply not only endanger future prospects, but very likely your entire property," and yet the same intelligent individual is now turning out the same or larger quantities at half the cost. Why? Because if he will not some one else will very soon be found willing and able to do so. If this is the case and it is too easily proved as regards the past, why do shareholders again listen to the same argument now? So far my strictures have been confined to the European establishment, but not in any way with a view to under-estimate the value of a good Manager. My object has been, and will continue to be, to show not only the possibility, but the absolute necessity of amalgamation with a good head and subordinates– Natives if they can be found fit for the work in preference to Europeans—solely on the score of expenses; but when, as at the present moment it is becoming in many instances a question of actual existence, one saving clause points to amalgamation, and my next will be written to further this contention, on the basis of the old motto which in addition to the great economy, says "union is strength."

CONSULAR TRADE REPORTS.

TEA IN AMOY.

The report of Mr. C. W. R. Allen on the trade of Amoy of 1886 is as follows:—

Residents of Amoy inform me that they expect shortly a crisis in the affairs of the port. Amoy as a place of business, is rather curiously circumstanced. Its prosperity is due to two causes, one to its being the port of supply to the neighbourhood, the other to its being the port of transhipment to Formosa. Now so far as exports are concerned—and foreign merchants are more interested in these than in imports, which are mainly in Chinese hands the Formosa trade is more valuable than the local. Tea is largely sent from Northern and sugar from Southern, Formosa, and shipped hence in ocean-going steamers to Europe and America, because Amoy not only possesses a splendid harbour, but is in telegraphic communication with the rest of the world. North Formosa boasts of two ports, Tamsui and Kelung. The former has for a harbour only the *embouchure* of a small river, across the mouth of which a bar runs, closing it to all but vessels of light draught. Kelung, on the contrary, has a fair harbour, with accommodation for perhaps three large steamers at once. Unfortunately tea has to be brought a longer distance, and with greater difficulty, to be shipped at Kelung than it has to be shipped at Tamsui. Hitherto it has been found that the cheapest method of dealing with it is to ship it at Tamsui for Amoy, and to tranship thence. Now however the Chinese purpose constructing a railway from the tea districts to Kelung and to lay a submarine cable from the mainland to Formosa. When these two are completed the tea will be shipped in ocean-going steamers calling at Kelung. At this moment all the business in Formosa is done by branches of Amoy firms, but it is said by some that when the projected improvements are carried out the firms themselves will be at Tamsui, and only the branches here. How this will be remains to be seen, but at present the work is not even begun. A British merchant in Amoy points out to me the disadvantages of the projected scheme as follows:—The tea districts in Formosa are situated on the hills at the top of the water system of the Tamsui River. From those hills the tea is brought down the main branch, or one of its affluents, to Twa to Sia or Banka, towns at the junction of these affluents with the main river. Here the tea is packed and sent down for shipment. Freight from Tamsui to Amoy is only 10c. per half-chest. Suppose that the railway does bring the tea from the tea districts to Kelung it can scarcely charge less than 10c. a package. Kelung harbour, though a good one, cannot for a moment compare with Amoy harbour, either for convenience or ease of access (it has a bar at the mouth), and is moreover out of the direct line taken by steamers from Shanghai to Hongkong and Europe, which Amoy is not. If we also consider the expense of removing establishments across the Formosan Channel we must, I think, conclude that our fears of the increase of Tamsui at the expense of Amoy are perfectly groundless.

NINGPO.

The report of Consul Cooper on the trade of Ningpo for 1886 says:—

The return from green teas of 1885 proved so satisfactory that twenty-three establishments in place of 19 of the previous year were started for its preparation. Settlements of accounts are not yet complete, but there is little expectation of large profits forthcoming. The market opened late. But a few hundred pounds of black tea left the port. The delicate flavoured teas of this Consular district find a ready sale among Chinese themselves in their natural dried state, as prepared by the growers.—*L. & C. Express.*

PLANTING COMPANIES AND SOCIETIES IN JAVA.

THE COFFEE MARKET.

Nearly a twelvemonth ago the coffee market began to give signs of recovery from the prolonged torpor and depression which had marked it for so many years. Since May, 1886, the advance has been so rapid that prices for good ordinary are now more than twice as high as at that period. Speculators are masters of the article, and having awaited their day so long and patiently, they now make the most of it, leaving it to the trade and exporters to extricate themselves as best they can. In fact, the position of the article is greatly changed, and instead of purchases being restricted to the wants for consumption, large transactions take place between speculators, agents and others, whose sole idea it is to make money faster than is possible by the slower but surer way of ordinary business.

We (*Indische Mercuur*) have before us a number of reports which prove that in London and Havre, as well as in New York and Rio, an intense speculation fever is raging, and that serious commercial men fear the inevitable reaction, though quotations for the article will at all events remain high.

The one compares the coffee market with Monaco, the other with an overheated engine; all are of opinion that moderation is advisable. From Havre we have the intelligence that the deposit, at first frcs. 3 and later on frcs. 6, has now been fixed at frcs. 12, and that a certain number of commercial houses look on the matter as so dangerous that they refuse for the moment to do any transactions on futures. As an example of what is going on in Havre, we may quote that some few days ago the rise in a couple of hours was not less than frcs. 8! The following day, on account of less favourable news from New York prices went down from frcs. 3 to frcs. 4. In London the state of affairs is not better. An invoice of old Yellow Santos fetched 91s 6d!

The latest news about the crops in the different lands of production are not very favourable. The

Rio crop is estimated at about 2 to 2½ millions of bags, and the figures of the Java crop are becoming smaller every day.—*L. & C. Exvress*, June 10th.

PARCHMENT COFFEE.

SHEVAROY PLANTERS' ASSOCIATION.

COFFEE:—Read letter from Messrs. Patry and Pasteur, dated 15th April, giving equivalents in cwts. of the various packages of coffee as follows:—Casks average 8 cwt. tierces and barrels together 4 cwt., bags and piculs 1¼ cwt. Read the following letter from Mr. H. Pasteur, dated London, 4th April, *re* curing of coffee in London. Dear Sir.—I have duly received your letter of Feb. 25th and am extremely obliged to you for the kind manner in which you allude to what I may have been able to do for the planting community in India whose interests have and will always command my warmest sympathy. The question of preparing parchment coffee in London is a very difficult one, as we have to fight here against great drawbacks, not to speak of vested interests abroad, which certainly will not facilitate matters when it is a question of the possibility of their losing business. As regards Ceylon and to some extent India, I have always expressed the opinion that the coffee was so well and carefully prepared under existing arrangements, that preparation in London was not likely to show such promising results as in the case of central America, for example, where local preparation was more primitive, and where coffee once peeled was liable, from length of journey and other causes, to lose so much colour before it could reach our market. To mention some of the drawbacks and difficulties thrown in the way of the London curing I may mention that the freight charged for parchment by the "Klyde" at Malabar coast is at the rate of 10 cwt. for a ton instead of 18 cwt. for a ton of cleaned coffee! We have also had some shipments this season of which the parchment appeared to have been overdried, being much broken. Two marks of E. I. coffee, peeled in London, were sold by us at auction last week and realised 85-9 and 85-1; whilst the same marks at the same sale cured in India realised 86-9 and 86-9: whilst a third mark was sold at 2-6 per cwt. more for the London peeled than for the Indian cured portion. The cost of peeling, sizing and preparing for sale parchment coffee in London is 2-6 per cwt. as against 10d per cwt. for landing and preparing for sale clean coffee, The weight of a parcel of 129 bags parchment was cwt. 119-3-24 nett, and the nett weight after husking and sizing was cwt. 100-3-2 nett, showing a loss in the operation of cwt. 19-0-22 or 16 per cent. In the case of Costa Rica, Guatemala and other Central American coffees, shipmen s of parchment to London continue to give splendid results. A parcel of Costa Rica last week sold at auction at 92-6 per cwt. a price unheard of for Costa Rica, the coffee came out here *fine bright deep blue*; the highest price realised so far for Costa Rica cured abroad was 85 per cwt. This shows conclusively that London peeling does not spoil coffee, on the contrary, and that my contention that parchment preserves the colour of the coffee is correct. But for this, parchment must be dried properly, neither too much nor too little, and that is a point which planters or experts on your side can alone decide. I may say that the colour of the Shevaroy coffee is better this season than I have seen it yet, and as a consequence it sells as well as Coorg. I am much at your service for any further information you may wish to have. —*M. Mail.*

INDIAN TEA.

38, MINCING LANE, June, 1887.

ANNUAL REVIEW.—The events which have marked the course of the season now concluded will make it a memorable one in the history of the Industry.

The features which attract attention are—(1), the great increase in production; (2), the still larger increase in consumption; (3), a range of price for much of the crop unprecedentedly low; (4), the ability which producers have shown to cope with conditions whih at first sight seemed most discouraging.

In many respects the features of 1884-5 have been reproduced. In that season there was a large supply of low grade tea, cheap prices for these leading to a great advance in consumption; while fine teas maintained high values. This was followed by the finer crop of 1885; higher prices for the low grades; a marked reduction in the value of fine; and an apparent check to consumption. The narrow range between the price of fine and common which marked that year, undoubtedly led a number of producers to aim at large rather than fine crops, which resulted in the total production of 1886 exceeding by four or five million lb. the estimate of the Calcutta authorities. In view of such a policy being adopted we wrote a year ago, with reference to the comparatively low rates which had been ruling for fine tea "to what extent conditions so unfavourable to high prices may be modified in the future it is difficult to foresee—but in any case we cannot recommend producers to pursue any policy but that of making the finest quality possible consistent with a fair yield;" the result has justified the opinion then expressed.

References to the past, however, are only useful to the extent of the guidance which they afford to the future, and from all we hear the effect of the past season's experience will be to check the tendency to make a large yield irrespective of quality: the result will be a finer crop, showing little more than the natural increase due to higher cultivation, or derivable from fresh acreage bearing; which view is consistent with the Calcutta estimate of 82 million lb. as the probable total of this year's supply. Assuming this to be the case, the values of fine and common may again come nearer together; and the increasing supplies from Ceylon will operate in this direction, as the policy mainly pursued in the Island—wisely, as we think—is to make tea of such quality that it is valued by the Trade above the level of common, and up to that of medium and fine Indian, although no tea has yet been produced which has the special characteristics of the finest Assam and Darjeeling tea. We doubt whether the increased quantity of fine tea which we shall probably receive will have so marked an effect upon prices as would have been the case a few years ago: as the reported inferiority of the new China crop will lessen the supply of tea over 1s. per lb. and enable the Trade to absorb a larger quantity of Indian and Ceylon. Consumers also are becoming more alive to the merits of "good" as opposed to "cheap" tea—whether China or Indian and their appreciation of the superior value from an economical point of view of Indian—to which Mr. Goschen alluded in his Budget speech—largely accounts for its increased consumption.

Another year's operations being entered upon, a close analysis of the past crop is unnecessary, the judgment of the Trade having been shown ere this by the prices paid. Assam gardens generally speaking, have maintained their reputation; but other districts, especially Cachar, Sylhet and Dooars, have not been so successful, and the very unsatisfactory prices which have ruled for most of their tea is attributable to the large proportion made of tea not actually of common quality but wanting distinctive character in cup, and of low grade in leaf. The large consumption may be attributed not only to the increased supply of tea selling at very cheap prices, but to the fact that this tea, comparatively inferior as it was to the finer crop of 1885, was sufficiently superior in cup to the China Teas obtainable at the same quotations to displace them. Whether this turning of the scale in favour of Indian would have occurred if prices for China had been materially lowered earlier in the season is an open question; and it is necessary to consider what may be the effect upon inferior kinds of Indian should China send us during the coming season heavy supplies laid down at a low cost, as some anticipate.

Taking the general average of the Tea of the present day, and comparing it as well as memory permits with the crops of ten years ago, a marked and general change in character is noticeable in the direction of lighter fermentation combined with more flavour and aroma; and this we take to be due to

the fact that the machinery now in use is best fitted for producing tea of this type, and also that the rapidity with which all the operations of manufacture are now of necessity carried out is not favourable to the processes by which the ripe and mellow teas of past times were produced. The present type is undoubtedly popular, but it has one attendant disadvantage: viz., that tea has less keeping quality. As tea is grown not to keep but to sell, it may be thought that this is immaterial, but it is not so to buyers; and the fear of loss through depreciation partly accounts for the "hand to mouth" system of buying, and fully explains the unwillingness of all but the boldest dealers to operate with confidence, and so lend support to weak markets when perhaps they all agree that prices are unduly depressed.

One of the difficulties of the future which must be faced and thought out is the problem of how to decrease the number of breaks. The difficulty is augmented by the growth of Ceylon, and the large number of samples which so many small and separate estates send to swell the total. Some dealers have different tasters for Ceylon and Indian, but it is doubtful if this will be found practicable when the two sorts come more closely into competition, and are eventually regarded as much parts of a whole as the produce of the different districts of India now are. It has been suggested to lessen the number of samples by making "unassorted" tea, but we feel this would be most unwise to attempt upon any large scale, for it would overstock the market with tea of a uniform grade, which would probably fall to the level of souchong or common pekoe. The wide variety in the type, make, and grade of Indian tea has from the beginning been of the highest value in assisting its progress; and the same feature of variety is now helping Ceylon to push its way. There is nothing which dealers seek for and appreciate more keenly than "individuality" in tea, and this is generally the secret of the prices paid for certain marks—which it would be invidious to specify—month after month however flat or irregular the general market may be. To no description does this apply so much as to Darjeeling, for in no other growth is there such a wide difference between the value of special flavour or quality and the value of plain or pointless tea. The solution which at present seems most practicable is to raise the size of breaks by putting together parcels of similar grade and value, either at the factory or in London. This may involve some expense in providing accommodation where it is inadequate, or in bulking charges, but such may prove a lesser disadvantage than the risk of tea passing the Auction without being properly valued by the Trade. The objection which might once have been raised that only a few buyers could take large breaks, and that small buyers would be debarred from bidding, has not the same force now that prices are so much lower, and quotations for many kinds adjusted to fractions of a penny: while, as a matter of fact for twenty years and more the buyers have been used to deal in China tea in lines ranging from 100 to 1,000 packages. We recommend factory bulking, if it can be done so well as to preclude the disputes which arise when variations, which cannot always be detected on inspection, are afterwards found: experience shows that many buyers give a decided preference to it, and in the case of fine descriptions the advantage of being able, through good factory bulking, to sell without turning the tea out, is often represented by pence per lb.

These, however, are matters of detail, which must be worked out by managers as varying circumstances permit: the readiness shown to act upon suggestions from this side, and to study the wants of the Trade, encourages the hope that difficulties will be met and surmounted as they arise.

It is of more importance to consider how to enlarge the area of Consumption without further reducing prices. We look with hope to a development of the Export trade, both to the Continent and to the States, but especially to Canada, where we learn there is a growing demand for black tea in place of the Japan, and China Green, now mainly used; and we think that the prices now reached will open to Indian tea the door which real merit has not been able to force. A considerable quantity between 8d. and 1s. has this season been exported—tea with small even leaf, and flavour or plain liquor; broken leaf, or finer teas at a higher price being declined; and if such can be sold at prices which make them cheaper than China Congou or Java tea—as during the past season—the business should grow. The total Home Consumption during the next 12 months should be about 187 million lb., allowing for the average annual increase of the past six years. Towards this India and Ceylon will probably contribute a supply of 100 million lb, equal to 53 per cent of the required quantity: the proportion now reached is about 50 per cent., so a further increase is necessary, and a monthly Delivery of 7 million lb. of Indian and 1¼ million lb. of Ceylon is required to keep the statistical position sound. Is this possible? We think so, and at prices which will leave a fair profit to producers; but it is evident that while economy is not forgotten no pains must be spared to keep quality up to the point which will ensure Indian tea maintaining its popularity with consumers.

The following are the statistics for the past three seasons, dating from 1st June to 31st May:—

	1886-87.	1885-86.	1884-85.
Total Import.

WM. JAS. & HY. THOMPSON.

THE CEYLON ESTATES INVESTMENT ASSOCIATION (LIMITED).

Report by the Directors to the Third Ordinary General Meeting of the Company, to be held on Wednesday, the 8th day of June, 1887, at Twelve o'clock noon, within the Accountant's Hall, West Nile Street, Glasgow.

The Directors beg to submit herewith the Accounts for the year to 31st March, 1887, and they are pleased to state that the results have been fairly satisfactory.

The returns from the estates, which are rather better than last year, would have exhibited better results, had it not been for the occurrence of a very severe attack of leaf disease, which reduced the coffee crop to nearly sixty per cent. below the estimate. The price realised, however, was good, being about 83s 3d per cwt. as against 68s in the previous year. The outlook for the current year is good, both as regards crop and price.

The price of cinchona bas been unprecedentedly low. the shipments from Ceylon continuing to be very heavy. Latest advices point to a very material falling-off in these, but it is impossible to speak with certainty on this point.

The result of Tea-planting operations has so far proved satisfactory, and the Directors anticipate largely increasing returns from this product.

The mortgages on estates in Ceylon have been reduced during the year by £1,565 0s 3d, and a farther reduction will take place at 30th June, to the extent of £1,500 on Cranley, the mortgage on which will then stand at £6,000.

In addition it is expected that the Bond on Hallowella, amounting to £3,679 13s 11d, will be paid off at the beginning of July.

The balance at the credit of Profit and Loss Account, including £245 16s 6d brought forward from last year is	£1,700	11 1
from which the Directors recommend that a Dividend of 4½ per cent be paid, which will require..	£1,350	0 0
Leaving	£350	11 1

to be carried forward to next year.

The Directors who retire at this time, in conformity to the Articles of the Association, are Mr. Wright and Mr. MacBrayne, and they are eligible and offer themselves for re-election.

The Auditor Mr. Moore, C. A., also retires, and he is eligible to be re-appointed.

J. BROOKS WRIGHT, *Chairman.*
BROWN AND FLEMING, C.A., *Joint Secretaries.*

BROWN & FLEMING, C.A.,
Joint Secretaries.

REPORT OF THE PROCEEDINGS AT THE ANNUAL ORDINARY GENERAL MEETING OF THE MEMBERS OF THE COMPANY, 8TH JUNE 1887.

The Third Ordinary General Meeting of the Ceylon Estates Investment Association, Limited, was held in the Accountants' Hall, West Nile Street, Glasgow, on 8th June, 1887, for the purpose of receiving the Directors' Report and Statement of Accounts for the year ending 31st March 1887, and electing Directors and Auditor.

The Vice-Chairman, Mr. Nathaniel Spens, C.A., presided in the unavoidable absence of the Chairman, Mr. Wright; and there were present: Rev. Peter Grant, D.D. and Messrs. J. B. MacBrayne, Robert Davidson, William Bottomley, Jun.; James M'Kinnon, George Duthie, Henry Knox Dick, Wm. Towers-Clark, and others.

Mr. BROWN, of Brown & Fleming, C. A., Secretaries, read the notice calling the meeting.

The CHAIRMAN said—I suppose we may hold the report as read. I don't think we need trouble you with it. I regret very much that owing to illness, our Chairman, Mr. Brooks Wright, is unable to be with us today. I am glad to say that he is recovering, and I hope that, on another occasion, he will be able to take his place in the chair. (Applause.) It therefore devolves upon me, gentlemen, to move the adoption of this, our second report. It is a great satisfaction to my colleagues and myself that we should be able to meet the Shareholders with another statement showing another dividend, more particularly because this year we had to contend, as the report shows, with a very short coffee crop. As we have not yet reached the stage of development of our tea, which makes us more independent of coffee, we were very glad indeed when we found that, by a rise in the price of coffee, and by our being able to harvest a considerable amount of cinchona, notwithstanding the very low prices we got for that product, we were able to maintain the results of last year. I think, in this Company, we have now come to the stage when we may look forward to the estates bearing a large quantity of tea, and that, therefore, in the future we will probably be able to rely, from our three sources of profit—coffee, tea, and cinchona—on the results of our income being steadier, and, I believe, also considerably increased, as compared with anything we have experienced hitherto. There is one point about the Company to which I desire to refer, but which has, perhaps, more reference to the past—to the days before we were turned into this Company. It is, as you will observe from the accounts, that our loans are being gradually, but surely and steadily, repaid; and, I am glad to think, being repaid without any loss to the Association. (Applause.) The amount of the loans in the balance sheet stands at £12,917, and we expect that, within the next few months, they will be reduced, as you will see from the report, by somewhat over £5,000. The result will be that we will have a little over £7,000 upon loans over two estates, and both of those are, in my opinion, about as safe investments as any company or society could have. With the reduction and the repayment of the two loans, mentioned in the report, your business will then become very much limited to working our two estates. In regard to these estates, it will probably be of interest to you to know that on the larger estate of Glencairn, the extent of which is about 592 acres, we have now got 363 acres planted up with tea. We had last year a crop of tea of nearly 30 000 lb. The coming year we expect to have about 50,000 lb., and ultimately we hope we shall have, from that estate, nearer 100,000 lb. The advantage of the tea crop is—and it is one of considerable importance, we think—that it is expected to prove a much steadier crop than coffee has been. That has been the experience of other companies, and we believe that there will be, for some time, a steady progressive increase in our income from it. I myself do not hope to see any much further extension of tea on this estate, as coffee is at present giving us fair crops, and, with the advancing prices, I think it will pay as well as tea. We cannot cultivate them together, but we have to choose between the one or the other. On the estate of Macduff, which extends to 221 acres, we have planted with tea nearly 100 acres, and it gave a yield last year of about 7,000 lb. green leaf. This year we expect to have about 40,000 lb. green leaf. There is one point of interest to the shareholders, which is, that our Glencairn tea is being sold under the name of "Glencairn Tea." We make it ourselves, and in the reports of produce brokers the high quality of Glencairn tea has several times been remarked. I may mention that these brokers are not our produce brokers, so that it is independent testimony of the good tea produced. (Applause.) In regard to Macduff tea, we have not yet sold it under the name of "Macduff Tea," not because we do not think quite as highly of it, but because a smaller quantity is being produced, and we have not yet got the requisite machinery for manufacturing it. At present it is being sold on the estate as green leaf. I have no doubt it will be sold in London under its own name by-and-bye, and prove satisfactory.

I think the shareholders will see from all these statements that we have reason to be satisfied with our property. There is no doubt that the repayment of our loans will deprive us of the income which we have had in the past from borrowing upon debentures and lending at a little higher rate in Ceylon. On the other hand, the shareholders will be relieved shortly of any liability upon debentures, and a considerable first charge on the income will be cancelled. Your returns will depend upon what the two estates yield to you. These cost you some £5,000 less than your paid-up capital. If we thought it unlikely that we should get a good return, we would have to consider whether we should

not realise our estates. I believe we would be able to do so, at any rate, at the prices at which they stand in our books. When we lent upon them they were valued at over £50,000, and we hold them at about £25,000. I believe that in a very short time you could easily realise your £25,000. (Applause.) Your Secretaries have, however, submitted to the Directors a statement showing what they think might, when the tea is in full bearing, be the return from these estates. It will be some time yet before your estates are up to their full productive power; but certainly, from what has been shown to us, we think that there is a fair prospect of our getting so considerable a return as to make it undesirable to wind up the Company. In point of fact, we should rest content with our success, and continue to work these two estates, which will now have three classes of products, and which, we believe, will continue to yield to the shareholders satisfactory and increasing returns. (Applause.)

If there are any questions to be asked, I shall be glad to answer them. Meantime, I beg to move the adoption of the report. (Applause.)

Rev. Dr. GRANT said:—I have much pleasure in seconding the motion that has been made by the Chairman. He has stated so well, and so fully, the present position of the Company that it would be altogether superfluous in me to add any remark. I may simply state that I am satisfied that, having regard to the nature of the properties we hold, and also the loans, there is every reason to believe that this Company will enjoy a much larger measure of prosperity than it has done for many years past.

The report was unanimously adopted.

Mr. ROBERT DAVIDSON:—I have great pleasure in proposing the re-election of Mr. J. Brooks Wright and Mr. J. B. MacBrayne as Directors of the Company. I think we cannot do better than leave it in their hands. They know the Company from the very commencement, have taken a great interest in it, and have brought it to the present satisfactory state that it is in.

Mr. Wm. Bottomley, Junr.—I have much pleasure in seconding the re-election of the Directors that now retire. We all feel that we are indebted to them for their great attention to the Company.

The motion was unanimously agreed to.

Mr. James M'Kinnon.—I rise to move the reappointment of Mr. Alex. Moore, C.A., as Auditor, and that his remuneration be ten guineas.

Mr. George Duthie.—I beg to second Mr. Moore's appointment.

The motion was unanimously agreed to.

A vote of thanks to the Chairman terminated the proceedings.

A COFFEE RING.

(*Daily Telegraph*, June 16th.)

It might be imagined, from the existence of a coffee-room in every hotel, inn, or tavern of any pretensions in the British Isles, that the use of coffee is much more extended among us than is really the case. In France the consumption of coffee is ten times, and in the United States five times, greater than that of tea, while in the United Kingdom the annual consumption of tea is very nearly five pounds per head of the entire population, while that of coffee is less than one pound per head. Three explanations have been suggested by experts for this seeming anomaly. The first is a belief that coffee is heating, and more suited to a dry than to a moist climate; the second, the heavy taxation to which coffee was subjected by Mr. Pitt, and remained in force, with slight modifications, until, in 1872, Mr. Lowe, then Chancellor of the Exchequer, reduced the duty to fourteen shillings per hundredweight and to twopence per pound for the kiln-dried, roasted or ground article; and the third, the unconquerable indisposition of the consuming population to put themselves to the smallest extra trouble and inconvenience in preparing coffee for their immediate use, instead of resorting to the cheaper and more popular beverage, tea. Few are aware that the use of tea and coffee in Western Europe is, comparatively speaking, a modern innovation. In that instructive and interesting work, "The Dawn of British Trade to the East Indies, as Recorded in the Court Minutes of the East India Company between 1599 and 1603"—for which we are indebted to the industry and research of that indefatigable antiquary, the late Mr. Henry Stevens, of Vermont, who supplied American books to the British Museum for many years—no mention of either tea or coffee occurs. We learn, indeed, from Mr. Stevens that in 1603 pepper was so valuable a commodity as to necessitate "the providinge of six sewtes of canves dublett and hose without pocketts for six porters to weare while imploied in the fillinge of bagges with pepper brought home by the goode shippe Assention from the East Indies." It is obvious from this entry that when a pound of pepper was worth about twenty-five shillings the porters engaged in unloading it could not be trusted with pockets in their canvas suits. Not a pound of tea or coffee seems, however to have been imported to this country from the East down to 1603, in which year Queen Elizabeth died; and we know from Mr. Froude's "History of England" that the Virgin Queen and her maids of honour breakfasted upon shins of beef and tankards of small beer, and washed their hands—of which, by the way, the vain Queen was excessively proud—with "Castle," or Castil, "soape," worth about ten shillings a bar. The first mention of tea—or, as it was then called, tay—as an article of British commerce occurs in a letter written by a Mr. Wickham, on the 27th of June, 1615, which appears in the records of the East India Company. Shortly after that date, small parcels of tea, valued at ten pounds sterling per pound, were imported from China to the East Indies, whence they made their way to London as presents to some of its wealthy citizens. The first large consignment of tea was received in 1657 by Mr. Thomas Garway, a London merchant, and with it he opened "a stand," known in our times as "Garraway's Coffee House," for the sale, not of coffee, but of tea.

The first coffee-house really deserving to bear that name which was opened in the Metropolis for the sale of the decoction from the Arabian berry was established in 1652 by Pasqua, in Newman's-court, Cornhill. Pasqua, a Greek, was servant to Mr. Edwards, a Turkey merchant, and the taste for the new beverage increased so rapidly that coffee-houses became common in London at the date of the Restoration of Charles II. It is recorded in "Evelyn's Diary," on May 10th, 1637, that "there came in that year to the college of Balliol, in Oxford, one Nathaniel Conopios, out of Greece, who was the first that ever I saw drink coffee, which custom came not into England until about thirty years later." D'Israeli mentions, in his "Curiosities of Literature," that a great prejudice against the use of coffee existed among the women of France and England, on the ground that it was supposed to be the cause of sterility among them. When, therefore, the London coffee-houses were burnt down in the Great Fire of 1665, a "Women's Petition against Coffee" was extensively signed, praying that the shops and taverns where the pernicious beverage was prepared and sold might not be rebuilt. A more reasonable antipathy to coffee-houses sprang up in 1675, when they were temporarily closed by Danby, one of Charles II.'s Ministers, because of their Puritan origin. They were reopened, however, next year, at the earnest solicitation of the traders, and for a while

coffee was more popular than tea. Alexander Pope resembled Voltaire in his inordinate liking for the former, and a well-known passage in "The Rape of the Lock" tells us that "coffee, which makes the politician wise, And see through all things with his half-shut eyes, Sent up new vapours to the Baron's brain, New stratagems the radiant lock to gain." The demand for the berry soon became so great that Arabia was unable to supply enough. It began, therefore, to be cultivated in Batavia and Java by the Dutch, by the inhabitants of the West Indies, and by the planters of Brazil. In England the best coffee is supposed to be a mixture of Mocha and Plantation, while in the United States there is an immense importation of the Rio berry.

PINEAPPLE AND COCONUT CULTIVATION IN FLORIDA.

Coconut raising is a growing industry in Southern Florida. Pineapple and coconuts pay very well. Ten thousand pineapples can be raised, it is said, to an acre, and the same amount of space will support fifty coconut trees. The latter require very little cultivation. They begin to bear at from nine to twelve years of age, and produce from 80 to 150 nuts to the tree. They bring about five cents apiece to the grower. Many groves have been planted within a few years. One new Jersey gentleman has 330,000 trees.—*P.M. Budget*, June 6th.

DEMAND AND SUPPLY: TEA.

The development of tea-planting in India furnishes one of the most extraordinary chapters in the economic history of this country. It is about 30 years ago, that a practical beginning was made with it, and one of the first concerns, the Assam Company, had to pass through a severe trial as some people in Calcutta may still remember; but fortunately it stood the test, and has become the largest and one of the most successful concerns in this industry. In the early days of tea-planting there were many contingencies opposing its progress, but apparently nothing could arrest it, neither the unhealthiness of the climate to the early settlers, nor the vexations of the land laws and labour enactments. The absence of roads, and the difficulty of navigation in rivers unsurveyed and full of snags, proved but temporary barriers to an enterprize, which, in its rapid development, has no comparison in other countries.

Only relatively it may be compared with the activity which prevailed in the newly discovered gold-fields of California and Australia, or with the development of sheep-farming and horse-breeding in the colonies, but the comparison is imperfect in many ways. For tea cultivation the land was secured in unhealthy outlying hilly districts, labour had to be imported to clear the land, there was the difficulty of getting good seed; of rearing seedlings, and of keeping the ground clear, and then they had to wait three or four years before getting the first crop, provided in the meantime the cultivation was not interfered with by red spider, blight or any other contingency. It was sinking money with interest upon interest, in expectation that the result would in the end prove beneficial and lasting. This chapter is not yet closed, but with a nucleus garden in full bearing, the extension of cultivation is comparatively safer than opening out new ones in this way; every year more area is added to the cultivation, which explains the annual increase of manufactured tea. It is almost certain that in a few years hence 100 millions of pounds will be available for export and local consumption.

Besides this increase from India proper there is a rapid development of the same industry in Ceylon, which attracts the attention of all who have invested money in this undertaking.

In view of such stupendous strides by which the supply is being augmented, we look with some anxiety to discover the sources of demand which has stimulated this feverish activity.

It is a generally asserted and accepted belief that, when there is a demand for an article, the supply will be forthcoming to meet it; but in this case it looks very much, as if an enormous supply is being manufactured for which by forced measures a demand has to be created. According to the principles of National economy, this is really a most artificial and unnatural proceeding, upsetting all the preconceived notions of free-traders.

But this is not all—Indian tea had to force itself upon the attention of the trade, in competition with a well developed and established business of old standing; the tea trade from China. In spite of its inherent good qualities of strength in liquor and appearance in leaf, it had to conquer a market and overcome a prejudice of taste with consumers accustomed to the China beverage.

Last but not least it must be borne in mind, that the countries accustomed to drink tea are limited to England, America, Russia, Australia and Scandinavia; besides what is consumed in China and the neighbouring countries of Central Asia. Most of these countries have a rapidly increasing population, but beyond this little new ground has been opened out for consumption, though the Calcutta Tea Syndicate has made praiseworthy efforts to introduce it elsewhere.

If this is then a correct exhibition of the tea industry in India and of the prospects abroad, we fail to discover any prompt resources to improve prices. Apparently there is nothing to look to but a saving in cost of production, to improve the remunerative returns from tea-planting. A preferential duty in favour of Indian tea over China produce in the English and Colonial market, may cause a reaction, but this contingency is at present out of reckoning, and will require years of active agitation to influence home circles.

It has required a great deal of pushing and touting from India, to interest the home trade, and it has required a great deal of manipulating and mixing to assimilate Indian tea with China brands in order to suit the taste of the consumer. The quantity now annually sold shows, that this work has been well done and effectively performed. We have shown a drark side of the picture, still we are far from taking a pessimist view of the general situation for tea in this country. An enterprize, that has shown so much vitality, that has overcome so many obstacles, must have the elements in it to triumph over present difficulties. However, it is desirable to shorten the trial, and to do so, courage and prudence must prevail. Courage that will abandon unremunerative parts of cultivation and prudence in the extension of paying properties; economy in working expenses, coupled with reduction in ordinary charges, whilst it passes from the producer to the consumer. We are aware, that most of these items have had the careful attention of the Calcutta Agency Houses, representing the proprietary capital invested in tea, and we sympathise with the efforts, made by shippers, to break through the combination of shipowners, who try to impose upon them rates of freight by artificial means. Let them but persevere and success is certain, because every year larger and faster steamers are built, which with improvements in machinery can supply speed with economy. Finally we could suggest that more efforts be made to make tea a cheap and favourite beverage for the native population of this country. For common tea the price is now very low and practically within reach of the great mass of the people. There is no prejudice against it either of caste or religion; it is often solicited by native servants of European households during the rainy season and cold weather months, which shows that the natives are sensible of its healthy effect upon the system.

It is well-known that in all Central Asia, in the countries bordering upon India, the people are addicted to tea drinking, and it forms with them a favorite beverage; practically the people of Asia with the exception of India, Burmah and the Islands of the Malay Archipelago are ardent consumers of tea. Efforts have repeatedly been made to increase the trade in "brick tea" across the border, but very little has yet been done to introduce it, and make it popular amongst the inhabitants of this country.

Of late we hear constantly of the cry of increasing drunkenness, the extension in the sale of obnoxious, intoxicating liquors and protests against the spread of the outstill system; why not combat this evil, by offering a cheap health-preserving beverage to the people as a substitute; instead of inveighing against the inroads of drunken habits and calling for repressive measures to check the sale of intoxicating liquors. We see in this direction a great future for the Indian tea trade which while benefiting the industry would exercise a great influence for good on the people. Doctors and Missionaries without detriment to their calling could do much to make tea-drinking popular with the people of this country and the more enlightened section of the Native community might co-operate and combine in their efforts to encourage it. We recommend this suggestion to the Calcutta Tea Association, but must leave them to concert practical measures for carrying it into effect.

Tea at four annas a pound or a 4 oz. packet for an anna, packed and made up at the factory in stanial, labelled and marked, should be salcable in every bazaar; retail dealers being allowed a liberal discount for introducing it. The Tea Syndicate should prepare a standard quality to insure uniformity, as much as possible, besides providing a label with a registered trade-mark.

The disposal of cheap common tea in India, upon which all intermediate charges weigh comparatively heavily, would not only curtail the amount for export to other quarters, where it merely helps to depress the market, but would gradually open a large local market and restore the tea industry to a healthy and prosperous condition. If it once becomes a habit with the population of this country to consume tea, we shall see a growing demand for an article which is now forced by over-supply in excessive quantity in the home market.

(The writer of this article, was not at the time aware that his suggestion about selling the low class teas in this country had already been taken up and was being practically dealt with.)—*Indian Financial Review.*

PLANTING IN NETHERLANDS INDIA.

(*Translated for the Straits Times*)

The cinchona planters in Java hope to make head against the low prices likely to rule in the near future by devoting their energies to the production of bark containing a high percentage of quinine. In their opinion, this new departure will improve their prospects considerably, provided care be taken to keep cinchona planting within moderate bounds. Those interested in the movement intended to send out an expert to Ceylon, to see how matters stand there with his own eyes, with instructions to judge for himself and not rely on hear say. He will be commissioned to make diligent enquiries on the spot, and make an approximate estimate of how long it would take for the output of bark in Ceylon to be checked for good. These planters also purpose, by means of joint action, to aid one another in passing through the expected period of low quotations accompanied by production of inferior barks.

The advantage of having more than one string to a bow has signally become prominent in the case of Java tea. For instance when the London Market proved slack, that article oftentimes found ready sale on the continent. Hence it is that, last season, Java tea did not show any great decline in operations, and sometimes realised higher prices than Indian tea of like quality. This mainly arises from improvements in the article arising from the more general use of seeds from India and Ceylon.

Among the country people in Palembang, the Government has been making strenuous efforts to push on coconut growing. Each family has been directed to plant at least ten coconuts. The people did not fail to follow the injunction. This result has proved encouraging enough to induce the Government to go a step further in the same direction. The alarming diminution in the number of India rubber trees in consequence of the reckless felling to which they had been subjected, has aroused the local authorities to take active measures to stay the mischief. The natives have hence been enjoined to set to work planting these trees so far as lies in their power, more than they have hitherto done, but without neglecting the planting of rattans and other useful articles.

In Palembang, plantation enterprise has made a start under circumstances of considerable difficulty in keeping together coolies recruited at heavy expense. These fellows notwithstanding contracts and agreements, take every opportunity of shirking the work they had stipulated to do. The planters finding themselves quite at the mercy of their labourers, have applied to the Netherlands Indian Government for protection in the shape of a drastic coolie ordinance. The planters there confidently hope for something of the kind being conceded to them erelong, from the powerful influences at their command in official circles at Batavia.

On the East coast of Sumatra, planting enterprise is in a sufficiently forward state to admit of a railway in Langkat being taken in hand. The success hitherto of the Deli railway is a stimulus to further ventures in the same direction. From political point of view, the more railways there the better. More rapid means of communication will form the surest mean to curb disorder and check tribulent elements.

THE FUTURE OF CINCHONA BARK CROPS FROM CEYLON.

We have been favoured with the following extracts from the letter of a well-known proprietor of estates in Southern India now in England, and who is very anxious—like so many more—to get reliable information in reference to the Ceylon cinchona enterprise and the future prospects of crop-harvestings. The information he seeks is much more easily put in the form of questions than it is to supply the answer thereto. Here is the letter in all its suggestiveness:—

We all in England are most puzzled about cinchona in Ceylon: the reports we get are entirely contradictory. —— who lately returned from a tour through Ceylon speaks of the "uprooting" as enormous, yet the root bark sold in London last year was only 1,029,000 lb. which at the rate of 1 lb to a tree would give only 1,029,000 as trees uprooted out of the estimated 50,000,000. The following figures published by Woodhouse & Co. are both instructive and puzzling, but you may take them as correct, as Woodhouse & Co. are most careful:—

Analysis of Ceylon bark offered at public sales for the last four years:—

	Renewed.	Natural stem.	Root.	Branch:
	per cent.	per cent.	per cent.	per cent.
1883... ...	16	30	3½	41
1884	36	17	4	43
1885... ..	38	9	5	51
1886... ...	26	*43	6¾	22
4 months.				
1887... ...	35	*50	9	6

* This seems to point to much coppicing being done, but then why does the branch fall off so much. When a tree is coppiced, it gives its proportion of branch as well as stem.

Then again the relative proportions of renewed and branch in the years 1884 and 1885 seem strange as when much shaving and stripping go on, but few branches are cut.

I shall be exceedingly obliged if you will give me your opinion as to the prospect of Ceylon bark shipments for the future and answers to the following questions, As I have a copy of this, the number to the answer will do. It is I know impossible to answer these questions with any accuracy but please make guesses for my private information:—

1. What is the probable total yield of bark (dry) per tree uprooted in Ceylon taking the average of all trees uprooted large and small, dead and dying?

2. Of the total yield of dry bark per tree uprooted what would be the proportion of root?

3. Probable yield of harvest bark (bark from uprooted trees not included) per tree per annum old and young, barked or not barked, taking average for all the trees growing in Ceylon.

People talk about decreased shipments in future, but if much coppicing and uprooting is done during the next two years, are not the shipments likely to be large? I shall be very much obliged if you will give me your opinion. I have a good deal of cinchona now and must be guided in cropping by the prospects of Ceylon shipments.

4. People again talk of the great mortality among cinchona trees after they reach five years old; what do you imagine to be the percentage of mortality among trees over five years on estates where cinchonas do not grow very well?

5. What might it be on estates where they do grow well?

6. Supposing the acreage planted with cinchona in Ceylon to be 50,000 acres, what would be the proportions where cinchona grows well, and where badly?

Question 3. The average yield of bark (dry) per tree (succirubra and officinalis) uprooted on all the Nilgiri Government estates in 1885 was 3.80.

Increasing Consumption of Bark.—Dr. Cornish of Madras says the consumption might be largely increased in India.

In Burma, fever must be the prevalent disease owing to the extent of swamps and rice cultivation also of jungle. Quinetum made from branch bark which is now flooding and depressing the market in Europe and put up in small bottles might be distributed throughout India and Burma by the Government servants. In China the consumption might be enormous. Small bottles of quinetum might be distributed there through the Missionaries; also in Africa. It would have to be given gratis at first until the people appreciated it.

If any scheme could be formed for this I would join it. Of the bark sold in London in March ¼ yielded under 1½ per cent of quinine. All the buyers say that if ¼ of the bark could be taken off the market prices would rise at once. In December the market was rising. I sold then at 4d the unit. I attended the sale, the competition was brisk and prices would have gone on rising, but for the enormous imports from Ceylon during the first 4 months of this year. For your own information make a little calculation of the profit you would make if you *threw away* all your bark under 1½ per cent and sold the remainder at 4½d the unit.

The unit at present through the enormous receipts from Ceylon has been knocked down to 2½ to 3d.

We and other Ceylon residents would be as much pleased as this Indian Cinchona proprietor to have reliable answers to the very practical questions he puts; but we fear it is impossible to look for them. The area of the cinchona region in Ceylon is so wide and the circumstances of cinchona fields and of soil and climate are so varied that it is impossible to say from the experience gained in one locality what the average for outturn or mortality throughout the country may be. All that we can do is to show some of the good results gained in the cultivation of cinchona and leave inferences to be drawn as to what the averages may be. Coppiced succirubra trees in Ceylon at a medium elevation have given 8 lb. per tree of dry bark (quill, branch, and shavings). Officinalis trees, 6 years old, rooted up in Dimbula, averaged 4¾ lb. dry bark. Seven years old trees are considered to be equal each to one lb. of dry bark per tree per annum; indeed if only planted 300 trees to the acre, some planters count on this quantity twice a year. Now the great fact shewn by Messrs. Woodhouse's figures is that the uprooting process has not been going on to the extent some people imagine. On the contrary in a large number of districts, cinchona seems to be established if not as a perennial tree, at least with a certain lease of life, even although liable to be shaved annually or biennially. Of course there has been a considerable proportion of uprooting and dying out; and 50,000 acres is now far too high an estimate for the extent under cinchona. But a great deal remains; and under the influence of the fear that Java is going to fill the market erelong, we suspect Ceylon planters are bound to keep up heavy cinchona exports until that evil day for them, set in.

LETTERS FROM JAMAICA:—NO XVIII.

WEATHER AND CROPS—BLUE MOUNTAIN COFFEE—ADULTERATION—COFFEE IN CEYLON, INDIA AND BRAZIL—PROSPECTS FOR INVESTORS IN JAMAICA.

Blue Mountain District, Jamaica, 14th May, 1887.

The weather for some weeks has been cool and pleasant, and lately a forecast of the "May seasons," equivalent to our Ceylon "little monsoon," was heralded in very nice showers, just the weather for planting. Truly April and May would seem, from my present experiences, to be the best months for planting in Jamaica. Indeed there are not many months in the High Blue Mountain District during which good stumps might not be safely put in, as the soil is always moist and cool, and mist and light showers frequent. As regards crops the promises for 1887-88 are so far above the average, especially in the lower districts which have now blossomed, I scarcely remember to have seen a finer or more perfect blossom; and the weather has since been suitable to set it, if we but have an average season, and fine weather for the *bona fide* Blue Mountain estates at a high elevation, crops will be as large as they are small this year; most estates will not yield half as much as they did last crop. I have heard that one property, which gave 10 tierces last year, is not expected to give more than two or three, and another which gave 25 tierces is only to yield some 8 or 10 this season, so very dreadfully did most of the high properties suffer from the awful cyclones of June and August 1886. As but about 10,000 cwt. of genuine Blue Mountain coffee are calculated to be shipped during a good average year, the supply is likely to be very short in the Liverpool market, and prices should consequently rise though they have not yet done so in proportion to the medium qualities in London, because of the short supplies from Brazil. It would be very satisfactory to planters on this side of the water, to get some really authenticated information as to the cause of the smallness of the Brazil crop, and to learn if it is true, that that immense coffee-producing country is never likely again to ship such enormous crops as six million bags, as has been on some occasions accomplished. I suppose the *Tropical Agriculturist* is sure to give its readers the most valuable information, to all interested in coffee whether as growers, buyers, or sellers. If our Home Government would but do coffee planters justice, and stop roguery by preventing coffee being sold in an adulterated state, and let people mix their own chicory or what other abomination which they seem to deem palatable for themselves, it would help much to sustain British coffee planters in these days of leaf disease and small crops, to compete more successfully against those more favoured countries yielding heavier crops; for no doubt in the long run, "quantity pays better than quality."

I have read in the local *Gleaner* an extract from a report of Mr. Pasteur, the well-known and experienced Mincing Lane broker, on the coffees exhibited at the "Colinderies" who gives his opinion that India now stands first and foremost among British possessions both for the quantity and quality of its production, but I doubt

whether even "Cannon's celebrated Mysore" coffee fetches as high prices as some of our favoured Jamaica brands which sell at between 130s and 140s a cwt., but of course Mysore, Coorg, and the Nilgiris have the pull in heavier crops, cheaper and more abundant labour, easier means of transport, and getting the coffee cured *off* the estate. Mr. Pasteur regrets that the fine samples which were exhibited in the Ceylon Court were but the last vanishing remains of what even nine or ten years ago was the most extensive and most flourishing of the coffee crops raised on British soil, by British enterprise and capital. But we will hope it may prove *not* the last vanishing remains "for latest Ceylon advices seem to point, as if 'King Coffee' were in a measure to become 'redivivus.' It may probably be the growth of tea, cinchona and other new products are supplying the need that coffee experienced from being too much left to its own sweet surroundings, *all* the jungle and bush being ruthlessly cut away helping no doubt to introduce, foster and spread leaf disease: which may now be becoming less virulent in its attacks. What Mr. Pasteur says of the *fine samples* of Ceylon coffee after years of leaf disease convinces me I am right in supposing that, if the Ceylon plan of curing factories had been adopted in Jamaica, Blue Mountain coffee need not have sold any lower than it does now, or been in any way deteriorated by being cured for shipment at the sea level; for surely it is not the *curing* in the hills that gives Blue Mountain coffee its well-earned and established reputation; but the soil, the climate, the elevation and the extraordinary suitableness of Jamaica for the growth and cultivation of the coffee tree that produces such results. I note that Mr. Pasteur thinks Jamaica the most hopeful of our colonies for the investment of capital in coffee plantations, but I would caution any capitalists or experienced coffee planters not to act hurriedly, but come out to see for themselves: true there is plenty of virgin land left, thousands of acres, as stated by Mr. D. Morris now sub-Director of the Royal Gardens, Kew, but it is mostly inaccessible, very steep and exposed to hurricanes and Northers. Moreover, any extensive addition to the present area under cultivation would add to the already existing scarcity and dearness of labour, and unless Government opened up the country by good cart roads, the expenses of transport would be very considerable, and as crops to the acre not so heavy in Jamaica as in India, Ceylon, Brazil and Central America, the cost of placing it on boardship would be largely enhanced. To those who like myself have been so fortunate as to secure an old coffee plantation with some available forest left, and works and buildings erected and within a reasonable distance of Kingston, it is a different matter, and they may be able after patient toil to work out an independence, for coffee seems to take longer to come into full bearing than it does in Ceylon, but of its *lasting* qualities there can be no doubt as evinced by many fine patches of coffee, which must have been in its prime during the old slavery days, and are still in existence, and looking and bearing well. There are but few chances now of meeting with an old coffee property; most of them are too far gone, or have no "back sands," but if one such would be met with, and capital judiciously expended by an experienced planter, the results would by God's blessing be certain to turn out a successful and paying investment. W. S.

CINCHONA IN JAVA.

The Netherlands Indian news contained in the *Straits Times* received by the M. M. steamer contained the information that the Java cinchona planters had resolved to send one of their number to Ceylon to see and report to them what were the actual facts as regards this product in our island and to gather statistics as to our probable future export of bark. In the paper received by the P. & O. steamer last night we learn that the Java planters are seriously alarmed at the enormous outturn which continues from Ceylon, thus keeping prices down; but that it is firmly believed that the superior quality of Java bark will gain for it the ultimate victory. The most startling piece of news, however, is that the Government have resolved to retire from competition with private growers and are to sell their plantations. The reason of this is said to be that the upkeep of the gardens is being conducted at a dead loss; but it is added, that from the outset the Government never intended to grow cinchona for the sake of gain; and now that its example has been followed so largely by private individuals it can retire from its position of "nursing mother." As many of the trees on these plantations are the finest in the world as regards richness of the bark in quinine sulphate, there is likely to be brisk competition among buyers. The following are the paragraphs referred to:—

Now that cinchona growing no longer proves so profitable as of yore, the Government is said to intend to sell its plantations where the cultivation of bark has been carried on for years. Planters in spite of the low prices ruling for bark, do manage to realise a little profit. The Government, notwithstanding the extensive area under cinchona always kept up to the mark, cannot see its way to secure a remunerative return. At the outset it was never intended by the Government to grow cinchona for the sake of gain, but to get a good example in cultivating that useful tree. The Government in fact wishes to get rid of valuable property which will yield handsomely under good management, because somehow or other, it cannot ensure the securing of the latter. For deriving the income of the State party from the produce of the soil, a good case can be made out. In Europe the idea of the State turning planter or miner is decried on the ground of its never securing good work, but, even there, this long received doctrine does not now command unqualified acceptance. In colonies, this principle does not suit all cases, especially when Government management comes up to the standard aimed at in private enterprise. If the sale be carried out, the cinchona plantations will readily find buyers.

The cinchona planters in Java look forward with alarm and apprehension to the struggle for existence between them and their fellows in Ceylon, from whence an enormous output of bark keeps down prices to a ruinous extent, without any prospect of the outturn lessening for the present. Java bark will undoubtedly gain the mastery from superior quality. Meanwhile planters there handicapped as they are by fiscal burdens and hindrances unknown in Ceylon, will be hard put to it. For them the outlook at present is dark enough. Few of them expect better times to set in immediately after the anticipated victory.

COMMERCIAL "RINGS": COFFEE.

Both the coffee ring in New York and the corn ring in Chicago have broken down. The leading "bull" house in each "corner" has been ruined. Certain firms had deliberately set themselves to buy up all the available corn and coffee with the view of reselling it an enormously increased price; but the supply proved to be greater than they had anticipated, their purchasing power became exhausted, and, dreading the consequence of having on their hands vast stores of corn and coffee which nobody wanted, they began to sell. The immediate result was a panic. Prices declined with terrible

suddenness; the "bulls" could not obtain even cost price for their wares; and so the whole fabric so carefully built up came tumbling about their ears, overwhelming them with swift and utter ruin. One firm lost half-a-million dollars in a day. There are sixteen million bushels of wheat held by the collapsed ring to be sold under the hammer for whatever it will fetch. The coffee ring forced the price of that commodity from 6½ to 22 cents per pound. These are some of the facts of this stupendous "operation." The failure of the firms engaged in it is the least evil result. Not only have the consumers, the legitimate buyers, had to pay an artificially increased price, but the whole market has been demoralised. The enormous auction of the Chicago "ring" drew into the city about half a million bushels of wheat every day. Everybody who had wheat to sell sent it to Chicago, and there it is now, drugging the market. For weeks corn and coffee have been kept up to famine prices. The supply has consequently been unduly stimulated. The reaction will so convulse the whole productive and commercial system, from the grower to the consumer, that many an honest man will today find ruin knocking at his door. And all for what? That a dozen men in Chicago and a dozen men in New York may by one gigantic "gamble" make colossal fortunes. There is no term in the vocabulary of legitimate commerce to describe this proceeding. It is an infamous conspiracy, entered into for private gain and with an utter disregard of the public interest. If not technically a crime, it is so morally. People who engage in "corners" are enemies of society.

These disgraceful enterprises are peculiarly American. They are intimately associated with two leading American traits—the haste to become rich and the worship of "big" things. The haste to become rich is stimulated by the universal admiration the American people have for the man with a "big pile." A ten-million-dollar man is a popular deity; and whatever it is—a prairie, a mountain, a river, a city, a benefaction, or a crime—the admiration it excites is measured by its "bigness." But there are signs that the Socialistic democracy of America is beginning to resent the special form of the tyranny of capital which is exhibited in these "corners." Here are men who, by sheer force of the command of capital, propose to lock up and monopolize the possession of the first article of food, with the view of compelling people, under fear of starvation if need be, to buy from them at whatever price they may choose to demand. It is true the American people have not hitherto seen the matter quite in that light; but they have been dazzled by the "bigness" of the thing, and we believe the flashy brilliancy which has blinded them is beginning to wear off. There can be in the breasts of thousands of Americans today nothing but feelings of resentment and disgust towards the defeated and ruined confederacy. And we may hope that similar feelings on the part of the English commercial classes will prevent the idea from ever taking root here. We had a cotton corner in Manchester some few years ago, and there have been attempts at a pig-iron ring in Glasgow. But in no case that we are aware of has the scheme succeeded; and we may hope that, beyond the natural shrinking from the risks that must be run, there is in the English mercantile mind a repugnance to these disgraceful plots against legitimate trade and against society in general. Why, society would become impossible if it was always to be placed at the mercy of some great combination formed for the purpose of creating a monopoly of a necessary of existence. What if all our ship-owners, our railway companies, our corn-factors, and cattle-breeder were to combine in order to exact for their services or their commodities some unheard-of price which would enrich them while impoverishing everybody else? These considerations are beginning to be understood in America; they are already, we hope understood in England.

If we insist with special earnestness on the iniquity of the system, it is because we are conscious that public opinion is more powerful to check it than legislation. "Cornering" is even more difficult than boycotting to define as a legal offence. When a man goes into the market, buys wheat and pays for it, how are we to limit his purchases? Having bought, he declines to sell, and why should he sell if he has a mind to hold? At what point does legitimate trading suddenly become transformed into mad speculation, involving the public in the greatest inconvenience and entailing loss or ruin upon thousands of innocent people? All this is extremely difficult to define in terms which would give society a legal hold upon the offender. But public opinion soon perceives where legitimate trading ends and "cornering" begins; and public opinion has its own way of hanging Haman on the gallows prepared for Mordecai.—*St. James's Budget.*

Tea for the Masses.—With regard to the recent movement in Calcutta to cultivate a taste for tea among the inhabitants of India, the *Englishman* of the 25th instant says:—"Today we have the pleasure of publishing the prospectus of the 'Indian Tea Supply Company, Limited,' the shares in which we expect will be quickly taken up. The scheme has commended itself widely, so that not only is there enthusiasm about it in Calcutta, but already, before the appearance of an advertisement, the Managing Agents are receiving letters about it from all parts of India."—*Pioneer.*

The Amsterdam Quinine Works.—In the *India Mercury* some additional particulars are given concerning the future of this concern, which was sold the other day by public auction at about 8,400*l.* It is proposed to furnish the works with improved machinery for the extraction of alkaloids from cinchona bark, and thus to increase the producing capacity from 8,000 lb., the former standard, to 18,000 lb. per annum. This will entail an outlay of about 2,800*l.* The works will resume operations with a capital of 21,000*l.*, of which the public will be invited to contribute 8,500*l.*, in shares of 500 florins, or about 42*l.* each. The purchaser of the concern, Mr. W. Sieger, together with a few well-known Amsterdam firms, among which are the Dutch Trading Company, S. B. Zeveryn, A. d'Ailly & Sons, and C. F. Boehringer & Sons, of Mannheim. The latter firm will take over technical management of the new company, and a chemist trained at their Mannheim works has been appointed technical manager of the Amsterdam manufactory. —*Chemist and Druggist.*

Ecuador Cinchona.—The falling-off in the Cinchona Bark Trade of South American States is very noticeable:—Of Peruvian bark, 2,987 quintals (value 8,961*l.*) were exported in 1885, and only 613 quintals (value 2,452*l.*) in 1886. This is the only article showing a decrease during the past year, and it may be noted that the collection of cinchona has now been almost abandoned, owing to the difficulty of its transport through the forests of the interior, and the fact that its value has so declined as to render the product insufficient to cover expenses and freight. The abolition of export dues and reduction in freight, have not been found sufficient to overcome this drawback.

BRICK TEAS.—On the various sorts of brick teas imported through Kiachta the Irkutsk Customs authorities are ordered from St. Petersburg to levy duties of two, six, and eleven roubles per pood respectively.—*L. & C. Express.*

COCONUTS AND COPRA IN NEW GUINEA.—We have had an application from the Colonial Secretary's Office for a copy of our work "All about the Coconut Palm," to be sent to the Special Commissioner, New Guinea, who has applied for information respecting the industry of copra-making &c.

HELOPELTIS.—A planter writes :—"A short account of the life of this insect would be of interest tomyself and others. Are they indigenous? At what rate are they supposed to increase? Where are the eggs and young to be found? &c. Have any other means besides catching been suggested for destroying them?"—This enquiry just shows the importance of every well-ordered Estate having a small Library of books of reference including a set of the volumes of the *Tropical Agriculturist* in which nearly every possible enquiry as to our chief products and their enemies will find an answer. In vol. IV, page 327-9 our correspondent will find the particulars of *Helopeltis*, which he requires, in a Report by Dr. Trimen.

THE LIFE OF TEA IN ASSAM.—"But it is from Northern India and Assam mainly that we must gain the information calculated to relieve the suspicion that the tea-bush under pruning is short-lived. One authority writing on tea either in Assam or China, speaks of 100 years as the life of a tea-bush; but we cannot recall where we read that statement whether in Fortune's or Colquhoun's book? Of more intimate bearing is the fact that the original Assam Company began operations in the "forties," their first shipment of tea being made in 1847. It will be of special interest to learn whether the clearing from which this was gathered is still in operation and if not, what is the age of the oldest garden in regular and full cultivation in Assam? This is a question which we hope to have answered in due course by one or other of the Ceylon men now in Northern India who get the *Overland Observer* or by an Assam planter who will read of this discussion in his *Tropical Agriculturist*."—*Overland Observer*, May 23rd. On the above, a former resident in Ceylon writes :—"The first opened gardens of the Company are still bearing. Ordinary pruning does not seem to tell on the tea tree; but double pruning where the stems are cut down to and under the surface of the soil and till the field looks like a piece of ground hoed up and ready for planting, such pruning is often followed by a slight percentage of mortality.—ASSAM, June, 1887."

TEA FOR CANADA.—It is reported that the direct orders for tea for the Canadian market sent out from Montreal to China and Japan up to the beginning of the current month show a decrease of 25 per cent. against the corresponding period last year. The fall off is, it is suggested, partly accounted for by the changes in the trade, which enable importers ordering direct to obtain supplies so much more rapidly than formerly that they do not need to hold one-fourth the stocks they held in former years, hence they order more frequently as the need arises. Another explanation is said to be the fact that any army of tea merchants from England has lately invaded Canada, and is offering black teas at very low prices throughout the Dominion. Montreal dealers are said to be to some extent alarmed by the scarcity of business in new season's China and Japan teas.—*L. & C. Express*, June 17th.

COFFEE.—A collapse of the coffee and wheat speculations has unsettled the New York Stock market. All prices have declined, the selling being general in speculative shares. Several "operators" in Wall-street have suspended payment. The panic in the coffee market caused the price to drop on the 14th instant. 3 cents per pound, with sales of 400,000 bags, breaking the leading "bull" house and several minor dealers. Messrs. B. G. Arnold and Co., of New York, coffee merchants, have suspended payment. Their liabilities are reported to exceed $1,000,000. Messrs. Mackey and Small, coffee-brokers, have also supended, their liabilities amounting to $150,000. Messrs. Kershew and Co., the firm which took the leading part in managing the Chicago wheat "corner," have suspended payment. Many smaller houses have also failed, the collective losses of these operators amounting to $8,000,000. General gratification is expressed throughout the country that the speculators who "engineered" the coffee and wheat corners have succumbed.—*L. & C. Express*, June 17th.

CINCHONA MARKET PROSPECTS.—A planter writes :—"My London friends send me enclosed cutting from the *Public Ledger* of 24th June :—

CINCHONA has been quiet and no auctions have been held, owing to the Jubilee celebrations. The public auctions held on the 2nd instant at Amsterdam resulted as follows : 1,065 bales and 160 cases Java, for account of the N. T. Jo., the Succirubra sold at 25c to 99c, C. Schuhkraft 15c to 76c, Ledgeriana 7c to 102c, C. Anglica 27c to 79c, C. Officinalis 58c to 61c; and for private account. The C. Succirubra sold at 17c to 108c, C. Ledgeriana 10c to 85c, C. Officinalis 27c to 55c.

Statement of the movements of "Peruvian Bark" in the United Kingdom, according to the Board of Trade Returns, for the first 5 months of the years—

	1887. cwt.	1886. cwt.	1885. cwt.
Imports	71,415	58,691	47,995
Exports	68,833	47,431	40,438
Left for Home Use ...	2,582	11,260	7,557
Declared value, imports	£346,205	349,466	354,417

Statement of the movements of all sorts of Medicinal Bark in London in packages during the past two years :—

	12 months June-May. 1886.	12 months June-May. 1885.	12 months June-May. 1886.	12 months June-May 1885.
Total 12 mths.	75,494	62,753	78,678	75,309

Statement of the Landings, Deliveries and Stocks, of "Medicinal Bark" in London for the first 5 months of the year—

		1887.	1886.	1885.
Landed	pkgs	34,037	28,748	21,347
Delivered	...	36,152	26,460	25,243
Stock, May 31 ...	...	60,224	64,005	76,573

The following statement exhibits the total quantities exported from Ceylon to all parts from 1st October (commencement of season) to 19th May :—

Season 1886-87	lb. 9,512,402
1885-86	9,794,456
1884-85	6,766,195
1883-84	4,878,341

The following is a statement of the exports from Java to all parts from 1st July (commencement of season) to March 31 :—

	Private.	Govt.	Total.
Season 1886-87 Amst. lb	1,357,576	571,320	1,928.896
1885-86	866,672	349,209	1,215,881
1884-85	653,745	345,978	999,723
1883-84	616,202	410,275	1,026,477

"The total shipments from Ceylon 1886-87 during the past 30 weeks only seemed a decrease of 260,000 lb. 1885-86 but the telegraphic communications from Ceylon since that date ought to show our London friends a decrease of nearly 1,500,000 lb. in Ceylon bark. The worst feature is the increase in Java bark of 700,000 lb. which doubtless contains a larger percentage of sulphate"

The weekly shipments of bark hence are of course telegraphed to several London firms, so that dealers generally must be well acquainted with the information.

THE WEST INDIES AT THE COLONIAL AND INDIAN EXHIBITION 1886: NEW TROPICAL PRODUCTS PORTION.

BY SIR AUGUSTUS ADDERLEY, K.C.M.G.

(From address delivered before the Society of Arts.)

SUGAR.—Sugar, as the main staple, has become so much reduced in value that it is a serious question whether cultivation by the same proprietors can be continued for long unless some remedy can be found to counterbalance the effect of the European bounty system upon our unsubsidised cane-sugar production. The extension to the British West Indies of the most favoured nation clause in existing treaties with the United States, is also of much importance. The bounty system is gradually forcing the production of sugar out of its natural channel. This is evident by the fact that 2,500,000 tons of beet sugar are now produced, all under the bounty system, while the production of the unsubsidised sugar is reduced to 2,000,000 of tons, all the product of the sugarcane. This is free trade with a vengeance, and the serious part of it is that we are ruining our own industries to create a monopoly for foreign countries. A great responsibility rests on England for all these troubles—troubles which, fortunatly perhaps for the West Indies, are extending to the home industries. A serious effort should be made to stop the storm of discontent which is slowly and surely spreading throughout England and in the West India Colonies. "A stitch in time saves nine;" unfair trading ought no longer to be tolerated by our rulers or people.

The sugar supply of the world is mostly derived from the sugar-cane, from beet-root, and to a small extent from the sugar-maple and other vegetable sources.

The two largest consuming countries are England and the United States, the latter country slightly in excess of the former—say 1,300,000 tons for United States, as against 1,200,000 tons for England.

All the sugars at the exhibition from the West Indies were produced from the sugarcane, and the approximate annual production is about 280,000 tons, if we include British Guiana.

Mr. Lubbock thus reports on these:—

"The sugars exhibited by these Colonies are various, and include the brown Muscovado, so much liked by our refiners and those of the United States; fine yellow Muscovado, suited for grocery purposes, which chiefly come from Barbadoes; the well-known bright yellow crystallised, mostly from Demerara, but now also largely produced in Trinidad, Barbadoes, and some of the other islands; and finally, white crystals. These sugars are all eminently suitable for the English market, except the white crystals, which cannot compete with those of our refiners, not on account of any real inferiority, but from the impossibility of producing, at a cost which would be profitable, that sparkling appearance which our refiners, working on a large scale, can produce at a merely trifling expense."

Raw cane-sugars are most agreeable to the taste, whilst a similar kind of beet-sugar is most disagreeable in taste and smell, which adjuncts are only to be eliminated by a refining process. Consumers should note this. Kidney diseases are also said to be developed where beet-root sugar is consumed.

COCOA.—Cocoa, or cacao, is the prepared seed of a tree originally discovered in the tropical parts of America. Its botanical name is *Theobroma cacao*. The seed is enclosed in a long pod, varying from 7 to 10 inches. The plants with pods on were exhibited in the Trinidad Court. Its value depends a good deal upon the treatment of the seed.

Mr. Henry Pasteur gives the following particulars of cocoa:—

Cocoa, unlike coffee, requires no expensive machinery for its preparation; wooden boxes for the fermentation, and wooden platforms for the drying, covered with a moveable shed, are all that is wanted; and it is strange that such a large proportion of our West India Colonies should ship their produce without using these simple means of curing properly. There are several modes used in our Colonies for curing cocoa, to render it fit for shipment to the consuming countries. The simplest method is to take the pod, and strip it from the seed, wash the seed, and then dry it in the sun. The better plan is to place a quantity of seed—still enveloped in its copious, sweetish pulp—in boxes closely covered, and to allow it to ferment for some days; it is then washed free of the mucilage that is still left on the surface, and after that picked and dried. A further improvement has been made upon this treatment by refraining from the washing away of the mucilage after the fermentation has taken place, and allowing it to dry upon the shell which encloses the seed. This process is coming more generally into use, both in Trinidad and Grenada. Cocoa requires a rich, deep, moist soil, and seems to flourish best at a low elevation. The rainfall in Trinidad averages 66 inches annually, and the finest cocoa is grown at an elevation of from 60 to 200 feet above the sea leval; the difficulty is in finding land and climate approaching to these conditions. The planter, finding the position and soil suitable for the enterprise, and willing to be patient until his cocoa tree has arrived at maturity, will find in the fourth year results sufficient to pay him. The world's production of cocoa has been variously estimated at 100,000,000 lb. to 120,000,000, of which our English Colonies furnish quite 25,000,000 lb. which mostly find their way to London. In Trinidad only, there is a competition on the part of the United States of America and France for the inferior qualities, which are sold at the shipping port, all the finer estate cocoa being sent here. The home consumption of Great Britain shows a steady increase of about 750,000 lb. yearly, the consumption, in 1885, being 14,500,000 lb. The English Government has taken Trinidad and Grenada cocoa for the Navy during the last seven or eight years, in preference to other sorts.

The largest growing country is Ecuador, of which the produce is known in the market under the name of Guayaquil cocoa, and the extent of its crop, as well as that of the Brazilian province of Para, have a marked influence on the prices realised for all kinds of cocoa. Those crops vary considerably from year to year in extent, Guayaquil more especially. In our own Colonies, Trinidad shows an increase, the crop of 1885 amounting to 14,000,000 lb.; but in Grenada, St. Lucia, Dominica, and Jamaica, the quantity produced the last year or two does not seem to have varied. In seeking for a reason for the want of the extension of planting and cultivation to meet the increase of consumption, it may perhaps be found in the initial expense in the forming of new plantations. The trees do not yield tribute sufficiently remunerative until the fourth year. This waiting for results has no doubt prevented enterprise. The following is from my special report:—In making a report upon the value and quality of West India cocoa, I have, in the first place, to take into consideration the ultimate destination to which the varieties of cocoa go. In the manufacture in Great Britain during the last fifteen years, an important alteration has taken place in the mode in which it is distributed for consumption. A few large manufacturers have taken the trade out of the hands of the general wholesale dealer, who used to have, each his own way, a preparation of cocoa, such as what is called "nibs," "flake," "suluble," &c. This individual treatment has been mostly superseded by large manufacturers, who, by a specific and scientific treatmet of the article, have introduced preparations superior to those made by the efforts of the dealers. In a measure this partial monopoly has been brought about by their taking care to make known to the public their several productions; the public, when wanting cocoa or chocolate, asking for the "advertised article."

As regards Trinidad cocoa, in the curing of it for the English manufacturer, I should hardly like to propose any alteration, but in view of the increasing production, which I should hope, judging from the very permanent value established for it, will induce planters still to go on freely cultivating it. Consideration must be given to the value of cocoa in the opinion

of German and French buyers. The Continental buyers always seek after colour (the same thing rules them in their purchases of coffee). The English buyer, as a rule, goes for the intrinsic quality and proved flavour. The Continental buyer likes large size, the shell to be red, inside kernal to be evenly fermented, and a light reddish-brown or chocolate colour. It may be that these things constitute a certain indication of quality. The individual samples shown in the Trinidad Court were all well-known marks, and produce of estates to which the buyers in the London market have established a relative value according to their merit. The higher priced ones are lifted out of the reach of the Continental buyer by the English manufacturers' determination to keep them for their own use. With regard to the extraordinary and peculiar level to which a number of these estates and marks have been kept in price, I may mention that the greater proportion is bought by one firm, and the only disturbance of these prices is the competition for a portion of these from the other English manufacturers. This competition has been mostly for fine qualities, avoiding the too highly fermented samples. Of the 48 specimens exhibited, prices realised show the buyers' estimation, viz., 94s. to 96s. per cwt. On the first 15 samples there was to be observed a bloom (like the bloom on the plum) on most of them; this I have always considered an indication of fine quality. It may arise from a slight secondary fermentation, and the superior character of the pulp, dried upon the shell, imparting to the cocoa a finer flavour. I believe the qualities possessed by the pulp influence the flavour of all unwashed cocoa. From Granada we had ten samples, from eight small estates, of the best character. Considering that their production is the next largest to Trinidad of our Colonial growth, it is a pity that it was not better represented. Dominica sent us a number of very attractive samples, sound in condition, mostly washed, and presented a bright pale red and red shell. This cocoa is larger and more even in size than Granada, but the flavour of the part fermented and unfermented is slightly bitter; but it is evidently worth trying to improve the curing. The remaining sample, representing the crop of 1884, mixed, fermented, present value about 60s. Jamaica cocoa is a very thin bean of poor growth and quality; no care seems to have been taken in its preparation. Unless better seed can be planted, there seems no hope of any great improvement taking place in its production, as the taste and flavour of the nut is now very "bitter and acrid." It is apparently the most "inferior" of the cocoa trees. Values from 70s. to 54s. per cwt.

Barbadoes.—One, red, part fermented, value 68s. The exhibits from Jamaica, Dominica, and St. Vincent, nearly all cocoa that had been washed and dried, unfermented, partly fermented, and out of the whole number perhaps only three fully fermented, did not represent the cocoa as delivered in London. I have come to the conclusion that the washing process—the contact of water, notwithsanding the attempted drying—seems to leave a moisture, which is thrown out on the surface of the shell, entirely altering its appearance from the bright pale red and red samples exhibited. When offered in the market here, they present a grey and greyish-red appearance, the fruit often being mouldy, the result probably of packing in bulk and transport.

The exhibit of cocoa butter or fat had a significance and interest on account of its representing a new process of manufacturing cocoa, the admixture of farina and other substances not being followed, and the fat extracted, so that it is likely to largely increase the quantity of cocoa used in the manufacture of the prepared article as used by the public. It is also valuable for medicinal purposes for making ointments, &c., in consequence of its not turning rancid. The deliveries of cocoa for consumption—say, the 14,000,000 lbs. of 1885—would probably represent in weight over 20,000,000 lbs. of cocoa when manufactured. I may mention that, at a cocoa stall, we sold pure unadulterated cocoa, the idea being that for the working man it is an important beverage, more nutritious and cheaper than the adulterated article.

COFFEE.

The following is from a memorandum given me by Mr. H. Pasteur:—The total production of coffee in the world is roughly estimated at about 600,000 to 650,000 tons, of which Brazil alone produces between 340,000 and 380,000 tons, and Java 60,000 to 90,000 tons, the proportion of British-grown coffee being only about 35.000 tons, of which India contributes 15,000 to 18,000 tons, Ceylon 10,000 to 12,000 tons, and Jamaica 4,000 to 5,000 tons. Although numerically very small, the productions of our Colonies and of India occupy the front rank owing to their excellence. Nowhere is finer coffee grown than in India and Jamaica, and its value, as well as that of Ceylon, is firmly established above that of all other kinds, even of Mocha, which at one time stood above all others.

Jamaica.—Coffee is grown in almost every one of the West India Islands, but Jamaica is the only one where the cultivation is carried out on an extensive scale, the quantity exported in 1885 amounting to 80,600 cwt., and occupyiny the third rank in value of the products exported from the island. From 8,000 to 10,000 cwt. are produced annually on plantations situated on the high lands of the Blue Mountains, which have long been known as one of the finest coffee-growing districts in the world, thanks to a fine rich soil and a favourable climate, combined with all the care and intelligence which the means of European planters can command. The coffee from those favoured localities is all consumed in this country, and realises almost the highest prices in the market—say, from 90s. to 140s. per cwt. The remaining 60,000 to 70,000 cwt. are grown in various parts of the island; some in the Manchester district is of medium quality and well prepared, but the greater portion is cultivated in small patches or gardens, by settlers and small proprietors who do not possess the knowledge or the means of preparing their crops properly; or in the low country, where an inferior quality is raised; hence the great difference in prices between "fine mountain" and the ordinary Jamaica. The want of proper curing establishments, is much felt in many parts; it is probable, too, that the plants are not raised from good seed, and that better cultivation and manuring are needed. But even this will not suffice to ensure the good quality of the crop, unless due attention is paid to picking at the right moment, and to immediate pulping and thorough drying of the parchment. This should ensure the proper colour, but, in the absence of the necessary appliances, the planter would best consult his interest by sending his parchment to be peeled, &c., at the nearest works, or better still, by shipping in to London for treatment. Ordinary Jamaica coffee is now selling here at from 50s. to 53s. per cwt. and there is every reason to believe that, with better care in picking and curing, and with quick despatch of the parchment to London, the grower might obtain from 10s. to 12s. per cwt. more than he does at present. There does not seem to be any good reason why, in a country where the highest priced coffee is grown, the bulk of the production should rank on a par with common Brazil, or the lowest known qualities. The extensive planting of the Liberian variety, which appears to be going on in Jamaica and other places, will most probably lead to disappointment; the quality is so poor, so deficient in strength and aroma, and so little appreciated in the home markets, that any material increase in the supply must inevitable lead to a lower range of prices, which will fail to repay the outlay. The Jamaica plantations appear to have been so far quite free from leaf-disease, flies, or other enemies of the coffee tree, and there is an abundance of forest lands of proper elevation in the St. Ann and Clarendon districts, and the northern slopes of the Blue Mountains, suitable for extending the cultivation of the finer classes, which ought to give handsome returns for the capital so invested.

Of the sixty-nine samples exhibited in the Jamaica Court, sixteen are parchment and cherry; nine from

the finest estates are worth from 110s. to 140s. per cwt., averaging 120s. to 125s.; eight average 90s. per cwt., eight more 75s. per cwt.; eight are worth from 54s. to 65s.; and two about 47s. There are also twelve samples of Peaberry from 70s. for the lowest to 105s. for the best; and two samples of Liberian worth 56s. and 50s. per cwt. St. Kitts, Antigua, and Montserrat sent coffee, good quality to ordinary, value 60s. to 50s. per cwt.

Dominica.—Coffee was, at the beginning of the present century, the leading article of export from this island, and it was then considered one of the best kinds produced in the West Indies. The trees, however, were attacked, some forty years ago, by an insect blight, which spread devastation among the plantations, and destroyed the greater portion of them, so reducing the production that at the present time it is hardly equal to the consumption of the island. Cultivation is now reviving to some extent, and it appears that the blight, although still in existence, is comparatively harmless at high elevations. The Liberian variety has also been introduced. There is an abundance of fine forest land and rich soil on the slopes of the bold mountains which cover the country, with plenty of moisture, conditions which are eminently favourable to the growth of coffee. Of the ten samples exhibited, two are of very small, hard, heavy, greenish bean, worth about 70s. per cwt., one pale native kind 50s., one Liberian 52s.; the remainder are of a good size, greenish to rather good green colour, and if properly picked and prepared would be worth from 63s. to 76s. per cwt.

Barbadoes.—One sample, ordinary pale uneven native sort, 52s., and one sample of very well prepared good bluish plantation, of even size, though a little rough, 80s. per cwt.

Grenada.—One sample, large pale greenish, useful quality, 54s.

Tobago.—Two samples of dull greenish and brownish Creole coffee, not sized, but good of its kind, 56s. to 58s. per cwt.

Trinidad.—Ten samples are exhibited. Two of them consist of very common dull brown and red badly prepared coffee, worth 47s.; four are Creole, or pale native kind, of a useful quality, ranging in value from 52s. to 54s.; the others are better, and, with more care in their preparation, might be turned into good coffee, worth probably 60s. or 70s.; but being imperfectly picked, and of a brownish colour, their value is reduced to 58s. to 60s. per cwt. There appears to be a good deal of land suitable for opening into coffee gardens or plantations, and planting has been carried on lately on a larger scale. It is to be hoped that the botanic gardens which supply plants from their nurseries will endeavour to provide none but those grown from the best seed of *Coffea arabica*, which can easily be procured from Jamaica or from New Grenada. In an island where the cultivation and preparation of cocoa has been brought to such a degree of perfection, there ought to be no lack of skilled labour to prepare coffee much better than is apparent from the samples exhibited. The shape and size of the berries show that the soil and climate are favourable, and that it is only labour, care, and skill which are required to give the coffee its proper value.

In concluding this report, it is difficult to avoid alluding to the extraordinary treatment to which coffee is subjected at the hands of the British Government. Were the same amount of fair play and protection against fraud extended to it as is accorded to tea, it is probable that the greater portion of the 35,000 tons of British-grown coffee would be retained for home consumption, instead of a paltry 14,000 tons, or at the rate of about 15 ozs. per head of population per annum, against 2¾ lb. per head in France, 5 lb. in Germany, 7¾ lb. in the United States, &c. It would almost seem as if the Treasury, which is directly responsible for the legislation on the subject, was bent upon discouraging, by every means in its power, the use of one of the most delicious and beneficent of the non-alcoholic drinks, by the sanction which it gives to its adulteration with any vegetable matter; it is impossible to recognise coffee in the wretched mixtures which are sold in every shop and store, or in the thick, dark liquid which is served under that name in many of the coffee palaces and temperance houses throughout the kingdom. No wonder that consumption decreases year by year, not of coffee alone, but even of chicory and mixtures. The Local Government Board and the Board of H.M.'s Customs join, in their annual reports, in ascribing the diminishing revenue from coffee and chicory to adulteration, and in condemning the present legislation on the subject. Surely those who are engaged in the cultivation, importation, and trading in coffee, ought to combine to make an effort to obtain redress for what is acknowledged almost on all hands to be a crying injustice.

TOBACCO.

St. Lucia Tobacco.—From the size and development of the leaf, it would seem that the soil might be made suitable to the growth of tobacco, provided great care and attention were paid to the choice of the seed and the selection of the site. The sample exhibited indicates that, with careful cultivation, very saleable tobacco might be produced.

Trinidad Tobacco is too thin for English use. The sample grown by J. J. St. Hill wants body to produce more elasticity in the leaf. The sample grown by C. Fabian and Son has more body, but from the size of its leaf would only be suitable for fillers. The tobacco used in the manufacture of segars from Barbadoes and Antigua, is hardly (in comparison with segar tobaccos of other growths) suitable for anything but very common descriptions, and limited to local consumption only. The specimens from Jamaica and Trinidad exhibit better material and workmanship, and may be classed as good medium sorts, but, as such, their production can only have a local interest. The segar manufacturers in England, and in Europe generally, have at their command a great variety of the best growths which the world supplies, and of the best skilled labour. A genuine import trade in anything but certain specialities, such as finest Havana and Manilla segars, cannot be looked for as possible in England or the Continent, and, apart from the disadvantage of differential duties which some imports would have to encounter, even the best specimens from these islands could not compete in quality or economy with ordinary medium goods manufactured here and elsewhere. I may mention, however, in spite of this report, that Trinidad segars sold well at the Exhibition, as did those of the Bahamas, made, however, in the latter case, from Cuba leaf. In referring to these Bahamas manufactured segars, which are equal to the finest Havana, I may here give an illustration of the shrewdness of our American cousins in all matters connected with the introduction of new industries into any portion of their possessions. Their tariff puts a very heavy duty on segars from Cuba, whilst the leaf tobacco is admitted at a much lower duty. As a result, Key West, an island off the Florida coast, belonging to the United States, has monopolised all the segar trade of the Cubans with the United States. A large number of Cubans have settled and established factories there; the population has increased twenty times during the last ten years, land has been bought up, and more enhanced in value, and a most thriving community now exists. Cubans are ready to do the same work for Nassau, if some concession on the duty could be made by the Home Government, on British Colonial manufactured segars imported into England. I fear it is hopeless to expect this, but with the bounty system in foreign countries continued for long, the time will come when we shall have to win back our prosperity by such a process, and up-hill work will it be. There are good grounds for the conclusion that many of our West Indian Colonies possess the capabilities necessary for the successful cultivation of marketable tobaccos, and even, in some instances, of the higher and more costly classes, suitable for the manufacture of segars. The tobacco leaf, when grown in countries far apart from each other, varies greatly

in character and appearance, and at least in as great a degree as any other vegetable production. This variety and divergence may be partly owing to the selective agency of the cultivators, but the sole effect of soil and climate seems, more than any other cause, to impress a certain definite character on the respective growth of each country. For example, certain southern parts of the United States, in which tobacco is so largely and successfully cultivated, can only produce the heavy sorts suitable for smoking in the pipe; and the States, notwithstanding the variety of soil and climate, and the extent of territory at their command, have to draw their supply of the finer sorts from distant and foreign sources. I venture to point to the obvious conclusion that the acquisition of a true knowledge of the special class of tobacco naturally produced in their various localities is the first of all necessary. It would be a waste of effort to attempt the growth of any other variety, or to prepare it for a purpose to which it is not adapted, whether for segars, the pipe, or for cigarettes. It may also be mentioned that, though tobacco of a sort will grow almost anywhere, it is only in special limited localities, even in the countries which have proved well adapted for its cultivation, that the superior and paying classes of each sort can alone be produced. This points to the necessity of a careful and experimental selection of site, and of due observation of results, guided, if possible, by a knowledge of the article itself, a knowledge of the constituents of soils, and of the requirements of the world's markets.

SPONGES

The exhibits of this useful article were chiefly from the Bahamas. There are many varieties; the principal in order of their value are the sheepwool, white reef, Abaco velvet, dark reef, boat, hardhead, grass, yellow, and glove, principally used for mechanical, surgical, and bathing purposes. The best description of Bahamas is inferior to those of the Mediterranean, although the sheepwool, for bathing purposes, is stronger in texture and more durable than the Mediterranean kind, but not so good-looking. The exports amount to £60,000 annually. The bulk of the Bahamas sponge is taken by the United States and part by France. Sponges were first discovered in the Bahamas by Sir John Lees, the father of the present Governor of Barbadoes. A question in my mind is whether the existing sponge beds, if continually fished, as at present, are not likely to be exhausted, and whether, to gaurd against this, it would not be possible to institute a periodical close time for the protection during the reproductive season, or, at all events, a close time in certain areas which have been fished for years, to act as nurseries, and allow the germs or embryos to be distributed to the other waters.

The importation of the germs of the finer kinds of the Mediterranean sponge is well worth the effort. Success, which is more than probable, would enormously increase the value of the fisheries. I understand sponges have been successfully cultivated by cuttings, both in florida and by Professor Schmidt and Mr. Gregor Buccich in the Adriatic Sea. I believe these experiments were only stopped by the hostility of the fishermen.

FIBRES.

Of these raw materials, the West Indies have, until the present time contributed little—that there is scope for a large trade few can doubt. In the Indian Section, where the flora is so similar to the West Indies, the extensive collection of raw materials have been submitted to an exhaustive examination by Mr. C. F. Cross and others. Their report contains full accounts of the scientific methods pursued, and should be studied by all who are interested in this subject.

Mr. Cross has kindly made the following report for me:—

Monocotyledonous Fibre.—In this are included all the lower grades of textile fibre, used for ropes and coarser twines, obtained from plants of the aloe and plantain orders. Not only is the climate of the West Indies especially adapted to the production of these in full luxuriance, but many of them grow under conditions the least favourable to other forms of vegetation—*i.e.*, on barren or rocky soils. Such considerations, or a collateral purpose of cultivation, for fruit or seed, as in the case of the banana, may determine an advantageous cultivation, by outweighing the disadvantages of low yield of fibre and difficulty of isolation. Taking this latter case, by reason of its importance, first: what prospect is there of working up the refuse banana stalks into a paper material, to sell in European markets at a remunerative price? Mr. Morris has dealt with the question of preliminary treatment of the stems in his paper read before the Institute of Jamaica, February 1884, and I can, from my point of view, fully endorse what he says. But in my opinion, the treatment he recommends, though perfectly good as far as it goes, must be supplemented; the material must be so prepared as to yield to the paper maker here not 30 per cent., but 50 to 60 per cent, and to sell at about £8 a ton. So to concentrate the substance, a process of boiling is necessary, with the addition of a cheap base, such as lime or even chalk to neutralise the acids of the plant, and allow of boiling in iron vessels. Having thus got rid of soluble matters, the material must be crushed or stamped, and washed, to remove cellular matter, and lastly, dried and presspacked. The chief point to consider is the probable yield of such a product. Mr. C. M. King, who has been associated with me in this Exhibition work, during his residence in Jamaica, investigated the yield obtained by treatment with the Ekman process, which he found 1½ per cent. on the green stems. Such a product was, of course, much more highly "cleaned" than the one we have been considering. Estimating for the difference, the yield of paper-making material on the above treatment may be taken at, say, 2 per cent. On 100 tons of green stems, therefore, £16 represents the trading basis, *i.e.*, the sum out of which all charges and the profits are to be met. There is as far as I can see, nothing further to be said on this vexed question: it should be solved by a definitive trial, and it should be borne in mind that such an enterprise, established on the basis of a satisfactory issue of the trial, could only be successfully carried on by a co-operative union of those interested. Coming now the higher group, *i.e.*, the textile fibres obtainable from Monocotyledons, the most expedient course would be to select two fibres, one coarse and one fine—say, for instance *Fourcroya gignated* and *Acrocomia* (the *Gru-gru* fibre exhibited in the St. Vincent Court). These fibres have proved themselves, on the results of investigation of the prepared specimens, to be the most valuable. All that is wanted for a commercial estimate is the cost of preparation in a satisfactory condition. This will very much depend upon the yield on the green substance, and the process adopted for obtaining the fibre; upon the selection of a machine for the purpose I am not prepared to advise. I should recommend a preliminary steeping of the green substance, and with the addition of an anti-ferment, such as sulphite of soda, or preferably, sulphite of lime, in virtue of its relative cheapness. I base this recommendation upon the recognised advantages of the steep, together with the common experience of the dangers attending a fermentation which is difficult to control.

Dicotyledonous Fibres.—Of these we may also distinguish two grades, the lower available for paper-making, the higher for textiles. Of the former I selected for investigation from amongst those exhibited the sugar-bark fibre, *Malva viscus*, *Malva sylvestris* and *Daphnopsis*, all in the Jamaica Court. These give from 58 to 63 per cent. cellulose, and are easily treated. I should advise the preparation of further and larger specimens, so as to determine the cost of production on the one hand, and selling value on the other; for the latter a paper-making trial is necessary. Of the above three I should prefer to give the preference to the *Malva*, on account of the superior length of its ultimate fibre.

(*b*) *Textiles.*—Of the jute class, the *Mahoe* is worthy of special notice; I have given in my official report the results of the analysis of the specimens exhibited. I am of opinion that this fibre is capable of con-

siderable improvement in quality upon that exhibited. It would be well to look into this matter from the botanical point of view. By modifying the conditions of growth, introducing such artificial restrictions as are known to contribute to the development and improvement of fibre, doubtless a much superier product can be obtained. Secondly, I would call attention to plants of the species *Sida*, mentioned in Mr. Morris's report above mentioned. In the Indian and Queensland Sections there are excellent specimens exhibited of the best fibre of this plant. It is of the jute class, but in all respects superior. The probable future of this fibre is fully discussed in my official report. Without going over this discussion again, I may call attention to the general conclusion that it is a fibre destined to displace jute in many of its applications. The separation of the fibre is a simple process, requiring only a preliminary retting treatment; and although no specimens were exhibited in the West Indian Section, I think it, nevertheless, a matter of interest to the authorities as a probable item in future commerce in fibrous raw materials.

In the higher grade textiles, *Rhea*, or *Ramie*, is the only fibre which appears to adapt itself to the particular conditions, agricultural and otherwise, of West Indian planting. Upon this fibre there is nothing that I can say beyond expressing my opinion that the estimates which have been formed of its capabilities are, in many cases, inflated, and the line of treatment at present adopted for isolating the fibre (Fremy-Urbain process) is not altogether sound. The treatment I should recommend is to strip the stems, and boil the bark strips in a solution of sulphite of soda, then wash, to thoroughly free from all non-fibrous matter. This chemical is now prepared in a highly concentrated form by Messrs. Gaskell, Deacon, and Co., at so low a rate (£7 a ton) as to be well within the range of a number of applications, formerly prohibited by excessive cost. Its employment upon vegetable fibrous materials, in preference to all other alkaline reagents, for the purposes of purification, is justified, not only on theoretical grounds but by the results of processes now working on the large scale.

In conclusion, I would point out that there are now generally recognised methods of investigating fibres and fibrous materials which effectually solve all problems both of treatment and application, without recourse to the uncertain process of what is termed practical experience. At least, therefore, in the early stages of development, the co-operation of scientific investigation will be found the most effectual aid to progress. Should any of the Government chemists in the several islands require special information as to these methods, I shall be glad to afford whatever it is in my power to do.

COTTON.—Of this product the West Indies at one time supplied the largest quantity. The samples from the Bahamas ran most regularly, and were quite up to American growths of the same grades. Attention might be turned to it again. The bug, of course, is a great enemy, and labour is another difficult. The association, however, of cotton with slavery is now a thing of the past, and on the principle of not putting too many eggs in one basket, this useful product should be more grown.

RED OR NANKEEN COTTON.—Great attention has been given to this, and large quantities could be sold at from 5½d. to 6d. per lb., and if, as has been stated, the bug does not attack this kind of cotton, it ought to well repay the growers. Not only would there be a great demand for hosiery, but also for clothing for the troops in India. Some of the samples sent have been worked up into cloth, and have been submitted to the India-office and War-office for use as Kharki clothing for the troops. The report is favourable, and the colour stands well. The hosiery is excellent, soft, warm, and a nice natural colour. Large tracts should be at once planted out, and, as uniformity of colour is of very great importance, care should be taken to avoid mixture and any other treatment that would be likely to cause a variation of colour.

MEDICINAL PLANTS

I may mention medicinal plants, but it would be obviously impossible to review the enormous mass of exhibits under this head in a paper like this. They are amply detailed in my report on products. Dr. B H. Paul's report to the Royal Commission is well worth perusal. Of cinchona from Jamaica he says:—Some very fine samples of cultivated cinchona bark were also shown in the Jamaica Court. The growth of cinchona in the island was introduced experimentally by Government in 1866, and upwards of 150 acres are now under cultivation. Some of the bark grown in Jamaica is of very good quality.

The samples of Jamaica-grown cinchona bark received from the Jamaica Court give the following results, on analysis by Dr. B. H. Paul:—

	Officinalis quill. per cent.	Hybrid quill. per cent.	Succirubra renewed. per cent.
Quinine	3·86	8·17	2·97
Quinidine	Trace	Trace	0·51
Cinchonidine	0·67	1·95	1·50
Cinchonine	0·05	0·47	2·30
Amorphous alkaloid ...	0·26	0·85	1·06
Total alkaloid ...	4·84	6·44	8·34

KOLA-NUT.

The nut of the *Cola acuminata* (also called *Sterculia acuminata*, Gourou Ombéné, Nangoué, Kokkorokou, Female Kola, Bissy-Bissy, and Coorooah), is destined to play an important part, both in commerce and medicine. In an exhaustive paper by Professors Heckel and Schlagdenhauffen, the eminent French chemists, kola is ranked equal to tea, coffee, matè and cocoa. They found the nut to contain over 2 per cent. of caffeine, as much, and, in good parcels, rather more than is contained in coffee, besides about 36 per cent. of sugar and starch, and other imporant constituents which determine the use of the nut as a food and medicine.

The properties claimed for the nut are: for checking dysentery and diarrhœa, more especially when contracted in the tropics, many cases of Cochin-China diarrhœa having been entirely cured; for restoring impaired digestion; for nervous debility arising from the group of symptoms known professionally as neurasthenia, which consists of chronic excruciating headaches, loss of appetite, costiveness, exhaustion, &c.; for restoring the system when under influence of alcohol, and to prevent a return to the habit of drinking. The latter property is claimed for it in "New Commercial Plants and Drugs," where it is related that a Jamaica planter treated the negroes with the fresh nut when in a state of drunkenness; the good effect is probably due to the caffeine in the nut combined with the tonic action of the other constituents upon the nervous system; the statement that after the use of the kola nut the patient does not return to drink is, no doubt, explained by its stimulating property inducing so healthy an action upon the system that the want or craving for spirit is not felt.

The nut is ground and mixed with coffee, much to the gain of the latter in so far as stimulating effects are concerned, and for this purpose the price at which the nuts are obtainable make a very advantageous pecuniary difference to the dealer. When the nut contains over 2 per cent. of caffeine, and can be had at 5d. or 6d. per lb. it pays to extract caffeine from them instead of from coffee. They form, also, the basis of a patented aërated drink and beer. Ground and made into a paste, the Kola nut is now coming to the front as a beverage. The nut has the singular property of clarifying beer and spirits, and rendering the foulest water healthful; this action is due to the gum it contains. The tree, which stands from thirty to sixty feet high, resembling in general aspect the chestnut, frequents the moist hot woods of Western Africa, and has been successfully introduced into the East and West Indies, Seychelles, Ceylon, Mauritius, Zanzibar, Guadaloupe, Cayenne, Cochin China, and the Gaboon. It likes low, moist lands, at the level of the sea, or a little above, but it does not do well above 800 to 900 feet. It yields its first crop at the age of five years, and is in full bearing at ten years; a single tree then yields an average of 120 lbs. of seed annually, the flowering being continuous after maturity. There are two crops—in October or November, and in May

or June. The seeds are gathered when the dehiscence of the capsule takes place. They should be carefully freed from the husk and episperm (all damaged and worm-eaten ones being removed), and if it is desired to ship them in a fresh state, it should be done in baskets lined with some large thick leaves, Fresh nuts are generally sold at the rate of 40s. to 50s. per cwt., but the market for fresh seed is very limited.

To dry the seed, so as to lose as little weight and properties as possible, they should be placed in layers on trays in the shade, where there is plenty of air, and left till perfectly brown and dry. So treated, they will have a fine appearance, being neither blackened or shrivelled, which is the case when allowed to dry in the sun, when they lose much in weight by a too rapid exhaustion of the moisture.

For many purposes, slow drying is not absolutely necessary, for instance, in cases where the nuts are consumed in a powdered state; but every care must be taken to prevent their becoming mouldy or worm-eaten; a parcel of nuts with the faintest odour of mustiness would be discarded by manufacturers. The prices vary a good deal according to supplies and quality. A nut with a good appearance may fetch as much as 70s. to 90s. per cwt., whereas small shrivelled-up nuts have sold for 20s. to 35s.

This tree is certainly worthy of a more extensive cultivation, and would yield a handsome return to those having low-lying lands unfit for other products. The demand would greatly increase if manufacturers were assured of a continuous supply, enabling them to introduce permanent articles, which they are now precluded from doing for want of reliance upon the present shippers. A very useful little pamphlet on the medicinal and other drugs has been published by Mr. E. M. Holmes, curator of the museum of the pharmaceutical Society.

STARCHES.

Many of these on examination have proved suitable for sizing and finishing of textile fabrics.

FRUIT.

I need not discuss. West Indians are alive to its importance. The rapidly increasing population of the American continent will absorb as much as can be grown. The difficulty is safe transportation. Growers of pines, bananas, and oranges, should avoid being shippers.

The orange tree disease in the Bahamas has almost ruined that branch of trade. It is to be hoped that it will not extend to Jamaica.

KUS-KUS.

The Kus-Kus grass, which is abundant in the West Indies, is barely utilised at all; whereas in India it is a well-known article of commerce, and advantageously employed in the manufacture of fans, window blinds, and screens. Being delicately scented, when damp, it produces a cool and refreshing odour. We had fine samples in the Exhibition, but none manufactured.

DAGGER OR YUCCA PLANT.

The various articles exhibited made from this plant attracted very great attention, and elicited many inquiries from dealers as well as visitors.

While the fancy manufactured articles must not be neglected, a good deal of the ribbon of a more rigid character might be sent to England. This would enable manufacturers and purchasers not only to make independent experiments with the substance, but to work it up into various articles in accordance with the prevailing taste and fashion.

It is well worth attention, but the slow growth of the plant is rather against large exports. It grows in poor land.

PALMETTO PLAITS.

We made many inquiries with respect to these. There is, no doubt, a market for them; if a factory could be established, and a sufficient quantity sent on to create a demand for them, very large quantities, indeed, could be sold. The Jamaica and Bahama exhibits were excellent. The sale is only a question of price.

DISCUSSION.

Mr. MORRIS did not quite know what the reader of the paper meant by saying that coffee should be sent home in the parchment. Coffee was never exported in this state, and, if it were, he believed it would not find a market. With regard to kola nuts, his opinion was that there was no real commercial demand for them in this country at present. The only people who consumed these nuts to any extent were those on the West Coast of Africa. He had heard that a kind of chocolate or cocoa had been prepared from kola nuts, but he believed this was only an experiment. He considered that if the nuts were grown in the West Indies it would be at a loss, owing to there being no market for them. The reader of the paper stated that each pod contained fifteen seeds, but if so, this must be a new variety, for he had never seen one containing more than three to six seeds, which of course are different from the "nuts" composed of the divided cotyledons. Of these there might be and number up to thirty.

Mr. LASCELLES-SCOTT said with regard to the sugar industry, he had good reason for believing that a remedy, other than by fiscal arrangements, was not far distant, for Professor Robert Galloway, of Dublin, had lately devised a process whereby the enormous waste which at present occurred in the extraction of crystallised sugar from juice would be considerably reduced. With regard to kola nuts, he believed that when their composition was known that there would be a great demand for them. A friend of his had just received an order for twenty tons of these nuts, and a further supply had been asked for them. The manufacture of kola paste and chocolate was continually increasing, and it had been favourably reported upon by the engineers who were laying some railway lines in the Soudan. In the catalogue of the Colonial Exhibition reference was made to the plant *Siegesbeckia Orientalis*, and this plant he found had obtained a large reputation in the Mauritius, so much so that he believed in the future it would be found to be of great value in *materia medica*. In the Mauritius the plant was known as the divine herb, and in this country it had been tried by one or two medical gentlemen, who had reported most favourably upon it. Dealing with the subject of fibres, he produced a specimen which he said belonged to the silk or cotton orders, and as the fibre had a peculiar absorbing quality, he thought it was particularly well adapted for the manufacture of surgical dressings. He strongly recommended the cultivation of this plant, believing that in the future it would find a ready market.

SIR AUGUSTUS ADDERLEY said he concurred to some extent in the opening remarks of Sir Rawson Rawson, that as the sugar industry was not prospering they should look to other products for improving the condition of the West Indian Colonies. As to the competition to develop in the future, from Queensland and India, in growing sugar cane, West Indian planters only wanted fair play; they were quite ready to fight the world, and give in if they could not make sugar as cheap. The sugar bounties should be abolished for their unfairness, and as adverse to the principles of free trade. Planters should watch the markets in order to see what was wanted, and not go on planting products which were evidently being over-produced. As to there being no market for kola nuts, he might say that he had lately sent out a large order to Trinidad, but had not been able to get the order filled. His remarks as to the parchment on coffee were based on the suggestions of M. Pasteur, and a considerable quantity was now denuded of the parchment in London. With regard to not having touched on products of British Honduras, he felt that it was impossible in a paper dealing with the West Indies to properly deal with this colony, considering that it would require a paper to itself. British Honduras merely required capital and cheap labour in order to develop its resources. As to the silk cotton referred to by Mr. Lascelles Scott, he believed it was being taken up in Germany for bedding, though he thought the fibre was not sufficiently long for the manufacture of surgical bandages. There was some similar cotton in the Exhibition which came from Jamaica, which had a very long fibre, and this, he believed, might be worked up for surgical bandages.

The following letter and enclosure have been received from Mr. D. Morris, assistant director, Kew-gardens, since the meeting:—

24th May, 1887.

DEAR SIR,—In the discussion which followed the reading of Sir Augustus Adderley's paper on the "West Indies at the Colonial and Indian Exhibition," the question was raised whether there is at present such a demand for kola nuts as to justify its being recommended to be grown by small growers in the West Indies. I made a statement on the subject which was contradicted by Mr. Lascelles Scott. In order to obtain an authoritative statement on the subject, Messrs. Burgoyne, Burbidge, Cyriax, and Farries—possibly the largest wholesale druggists and manufacturers of pharmaceutical preparations—were asked the present price of kola, and whether there was any demand for it. Their reply I enclose herewith.

16, Coleman-street, London, E.C., May 21st, 1887.

DEAR SIR,—Replying to your esteemed favour of 18th inst., in *re* kola nuts, we beg to say that there is but little demand here for these nuts. Occasionally small parcels are disposed of at from 3d. to 4d. per lb., but if a large parcel were put on the market we doubt if they would find a ready sale, and possibly would not fetch more than 2d. per lb.—We remain, dear Sir, yours faithfully, BURGOYNE, BURBIDGES, CYRIAX, AND FARRIES, *per* H ARNOLD.—*Journal of the Society of Arts.*

CAPE DRUGS.

Very little indeed is known of the medicinal agents employed by the natives of South Africa. The bulb of the *jeukbol* (*Drimia ciliaris*), much resembling the officinal squill, is used as an emetic, expectorant, and diuretic; its juice is highly irritating in contact with the skin, hence the local name, meaning "itch-bulb." A curious animal product, termed *hyraceum* by pharmacists, is said to be employed with the same effect as *castoreum*.

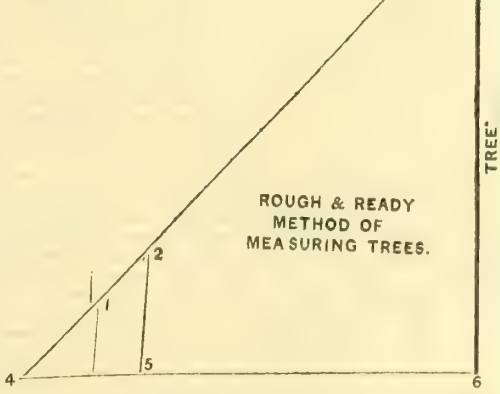
The prominent native narcotic is tobacco, which is extensively planted. The manner of preparing it, however, must in a great measure destroy its flavour; it is mashed together in a hollow piece of wood, by means of a heavy pole, into little round balls of the size of an orange, which, when dry, are broken into smaller pieces. The leaves of a composite plant, *Parchonanthus camphoratus*, when dried, are smoked by the Hottentots and Bushmen instead of tobacco exhibiting slight narcotic effects; in the form of infusion they promote perspiration, and are said to be useful in spasmodic asthama. The beautiful-flowered labiate plant, *Leonotus leonurus*, is abundant at the Cape, and is also smoked by the Hottentots instead of tobacco, with similar narcotic symptoms to the preceding. Near Delagoa Bay the natives have a curious custom of drawing snuff up their nostrils through a long, hollow bone from a bird's wing.

The stem of a shrub, *Derris uliginosa*, is beaten and placed in still waters as a fish poison in Zambesiland. The fruit of *Randia kraussii* is similarly employed.—*Journal of the Society of Arts.*

CULTIVATION OF RAMIE IN SPAIN.

Consul Wooldridge, of Barcelona, says that agriculturists in the Gerona district have lately been turning their attention seriously to the cultivation of the ramie plant. For some years past, in consequence of the ravages of the phylloxera and other vine pests, and of the increasing importation of cereals from America and elsewhere, the cultivation of the vine and of cereals has ceased to be as profitable as formerly in Gerona. It having been found that the climate and soil are in every way suited to the cultivation of ramie, and that the few trials that have been made have resulted in success, a factory for decortication has lately been erected, its inauguration having been attended by the notables of Catalonia. It is said that the ramie plant is destined to replace not only the hemp and flax which is imported from France for the manufacture of textiles in Barcelona, but even that of cotton. The plant at present grown belongs to the family of the *Urticaceas*, and grows to a height of from sixty to ninety inches. It is essentially a textile plant and two cuttings may be made in one year, and cultivated under good conditions, a hectare would grow from 3,000 to 10,000 kilogrammes of stalks. At present there are few reaping machines, but as labour is cheap, the weeding and pulling of the crop is effected without much expense. The plantations at Torroella de Montgri, the district of Gerona in question have an extent of 130 hectares, but there is land disposable for the culture extending over 3,000 hectares. The price of ramie in Spain is about 8s. per 100 kilogrammes. There are three decorticating machines at work, moved by a steam-engine of 15 horse-power. Each machine decorticates 215 kilogrammes of stem in twelve hours, from which are obtained 43 kilogrammers of thread, requiring but two workmen to manage each machine—one to introduce the stalks the other to receive the fibre—and the expense is about 10s. 5d. per 150 kilogrammes of thread per day.—*Journal of the Society of Arts.*

MEASURING TREES.—There is a great amount of ingenuity exercised to invent instruments that will readily measure the heights of trees or other objects of similar character. But the traveller need take nothing along with him but a tape line and a jack-knife. First cut a stick thick enough to drive in the earth. Let it be four or five feet long, and drive it into the earth at any spot convenient, only being careful to have it on a part of the ground evidently level to the base of the tree. This will be the stick at 2. Drive another of about the same or any length at any indifinite distance from 2. This will be 1. Then with the eye and a temporary guide find on 1 exact spot on its surface that will be in exact line with 2, and the top of the tree at 3. We have then a straight line from 3 to 2 and 1. Then, by the eye at 2, striking the spot at 1, we find where the line will strike the earth at 4. We have then a right angle triangle 2, 4, 5. Now



we call into our aid the well-known geometrical theorem that the proportions of right angle triangles are always the same. With our tape line we find the base line 4 to 5, say 10 feet, and the perpendicular 5 feet. Then we measure on the ground from 4 to 6 and find it, say 100 feet. The whole question then resolves itself into one which the well-known arithmetical rule of proportion readily solves: If a base line of 10 feet gives a perpendicular of 5 feet, a base line of 100 gives a perpendicular of 50 feet which is the height of the tree. This may not come within an inch or two of absolute accuracy as a regular instrument would, but it serves all practical purposes.—*Gardeners' Monthly.*

From Editorial Notes in the *Gardeners' Monthly*, an American periodical, we quote as follows:—

CEDRELA SINENSIS.—This tree, as rapid growing and with foliage and habit much like an Ailanthus, stands our climate as well, and will probably become popular.

PINUS EXCELSA.—The Bhotan Pine seems as hardly as the common white Pine, and is very beautiful. There are a number of mature trees in the vicinity. They are still regarded as among rare trees in nurseries.

SWAMP TREES IN DRY GROUND.—The Sweet Gum, Red Maple, Deciduous Cypress and other trees usually found in swamps, grow better on dry garden ground than in their native localities, but do not produce perfect seed as readily.

HAWTHORN TREES.—Wherever the different species of Cratægus will thrive, there are few things more beautiful. One of the grandest sights to our mind, on the grounds of Ellwanger & Barry at Rochester, is a fine tree of the scarlet fruited Hawthorn. It bears fruits as large as cherries, which are very good to eat.—[Has the Hawthorn ever succeeded in Ceylon?—ED.]

HOW FORESTS FOLLOW RAINFALL.—A contemporary says:—"It is significantly said of the great Texas drought, which extends across that State for several hundred miles, that it decreases in severity as it approaches the pineries. That is a point for "Arbor Day." Which is, that people should not plant trees for profit where dry climates exist. The pineries only establish themselves where there is a fair annual rainfall with some certainty.

FRUIT OR VEGETABLE.—A New York correspondent says:—"Will you kindly inform me whether a tomato is classed as a fruit or a vegetable?" The horticultural answer is, that it is a vegetable. If the question were put to a botanist he would answer that it was a fruit. He would say the same of a pine cone with its seeds, or of a spike with its hay seed. On the other hand he would say that a pear was a vegetable, if the question were one that bore on the distinction between plants and animals. We see that the answer depends on the view of the questioner. In the household, a fruit which is generally eaten cooked would be a vegetable; that which is generally eaten uncooked would be fruit. We use the word "generally," because the lines sometimes overlap. A squash and a water-melon are both fruits botanically, but the squash is classed conventionally as a vegetable, and the water-melon as a fruit! the cooking idea, evidently deciding the case. Much depends on the class in which the subject under discussion was originally introduced under. The tomato was first introduced to gastronomy by the cook; in subsequent years it has been found good to eat raw. But the law of priority gives the class to the cook; it is a vegetable. It is the general or original uses of the article that decide its class when we come to arbitrary classification, outside of science.

A CALIFORNIAN FLORAL FETE.—California must indeed be a land of flowers, judging by the festival that, extending over two weeks, has excited the famous old town of Los Angeles. Hundreds of contributors of cut flowers, poured them in from all parts of the country. Designs, as they are called, of cut flowers, furnished fresh novelities every day. The "unveiling of a floral ship" was the great work of the first day. The sum, of $969.60, taken in that day, shows how popular the floral ship must have been, though the prayer of Reverend Joseph Pendleton, or the address of his Honor the Mayor, may have divided the attractions of the day with the ship. On the second day, a great attraction was the American flag—the red being of Zonale Pelargoniums, the white of Pyrethrum, and the blue of Heliotrope. A grand cross which had been used the day before in Episcopal services, was exhibited. The golden colors, made of yellow Marigolds. A huge shield made of Marigolds, Roses, Geraniums and stock Gillies, was sent by Mrs. Crocker as a contribution from the Citrus Valley. A huge fan, the rays fifteen feet long, was a "design" highly applauded. A huge snow-shoe, made of White Pyrethrum and Geraniums, divided the applause with it, bringing cooling memories into a warm day. The floral ship was 13 feet long, and bore a cargo of oranges. The grand design, however, was the famous shoe of Mother Goose, in which her huge family of children where all represented—as large as life. Geraniums made the shoe, except Marigolds were at the heel, and a binding of Smilax fringed the orifice. Cut flowers were sold, ice cream, lemonade and everything useful in such a gathering, everything having a booth to itself, and the materials sold with the attendants being almost smothered in flowers. These attendants—young ladies—are described as being truly lovely, though when a reporter suggested this to one of the young ladies, she replied to him "now don't be soft." She was after his cash just then instead of his compliments. It was an example of misplaced confidence at that time. Roses seem to be the favourite flower as well as elsewhere. A branch of the Washington Noisette, had 13 flowers full blown and 57 unexpanded buds. Mrs. Heaver exhibited 100 named varieties in cut flowers. Mrs. Fox sent a flower of Pau Neyron that measured 18 inches round. The "shoe design" was 6 feet long and 3 feet high. The public school children sent a huge painter's easel, with geometrical ferns arranged in flowers. The triangle was made of Lilies. The Public School Booth however gave diversions for the designs, in literary exercises in the form of criticisms on poetry. The illustrations were however given in floral designs. Some connected with the Merchant of Venice were quite taking. The door money taken in during the first four days was $3053.80. The proceeds all go to charitable purposes.

WHAT ONE WOMAN DID.—A Massachussets woman, having an hour or two each day to spare from housework, decided to try raising Strawberries for market on a piece of land about 57 feet square. The plants were well taken care of through the season, and the last of October the bed received a final hoeing, and a little later the plants were mulched about 2 inches deep with Pine needles. Before the picking season commenced, she bargained with a market-man, a mile and a half distant, to take all her berries, by allowing him, as his share, four cents a basket for all berries sold for 20 cents and over, and three cents for those bringing less. In picking she was careful to put in only sound fruit, to have as large berries at the bottom of the basket as on top, and to have them heaped as high as the crate would allow. It being a poor year for Strawberries, owing to drought, which did not affect her low ground, she received good prices. None were sold for less than 15 cents a basket. The entire crop sold was 350 baskets, for which she received 52·80 dols. Expenses were 21·55 dols., leaving a nett profit of 31·25 dols.—*American Agriculturist.*

TEA IN ENGLAND 40 YEARS AGO.—A planting friend has copied the following and sent it to us to publish:—

THE TEA TRADE.—The hedges about London seem to be in a very healthy state. We have heard it stated by a gentleman whose news is relied upon by all persons in the trade that there will be a capital crop of Souchong in the fields off Primrose Hill. We have tasted a leaf or two near Greenwich, and can safely predict the English market will be unusually glutted this year with a quantity of full flavoured Bohea. The Hyson is partly spoilt by the caterpillars, and the blight has taken the bloom off the Twankay, in the plantations about Enfield, though it is expected they will be passed off in the provincial towns as good for mixing when seasoned with a little Gunpowder that is now being grown in pots at the large market-gardener's at Woolwich. There will be a good supply of green tea at 4s. a lb. if the sloe-bushes at Bayswater only keep their present appearance. There is no truth whatever in the report that the interior of Leicester Square is to be cultivated for this article of commerce by a Hongkong merchant. There is no necessity for it as long as there are so many fields yet unexplored in the vicinity of the metropolis, besides, the nettles that abound there have been found to be unfavourable to the growth of the celestial plant.—*Punch*, July-Dec., 1845.

CINCHONA BARK.

We should like to know from Messrs. Arbuthnot, Latham & Co. to what "figures" they refer, when in a circular letter intended for wide publicity they make so unqualified a statement as "the figures given by the *Ceylon Observer* were "found on investigation to be absolutely unreliable." We have been most cautious year after year not to give in to the general anticipation that the Ceylon exports of cinchona barks were to drop suddenly by 40 to 50 per cent. We have uniformly warned our home readers that it was absolutely impossible to give a reliable estimate beforehand—early in October last we said, the shipments for 1886-7 might be anything between 11 and 14 million lb., and finally in that month we adopted 12 million lb. as a working hypothesis, going higher in doing so than most other estimators. Already we are up to 11¾ millions, and with 2½ months of the season yet to pass, it is probable the 14 millions of exports may be made up.

The following letter has been circulated by Messrs. Stanes & Co. of Coimbatore.

London, 27th May, 1887.

Dear Sirs,—As you have a good deal of cinchona growing in the Neilgherry and Wynaad district, and you may be asked as to its future prospects the following information may be interesting to you.

The moderate supplies brought forward at auction this week met with a steady competition. The quantity offered was less than at any previous sale this year, but proved quite sufficient for the demand and prices remained unchanged.

It is very difficult to forecast the future, for it appears to depend mainly on the supplies from Ceylon and what these are likely to be, it is almost impossible to ascertain, the figures given in the Ceylon *Observer* and the estimates sent by Ceylon Firms being found on investigation to be absolutely unreliable. The general opinion seems to be that supplies from Ceylon will not fall off materially for the next 2 or 3 years. Up to the end of April this year shipments have only been the same as in the first 4 months of last year, but the low price ruling on this side has probably tended to check shipments, and although our stock of bark is not large, the stocks of quinine stored on the continent and in the United States are very large indeed, and the market for quinine is very weak. The imports of quinine into America for the first 4 months of the year are 850,000 oz. against 400,000 last year, and they have also bought bark very freely.

India and Java will no doubt send more bark during the next 2 years than hitherto, and the Java bark is said to be exceedingly rich; but we do not anticipate that the imports will be so excessive as to overwhelm us, especially if shipments from Ceylon should fall off.

We send you some interesting figures, shewing first, the proportion of root bark out of the total shipments, which has some indication of what has been cut down, but we look upon the estimate given in Messrs. Ferguson's Directory as to the quantity of trees cut down, and rooted up to make way for tea as untrustworthy. You will notice also that the Board of Trade returns are totally at variance with figures given in Smith's list.

On the whole we should recommend your shipping any bark suitable for Druggists, say shew bark and quills, as quickly as possible while the demand lasts for this class of bark; but for ordinary manufacturing bark we think prices will certainly be as high, if not higher, next year than they are now, and when a big war does take place, (and we certainly believe it will come within the next year or two) the demand for quinine will be very large indeed.—We are, Dear Sir,

Arbuthnot, Latham & Co.

The estimate 1,500 trees to the acre.

This would work out as follows:—16,000 acres + ,500 trees = 24,000,000 trees. If each tree gave only 1 lb. bark it would be equivalent to half entire shipments of bark from Ceylon from 1883 to date.

TEA IN TRAVANCORE.

A short time ago we had the pleasure to place on record the shipment of the first break of Ashambo tea. We have now equal pleasure in recording the following in reference to the same shipment which we extract from the Mincing Lane jottings of our contemporary, the *Indian Tea Gazette*. "A small shipment of unassorted Travancore tea from Seafield Estate offered this week showed most excellent quality and strength and realized the full price of 1s 7d per lb. The teas from this district will undoubtedly become popular if due regard is paid to manufacture. They possess a flavour very similar to that of Ceylon tea which is often combined with the strength of Assams." We have no doubt that this account will be most gratifying and encouraging to all who are interested in the development and success of useful industry in our country; and we most cordially congratulate Mr. James Fraser, Proprietor of the Seafield Estate, on the excellent testimony which his tea has obtained in the London market. To him belongs the sole credit of having introduced this industry on our hills since the failure of the coffee enterprise and practically proving to our countrymen the truth that patient toil which is undaunted by difficulties is rewarded with success. Travancore owes a debt of gratitude to the presence within its limits of such noble-minded gentlemen and hence our Government ought to try to encourage their residence here in every reasonable way. But for some reason or other, the contrary is the case. The fall of the revenue from the coffee districts seems to have been the signal for the partial or total abandonment of the Hill roads, which, we hear, are now so far neglected as to be overgrown with jungle to the serious disadvantage and danger of the hill-faring population. But we trust greater patience will be exercised in this direction, and every help and encouragement held out of these European gentlemen, who are the true pioneers of the development of the material resources of our country. We respectfully call the attention of our excellent Dewan to the needs of the old coffee districts, and issue orders, that they may be fully supplied.—*Travancore Times*, July 1st.

DESCRIPTION BY LADY EGERTON OF A VISIT TO A CEYLON TEA PLANTATION.

The number (June 11th) of the *Field*, which contains a letter written by the Hon. Lady Grey Egerton, who recently visited this island, cannot fail to be interesting to Ceylon readers, tea planters especially and more particularly the first paragraph and two concluding ones. The estate visited was "Portswood" near Nuwara Eliya, as Ceylon readers would readily be able to trace, and what has surprized the owner and manager most is that Lady Egerton, who did not make a note on the estate so far as was seen, carried away such an accurate account of all she saw in tea-making, &c. The concluding remarks are pointed and deserving of particular note, and the opening paragraphs cannot be otherwise than gratifying to all in Ceylon who met the accomplished lady-writer. Sir Philip B. Grey Egerton with Lady Egerton, his brother Col. Egerton and his son and daughter travelled through India and visited Ceylon twice in the early part of the present year. The impressions formed of our little island are pleasantly given by Lady Egerton in the letter published in the *Field*, which we take over in full:—

The old story—a winter out of England, complete change, was all that was required to make me perfectly well and strong again. But the change must be not merely to the Riviera, or to any of the usual winter resorts, where I should most likely meet again the same friends I knew in England, and live again much the same life as before. But it must be a complete and entire change from anything I had seen or done previously. And that is how I found myself in Ceylon and am able to give this account of a visit to a tea plantation, and to write with a certain amount of authority upon tea, cinchona, coffee, and all the new and strange things in this "Enchanted Island"—certainly with its beautiful climate, tropical vegetation and pure atmosphere, the most radical change conceivable from poor old England.

Directly on landing at Colombo we were recommended to go up to Nuwara Eliya, to refresh ourselves after the heat we had undergone in our Indian wanderings. This must be pronounced Newralia, and having once written it with its full number of letters, I shall for the future give its abbreviation. It is the hill station of Ceylon, far away up among the highest mountains of the island, 6,200ft. above the sea. Here we found fresh air indeed; sometimes perhaps almost too much. But it was delightful to us after the heat of the low country, as while the sun was hot and bright in the middle of the day, the nights were cool, and occasionally quite frosty towards the morning. From the verandah of our little hotel, which rejoiced in the name of Criterion, you can sit and stare at the highest peak in Ceylon, Pidurutalgala, to ascend which a matter of 2,000ft before ten o'clock breakfast is what everyone staying at N. Eliya feels him or herself called upon to do before leaving the place.

Naturally by the time of our arrival at N. Eliya, we already knew a good deal about the important subject (to Ceylon) of tea, since everyone we had met at Colombo and elsewhere talked of nothing else, tea tea; its past, present, and future. So we gladly accepted an invitation from the owner of some large plantations near to have tiffin at his bungalow, visit his plantations of tea and cinchona, and be shown the whole process of preparing the leaves of the former for use.

Carriages for hire in N. Eliya are very scarce, and as the French say, "leave much to be desired;" so we felt ourselves lucky in securing for the drive a fairly good sample of one of the back-to-back carriages, with roof to keep off the sun, very generally used in Ceylon; it was provided with two wretched looking horses—a big one and a little one—but I must allow they went very well, although it was the last thing that could have been expected from them. Two bare-legged natives came with the carriage, one to drive and the other to run along and shout, if necessary, at the passing bullock carts, and at other times to perch himself on the step or anywhere else at our feet. Both men were entirely ignorant of English, so that conversation with them was impossible, for I need hardly add that we were equally ignorant of Sinhalese or Tamil, one or both of which languages they presumably spoke. It was a lovely drive; the road wound round the steep sides of the hills, following the course of the ravines, with dense jungle on both sides. Every now and then came a tea or cinchona plantation and then sometimes a fresh clearance preparing for plantations, with the paths already made, and deep trenches dug for draining off the heavy rains, while the stems of the old jungle trees were left still standing in the ground, three or four feet high with their felled trunks bare of boughs, lying at full length beside them. These clearances looked desolate in the extreme, but still they held a promise of better things to come.

After a drive of about six miles we turned off the main road to our friend's bungalow, a large low one-storied building, with verandah running round it, covered with creepers, and a garden in front full of roses, geraniums, and mignonette, and passion flowers hanging from the trees round. Being so high up, European flowers do well; and, after seeing so much tropical vegetation, it was delightful to meet old friends again.

Our host, Mr. G., met us on the steps, and the son of the house, with his hair, beard, and eyebrows much singed. There had been a great burning of

coarse grass that morning when, the wind suddenly undertook to change and the fire to burn in the direction of the bungalow, making it most necessary it should be put out. He had rather suffered from his exertions, and considered the coolies had not backed him up well or shown much eagerness to face the fire. One man against a biggish fire must feel rather overmatched; still, as I thought of the coolies with their bare feet and legs, and with no clothes to speak of, I felt as if I could quite understand their hesitation.

We at once started to see the plantations. The tea is planted in rows up the sides of the hills, the plants being quite small, kept pruned back to about 3 ft. high. They look rather like young orange trees, and are, on the whole very hardy; though the frost sometimes nips the young shoots, they quickly recover. They stand the changes of climate much better than coffee, having a long tap root, while the roots of the coffee plant are nearer the surface. Bands of women were busy picking off the leaves.

Many planters (our host among the number) consider women to be better pickers than men; they pick more delicately and carefully, and without injuring the shoot for the next picking. The three different kinds of tea—flowery orange Pekoe, Pekoe and Souchong—all grow at the end of the same shoot, orange Pekoe being the bud at the end, which is as yet scarcely a leaf, Pekoe the next, and Souchong the third; these the women nip neatly off at one pinch of the finger and thumb. Flowery orange Pekoe is the best and highest priced tea; it is bought up for the Russian market. Pekoe fetches the next price, and then Souchong. The best teas only were made at the plantation, or, indeed, anywhere in Ceylon. Coarser leaves are thrown away, or sold as Congu.

For leaf-picking good workwomen get about 7d a day. Our host was very proud of his pickers, and pointed out how clean and tidy they were. As to cleanliness, being all of a deep brown colour, they would perhaps, scarcely show dirt; but the effect of their bare dark limbs against their rose-coloured kombhoys was most picturesque. It was always a constant marvel to me how the women, not only in Ceylon but all over India, managed to keep themselves so tidily coveredup with these kombhoys—merely very long bright-coloured cloths—wound round them, first as a skirt, and then down across the body in front and thrown over one shoulder. It certainly seems to give them occupation, as at spare moments they are always arranging themselves; but that appears to be only because it amuses them, and not because the thing really requires it.

From tea we went on to cinchona plantations. There trees grow to the height of young saplings, and have a large and handsome leaf. It is, of course, the bark of this plant that is valuable. Strange to say, they cannot prepare quinine in the island, but when the bark is dried it is sent in bulk to England to be eventually returned to the East as quinine. The cinchona plantations round N. Eliya have suffered much this year: there was a harder frost in March than has been known for some years, which killed many cinchona trees in exposed places or damp ground. Our host had prepared himself for such an emergency by planting tea between the rows of cinchona. As long as the cinchona trees were there, the tea plants remained small, being overshadowed; but they will quickly now make good plants being by this time well rooted. It is difficult to realise how fast everything grows in this country. The cinchona renews its bark and can be re-peeled every eight months. Great care has naturally to be taken to peel only the very outer bark, and not to injure the inner ones, or the tree would die, killing the golden goose with a vengeance. The instant a man has removed the bark, a woman wraps that part of the stem up with grass. She does this at the rate of eight trees for three quarters of a penny, the cutting and bringing the grass being included; so that labour is not dear in Ceylon. A man earns about 8d to 9d per diem on the plantations. But their wants are so small in this climate—a little rice and a few bananas; let them be sure of that and they are quite happy spending anything that is to the good in adorning themselves with massive silver jewellery.

The English market has been overstocked with cinchona bark lately and prices have gone down immensely. Our host said he had thousands of pounds of it in England which he was holding back to sell when prices ruled higher. All these plantations are given such a desolate, untidy look by the charred stems of the old jungle trees being left standing, and their trunks lying about in all directions, that I ventured to ask my host why he did not have it all cleared away and the place made tidy; but it appeared that the roots kept the earth from being washed away, and the decaying logs acted as manure, Doubtless he was right, as the same thing is done all over the country, but from an æsthetic point of view it looks dreary and untidy in the extreme.

The walk was delightful; a great deal of the jungle on this estate is not cleared away, so the path wound along the hillside, now through a plantation, now skirting thick jungle. Here we saw the iron tree with its bright red foliage, and old rhododendrons, grown into regular forest trees; here were orchids innumerable, but, alas, not in flower, and tree ferns, and nilloo the favourite food, one is told, of the elephant—which no longer wanders at its own sweet will over the estate, as it did fifteen years ago, before the jungle had been interfered with, and when these plantations were not. Pleasanter for the proprietor and inhabitants of the place, still, I should have liked to have seen one of the huge beasts come crashing through, though very likely merely hearing it would have been enough to send us all flying. To make up for the want of elephants, we saw where a cheetah had been seen the night before, and where it was to be waited for on this coming night; and we were also shown the tree on which a couple of years ago another cheetah had been seen by the son of the house and a friend. The friend had been in such a hurry, that in pulling out his revolver it went off and shot him through the leg instead of the cheetah through the heart.

After tiffin we were taken to see the process of tea-making. Given the best quality of tea plants to work with—which I understood to be a hybrid between the Assam tea plant and an indigenous one—we learnt that any difference in the quality of the tea made was sometimes owing to carelessness or remissness in the making; therefore, if the price of your tea, as compared with that of other people's goes down, you have only yourself or your superintendent to blame. Great care, nicety, and attention are required; the exact amount of fermentation and of firing appear to be the critical points. We saw the green leaves brought in by the pickers and placed in layers to wither, which they do in about twenty-four to thirty hours. They are then put into the rolling machine, which twists and turns about, until it has rolled the leaves tightly up. I must be excused describing machinery, for I fear I should give no very clear idea of it if I attempted to do so. After rolling the tea is put into large flat baskets to ferment. This is a critical stage of the tea-making, as it should be neither over nor under fermented. As soon as it shows itself of the proper colour (poor leaf which was once green, and that only the day before yesterday!), it is put on trays and fired over charcoal. Again a delicate process, to judge when it is sufficiently fired. Now they begin to separate the three sizes by putting the tea through sieves. Orange pekoe, being the smallest, drops through, and the remainder is fired again; and once more put in a sieve, this time a coarser one, when the pekoe drops through, and so on. This ends the process, but before packing the tea is always given a final firing, and then at once, while still warm, put down in lead, to keep the aroma strong and fresh. As I saw the care taken to do this, I could not help thinking of the way that everywhere in England you see the tea left open and messed about, entirely regardless of the escape of this famous aroma. Everything at the factory was beautifully clean, machinery used wherever possible, and the worker's hands always being washed. The machinery and plant for tea-making is, of course, a very heavy outlay, as firing as well as rolling is now done by it. So from small plantations the leaf is sold in its green state to the large factories and prepared by them.

But, seeing all this had taken time, and we had a longish drive home before us, by a very pretty road certainly, but also by what we thought rather a dangerous one; so we were taken back to the bungalow, given an excellent cup of Ceylon tea, and started off home again. Soon the moon came out and flooded us with her white light—such a different moon to our English one, no longer with the accustomed man's face upon it, but with something quite different, rather like Britannia and her shield. The Great Bear was low in the sky, and standing on his tail. We looked for the Southern Cross, but it had not risen. Every now and then we had to pass a bullock waggon, when both our running syce and the driver shouted wildly, and poured out floods of strange language, with the result of the bullocks being leisurely, very leisurely, and apparently with great effort, pulled a hair's breadth to one side, by way of allowing us to pass. Then we saw the lights of the Criterion; and so ended my first visit to a tea plantation.

We returned with the conviction increased, which had been growing on us ever since we landed on the island, that Ceylon has a prosperous future before her. She has now apparently pulled through the terrible reverse of the coffee disease, which nearly ruined her. At that time the island was largely planted with coffee trees, and coffee was by far its most paying product. Large sums of money were invested in these plantations, which were most successful, till this disease appeared in 1869. It is a kind of fungus which grows on the plant. The disease rapidly spread, though, owing to various reasons (a rise in the price of coffee being one), the effects on the general prosperity were not at first apparent. But by 1879 the disease had penetrated everywhere, and the coffee planters saw themselves ruined. The moral of the failure seems to be, "Don't put all your eggs into one basket." With so many and such varied plants as flourish in Ceylon, it should be almost impossible to go far wrong in judging what will pay for cultivation, and, as roads and railways open up the country, produce will be more and more easily disposed of. The railway is now open to Nanuoya; and all along it, soon after leaving Kandy, the whole country is either being laid out in tea and other plantations, but principally in tea, or else the plantations are already in full work. Before the railway was begun to be made, most of that part of the country was dense jungle. It is now being cleared so fast that the Government has lately made a rule to sell no more land above 4,000 ft. from the sea level. Clearing the hill-top has been found to be injurious to this country, as the heavy rains then wash away the soil, which is prevented when the hill tops are covered with this dense jungle.

The very air of Ceylon just now seems full of prosperity. You see prosperity in everyone's face; you hear it in their talk; everybody you meet is overflowing with energy and hope. There is a kind of revelling in present good things and hope of still better things to come, that is most exhilarating even to the outsider. After the long season of agricultural depression in England where it almost seems as if agriculture were played out—where at once the wildest schemes and the most radical changes are discussad as possible remedies for it on all sides, from jam-making and chicken-rearing to the nationalization of the land, and yet where all the schemes mooted seem to end in giving, after all only temporary relief, to be all more or less uncomfortable makeshifts—it is delightful to come to a country of which agricultural depression is not supposed to be the normal state, but which, having pulled through one reverse, seems able, with good reason, to look forward to another time of success and plenty.

But it is not as yet all clear sailing and *couleur de rose* with the planters [and settlers in Ceylon. They have just received rather a blow from the Home Government, and feel themselves desperately aggrieved in consequence. It can be imagined how roads, and especially railroads, open up a country; but till one has seen the thing, one can hardly realize how hopeless it is to bring down produce without a railway to compete with that part of the country happy enough to possess one. The railway is now open to Nanuoya and even while it was being constructed, it was always considered that in order to make it pay, it would be essential to continue it some twenty-five miles farther and so open out the rich Province of Uva. To do this however, a public loan was necessary and the Home Government must be consulted. Many papers were written last year on this subject on the advantage of this railway and sent in to the Colonial Office. They were backed by a strong letter from the Governor. The colonists felt themselves sure of their railway—felt that it was as good as made—when the reply to their petitions arrived, and the Colonial Office refused consent. "The present railroad does not pay," they said, "let it pay first." "Yes," reply the colonists "but the present railway does not go far enough, leaves untapped the finest and most fruitful part of the island; give us twenty-five miles more railroad and a narrow gauge afterwards as a feeder and see if it does not pay." A cry of rage and indignation has gone up from the disappointed Colony. Loud talk goes on, stormy meetings are held; but which will perhaps eventually prove of the most use, they have also got Mr. ——— to come over and give his opinions on the subject, Mr. ———, who did the Darjeeling 2ft. 6in. railway, and is considered the great authority on Indian lines. Backed by his independent opinion, which they make no doubt will be in their favour, they still hope to persuade the Colonial Office to consider this fatal refusal. Energetic and sanguine people I wish them and their railway all the success they deserve.

HENRIETTA GREY EGERTON.

THE CHINA TEA TRADE AND THIS SEASON'S SHIPMENTS.

The *N.-C. Daily News* says the "Moyune," with the first teas from Hankow, arrived in the Thames on the 25th June, making the voyage in thirty-seven days from Hankow, or thirty-five from Shanghai, or at an average speed of thirteen knots an hour. The "Glenogle" passed the Canal some time before the 24th June, and was apparently about keeping her distance from the "Moyune." The advices received in Hongkong give the 26th as the date of the "Moyune"'s arrival.

The same paper says:—News has been received by wire of the sale of about half the cargo of the "Moyune" on the 27th June. Prices were the lowest ever known for the first new teas, and about 2d a pound, or nearly 25 per cent under last year's opening rates for Shantams, which, costing by the book 7½d, were sold at 6¼d. Medium teas are scraping out in some cases, or giving small losses, while the few fine teas sold are said to be covering cost. This is a very melancholy result when it is remembered that there was no more new tea to arrive for at least a week, that the crop generally is going forward much more slowly than usual, and that it must be known at home that second-crop tea has not yet made its appearance at Hankow to any extent. The China tea trade, say the pessimists, is finished; the warnings that have been reiterated year after year have been justified at last.

In a subsequent issue the *Daily News* says:—The tea news from home is not really so bad as it seemed at first. Only common teas are losing money, and the market seems to be strengthening for good teas. Meanwhile, there are only common teas on the market here, which buyers generally do not care to touch, and this restricts shipments, and must react favourably on the home market.

The foregoing paragraph elicited the following letter signed "C. C. J.":—In these days of overproduction and keen competition we have to be contended with very little, but it was with some surprise that I gathered from your leaderette this morning that "the tea news from home is not really so bad as it seemed at first," and that the restriction of shipments "must react favourably on the home markets." In speaking of the results of the shipments per "Moyune," we must bear in mind the exceptionally favourable circumstances under which her cargo was placed on the London market, that is to say, she is a week ahead of any other steamer and the export to London to date is

by far the smallest that has been known for many years. The quality of the crop is not so good as last season, but in the opinion of many of our best experts it was a crop suited to the London trade, in that it possessed greater strength than last season's teas. In spite of all this the London sales show the lowest range of prices ever witnessed for first arrivals. With the extraordinarily small supply of finest teas the prices paid are not equal to what might have been expected, and if we look at the quotations for common teas, of which the crop chiefly consists, we shall not find much ground for hope or consolation. The opening prices for the past five years have been:—

1887	1886	1885	1884	1883
C¾d.	8½ *a* 10d.	8¼ *a* 8¾d.	8¾d.	11½d. per lb.

In 1884 the home brokers remarked that opening prices were 2d. *a* 3d. under the usual price for first teas. We now see a further fall of 2d. per lb. and say "it it not really so bad." Private advices today report the market weak and prices likely to decline.

We will now look at prospects and to understand these it will be necessary first to look at home requirements. The deliveries of China, Congou and Souchong for the four months from February to May this year amount 31 millions against 36 millions for the same four months last year, and we may safely take this to indicate that deliveries for the next twelve months will show an equal falling off or say 15 millions less than last year. Thus we arrive at probable consumption, say:—

	lb.
Deliveries from 1st June, 1886 to 31st May, 1887	...112,000,000
Less probable falling off ...	... 15,000,000
Probable consumption 1887-88	... 97,000,000

Our shipments last year from all China to London were as nearly as possible 117,000,000 lb. or 20 millions over probable requirements. With the largest first crop on record from the North of China and a full first crop from the Southern Ports it is most improbable that we can bring our export this year down to a proper level; especially as we must not ignore the heavy stock of good consumable Congou and Souchong already in the London warehouses.

If the present crop had been as fine as last season's the decrease in consumption might have been arrested, but as the quality has already been condemned by home buyers, I do not think I am taking a pessimist view of things when I anticipate the smallest consumption for many years, and the lowest range of prices ever known in the annals of the China Tea Trade.—*Hongkong Daily Press*, July 7th.

TOBACCO, KAPOK AND COFFEE IN NETHERLANDS INDIA.

(*Translated for the Straits Times.*)

The planting community in Java recently memorialised the Netherlands India Government to help them under present adverse circumstances by pecuniarily aiding the starting of experimental stations there, for the cultivation of produce articles. To their bitter disappointment, it has curtly declined to meet their wishes at all without deigning to assign the reason why.

A Java planter who has been over to British North Borneo to see for himself how matters really stand in that land of promise assures the Samarang *Locomotief* that, though tobacco does thrive there so far, that branch of cultivation has not made much progress from the difficulties in the way. At present, so he says, Deli planters need not dread North Borneo competition. Tobacco growing is no easy matter. Even in Deli, it took a good deal of hard work and toil at the outset, before the pioneer settlers could make their ventures pay. But now business enterprise there is in experienced hands. Chinese coolies are so dear nowadays that it will be no easy matter to secure suitable ones for work in North Borneo. The latter country has one advantage in the Government being helpful indeed. This circumstance undoubtedly gives a decided push to planting enterprise. Official assistance was afforded to the visitors from Java even in the smallest matters. The gentleman in question and his associates were highly pleased with their reception by the Governor of British North Borneo.

A silk cotton or Kapok factory, so says the Surabaya *Courant*, has been started in Kedirie in Java under European management, with every prospect of financial success. Within the last two years, Kapok has been coming into greater prominence in the commercial world. Formerly it was deemed useful only for filling mattresses and for other unimportant purposes. Now means have been devised to spin Kapok with the result of establishing an almost unlimited demand for it in different parts of the world. The wasteful method of cleaning it by manual labour has long been superseded by steam machinery being availed of for the purpose, thereby lessening working expenses considerably. From the seeds an oil has been extracted which answers admirably for lubricating purposes, as proven by actual experiment. The resulting oilcake has turned out to be highly suitable for manure owing to its containing a heavy percentage of nitrogen. The husk of the fruit also proves serviceable as fuel.

The Government coffee crop in Java this year is estimated at hardly half a million of piculs, nearly fifty per cent below the average. The private crop is equally short. This dismal lookout, arises from the spread of leaf disease. No wonder that prices steadily rise, and keep at figures gladdening indeed to growers who have battled long enough with adverse fate.

TOBACCO AND COFFEE IN DELI.

(Translated for the *Straits Times.*)

A correspondent of the *Courant* has been touring in the Madras presidency especially in the tobacco districts, of which Trichinopoly enjoys a high reputation for cigars both in India and Ceylon. He says that the Tamils of Trichinopoly are preeminently tobacco growers. The article is planted and harvested in the native fashion.

Among them European landownership does not exist. The letting of land on lease is also unknown. Europeans have no influence whatever on the method of cultivation, and have been unable to introduce the least improvement. All that European dealers can do is to buy up the tobacco. The leaf produced is fairly large and somewhat rough looking, but answers requirements in colour, and yields white ashes. Of it, native workmen make cigars which are forwarded all over India from Madras. Amateurs praise highly the aroma of these cigars. Owing however to the inferior leaf used as cover they do not look well. The consequence is that certain firms at Madras have struck out a new line for themselves, and have set to work turning out local cigars with coverings of Deli leaf. The Deli cigars of Oakes & Co., have already acquired a high reputation. There is hence, every prospect of Madras becoming an outlet for Deli tobacco on a small scale.

The Deli *Courant* quotes from a French newspaper a paragraph drawing attention to the fact that coffee leaf disease only appears in countries where the Arabian variety is grown, and that the Liberian kind is proof against this disease. This immunity is ascribed to the roots of Liberian coffee going deeper into the soil than those of the Arabian one. On this ground, he recommends parties desirous of embarking in coffee growing to go in heartily for Liberian, and start extensive plantations of it in the Malayan Peninsula, where they will be sure to prove remunerative, when Ceylon, Java and Brazil will all be handicapped by disease on coffee estates.

THE PANTOLA TEA COMPANY, LIMITED.

Capital paid up, £65,820. Area under cultivation, 1,184 acres.

Out-turn.—The crop estimate was for 608,000 lb. of tea, to cost £24,856, total expenditure. The actual outturn was 616,511 lb., costing £23,101 1s 2d, but with

commission to managers, &c., added, £24,095 8s 10d, being an increase of 5,541 lb. over the estimate, and of 135,248 lb. over last year's crop.

The produce has been all disposed of as follows:—

Sold in London	619,299 lb.
,, India	865 ,,
,, New Zealand	15,916 ,,
Account Sales, Net Weight ...	636,080 ,,
Loss in Taring, Trade Allowance, &c.	7,461 ,,
Invoiced Weight	643,541 ,,

The whole thus accounted for realised, with £514 10s 7d proceeds of tea seed, the gross sum of £31,636 4s 11d, being slightly under an average of 1s per lb., shewing a drop of 2·16d. per lb. from the average price realised for last year's crop. The general fall in value of Indian tea was, however, rather more than this, the average of all sales in Miucing Lane being 1s. in 1886 against 1s 2¼d in 1885. The net profit of the season's working, after deducting commissions to managers and agents, amounted to £7,540 16s 1d, and the Board paid on account from this an *ad interim* dividend, in December last, at the rate of 4 per cent, which absorbed £2,633 4s, thus leaving a balance of £4,907 12s 1d. This sum, with the balance brought forward from last account, gives an available total at the credit of profit and loss, of £5,269 12s 10d, which the board recommends shall be dealt with as follows:—

To the payment of a final dividend at the rate of 6 per cent, bringing up the total dividend of the year to 10 per cent.	£3,949 16 0
To be transferred to form a reserve fund	1,000 0 0
To carry forward to next account a balance of	319 16 10
	£5,269 12 10

The results of working since the first formation of the company three years ago are shown in the subjoined tabular form.

Area Under Cultivation.	1884. Acres.	1885. Acres.	1886. Acres.
Mature Plant	425	982	1,013
Young Plant	171	180	171
Total cultivation ..	596	1,162	1,184
Total Crops—Account sales weight ..	lb. 254,200	lb. 501,774	lb. 636,080
Yield per acre of Mature Plant ..	lb. 620	lb. 511	lb. 628
	s. d.	s. d.	s. d.
Realized Price, per lb..	1 0·62	1 2·09	0 11·93
Total cost per lb. ..	0 9.94	0 10·92	0 9·09
Net Profit per lb..	0 2·68	0 3·17	0 2·84
Dividends paid ..	10 per ct.	10 per ct.	10 per ct.

This record the board considered extremely satisfactory, and reflects much credit on the local management in Assam. The most noticeable feature being the large and steadily increasing yield per acre, an increment, which may be expected to go on for some years to come, as the managing director estimates that the entire cultivated area will yield not less than 720 lb. of similar tea, per acre, when in full bearing of, say, eight years old.

Estimates.—These are given in detail for both Indian and English expenditure; they point to an out-turn of 673,600 lb. of tea, to cost a gross sum of £26,137, or an average of 9.12d. per lb. in London, sale charges inclusive. As the estimates have been framed with great caution, there is very little doubt that the quantity estimated for will be at least obtained, while the expenditure on the other hand will probably be less.

Extensions.—About 12 acres have been planted at Eriabari and nurseries sufficient to plant out 70 additional acres were put down during the last cold weather at Panitola.

The saw mills at Hukanpukri have worked satisfactorily throughout the year.

The managing director in Assam, Mr. A. W. Madden, is at present in England on leave. He reports that he left the several properties in the high state of cultivation which has been the characteristic of this company's estates; that the machinery is in admirable order—there being a reserve of steam power and machinery at each factory—and he speaks in high terms of all the managers employed under him.—*H. & C. Mail.*

COCONUT PEARLS.

Our readers may remember a recent notice in our columns of pearl-like concretions found in coconuts, so rare that we have never seen one or even heard of its being found in Ceylon. The case appears to be different in the Eastern Archipelago, however; probably in consequence of a greater abundance of carbonate of lime in the oil in which coconuts are grown. We confess to a good deal of surprise to learn that formations in juice apparently entirely saccharine should consist of pure carbonate of lime. Specimens of the coconut pearls ought to be obtained for our Museum. The "tabasheer" to which Mr. Thiselton Dyer alludes is a silicious concretion found in bamboos. We quote from *Nature*:

The following letter has been sent to us by Dr. Sydney J. Hickson:—

"During my recent travels in North Celebes I was frequently asked by the Dutch planters, and others, if I had ever seen a 'coconut stone.' These stones are said to be very rarely found (1 in 2,000 or more) in the perisperm of the coconut, and when found are kept by the natives as a charm against disease and evil spirits. This story of the coconut stone was so constantly told me, and in every case without any variation in its details, that I made every effort before leaving to obtain some specimens, and eventually succeeded in obtaining two.

"One of these is nearly a perfect sphere, 14 mm. in diameter, and the other, rather smaller in size, is irregularly pear-shaped. In both specimens the surface is worn nearly smooth by friction. The spherical one I have had cut into two halves, but I can find no concentric or other markings on the polished cut surfaces.

"Dr. Kimmins has kindly submitted one-half to a careful chemical analysis, and finds that it consists of pure carbonate of lime without any trace of other salts or vegetable tissue.

"I should be very glad if any of your readers could inform me if there are any of these stones in any of the Museums, or if there is any evidence beyond mere hearsay for their existence in the perisperm of the coconut."

On this letter Mr. Thiselton Dyer, to whom we sent it, has been good enough to make the following remarks:—

Dr. Hickson's account of the calcareous concretions occasionally found in the central hollow (filled with fluid—the so-called "milk") of the endosperm of the seed of the coconut is extremely interesting. It appears to me a phenomenon of the same order as tabasheer, to which I recently drew attention in this journal.

The circumstances of the occurrence of these stones or "pearls" are in many respects parallel to those which attend the formation of tabasheer. In both cases, mineral matter in palpable masses is withdrawn from solution in considerable volumes of fluid contained in tolerably large cavities in living plants—and in both instances they are Monocotyledons.

In the case of the coconut pearls the material in calcium carbonate, and this is well known to concrete is a peculiar manner from solutions in which organic matter is also present.

In my note on tabasheer I referred to the reported occurrence of mineral concretions in the wood of various tropical Dicotyledonous trees. Tabasheer is too well known to be pooh-poohed; but some of my scientific friends expressed a polite incredulity as to the other cases. I learn, however, from Prof. Judd, F.R.S., that he has obtained a specimen of apatite found in cutting up a mass of teak-wood. The occurrence of this mineral under these circumstances has long been recorded; but I have never had the good fortune to see a specimen.

Returning to coconut pearls, I send you a note which the *Tropical Agriculturist* for April last quotes from the *Straits Times*:—

"A trade journal appearing in Java gives the following particulars regarding a peculiar kind of pearl found in this part of the world:—It is well known that pearls have been met with within oysters and mussels. Sometimes even trees yield pearls. In the proceedings of the Boston Society of Natural History, there is a paper by Mr. J. Bacon regarding the kind of pearls often found within coconuts. The specimens shown have been bought at Singapore. They are said to be so rare in the East Indies as to be highly prized by the native rajahs, and worn by them as precious stones. Mr. Bacon himself possessed a small pearl of this sort. It is said that when allowed to grow, they will reach the size of cherries. This pearl resembles the common variety in smoothness, whiteness, and scant lustre of surface. It is harder than it, and almost as hard as feldspar or opal. The common pearl varies in hardness, but is never harder than feldspar. The coconut pearl consists of carbonate of lime, with very few organic substances remaining after treatment with acid solutions. This organic matter is insoluble, shows no trace of vegetable substances after microscopical examination, and seems to be akin to albumen in structure. In the common pearl there is also found an albuminous substance, but the latter remains unchanged in appearance and lustre even after the calcareous constituent parts have been dissolved away. In other respects microscopical research has brought out the fact that the coconut pearl is formed of concentric layers without any nucleus. The whole mass is made up of layers of fine crystalline fibres. Prof. Bleekrode, in commenting on the former in a Dutch scientific periodical, says that Rumphius, the famous botanist, had in his 'Herbarium Amboinense,' given full particulars of this petrifaction in the coconut. Rumphius has even illustrated his account of it by accompanying drawings of the two forms in which this kind of pearl is met with—pear-shaped and round, either of uniform appearance or with red edges. Hardly one in a thousand coconuts on the average displays this strange peculiarity. The formation of the latter is always a remarkable phenomenon, hard to account for, from the water in the nuts generally lacking the chemical substances favouring abnormal growth of the kind. Rumphius states for a fact that coconuts from Macassar yield more pearls than those from other places. This scientist, in 1682, sent, as a present to the Grand Duke of Tuscany, a ring in which a coconut pearl had been set. Similar pearl-like formations are met with in other East Indian fruits, such as the waringin, the pomegranate, and the kechubong."

To this may be conveniently added two brief extracts from the long and admirable account given by Rumphius:—"*Calappites* Belgis *Calappus-Steen*, Malaicensibus *Mestica Calappa*, albus est lapillus instar marmoris seu silicis albi, durus, planus, ac glaber, cujus putaveram alio loco inter lapides ac mineras descriptionem dedisse, quum vero in *Calappa nuce* inveniatur, ac sollicitus sim, opus illud a me forte non absolutum iri, animo induxi hic loci ejus exhibere descriptionem. Est itaque albus ac politus seu glaber lapillus in interiore *Calappæ nucis* parte concrescens, nunc putamini fixus, nunc vero media in lympha natans, diversæ ac duplicis potissimum formæ" (Rumphius, "Herbarium Amboinense," vol. i. pp. 21, 22.)

"Incolæ plurimum omnes *Mesticas* amant, quarum quasdam tanti æstimant, ut optimis etiam præferant gemmis; plurimas enim ipsis tribuunt immo sine dubio superstitiosas etiam virtutes, gestant enim has ad nudum corpus, in annulis, et armis, ad prosperum conatuum successum obtinendum. Elegantissimos ac rotundissimos hujus Calappi lapillos, seu *Calappites* imponunt annulis suis, vel etiam tellis adpendent, non auro, sed argento circumdatos, dicentes melius hoc cum natura *Calappites* convenire" (p. 22.)

If Dr. Hickson would present one of his pearls to the Kew Museum, it would, I am sure, interest a great many persons who would be glad to see an authentic specimen of so interesting a curiosity.

CEYLON UPCOUNTRY PLANTING REPORT.

IS THE COFFEE INDUSTRY GOING TO REVIVE?—KIND OF LABOR WANTED—AN AFFECTING SCENE—THE COLOMBO TEA SALES—RAIN WANTED.

18th July, 1887.

Arabian COFFEE is being planted, although not to any appreciable extent. Yet the natives, Sinhalese and Moors, are at it, and with the prospect of high prices ruling it will likely extend. One of those now in the field is quite enthusiastic over the growth. It is the old days back again, he said, and "the earth sickness" as he called it, which blighted and stunted even young coffee on virgin land, is all gone now. "Just plant a bit and see" was his answer to my incredulous reply. We all know that during the decadence of coffee, and especially toward the end, the vitality of the plant, or the fertility of the soil, or something was at fault, for in those latter days young coffee would not come on. If it be that the conditions are changed, so that, where formerly there was a sickly struggle, there is now in its place a vigorous growth, the fact is worth noting, and the consequences may be widespread. The native patches may again reappear, and that sea of poverty whose tide has overwhelmed so many of our native fellow-subjects may have marked its highest level and begun to recede.

THE COOLY still keeps coming in from the Coast, but not in very big gangs. The men too predominate as far as I have been able to observe, which is not exactly what we want, but when in former years the Coast was tapped for coolies, the male labourer was then more highly valued, and very likely it is the obtaining of the old traditions which produces the present proportions. By and bye it will filter through the masses that for good pluckers there is an abundant silver harvest to be reaped, and that the hand of a woman or a child is unmatched in that light work, and then the wives and little ones will join the exodus.

We are not in the habit of ascribing to RAMASAMI much sentiment or affection, and a touching little scene which I saw a day or two ago was almost a revelation. It disclosed a breadth of affecting tenderness I was hardly prepared for. There was an arrival from the Coast, two kanganies who were partners met, the one who had been home had brought in eleven new coolies, and the fellow who had been looking after the joint interest in the absence of the other was so much affected, as to fall upon the neck of his chum and weep. What caused the tears was the question. Another planter who was standing by was as much taken aback at the display as I was, and he solved the problem by fancying that the man who had just come in was the man with the coin, and that hearing of this increase to the joint gang there was opened such a vista of future prosperity in the way of head-money and cooly chiselings that the stay-on-the-estate partner found his joy deep enough for tears. Although I should have liked to have been otherwise able to explain the cause of this sudden blooming of affection, yet I rather fear that the solution of the cynical on-looker had much truth in it, and that the sniffering, sobbing and

"the purling tears" had their source in the worship of the prosaic rupee.

The late Colombo TEA SALES are not giving satisfaction to several who send their produce thereto. The low bids and the better prices secured in private are regarded as somewhat of a hole-and-corner kind of style of doing things which ought to be avoided. When you find a lot where the bidding closes at 88 cents, and the same evening R1·15 offered and which was afterwards further improved, there is then clearly some food for thought. I saw a broker's letter on the subject with an explanation, but even with that the difficulties did not all disappear. A few more instances of this kind and our local market will fall into disrepute.

The Weather is hot and dry, and as for the tea plants lately put out, they are having a roughtime of it, and must be getting up no end of a thirst. I would, however, we had a shower. PEPPERCORN.

AN INDIAN GOVERNMENT (THAT OF THE N. W. PROVINCES) ENCOURAGING THE USE OF TEA.

The following curious and interesting information is furnished by the *Pioneer*:—

The Excise Report for these Provinces for the year 1886 is remarkable in two or three respects. It contains a novel and interesting suggestion regarding tea, which we reserve on account of its importance for fuller treatment. Briefly the Government explains that in as humble way, and with the good help of various wealthy Municipalities, it has for some time past been endeavouring to increase the sale of tea, both in the dry and in the prepared state, among the native population; and that it regards the spread of a taste for tea-drinking as the most effectual way of counteracting the craving for alcohol which the excise laws seem in vain to strive against. This position is a novel one to persons who, when they have nothing better to do, are ready to run a tilt against Government for encouraging dram-drinking among the population by means of its distilleries and excise shops. The local Government's contention is that it does all it can by its excise laws to make drinking difficult and costly, and yet the people will drink, and will add to the revenue. Our inquiries regarding the experiments alluded to by the Government lead us to the belief that they would have succeeded better had their main direction been somewhat different. The Aligarh attempts, for example, have been mainly restricted to selling ready-made cups of tea, and subsidising persons to keep a tea-house, There are many obstacles to such a scheme. The people are not sufficiently "clubable" to enjoy a coffee-shop: milk and sugar add to the price of the article: the sale stops in the hot weather months, for our native friends do not see the force of increasing during that season the natural temperature of the body. Anyhow, no tea-shop seems to properly pay its way. A more hopeful policy would be to do as the recently formed Calcutta Association appears to contemplate, namely, to sell dry tea as cheap as possible in small quantities in all our large cities, and leave to domestic enterprise the task of finding out how to make it. Why should the Government suggest to its subjects that the only way to drink tea is with milk and sugar? These accessories are the greatest bar to the spread of tea-drinking in India, for sugar costs something, and milk is an impossible luxury among the poor, to whom tea by itself would be a real stimulant and an efficient medicine in feverish times. The Chinese do not want milk and sugar, and our aim should be to educate a people, as poor and as parsimonious at the Chinese, to take to tea as the cheapest and the best of all possible stimulants. It is pure insularity on our part to try to make them regard it as inseparably connected with articles which have no necessary connection with it.

POISONING BY NUTMEG.—A case of poisoning by nutmeg is recorded in the *British Medical Journal* (p. 1085), in which one nutmeg had been eaten by a patient as a cure for diarrhœa. It caused him to become giddy, stupid and very drowsy all next day. The narcotic properties of these seeds, and of others of the same natural order, do not appear to be generally known, and seem worthy of investigation.—*Pharmaceutical Journal.*

PLANTERS' ASSOCIATION OF CEYLON.—We have received copy of report for year ending February 1887 which contains among other matters, a good deal about the following subjects of interest, generally to planters:—Admixture and Adulteration of Coffee, Mr. A. E. Scovell on the Tea Market, Ceylon Tea Syndicate, Analyses of Ceylon Soils, Cinchona Statistics, Report on Cinchona Cultivation in Java, Prædial Products Ordinance.

CACAO HUSKS.—The husks or shells of cacao seed are sometimes utilized for making a cheap beverage, and are also said to be employed in adulterating ground spices. Mr. P. S. Clarkson reports (*Amer. Journ. Pharm.*, June, p. 277) that he has found them to yield 9·07 per cent. of ash, which besides the usual constituents, contained aluminium, also found by Wanklyn in the ash of cacao. In addition there were obtained 0·9 per cent. of an alkaloid that gave the usual reactions for theobromine; 5·32 per cent. of a fat corresponding with cacao butter; 0·93 per cent. of an odorous resin soluble in ether and alcohol, as well as albuminoids and colouring matter.—*Pharmaceutical Journal.*

WATERING TREES AGAINST WALLS.—After the cold and dry spring came to an end, and in spite of the heavy snowfalls, which should have moistened the soil but did not, the latter was very dry about the roots of wall trees on south and east aspects at Longford. The borders therefore were thoroughly watered then, most of the trees being soon afterwards in flower. Since the formation of the fruits the borders have received several waterings, to preserve the borders in health and to prevent fruit dropping. There is at all times more absorption of moisture at the roots of wall trees than is the case with trees growing in the open, by reason of the closeness of both soil and roots to bricks and mortar, and the warmth imparted thereto by the sun, as well as the extra drainage afforded to the soil in which the trees are growing by the foundation of the wall.—H. W. WARD.—*Gardeners' Chronicle.*

SUPERPHOSPHATE OF LIME.—Mr. Samuel Barlow, Stakehill House, Castleton, Manchester, has contributed an interesting article to the *Agricultural Gazette*. He states that, having a field of Turnips badly infested with fly, he tried the experiment of dusting a few of the plants with superphosphate of lime, and found that it destroyed the fly entirely. He then had the whole field done with the superphosphate, and the result was the entire annihilation of the fly. He also had some large plants of Pansies that were badly infested with slugs—hundreds sheltered themselves under the tufts of foliage, and had to be picked off. A dressing of superphospate was placed on the soil below the tufts, with the result that the slugs were quite destroyed; it also kills wood-lice. Mr. Barlow recommends a dressing of superphosphate of lime on all garden crops, and plants attacked by slugs, snails, &c. "This application is sure to be much more effective than dusting with powdered quicklime, which changes to carbonate of lime on exposure to the atmosphere for a few minutes, and is then harmless to slugs. I found by experiments that after superphosphate of lime had been rained upon for ten hours, it was still powerful to destroy slugs. The superphosphate employed is the ordinary 25 to 28 soluble."—R. D.—*Gardeners' Chronicle.*

USEFUL PLANTS OF MAURITIUS.

Fibre-yielding plants flourish uncommonly well in Mauritius, as proved by the experimental culture at the Botanic Garden. Cotton is grown in very small quantity. The American aloe (*Agave Americana*) has been tried with success, and machinery adapted to the separation of the fibre. A local speciality in fibrous plants is the *vacoa* or *vacois* (*Pandanus odoratissimus*), whose long tough leaves are thrashed out, and manufactured into bags for shipping sugar in.

The woods of the island show greater variety, but the supplies have been terribly curtailed by the destruction of the forests, to make room for sugar plantations. The principal timber trees are as follows:—Ebony (*Diospyros reticulata*) grows to a considerable size; olive wood (*Olea lancea*) is elastic and good for shafts, tool handles, &c.; *colophane* (*Colophonia mauritiana*), a large tree often attaining a diameter of 6 feet, gives a resinous heavy wood much used for cart-frames, wheels, shipbuilding, railway brakes, carriages, and wagons; ironwood (*Stadtmannia sideroxylon*), almost indestructable in house building; several kinds of *bois de natte* from *Labourdonnaia spp.*, useful in all kinds of construction, and the barks good for dyeing and tanning; also the woods of *Jossinia lucida*, *Memecylon tinervo*, *Syzygium sp.*, *Mangifera indica*, *Heritiera littoralis* and *Acacia alta*.—*Journal of the Society of Arts.*

SENNA.

Agricultural School, Minuwangoda, 12th July 1887.

SIR,—I believe the senna plant (*Cassia obtusifolia*), will thrive in many districts of Ceylon and will form a good industry for natives, &c., who will take to its growing. The leaves can be exported and fetch a good price in England as I see from your *T. A.* also. It is generally exported from Tinnevelly, and through the courtesy of Mr. Ewart of Vinidupatti I have obtained some seeds which I hope to try and send you the results. Until then I hope the instructions given by Mr. Ewart will be useful and interesting.—Faithfully yours,

W. ARTHUR DE SILVA,
Agricultural Instructor.

(*Extract from Mr. Ewart's Letter.*)

VINIDUPATTI, 4th July 1887.

This plant grows wild over a large portion of this district and the leaves are collected and shipped to England. The cultivation is chiefly carried on near the town of Tinnevelly on lands which are able to be irrigated by the Jampapurni river, the river comes in flood with the burst of the S. West monsoon, but the rains seldom get over the Travancore hills into Tinnevelly. The seed is sown in June or July, according to the burst of the monsoon, and a shower is generally taken advantage of to sow. If no rain water is turned on to the land and the seed sown after 3 weeks or so, when the plants are well above ground they are irrigated once in 3 days or when occasion requires according to what rain falls after two months picking commences and is carried on for two to four months. Second pickings are secured by plucking off the flowers. The plants are pulled up at the end of the picking, and fresh seeds planted every year. The leaves must be dried in the shade. This senna is called 'Nanga Senna,' and is valued in London at about 1/ per lb. according to colour and size of leaf.

* * * * * * *

(Signed) E. M. EWART.

[The narrow and broad leaved medicinal sennas have been several times introduced into and experimented on in Ceylon, and as far as I recollect without any favourable result. The fact is that Ceylon cannot in any way compete with Tinnevelly in raising such a cheap drug as senna, and unless hereafter, in connection with the irrigation scheme of Kalawewa it can be raised by irrigation. I do not see that any object will be gained by the cultivation of senna in Ceylon.—*W. F.*]

KOLA NUTS.

Before replying to the letter of Mr. Lascelles-Scott, there are one or two points to be noticed in reference to the letter from Mr. Thos. Christy, which appeared in your last *Journal*. That gentleman states that my valuation of 3d. to 4d. per pound for kola nuts was written to the best of my knowledge in regard to the fortnightly auction sales; such was not entirely the case, my valuation was based upon what I knew had been, and probably would again be realised for this article both in public and private sales; but even supposing that the price of 4d. per pound had only been obtained in the public drug sales, what further criterion of the market value of the article does Mr. Christy look for? With regard to that gentleman's statement that "kola nuts came to Liverpool, and are sold there," one would infer that a regular market was established there for this produce. The following report, from a well-known firm of brokers in that city, tends to show that the market there is even in a more precarious condition than here:—"Your note to hand *re* kola nuts; none here, and there is no inquiry at present: they only come in small lots, and at very irregular times, no record has been left of imports; demand is very uncertain, and value has varied accordingly; when there has been no chance of selling, lots have, at different times, had to be thrown away, as they do not keep, soon becoming rotten." This statement is also confirmed by another Liverpool broker. These facts seem to me to entirely disprove what Mr. Christy says, viz., "that the demand for sound kola nuts is far beyond the supplies."

The letter of Mr. Lascelles-Scott does not throw any light upon the present market value of kola nuts. It is quite true that I asked Mr. Lascelles-Scott 8d. per pound for half a hundredweight of kola nuts, but in discussing the value of this article one does not expect retail quantities to be placed upon the same basis as market quantities, and I would here remind that gentleman that my original valuation was based upon the question. "Would an importer find a ready sale, and if so, at what price for a quantity of kola?"

HENRY R. ARNOLD.

16, Coleman-street, London, E. C.,
June 9th, 1887.

Mr. Christy's letter in the *Journal* for June 3 fully confirms the views expressed by me respecting kola nuts. There is no regular quotation for them; the demand is uncertain and spasmodic, and, therefore, the planters in the West Indies, tempted by Sir Augustus Adderley's recommendation to invest in the cultivation, are liable to find both their time and money thrown away. This is all I wished to say, and, so far, nothing has been gained by Mr. Christy, except indicating the source of the information contained in Sir Augustus Adderley's paper.

The merits of kola nuts, *per se*, I do not touch. They may have, or they may not have a future. At present it is purely conjectural. Under these circumstances was it wise to recommend without qualification a purely speculative cultivation to small growers in the West Indies, when plenty of others, with certain returns, were within their reach?

It may be not out of place also to point out, in reply to both Mr. Christy and Mr. Lascelles-Scott, that the idea of making chocolate from kola nuts was first suggested in my "Annual Report on the Public Gardens of Jamaica," in 1882. This was nearly two years before it was taken up by Mr. Christy.

Coffee in parchment, and also in cherry, has been exported on trial from the West Indies, but the prices offered by the merchants were too low to be remunerative. Hence the growers prefer to pulp and clean their coffee themselves, and so place it in the market at first hand. They are evidently the sole judges of what pays them best.—D. MORRIS.—9th June, 1887.—*Journal of the Society of Arts.*

JOHORE AS A TEA-PRODUCING COUNTRY

SIR,—Having received samples of Johore teas, I sent them to be reported on in Colombo, and thinking that it might interest some of your readers to know what

those teas are like, I send you the report for publication along with these notes. Tea is only in its experimental stage in Johore. The great drawback to planting there has been the want of proper labor. Chinese are plentiful and do contract work, such as roading, draining, &c. very well, but as a day laborer, John is a failure. Tamils have gone over in small gangs, but the Indian Government would not allow the planters to recruit labor on the Coast and take them to Johore, because there was no British Resident in the Sultan's territory. This has now been overcome by the Sultan allowing a protector of Immigrants to be stationed there; so the British Government have now no objection to coolies going over. They are paid much about what we pay in Ceylon. The Sultan offers every attraction to Europeans to open up land. There are thousands of acres of virgin forest to choose from, and roads are being constructed to open up those parts that are inaccessible by river. The rainfall is very evenly distributed over the year, and exceeds 100 inches. Now that the labor question is solved, I have no doubt that Johore will be able to compete favorably with India and Ceylon in the tea markets of the world.—I am, &c.

EASTWARD HO.

Colombo, 23rd June 1887.

The following is the report alluded to above:—

Having examined and tasted the following teas, we now beg to hand our report and valuations, as under, viz.:—

Johore Estate.

Mark.	Description.	London value.	Colombo equivalent @ Exch. 1/5 1-16.	Remarks.
Johore	Bro. Pekoe 1/3, 1/4,	80 cts.		Blackish, even semi-broken Pekoe and Fannings, leaf mixed, with ends soft flavory liquor, wanting strength, little flat.
Do.	Pekoe	1/0½, 1/1	63 „	Blackish, greyish, fairly made Pekoe Souchong leaf, few ends, plain dark liquor, fair strength.
Do.	Souchong/	10½, /11	51 „	Blackish well made Pekoe Souchong leaf, dark malty liquor, very flat.

A. H. THOMPSON,
p. p. Somerville & Co.

These teas have gone off; otherwise they liquor fairly well and the appearance is good. The liquors are more on Indian than Ceylon style.—A. H. T.—Local "Times."

KOLA NUTS.

Sir Augustus Adderley very much understated the following items of information, viz., the value of kola nuts, and the preparation of coffee in London; and Mr. D. Morris, the Assistant-Director of the Government Gardens, Kew, made matters worse by getting a letter from a well-known firm of druggists to support his criticism on the paper. Mr. Lascelles-Scott tried to set Mr. Morris right at the meeting, as he was working at this important article, and knew the facts of the case. In regard to the letter signed by Mr. H. Arnold (on behalf of Messrs. Burgoyne and Co.), he wrote to the best of his knowledge in regard to the fortnightly auction sales; but the fact is that kola nuts come to Liverpool, and are sold there; and when they come to London the brokers offer them direct to us, as they know we are the buyers. Besides these, quantities come to us and other consumers direct from the West Coast, and therefore do not appear on the market reports. This explanation is only due to Sir Augustus Adderley, who had evidently taken much pains to master the facts he placed before the Society.

The demand for *sound* kola is far beyond the supplies, and lately 1s. per lb. has been paid here for sound nuts for the whole parcel received. We have orders, which we are trying to execute, for 30 tons, and 100 tons would be taken if we could only get supplies of *sound* nuts, dried in the shade, at 5d. or 6d. per lb.

Kola chocolate is selling at 4s. per lb., and since it has been found of so much service in the hospitals, its regular use is ensured. We suffer in this country owing to the Government having no one to advise on such a food as this for the troops, and if I could have been present at the meeting, I should have said much more than you can afford me space for. Three of the Governments of Europe have ordered the preparation of the kola paste in quantity for army food. The experiments show that men can subsist on one ounce of kola for twenty-four hours, without the gnawing feeling of hunger and thirst, and when they can get food, they do not suffer from any inconvenience. This is thought to be due to the caffeine combined with the other constituents of the nuts, when mixed with a vegetable fat.

Wherever coffee has been found indigenous, it has been observed that the natives pick it and dry it in the cherry, or outer skin, and it is well known that this improves the quality, and the flavour is better retained, even for years. In many places merchants can command supplies of coffee in the form of "dry cherry," or in the "parchment," and some parcels in the cherry I sold to houses who roasted it with the outside jacket on, but as this required experienced roasting, the proprietors of the coffee warehouses saw the necessity, and ordered sets of the most approved coffee-dressing machinery, and erected them in London, and large quantities of coffee are treated here which command the full market price. During the last two months I have been seeking for some means of turning the large stock of coffee husks to some account, with the professional assistance of Mr. R. H. Harland, F. C. S., and of Messrs. Cross and Bevan; coffee dressers can find no use for these husks. The great advantage of this established enterprise is that the large companies opening up Africa can purchase the dried coffee in small quantities, and have it home in bags, and as soon as it arrives it can be sent at once to the warehouses to be decorticated, and placed on the market. Messrs. Major and Field, of Red Lion Wharf, allow me to state that in 1886 they decorticated 10,000 bags of coffee, and that in one vessel they received over 3,000 bags of coffee in parchment to be decorticated. They further state that they have 100 tons of the husk which they would be glad to find a use for at a very low price. I hope that the readers of the Society of Arts *Journal* will be able to turn to account this information, and feel disposed to circulate it among their friends, as coffee has risen so enormously in price during the last few months.

In conclusion, I would like to put on record another fact, viz., that kola is being mixed with some of the preparations of coffee which enables the vendors to state that their mixture contains "no chicory," which is of great importance now that it is proved that the addition of chicory conduces to the growth of hæmorrhoids.—THOS. CHRISTY.—*Journal of the Society of Arts.*

CAOUTCHOUC-YIELDING PLANTS.

The remarks which appeared in the issue of the *Journal* for June 3, on "The Useful Plants of Mauritius" are important to those who take an interest in the flora of Mauritius, and more especially to those who would like to see our Colonies producing those vegetable products which we are obliged to seek elsewhere.

I wish, however, to point out an important omission which deserves attention. Of course, in a botanic garden, it is impossible to find room for everything, and I would venture to say that our Colonial friends in this respect are too exclusive; a great deal is left outside for want of space, attractiveness apparent absence of utility, and difficulty of adapting

a "place" suitable for the *locale* of a botanical "ragamuffin." Instead of concentrating attention to making a garden neat and prim, and cultivating what, *a priori*, is known to do well, it would be better to turn ome attention to the cultivation of those plants which are not indigenous, but from which important products are obtained. This need not interfere with the present arrangement of making a botanic garden pleasant to the eye and enjoyable as a promenade, &c.

A few years ago I met with a gentleman who had spent some time in this island. He informed me that on some elevated rocky parts, which were almost destitute of vegetation, a creeping plant grew in luxuriance, the juice of which contained a large quantity of caoutchouc. From his description, I concluded that this plant was probably a creeping or trailing *Apocyna*.

It seems to me that it is very desirable to clear this matter up, for if caoutchouc-yielding plant can be so easily grown on such a spot, we have a very simple way of utilising land which is not likely to be productive as it is, and which is beyond the reach of any ordinary agricultural process of being reclaimed.

The *Mangifera indica* (see "Useful Plants of Mauritius") is also said to grow on this island. It would be interesting to know if this plant is botanically allied to the *Mangabiera* (*Hancornia speciosa*), which yields Pernambuco and Ceara rubber. The geographical and climatological condition of Mauritius seem favourable for the cultivation of this plant, provided it is grown on land with an ordinary good subsoil. It stands long drought fairly well at Ceara.

We must bear in mind that West African rubber is principally obtained from varieties of *Apocyna*, which are natives of Madagascar. Some varieties of this class of rubber are fairly good; this fact makes it more difficult to understand why an article of higher commercial importance cannot be produced generally.

I am surprised to find that some writers on botany say that the *Vinca* and *Neria* do not produce lactescent juice, and hence are devoid of caoutchouc. Our common garden periwinkle contains it, and when I was in Demarara, a few years ago, I was struck with the amount of cautchouc contained in the *Oleander*.

It would be interesting to know whether any of our own herbaceous or sub-shrubby plants, which are known to contain caoutchouc, could be profitably cultivated in warmer latitudes.

There are instances of plants, which are herbaceous in this country, having arborescent representatives in warm climates. The *Euphorbiacæ* is a familiar illustration, one species of which yields the Para rubber; our common representative is a weed called the "Caper Plant." I remember planting out a number of these seedlings some years ago at Mitcham, and was surprised at the amount of lactescent juice which the mature plant yielded. The juice contained caoutchouc in rather large quantity.

I prepared in 1861 a quantity of caoutchouc obtained from the flower stem of the common dandelion, and it was exhibited at Guy's Hospital *soirée*. I was led to extract this from the report of an analysis of the juice of this plant contained in Dr. Pereira's "Materia Medica."

The best way of preserving these specimens is to place the caoutchouc in ether containing a small quantity of alcohol. In this mixture caoutchouc remains white and unaltered for a long time; exposed to the air, even in well-stoppered bottles, it rapidly turns brown.

I may note here that the *Chicoraceæ*, although lactescent, are said by some writers not to contain caoutchouc; these remarks respecting taraxacum are in contradiction to this. The common sow-thistle also contains this principle, although in smaller quantity. The *Sapotaceæ*, although lactescent, do not yield caoutchouc, at least I have not met with a single case in proof of its being otherwise. The concrete juices of these plants are called in commerce "butters," and consist mainly of fatty or oleaginous principles. Galam butter is obtained from a plant belonging to this order, *Bassia Parkii* (being first mentioned by Mungo Park).—THOMAS T. P. BRUCE WARREN.—*Journal of the Society of Arts.*

AGRICULTURE ON THE CONTINENT OF EUROPE.

(Special Letter.)

PARIS, June 11.

It is ever a critical period for stock when they quit their winter rations for the young and succulent fodder of spring. In no case ought the transition to be made hastily. The German farmers are in this respect very prudent; they always arrange to have a reserve of dry fodder to mix with the first grass and clover of the new season. Decorticated cotton cake is also a corrective—when hay is not forthcoming—for the laxity, immature green soiling produces. Indeed bean meal or refuse grain will also prove binding against scour. It is not alone distention of the stomach or hove, that is to be feared with live stock, from greediness over unripe herbage, but the permanent injury the intestinal organs may sustain.

In the east of France, Germany and Italy, the young and succulent fodder is mown in the evening, left in the swath all night, and carted in the morning for the day's consumption. This arrangement does not wither the soiling, as in the case when mown and exposed to the sun, while depriving it of its immediate power of active fermentation. Also faded green forage has the tendency to ball or lump in an animal's stomach and produces much intestinal derangement.

As the green fodder is very aqueous, it is furthermore prudent not to allow the animals to drink till they have completely terminated their feed. In the mixed, dry and green rations after the third day, the dry stuff should be gradually diminished till the tenth day. It is not a bad plan to augment the supply of salt during this graduating period which will thereby stimulate digestion. Many farmers with good dairy cows, give them a little cake all through the grass season and superior cattle will ever repay generous feeding. There are farmers who before turning the cattle out on spring pasture, give them a feed of hay every morning for a week. This blunts the edge of gluttony.

The great importance given to oil-cake as an auxiliary food raises the pertinent question in what form smashed, steeped, or in meal can it be most profitably employed? Concentrated rations are most useful when given under a form which permits them to be readily digested. The experiments of Professor Kühn of Möckern show that if anything concentrated food is less assimilable in the liquid than in the pulverous or mealy, dry state softened by steeping, such food is swallowed, not masticated by the animal; and in the case of ruminants passes directly into the third stomach and so escapes cudding. Now rumination plays an important part in digestion. Dry and mealy rations should then be moistened, but not wet or sprinkled over other food. In the case of rape-cake the steeping produces a penetrating odor which communicates a taste to the milk and butter, and occasionally affects the animal's health. It is considered that more deleterious foreign matters find their way into oleaginous food when in the state of cake than if in the sifted meal form. True, the latter can be on the other hand adulterated; but against this there is the usual protection of purchasing from respectable houses and co-operatively.

As well-water in villages can be poisoned with typhoid-fever germs due to infiltration of water-closet matters, there is nothing extraordinary in findings the oozing of manure heaps into cattle ponds, producing an equally detrimental effect on stock. Cattle prefer to spring, flowing and soft water, even though the latter be stagnant or muddy. In this state no serious results may ensue. Abortion in cows is often produced from drink-water impurities and the scour which so frequently afflicts calves may

date its origin from the same cause. In those cases where butter prepared with the most extreme care, unobjectionable in the very fresh state, but becoming rancid and offensive two days later may not that puzzle be solved by the organic poisons in putrefied drinking-water?

Cider-making is on the increase in France since the destruction of about one-third of the total of the vineyards. In any case the beverage has been peculiar since the 11th century to Normandy, Picardy, and Brittany, as wine has been to other regions. Where climate and soil suit the growth of apple trees, cider can be prepared and if it be well made the beverage is healthy, stimulating and nourishing. From the time of Columella the secret of cider making has remained unchanged. Select three classes of apples, sweet, bitter and acid in equal proportions. However, in the valley of the Auge where the best French cider comes from no acid apples are employed. Care should be taken to select the fruit arriving at a common period of maturity. The sweet apples produce an agreeable drink, but weak in color and not keeping long; the bitter impart strength, but tend to thicken the beverage, while the acid apples yield a weak cider, thin and apt to brown when in cask. As the artist when painting Venus borrowed a grace wherever he could find it, so perhaps the principle may be applied to cider-making in selecting the apples.

Bitter apples yield the least juice; but aginst this, the juice has strength and keeping quality. Sweet apples give more and acid apples most juice. Over-ripe apples weaken the cider and injure its flavor, while those from old trees yield a cider very strong. Not much error will be committed if well-matured large apples and of different varieties be chosen. It is when the apples commence to turn yellow exhale their well-known odor, and especially when plenty of sound fruit has fallen on the ground that the moment has arrived for the harvest, selecting dry weather if possible, as apples when wet and put in heaps "must" rapidly. The apples are allowed to remain under a dry and aerated shed, but not exposed to frosts for one to three weeks. The old pulping mill is now discarded, wherein a deep circular trough in wood or flags twenty yards in circumference, the apples were ground under a running mill-stone weighing a ton and worked by a horse. The pulp or "cheese" is allowed to rest for a night to ferment. It is an error to suppose the seeds of the apple injure the quality of the cider; the contrary is the case, as they impart an aroma to the juice and assist its keeping. Of the modern cider mill, the models are legion.

If the cider be destined for long keeping no water is added; if otherwise, one quart of water per thirty-four pounds of fruit is mixed during the grinding. The best water is that from a pond and the worst from a well. The pulp is placed in hair-cloth bags inside a strong box and pressed; the aim should be to have the juice clear, rich by 10 per cent. in sugar, and registering a specific gravity of 1·07. Next, the juice is drawn off to a vat or into wine-hogsheads, and successively racking it in different casks as the scum rises, and which should be skimmed off and the lee subsides. If the fermentation has been uniform, 7 to 10 days will be sufficient for the clarification. Then the fermentation should be checked by excluding connection with the air.

In March it will be ready for bottling; if it does not require fining to remove thickness or ropiness, and which isinglass or stewed pears and apples will correct. To check fermentation a bit of sulphur is burned on the end of a stick inside a half-field cask, the cider is then shaken to absorb the fumes. This doctoring generally tells its own tale. To color cider, cochineal, burnt sugar, &c., are employed; and cloves, cinnamon, &c., to give it aroma. Effervescing or champagne cider is made by abruptly checking the incipient fermentation with a little burning sulphur or some blazing brandy, and drawing off into earthern bottles with tied down and sealed corks. First class bottled cider has kept good for eight years.

In France, care is taken never to alter the quality of the soil which produces good apples. All animal manures are studiously avoided; only a compost of the residue of the cider press and a little lime strewn at the foot of the trees is all the manuring required. On an average one tone of apples yield 120 gallons of good cider and 12 gallons of brandy. With the extension of apple culture is developing the distillation of apple brandy.

A good deal of discussion is still taking place respecting the Goetz method for laying down land to permanent pasture. His experiments commenced in 1873-4, and he maintains he can by careful top-dressing fertilizers indefinitely obtain a return of 4 to 5 tons of hay per acre. Practical men are not so enthusiastic. M. Goetz makes a selection of thirteen or seventeen choice grasses suited to the locality. The mixture he sows at the rate of 60 to 70 lb. per acre, that which represents a cost of 50 to 60 fr. He excludes clover lucerne, sainfoin &c., which tap the subsoil for mineral food. Thus, the surface soil is his working area. And for success even here the application of fertilizers must be liberal. Hence the plan would suit poor, thin soils or those exhausted or tired from clover cropping. In reality, four grasses form the bases of the sowing. Fromental (*avena elatior*), dactyle (*Dactylis glomerata*), ray grass (*Solium perenne*) and the woolly houlque (*Holcus lanatus*) in the proportion of one-half, one-fifth, and one-seventh, respectively; the other varieties are generally selected for their odoriferous qualities.

It is a good plan for the farmer to raise each variety of grass seed himself. In spring, if the soil has been well prepared and the sowing period favorable, two months will suffice for producing an excellent green carpet. The following spring the fertilizers—nitrate of soda or sulphate of ammonia &c., as may best suit the land, are applied at the rate of one to three cwts. per acre. When the crop is intended to be cut for hay, the grass should be mown when coming into flower; if later, the principal grasses will become hard and woody. Purchases of Goetz—raised hay assert, it lacks the fineness and aroma of that from natural meadow, so never brings so high a price; but the yield is heavier, the latter whenever laid is thus difficult to mow by the machine. The Goetz system has certainly succeeded in the case of poor, almost of worthless lands, in producing an abundant supply of fodder for the support of six cows per five acres.

Horse breeders in Normandy and Limousin before turning yearlings into meadows in spring, prepare them for the change by augmenting the ration of carrots; the latter are cooling and aqueous and suit admirably the transition. The feet of the foals are carefully pared flat before quitting the sheds. It is during this period that foals ought to be studiously well fed; hence, select appropriate pasturages. In Normandy, there are meadows having a special repute for the rearing of foals. If the latter be of pure blood and destined for the saddle, it would not be right to place them in an over rich pasture; that would be rather to fatten them at the expense of their development. On the contrary foals which promise to become large and heavy in build, ought not to be brought up on meagre pastures; such would tend to make them flat-sided and spindle-legged. Many breeders supplement the poverty of the herbage by auxiliary rations of crushed oats or barley; but nothing can replace good meadow feeding in May and June united to continual exercise.

When several foals of different ages have to be reared together, the youngest are allowed to enter the meadow some time in advance. This plan enables them to nip the delicate ends of the grass, for the older stock will be ever able to find sufficient for themselves. When the foals are not the product of native, that is of acclimatised races, it is better to enclose them under shed during night. A foal in robust health will eat nearly all the night. In July when the supply of grass in warm climates diminishes, it will be necessary to augment the auxiliary grain rations. If the season be very dry the foals are brought into

the stables from eleven to five and given a supplement of hay, &c.

Artificial butter, no matter under what name it may be called, is not in favor with the French hygienic commissioners. In ithis attitude of suspicion they are surpassed by the police authorities of Berlin. In Paris extreme rigor is exercised towards the vendors of Simili-butter. Its name must be specially labelled on the shop ensign and stamped into the stuff itself. It is not that the material if carefully prepared be not good for cooking and pastry purposes; but unfortunately the belief is general, that all kinds of grease are employed to make the artificial butter that from horses &c., as well as oxen, not even excluding the fat of diseased animals. If the fats were subjected to a high temperature, contagious disease-germs would be destroyed; but this is not so, as that would eliminate the power of the grease to take the butter, the "meadow" aroma and which no chemical doctoring can communicate. It is curious nearly all the fat of the abattoirs of this city is sent to Holland to be made into Simili-butter which is then exported to Paris.

THE AGRICULTURAL PESTS OF INDIA.

The Agricultural Pests of India and of Eastern and Southern Asia: Vegetable and Animal, injurious to Man and his Products. By Surgeon-General Edward Balfour, author of of "The Cyclopædia of India," &c. (London: Bernard Quaritch, 1887.)

Considerable attention has been directed lately to agricultural pests of all kinds, and especially to insect pests, in various countries, because the injuries occasioned to crops by their agency have greatly increased, and in some instances altogether new disorders and diseases attributable to them have appeared. The universal international exchange of agricultural produce and other commodities has tended and must tend to distribute insects, fungi, and other sources of evil to mankind, animals, and plants, throughout the world. Thus the terrible scourge of the vine, the *Phylloxera vastatrix*, was first introduced into the French vineyards with plants, or cuttings, of vines imported from the United States. Very many insects most noxious to agricultural, fruit, and garden crops, in the United States were brought there with plants, cuttings, fruits, and seeds. The elm-leaf beetle, *Galeruca xanthomelæna*, which is now seriously damaging elm-trees, was not known in the United States until 1837, and came probably from France, or Germany, where it had been a troublesome pest long before that date. The hop fly, *Iphis humuli*, called the "barometer of poverty" by a Kentish historian of hop culture, has only recently visited the hop plantations of America; yet it caused almost a fatal blight last year in those of the Eastern States, upon an area of nearly 10,000 acres. Without any doubt this insect was conveyed from England in "hop-sets." The Hessian fly has been conveyed to Great Britain by some means or other not yet discovered during the last year, and bids fair to be a dangerous and permanent scourge to the wheat and oat crops of this country.

It is the same with moulds, or mildews, or "blights," occasioned by fungi. The vine mildew, *Oidium tuckerii*, was not dreamed of in France until 1845. The potato mould, *Peronospora infestans*, had shown no important sign in Great Britain until 1844. The coffee mildew, *Hemileia vastatrix*, did no serious harm in the coffee plantations of Ceylon until after 1870; but during the last ten years it has enormously decreased their yield.

Diseases of animals have also been greatly intensified during the past thirty years in Great Britain and in other countries. In India, as we gather from this little book of Surgeon-General Balfour, anthrax, pleuropneumonia, rinderpest, foot-and-mouth disease, are so rampant that the Madras Government has recently appointed an inspector of cattle diseases with a sufficient staff under him.

There is no doubt that the attacks of certain insects and parasitic fungi are more frequent and more fatal than formerly. Hop blights from aphides and mildew, *Spærotheca castagnei*, are far more common and destructive in England than they were fifty years back; and the orange-growers of Florida, California, and other places where oranges are cultivated, are at their wits' end to combat the ravages of scale insects, Coccidæ, which have greately increased since 1870.

It is a moot point as to whether this is due, or not, to modern and more artificial systems of cultivation, which may be more favourable to the spread of insects and parasitic fungi. Or it may be that these new systems interfere with the balance of Nature by decreasing parasitic and other insects, and birds and other animals, which are the natural foes of injurious insects. It has been discovered by Prof. Forbes of Illinois, that several species of the Carabidæ and Coccinellidæ eat the spores of fungi; therefore an unusual increase in the number of birds, or other foes of these insects, might occasion a serious spread of mildews.

The importance of the subject of agricultural pests cannot be overrated. It is now fully recognized by the Government of the United States, who have a distinguished entomologist upon the staff of the National Agricultural Department. Besides this, many of the States have their own entomologists, who furnish frequent and valuable reports and advice as to methods of treatment. In England the Ariicultural Department of the Privy Council have lately issued a series of reports upon insects injurious to crops, written by Mr. Charles Whitehead; and Miss Ormerod, the entomologist of the Royal Agricultural Society, has published annual reports for upwards of ten years, which have been of the utmost value and practical benefit to agriculturists. And in India, as Surgeon-General Balfour tells us in this work, the serious injuries caused by insects and other animals, fungi, and bacilli, to mankind, animals, and plants, have at last attracted the attention of the Government of India, and it is proposed to invite communication from those engaged in agriculture, forestry, and horticulture in that country, to furnish matter for periodical reports like those issued from time to time by Miss Ormerod. These would of course be published in the vernacular, and should be illustrated by woodcuts, as Miss Ormerod suggests in her comprehensive letter in the preface of "Agricultural Pests of India." It is much to be hoped that a competent entomologist may be appointed in India to direct this work.

Surgeon-General Balfour, so far back as 1880, recommended the Secretary of State for India to obtain reports on the diseases of cattle and plants, and on creatures noxious to mankind and vegetation. In his admirable "Cyclopædia of India and of Eastern and Southern Asia," published in 1885, he gave a general view of the entomology of these regions, and described the losses sustained by agriculturists from these and similar causes. He has followed this up with the work now under review.

Though a small book, the "Agricultural Pests of India" is very ambitious in design, as it treats not only of insects and fungi and animals injurious to mankind and agricultural crops, but of all manner of birds, beasts, and fishes. Several of these cannot, even by the greatest stretch of the imagination, be classified as pests to agriculture, and seem to be altogether out of place in this category. Under the heading "Fish," sharks and siluroids are described, though it is not by any means clear in what way they are agricultural pests, except, perhaps, that they might bite off limbs of unwary agriculturists disporting in the sea. The book should have been styled the "Natural History of India," or "A Manual of the Natural History of India," rather than the "Agricultural Pests of India." But the fact that rather too many subjects are dealt with cannot be held to be a very serious fault in a compilation containing an immense amount of surviceable information arranged alphabetically, together with a good index, so that any head can be quickly found. The author had great opportunities of acquiring knowledge of the branches of natural history he has here dis-

cussed while he was engaged in forming the Government central Museum at Madras, and other museums in various parts of India, as well as in the preparation of "The Cyclopædia of India" and his work on "The Timber Trees of India." He was therefore very well qualified to prepare this manual or dictionary of natural history, which will serve to show Indian agriculturists what are the principal foes of their crops and herds. No remedies or methods of prevention are given in detail. Some general instructions appear in the introductory chapters, such as to farm cleanly, and to use certain washes and powders in case of the attack of some insects. These, however, have evidently been taken from lists of remedies prescribed by American and English practical entomologists, and have not been actually tried in India. Now that Surgeon-General Balfour has demonstrated the dangers, and indicated general remedies which have been found advantageous in other climes, the farmers, the foresters, and fruit-growers of India should at once make experiments, and prove for themselves whether these are as efficacious in the fiery heat of the East as in the temperate climates of Great Britain and America.

This notice cannot be concluded without an allusion to some of the errors which have been carelessly allowed to remain in the book, having evidently escaped the notice of the eminent scientific man who "revised nearly the whole in manuscript, and the proofs as they passed through the press." It is not to be expected that Surgeon-General Balfour should be a skilled entomologist, but it is very unfortunate for him that those on whom he relied for assistance should have so signally failed him. He says that the *Cecidomyia tritici* is the Hessian fly of Europe and America. In reality the Hessian fly of Europe and America is *Cecindomyia destructor*, named so by Say long ago, and is completely and specificially distinct from *Cecidomyia tritici*, which is the true wheat midge of Great Britain. This is a mistake which appears unpardonable in a scientific reviser. On p. 45 it is stated that "the species of Necrophorus and Silpha are useful; they feed on carrion, and by scratching the ground from under dead animals they partially bury them." As a fact the *Silpha opaca*, and another species, the *Silpha atrata*, eat and seriously injure plants of beet and mangelwurzel, as has been shown by Curtis and Miss Ormerod in England, by Guérin Méneville in France, and Taschenberg in Germany. It need hardly be said that correct information as to the habits of insects is as necessary as accurate nomenclature—at least to agriculturists.

Again, under the heading Buprestidæ and Elateridæ (click beetles) it is remarked that the larvæ feed on living wood, and are more or less injurious. The wire-worm, the larva of *Elatar lineatus*, is fearfully destructive to the roots of crops of all kinds. In the description of Elateridæ, further on, this kind of mischief is attributed to their larvæ; so that there are two utterly conflicting accounts of the habits of these insects, calculated to puzzle the inquiring Indian farmers.

A sweeping statement that "all the weevil family insert their eggs in the stigma of the flower" cannot be supported, and is utterly opposed to the experience of observers. A few species do this, but others deposit their eggs in a variety of places. Of weevils it is also said that they "attack principally in their larval stage every part of vegetable tissues." As a fact, many weevils do incredible harm to vegetation in their perfect or weevil form, and it would be difficult for the larvæ—mere maggots—to hold on to leaves.

Sitonas, described as attacking stored grain and seed, have been evidently mistaken for species of Bruchi.

These and other mistakes ought to be corrected before the work is put into the hands of the agriculturists of India as a text-book for their guidance.—*Nature.*

Small cast-iron pieces can be tinned by first thoroughly cleaning the articles to be tinned, and immersed in a bath of one ounce cream of tartar, one ounce protochloride of tin and ten quarts of water. The bath should be kept at a temperature of 190° in a stone vessel. Pieces of zinc should be thrown into the bath.—*American Cultivator.*

THE ESSENTIAL OIL TRADE.—The following particulars are taken from Messrs. Schimmel & Co.'s semi-annual report on the essential oil trade:—

CINNAMON OIL.—The prices of cinnamon chips have advanced by about 15 per cent. since last November, and may not improbably rise further still, as the shipments fell off last year. As regards the oil itself, the Ceylon statistics, which give a total export of 139,094 oz. for 1886, doubtless include the oil distilled from the leaves and roots, for there is no question that the production of true oil of cinnamon bark in Ceylon is as yet so small as not to exceed 10 per cent. of the total exports quoted under the heading "cinnamon oil."

CUSCUS OIL.—Judging from the quantities offered by him, it appears, that the manufacturer of this oil on the island of Réunion, whose product has only recently been placed on the market, considers that there is an unlimited demand for this oil. Such is not the case, however, for the use of so expensive an article must necessarily be a very restricted one.—*Chemist and Druggist.*

RUBBER.—Dr. William Roxburgh, Superintendent of the Botanic Garden at Calcutta, sent, in 1811, a sample of India-rubber from Bengal, and also a paper on the teak tree of the East Indies, then used for shipbuilding. He also communicated suggestions on the means of supplying food to the natives of India when the rice crop proves deficient. The thirty-third volume of the *Transactions* contains a portrait of Dr. Roxburgh, who died in 1815, and an account of his labours. Subsequently, Dr. Wallich, Superintendent of the Botanic Garden at Calcutta, communicated to the Society a full catalogue of Indian woods (*Transactions*, vol. 48, p. 439). In connection with the introduction of an india-rubber from Bengal, mention may be made of the first introduction of guttapercha from Singapore. Dr. Montgomerie sent a specimen to the Society in 1843, and in 1845 a gold medal was awarded to him for the introduction of this substance into England. In 1815, the gold Isis medal was awarded to Mr. Thomas Hobiyn, for preparing rice in the island of Ceylon by means of improved machinery.—*Journal of the Society of Arts.*

TEA.—Great interest was felt in England about 1820 in the spread of tea culture in our Colonies, and the Society of Arts took the matter up. A gold medal was offered to the person who should communicate, from information obtained in China, the best and most authentic account of the culture of the plant or plants, the leaves of which furnish the different kinds of tea, together with the method of gathering, drying, and otherwise preparing the leaves. The gold medal, or fifty guineas, was offered to the person who should grow and prepare the greatest quantity of China tea, of good quality, not being less than twenty pounds weight, in the island of Jamaica, or in any other British West Indian Colony, and should import the same into Great Britain. The same premium was offered for the Colonies of the Cape of Good Hope, the Mauritius, and New South Wales. In 1788, Sir Joseph Banks suggested to the Court of Directors of the East Indian Company the practicability of cultivating the tea plant in British India; but it was not until 1834 that the subject was submitted to his Council by Lord W. Bentinck, Governor-General. In 1835, information arrived in Calcutta that the tea plant was found indigenous in some districts in Upper Assam, and in 1838, the Chairman of the East India Company sent a sample of this wild tea to the Society, which was referred to the Commitee of Colonies and Trade. Subsequently, the Society awarded the gold medal to Mr. C. A. Bruce, "for his meritorious services in discovering the indigenous tea tracts, and cultivating and preparing tea in Assam." It will be remembered by readers of the *Journal* that Mr. Berry White, in his paper on on the "Indian Tea Industry," denies to Mr. Bruce the honour of being the first discoverer of the tea plant in Assam (see *ante* p. 735).—*Journal of the Society of Arts.*

NATIVE INDUSTRIES;

AND THE COMPARATIVE SCARCITY AND DEARNESS OF MILK, BUTTER AND POULTRY IN CEYLON.

It is often said that success does not always attend the attempts of those officials, more zealous than the general course of their brethren, who take a real abiding interest in everything appertaining to the welfare of the people under their care, because their experiments are often at variance with native traditions, customs and general experience. Of this type may be considered the various endeavours by Assistant Agents and others to get introduced into our agricultural districts farm implements from the West even of the most primitive, simple construction, according to English notions. Time and money, eloquence direct and interpreted, influence and example, an infinity of patience :—all have been thrown away in the case of threshing and winnowing machines, of improved reapers and even ploughs. True, under the latter head, there are experiments still being made under the auspices of the Public Instruction Department, and we wish them all success. But certainly there is no more uphill work than to get an oriental agricultural people—conservative beyond the wildest dreams of old Tories—to try anything novel in respect of the industries which they consider peculiarly their own as having descended to them from time immemorial. But while we may be able to realize to some extent why new-fangled notions and especially machines are an abhorrence to the rural Sinhalese, it is beyond most Colonists to understand how it is that the people do not extend those industries which are peculiarly their own, in their own way, with the abundance of resources at their command, so that they may become adequate in some measure to the growing wants of the community around them. Why in fact are the everyday necessities of the household and table in Ceylon so comparatively scarce, and and why as markets are brought within reach of the people far and near, away in the interior as on the coast, do the supplies in place of improving and increasing seem to fall off both in quantity and quality? No one wishes to introduce new "machines" to better the people in respect of increasing the supply of milk, butter and poultry, and yet a people who are described as far from well off, and who are most advantageously situated,—say over a wide extent of the revenue districts of Uva, Kotmale, Matale not to speak of the lowcountry,—leave the towns within their reach unsupplied in respect of articles of daily consumption, in regard to which only inertness, downright laziness or the crassest ignorance can account for their failing to supply. A vast deal might be written about the immense room for improvement in the type of the larger stock appertaining to a rural population in Ceylon: in the breed of cattle, sheep, goats and pigs. But it may be urged that a native must be a man of some substance and capital to possess many of such animals, much less to secure the means of improving his stock. No such apology we take it can be offered in respect of poultry: the poorest of villagers at one time or other has the means, if he has only the inclination and industry, of improving and multiplying his stock; and yet how true the piteure in reference to this feature and other features of rural life among the farmers and peasantry of the Central and Uva Provinces is afforded by the old resident who writes to us as follows :—

"The question of *milk, butter and poultry*, I think you ought to take up again, as I recollect you did years ago. Within the last 23 years of my experience, I think I can honestly say that I have not seen one bit of improvement in the breed of cattle, horses, sheep, pigs, fowls, turkeys, guinea-fowls, pigeons, ducks &c., &c., so far as the native has to do with this industry, nor has—as I think your own experience will tell you—the *supply* ever over reached the *demand:* and this too notwithstanding that the finest breeds of these useful creatures have been and are being daily introduced by Europeans at great expense.

Exactly the same thing applies to Vegetables—the only exceptions, so far as I know, being the *cush-cush* yam introduced by Mr. A. Whyte, now largely cultivated in the Central Province and low country; and the *cho-cho* and *tree tomato* introduced by Mr. Nock and Dr. Trimen. Then what conclusions can we draw? What is the benefit of all this high-class education to the native, if no practical results follow? If the young inheritor of ancestral lands is too mighty a man to cultivate his own ground, surely it is his duty to instruct, and in a measure insist on his less enlightened countrymen under him, to do so. The subject is a *big one*, and I am glad to see that the Agents are doing their best throughout the Province to instil into the native *a desire to increase his resources of revenue*, which in most cases Appuhamy does not appreciate."

The Agents and their Assistants could not fail of a considerable measure of success if they really made their headmen understand that they attached importance to the villagers improving and adding to their stock of poultry and of supplying the towns within reach with larger supplies of vegetables, milk, butter, &c. Many years ago when detachments of the Ceylon Rifles were dotted at various stations over the island, we remember how a worthy Irish lieutenant secured the goodwill of the natives around his station by the practical interest which he—a farmer's son brought up very much on potatoes, pork and milk—took in improving the vegetable gardens, the poultry yards, piggeries and cattle of the neighbourhood. Never should Swift's words be forgotten by practical administrators in Ceylon :—"Whoever could make two ears of corn, or two blades of grass, to grow upon a spot of ground where only one grew before, would deserve better of mankind, and do more essential service to his country, than the whole race of politicians put together." Golden words to be remembered not simply by the revenue officer, but by every public servant, every colonist, every man in a position to influence his neighbours, native cultivators especially, in the island.

To illustrate more particularly the present condition of affairs, we quote again from a competent upcountry critic :—

"To come to more practical matters, how are you off for fresh butter in Colombo? I can tell you this luxury is at a premium here; contracts for the supply for a *year* are going a begging at a trifle over R1·50 per lb., and the retail price is R1·75 and even more. This ought to pay producers well, but the fact is that in and around Nuwara Eliya the fodder is so poor, and the climate so detrimental to the health of cattle, that dairy produce can be brought into the market at a much lower rate, at low elevations, where the pastures are more nutritious and the climate for stock better.

"Another bazaar commodity we pay very high for here is *poultry*. I know your appus charge you pretty stiff prices in Colombo, but what would you say to

A curry fowl	..	R0·75 to 1·00
Roasting ,,	..	1·50
Duck	..	1·75
Turkey	..	8·00 to 10·00
Goose	..	6·00 to 7·00

"These prices, I should think, would be apt to make the mouths of some of our lowcountry thrifty housewives water.

"But another view of the question is, why on earth do not the natives, who are being educated to such an extent, and who ought now to be wide-awake to their own interests, go in for poultry-farming; the outlay for a good cross-breed of fowls is small and the paddy is reared on their little farms. Not one single specimen of fowl, duck, turkey or even a *goose*, was exhibited by a native at the late Kandy Show!

"This industry alone would be an enormous source of wealth to the native; but the subject wants an abler pen than mine to work it out, and I think it is well worth your own attention, as an expounder of the public weal. Poultry in India, I see by bazaar prices, average about one-fifth the rate paid here!"

As regards fresh butter, it was very striking when depression through the failure of coffee was at its lowest, to find so many good housewives, and for that matter practical bachelors on up-country estates ready to supply the Colombo market or households! Butter could be got from nearly every planting district within reach of the railway. But with the rise and progress of tea, a change has come: time, attention and labour are required in another and more profitable direction. Were it so with the native also, of course there could be no good ground for complaint. But it is not the case that New Products—save to the most limited extent—can be said to interfere with native industry in the direction we refer to. Our very great dependence on India for supplies of not only cattle, sheep and goats; but of poultry and vegetables—and our large and increasing importation of tinned milk and butter—constitute a grave reflection on the rural Sinhalese and Tamils in Ceylon, and to some extent this must be said to reflect on the headmen and European public servants placed over them. Nowhere in this island, outside the towns, has the "earth hunger" grown to an extent to interfere with the means of each householder having a vegetable garden or poultry range. For the latter, the roadside and the field are freely open, and for eggs and fowls there is ever a ready profitable market. Why should Uva villagers be hard up with Nuwara Eliya and the Nanuoya station within reach for all the poultry, cabbages, &c., they can produce. Nothing but active travelling Agents and the establishment of rural Agricultural Shows with prize-lists can waken the people in these distant valleys from their torpidity and ignorance. The Kandy Show carries its own lessons on the very face of the list of exhibits. We need scarcely apply them. But one thing is evident, namely, that to improve and increase native exhibits at the "head centre," special efforts must be made in and around the villages. Each town or division ought to have its own Agri-Horticultural Show, and pleased we are to see that already Mr. Burrows is up and doing in Matale. As we have often said, at least every revenue station in the island ought to have its "Show," and there is room for Mr. Sharpe's and Mr. King's assistants to devise native gathering and displays at such stations as Gampola, Nawalapitiya, Haldummulla, Passara, Wilson's Bungalow, &c., apart from the big Agri-Horticultural Show at the provincial capitals.

BRICK TEA.—A tea estate proprietor asks if anyone in Ceylon has got a sample of "brick-tea"? If not, surely some of our brokers can readily get a few samples for the enlightenment of their customers who want to see how the Russian tea marke is served

COFFEE.—Finley Acker, of Philadelphia, in his admirable little magazine, *Table Talk*, referring to the coffee speculation, says: "Perhaps, in a later generation, one of our eminent statesmen may have sufficient moral courage and intellectual ability to solve the problem of how gambling in food products may be prevented, and yet our legitimate freedom in merchandising be maintained. The statesman who accomplishes this task will be more deserving of our thanks than if he discovered the North Pole, or completed the Nicaraguan Canal." —*American Grocer*, June 8th.

TEA IN HAPUTALE.—Until quite recently Haputale had always been regarded as perhaps less generally suited for the successful cultivation of tea than any other whilom coffee districts in the island, if we except Dumbera. But there does not seem to be any limit to the ubiquity of tea throughout the coffee districts, for we have just seen a few extracts from a report of Mr. C. S. Armstrong on the Gonamatawa estate, in which he spoke very favorably of its prospects as a producer of tea. He says:—"Tea here is an undoubted success; both at the very top and at the bottom of the estate it is doing equally well." The Haputale estates with their fine soil ought certainly to grow tea luxuriantly, and from enquiries we have made there seems to be no ill effect from the long drought generally experienced in June and July; and he growth of the young tea is not apparently checked in the slightest by it. We never entertained any doubt as to the success of tea in the Haldumulla, Koslande, and Kandapolla divisions of this district, seeing that the rainfall is abundant and fairly well distributed, whilst the soil is good. But the same may now be said of the whole district, and in this firm conviction tea is being rapidly extended, though planters do not care to substitute it for their fine coffee, so long as there is any prospect of good prices ruling for the latter. It will interest Uva men to know that a sample of Gonamatawa tea was within the last fortnight valued at 1/8 to 1/9 for Broken Pekoe, and 11d. for Pekoe Souchong—very fair prices as things go now-a-days.—Local "Times."

SUNFLOWER SEED.—We have been kindly furnished with the following particulars regarding the results of the experiment at Hanguranketa, to which Mr. Le Mesurier refers in his Administration Reports, from which it will be seen that the cultivation of the Sunflower, however ornamental, is not sufficiently profitably useful to tempt capitalists:—"A shipment of 14 bags was forwarded in July of last year—the first time I believe that this seed was ever sent from Ceylon to London—and our agents wrote back that the seed was not at all well known, though some of it was from time to time offered from Bombay and Calcutta. This parcel was sold at £6 per ton; and this rate was obtained through there having been another lot of 644 bags from Calcutta in the same broker's hands, who got the buyer to take the 14 bags at the same rate. The Ceylon Sunflower seed was inferior in quality to Calcutta. The latter was of a better colour and more free from husk than ours. The freight per steamer was 40s. per ton of 16 cwts., and the net proceeds amounted to £1. 1s. 11d. for a parcel of cwt. 13. 1. 22. showing a result of £0. 1s. 6½d. per cwt. A second parcel of 33 bags was sent in December last and this sold at £5 per ton. Freight was st 30s., and the net proceeds amounted to £3. 11s. 0d. or £0. 2s. 2½d. per cwt. The value in London may be taken at £5 per ton. The seed must be nearly white, round and oleaginous. The dried flower is thrown away after the seed is removed. This accounts for the *flower* and the *seed*; the stem is allowed to remain in the earth and it blossoms again. In my opinion, it is not worth cultivating for export. There is a good deal of trouble, and all for about 2s per cwt. result!"—Local "Examiner"

Correspondence.

To the Editor of the "Ceylon Observer."

THE RIGHT SEASON TO PRUNE TEA?

Matale, 21st March 1887.

DEAR SIR,—Have any of the Ceylon planters yet tried pruning during the hot months. In India, it is done during the cool weather when tea has ceased flushing. Why not try it here at that time? My idea is that tea should be pruned during March, when there are likely to be a few showers. In April more rain falls when the shoots can be plucked, so that we can pluck during our best flushing months.

As is done now, tea is pruned either in June, July, or September-October, when we usually have good heavy flushes, while during the dry non-flushing months we lose nothing by pruning. I finished pruning on the 10th of February, and last week I plucked those portions. Although as you all know we have had a very dry season, the growth is strong and succulent. I do not recommend pruning in January and February as a long drought then follows and the shoots are stunted, but what I recommend is pruning about three or four weeks before the rains set in. This might be tried on a few acres at different elevations.

B. E.

[We greatly regret that this letter should have got mislaid. The subject is one of much interest, and experiments over all the months of the year ought ere long to give decisive results. It stands to reason that, as a rule, pruning should take place at seasons when, though rain may not be actually falling, gentle showers may be speedily expected.—ED.]

HOWARD'S QUININE.

Stratford, near London, E., 15th June 1887.

GENTLEMEN,—Your issue of 23rd May contains a letter signed "Cheap and Pure Quinine." The statements in the above letter, with regard to ourselves, are absolutely false as we have never made, put up, or sold, any second quality quinine. To please our customers in different markets, we have several labels, some, for instance, not in English at all, but, whatever variation in colour, or language, the label shows there is none in the quinine inside the bottle.

The black and gold label was requisitioned from the East because the white and black in the rainy season sometimes developes stains.—Yours truly,

HOWARD & SONS.

[We are very much surprised that Messrs. Howard & Sons, in sending this letter, take not the slightest notice of the full and absolute correction offered of the mistake made by a correspondent, in the very next issue of our daily journal. Messrs. Howard & Sons receive our *Overland Observer*: on page 476, the letter they refer to appears, and on p. 478 the reply and correction by Mr. Ballard with our remarks—all *in the same issue* of our Overland paper! We repeat our opinion that Messrs. Howard & Sons should have only one label and one colour for their one quality of quinine to save any chance of misapprehension—especially in the East.—ED.]

PACKING TEA.

DEAR SIR—The following observations by one of the leading merchants in London, sent for my own guidance, are so valuable, that I think they should be made generally known. R. W. J.

"The SIZE of Packages most desirable for tea must depend on many circumstances and much on the quantity dispatched. But as some general guide, it is as well to bear in mind the practice and wants of the trade; but do not consider yourself too much fettered.

"Lots under 8 chests, or 8 half-chests, or 20 boxes, are technically 'small lots,' are excluded from the general sales and taken afterwards separately, when as a rule most of the trade have left the sale-rooms, and therefore, as a rule, cannot receive full justice; but even that has its exceptions.

"The bigger the lots are the more useful they are to, and therefore more liked by, large dealers, who would sooner have large lots of chests, but where they cannot would rather have half-chests than a few chests—the *many* are useful: if several of their travellers sell the same tea, several of their customers can get some of it. Large dealers are our most important, but not our only customers.

"A draft allowance to the buyer is made of 1 lb. per package on all packages weighing gross over 28 lb., *i.e.*, you receive a short payment to this extent. It is not much on large, but is a heavy charge on very small packages.

"It is well to sort tea if quantity be such that it can be sorted without making the breaks 'small lots.' It is well not to oversort—say, excluding dust, two sorts or at outside three sorts.

Let your *packages* of any sort of tea run even in both nett and gross weight—say for pekoe sou: chests 90 lb., half-chests 45 lb.; broken tea may run heavier, but let them be as uniform as possible, see that scales are right and give ½ lb. over in each package. We have this week a lot landing 13 per cent over and above invoice weights—a mistake in scales we suppose."

CEYLON TEA PACKETS FOR FOREIGN MARKETS.

Under this heading the Ceylon Tea and Coffee Company, Ltd., combine useful information and an advertisement, thus:—

29th June 1887.

SIR,—I am directed to forward you the annexed copy of letter received from the Chief Secretary H. M. Customs (London), regarding the above as being of direct interest to Ceylon tea growers. This privilege now acceded permits the repacking of Ceylon teas in any sized packets—whether in kilo, or kilogramme, Spanish pound or otherwise—suitable for foreign and Continental markets in English Bond (*i.e.* duty free). The Directors cannot but congratulate themselves upon having secured this privilege, which has hitherto been religiously refused to all applicants, and believe that a resulting foreign demand will arise for your teas. The Company has its own bonded premises and will be pleased to pack planters' teas duty free for any market, colonial or Continental, in any size case or package.—Yours, &c.,

J. C. P. AYRES,
Secretary.

(Copy.)

Custom House, London, 3rd May 1887.

The Managing Director Ceylon Tea and Coffee Company, 10, Golden Lane, E.C.

SIR,—With reference to your letters of the 18th and 26th ultimo, requesting that tea may be packed in French weights in bond, I am desired by the Board to state that, upon a reconsideration of the subject, they will not object to the parcels of tea being made up according to foreign weights, the officers being satisfied that the weight mentioned on the label attached to the package corresponds with the actual weight of the tea in the package, and on the distinct understanding that the accounts as far as they relate to this department, are in all respects, to be kept according to the British Standard weights, and that the regulations in other respects are complied with.—I am, sir, your obedient servant,

(Signed) H. MURRAY.

AN ENEMY OF COFFEE.

Coonoor, July 9th, 1887.

DEAR SIR,—By this mail I send you a small tin box containing what is to us a new insect, adhering to coffee and fig leaves.

Could you kindly name them ; and inform me if they are themselves injurious to coffee, or are allied to injurious insects?—Yours truly, W. R. J.

[A mealy bug belonging to the family Coccidæ (scale insect).—S. G.]

TRAVANCORE,—STILL TO THE FORE!

Pisgah, Trevandum, 13th July 1887.

DEAR SIR,—I appear before you, and (if you please) through you, before the world, to ask for a little attention to the interests of the planters in Travancore. Though few in number, and located in a place which looks small at one extremity of the map of India, they are of too great importance to allow the busy affairs of this world to pass on without asserting their share of influence in them. True it is that for some years past they have not done themselves justice in keeping their doings before the public ; and thus they have deprived the reading world in general, and yourself, Mr. Editor, in particular, of all the benefits which might have been received by the report of things here.

I therefore feel bound to assure all concerned, that the planting enterprise in Travancore has not dropped out of the world. It is admitted that there has been depression here as elsewhere : but it can also be asserted that there is much worth knowing, and that the planters in Travancore are making up to the determination of showing that they can well hold up their heads among the larger numbers of their brethren, wherever and whatever they may be.

I hope soon to be able to present to you for publication a good statistical account of the estates in Travancore, and the work on them : and I write this letter as merely introductory.

In this country, as in Ceylon, tea is taking the place of coffee ; and I have an extract before me which gives good reason to hope that success awaits the cultivation of tea in Travancore.

In Messrs. Wilson, Smithett & Co.'s circular, May 1887, they say: "A small shipment of unassorted Travancore from Seafield estate offered this week showed most excellent quality and strength ; and realized the full price of 1s. 7d. per lb. The teas from this district will undoubtedly become popular, if due regard is paid to manufacture ; they possess a flavour very similar to that of Ceylon tea, which is often combined with the strength of Assam." I may add that tea from Conmudi estate realized about 1s. 4d. in the London market. *Au revoir.*—Yours faithfully, JOHN COX, Chairman, Travancore Planters' Association.

[We shall be very glad to publish the promised information about a district in which Ceylon planters have ever taken a deep interest (since the days when the Grants and the Frasers sought fresh fields in Southern India. Has our correspondent noticed that Mr. Berry White in his Jubilee Lecture on tea declared the Travancore soil to be superior to that of Ceylon.—ED.]

COFFEE IN JAVA.—It will be seen from the Netherlands Indian news quoted from the *Straits Times* in another column that the Government coffee crop in Java is estimated at only half a million piculs for this year, the cause of this decrease being leaf disease. We hope that the Dutch planters will not be misled by the statement of a French journal quoted by the Deli *Courant* as to the immunity of Liberian coffee from *hemileia* : experience in Ceylon has not borne this out.

PROSPECTS OF THE JUTE CROP IN BENGAL.—The report to the end of June 1887 is as follows:—"On the whole, so far as can be judged of at present, it may be said that the area sown this year is about ten per cent. above that of last year; and taking into consideration the facts that the area sown is above the normal and that the deficient outturn caused by floods in some districts will be counterbalanced by the bumper yield in others, it may be expected that the total outturn will be a full average. Much will, however, depend on the distribution of rainfall in the latter half of July and be ginning of August."

COCA AND CINCHONA.—Recently Dr. H. H. Rusby gave an interesting account before the Academy of Sciences of a trip across the Continent of South America. He was sent out by a prominent drug firm to make a special study of coca and cinchona. He landed on the west coast at Arica in Chili, crossed the Andes on foot to La Paz reaching the head waters of the Madeira River, down which he floated until he met the Amazon, which carried him to the coast. He was absent two years, during one of which he was supposed to have been lost, as no word was heard from him. He had a tough time of it with the natives. The scientific world, however, has been the gainer. Dr. Rusby brought back 60,000 specimens of plants, a large number of which are new to science; several thousands specimens of birds and larger animals. Among his discoveries was a new specimen of fish which has regular teeth, set in sockets, is carnivorous in its habits and regularly masticates its food. Another species kills its prey by a blow or stab of its pectoral fin, which is connected with a poison sack. Columbia College has given Prof. Rusby a room for the preparation and classification of his collection which work will require several years.—*American Grocer*, June 8th.

"THE YOUNG TEA PLANTER'S COMPANION."—The literature of tea planting and manufacture is becoming abundant. The latest addition to the Bibliography of Tea is "The Young Tea Planter's Companion, a Practical Treatise on the Management of a Tea Garden in Assam." The author is Mr. F. T. R. Deas, nephew of the Lord of Session of the same name, to whom the work is dedicated. Although prepared for the latitude and local circumstances of Assam and laying down the rule that all pruning should be finished in January, if possible, there is much in the little book which is of general interest and usefulness. It is published for the benefit of "supernumerary assistants" suddenly raised to the charge of a garden and who have had little chance of working out estimates, &c. Amongst the matter are full instructions regarding buildings, illustrated by drawings. We notice that there is a special appendix devoted to praise of Greig's "XL all" tea machinery, which has long been to us as puzzling a problem as the Sphinx. Prose passes into poetry in the engineer's own description of his machines,

"———— With his hair on end,
At his own wonders wondering,"

and now Mr. Deas says they work sweetly, bu where ? We have never seen one at work or heard of it in Ceylon, except in a mysterious reference to Messrs. Brown & Co. The machines are exceedingly cheap, and if they are equal to the descriptions given of them, why did Messrs. Davies & Co., Messrs. Brown & Co., and the maker never succeed in introducing them to Ceylon factories ? We may notice Mr. Deas' book further when we have had time to go over the varied contents.

COCONUTS IN THE NORTH-WESTERN PROVINCE.

(Written for the "Tropical Agriculturist.")

Repudiating any intention of crying down the main agricultural staple of our beautiful and fertile island—Tea—it would seem to the writer a vast pity that Europeans have not, since devastation overwhelmed their coffee fields, turned their eyes in search of an investment more safe, more profitable and more permanent. There is and there will be success—immense success—in tea cultivation, that the question has already been raised "How long will it last?" That *all* cannot succeed is a certainty, that some being able to pay working expenses for a time will ultimately succumb to a glutted market, and be ruined, is more than a possibility. Why then not seek out a product which is indigenous* to Ceylon, the fruit of which is, in part, consumed by inhabitants of Ceylon, the fibre of which is ubiquitous in Ceylon—the very leaves of which (besides other parts of the tree) may be turned into rupees, viz:—the coconut, which may be said to yield returns up to the age of 100 years—a permanency for the next two or three generations. The answer to all this is trite, and time-worn as it is fallacious:—"Oh, I cannot wait 12 or 15 years for a return, the coconut is essentially a native-grown product and only suited for natives, with whom an Englishman cannot possibly compete successfully—give me something that makes money quicker than that"—and so, without further troubling the mind, the subject is dismissed and the idea scouted as preposterous. Let us see. In the first place the coconut tree properly treated and on fair ground may be expected to yield *profitable* returns in the 6th or 7th year, irrespective of any profit made by growing minor products *(e.g.* plantains*)* on the same land, at a comparatively small outlay; secondly, the very fact of its being so extensively cultivated by natives, who know the real value of money far better than many Englishmen, ought to prove its desirability as an investment; thirdly, it is hardly a case of 'competition.' The native, as a rule, leaves the trees very much alone, though he is now becoming more enlightened in his views of cultivation and manuring, which the European would be able to carry out scientifically and, with capital to back it up, far outstrip the efforts of his native neighbour; and so, though spending more on his trees, he will get larger returns and learn that there are few trees which repay so well any trouble or money expended upon them as the coconut. The very permanency of the plantation, with enhanced value of land year by year, is a point not to be forgotten; and though it will not yield enough profit to send its owner home—a millionaire—in a short time, it will always form a competency for him and his children, ay, and their children perhaps. The activity of the natives in the North-Western Province above Madampe is most marked, especially during this and last year—old gardens have been cleaned up and replanted, new gardens have been formed, and from Chilaw to Puttalam, formerly a vast stretch of jungle, the road is now fringed with well-kept and thriving gardens, some small, some large, and each monsoon sees farther extension. Transport is handy, land is cheap, and there is a ready market for all one can grow in the way of ground crops. The one want of the district is English capital and English enterprize—given this, and in a few years this district will be the finest and most famous in the island.

George D. Miller.

Rajakadaluwa, Chilaw, July 1887.

* Not so! Though the coconut has been so long established as to have found a permanent and congenial home here; yet it is clearly proved to have come to Ceylon, most likely from the Indian Archipelago, where de Candolle thinks this palm had its origin.—Ed.

OBSERVATIONS ON COCONUT PLANTING.

(By a Native.)

The natives, especially in the southern districts, grow coconuts better than any planter here in the Western Province. They are generally small land-owners, and all the lands excepting of course paddy fields are planted with coconut trees. The cultivation is continuous; when the 1st batch of trees gets taller, they plant another batch, &c. It is not uncommon to see coconut trees of three distinct ages on the same land. I mentioned that the native cultivator of the Southern Province does better than the planter who gets his estate manured and digged with considerable expense. The fact is that the soil and the climate of the Southern Province agree better. The coconut may be called a very hardy tree. It thrives in sandy soils as well as in the most hard cabooky hills, but in the former class of soils it produces much better. I have seen in the Southern Province some trees in sandy soil yielding above 50 nuts each in a single season. But another observation made by me is, that commencing from Galle, the coconut tree produces very well on the sea coast, but as we get nearer to Colombo we see a falling-off in the produce, and at last from Kalutara upwards, we see a lot of trees near the coast, but with almost bare tops. But how can we account for this falling-off in the fertility when it reaches Colombo. The same kind of soils at Galle produces five times better. My opinion is that this is owing to the change of climate.—W. A. D. S.

Minuwangoda.

ASSAM COMPANY.

At the meeting of the above company, held on Monday, the following report was presented:—"Your directors present to you their report of the operations of the company for the year, which ended Dec. 31st, 1886. The quantity of tea packed and despatched from the gardens during the past season amounted to 2,339,006lb., which is 551,194lb., less than the superintendent's estimate, and 249,769lb. less than was packed in the previous year. This short outturn has been accounted for by Mr. Philips in the following terms:—'1. Deficient rainfall during the early part of the year, and the prevalence of cold weather throughout July, August, and September. 2. The efforts made to gather finer leaves than in 1885 in the early part of the season caused a diminution of quantity. 3. The necessity of easy treatment of the trees in the gardens in all divisions, to enable them to recover lost vigour, and to maintain them in future good yielding condition. These causes specially accounted for short crops in the gardens of the Satsooeah and Gelakey divisions, and the easy treatment of 1886 will undoubtedly produce good results in 1887 both in quantity and quality. Your directors are not satisfied of the sufficiency of these causes to account for the disappointing results of this year. They have come to the conclusion that considerable changes are necessary in the working of the company, and they have under their consideration a scheme for its reorganisation and management, under which packing of the tea of each large garden will be done on the spot, instead of being dealt with at the central factory in Nazerah. This, and a more direct responsibility on the part of the managers of the divisions, will, the board hope, meet some of the difficulties under which our administration has been labouring, and produce better results in future. Owing to the large quantity of Indian and Ceylon tea imported, prices were lower last year than they have ever been before; and although the first shipments of our crop were of excellent quality and sold well, the general average price fell as the sales advanced to 11½d. per lb, or 1½d per lb less than was obtained for the crop of

the previous year. The expenditure in India during the year was £101,068 17s 8d taking the Rupee at par, or £80,642 2s 7d., after deducting the difference in the rate of exchange, being £1,371 5s 8d more than the expenditure of last year, and £7,150 0s 4d. less than the Superintendent's estimate. The results for the year stand thus:—Tea sales, gross proceeds, £114,810 15s 2d; tea seed sold in India, £2,739 5s d; sundry receipts in India, £1.673 7s; sundries, £350 14s; total, £119,574 1s 9d. Expenditure in India at par, £101,068 17s 8d; less Exchange £20,426 15s 1d; total, £80,642 2s 7d. Expenditure in England, £21,653 13s 4d; total expenditure, £102,295 15s 11d. Net profit, £17,278 5s 10d. The profit of the year, therefore, amount to £17,278 5s 10d to which is to be added the balance brought from 1885 of £2,074 10s 1d, making a total of £19,352 15s 11d, out of which we propose to pay a dividend at the rate of 10 per cent. for the year, and to carry forward £636 15s 11d. In January last an interim dividend was paid at the rate of 5 per cent, or £1 per share, and the balance of 5 per cent., or £1 per share, will be payable on July 1st. Mr. Phillips estimates the crop of manufactured tea for the current season at 2,629,100 lb. and the expenditure in India at R10,95,684.—*H. & C. Mail.*

[Of course the Directors of the Assam Company know their own affairs better than outsiders, but certainly outsiders will feel that the "management" has been wrongly blamed for what it could not help—deficient produce and low prices.—ED.]

THE SCOTTISH ASSAM TEA COMPANY, LIMITED.

The meeting of the above company was held on Wednesday. The following is an extract from the report submitted to the meeting:—"Calculated on the usual basis of 4lb. green leaf to 1lb. manufactered tea, the total produce during season 1886 amounted to 202,584lb. of tea, as against 187,805lb. in 1885, being an increase of 14,779 lb. Deducting loss by weighing, samples, and usual buyers' allowance of 1lb. per chest the total quantity of tea available for sale amounted to 199,822lb. as against 185,611 lb. in 1885, being an increase of 14,211 lb. This has all been realised, producing a gross sum of £13,812 1s. 11d., being an average of fully 1s 4½d. per lb. as against an average price for 1885 of nearly 1s 4½d, per lb. From the profit and loss account, it will be observed that the total revenue for the year 1886 amounted to £14,892 4s 3d., and that the total expenditure was £9,591 4s 1d, showing a surplus on the year's transactions of £5,301 0s 2d; to which there falls to be added the balance brought forward from last year, £439 6s 4d, making a sum at credit of profit and loss account as at December 31st, 1886, £5,740 6s 6d. Until the resources of the company are more fully developed, and its dividend-earning capabilities placed upon a more solid basis, your directors are of opinion that, with the view of obviating fluctuation of the dividend, any surplus profit beyond what is necessary to pay a dividend of 5 per cent. should be carried to credit of a reserve fund account, to be applied should occasion arise, towards the equalization up to 5 per cent. of the dividends of subsequent years. They recommend this course the more strongly on the present occasion, because, as will be seen on comparing the accounts of the two last years, the surplus to be so carried to reserve fund account arises entirely from the exceptionally favourable rates of exchange which prevailed during 1886, and not from extra profit derived from the ordinary operations of the company. They accordingly propose that out of the above sum of £5,740 6s 6d, £1,000 should first be carried to said reserve fund account; that a dividend of 5 per cent, free of income-tax, requiring £3,979 10s, should next be paid to the share-holders; and that the balance of £760 16s 6d should be carried forward to next account, subject to deduction for directors' fees, income-tax, and commission payable to the manager all for year 1886. This is now the fourth consecutive occasion on which your directors have had the satisfaction of proposing a 5 per cent dividend, and they are hopeful that under the arrangement, before referred to this rate of dividend may at least be maintained. The number of coolies on the gardens at Dec. 31st, 1886, stood as follows:—342 men, 279 women, 88 children—total, 709. The average monthly number of labourers on the gardens during 1886 was 721, and the percentage of time-expirees who renewed their agreements was 72·2. Owing to the gradual increase of the cultivated area, the gardens had become somewhat undermanned as at December 31st last and that with an increased labour force, and consequent higher state of cultivation, it is thought that improved results might fairly be anticipated. Accordingly since December 31st the coolie staff has been considerably reinforced, and the number of coolies on the gardens at March 31st, 1887, was 861. It is hoped that the expense necessarily entailed by the importation and maintenance of this large additional number of coolies will be fully recouped by the results of the greater facilities thereby placed at the managers' disposal for cultivation, plucking, and manufacture."—*H. & C. Mail.*

COLONIAL INDUSTRIES.

NATAL:—TEA-GROWING ON THE NORTHERN COAST. SUCCESSFUL RESULTS.

Mr. Morton Green has just returned from a visit to the tea gardens of Victoria County, where he has been the guest of Mr. J. L. Hulett, M.L.C. of Kearsney Estate, Nonoti, and is quite surprised at the progress the industry has made in that part of the colony. He says Mr. Hulett has 170 acres at present under cultivation on his farm, and besides this has 2,000 acres in hand which is in every way suitable for tea growing. In the immediate neighbourhood of Kearsney Messrs. Lyle & Reynolds have 100 acres under cultivation with the manufacture of the tea going on at the same time. Adjoining Hulett's place, Clayton and Ashwell have 30 acres under cultivation. Hindson 25 acres Peachy 20 acres, Thring 10 acres, and Balcomb 10 acres. Mr. Hulett informed Mr. Green that he planted his total the first five acres as an experiment in 1880, and crop this season will be about 55,000lb. of manufactured tea. Mr. Hulett estimates that the total weight of tea made in the colony this year will exceed 80,000 lb. and he has already sold his crop at a very encouraging figure. Having the foresight to plant timber-bearing trees ahead of his tea culture the result is that Mr. Hulett is now sawing up his own wood for the purpose of packing the tea. He has now sufficient material in hand to supply himself with packing cases for many years to come. On this estate Mr. Green also saw Davidson's "Sirocco," or tea-firing machine, in full work, and giving the most satisfactory results. Mr. Hulett, we understand, also uses Greig's "Drier," and Jackson's "Excelsior Roller," the whole being driven by an excellent engine, which also drives a circular saw for cutting the planks, mealie mills, &c. In fact the impression left on Mr. Green's mind, combined with his recent home knowledge, was the ensured success of the Natal tea-growing industry. The plantations, he says, were in excellent order throughout; and as an answer to those who carp and cavil at the tea industry being interfered with by failure in the tea trees, Mr. Green was shown a hybrid tea plant planted twenty-four years ago, which measures across the top ten feet in diameter, being a sort of grandfather to the surrounding plantation. As a further illustration of the hardiness of the tea culture, Mr. Green was told that Mr. Brickhill has two similar trees on his estate; and these places of culture being widely apart, viz., the Umbilo and Nonoti, it is only fair to assume that nearly the whole of the intermediate country would be suitable for tea growing, which view was endorsed by Mr. Hulett during a conversation with his guest Mr. Green. We understood that within a three-mile radius of Kearsney there are 370 acres of land under tea cultivation and doing exceedingly well. Mr. Green further reminds us that in consequence of the increased work entailed on him by the tea industry, Mr. Hulett has been unable to avail himself of the enormous yield from his orchard,

where we are assured fruit in bushels of all descriptions lies rotting on the ground for want of transport and a market. As a proof of Mr. Hulett's thorough earnestness it may be stated that his homestead has been considerably neglected in order that all his energies and capital might be devoted to erecting necessary buildings and machinery used in the manufacture of tea. In his labours Mr. Hulett is ably assisted by a grown-up family of five sons. One of them takes charge of the machinery and saw benches, another solders up the tea chests, another works as a carpenter, while the others look after the labourers in the plantation. Mr. Green showed us some excellent views of the Kearsney estate, comprising the different fields under cultivation, the tea-house, &c., which all tend to prove what can be done by perseverance to remove the stigma on the colony that Natal is a land of samples.—*Natal Mercury*, May 4th.

[We were going to say that the labour difficulty would tell against Natal, but when the father and sons of a family work, as here described, the difficulty disappears.—ED.]

GENERAL PLANTING REPORT FROM THE CEYLON LOWCOUNTRY.

Hapitigam Korale.

So far July has been as wet as any former part of the monsoon season ; a wet July is not common in this part of the country but it occasionally occurs. For the last three months we have had rain ample for all our purposes and now we are getting rather more than we want. It is the scanty rainfall between the middle of December and the middle of April that tries us : our best, that is our richest soils do not stand dry weather well, and coconuts—our sole dependence—suffer accordingly. A tree that carries from six to ten gallons of water at its top needs a constant supply from the soil. The stiff, compact, impervious soil absorbs little water, however abundant that may be on the surface, and it very quickly yields that little to sun and wind when the supply ceases. The bankrupt soil ceasing to pay its debts to the tree and it in turn becomes insolvent, the leaves break down prematurely and hang about the stem ; as fresh flowers open they speedily drop all their germs, then the half-grown nuts drop and those that weather the season do not finally attain half their natural size. When on this deep, rich, heavy loam a coconut tree has succeeded in getting its roots down into a region, to which ordinary droughts do not reach, its fertility exceeds that of any other description of soil. I am not aware that any experiments have been instituted with the view of rendering this kind of soil more absorbent, but it seems probable that deep ploughing or digging, a moderate dressing of quicklime and a heavy one of river sand where available, would bring it more creditably through the dry seasons and very much to the profit of its owners. For my own part I have arrived at the opinion that a light loamy sand though very inferior in the elements of fertility is infinitely to be preferred. It is easier and cheaper to supply the necessary fertilizers to a comparatively poor soil that is mechanically perfect than to put and keep a stiff and impermeable one of very much higher fertility in the necessary mechanical condition.

Thirteen years ago I planted a piece of this rich clayey loam, but the jungle grew up so rapidly that in six months it was a close cover ten feet high and when in the following season I again cleared it I found that the wild pigs had destroyed every plant. In replanting it in 1875, I rooted out all the jungle. The failures of the second year were fully 50 per cent from the action of pigs and other causes, and for seven years I kept planting failures annually with the result that fully ten per cent of vacancies then existed and still remain as it was found impracticable to get up young plants. The original plants were very promising and many of them began to bear in the sixth and seventh years, but from that time there was a falling-off in cultivation and during the tenth and eleventh years nothing was done to it. Now in the twelfth year only 43 per cent of the existing plants are bearing or show an intention of bearing, and not one of the supplies either have done so or show any sign. Some of the larger trees bear very heavily above 100 nuts in the year and stand the dry seasons without much signs of distress, but it is to me very evident that the soil is year by year becoming more compact and impermeable. I have cleared it of undergrowth and have set a herd of cattle to keep down the grass and I propose during the N.-E. rains to dig it all over to the depth of 8 inches and keep it in fallow for twelve months, operations : that will absorb all its proceeds for two years.

On another place I put out 300 plants in 1879 on light and rather poor soil. Nothing was done for it except keeping down the jungle. One-half perished in the first dry season, and as the cattle had the full run of the ground for seven years, a large percentage were regularly eaten down and dwarfed. In May 1886, there were 100 that had formed a more or less length of stem and of these six had fruit and another six had produced barren flowers, in one case not less than 14. In July last year I dug the land mamotie deep, giving three quarts of fine ground bones to each tree that had a foot of stem and nothing but the benefit of the digging to those not so furnished. During the twelve months I have gathered 120 nuts from the six trees first in bearing, 29 others have produced fertile flowers and 30 have either produced barren flowers or have shown their first flower sheaths and I estimate that forty more will come in within the next twelve months. Then as to the rate of bearing: the six trees that began to bear early in their seventh year will in this their ninth year yield 400 nuts to which the 29 that have come in during the eighth year will add 600, so that the average yield will be about 25 nuts, several of the best trees doing their part with over 100 each. Many of the trees have made ten feet of stem during the year and the younger trees are equally rapid in their growth, the length of leaf having in many cases doubled. The land was exceedingly foul when I took it in hand, saturated with the seeds of annuals and the roots of perennials. I fenced in a couple of acres and have kept it fallow weeding and digging out roots of the perennials, which I have pretty well mastered, but the annuals seem inexhaustible, every shower of rain bringing out a fresh crop hardly less than its predecessor. I have given this two acres about 20 tons of cattle shed manure and expect great results if not from the secondary cultivation I am attempting, from the earlier bearing of my trees. I allowed the pasture grass to grow on the remainder of the land and trusted to hand weeding. I have got it into pretty good order now, but when I have foul land to deal with again I will keep it in fallow till the work is done for weeding. The grass has cost more than all the other work.

I have planted 20 acres last year and a like extent this year, so that I have now about 90 acres of coconuts, quite enough for me to manage. I have wrought on the goyiya system which gives the neighbouring villagers a part of the fertility of the land for clearing it. I get about R10 per acre for my share of the crops and R7 for the firewood; in all R17 per acre. Plants, holing, &c., cost R7 per acre, so that a profit of R10 remains. I fancy that the R10 saved on felling and clearing, R10

gained by the land share of the crops and R10 saved in keeping the jungle for the first eighteen months will be the full value of the fertility taken out of the land especially as years must elapse before the coconuts can fully occupy the land and the land *will* grow something that will cause work.

THE SIZE OF THE BREAKS OF INDIAN AND CEYLON TEA.

We understand that the following notice has been posted in the Commercial Sale Rooms, and that it has received the assent of several of the largest operators in the market:—"That on and after September 1st next, all breaks of Indian, Ceylon, or Java tea of smaller quantity than twelve chests, twenty half-chests, or thirty boxes shall be considered small breaks, and sold at the conclusion of the sale." Several buyers would have raised the limit even higher, but thought it better that changes should be made gradually, so as to disturb existing arrangements as little as possible. The fixing of September 1st as the date on which the new rule shall take effect is because of the general opinion that during July and August the number of breaks of all kinds will not unduly tax the powers of the trade. But it is anticipated that a deadlock will inevitably arise in September unless some such change as is now proposed takes place, as supplies during the autumnal months are heavier than at any other time of the year. Importers and planters will have ample time to communicate with their Calcutta agents before the change takes place. But in any case they cannot be much surprised at the decision of the buyers, if they have followed the discussion that has been going on in our columns at intervals during the last year or two. If Indian tea is to take the lead, the opinion in the Lane is that we must soon see breaks of 50 or 100 chests the rule instead of the exception.—*H. & C. Mail*, July 1st.

JAVA AGRICULTURAL COMPANIES.

AMSTERDAM, June 29th.

Several banking institutions in this city connected with the Java trade have issued their annual reports during the past week, and all show more or less unfavourable results. From the profit and loss account of the Netherlands Trading Company for last year it appears that the commission earned by the factory at Batavia amounted to fl. 632,999, while the interest account shows a profit of fl. 987,165, the insurance account a profit of fl. 10,051 and an account of fl. 290,205, was earned on drafts, there being thus a total profit at Batavia of fl. 1,920,421. From this amount the following items have to be deducted:—Charges, fl. 409,997; writing off on agricultural undertakings in Netherlands India, fl. 1,847,494; bad and doubtful debts, fl. 90,942, and the profit and loss account of the Batavia agency, showing thus a total deficit of fl. 428,012. As regards the general profit and loss account the following items are published:—Writing off on agricultural undertakings in the West Indies and on factories there, fl. 438,689 ditto on bonds in said undertakings fl. 197,818; oss on goods consigned to China, fl.575, and general charges, fl 246,897. The following profits are booked:—Commission, fl. 834,396; interest, fl.1,330,237; total with other revenue, fl.2,218.025. The net profit is only fl.906,031, out of which a dividend of only fl.25 will be paid to shareholders. The shareholders of the Netherlands Agricultural Company held their annual meeting on the 18th instant, at which the directors presented their report. The result of the operations of the company has been unsatisfactory during the past year, which is chiefly to be ascribed to the low prices ruling for sugar. As many sugar manufacturers, working under contracts with the company, were unable to meet their engagements, the directors are obliged to afford considerable assistance and to close the profit and loss account with a deficit. During 1886 the company was concerned in thirty-one sugar manufactories, producing 959,616 piculs, which realised an average price of fl.76½ per picul, against 986,615 piculs at fl.10 64 in 1885, which is fl3 less. The company has continued relations with nine undertakings in coffee, one in coffee and cinchona, two in tea and cinchona, and one in cinchona, which have shown satisfactory results. According to the profit and loss account the commission earned at Batavia amounts to fl. 109,664 and the interest to fl. 1,144.938, while an amount of fl. 447,823 was expended in interest and redemption of the existing bonded loan and fl. 838,000 for reserves on doubtful debts, the deficit being thus fl. 58,031. The balance-sheet of the head office shows an amount of fl. 14,165 for commission obtained for the sale of produce, and fl. 31,118 for general charges and closes with a deficit of fl. 75,192. An amount of fl. 3,009,015 has been invested in stocks, while fl. 2,000,090 are deposited with the Netherlands Bank in Netherlands Stocks, against which the Java Bank has opened a credit in favour of the representative of the company in Java to avail of in case a profitable business could be done in loans or investment of money.

From the report of the Amsterdam Trading Company it appears that the profits earned on goods amounted to fl184,843; on commission, fl151,607: on interest, fl57,217 leaving a balanced profit of fl155,966, to which is added a commission of fl42,247, and the interest obtained by the head office of fl75,557; the total profit is fl296,093. After writing off fl43,805 for charges, fl15,557 loss on goods, and fl3,750 for the redemption of bonds, there remains a net profit of fl232,919, or more than 9 per cent. of the paid up capital of the company. The directors propose to use the profit for the promotion of a special reserve of fl199,667, and for covering a loss on debtors in Java during 1887 of fl32,000 while a balance of fl1;251 will be carried to new account. In consequence of the unfavourable condition of the Java sugar industry, and a probable loss of more than fl300,000 to be sustained from one of the sugar factories, in which the company is concerned the directors do not distribute among the shareholders the amount of interest earned during 1886, but they intend to establish an extraordinary reserved fund to the amount of fl400,000, to cover the loss named above.

In order to assist the Java sugar industry in its depressed condition, the tariff for the 1887 crop has been reduced, and with several undertakings contracts have been closed.

It may be said that there is much discontent about the working of almost all limited companies. Losses upon losses and "writing off" of enormous sums are every year laid before the shareholders, and the opinion is gaining ground that the managers are not acting with the prudence which should be expected from them.—*L. & C. Express.*

THE DIRECT TEA-EXPORTING COMPANY of Osaka made their fourth shipment of tea to America this season on the 14th inst., which consisted of 385 chests valued at from $20 to $35 per percul.—*Japan Weekly Mail.*

WYNAAD PLANTERS' ASSOCIATION.—From the proceedings of a general meeting, held on 6th July 1887, we quote the following:—

Cinchona.—The Honorary Secretary stated that the figures were fairly complete, and that the number of trees growing in Wynaad from the Ouchterlony Valley to North Wynaad, excluding Nellacotta and Neddiwuttum and Districts North and East of those boundaries, is given at:

Succirubra.	Ledgers.	Hybrids.
7¼ millions.	2½ millions.	⅝ of a million.

and that the outturn of bark in the next three years was estimated at 5 million lb. This includes very little Ledger bark, most of which would not be harvested before 1890. The Honorary Secretary was requested to communicate these figures to Government, as many members objected to giving details of their separate estates.

THE FUTURE OF THE NORTHERN TERRITORY OF AUSTRALIA.

LECTURE BY THE HON. J. L. PARSONS.

At the Adelaide Town Hall on Thursday evening, May 19, the Hon. J. L. Parsons (Government Resident in the Northern Territory) delivered a lecture entitled "The Northern Territory, with a Glance at Eastern Asia."

In the course of his lecture Mr. Parsons said he wondered how many in the audience could give him approximately the number of square miles and acres the Territory contains. The area is 531,402 square miles, and the acreage is 340,097,200 acres—a sufficiently extensive country, one would suppose, to inspire confidence and courage. At 5s. per acre it is worth more than £85,000,000 sterling. He found this fact received everywhere in the East with open-eyed astonishment, and frequently with thinly veiled incredulity. In this vast expanse of country there are, it is true, stony wastes, and so far as haphazard exploration has gone there are waterless areas and rocky and sterile ranges. But then there are vast rolling downs, wide well-grassed plains, rich alluvial flats, large navigable rivers, and metalliferous areas exceptionally rich in gold, tin copper, and silver. Port Darwin is the one great harbour of the north coast of Australia, with no competing second for situation, size, or safety. The rivers of the Territory—the Macarthur, Roper, Limmen, Hodgson, Robinson, Glyde's Inlet, the three Alligator rivers, the Adelaide, Daly, and Victoria—are so many waterways made by nature to settle and stock the lands. He could not say that squatting has been, even generally, up to the present a paying investment. But where in the wide world have pioneer operations been immediately successful? He would like to say that through good report and evil report, in the face of great difficulties and losses Mr. C. B. Fisher has acclimatized shorthorn cattle stocked various stations, and has for years supplied the whole population with good beef. As to mining, it was the construction of the overland telegraph which led to the discovery of gold. It would be tedious to trace the history of successive gold discoveries or to enter upon descriptions of the Margaret, the Twelve-mile, Pine and Bridge Creeks &c. From the Stapleton to the Stow, a distance of 100 miles, gold has been found. Quartz reefs have yielded up to 60, 70, and 80 ounces to the ton of stone. Pickets of the precious metal have been lighted upon of wonderful richness, and alluvial deposits have been unearthed which have made the miners' eyes gleam with a satisfied joy. Over 5 tons of gold are known to have been exported from Port Darwin, and year after year from 20,000 to 30,000 ounces pass through the Custom-house. A cake of 1,000 ounces of retorted gold from the Eleanor and Telegraph Claims will be seen at the Exhibition. Other valuable metals—tin, copper, and silver—are spread over a wide region, and the Rev. Tenison Woods confidently asserted that the country was exceptionally rich in minerals, only a small portion of which has been made known to the public. Of agriculture there is up to the present much less satisfactory accounts to give. It happens unfortunately in connection with the cultivation of land that no new country appears to profit by the dear bought experience of planters in other places. For the failure of agricultural experiments in the Territory, preventable blunders, such as the selection of unsuitable land, wasteful expenditure, and bad management, will in part account. He could not admit that it was owing either to unsuitability of climate, deficiency of rainfall, or poverty of soil. With the exception of a small area nature emphatically indicated by the ironstone rock which crops up that she never meant sugar-cane to be grown at certain places. At the Daly River the soil is magnificent, but the promoters who held the conditional grant of 20,000 acres lost heart owing to the repeated failures at Delissaville and the disastrous decline in the price of sugar. The present representative of agriculture on a large scale is Mr. Brandt, whose sugar plantation and mill are at Shoal Bay; but he had not plucked the fruits of success. The Chinese have gathered harvests of rice and sugar-cane from limited fields. It is to the banks of the rivers we must look for cultivation. There we have the soil which through innumerable ages, with an annual rainfall of over 60 inches, has been washed down from the hillside and upland. There water is stored by nature at the bottom of the hills for irrigation, and there are tidal rivers for waterways. The picked spots on these rivers are suited for coffee and a variety of products; the inferior areas for rice. The general character of land and scenery on the rivers is wonderfully similar to the vast rice regions of Saigon, only our soil has the advantage as to quality, and is virgin. In the new Government Garden sugar-cane, rice, tapioca, jute, ground nuts, indigo, ginger, and sesame are growing luxuriantly. There is a finer small crop of sugar-cane there than any he saw during his pilgrimage through the East, and much credit is due to Mr. Holtze, the Curator of the garden, for the intelligence and knowledge he manifests in his work. He was sad and sorry about agriculture, but he did not despair. People must not make any mistake about the climate. It was distinctly tropical on the north coast, and that fact must lie at the base of all action there. The mean temperature all the year round is 78°, and the thermometer has never been seen lower than 58°. The atmosphere is dank, steamy, and heavy, with moisture during the wet season, and dry parching, and malarial during the dry season. He was in good health there, but though they never have yellow fever or cholera or smallpox, most of them get smothered with prickly heat, they melt almost with moisture, and they have to beware of malaria with its fever and ague. The question of whether life not only is worth the living, but whether it can be lived at all, depends upon the liver; that important organ becomes a source of constant anxiety. For the labouring white man it must be said that he who puts forth his strength in the sun for eight hours a day during the whole year through finds out where he is. So long as the great existing meteorological laws last the climate will be tropical, and all that can be done is to minimize the evils that result by care, by change, and by rest. Then there is a great medley of races. It is estimated that all told the fixed and floating white population is about 2,000. There are between 4,000 and 5,000 Chinese, a sprinkling of Malays, Cingalese, and large tribes of aborigines, who claim and hold the country according to their tribal boundaries, and who are treacherous, cunning, powerful, and murderous. The facts mentioned must be kept distinctly in mind if the right answers are to be found to the next question—"What ought South Australia to do for the Northern Territory?" He thought it would save him from a great deal of rather perilous walking between naked swords if he were to turn to the Minister who had the control of the Territory and say, "Ask him." He would listen very closely, and probably should feel impelled to ask leave to amend a little and add a few things to the replies. For himself he had all the courage of his convictions, and the Minister had frankly told him to say what he liked. One thing cannot be done. We cannot sell the Nothern Territory to pay off our debts—at any rate, without the consent of the Imperial Government. South Australia does not possess the fee-simple of the country. She holds the Territory during Her Majesty's pleausre. Before the railway was undertaken the Bray Government brought the subject of the relation of the Territory to South Australia under the notice of the Imperial Government, and received from the Earl of Derby, the Colonial Secretay, the gratifying assurance that the Queen's Government recognised the public spirit and enterprise shown by South Australia, and had no declaration that there was no prospect of the terms of union being disturbed. But everyone should understand that while South Australia has a good looking title she does not possess a selling title. He advised the South Australians must get to know more about the Territory and understand it better. Ignorance is fatal and has been the parent of all procrastination and of all the blunders. We must not look to level balance sheets of expendi-

ture and income, and immediate return for investment made and work begun. The Government must show that it has faith in the country, and that no mere paltry question of a few thousand pounds shall stand in the way of opening the country, of giving mail communication, and inducing capital to come in and to continue in the country. Those who shrug their shoulders and smile with a touch of incredulous pity for those whose confidence is based upon experience and ascertained information should seriously set to the task of grasping the situation; and if, after due examination, they come to the conclusion that the Northern Territory is a white elephant, let it be distinctly proposed to the Imperial Government to take it back on payment of all its just debts and liabilities. He had not the slightest doubt that the Imperial Government would consent if the Legislature petitioned for resumption, and he was morally certain Victoria would take it over bag and baggage, public debt, and railway tomorrow. He did not imagine for a moment that South Australia would fling away such a magnificent heritage. He urged that the Parliament of South Australia must find time to consider and pass good and adapted laws. Legislation is now neglected. The land laws, mining laws, and the law relating to health are sadly in arrear. The people in the Territory have been knocking importunately at the door for years, but they get jammed on to the end of the session and nothing can be done. Then look at the so called-Justice Act. They have had to let loose two murderers caught red-handed with the blood of their victims, because of a defect in the Act, because having been tried by an incompetent Court they could not be tried by a competent Court. The Northern Territory wants a careful revisal and amendment of the laws and Customs duties, so as to secure an industrial, cultivating, delving, prosperous population. The racial question must be dealt with. Whatever may be our views with regard to the best class of labour, the principles must be laid down and procedure must be regulated by legislation. Among the great many things to be done were (1) the Transcontinental Railway, (2) the lighting of the entrances to the harbour, (3) proper quarantine provisions, (4) protection for the cable and telegraph line, and (5) the premier position of of Port Darwin to be steadily kept before the Imperial Government. All these press for attention. The Minister is willing to give them all attention, though they may not all be approved as they are represented or possible of immediate settlement.—*South Australian Register.*

[The northern portion of South Australia and Queensland ought to be governed as Crown Colonies, so that Indian labour might be introduced for the cultivation of the soil.—ED.]

EXPERIENCE OF COOLIE LIFE IN SUMATRA.

A DELI TOBACCO PLANTATION.

We have just found in our archives an unsigned article on "Coolie life on a Sumatra Tobacco Estate." The tone of the article is manly and straightforward and it is evidently written by an impartial observer. There are so many points in it which cannot fail to be of interest to Tobacco Planters coming to this country that we are constrained to publish it for their benefit, although it loses somewhat of the force and value from our ignorance of its author.

Most of your readers are probably aware of the existence of a small spot in Sumatra called Deli. It is situated on the north-west coast, at about 3.37 N. and 98.27 E. As this place is one of the great destinations of Chinese emigrants, and as much has been written about the immorality of the means by which coolies are obtained, the bondage in which they are held, and the cruel manner in which they are treated, it is my intention, as far as lies in my power, to lay before your readers a plain, impartial statement of what I have seen of the Chinese coolies' life in Deli during a period of five years' residence in that place. It will be necessary, in order to make plain the position of the Chinese coolies in Deli, to give a short sketch of Deli itself, and of the cultivation and manufacture of the tobacco plant there. Deli is accessible by steamer in two days and nights from Singapore, and in a night and a day from Penang. Messrs. Holt have a commodious steamer the "Ganymede" running from Singapore, and a Chinese firm have one from Penang. Upon reaching the mouth of the Deli river, a sampan conveys the visitor in about one hour up to the town of Laboean the port of Deli. There is little to charm the eye here, it is simply one street along the river bank, crowded on each side with a curious mixture of Chinese business houses and Malay attap-roofed tenements, dotted here and there with a somewhat cleaner and more imposing specimen of building inhabited by the few Dutch officials who, much to their disgust, are stationed here. The town is frequently under water to the extent of a foot to a foot and a half in depth from the overflow of the Deli river, which for pollution nearly rivals our much-abused Thames. Naturally, under such circumstances Laboean is not considered a healthy town; no planter stays longer in it than he can help, and during that time avoids drinking water. Yet I must say that those who are employed in the two European firms and Government Offices in the town do not complain of ill-health; however, a speaking fact is that the bulk of Government officials have, within the last few years, shifted further up the country to a town called Medan, of which more hereafter. There is one hotel at Laboean of which the less the said the better. A two hours' drive over a road which would be a disgrace in any civilised country, and which, by comparison, make the splendid roads of Hongkong appear to be an extravagant waste of money, brings one to the town of Medan, after pasing through on each side, plantations of that shapely tree, the nutmeg, the gardens containing which are mostly let out to the Chinese who seem to make money where Europeans fail. Medan is just the opposite of Laboean. Clean, fairly built, and rapidly improving, with a club, a theatre, a large hotel (for so small a place) the head-quarters of the Dutch Government, the offices of the Great Deli Maatschappy, the residences of the Assistant Resident and the Commandant of the troops; the civil and military hospitals; Europeans, Chinese and Indian stores, all indicate prosperity in this rising spot. From here branch out roads to every part of the tobacco growing districts, and when the railway, so much talked about comes, there is not the slightest doubt that Medan will be the head-quarters of all business in the country. The staff of officials consists of a Resident, or Assistant Resident, a Controleur, a Dutch interpreter, a Bailiff, and the usual number of under officials, also a prison and policemen, but such a prison and such policemen it would be difficult to find elsewhere. The military force is under a Commandant, generally in rank a major, whose position makes him a popular personage. The tobacco-growing districts are three at present: Deli, Lanket, and Serdang, but as the working of tobacco is pretty much the same in each, it will be necessary to describe one estate to give a fair sample to all. I shall do this in what appears to me the most practical way of dividing the subject into:—1st. The land. 2nd. The Coolie. 3rd. An outline of the work, from the opening of the division to the packing of the tobacco. 4th. The European staff. 5th. General remarks.

THE LAND.

To procure the right to cultivate a maiden piece much worry and more bribery has to be got through. The intending planter has first to seek his land amidst all the discomforts of hard living walks through dense forests teeming with leeches, mosquitoes and ferocious ants, weary hours of plodding through swamps and rivers not to mention encounters with plants prickly and tenacious. Woe to the prospector who does not keep a sharp look out ahead. Nature has a hundred sly traps to arrest the intruder on her virgin domain, ropes of graceful, trailing plants, pit falls of rotten trees, nets of tangled creepers teeming with garrisons of stinging ants, and last, but not least, cunning fishing lines of rattan slyly swinging up against one,

catching and holding fast until forfeit has been paid by either clothes or flesh. Having discovered and selected the spot desired, you mark your boundaries, travel back to civilization, begin the slow and uphill work of getting at the Sultan, and before the consent of this individual is obtained, many minor dignitaries of various grades have to be appeased with the customary palm oil. You have now to agree about the price of the land, for, I believe, 99 years. When all is settled so far the contract requires the seal of the Resident or Assistant Resident, for the Sultan cannot dispose of his land without the signature of this official. The soil of Deli and Lankat is strictly a rich vegetable deposit on a volcanic base, in some places lying a foot and a half to two feet in depth. In low, swampy land, a stiff, white clay in some parts, and in the higher plantations, a light reddish soil, with here and there patches of bare rock are found. I mention these facts as they are the guides to treating the tobacco plant at a certain stage of its growth. At other places are encountered large stretches of clear ground, covered with long stiff grass called *lalang*. There are two kinds of this grass, one a broad bladed kind, and another thin and spiral. Where the broad bladed grass grows, and given a sufficiency of rain, the tobacco plant grows well, but upon the land where the spiral blade is found the tobacco crop is patchy, thin yellow-looking, and meagre. Where the soil is stiff, white clay so hard at times that the hoe can scarcely penetrate it, the tobacco is generally large, oily and heavy, and after working seems to give the most even colour, a great desideratum. The rich soil has naturally the preference, and the tobacco grows in it to the greatest perfection, the best land of all being where the largest and heaviest jungles have previously stood, and in seeking land experienced planters give the preference to the latter kind above all others.

THE COOLIE.

Without the Chinese coolie, no tobacco could be grown in Deli, I know of no race who could, or would face the difficulties of clearing and preparing the land for that purpose, the pluck and perseverance of good Chinese workmen are astonishing. No European could do the work, and the natives are too idle to ever be of use in planting, and it is therefore a necessity that Chinese labour be obtained. There are three ways in which the coolies are engaged:—1st. The planter goes to Penang and places himself in communication with the coolie broker, and the planter and broker go together to the houses where the new immigrants are staying, and there see and pick out those suitable to the work. There are a variety of opinions as to which district supplies the best workmen, but men from the neighbourhood of Macao are universally condemned as incapable of field work, and but few are found in Deli working as coolies. Heilochongs, Khoh men, and Teochew men (Swatows) are usually preferred, and these are mostly employed, although the latter are a hot-tempered tribe. They are fine, powerful men, and mostly accustomed to field work. Managers who can speak Chinese ask the men if they would like to go to Deli to plant tobacco, and the desire to be chosen for the plantation seems to be universal. The planter having selected his coolies and agreed upon the advance to be made to them (I use the word "advance," because it is a sum outside the commission paid the broker and cannot be called purchase money,) coolies, broker, and planter, proceed to the Protector of Coolies, and a contract is entered into as follows:—The coolie agrees to plant, cut and sort tobacco during one season; to pay back all advances he may receive; to plant two feet by three; to cut ripe tobacco; to accept the following standard of valuation of tobacco; $8 per thousand trees for ripe, unbroken No. 1. $7, No. 2. $6, for No. 3. and so on, till $1, (the lowest valuation) is reached. That he will obey the manager and those whom the manager shall appoint to direct and carry out the work. That he will accept a certain price for other work, such as road and ditch making, and so forth necessary work coolies have to do out of growing seasons. There is a clause also that unripe tobacco shall not be received. There are some other stipulations as to holidays (which are given, one day out of every fourteen,) housing, &c., not at all necessary to repeat. This contract is read over (in Chinese) to the coolies, and upon these agreeing to the conditions (which they always do) they sign the contract. The Protector of Coolies in Penang is present to see that no advantage is taken of them, and it is entirely of their own free will that they engage. All these contracts are afterwards produced upon the arrival of the coolies in Deli, and are inspected by the Dutch authorities, who take care that the men are free labourers in every sense of the word, officials being specially appointed to that duty. The coolie is now supplied, at a fixed price, with the necessary implements for the cultivation of tobacco, and is drafted off to the division in which he is to work. Thus far as to the coolie engaged in Penang. The second way of obtaining hands is to send an old and trustworthy coolie or headman to China, who brings back with him a batch of his own clansmen, and similar contracts are entered into. The coolies obtained in this way are, as a rule, good, steady men. The third method is a most distinct refutation of the charge of inveigling the coolies. When all the tobacco is sorted off, in the way I shall presently describe, those men who have worked that crop can re-engage themselves for another season; and should they do so they receive $10 at once and $5 more on the Chinese New Year as an advance. It is by this method that the best men are obtained, as their experience enables them to do better for themselves and for their employers, by raising a more valuable and more carefully cultivated leaf. Many men do go away with their earnings, and after visiting their native country return and re-engage with their previous employers, and it is an undeniable fact that the old hands are in a majority on most estates, new men only being required to fill up, say, from five to twenty per cent. of the total number employed. The old coolies who re-engage have also the privilege of electing in what division they will work. On arriving at their destination they go to the coolie houses; not miserable hovels but houses, placed most conveniently near to their work; roomy, well drained and ventilated with beds on each side and a clear space in the centre. Two wells are dug outside the coolie houses, one for the men to bathe in, the other for drinking water, and in close proximity to the house stands a covered space where each coolie makes his cooking place. These houses are kept clean; the ditches are cleared out every morning before the holiday, and the interior is swept, as the *tandils* are liable to be fined should the houses under their care be found to be in a dirty condition. I do not pretend to say that from one holiday to another the houses are like new pins; but I do state that the Chinese in their own home of the coolie class in Hongkong are nothing like so well off as they are in a Deli coolie *kongsee*. At 5 a.m., a horn is blown by the headman of the division, when the coolies get up, bathe, and have their breakfast, which they cook themselves; at 6 a.m., the horn again sounds, and the men leave the houses for the field. Should a man be ill, he goes to the European who superintends the division, where he receives what medicine will suit his case, or should the assistant consider it beyond his knowledge, the coolie will receive a letter of admission to the hospital, where a qualified doctor will attend him. In the company with which I am best acquainted, to prevent mistakes, each assistant is provided with a brief but simple description of the diseases to which coolies are liable, with the necessary instructions how to treat the case, and strict rules were laid down as to what cases were at once to be sent to the doctors. The work goes on from 6 a.m., to 11 a.m., and when the heat is excessive, coolies are allowed to return to their houses a quarter of an hour sooner; time is now allowed them to bathe, cook, and sleep, and at 1 p.m., the horn is blown and the men are usually at work again a quarter of an hour later; at 6 a.m. work is finished for the day.

There are two classes of coolies, the bad and the good. The good coolie works hard, is attentive to the directions given him, plants fairly well, cleans his plants well, cuts ripe, and, in the majority of cases, makes a fair amount of profit. Such men are given more latitude as to working, as this kind of man requires but little looking after. He has come to make money and will make it, and any one who knows the Chinese character is well aware how plodding and persevering such a man will be. The other class will work only when the assistant or *tandil* is by, is generally dirty in his habits, slovenly in his work, and invariably comes out at the end of the crop on the wrong side of the balance. Such men as these (happy in the minority) require regular driving from their houses instead of going cheerfully to work as the others always do, and often this is not done without a liberal supply of stick and it is this class of men which is held up as the examples of the ill-treatment coolies receive. What is to be done with a man who owes money, is every day making a large debt, and sets himself deliberately to do no work? It is true that a coolie who refuses to work will be punished by the authorities if brought before them, but there are two reasons against sending men to prison ; the first is, it never does them any good, as they get less work to do in prison than on the estate ; secondly, the man has taken a field to cultivate, and every day he is absent from his work entails a serious loss to the estate; there is no cure for such men; he takes no notice of talking, and you can only appeal to their feelings by aid of a rattan, a few strokes of which, by the bye, is not to be compared to what was legally for years dealt out to soldiers and sailors. In Her Majesty's service this used to be called punishment, in the planter's case it is called ill-treatment. These men are such rascals that even if they make a good crop they sell it to some good coolies for a small sum, of course without the knowledge of the European, the reason for this is that they reckon, if they deliver the tobacco the money it is taxed it will never come to their hands, as it will be written off their debt; they are also in the habit of taking as many implements as they can get upon credit and sell them for cash to well-to-do coolies. Such men are the bane of the estate, ready for any row and invariably discontented; and yet if these men are sick they are as well treated as the best coolie, and the estate sees that they get a sufficiency of good food. Weak or sickly coolies are never put to field work, but are used for labour only fit for women.

THE WORK.

The portion of forest to be planted having been selected, a road is made straight through it, in the first place, the timber is felled, and a rough road made by the natives of the country, the Chinese coolies. being put on the road to make a ditch on each side and the earth thrown out of these ditches makes the foundation of the road, all the stumps of trees being rooted up, and a road ultimately made fit for our wheeled vehicles to travel over. The land to be planted is given out in sections to the natives, who fell the timber, and the monarchs of the forest lie piled up one on the other in all directions, just as they fall, a dense impenetrable mass of timber; and seen for the first time, it is almost incredible to the uninitiated that this colossal wood pile in three or four months will be a waving sea of green plants. Now the fields are given out to the planters, each coolie's field generally measuring 900 feet by 60 feet English measure. The coolies draw lots for the divisions, as scarcely two fields are alike, some having heavier timber to be disposed of than others; and some better ground than others. John Chinaman then sets to work not at all disheartened with the Herculean task before him, first he cuts away the underwood which has grown up since the felling of the trees, then he cuts away the branches, piling the smaller wood around the great trunks, and day after day, in a scorching heat, he keeps steadily chop, chop, chop, and on the whole length of the road the ring of the axe is heard. It is a pleasure to see is good coolie at work, how cleverly he picks out the right place to cut the wood, that may fall in a position most suitable for piling up, and to watch how doggedly he perseveres in a work that to most men the bare sight of would dishearten. Later on, when the wood is considered dry enough, it is fired, and dense columns of smoke and flame are seen the whole length of the division.

At night this scene is wild and grand, the thick, dark bush, brought out in strong relief, forming a black back-ground to a thousand blazing piles; and now and then, some dead trees catching fire, the tongues of flame leap high up as if attempting to reach the star-lit sky; the same large log, rolling into a blazing furnace of smaller branches, sends a glittering fountain of brilliant sparks to sport in the breeze. My pen could never describe so grand a pyrotechnical display, cascades of flame, fountains of sparks, palaces of fire, all are here. Truly the fire king holds high revels in Deli on the burning off the land for cultivation.—*Shakespeare.*

Day after day burning goes on; as the wood gets consumed and the fire dies out, the remnants are gathered and are repiled, until none is left but the incombustible trunks of a red wood that no ordinary fire will consume. Now the planter hoes the land, no more scrape, but each stroke cutting down half a foot to nine inches in the ground, and when the hoeing is half finished the seed beds or nurseries for the tobacco plant are made. A good piece of land is chosen for this, and the ground hoed deep and afterwards well thrown up, about 20 feet long by two feet broad, but the dimensions are a matter of taste. These beds are well raked and cleaned and made beautifully fine, and then beaten smooth with pieces of wood. The seed is then mixed with wood ashes and sown, and a covering is made over the bed to keep rain and sun out, for the young seedling is as delicate as a new-born babe, and in about six or seven days the young plants appear, and trouble at once begins. Morning and evening the seedlings are watered, and in another week the great enemy to the tobacco plant appears, and each coolie armed with a small straw has all he can do to pick off the worms which infest the beds in myriads: in some cases so great is this plague that the beds have to be cleaned twice a day. In thirty days from the sowing of the seed, the plant is ready for transplanting, and all this time the coolie has been burning his wood, hoeing his ground, and collecting the incombustible roots and unburnt débris. The portion he intends planting first is now prepared, and after being inspected and found in order, the next morning he takes out a number of plants required, and towards sun-down the planting begins. Taking a line with the distances marked on it, he measures where the holes are to be made, first digging up the soil in spots two feet from each other, until he has completed a line; he then moves three feet further and makes another line of holes, and so on, and this operation is the meaning of the clause in his agreement referring to his undertaking to plant "three feet by two." His friend, a good coolie, generally has a friend to help him plant, now pours water into each hole and when all the necessary holes are made, with his hand he works the ground fine and then carefully beds the young plant. I may state, to be more clearly understood, that the hole-making consists of a deep stroke of the hoe and then shaking the earth back into the cut of the hoe. This is very important, as should the coolie simply make a hole, the root of the young plant soon comes on hard ground and often perishes. The next morning all the plants are carefully protected from the sun by small planks about half a foot long and a few inches broad, but on some estates they use a cover made of long grass twisted in a triangle, the centre of which is crossed by bars of grass. In a few days the plant begins to spring up, and if the weather is favourable is soon strong enough to admit of the covers being removed. Every evening, for some days, these transplanted seedlings must be watered. Upon the removal of the protecting planks the seedling must be assisted by heaping up with the hand the loose earth around, and as the plant now grows the earth must be banked up until each row is

about one foot and a half high; the higher the eart is heaped, the stronger the earth is heaped, the stronger the plant and the better the quality of the leaf, and the deeper the earth has been hoed, the higher will be the banking. Every morning each plant has to be carefully inspected, and all worms taken off. Upon the plant reaching a certain height the topping operation begins, which process consists of nipping off the head of the plant.

The height for topping is one of most important parts of tobacco culture, and I will therefore say a few words about it. It is the duty of the European overseer to decide at what number of leaves the coole shall top; the usual way of judging is by the soil and the appearance of the plant. On a light poor soil, fourteen to sixteen leaves is the most a plant, however healthy looking, will stand, and even with only that number I have seen the bottom leaves dropping before the tops were ripe. Upon the white, stiff clayey soil, an average of eighteen leaves produces the best crop, on red soil very often, no matter how low you top, the plants do not ripen properly, and should there be a scarcity of rain nothing will save the crop; on rich, deep coloured land, twenty-two and twenty-four leaves are retained. It is usual in the trees first planted to top a few leaves higher than in later tobacco, the reason for this is that towards the end of the crop a great risk is run of being overtaken by the rainy season, and therefore it is advantageous to get the tobacco in as rapidly as possible. In about eighty or ninety days from transplanting the seedlings, the tobacco will be ripe. Tobacco in this condition can never be mistaken; the first sign of ripeness is a slight yellow at the tip of the leaf, and in a few days after the leaves have a thick appearance and stand well down from the plant, and shortly after this the leaf assumes a frosted appearance, and the tree is then ready for cutting. The coolie cuts the tree close to the ground and places it with great care in a long basket, avoiding over-packing as the weight of the upper trees will crush and quite spoil the lower ones, causing the leaf to be bruised, and all bruises in the green leaf make nasty black lines in in the cured leaf. The tobacco is now hung upon sticks by means of small ties of Manila hemp, ten tress being put upon each stick. The next morning, after the European has examined the tobacco and taxed it, the plants are hoisted to the highest part of the drying-shed, tier after tier, there to remain about fourteen-days, the plants being then taken down and stripped off their leaves, which are made up into bundles; broken tobacco and ground leaves in one bundle, good tobacco by itself. These bundles are taken down in bullock carts to the fermenting shed, and placed in large or small heaps according to the amount of oil and the thickness of the leaf, these heaps are turned over until it is considered that the leaf will stand a greater heat when two or three heaps are made into one, a bamboo being placed in the centre of the heap in which sticks are placed; by these sticks the heat of the heap is ascertained from time to time, and for this purpose on some estates thermometers are used. In course of time these heaps are again made larger, while the tobacco has acquired what is considered will be fixed colour of the leaf. As soon as the tobacco is at this stage, the sorting commences. Each coolie has before him many partitions made by small sticks being placed in the mats which cover the whole of the floor of the shed and the following is the usual order of sorting. Java leaf, dark leaf brown with oil, brown, fallow, light coloured and yellowish-red, dark and brown with spots very spotted, all colours uneven, coloured dark and brown slightly hard or dry, broken dark and brown, broken and light, spoiled tobacco, broken spotted, very much broken spotted, rotten tobacco. All the European assistants have to know these names in Chinese, so as to be able at any time to assist unpractised hands. Opposite the sorters sit the bunchers, who have to sort the different classes into lots and tie the leaves neatly into bundles, thirty-five leaves being placed in one bundle. These bundles are again put into heaps, and the heaps increased gradually in size until scarcely any heat is left in the largest heaps. The tobacco is then ready for shipment. It is baled under a press; in some places hydraulic power is used, in others a screw press worked by relays of coolies. During the time the coolies are in the shade they are paid extra for their work; and their food is supplied under the supervision of a European.

THE EUROPEAN STAFF.

According to the number of coolies employed, so is the staff of whites, in the portion of about 100 to 150 coolies to every European. Nice roomy houses are supplied to the Europeans, and they are provided with a pony and have medical advice free. The salaries vary from $60 to $175 per month, and on some estates commission is given to experienced men. These are not large amounts, when the cost of living in Deli, which is miserable and perfectly dear is considered. The duties of an assistant are to see that the coolies do their work properly, to look after the sick, to direct and overlook the field work, to superintend the making of roads and ditches, and the erection of necessary buildings in his division, to contract for work with the coolies or natives, and to tax and receive tobacco, in fact the whole working of a division is in the hands of the assistants. An assistant who looks well after his work will find his hands full for at least nine hours a day; and hard work it is, sometimes working in water with the fierce race of the sun pouring down almost burning one's life out, at other times toiling through acre after acre of land like ploughed fields. After the planting has commenced, his work is never finished until the sun goes down, then comes the taxing of the tobacco, no easy task, opening stick after stick of tobacco, judging not only the quality so as to fix the price, but also bearing in mind the work the coolie has done, in order to do justice, constantly on the watch for attempts of cheating, for the best coolie thinks it no sin to hang trees (already received and entered in the books), amongst new tobacco. The assistant is always liable to the coolie objecting to his valuation on the one hand, and to the manager's grumbling on the other. The poor assistant; his life would be worse than a convict's were it not for the festive gatherings held from time to time at a friend's house, which come like red-letter days in his dreary calendar. At the end of the crop the accounts are made up, the coolie having been debited with advances, implements, and expenses incurred including the tax paid for him by the estate to the Dutch Government and the price of his field; and he is credited with the amount of tobacco he has cut, and, if he has not been paid before, any contract work he may have done. During the season, which lasts from January until the first half of October the coolie has every fourteen days received an advance of $2 or $2.50 as subsistence money, and if he has required assistance in his work this has been given him, for which he has also to pay. Thus we find the Chinese coolie has willingly entered into an agreement with a European such agreement having been explained to him in his vernacular; he has entered into this contract beneath the eyes of the Government officials, he has been allowed to borrow money, he has been advanced the necessary amounts for food and clothing and implements, the seed has been supplied to him free of cost, his land has been drained for him his timber felled, for which a very moderate charge is made, he has been provided with a healthy and comfortable house, and if he has worked properly has been fairly dealt with and well treated. During his sickness he has deen cared for, and in return he has sold his tobacco to the manager at a price he has stipulated for by contract. At the end of his crop he has made a profit and finds himself at perfect liberty to go or re-engage, and yet we are constantly hearing the cry that coolie labour is unmitigated slavery. What is freedom, then? Where commence, where end? With regard to ill-usage, the cases are few and far between, and for the best of all reasons, that the majority of the coolies are good men, with the foresight to observe that their own interests are bound up in those of their employers, and the useless, lazy, or vagabond coolie soon clears out,

and is therefore, very much in the minority. That there have been cases of cruelty and ill-treatment I admit, but the victims are always idle, vicious or mutinous, and it is only in rare instances that cases of ill-treatment have occurred, and the prepetrators of the cruelties have always been severely punished by the Government. Then again, the punishment has been exaggerated, as it has seldom exceeded a simple thrashing, and is often only a single stroke of a cane, certainly on no more than almost every public schoolboy has experienced. The class of men who are assistants in the plantations are not to be compared to Negroes; they are certainly not a class who would be guilty of wanton cruelty to say nothing that they are themselves hard worked, and often enter into the coolies' troubles and difficulties with his crop, and by their superior knowledge are enabled to give the coolie valuable advice and assistance at critical times, and are often thus the means of increasing the man's average when the valuation takes place. It is astonishing the amount of virtuous indignation some people give vent to on the coolie question; but it generally happens that the outcry is greatest amongst persons possessing the least knowledge of the subject considered. Since leaving Sumatra, I have heard the coolie labour there referred to in the most prosperous terms, and stories related which it simply would be impossible could have occurred. I have learned, however, that the Magistrates who sit at the Hongkong Police Court are occasionally occupied with assaults by Europeans or natives, these mostly taking the forms of masters beating their servants, and I understand there are many European employers of native labour who, though they would raise their hands in pious horror at the relation of ridiculous stories of so-called cruelties on coolies in the countries where the latter flock for the sake of profitable labour, do not hesitate to cut their servant's small wages for the mishap of breaking a glass or a plate, or some similar petty offence against the pocket or pride of the magnanimous white malgré that this may mean so many bowls of rice less to the cook or the chair coolies' children, as the case may be, during the month. In a walk through the town, one day I came upon a public institution still standing in this city, as a monument of the majesty of the law and the humanitarian principles of British rule over subject races. From its appearance, it did not seem to have been very long out of use, and I wondered as I looked upon it how many poor wretches had had the blood drawn upon it from their quivering and blackened back for far less than a Deli plantation coolie has had a couple of stripes from a small rattan? It is a cheerful sign of the times that a Governor can come down from his high pedestal, as Her Britannic Majesty's representative, and succour a subject race (for such the Chinese must ever be considered in Hongkong so long as it remains a British colony) who had previously been subject to the barbarous punishments of flogging and branding. When I first heard of the latter punishment, and the offences for which it had been inflicted, I felt rather ashamed of my country, in fact I protested to my informant that there must or I would not believe that an English Government official would consent in these enlightened days that a man should be branded under the circumstances that may have been in this colony. There have been crimes committed by coolies on the Deli plantations, equal to anything that ever took place in this island, I believe, but no such fiendish punishment as the pressing of a red-hot iron, spluttering and hissing, into a man's living flesh, was ever adopted to punish wrongdoers or to deter others. However the branding-iron and the whipping-post are implements of the past, and those who favor their use may resign themselves to the new order of things.

There is a strong party in England, in fact the strongest party in England, inasmuch as it includes all the foremost men of the country, who will have no more of that sort of thing in any of Her Majesty's dominions, and it is a pity that a Governor, a follower of that faith, did not many years ago find his way to this colony to put a stop to the barbarities that have only in recent years ceased to obtain. In conclusion, I must not omit to give what is due to the officials of the Dutch Government in Deli, and that is that under no circumstances whatever do they gloss over or fail to sift to the bottom any cases of alleged cruelty to which their attention is drawn; and further, that they do not wait for the cases to creep up under the official nose, but given that a planter ill-uses a hired servant, contract coolie, or whatever other position the victim may be in, justice overtakes the wrong-doer and with swiftness and surety.

THE CHINA TEA TRADE.

A consular report on the commercial condition of Foochow contains a review of the Chinese tea season, 1886-87, from the pen of a resident British merchant largely interested in the trade. We glean a few interesting particulars. The favourable season of 1885-86 made cash plentiful and cheap at the beginning of the year under review, money was sent upcountry in large amount for the purchase of the new crop, and the keenness of competition thus brought about caused prices in the tea districts to rise from 5 to 10 per cent. The final result was, however, somewhat disastrous, for, though the crop was a fair average one, it proved not to be liked at home except as regards the leaf from a few districts, and moreover, some of the teas had been picked too young, making the liquor very thin. The sales in London thus proved unprofitable, and some tea showed from 20 to 30 per cent loss. One further feature of interest has been the great difficulty in selling in London the finest qualities, many of the crack crops being still unsold, entailing heavy loss to the importers. The demand has been for teas costing under 1s per lb., the result of cheap Indian teas. It is also worth noting, as showing how at last the eyes of the Chinese are beginning to open to the evils of adulteration, that at the beginning of the season a large quantity of the article expressively designated "lie tea" was offered for sale at Foochow, but was promptly seized and burned by the authorities. Proclamations were also issued warning the people of the consequences of continuing to make counterfeit tea and to place it on the market. One other point of interest is the great development in the manufacture of brick tea from dust and broken leaf by Russian merchants in China. Some of these firms at Hankow and Foochow are now employing steam machinery, and are putting forth every endeavour to make the bricks smaller in size and more attractive in appearance. The trade in this article with Central Asia is said to be increasing most rapidly. Cannot our Indian tea-growers extract a "tip" from these facts? —*Times of India.*

JOREHAUT TEA COMPANY, LIMITED.

Capital £100,000. Area under cultivation 4,425 acres. Directors, Messrs. W. C. Fairley (chairman), H. Burkinyoung, E. M. Stone, W. Sangster and W. Roberts, managing director.

The following report was submitted to the members at the twenty-eighth ordinary general meeting, held on Monday last.

The directors have the pleasure to inform the members of the Jorehaut Tea Company, Limited, that the gross profits realised by the crop of tea of 1886 have amounted to £26,528 5s 8d, being an increase of £4,203 16s 10d, over that of 1885; and they propose that the same shall be distributed as follows, viz.:—

Commission to staff	£3,316	0	0
Directors' extra fees	400	0	0
Income Tax	497	15	9
Dividend at 18 per cent ...	18,000	0	0
Reserve Fund	4,314	9	11
	£26,528	5	8

The quantity of tea manufactured amounted to 1,165,630 lb. being an increase of 51,744 lb. over the crop of 1885, and the average price was 1s 3-71d per lb. or about ¼d per lb. below the average price of th previous year's crop. The proceeds amounted t £75,657 19s 8d being an increase over 1885 of £2,03 16s 5d. Very low prices have prevailed for teas o

ordinary description, but the superior quality of our teas was fully maintained, and there was scarcely any falling off in the prices obtained for them.

The following statement shows the quantity of tea sold from each of our plantations in 1886, the proceeds of the sales, and the average prices:—

	lb.	£ s. d.	at s. d.
Cinnamara	...182,406	13,299 19 1	1 5·49
Dekhia Julee	...109,271	7,447 7 9	1 4·35
Koreekuttea	...111,301	7,378 3 0	1 3·90
Bokahoola	...123,908	8,169 3 0	1 3·82
Rungagora	... 84,512	5,470 18 6	1 3·53
Rungajaun	...104,071	6,723 3 4	1 3·50
Goreahabee	... 47,983	3,092 12 3	1 3·46
Hatteecoungie	... 87,275	5,534 2 4	1 3·21
Syeotty	...149,993	9,489 19 4	1 3·18
Numaligbur	...114,814	6,760 17 4	1 2·13
Oating	... 40,111	2,291 13 9	1 1·71
	1,155,645lb.	£75,657 19 8	at 1 3·71

The rates of Exchange between Calcutta and London were considerably lower in 1886 than in 1885, and although the drafts issued in Calcutta in 1886 amounted to £33 000 against £36,000 in 1885, yet the difference in the rates below 2s. per rupee was £11,537 4s. 2d. against £9,350 3s. 3d. in 1885, showing an increase of £2,187 0s. 11d.

Tea seed produced £106, unclaimed wages £150, and profit on sales of rice £5 13s. 1d., making the total amount to the credit of the profit and loss statement £87,456 16s. 11d., or an increase of £4,423 10s. 11d. over 1885.

The expenditure on the plantations in 1886 amounted to £34,778 3s. 2d., or £90 6s. 4d. below that in 1885, although the quantity of tea made and the area of land cultivated were larger than in 1885. A larger number of labourers would have been of much advantage, and hence the outlay may be considered to be below the average.

The general expenditure was £17,202 17s. 6d., being an increase of £38 16s. 10d. over that in 1885; further large sums were expended upon permanent buildings and barracks for labourers, and upon machinery, whereas the cost of importing labourers was less than in 1885, as there were fewer procurable.

It may be mentioned that the charge under the heading of interest account is made up as follows:—

Discount to buyers of tea		£533 0 6
Less: Interest on N.S.Wales stock	£135 6 8	
Interest on deposit at Bank ...	178 16 4	
Interest on credit balances in Calcutta	26 11 4	
		£340 14 4
		£192 6 2

The charges on tea and insurance were £8,747 10s. 7d., being £271 3s. 7d. in excess of 1885, but the charges on an increased number of 542 chests of tea are included in the above.

The usual annual contribution of £200 has been credited to the fire insurance on buildings, and as this fund now amounts to £800 it is deemed unnecessary to increase it, and it has been accordingly invested in the purchase of £863 13s. 9d. in 2½ per cent consols, redeemable in 1905.

Thus the total expenditure connected with the crop of 1886 was £60,928 11s. 3d., or £219 14s. 1d. above that of 1885.

The total receipts were...	...	£87,456 16 11
The total expenditure was	...	60,928 11 3
Leaving a gross profit of	...	£26,528 5 8

Great praise is due to Mr. J. F. Lawrence (who was acting superintendent in Assam during Mr. Huttmann's absence on leave) next to the members of our staff for the realization of this satisfactory result.

The following comparative statements show the operations of the company during the past three years:—

CROPS OF TEA AND OUTLAY ON PLANTATIONS.

In 1884	3,816 acres	1,206,677lb at 316 per acre	R367,152
In 1885	3,822 „	1,113,891 „ at 291 „	348,684
In 1886	3,765 „	1,165,635 „ at 309 „	347,781

GROSS EXPENDITURE AND COST PER POUND OF TEA SOLD, after deducting the difference in the rates of exchange:—

In 1884	£57,977, cost per lb.	0s 11·58d
In 1885	55,129, „	1 0
In 1886	53,605, „	0 11·13

ACCOUNT SALES WEIGHT OF TEA, AVERAGE PRICES AND PROCEEDS.

In 1884	1,200,538 lb.	at	1s 2·89d	£74,525
In 1885	1,102,196 „	at	1s 4·01	73,568
In 1886	1,155,645 „	at	1s 3·71	75,657

DIVIDEND.

The directors recommend the declaration of a dividend at the rate of 18 per cent, clear of income tax, payable on and after the 4th July, 1887, and the members will be asked to confirm this by resolution.

On crop 1884, a Dividend of 15 per cent. was paid.
„ 1885, „ 15 „ „
„ 1886, „ 18 „ is proposed

RESERVE FUND.

On 31st December, 1885, the amount to the credit of this account was	£7,211 18 6
Transferred from profit and loss account, 1885	3,554 1 1
As per balance sheet 31st Dec. 1886...	£10,765 19 7
To be transferred from profit and loss account, 1886	4,314 9 11
Total undivided profits ..	£15,080 9 6

£7,640 have been invested in £8,000 of New South Wales 3½ per cent. Stock, and
4,360 in £4,707 3s of 2½ per cent Consols.

£21,000

SEASON 1887.

The usual estimates for 1887 have been carefully prepared showing an expenditure on the plantations of rupees 377,486, and a crop of tea estimated to produce 1,245,200 lb.

The area under tea cultivation is as follows:—

Over three years of age.. ..	acres 3,905
Under three years of age ..	„ 298
Extensions made 1886-7	„ 203
Nurseries	„ 19
Total acres	4,425

Every attention is being given to increasing the number of labourers, extending the erection of permanent barracks for them, improving the water supply enlarging the tea-house accommodation, and providing new steam machinery.

The quantity of tea made to the 15th June amounted to 228,000 lb., being an increase of 49,360 lb. over the previous season to the same date.

Mr. Henry Burkinyoung, who retired by rotation from the direction, was re-elected, and the proposed dividend of 18 per cent was declared.

The chairman in justification of the policy of adding to the reserve fund, mentioned that in 1879 the company with difficulty paid a dividend of 5 per cent, and in 1880 gave no dividend at all. Since that time they had paid in dividends 81 per cent. The company has been formed 27 years, and the average dividend during that time has been £14 3s 3d per cent, a very creditable record.—*Home and Colonial Mail.*

INDIAN EXCISE AND TEA.

[In taking over the following article from the *Pioneer*, we would remark that while fever is prevalent in Ceylon and quinine powders are being distributed, good might be done, now and for the future, by distributing also small packets of tea. Acting on the weakly frame of Asiatics, tea alone is a cure for fever, and the creating a taste for this wholesome stimulant would be a good work on the part of Government and individuals. We call the special attention of the Governor to the matter. If a ruler in India finds it consistent with his functions to encourage tea versus spirit drinking, the example can be followed in Ceylon.—ED.]

Sir John Gorst's reply to a question about Bengal Excise to the effect that regulating drink is not the same as stimulating it, is the text on which Sir Alfred Lyall enlarges in his orders on the Excise Report of these Provinces for the past year. The year in point of income proved one of the best on record, and the Government is at some pains to show that the increase in revenue is not the result of additional encouragement or facilities for drinking given to the people. "The year was one of agricultural prosperity: it was held to be auspicious for Hindu marriages." These circumstances made it probable that there would be a considerably increased consumption of liquor, and the rise in the excise revenue simply indicated that "licit liquor was in the main consumed." This expression draws attention to a fact that is overlooked by the good people in England who choose to make the excise arrangements of India a subject for May meetings and other popular gatherings. In spite of the vigilance of excisemen, there can be no doubt that a very considerable amount of illicit manufacture of liquor is still carried on, and that the gallonage recorded in the official reports does not represent all that is drunk by the people. The popular drink in rural tracts can be made so simply that a lynx-eyed police need not know that anything was going on. The flowers of the mhowa tree are steeped for a week or ten days in a *gharra* of water until they ferment. The *gharra* then has only to be boiled over a fire of sticks, and the resultant spirit conveyed by means of a bamboo tube into another receptacle, and the poor man has his drink. It is weak and ill-flavoured to our notions, but it has been the drink of the lower orders in Hindustan since the mhowa tree first threw its protecting shade over the sultry land, and blossomed into graceful clusters of flowers. The theory of the Exeter Hall busybodies is that drink was unknown in India until British rule, and that drunkenness is the product of our excise laws. The modicum of truth that underlies these assertions is lost in their general absurdity. Certain classes have undoubtedly acquired under British influences a taste for strong drink. The Bengali Babu is said to be often addicted to rum and bad brandy, and native princes fall victims to more seductive stimulants. It is very deplorable that this should be so, and we may well be ashamed that intemperance so often accompanies English literature and the English language on their civilising mission in the East. But this unfortunate result is certainly unpremeditated on the part of the Government, and has in no way been fostered by its excise arrangements. To associate the habit of drink which the Bengali has acquired along with his acquisition of the English tongue and English dress, with the laws by which country-liquor and opium are placed under heavy restrictions, is to confound two things which have no connection with each other. The clamour against the outstills of Bengal has this justification, that the outstill system made liquor cheaper than it was under the distillery system. But under the outstill system drink was still dearer than it would be were there no excise law at all. To say, therefore, that the Bengal Government by means of outstills was ruining the morals of a naturally temperate race, was an absurd exaggeration of facts. The outstills led to more drinking than the alternative system because they made liquor cheaper than it was before. But the instinct for drink was already in the people, and our excise arrangements have simply repressed it. To use a familiar metaphor, the Government had long pressed the spring down. It partially removed the pressure; the spring flew up; and good folks were amazed to find how large a section of the community had been involuntarily kept sober by the repressive laws of the past.

This point is strongly brought out in Sir Alfred Lyall's orders, to which we have already referred. After citing some figures indicative of the general sobriety of the people and commenting on the alleged inaccuracy of the census statistics, he expresses his belief that "the demoralisation sometimes alleged to have been occasioned in British India by the excise laws of recent years is not to be found in any appreciable degree in these Provinces." The general effect of the excise laws, it is added, has been to diminish the facilities for obtaining such stimulants, and "to place frequent indulgence in them beyond the reach of the poor man's pocket." Sir Alfred Lyall considers that the flourishing state of the excise revenue, despite these repressive measures, argues the existence of a strong innate craving for some stimulant among the poorer classes. The solution of the problem, he philosophically suggests, possibly lies in the spread of tea drinking. This, if not an absolutely novel idea, is at least unfamiliar to Indian excise moralists. Sir Alfred Lyall is entitled to the credit of having first put it forward prominently as an administrative question. He first states the present effect of the excise law with uncompromising directness and plainness of language. "Were there no excise law, the villager of the central and eastern districts of the Province would certainly be able to buy the weak *mahua* liquor —which he prefers, and which in his opinion is the best specific against fever and ague in malarious tracts—for less than two annas the bottle. Under the present excise law he cannot buy this quantity for less than eight annas, and often has to walk long distances to obtain it. Nevertheless, among certain classes of the population, the craving for some sort of stimulant is too strong for excise regulations." The taste for alcoholic liquors and intoxicating drugs seems "ingrained among certain large sections of the labouring community." If these words could be read to an Exeter Hall audience, some of the listeners might carry home a grain of common sense. Sir Alfred Lyall then states the reasons which induce him to regard the problem capable of solution by means of tea. "In other Eastern countries these classes are large consumers of tea and coffee, and it may be conjectured that had these products been indigenous, to, or long cultivated in, the Indian peninsula, they would by this time have assumed as important a place in the domestic economy of Indian households as they occupy in China, Tibet, or Turkistan. It is upon these considerations that the North-Western Provinces Government have endeavoured to promote, by special measures, both the sale of dry tea in small packets in the larger towns and cities of the North-Western Provinces and Oudh, and the establishment of tea-shops on the model of European coffee-houses. Some of the larger municipalities have interested themselves in the experiment, and the Department of Agriculture and Commerce has been utilised to procure good tea at wholesale rates for the retail vendors. Sir Alfred Lyall observes with much interest the recent formation of an Association in Calcutta, which proposes to take the question up seriously and systematically in Bengal and in Upper India, and he is prepared to co-operate heartily with it should the Association see its way to extend its operations to any districts in these Provinces. The subject at first sight seems remote from the administration of Indian excise; but the experience of European countries has shown that it has in reality an essential connection with it."

If there be anything in the suggestion, it would do good in more ways than one. Not only would it improve the habits of the lower classes and add to their pleasures, but it would open up a vast future to the Indian tea grower. This aspect is too obvious to need discussion. We prefer to dwell on the more imaginative bearings of the suggestion. The introduction of tea into Europe has unquestionably been one of the influences which have refined society and given woman a higher place in it. Without tea Dr. Johnson's talk would have been clipped and stunted, and his friendships with wise and good women less assured. The poet's lines describe the change in modern manners with inimitable grace—

> Now stir the fire, and close the shutters fast,
> Let fall the curtains, wheel the sofa round,
> And, while the bubbling and loud-hissing urn
> Throws up a steamy column; and the cups,
> That cheer but not inebriate, wait on each,
> So let us welcome peaceful evening in.

But when Cowper wrote, not one household in a thousand had practical experience of the social pleasure he commemorated. With tea at ten shillings the pound, the artisan and the ploughman naturally stuck to the ale-house and left his wife at home. Now-a-days Cowper's picture may be seen repeated in millions of bumble homes in Europe, America and Australia. Tea may not have made history, but it has profoundly influenced communities. Is general acceptance in India within the next thirty years would be no more marvellous than has been its spread in Europe. And that this would be unaccompanied by any change in social habits and manners is an incredible supposition. The great flaw in native life is its want of sociability. There are signs that the barriers which pen womenkind within zenanas and shut up the men in their own households are beginning to break down. The introduction of the "social cup." which cheers and not inebriates, which is acceptable to the Hindu and runs against no damnatory clause in the Koran, would act as a powerful solvent on the churlish instincts of primitive manners. The theme is seductive, but space prevents us from pursuing it. We wish all success to the new Association in Calcutta, and congratulate it in having found a cordial ally in the Government of these Provinces.

FLORAL.

The London correspondent of the *Nilgiri Express* writes:—A striking feature of the markets and shops at the present season, is the huge quantities of roses offered for sale, both cut blooms, and plants in pots in full flower the large size, variety, and richness of coloring of the flowers being very remarkable. Amongst Noisettes, or indeed amongst the whole tribe of roses, and their name is legion, Maréchal Neil holds its own as first favourite, and obtains the highest price of any notwithstanding the free blooming nature of the plant and the vast quantities of its blossoms exposed for sale from all parts of England and sent to London by rail, road and Parcels Post. As an instance of the number of blooms of this rose that can be obtained from a given space, I visited a garden near London, a day or two ago, and saw a plant of the Maréchal Neil variety planted inside an ordinary greenhouse and the shoots trained along the roof, on wires about 9 inches from the glass, these were confined to a space measuring 37 feet by 9 feet, and from this plant had been cut this season, *i. e.*, from the 21st April to the 21st May 1,500 blooms, these were all sent to market realizing the sum of £22 or over 3/6d per dozen and the plant, at the time of my visit, was still blooming. Amongst tea roses Gloire Dijon with regard to yield of blooms gives even a better result than the Maréchal, flowering in fact, as no other rose knows how to, but the blooms are not quite so valuable. Both these roses, in fact, the teas and Noisettes generally are very impatient of pruning and are best left to themselves to grow as they like, the branches only being tied on the wires to keep them within bounds. Many a fine plants has been weakened and killed by the use of the knife on its shoots, in fact it is beginning to be recognized that pruning even the hybrid perpetual varieties is oftener carried to excess than otherwise, weak and diseased plants and small flowers being the invariable result. It has taken a long time however to make the public believe this. I can remember the pity and ridicule alternately extended to the late Mr. W. C. McIvor for the non pruning system adopted by him on some of his Neilgherry coffee estates. But at such an elevation which has proved the most successful, the non pruning system, or the heavy annual "handling" and knife pruning

I saw a very neat style of flower vase the other day in a shop in Covent Garden, it was made of colored willow ribs and rim interwoven, with platted rushes in basket work fashion with wicker bottom and the whole varnished. The rushes were as green as when they left their oozy beds, the varnish not only producing this result, but assisting in their preservation as well. They can be had to fit any size of flower pot, and have the advantage of being very pretty and novel. The London florists are well up in the manipulation of coloured leaves and shoots in the making up of bouquets, wreathes, &c. The autumn tinted leaves of the Virginian creeper, ivy, and many of the commoner kinds of leaves from our woods are extensively used as the season comes round, and at this time of year the young and delicate shoots of such trees as the plum in which state they are of a beautiful bronze tint, are sold in bunches in large quantities to the people of London. If your Neilgherry Sholas were within easy reach of modern Babylon and as free to the public as they are to the residents of Ootacamund, a "nice thing" could be made out of them each succeeding spring. No one who has once seen displayed the glorious beauty of the mantle of young leaves by these woods, during the month of May, can ever forget the sight. It can, I imagine, be seen in no other country. Let all who have never visited the Koondah Sholas do so at once and see for themselves what nature can do in the way of leaf colouring and then tell me whether their time has been wasted. Spring is very beautiful in England and so are the tints of autumn, but nothing approaching the indescribable variety and beauty of the Neilgherry woods, when arrayed in their spring covering of new leaves, can be seen here.

All through the spring months in London, delicate stove and greenhouse plants are hawked about the streets in immense quantities by costermongers and others on barrows and in donkey and pony cart loads. These plants are procured at Covent Garden market and are invariably well grown and splendidly flowered. And it is a strange sight indeed to see them being conveyed from street to street, without protection of any kind, exposed to every cold wind that blows and shower of rain and hail that falls. It is no uncommon thing for instance to see such plants as poinsettias,—that glory of Indian Gardens—Colens and many others equally tender being carried about and sold at wonderfully low prices. These are bought for the most part to adorn, for a brief space the drawing rooms of the purchasers and soon perish from the combined effects of change of temperature and gas. Millions of plants are reared annually by the London and suburban florists only to perish in this way, and thus the great trade in plants is kept up. One thing in connection with this curious trade is that the plants are invariably so well developed with regard to size, strength of stems and leaves, and number and splendour of their flowers. It is not unusual to see hundreds of plants of exquisite and newest varieties of pelargoniums, with heads 18 inches in diameter furnished with large healthy foliage down to the rim of the small pot in which they are grown, and carrying from 18 to 24 large trusses of fully blown flowers and being sold for 1s to 1/6d each. These plants have no other root room than that contained in a 6 inch pot, and the wonder is oftentimes expressed how and where the plants obtain food for such high development. This art would appear to be thoroughly understood by the London florists of to-day, and to have reached the utmost limit of its development from the apparent impossibility of obtaining higher results under such stringent conditions. The secret lies in potting the plants, in the first instance, in well prepared and nutritive soil and ramming the same as tightly into the pots as it is possible almost to make it, and subsequent feeding with some kind of liquid manure or fertilizer in the shape of powder. Many of the fertilizers sold at the present day are of wonderful power and produce marvellous results one of the best, I believe, being "Clay's Fertilizer."

As a general rule the roots of plants loosely potted quickly find their way through the porous soil to the walls of the pots leaving the greater part of the ball of earth unworked upon, but when firm potting is adopted the roots proceed slowly towards the outsides absorbing every nutritive particle in their progress, thus giving the plant a more certain chance of luxuriant development, and preventing the soil contained in the pot from becoming sour by the frequent application of liquids. Let those who are doubtful on this point

try the experiment of both systems under equal conditions and they will soon be convinced. Another very important advantage the firm potting and feeding system has over any other, is that it enables the grower of plants to make use of a much smaller sized pot, and it also economizes soil and space, besides a plant looks very much better in a small pot with the foliage covering the rim than when grown in one of a larger size with the foliage all within th erima nd with the whole of the pot fully displayed.

Amongst the fruits now on sale at Covent Garden may be named the Jaffa orange, a most delicious fruit without seeds and with a thick rind, it is a very large orange of an oblong shape and is much prized. It is now selling at from 1s to 1/6 per dozen. Australian apples too are on sale in abundance and of excellent quality. These are brought to England, I believe, via the Canal by the help of refrigerators, and the trade received a great impetus from the Indianand Colonia Exhibition of last year.

It has just been stated that two brothers named Chaffey have taken a holding of 250,000 acres along the Murray River for fruit growing purposes. Let us hope their efforts may be crowned with greater success than usually falls to the lot of such large land "holders." It has been estimated that the value of American apples sent to England last year amounted to 3,500,000 dollarls or about £700,000. Of this Canada contributed 451,000 dollars, worth. Lychees, a fruit not unknown on the Neilgherries, are always to be had in London in a dried state; they are imported direct from China packed in small boxes, and are now selling for 2s per lb. Loquats too from Madeira of good size and well ripened may be had six for 6d, or smaller size 12 for 6d. Pineapples and bananas in abundance from the West Indes, English grown strawberries at 2/6 and 3s per lb. and many other kinds of fruits both home grown and from abroad. But one looks in vain for any fruit from India. That trade as to be founded yet. When will the day arrive when we shall be able to obtain mangoes from Mysore, Bombay or Jaffna at the Covent Garden market in as good condition as we can now obtain Australian apples? Would it be impossible to utilize the refrigerator on board P. and O. steamers for the transmission of Indian fruit to English markets?

Be it known to all ye dwellers on the Blue Mountains, that at the present moment we people of England cannot buy a head of good lettuce under 6d, or a lb. of ripe tomatoes under 2/6.—HORTUS.

THE POSITION OF THE TEA MARKET.

The price of tea all round is at the present time lower than it has ever before been. There has probably never been so little interest shown in the arrival of a first ship's cargo of new season's produce, as has been this week evinced over the newly-arrived "Moyune" with the first cargo of new season's black teas; and there certainly never before has been so low a price as 7d per lb. accepted for good, sound, whole leaf new season's tea immediately after arrival. But 7d to 8d per lb. is all that can be obtained at public sale for a large quantity of very good new season's tea, while common grades have sold at even lower rates, and it is admitted that old first-crop teas are so good and so low in price that relatively the new teas cannot be described as being particularly cheap, even at the unprecedentedly low rates they are fetching. They can only be said to be relatively very low in price, as compared with the opening values given for new season's tea in former years.

The general position of the tea trade is of an exceptional character, and statistics alone are in some instances rather misleading unless taken in conjunction with known facts. For instance, taking the deliveries of the United Kingdom from the commencement of the present year up to the end of May, they will be found to be as follows in comparison with previous years

Five Months' Deliveries.			Five Months' Deliveries.		
1877	...	63,300,000	1883	...	71,400,000
1878	...	75,300,000	1884	...	71,800,000
1879	...	79,500,000	1885	...	99,700,000
1880	...	65,900,000	1886	...	72,600,000
1881	...	67,300,000	1887	...	76,100,000
1882	...	66,500,000			

From the above it would appear as though the consumption of tea was by no means in a very progressive condition, inasmuch as eight years ago. viz. in 1879, the five months' figures were in excess of those of the past five months, whilst in 1885 the figures were 23,000,000 lb. more. Inasmuch, however, as this period of five months includes the Budget month of April, the differences in the clearances will be found on examination to be almost entirely due to the presence or absence of great excitement in the market about that time. Both in 1878 and in 1879 there existed a great Budget scare, as also in 1885, and in the early spring of each of these years apprehensions as to the probability of an increase in the duties led to unusually heavy clearances, especially in 1885, when they were so enormously in excess of actual consumption requirements as to have anticipated them by some months. Nevertheless, although this goes far to prove that the mere figures are unreliable, it is by no means certain whether the consumption of Tea in the kingdom is in a progressive state. It can only be said that such may be the case at the present time, although the deliveries for the twelve calendar months of 1886 were 3,500,000 lb. less than in 1885. It certainly appears, on looking at the deliveries for the last twenty years, that the rate of progress year by year has been smaller during the last decade than in the previous one. In 1866 the clearances were 102,000,000 lb., and in ten years' time, viz., for the year 1875, they had crept up to 145,000,000 lb. But after the passage of a further ten years the deliveries for last year, 1886, only stood at 178,000.000 lb. In other words. the increase in deliveries during the first decade referred to was 42 per cent, and only 22 per cent during the latter one, and this is the more remarkable when taken in conjunction with a steady continuous drop in prices, besides the additional stimulus to demand given in the year 1865 by a reduction of the duty from 1s to 6d per lb. In 1866 the average bonded price of tea bought by Grocers was 1s 8d per lb., and it is now only 11d. This is a very considerable difference, and it might have been supposed that the rate of increase in consumption in face of such facts would have increased rather than have diminished, as has been shown to have been the case over the term of years dealt with.

Buyers in China appear to have been acting with some firmness in refusing to give any but very moderate prices for the new teas, and they will, no doubt, be taking careful note of the telegraphic advices that have been sent them from London this week, pointing out the complete absence of any rush after the new tea here.

The new tea is particularly low in price, but it is not especially cheap, and, taking everything into consideration, facts seem to point towards lower rather than higher prices as the season advances, in spite of the low rates already established.—*Produce Markets' Review*, July 2nd.

THE YAMASHIRO TEA-FIRING COMPANY at Fushimi has in course of erection an additional godown containing 500 pans.—*Japan Weekly Mail.*

TEA IN JAPAN.—The picking of the first tea crop has been finished in Shizuoka, and the picking of the second crop has been commnced.—*Japan Weekly Mail.*

EXPORT OF TEA FROM FIJI.—The *Fiji Times* of May 14th reports as follows:—By the "Arawatta" which left on Thursday the New Zealand Loan and Mercantile Agency shipped to Auckland the first large parcel of Fijian tea which has yet been exported. It consisted of 5,000 lbs. from the Alpha estate, in splendid order and condition. All the reports from experts as to the quality of this tea have been so favourable that it is reasonably expected to find a ready market at fair rates, and in the very probable event of this anticipation being realized it will represent the rift in the dark cloud which has for so long loured over the colony. This shipment will be followed by others in quantity each month, and success in the New Zealand and other markets cannot fail to attract attention to the colony as a tea growing country.

TEA IN BOGAWANTALAWA.

We are indebted to an occasional correspondent for the following particulars in connection with tea in Bogawantalawa:—"The ground planted up was a bit of Patana soil at the riverside in Bogawantalawa. Elevation would be about 4,300. Owing to the long-continued monsoon of 1886 and the very exceptional drought which followed upon it, this year has not been very good for tea up to date (16th May). However through Bogawantalawa the tea continues to look well and some of the finest of it is on the extreme high estates such as Loinorn and North Cove."

PAULONIA IMPERIALIS.

BY CASPAR HILLER.

This tree has not received the attention that its fast growing and value as timber deserves. Its growth exceeds any other tree in this locality,—has been grown of a circumference of 72 inches in twenty-five years. Its growth in comparison with chestnut is fully 2 to 1. Its durability as posts, in a trial of twelve years, shows it to be equal to chestnut.

It is quite hardy here, where our coldest winter days are from 12° to 15° below zero; but from the fact that its blossom buds freeze in the wood at about 12°, it is doubtful if it could be relied on much further north. On account of its spreading habit and dense foliage, it is not a good tree to plant along fence rows, or along highways. It should be planted forest like, 5 to 10 feet apart, and after growing several years should be cut off at the ground, and then it will make sprouts 10 or more feet high in one season.

The trees from time to time should be thinned out, so that by the end of ten or more years, the remaining trees should be 15 or more feet apart, according to thriftiness. The thick planting at first, is for the purpose of inducing upright growth, instead of the extended side branches. Plantings made on such rough parts of the farm that hardly pay for general farm crops, would no doubt in time become the most valuable part of the farm.

The thinnings on such plantings will be no small item in paying tax bills and interest on land.

Conestoga, Lancaster Co., Pa.

[The Paulonia is very highly esteemed for its timber in Japan.—ED. G. M. J.—*Gardeners' Monthly.*

[There are some seedlings of the tree at Hakgala, but they do not seem to flourish.—ED.]

COTTON AND VINE CULTIVATION IN BUSHIRE.

Consul Malcolm, in his last report, says that the cultivation of cotton in the environs of Bushire is somewhat peculiar as compared with the system existing in the interior, where the plants are annuals, and grown by irrigation, whereas in Bushire it is grown without any irrigation, and the plant lives up to twenty-five and thirty years without diminishing in yield. A plot of ground is ploughed up about three times during the rainy season, with the object of rendering the soil as soft as possible, then, just after the last rains, seeds first cleaned from every particle of the cotton, are soaked in water for two or three days, and then sown in furrows of about eight to ten inches deep, in rows of five or six feet apart. The seeds are thickly sown and covered over with earth; they begin to sprout in about ten days, and the plants are entirely left to the mercy of the elements, the only precaution taken being to prevent their being destroyed by cattle. With a heavy fall of rain after the sowing, the seeds, as a rule, die, or come up very sparsely, and fresh seeds have to be put down immediately. If the soil is rich and soft, the plants grow thickly, forming a sort of hedge, but as a rule only two or three plants survive in the space of a yard. The plants, if in good soil, begin to bear in the first or second year, and continue increasing in yield up to their fifth or sixth year, when they may be said to have arrived at maturity. During the successive rainy seasons the space between the rows is carefully ploughed up, and grain is sown, with double advantage, the ploughing being considered highly beneficial to the cotton, and its dead leaves in time serving as manure for the grain. Cattle are allowed to enter the cotton fields towards the end of autumn, as it is considered that they perform the work of pruning. A healthy plant is estimated to yield cotton to the value of eightpence, but the average yield may be taken at one shilling for every six plants. The plants blossom first in May, and the cotton is collected in July, when they blossom immediately a second time, reopening in September. The rearing of the vine is also, according to Consul Malcolm, peculiar in Bushire. On a declivity, a well about four feet in diameter is dug to a depth of sixteen feet, and a space of five feet is filled in with fresh soil well manured; then a healthy layer of the vine is put down early in March. For the first month it is watered four times, and then less frequently, about twice a month until the autumn. The reason of planting the vine in wells and on slopes is to prevent the scorching heat of the sun striking at the roots, and also to permit of rain water to collect therein during the winter months, which is the only means of watering the plant. The vine begins to bear from the first year, but the bunches are plucked off for the first three years. The plant attains its maturity in six years, when its yield varies, according to the soil and the attention it receives, from one hundred and thirty to seven hundred pounds of grapes.—*Journal of the Society of Arts.*

SERKYS TEA.

Under the above name, a medicinal tea has attracted some attention of late—though if we are to believe all that is said of it, its use is of great antiquity. It is advertised as "Dr. de Gardanier's Serkys of Asia, or Sarsaan's Imperial Tea, Preserver of Health, Youth, and Beauty," and in the printed description which accompanies each packet, the following statement is given:—"This great treasure until now enveloped in mystery, was discovered by the dervish who first brought to light the qualities of Moka, and by him presented

to the Sultan Osman I. It is a tea made from some of the most refreshing and balsamic plants which grow at the feet of the mountains of Mecca and Lebanon. It has all the beneficent qualities of the herbs of these countries, and the Sultanas, jealous of their youth and beauty, kept the secret for themselves alone.

"The tea is very refreshing. It faciltates the digestion, hardens the flesh, clears the complexion, and gives it the transparency and freshness of the Rose. The assiduous use of this tea, night and morning, will be followed with success in every case even when used by ladies of advanced age. It has the advantage of possessing a most agreeable taste, which has rendered it the favourite beverage of the Sultanas."

The following extract is then given from the works of Paul Lucas, who, in the history of his third journey to the East, made by order of Louis XIV., thus writes:—"In my last travels in the East I discovered the plants from which the Serkys is made. I was ignorant then that these plants were known in the seraglio, and that the Sultanas used them extensively. The Serkys is taken like ordinary tea with rum, cream, &c. After a slight infusion the water becomes amber-coloured. The tea has so many different tastes that it would be difficult to define them; it is very delicious, and unlike anything we have in Europe. I am assured that the Sultanas who use it very frequently long remain young and rosy. I was enabled to convince myself of the truth of this assertion. My quality of physician to the King of France gained me the favour of an introduction to the widow of Hassan Pacha, who was dangerously ill. Knowing that it was the custom for the two oldest ladies of the seraglio to wait upon the Sultana, what was my surprise to see with her two young persons of twenty-five or thirty years. I expressed my surprise to the people near me, and to the doctor of her Highness, who was one of my friends; they laughed, and assured me that the two ladies I believed to be so young were more than sixty years old, and that it was the continual drinking of the Serkys which had produced such an effect. When I had cured the Sultana by means of a plant which grows on Mount Argeis, I asked her through my friend the doctor for some of this marvellous tea, and she gave me a certain quantity, to show her gratitude.

"I do not intend to publish here the miracles to be wrought by means of Serkys, but after having carefully examined it I am able to state that it is a most excellent drink for the health; that it renews and purifies the blood, thus preventing all skin diseases; that its constant use preserves the skin in all its primitive vigour, and keeps off the germs of all diseases, thus maintaining the purity and freshness of youth, and constituting a real beauty, and so making all persons who use it frequently appear young and beautiful."

The tea, or rather the infusion, is prepared in the same way as Chinese tea. It is recommended to allow it to steep or draw not more than three or four minutes, and sweeten according to taste. It is sold in packets at a high price, the chief depôt being in Paris, with agencies in London. Probably for the purpose of preventing the identification of the plants used, the leaves are broken up into very small particles. Upon infusing a sample a strong smell of sage is given off, and the flavour of the infusion confirms the presence of this plant, though the leaves are so much broken that only occasional particles are found. Upon microscopical examination Professor Oliver detected the seeds of a Chenopodium probably *C. ambrosioides*, the leaf of which also seems to be present, mixed, however, with various other leaves apparently to increase its bulk.—JOHN R. JACKSON, Museum, Royal Gardens, Kew.—*Gardeners' Chronicle.*

CAOUTCHOUC-YIELDING PLANTS.

I gather from Mr. Jackson's remarks in page 772 of this *Journal*, under the above heading, that the authorities at Kew Gardens are taking an interest in this and similar matters. I was not aware of this when my notes were put together, so that I hope this explanation will dispel any idea (if such has arisen) of disrespectful feeling towards Kew.

With reference to Mr. Jackson's remarks on the *Mangifera indica* and the Mangabeira (*Hancornia speciosa*) which latter yields Pernambuco rubber, I may mention that when I was in Pernambuco a few years ago, I pointed out to a gentleman that the Mangabeira was an important rubber tree, and he remarked that "even if it were found to yield indiarubber, the tree was too valuable for its fruit to work on it for indiarubber."

The *Mangifera indica* (Anacardiacæ), Mr. Jackson says, is the mango tree of India. The Mangabeira (*Hancornia speciosa*) is the mango tree of Pernambuco. In suggesting that there might be a similarity in these plants, I was guided by the etymology of the names. We know that the action of the muscles concerned in utterance varies, especially in languages belonging to the Latin family; labial sounds are frequently transferred or blended into dentals, gutturals into palatals, and *vice versa*, so that a modest stretch of the imagination might have led any one to call these plants mango-bearing trees. In languages belonging to the Indo-European group this interchange is perceptible, but not so distinct.

It is a fact that Ceara rubber comes to hand in the form of masses made up of "tears," which would lead one to believe that the tree is punctured; when the sap exudes and dries up, probably closing the puncture; on removal of the tear a fresh exudation takes place.

I have not witnessed the collection of rubber at Ceara, but I mention this merely to show that it is a very different product from what we know as Pernambuco rubber. Since reading Mr. Jackson's notes, I have referred to a work on Brazil by Agassiz and his companions, in which an extract appears from Gardner's "Geological Notes." Gardner says "that a species of Caryoca called pike, a small tree belonging to the natural order Apocynaceæ, which produces a delicious fruit called *Mangaba*, is cultivated at Ceara."

It was this which led me to say this plant was the same as the rubber-producing tree of Pernambuco, but it was clearly a mistake to give it as the source of Ceara rubber, although, in fact, Pernambuco rubber is met with in commerce under the name of this place or province, and Mangabeira rubber is met with in commerce under this distinctive name.

There is a singular confusion in Gardner's notes, which perhaps Mr. Jackson will kindly explain. As far as I can see, the Caryoca does not belong to the Apocynaceæ, but to the Esculaceæ. It seems to me that this is an important matter, and deserves clearing up, for if it turns out to belong to the Apocynaceæ, it is probably a rubber-producing tree. There is a strong probability of its being identical with the Pernambuco tree.

Mr. Jackson's remark as to the Chicoraceæ would lead one to believe that because the dried juice of the dandelion and allied plants is inelastic, it does not contain caoutchouc.

I give here a translation from the *Moniteur Officiel* (Feb., 1887), respecting the extraction of caoutchouc from the *Sonchus oleraceus*. The process here given is pretty much the same which I have employed for the examination of milky juices for the last twenty-five years, and I can therefore add my testimony to its value. The main difference is that I have worked on the expressed juices of the fresh plant, whereas in this treatment the plant itself is used.

"To extract caoutchouc from this plant (*Sonchus oleraceus*), the plant is exhausted with bisulphide carbon, and the residue left on evaporation of the bisulphide is treated with boiling alcohol. The insoluble matter, which is crude caoutchouc, is warmed with an alcoholic solution of potash, and washed repeatedly with warm, weak alcohol.

"By this treatment fatty matters and wax, as well as chlorophyl, are removed. The residue is elastic, and strongly coloured, it presents all the properties of caoutchouc, dissolving entirely in chloroform, and bisulphide carbon, and partly in ether. We obtain 4·13 per cent. extractive matter, ·41 crude caoutchouc, which gives ·16 when purified.

"The plant may be exhausted with benzine after previous treatment with alcohol; the residue, on evaporation of the benzine, gives ·92 per cent. of the weight of the plant; which by treatment with alcohol gives ·27 per cent. caoutchouc nearly pure."

Of course in a warm climate these volatile solvents could not be used, but if we wish to know whether a plant contains caoutchouc, this process may be simplified. There is evidently a very erroneous method in use for precipitating these juices by alcohol, the result being that we get all the gum, mucilage, more or less extractive matter, hydrated resins, &c., all mixed with the caoutchouc if present. On a future occasion I hope to deal with the chemical treatment of these juices.—THOMAS T. P. BRUCE WARREN.—*Journal of the Society of Arts.*

MANDALAY MANGOES.

I noticed in your last issue (June 25th) an article on mangoes from Mandalay. My name is mentioned as an authority, but in this instance, not having seen the fruit it is impossible to say what it is. I take very little notice of what is told me about the fine flavour of this or that mango. A great deal depends upon where, and under what circumstances, you eat mangoes. I well remember the first I ever ate, and I thought it delicious; it was at a friend's house in Hong-kong. The fruit had been brought from Manilla. I was fresh from board-a-ship and had not tasted fruit for some time, and that was the reason I liked the "tea-and-turpentine," or better, the carrot-tasted mangoe from Manilla. I made careful notes about this fruit, and was able to compare it with good Indian mangoes. The gentleman writing from Mandalay was perhaps placed under somewhat similar circumstances; for he says:—"Nothing is more pleasant after having ridden from daybreak till noon." I quite agree with him and if he happened at noon to rest under one of our good *beeju* trees, or seedlings, and satisfied himself with a good meal of really nice sweet, juicy mangoes, it would make, I think, a lasting impression on him, and he would always say they were the best mangoes he had ever eaten. There are also *jungli* mangoes, or really wild fruit, the original species; and jungle mangoes, the deteriorated stock of cultivated fruits, grown from good fruits that have been eaten on the roadside and the seeds thrown away. It is, I should say, the latter the Mandalay gentleman has eaten, for I doubt if he would care to eat more than one of the real jungle mango, at least such as grow at the foot of the Himalayas; and I imagine it is the same species all through Burmah. Burmah being an "old" country, they must have carried on a systematic selection of this fine fruit by accident, the same as has been done in India.

About the so-called best mango—the *Bombay*—or, as it should be called the *Afooz* or *Alponzo*, as there are so many Bombay mangoes, it is no better than many in Tirhoot and Malda, or Madras. The much vaunted Malda *Fuslee* is really not to compare with some of the other Malda sorts. The real Bombay, is not a Bombay mango at all! It came orginally from Salem in Madras, and does so still. One of the great secrets about good mangoes is, that they should never be eaten fresh-gathered from the tree. This is the reason the *Bombay Afooz* is so good. It is gathered rather unripe, goes a journey of perhaps a week, and arrives in prime condition, no "string," no rank flavour, but something too delicious to describe in words. If this same mango had been eaten fresh-gathered, probably it would be pronounceed inferior.

I will refer to Firminger's description of a fruit called cherimoyer or cherimola (*Anona cherimolia*). One man says that no fruit in the world is like it, being the "masterpiece of nature." Dr. Lindley says: "One English pear or plum is worth all the cherimoyers in Peru." I should be inclined to say the same, in comparing mangoes of India to other mangoes of the world. The Indian mango is the result of cultivation of centuries. Very few people living in India know where the fine mangoes are, but I can say I have had opportunities of eating and seeing mangoes to which even the much-talked-of Bombay is a little inferior; even the fine English pear does not beat it in flavour. I hope shortly to give you a list of some really good mangoes from a catalogue of some 500 varieties of this fine fruit.—C. M.—*Indian Agriculturist.*

IPECACUANHA CULTIVATION IN INDIA.

The following correspondence has been published by the Madras Government:—

Letter from G. Bidie, Esq., M.B.,C.I.E., Surgeon-General with the Government of Madras, to the Secretary to Government, Revenue Department, dated Ootacamund, 20th May 1887, No. 150-O:—

I have the honor to suggest to the Right Honorable the Governor in Council that the cultivation of the ipecacuanha plant be pushed forward as energetically as possible, as it seems quite within the range of possibility that the supplies of the drug from South America may at any time cease. According to the *Chemist and Druggist* of the 29th January last, the stock in first hand in London, the chief emporium for the drug, was unprecedentedly low; and it is further stated, "the bulk of this stock, however, will be taken out of the market before the week is over, and, so far as we can ascertain, no further supplies of the drug are on their way."

2. I need hardly remind Government of the very great importance of ipecacuanha as a remedy for tropical dysentery and other diseases, and that the cessation of supplies would be nothing short of a calamity in India, as it would infallibly increase enormously the mortality and invaliding from dysentery amongst the servants of Government generally, and especially in the army both European and native. Of course the civil population of the country would also suffer, if deprived of the drug.

3. It appears to me therefore that the time has arrived for India to cultivate her own supplies of the precious root as in the case of cinchona, so as to be no longer dependent on Brazil, from which "unforeseen circumstances, such as war or epidemic, may at any time interrupt the supply."

4. From past experience, which has now extended over several years, the plant although not difficult to propagate is apparently by no means easy of culture, and requires climatic conditions which can only be secured within a limited area. It is to be feared, therefore, that for some time at any rate the culture of ipecacuanha as a mercantile product is not likely to be taken up by private individuals, although the price, which has never been below 4 shillings per pound, is such as is likely to render the industry remunerative. I trust therefore, that the Right Honorable the Governor in Council will see fit to adopt early measures for the culture of ipecacuanha on a practical scale at Nilambùr or any other site which may be deemed the most suitable by the Director of the Botanical Department.

Order—dated 30th May 1887, Mis. No. 3082, Revenue.

Forwarded to the Conservator of Forests, Southern Circle, and the Government Botanist for the favor of remarks, which should be submitted at a very early date. In order to avoid delay Colonel Campbell Walker's reply should be sent to Government direct a copy being sent to the Board for information.

Read—the following letter from M. A. Lawson, Esq., Government Botanist and Director of Cinchona Plantations, Nilgiris, to the Secretary to Government, Revenue Department, dated Ootacamund, 8th June 1887, No. 102:

I have the honor to acknowledge the receipt of G.O., No. 3082, dated the 30th May 1887, Revenue, with an accompanying letter from Surgeon-General G. Bidie on the subject of the cultivation of the ipecacuanha in Southern India, and to state that I have been pushing forward the propagation of this medicinal plant, as fast as possible, for the last eighteen months, in the nurseries attached to the Government Gardens, and that I have now a great many plants ready to put down.

2. I have tried growing the ipecacuanha in the Government Gardens at Barliyár, but they do not thrive there, neither the climate nor soil agreeing with them. The only place where I have seen them doing well is in the Government Teak Plantations at Nilambúr; and I advise Government to allow me to take up a quarter of an acre in that forest to put out more plants.

3. The forests are under the jurisdiction of Colonel Campbell Walker, Consertator of Forests, Southern Circle. I have not mentioned the subject of taking up a plot of ground in these forests to him, but I am sure, if there is no forestry objection to be raised to doing so, he will willingly assist me in growing the ipecacuanha there.

4. The Deputy Conservator of Forests stationed at Nilambúr is Mr. Hadfield, who, I am quite sure, would also render every assistance in the matter.

5. Dr. Bidie has not at all exaggerated the necessity of the case, if the reports from England of the scarcity of the drug are well founded, and I have no reason to believe that they are not.

Read— the following letter from Lieutenant-Colonel I. Campbell Walker, Conservator of Forests, Southern Circle, to the Secretary to Government, Revenue Department, dated Ootacamund, 15th June 1887, No. 54:—

Referring to G.O., of 30th ultimo, No. 3082, I have the honour to report that the only place where we have found the ipecacuanha thrive is Nilambúr, which is in my opinion due, not only to suitable condition of climate and soil, but to the presence of a competent resident agency which we have not got elsewhere.

I refer to the matter in paragraph 54 of my Administration Report for 1885-86, and in his report for 1885-86, the District Forest-officer (Mr. Hadfield) states that "there are twenty plants doing very well. The one reported last year as dead has shot up again from the roots."

2. Mr. Lawson has favored me with copy of his letter No. 102, of 14th instant, and I need scarcely say that there will not be the slightest objection to placing one-fourth of an acre at his disposal at Nilambúr or a larger area if required, and giving the cultivation every attention in accordance with his instructions.

3. I think this will be far the best course to adopt in view to extending the propagation of the plant; when Government are prepared to supply plants in large numbers free or at cost price, private enterprise will doubtless step in and take up the cultivation.

I would deprecate any attempt at planting on any scale by this department as being outside the legitimate sphere of its operations.

I forward copy of this letter to the Board as directed.

Order—dated 24th June, 1887, No. 613, Revenue.

The Government Botanist should arrange to plant out at Nilambúr all the ipecacuanha plants which are ready for removal. The Forest-officer stationed at Nilambúr will give Mr. Lawson every assistance and will have charge of the cultural operations.

2. His Excellency the Governor in Council hopes that private enterprise will render it unnecessary for the Government to undertake the cultivation of this valuable plant on any large scale. These papers will be laid upon the Editors' table and will also be communicated to the Chamber of Commerce and the Wynaad Planters' Association. The Government Botanist will furnish information regarding cultivation to any gentleman who may apply to him.

HOW TO MAKE TEA PAY.

(By one who has done it.)

MANUFACTURING.

This is the most important, most onerous and most worrying part of a planter's work. It was with a full appreciation of this that the author of the clever parody on the "Policeman's Song" made his chorus run:—

When the manufacturing season has begun
A planter's life is not a happy one.

Contrary to most of the divisions of operating on a tea garden manufacturing does not leave much scope for divergence of working, well withered leaf is well withered leaf whether Assam, China and whether for Lyle, Jackson or Kinmond's machine; the same with firing, there is only one way for well fired tea, it is in colouring of fermenting only that, as in pruning and plucking, a planter is a law unto himself and in many cases a terror to his Directors and Agents. To begin however, at the beginning.

Withering.—For this, ample accomodation must be provided. It is the most important stage of manufacturing. If leaf is not properly withered, really good tea cannot possibly be made. It is a matter of opinion whether to use *changs* or trays, the former are cheaper and I think equally good, but whichever you have have enough of them. Don't grudge expense in providing sufficient room for leaf. Don't boast that you do all your withering in one small house, as I have heard a planter do. Go and build another one twice as large and say nothing about it. You will get your reward when you draw your commission. Leaf is properly withered when it has lost all crispness and becomes sticky, if you take a handful up. Be careful not to overwither, better to be a little underdone. In the latter case you lose a few tips and get some broken tea, but you save the liquor, while in the former case all the strength has gone and you get a hard dry brassy liquor hardly better than toast and water, it will not inebriate certainly, but neither will it cheer either the drinker or the maker. Do not let leaf be handled more than is absolutely necessary, do not let it get dirtied, and above all never let it heat, coolness is the one great desideratum for leaf while being withered, rolled and coloured.*

Rolling.—Any machine will roll soft leaf well withered. No machine will roll badly withered leaf, nor leaf that would make leather take a back seat for hardness. As soon as leaf is withered it should be rolled off—rolling should be done as quickly as possible to prevent leaf heating on the table. It is best to roll twice, sieving out the fine leaf after first roll and then rolling the coarse leaf again, better to roll too hard than too light. Do not let leaf be accumulated in great heaps near the rolling table waiting to be rolled, nor should leaf be gathered on the *changs* till it is actually wanted. The withering men are very fond of collecting it beforehand in little heaps to put into baskets as soon as wanted, but this should not be allowed as it heats the leaf and turns it red.

Colouring.—For this light trays, say 7′ × 3′, are required, a loose wet cloth should be spread on the tray and then the rolled leaf spread on it to about an inch depth and then another wet cloth be put on top, perfect coolness is a *sine qua non*. The leaf must not get the slightest suspicion of heating. A dark room, with thatch roof, attached to the tea-house is the best for this purpose. There should be a good draught through the rooms; the cloth should be washed daily and steamed once a week, to prevent any sour smell, &c. And now as to the colouring itself. It should be done between the first and second rolling. There are only two kinds of tea which should be gone in for, the raw, under-fermented rasping light liquor, and the deep red, fully fermented, thick, dark liquor—these are the two kinds that are wanted on the market, the medium teas between these two kinds are not wanted. It is a great mistake to think that by sometimes making one kind and sometimes another they will mix well together, and that you'll get both flavour and strength and consequently a good price. If the tea were bought by consumers direct it might be so, but it is not, the people who buy our teas prefer to do their blending themselves, this should never be lost sight of. You are going out of your way when you attempt to blend teas. It is not your business; your aim should be each to establish some special character for your teas, let it be either the light rasping liquor or the full thick flavoury liquor, so that the buyers of your tea can always depend upon getting one particular kind from you. By having some special characteristic you obtain some standing for your tea, while without it there is nothing to save you from the ruck of common useful teas which are at such a discount in the market. It is a matter for

*So all experts told us, at one time, but recently withering has been done largely by warm and even hot air.—ED.

you individually to decide which kind of tea will suit your garden best, but having made up your mind once stick to it. The under-fermented rasping kind is the easier to make, as you have not to wait long for colour, 30 to 50 minutes being sufficient. The tea must, however, be fired off very briskly; for a dark thick liquor, three to four hours colouring is required, each table of leaf must be examined separately and not rolled for the second time till the desired colour has been obtained. Great care is necessary here, as leaf colours so much quicker on a hot day than a cold, and during the middle of the day, than it does in the morning; the leaf should be a bright deep red with hardly any green and the liquors should cream thickly when cold.

Firing.—There is not much to say about this, except that in this as in every stage of tea manufacture great care must be displayed. Do not fire off at too great a heat, let the tea be thoroughly crisp, do not take tea off the fires 15-annas done,* with the idea it will take on the rest, because it won't. It appears to do so, but it only dries outside. Let all your firing be done over the fires till quite completed. If it is necessary to keep one-half fired tea for any time keep it very thin and turn over frequently as it is apt to steam, in which event all briskness is lost. I refrain from entering on the vexed question as to which are the best drying machines, as beyond the scope of these articles, but if a coke machine is used the tea should, if possible, be finished over charcoal. I wish again to bring to the notice of every proprietor and manager the importance, I had almost said, necessity of having the tea-house under constant European supervision, so much care is required at every stage of the process of manufacture, and so much discretion is necessary in adapting the system adopted to the different kinds of circumstances, which, owing to weather, and other causes differ almost daily, that no native can be trusted entirely to work a tea-house to advantage alone. A manager's time is taken up so much with accounts, correspondence, &c., that he cannot possibly do justice to the tea-house as well. Only really good teas sell now well and such can only be had by the utmost care being taken of every little detail of the process, the neglect of any one of which being most disastrous.

DON'T.

Most of my readers have probably read the small book called "Don't" regarding good manners, &c., and I will conclude this article with some "Don't's" anent tea manufacture.

Don't put leaf in the tea-house or out in the sun to hasten withering. If you must warm it, put it in your dryer.

Don't imagine that collecting leaf in great heaps near the rolling machines, or that letting everyone walk to and fro over it, or that little coolie children playing with it improves it. These ideas are now exploded.

Don't squeeze all the juice out of the leaf in rolling and let it run all over the tea-house, it is now found best to keep it in the leaf.

Don't put the rolled leaf into boxes or in heaps a foot high to ferment. Sour tea does not sell so well now as it used to.

Don't keep your drying machines or *chulas* at a low temperature to save fuel; the tea will often come out quite dull enough without this.

Don't try and make one *batti-wallah* do the work of four, better have four men to do the work of one.

Don't put too much faith in the instructions and suggestions frequently appended to brokers' valuations. It's a case of the blind leading those who can see.

Don't trust to your sirdar to give fair samples of his previous day's manufacture. A good sirdar always tries to please his master.

Don't try and work your machinery without oil to save expense; accidents will happen even in the best regulated families.

* Meaning 1-16th less than complete.—ED.

Don't fix your rolling machines so loosely that when you start working they look as if they were off for a tour round the tea-house.

Don't boast when you get a broker's report describing your tea as brassy, wait till you get the brass from the buyer and then talk about it.

Don't at the beginning of a season, tell all your neighbours how much tea you will make and what you are going to get for it. Estimates made at the end of a season are most reliable.

Don't when calculating outturns per acre count your ten-year-old tea as not yet in full bearing, the correct figures are now published in the Directories.—*Indian Planters' Gazette.*

SWEET LEMONS.—Sweet lemons are a favourite Mexican dainty. They are the shape, color and size of the lemons of commerce, but are sweeter than bananas.—*Gardeners' Monthly.*

POTATO CULTURE.—Some carefully conducted experiments have been made in England at Chiswick, which Dr. Masters summarises as follows:—1, earthing up produces a crop of more uniform and of superior quality, even if less in quantity; 2, that bending the haulms occasions a diminished yield; 3, that a larger aggregate produce is derived from planting whole tubers than from the employment of cut sets.—*Gardeners' Monthly.*

MUM IS THE WORD FOR CHRYSANTHEMUM.—The *Journal of Horticulture* says:—"An American writer wishes that 'the name Chrysanthemum could be shortened, as it causes some trouble to those who are not familiar with botanical names. We hear them called Cassanthiums, Chrysantheums, as well as Chrysantumbums, Chrysants and Chryschianthems.' To these might be added a daring abbreviation in common use amongst English growers—namely, 'the Mums.'" As they are jovial flowers about Christmas time, some American ladies call them Christmas Anthems.—*Gardeners' Monthly.*

A MONEY LESSON FROM RHUBARBS.—Faith is said to be the evidence of things unseen, and it is this faith that sees money where ordinary eyes cannot, that makes the fortune of many a nurseryman and market gardener. Everybody has heard of Myatt's Victoria, Myatt's Linnæus, Myatt's Prince Albert, and possibly other varieties of rhubbarb. The Myatts live at Deptford in England. Over, seventy years ago, old Joseph Myatt had faith there was money in rhubarb. He sent five bunches to Deptford market, but two were brought back as unsaleable. Instead of getting out of heart he sent ten bunches at the next market, and all were sold. He persevered, and finally acres on acres were produced, and the immense fortune which faith saw was realized.—*Gardener's Monthly.*

[Rhubarb grows very well in the hill country, and if only someone would take up the cultivation on a large scale, we are sure it would pay handsomely. Cwts could be sold every week.—ED.]

COCONUT BUTTER.—Liebig devoted a great deal of time to experiments to discover a process of making a *pure* fat free from acids or other foreign matter, and asserted that the discovery of such a process was a certain fortune for the inventor. A German professor, Dr. Schlink, is said to have successfully solved the problem, producing from the common grades of coconut oil a brilliant white substance somewhat harder than butter, odourless, tasteless, and containing neither acids, water, nor mineral matter. In fact, it is a pure vegetable fat, and it is claimed that it will prove for culinary and edible purposes much superior to butter, lard or tallow, all of which contain acids that through heat separate from the fat and cause the fermentation and unpleasant odours and tastes that are so well known. It is said that dyspeptics will find this new substance perfectly digestible, and that it will take the place in medicine of cod-liver oil in the treatment of consumption. A factory has been established in Germany for its manufacture and another is in course of erection, and there is thus a prospect that within a few years "vegetable butter" will be as well and more favourably known than butterine, butter, and oleomargarine.—*Invention.*

IF we are to believe a contemporary, a very important use has been discovered for the *Erythroxylon Coca*. It is nothing less than as a remedy for cholera. It appears that cholera of a very bad type broke out in Buenos Ayres, and the chewing of the leaves of the Coca is said to have cured many cases. The truth of this statement is worthy of investigation.—*Indian Agriculturist.*

WE note that part I of Dr. George King's monograph on the species of *Ficus* of the Indo-Malayan and Chinese countries has recently been issued. It deals with *Palæomorpha* and *Urostigma*. Fig trees form such a prominent feature in tropical vegetation generally, that we have no doubt this work will prove useful to botanists. This part is illustrated with nearly one hundred plates.—*Indian Agriculturist.*

A FRENCH DISCOVERY OF A CURE FOR GRAPE MILDEW.—Lime and sulphate of copper has been found, when syringed over grapes, as a perfect cure for mildew. The solution is thus prepared: From 30 pounds to 50 pounds of lime and sulphate; each is dissolved in a barrel containing about 100 gallons of water. The operator dips a small heath broom in the liquid, and walking backwards sprinkles the vines. About 14 quarts to 1000 vines, the expense being a little over five dollars an acre.—*Gardeners' Monthly.* [We should think the application would be good for any kind of blight, insect or fungus.—ED.]

CAPE TOWN BOTANIC GARDENS.—This garden has a Government subvention of £500, increased by voluntary subscription to £554. To make both ends meet the garden has to carry on a commercial speculation fatal to the true interests of the establishment, and one not calculated to ensure the goodwill of the legitimate traders. The Director continues to afford information on plants likely to be useful in the colonies for sheep-feeding and other purposes. The herbarium is in good condition.—*Gardeners' Chronicle.*

GERMINATION OF BRAZIL NUTS (Bertholletia excelsa).—With a view to introducing into Queensland this valuable tree a large quantity of freshly imported seeds was purchased for Kew from a London wholesale house, and at once packed in cases with moist soil, and forwarded to the Botanical Gardens at Brisbane. To test the seeds a sowing was made at Kew at the same time. Several of these germinated a few weeks after they were sown, whilst others have remained in the soil without showing any signs of growth till the beginning of this month. We have in this a proof that under certain favourable conditions the seeds of the Brazil Nut will keep fresh, and retain the power to germinate, for at least two years. As these seeds are generally considered among those which soonest lose their germinating power, owing to the large quantity of oil they contain, it is worth recording that they may be kept fresh for a period of two years at least.—*Gardeners' Chronicle.*

WEATHER.—A Belgian scientist, we are told, has been at the pains of calculating that the weather on our globe repeats itself in cycles of sixty-two years. He shows that the barometric and thermometric readings in London for 1885, 1886 and 1887 are practically the same as those for 1823, 1824, and 1825, and he asks men with more means than he possesses to continue the comparison through the complete cycle of sixty-two years. Then he argues that "if we can refer to a year which had practically the same weather as that which we are experiencing this year, it is of a greatest importance that the astronomical authorities of each country should utilize that knowledge to the advantage of the commercial and agricultural industries of the community generally." He also proposes to show, by an examination of the moon's phases at an interval of sixty-two years, that not only has the moon an influence on the weather, but that the moon is the cause of the weather.—*Indian Agriculturist.* [Against which conclusion the majority of scientists protest as many do against the influence of sun-spots on our meteorology. But even the most advanced scientists have much to learn.—ED.]

TONQUIN BEANS.—The Tonquin, or, as it is sometimes called, the Tonga Bean, the seed of Dipteryx odorata, Willd., is well known for its fragrance, resembling that of newly-mown hay, and hence it was much valued, at one time, for scenting snuff and at the present time for sachets and handkerchief perfumes. The tree is a native of Guiana, and grows to a height of from 60 to 70 feet, with a diameter of from 1 to 2 feet. The wood is very hard and durable, and is said to bear a greater strain than any other wood in the colony. It is chiefly used for shafts, mill wheels, cogs, &c. The principal value of the tree, however, is for the seeds, the best qualities of which always fetch a high price in the English market, the finest Angostura Beans realising at the present time 8*s.* 6*d.* per pound wholesale, the second and third qualities fetching 4*s.* and 2*s.* respectively. In a report on the trade of the State of Bolivar for the year 1886 it is stated that the crop of Beans was unusually large and far exceeded the crops of the previous five years. The quantity of Beans collected in the great forests of the territory of Caura and prepared for exportation exceeded 350,000 lb. weight. The total quantity exported from Ciudad Bolivar, according to the returns of the agents of the parties who hold the exclusive privilege of collecting and exporting the vegetable products of the above-named territory, was 298,000 lb. nett weight. Previous to the year 1883, before the collecting and exporting this valuable fruit became a monopoly, the merchants of Ciudad Bolivar paid the Government an export duty of 35 cents per pound—three and a half times as much as that now paid by the parties holding the exclusive privilege of exporting this seed. The quantities exported fluctuate considerably, as will be seen from the following statement:—1882, 89,965 lb.; 1883, 153,138 lb.; 1884, 150,681 lb.; 1885, 35,325 lb.; 1886, 298,000 lb.—*Gardeners' Chronicle.*

THE Excise report of the North-Western Provinces and Oudh for 1887 has one remarkable feature about it. After reviewing the measures adopted to restrict the consumption of liquor by the poorer classes of the people, Sir Alfred Lyall says:—"In other Eastern countries these classes are large consumers of tea and coffee, and it may be conjectured that had these products been indigenous to, or long cultivated in the Indian peninsula, they would by this time have assumed as important a place in the domestic economy of Indian households as they occupy in China, Thibet, or Turkistan. It is upon these considerations that the North-Western Provinces Government have endeavoured to promote, by special measure, both the sale of dry tea in small packets, in the larger towns and cities of the North-Western Provinces and Oudh, and the establishment of tea-shops on the model of European coffee-houses. Some of the larger municipalities have interested themselves in the experiment and the Department of Agriculture and Commerce was utilised to procure good tea at wholesale rates for the retail vendors. Sir Alfred Lyall observes with much interest the recent formation of an Association in Culcutta, which proposes to take the question up seriously and systematically in Bengal and in Upper India, and he is prepared to co-operate heartily with it should the Association see its way to extend operations to any districts in these Provinces. The subject at first sight seems remote from the administration of Indian excise; but the experience of European countries has shown that it has in reality an essential connection with it." This is the first instance of the kind we know of, where an administration has laid itself out to counteract the evils of drunkenness by promoting and encouraging the consumption of tea. We have already stated the causes which, in our opinion, have prevented the people of India becoming a nation of tea drinkers; but a change has come over the spirits of the Indian tea-dealers, which cannot fail to have very wide reaching effects. We heartily wish Sir Alfred Lyall success in his endeavours to promote a liking for tea among the people under his care, and hope that other administrations will not be slow to follow in his footsteps.—*Indian Agriculturist.*

THE PRESENT VALUES OF STRAITS PRODUCE.—I.

(*Straits Times*, July 13th.)

The values of Straits Produce so materially affect the welfare of our Colony, that it is rather surprising that more general attention is not devoted to a subject which is so full of interest in itself and which has such an immediate bearing on our present and future prospects. To any one who has felt the charms and experienced the woes of a speculative business in the Far East, the list of market quotations which we publish daily at the top of one of our columns is more stirring than the most exciting romance and more pregnant with human interest than anything written since the days of Shakespeare. The dull and prosaic list of market quotations means Profit and Loss, and Profit and Loss are probably the most powerful influences of modern society. There has been quite a revolution of late years in the prices of Straits Produce which has largely contributed to the prosperity of the Colony, in which many a man has participated without grealy troubling himself as to whether gambier is firm, pepper weak, or tin dull and heavy. There are, of course, a number of gentlemen whose sole study and care are concentrated on produce freights and exchange; we need hardly say that we do not write for the benefit of these specialists, but with a view of demonstrating to the general public, to whom gambier is an unknown quantity, and pepper a pungent powder kept in a cruet, that high prices for Straits Produce are for the benefit of all concerned Prices of Straits Produce are at present running high with, it would appear, but a small prospect of any immediate and disastrous reaction. We quote by way of text the following extracts from our prices current of yesterday:—

Gambier.. ..	...	$ 6·65
Black Pepper ...	...	23·50
Bali Coffee ...	...	27·00
Tapioca Small Flake	...	6·00
Cloves, Amboina...	...	42·00
Tin	...	38·25
Sago Flour, Sarawak	...	1·97½

With the solitary exception of Sago Flour, all of these quotations shew a very high range of prices which must of necessity be very remunerative to producers and leave a good margin of profit to Singapore and Penang merchants. Take, for instance, tapioca, which now realises $6 per picul against from $3 to $3·50 for cost of production. It will be seen at a glance that the fortunate owners of tapioca estates in full swing must clear close upon 100 per cent on every picul which they sell.* Yet we all known what a deal of sheer nonsense has been said and printed concerning the alleged iniquity of levying a most moderate land tax on estates which yield fabulous profits to their owners. It is a far cry to the day when gambier, which is now worth between $6 and $7 per picul, was exchangeable for a picul of rice, but within the last ten years still more marvellous changes have taken place in the values of produce. Ten years ago Black Pepper was worth about $7 per picul, and Cubebs sold for say $5 per picul. Cubebs are but a variety of the pepper vine, and the berries of the cubeb vine are in the first place distinguished from ordinary black pepper by means of a short stalk, so that if we may use a familiar illustration, a cubeb in appearance is to a pepper berry as a comma is to a full stop. Of course there are certain other properties peculiar to the cubeb which are known to all and sundry who can distinguish between a cubeb and a cow. In the halcyon days of 1877-1879 when cubebs sold for $5 per picul, it used to be a practice of our Chinese friends to rub off the stalks of the cubeb berries and mix them in with the ordinary pepper. Many a man has administered a considerable dose of cubeb to himself when he thought he was going in for nothing more pungent than pepper. This is an accident not likely to happen now-a-days, for, although black pepper is now quoted at $23·50, cubebs are wanted at $80 per picul, and really pure cubebs, free from stalks, sand, jungle berries, and foreign matter generally, would fetch a good deal more. Nobody mixes cubebs with pepper now, and the progress of adulteration in this particular direction has been most successfully checked.

Another very striking feature of our commerce is the manner in which we profit by the disasters and misfortunes which befall our fellow men in other parts of the world. Take Coffee as an example. Coffee plantations have been started pretty well all over Singapore, Johore, and certain districts of the Protected Native States. Since coffee planting became a feature of Singapore enterprise we have seen the ruin of Ceylon as a coffee growing country, leaf disease has wasted the splendid estates of Java, and finally the vast production of Brazil has been cut off to a very large extent by the same causes which have wrought such havoc in Ceylon and Java. The natural result has been that coffee of all descriptions has risen enormously in value, considerably over 100 per cent and a healthy coffee estate in full bearing has become the first cousin to a "bonanza" gold mine. We doubt, however, if the poor and exhausted land of Singapore will do for coffee, but plantations on the virgin soil of the peninsula have brilliant prospects before them, and to go yet a little further afield, there appears to be no doubt but that some of the, finest coffee land in the world is to be found in the newly opened districts of British North Borneo. The wasted fields of Ceylon have never recovered themselves, the same thing is now being experienced in Java, and if the information at present to hand about Brazil is anywhere near the mark, prices of coffee must rule high for years to come. It needs no prophet to tell us how beneficial the disasters of other countries will be to us in this instance, however much we may deplore them.*

* Things have greatly changed since we visited Singapore in 1881, when the chief grower of tapioca, Mr. Chasserieau, told us he had some hundreds of tons unsaleable in the London market.—ED.

II.

(*S. T.*, July 14th.)

We have already instanced the causes of the enhanced prices of coffee as an illustration of the fact that our prosperity is sometimes built up from the ruins of less favoured countries; it may be of interest to work out this idea yet a little further, and perhaps nothing more extraordinary can be found in the whole history of Straits Produce than the fluctuation in values of Amboina cloves. About the period when our Unofficial Members of Council were lads at school, Amboina cloves were worth $7 per picul; they are now quoted at $42, and even this latter quotation is as nothing to the price which they used to fetch at one time. For there is a historical interest attaching to Amboina cloves with which few of our products are gifted. Sir Francis Drake drove a fine trade in cloves when he cruised about the Molucca Islands in the glorious days of Queen Elizabeth. Drake is reported to have sold his "Amboinas" for their weight in gold, for which he had paid with powder and shot. Thus Sir Francis thoroughly understood the quintessential principle of buying cheap and selling dear, and it is not surprising to find that our gallant free-trader on returning to London after one of these cruises paid £47 for every £1 invested by the shareholders in his produce venture. We may now follow the course of the clove market in a less remote and less picturesque period. A few years ago the prices of Amboina cloves after many fluctuations remained dull and dragging at about $17. They got to be quite a drug in the Amboina market, but nevertheless a few hundred piculs were bought at that price by the branch house of a Singapore firm; further quantities were offered at low prices, but the firm in question refused either to buy more cloves or take them on consignment against advances. When the cloves finally reached Singapore, the news was telegraphed of the total loss of the Zanzibar crop; it was said at the time that whole plantations were destroyed in Zanzibar by bush fires, and the entire lot of "Amboinas," bought at $17, was sold on ar-

* Yes, but, with leaf disease on coffee bushes in the Straits, he must be a bold man who risks large capital in the pursuit.—ED.

rival at $43\frac{3}{4}$ per picul. With a view of pointing a moral, it may as well be said that the sellers could never forgive themselves for not having bought up the entire crop. Since then, Amboina cloves have again dropped to $17, and are now quoted at $42. From which it would appear that the fragrant clove offers a wide scope for a series of plunging speculations.

The market price of tin is a matter of political importance to our Government, and until agriculture has a firmer hold in the Native States, it is essential, for the prosperity of the peninsula, that rates should rule high. The price we quoted yesterday was $38·25, and when it is considered that within the last ten years it has been sold as low as $18, it is evident that present rates must be extremely satisfactory, and that tin-mining, conducted with ordinary good management, cannot fail to be very remunerative.

We have now taken up the various staples of our trade of which we quoted the current rates in our article of yesterday, with the exception of sago flour, which, in vivid contrast to all other descriptions of produce, has fallen to the extraordinary low price of $\$1·97\frac{1}{2}$ for "Sarawak." It is characteristic of the good fortune of this colony that the very marked decline in prices of sago flour has in no way affected the volume of its production. There is as much sago flour made at $\$1·97\frac{1}{2}$ as when Singapore washings, said to be equal to Sarawak, fetched $4, Here we have a fall of 50 per cent without diminishing the supplies of the product, which are as abundant as ever. In 1880 prices of this staple were forced up to between £16 and £17 per ton whereas Powell's latest telegram quotes it at £7 9/.

Sago is well worthy of the study of an economist; Nature has stored up such vast and well nigh illimitable stores of food in the shape of sago forests, as to excite the wonder of all who have studied the subject and the sago palm is a reproductive plant, so that no amount of felling and cutting can subdue its wonderful fertility. The world at present draws its supplies of sago from Borneo and Sumatra, but the true home of the flour giving palm is to be found in the Moluccas and New Guinea. The voyager in these regions may steam past miles and miles of apparently never-ending sago forest, the trees of which will yield about double the quantity of Bornean and Sumatran palms, and the produce of which will work up into a much finer description of flour, owing to the fact that they are grown in very rich soil, and that with such inexhaustible supplies to go upon, there is never any need to cut down young and immature trees, which necessarily yield but very poor stuff. These superb territories, however, are under Dutch rule, and although there is much in the Dutch system of Government which is admirable, yet it is an undeniable fact that from a commercial point of view it is a distinct failure, and that our friends from Holland cannot develop their territories in the same way as we open up our new countries. An effort has been made by Englishmen to tap the sago forests of the Moluccas and New Guinea. The enterprise was overwhelmed in ruin and disaster, but there were some features connected with it which are worth recording, and which may possibly be of some value to such of our readers as are interested in such matters. We shall therefore devote a considerable portion of our next article to a brief sketch of the working of this product.

III.

(*S. T.*, July 15th.)

We have now to deal with the effort made by English enterprise to develop the sago trade of the Dutch possessions in the Moluccas and New Guinea. The manufacture of sago flour presents but one difficulty, and that is the peculiar manner in which the weight of the mass of pith constituting the value of the tree is supported. The bark of the tree is a mere shell, and just serves as a sort of wrapper enclosing the sago pith, the weight of this pith being carried by closely interwoven fibres of extraordinary rigidity whose tough and wire-like properties are the despair of the manufacturer. The gentle natives who have to deal with this difficulty, solve a problem which has puzzled many a wiser head, in their own aboriginal way. These children of the sun simply drive a few nails into a board, and with this primitive implement they manage to rasp thousands upon thousands of tons of merchantable sago flour out of their forests. It is marvellous how the trade of the world is built up by the spasmodic efforts of myriads of naked savages. It is precisely in the same manner that our gum copal trade is kept going. The trader in New Guinea who finally succeeds in shipping gum by thousands of piculs, has to commence his career by confronting the leisurely Papuan, who with all imaginable solemnity will bring along, say, two catties of milky copal into which he has popped a few stones and a liberal percentage of common or garden sand, in order to guard against any undue loss in weight. For this commodity the New Guinea seller will ask a choice assortment of plates, knives, cloth, and powder. He is finally dismissed with a couple of beads or a yard of cloth which he will never wear. It is simply incomprehensible what the natives of Netherlands New Guinea do with the square miles of *kain papua* which are manufactured for their especial benefit. They certainly do not wear it, for they eschew clothing in any shape or form, and nothing in the world will induce their ladies to wear anything warmer than a string of beads or a brass wire bracelet. It is said that the bales of cloth which they buy in exchange for their produce are buried in the ground as a propitiatory offering to their gods, and this appears to be as reasonable an explanation as any other. It is precisely in this peddling way that quantities of New Guinea gum representing large sums of money are collected, and, to revert once more to sago flour, we find that thousands of tons of this staple are turned out by natives who work up the raw material with a rasp made of a board with a few nails driven through it. The cost of production would be greatly reduced, however, if machinery could be brought to bear on the rebellious fibre which could deal with it successfully. A trial was made at Messrs. Riley Hargreaves' works some years ago with a disintegrator, a piece of machinery originally intended, we believe, for a sugar mill. The principle of this machine is that a number of hammers are fixed on a circular plate which is made to revolve at a high speed in an iron box. These hammers simply smash up and disintegrate everything which gets in the way, and there is scarcely any material which can resist the action of such a machine. When an experimental trial of the disintegrator was made in Singapore, it was found that the sago pith which had run through it came out like saw dust, or if a stream of water was kept going at the same time the sago came out in the form of a pulpy paste which only wanted washing and drying to convert it into first class sago flour. It was evident that some modifications which only experience could suggest would be required to make the machine a perfect success, but it answered expectations so well that the plant was bought and shipped at Amboina where a large factory was built for the purpose of turning out sago flour in great quantities. The machinery in Amboina was used for washing purposes, which could have been done as well if not better by hand, but through some inconceivable mismanagement, the disintegrator, which was to be *the* feature of the entire factory as a labour saving machine, was never put into motion, although, there were fine big sago palms growing at the very doors of the building. The Singapore experiment seems to show, however, that a disintegrator is the machine required for the treatment of sago fibres and which will permit of the flour being turned out an an extraordinarily low price. The Amboina factory finally collapsed, the buildings and machinary were sold for a price which hardly covered the freight on the materials sent down for their construction, and a small steamer which had been bought for the purpose of feeding the mill with raw sago from the surrounding islands and New Guinea, was found to be half full of water while lying at anchor in a Dutch port, put up for sale by auction in that condition, and thus disposed of for the sum of 700 guilders. We have no doubt that Singapore ventures

in sago will result very differently, and it is to be hoped that profitable results will be enhanced by the recovery of prices from their present low level.* It is for the interests of every one in the Colony that produce should maintain high values; the more the Chinese and natives get for their merchandise, the more money they will have to spend on English manufactures, opium and alcohol, and the colony is to be congratulated on the very satisfactory range of prices now ruling.

CHINA AND JAPAN TEA EXPORTS: 1887-88.

It will be seen by the subjoined returns, taken as usual from the Hongkong Chamber of Commerce price current, that the large comparative decrease in the shipments this year of 28 millions of pounds remains unaltered, and, however the figures may ebb and flow during the remainder of the season, there appears to be every probability that this season's exports from China to the United Kingdom will show a large short-fall, unless prices of low classed teas advance considerably.

The Chinese dealers are so satisfied this will be the case, that, in the face of unfavourable results of the first shipments of the new season's teas, they have refused to sell, except at higher prices, and strange to say they have succeeded in obtaining them. The Chinese dealers at all the treaty ports assert that the second crop will be at least fifty per cent short of last year's, and that the quality of what comes forward will not be fit for the English market. When we consider all the disadvantages which teas selling in England at 4½d to 6d per pound (which forms so large a portion of the China supply) have to encounter, we are not surprized, that those interested in the China tea trade take rather a doleful view of its prospects.

At one time, we thought it would be a very good thing for Indian and Ceylon tea, if the home duty was reduced to threepence per pound by cheapening the commodity, but we now see that it would be just the reverse. Until quite recently the home duty on Indian and Ceylon teas amounted to 50 per cent of their value; on a large portion of the China supply, it is at least 100 per cent. Good teas, therefore, have an advantage of 3d per pound, as regards duty, over low classed China teas.

Then again, the advantage of 40 per cent at present gained in exchange is equal on good teas to about 4½d per pound, which leaves more than 100 per cent over the English charges. On low classed China teas, the 40 per cent barely covers them. We are at present paying thirty shillings per ton freight, the Chinese pay more than double our rate. When we reckon up the lekin and export duties in China, the cost of manufacture and manipulation to obtain the various qualities which constitute the China supply; the cost of packages, transport, and middlemen's profit, it will be admitted that the Chinese grower does not get much out of the 4½d to 6d per pound, which his second crop realizes at Hankow and Foochow. We need not therefore be surprized if the general opinion amongst the Chinese of a short export this season ultimately proves to be the case. John Chinaman is not likely to go to the trouble of plucking his second and third crop leaves and carrying them to market for little or nothing for a very long time.

To Ceylon planters who pluck all the year round every eight or ten days it must be a puzzle to understand what is meant by the Chinese first, second and third crops, and we confess our inability to throw much light on the Chinese system of cropping. We certainly require more information on the subject.

It will be noticed by the figures below that the shipments direct to the Continent are double what they were last year; this is owing to the "Gleneagles" and the "Moskwa" taking full cargoes direct to Odessa. Although the Foochow market has been open for a fortnight, the returns show no exports to Australia, but since the returns to the 8th inst. were made up, four steamers have cleared for the colonies:—

PERAK GOVERNMENT COFFEE.

A supplement to the *Government Gazette* published on Thursday contains the following letter from Messrs. Sandilands Buttery & Co. to Jno. F. M'Cock, Esq., Superintendent of Government Plantations, Perak.

21st June, 1887.

Dear Sir,—By the mail just arrived, we have received advice of the sale of Perak Government Coffee. On 6th instant, we sent you copies of report and valuation of the same, and from which you would note that, after being husked, it was re-packed into 11 bags.

The sale prices are as under:—

10 bags	Bold,	...	at 106/	per cwt.
15 "	Medium,	...	at 103/	"
11 "	Smaller,	...	at 98/6	"
2 "	Friaga,	...	at 83/6	"
3 "	Peaberry	...	at 105/	"
1 packet	Elephants,	...	at 91/	"

Our London firm writes thus:—

"We offered the whole for public sale on 18th May, and sold the whole with good competition at very high prices, and we have no doubt the result will be considered very satisfactory by the Perak Government.

On landing the shipment weighed...69 cwt. 2 qr. 20 lb.
After husking the weight was..... ...57 " 3 " 2 "

"At our request Mr. Swettenham inspected the quality, which is a kind in high estimation with the trade, and if planters could be induced to open plantations in the district where this quality was grown, planting from the same seed, the enterprise would probably be a very successful one."—We are, &c.

SANDILANDS BUTTERY & CO.

—*Straits Times.*

[The coffee seems to have been well dried in the parchment, and the soil and climate are doubtless good, but planters in Ceylon will smile at "planting from the same seed."—ED.]

CEYLON UPCOUNTRY PLANTING REPORT.

EXTRAORDINARY WEATHER—CACAO—DADAP AS A SHADE FOR CACAO—BUG COMING TO AN END—KELUNA POONAC.

1st August 1887.

We are all agreed that as far as weather is concerned this is an extraordinary season. As for planting, unless you were fortunate enough to have put your plants out very early, the work is still to be done, and here we are, past the middle of the monsoon, with the worst half to come. It is the bold man who has scored this season, where he has suffered

* The enormous numbers of the palms said to exist renders a rise in price improbable. Sago is used sometimes to feed calves.—ED.

is where he planted latest, and when he had a right to feel that he was safe. The very early plantings as a rule have been successful.

Cacao is showing that this dry season is not to its liking, although it is still on the whole doing fairly well. There is a gauntness however about and evidently spreading, which a good soaking would do more to remove than aught else I know. The crop being gathered at present is scanty, but good blossoms are out and have been out.

The dadap as a shade for cacao commends itself to many. It has perhaps one objection, that it grows so fast, and when you thin it out, it is hard to know what to do with the loppings as the coolies have an objection to the thorns. Still this evil is not without its accompanying good, for it allows you to regulate the shade according to the season. Even a mistake of cutting away too much is very soon righted, by the rapidity of the tree's growth. I know of one very bad piece of cacao, which had disappointed, and promised to do nought else than disappoint, being quite brought round by the help of dadap. Where before there were leafless branches, shrivelled and blackened pods, indeed, trees which had become the home of every enemy of their species, and were sick unto death, there are now umbrageous, sturdy specimens of cacao, full of beauty and promise—a pleasure for any planter to look at. Cacao is a product that wants a deal of attention, there is always some enemy about to be circumvented, watched, captured and slain, and on small acreages this can be most effectually done.

From what I see of bug it seems to be disappearing, getting that white colour which indicate that for the time being its race has been run. In its place there is now, however, leaf disease, but that as compared with the other is a small matter. Still it is hard on the coffee tree, and especially on its owner. There are fine coffee crops in Dumbara, but the want of rain endangers them now, and should it continue much longer most of the crop will be light.

The tree which the Sinhalese call "kekuna," and from the nut of which they extract an oil is finding a new value from the fact that the "kekuna" poonac is a fine manure. Its fertilizing qualities are well enough known to the Sinhalese cultivator, who from time to time has applied it to his paddy fields, but the knowledge of its worth is spreading beyond the Sinhalese village, and experiments are being made with it on tea and cacao. Those who have tried it on cacao take all they can get, which is a satisfactory testimonial. Should the results of the application of this new local manure be satisfactory in regard to tea, there will be a wider field opened out, than any possible supply can overtake. In these days when there is so much poverty among the natives if this hitherto unmarketable stuff could find a sale, it would be a help of a small kind.*

PEPPERCORN.

OBSERVATIONS ON COCONUT PLANTING.

Minuwangoda.

Like all other plants the coconut also requires manuring where they are not favoured with good climatic influences and fertile soil. In many estates, cattle-folding is adopted as one of the chief forms of manuring. The soil is dug round the trees and two pairs of cattle are generally tied for five nights. So far this practice is good as both the droppings and urine are utilized; but a large proportion of the valuable fertilizing matters especially ammonia is lost to the tree. As the droppings are exposed for five days, they begin to putrefy and free ammonia begins to evaporate. To check this wasteful system, there is only one trifling thing to be done, which most planters overlook.

As the trees are manured each day, the droppings should be covered with some refuse—fibre dust will do very well if it can be procured easily; this dust has the property of absorbing ammonia and other gases. If refuse is unobtainable the droppings should be covered over with soil. Thus a vast amount of ammonia could be utilized by a simple method. In several estates heaps of fibre dust are allowed to be useless: and will not this be a good system to utilize the same?

W. A. D. S.

* The difficulty will be the same as that which beset a German genius once connected with the railway. He was going to light Colombo with gas from the nuts, if only he could procure a sufficiency of them which he did not.—ED.

NETHERLANDS INDIA NEWS.

(*Translated for the Straits Times*)

Sugar growers in Java so long labouring under apparently hopeless depresssion, are eagerly scanning a bright spot in the horizon giving fair promises of a turn for the better from a wholly unexpected quarter. These gladdening tidings come from East Java where an enterprising sugar planter has under cultivation cane from Borneo, which bids fair to yield 250 piculs of sugar per bouw, twice as much as has been hitherto the case in Java, even under most favourable circumstances. Should it turn out that this result is realisable on a grand scale without too heavy an expense, sugar growing in Java has a splendid future before it.

The *Locomotief* draws attention to the advantages of the sunflower as a means to ward off fever. The sunflower, owing to its strongly absorbent powers, draws to itself the miasmatic vapours arising out of the soil. In Samarang especially it is likely to prove advantageous from the prevalence of fever there.

A German tobacco planter in Deli describes in a newspaper appearing in Germany the difficulties attending the clearing away of trunks of trees there. He says that he has made trials with dynamite in this respect but always failed. He enquires what he must do to turn to the fullest account the opportunity afforded by this explosive to remove from his fields, the trunks and roots of trees most of which are centuries old.

By last advices from Bali, the picking of coffee was in full swing. In consequence of the high prices ruling for that article, the pickers, proceed recklessly to work and gather all they can no matter how inferior the quality so long as they can find purchasers. Beans both ripe and unripe were freely offered for sale in the market. In the independent native states there, the production of this article is falling off owing to most of the coffee trees having recently died out. Fresh plantations have not been laid out in time

It is a well known fact that certain plants feed on insects which they entrap by means of special appliances. So far as the available facts admit of drawing a conclusion, fishes are the highest grade of the Animal Kingdom which fall a prey to flesheating plants. The latter flourish in brooks and rivers. Recently, Dr. Van Noote made known in a scientific periodical additional facts which far surpass anything known hitherto regarding flesheating plants. In the jungle in the neigpbourhood of Unarang near Samarang in Java there are said to be trees which catch birds. The truth of this lies beyond any doubt. Observation has established the fact that birds do get entangled among the flowers which grow in clusters on these trees and secrete a sticky substance. Birds when once they get caught in this substance cannot come away. They die and are decomposed till at length the bones alone remain. It is certain that in this instance we have to do with a bird-catching tree, but the question arises; does the tree feed itself with the flesh of the birds? On these trees, observers have found birds just caught still alive, dead birds, and skeletons in various stages of decomposition

Living birds released from the grip of the tree, always die within a couple of days. The importance of this information is manifest. The Batavia *Nieuwsblad* from which the forgoing particulars are taken, urges people who may happen to frequent the jungle in question to take strict note of the phenomenon, and secure for examination a branch with flowers of the bird-catching tree. Such a botanical rarity calls for close investigation.

It is reported that the beer brewed at Batavia is of such a nature, as to fully establish the fact, that a brewery in Java is not only practicable but also remunerative. The quality of the brew has proved incontestably excellent, and compares favourably with that of beer imported from Holland.

The Surabaya sugar planters' association has just published statistical returns regarding that branch of plantation enterprise there. The times are so hard in that quarter that out of 183 estates which grew sugar there last year, no less than 12 have suspended operations this year. The Java sugar yield in 1887 is estimated at nearly five and a quarter millions of piculs against a total of over six millions in 1886.

In parts of Java where tobacco growing used to flourish, that branch of industry is now in decadence. Several estates have proved so unremunerative as to be abandoned.

EFFECTS OF TEA-TASTING.—The abuse of alcohol, tobacco, opium and quinine seriously affects the sight, but tea has not been considered liable to have such influence. The greatest of Russian tea merchants, M, Molchanoff, has, however, been seeking treatment in Paris for weakness of vision induced by the prolonged practice of tea-tasting. —*American Cultivator.*

"THE TROPICAL AGRICULTURIST" is attracting the attention, we are glad to find, of enlightened administrators in the Southern Colonies. Last mail brought us an order sent by direction of the Minister of Public Instruction in New South Wales, for three complete sets of our six volumes of the T. A. for use in his Department. A large portion of New South Wales, it will be remembered, is sub-tropical, and some ex-Ceylon planters like Messrs. Bluett and John Gray are we believe among the cultivators of sugar and other tropical products on the Clarence river and other districts of that colony bordering on Queensland.

PLOUGHING MATCHES, EXHIBITIONS, &C.—The Madras Director of Agriculture reports:—In this connection I must refer to a fact of great promise. A student of the School of Agriculture, by name Sami Aiyangar, the son of a well-to-do Brahman landholder in the Tinnevelly district, undertook to spend his school recess in the months of July and August 1885, in holding, in his native district, a series of ploughing demonstrations wherein he showed the advantages of using improved ploughs practically. A large number of ryots witnessed his demonstrations and showed much interest in them. A demand for the improved ploughs arose, which, it is understood, a local agricultural association has taken steps to meet by local manufacture. Government expressed their satisfaction with Sami Aiyangar's efforts and directed his report to be printed and laid on the Editors' table. His travelling expenses were paid and a further sum of Rs. 200 was placed at his disposal to enable him to conduct similar demonstrations during his recess in July and August last. A sort of travelling ploughing show was then held by him, under the supervision of the Assistant Director, Mr. Benson, in the South Arcot, Tanjore, Trichinopoly, Madura and Tinnevelly districts. The leading firms engaged in the manufacture and sale of agricultural implements furnished patterns for exhibition and made arrangments for carrying with the party a stock of implements in order that ryots might be supplied with such patterns as met with their approval.

THE CHINA TEA TRADE.—A correspondent writes from Shanghai, under date 8th July: —"It may interest you to know that nearly all the chazees (tea tasters) from home this year for the Hankow market brought out samples of Ceylon and Indian teas, showing that they now realise the necessity of something being done to improve the manufacture of China teas. This I fear will be a difficult matter as far as the Hankow and Kuikiang market are concerned, as so long as the teamen (native) find buyers for their teas they won't improve the manufacture of them. The teamen in Canton are more alive to the fact that it will be more to their advantage to follow the advice which has been for some years brought before them by foreign buyers, namely that unless they look to the manufacture of their teas and improve it they will be at no distant time left out in the cold by Indian and Ceylon teas."

COFFEE DONE FOR—BETTER TRY CHICORY!—Such is the heading put to the following extract from the Norwich *Argus* by the correspondent who sends it to us, and who adds:—"Another rare opportunity for the sanguine to make a fortune —or experience: another prickly-comfrey failure!"

Chicory is a perennial plant seldom grown in England, but there is no reason why it should not be cultivated, the soil and climate being suitable. It has a root similar to a carrot, but smaller, growing one to two feet in the ground. The plant is in the form of a lettuce, bearing after the first year blue flowers upon a rough leafy stem, which shoots up from one to six feet high. It has long been grown on the Continent as a herbage and pasturage plant, while the roots, as is well known, are largely used as a substitute for coffee. It was introduced into this country by Arthur Young in 1780, and was grown principally for sheep-feed; it was at that time found very profitable, as it did well on almost any kind of land, and was considered to keep more sheep per acre during the early summer months than any other kind of herbage plant. Lucerne will not succeed on any soil not of the best quality, but chicory has been found profitable on poor sandy soils which are weak and require rest, as well as on richer soils. It will last for seven or eight years, and yield several cuttings each year, though a full crop is not obtained the first year. The mode of culture for a fodder of herbage crop in this country has been as follows:—Prepare the soil by thorough cleansing and pulverisation as early in the spring as the weather will permit; apply a good coat of partially-decayed farm-yard dung, and drill in the seed during March, about four lb. per acre, with about nine inches between the rows. When the plants are about five inches high they should be carefully singled out, leaving them about six inches apart. Of course the land should be kept well clean, especially in the first season, and afterwards ordinary attention will suffice. The crop will continue luxuriant for five years at least, and frequently for eight or ten years; when the plants being to show signs of failure, the land should be cleared of the roots, and another course of cropping pursued for a few years. The crop is more useful to consume in hovel or yard than to graze. Although it will fatten a considerable number of sheep, they nip off the radical leaves shooting up close to the ground, and the stalks do not afford them sufficient nutriment. When allowed to attain its full growth, but not permitting the flower to appear, its full perfection is reached, and, being then cut off close to the ground, is relished by all kinds of stock. It is a plant of speedy growth and whether the season is wet or dry, can be depended upon. The plant has also been grown in England as a root-crop, being used when dried as a substitute for coffee, but the profit attending this mode of growing it would seem to be uncertain, the crop varying from eight to sixteen tons an acre, and the expenses being heavy. There seems, however, no reason why it should not be grown as herbage plant for the use of cattle and sheep, especially by small occupiers. At the present time it is scarcely heard of in England, but probably it might again be grown with advantage to all concerned.

FRUITS OF SIERRA LEONE.

The following is from a report by the honorary secretary of the Sierra Leone Botanical Society on the fruits of that settlement, printed in the *Board of Trade Journal* :—

"The chief fruits grown in Sierra Leone, together with prices locally obtained, are as follows :—The pine-apple, sold at 10d. per dozen; the banana, sold at 8d. a bunch; the cashew; coconuts, sold at 6d. per dozen; the cucumber; the red guava, sold at about 2s. per bushel; the white guava; the lime, sold at 6d. to 8d. per hundred; the locust;* the mango, sold at 3d. per dozen; the orange; the papaw; the pear,† sold at 6d. to 9d. per dozen; the plantain, sold at 3d. to 8d. per bunch, and the black or velvet tamarind.

The chief fruits exported in a green state are pine-apples, bananas, plantains, pears, mangoes, limes, and oranges, of which pine-apples constitute the bulk of the export to Great Britain and France. It would appear from the Custom-house returns that during the year 1883 as many as 68,792 pines were exported to the United Kingdom and France. This quantity could be annually maintained and considerably exceeded if the trade were remunerative, and the large quantities which are produced in the Timneh country induced to flow abroad through the settlement. But the loss sustained by the fruits arriving at their destination in bad condition has checked the continuity of the supply and growth of exports.

"Almost the whole of the bananas, plantains, pears, mangoes, limes, and oranges grown in Sierra Leone go to the Gambia, Goree, and Senegal, whilst some pines also are exported to those places.

"There is no export of preserved fruits, and coconut is the only fruit of the settlement exported in a dry state, and in that state, in which it takes the name of coprah, it is not used as fruit.

"But the waste of economic matter in the shape of shell, husk, and fibre thrown away after separation of the kernel for coprah, and perhaps the reduction in the price of coprah during the past four or five years, have stimulated the growth since last year of an export of coconuts in husk, chiefly to Europe, where the now neglected materials may be used in the manufacture of ropes and matting, and the kernel in its free state used as fruit.

"Besides the suggestion just made relative to coconuts, it is not unworthy of record regarding mango, that its abundance and cheapness here, and the capacity which Sierra Leone has for its increased production, are conditions which point to the necessity for studying how and where it may be turned to account as an article of export, either green to be used in the manufacture of spirits, which it is said may be profitably produced from it, or for composition as fruit, or in a dried or preserved state. When in a fresh state, and before it is fully ripe, it is employed locally as, and is found to be good substitute for English apple sauce.

"Like pine-apples, the other exportable fruits above referred to may be produced in larger quantities than the present yield, but the drawbacks to their more extensive production, and to a greater investment in the fruit trade, are mainly for the Gambia, Goree, and Senegal countries almost destitute of fruits, the want of regular steam communication with them, and of precision in the dates of arrival and departure of the steam vessels now taking freight from Sierra Leone; and for Europe, the absence of quick transit, as well as vessels specially adapted for receiving and conveying fruit.

"The export trade in two of the fruits of the settlement is likely to gain a new impetus, viz., cahsew and velvet tamarind, for the stone of the cashew is in great demand in Germany, where it is used in confectionery, and is sold there at 9s. a cwt., though it is only thrown into the dust heap here.* Velvet tamarind is being somewhat extensively used in pharmacy in France. The knowledge of the demand for these fruits in Europe is all that is necessary to infuse activity in their cultivation, and in their export hence." —*Journal of the Society of Arts.*

* Query—loquat?—ED.

† *Pears* plentiful in the markets of Sierra Leone? If the true pear is meant and not the avocada, it would be interesting to know what variety ?—ED.

OF GRASS-CUTTERS.

Excepting down in Lower Bengal, Assam and Bombay, where grass grows luxuriantly and where the sickle is required to cut it, the *koorpa* is the implement used by the grass-cutter throughout India generally. For the luxuriant growth of preserved grasslands in cantonments and rukh lands and on railway embankments, the sickle is also requisitioned, but for cutting grass of which the roots form the bulk, the *koorpa* is essential. We are all familiar with the sickle, but the *koorpa* may require a little description here, not because it is an unfamiliar object—nothing of the sort—but its associations with so humble an individual as the grass-cutter may have left it overlooked. It can be briefly described as a piece of iron about 8 inches long, 4½ broad and about ⅜ to ½ an inch thick; one and of which is broadened and made sharp for cutting up the grass roots; the other end being spiked and fitted into a wooden handle. *Koorpas* are made out of old wheel-tyres axles or indeed any piece of iron capable of being wrought and are of various sizes; the dimensions given being the average. The young grass-cutter has a diminutive weapon made for him which as he advances in years, is replaced by a heavier one, until he is able with increasing strength, to handle the "regulation" *koorpa*. Economic reasons often weigh with the grass-cutter in selecting his *koorpa*. For instance, I asked Shaddan one day why he used such an unwieldy *koorpa*—his particular *koorpa* weighing at least seven pounds. His answer given readily enough was that it would last all the longer, and as he happened to have secured a good piece of iron, he got Boor Singh the Sudder *lohar*, to make him the *koorpa* in question, and as it was getting less in size every day with constant use and sharpening, it would in a few years, be of comfortable dimensions. Shaddan showed me a *koorpa* once his grandfather's, now a small stump a few inches long. This Shaddan, had rehandled for his son Thiria, who, he said, was learning to use it pretty well, and for whom some fine day he would have to get another one, when it would be handed over to a still younger son. Thus, you see that the *koorpa* is made in the first instance, by the grass cutter, of serviceable but unwieldy size. After a few years it gets gradually smaller when he hands over the now short stump to his son to practise grass-cutting on. When the *koorpa* is no longer serviceable for cutting up grass-roots, the handle is taken out and the spiked end driven into the wall of the grass-cutter's hut, where it serves as a peg for hanging the grass net on. There is some ingenuity displayed in the making of *koorpa* handles. The main object seems to be to have a slight bend in the middle, this bend gives the needful fulcrum, enabling the grass-cutter to root up his grass more readily. The grass-cutter's *koorpa* is as essential to him as the curry stone is to a *bowarchi*, or a stick to a *chowkedar*; and it is always carried ready to chop up any tuft that may offer. *Koorpas* seem to vary little in appearance throughout India. Another article comprised in the stock-in-trade of the grass-cutter is the *kanta*, a forked branch of the *babul* or *peepul* tree—an article about one yard long, fork and all. This is used by him for beating out the soil from the roots of the grass.

The *jhola* or net completes the three articles required by the grass-cutter, and is an ordinary twine-made net, capable of holding a maund or so of grass.

To the grass-cutter, the monsoons are a godsend indeed; for then the grass sprouts up and he can with little difficulty cut from two to three maunds a day. It is after a long drought that the grass-cutter finds

* Beyond measure strange, for in Ceylon the kernel of the cashew constitutes not merely a confection but a food.—ED.

his work arduous. He not only finds it difficult to collect his maund or two daily, owing to the scarcity of grass; but has often to go long distances—in some stations 14 or 15 miles—to rivers, the moisture from which preserves a little succour for the grass on its bank. Where rivers are out of the question, the grass-cutters are sorely tried. One may see them on the parched and arid plains trying to get a few tufts of grass on the shady side of *nullas* and mounds, or furtively stealing round villages where the moisture from irrigation permits old tufts to spring up on the borders of tobacco, pumpkin or other vegetable plots. The grass-cutter, often in his incursions into these preserved lands, is laid hands on by the villagers, and it is only owing to his speed of foot that many fatalities are averted. The grass-cutter, knowing well he is on forbidden ground, soon "makes tracks" when he sees any one coming. The commotion caused by the event of a grass-cutter being pounced on by the villagers is ludicrous in the extreme—men, women and children, with the usual accompaniment of pariah dogs, all howling and yelling after the unfortunate runaway as he makes off with his pound or two of grass slung over his shoulder, and his pigtail flying behind him. The grass-cutter is not always so lucky as to escape unscathed, and many a man can show you marks of these encounters. He will also smilingly refer to his sharp *koorpa* as accounting for many a vicious cut made at his would-be capturers. Thus passing through many vicissitudes, the unfortunate grass-cutter, after a long day's work, lasting often from 8 a.m, to midnight, tired, worn out and hungry, has earned the miserable sum of four to six annas, out of which he has to keep his tat and family too, if he has got one. No wonder, under these circumstances, the grass-cutter has recourse to the reprehensible practice of damping his grass. On his return from his day's work the grass cutter, who has to be careful of his hardly accumulated gathering takes it into his hut with him to keep it secure; previously giving it a dash of water. Naturally, grass so subjected gets fusty through being kept in a closed hut all night and is scarcely calculated to keep animals in good condition. In the early morning the grass-cutter is up betimes, and gives his grass an extra dash of water to "liven it up."

He will tell you, of course that its dampness is due to the moist nature of the soil on the river-bank where he cut it yesterday. Now from this practice, as well as the fact that grass-cutters are in the habit of grubbing up grass from delectable spots, where dead animals have been thrown out to rot, it may be assumed that the grass-cutter's only care is to get his quantum of grass as best he can. He considers not that the animal may have died from anthrax, fever or other malignant and infectious diseases; or that some millions of the bacteria spore or germ of the disease may be carried in by him in his bundle of grass. But you who employ him find your horses die from anthrax, or pleuro-pneumonia. If you command a regiment of cavalry, your horses are reduced by a troop or two, if you don't lose half your regiment in the event of Mr. Grass-cutter cutting up those luxuriant tufts over the last resting place of zemindar Mahomdu's favourite mare, who, it seems, one day refused her usual feed of *gour* and *chunna*, swelled up about the head, ran from eyes and nose for a day or two, and died. *Wah! Wah!*.

The wretched brutes one sees at the end of cavalry troop lines, or outside grass-cutter's huts, feeding on the modicum of grain which Government have ordained the grass-cutter must feed his tat on are, to say the least of them, a disgrace to humanity. They are weak, attenuated, sore-backed brutes, cow-hocked, with their four knees knocking together in such a fashion as to impress one with the idea that they are about to double up altogether. Notice these brutes, as they start off on their day's work about 8 a.m. bestridden by the lanky grass-cutter, with his *bahhli-bahhlie* alight; or as they come home late at night laden with grass, and with the lanky grass-cutter still on the top labouring along, stumbling every other step from sheer debility, and judge for yourself if such a system is creditable to us. But it may be asked where is the remedy? The answer is to have carefully selected grass lands well irrigated, whence you can ensure a plentiful supply of grass all the year round. With these and a few fields of lucerne you can make up a comparatively laxative fodder which will counteract the foul and flatulent, though nutritious *chunna* on which you feed your horses as a rule. Surely, wherever Government have cavalry or cattle of any sort, they can enclose a piece of land for grass production as well. They can do this for parade grounds and cantonments; and, the civil portion of the community, having regard for sound wholesome grass crops, can manage to do likewise. It remains in this nineteenth century to be recorded that a powerful Government with an unlimited exchequer, allow their cavalry horses to die from contagious and infectious diseases; their men from diseases brought on from drinking impure milk and eating unsound and diseased meat: and all because no one will take the trouble to select good grass lands.

The grass-cutter is about the most miserable and hard-worked mortal, employed under the benificent *Sarkar*, and his state requires looking into, not only on his account alone, but with a view to lessening those outbreaks of anthrax, &c., that are, in the main, caused through horses being fed on infected grass, an annual loss that would more than cover the most elaborate and secure grass-scheme that could be devised.

It is feared that there is less known than there should be about the grass-cutter and his works generally.—J. J. in *C. and M. Gazette*.

THE MAHOGANY TREE IN THE MADRAS PRESIDENCY.

In a paper sent to us by the Madras Government, Mr. Gamble, the Conservator of Forests for the Northern Circle, reported on Mahogany seed and some plants which he had distributed.

3. The Collector of Kistna reports as follows:—

"The mahogany trees, about 1,500 in number, were planted out 36×36 in the Weld plantation at Masulipatam. They were underplanted 9×9 with other indigenous and exotic species, list of which is enclosed.

"The plantation has not been surveyed, but is probably between 60 and 80 acres. The soil is sandy containing a varying proportion of clay and shows in places slight traces of salt.

"The mahogany are thriving well and are from 2 to 4 feet high. Very few of them have died up to date, although they, in common with many other species, have lost many leaves and their terminal shoots through the attacks of a caterpillar; of the other trees *Terminalia Arjuna* and *Cedrela Toona* seem to be thriving best. But it is impossible to pronounce a decided opinion regarding either them or the mahoganies till they have passed through the ordeal of the approaching hot weather.

"There are about 3,780 plants in pots in the nursery which will be ready to plant out next July."

The District Forest-officer gave me good accounts of this plantation on the occasion of my recent visit to the district, and it is to be hoped that it will be a success. But the other trees must not be allowed to overtop and kill the mahogany.

4. From Nellore a full report has been received which is as follows:—

"1. The first lot of seed supplied by you in 1885 gave 300 plants, of which 105 died and 195 were put out into the jungle in January 1886, viz.:—

In the 5th Khandam near Khasba 140 plants
" 2nd " " Penubakam 55 "

"Of the former four have died since and three of the latter. They have not grown very well, but they are still healthy and strong.

"2. Seven hundred plants were sent by you from Madras in August 1886. Of these, 650 were allotted for planting on some good land near Penubakam village, which was cleared of all jungle, a few large trees only being left.

"Out of the 650, 96 plants died before the land was ready so that only 554 were planted out at thirty feet; eighty-six have died since, *leaving* 468 *as alive on 25th January* 1887. They are looking well and seem likely to make some good growth in the hot weather. They did not suffer much from the cyclone. I am now having them shaded with alli branches and a chatti will be buried near each plant to ensure proper watering and to induce the roots to grow downwards.

"The remaining fifty plants (out of the 700) were sent to Khasba, where thirty-one were planted at about thirty feet distance on the high land near the Forest-office and twelve near on the low land near the Kuppam where the soil is good; the remaining seven plants died on the way up.

"Out of the forty-three plants put out, there are only thirty-five now alive and growing well, eight plants having been killed by the storm of November 9th.

"3. 10 lb. of seed were received from you in September and October 1886. The whole was sown at once at Sriharikót in small palmyra baskets (one seed to each) and orders given that the directions for sowing, which accompanied the seed, should be carefully attended to.

"The sowings only gave—

	Of which died on 25th January.
240 plants at Khasba	11
322 do. at Penubakam	14

"So that there are only available—

229 at Khasba.
308 „ Penubakam.

Total ... 537

"There are mostly well-grown seedlings 6—12 inches high, firmly established and ought to be planted out immediately. Instead of transplanting from the small basket where it rotted, the basket was slipped inside a larger one, the intervening space being filled with earth. With this plan there is much less risk in transplanting and one is quite sure of the roots being neither injured nor doubled up.

"*Conclusions.*—The results of the last sowing are disappointing, but as the forester appears to have done the work with great care, the only mistake being that he sowed the seed at Khasba in sand instead of in good soil, I conclude that the seed was not so good as that sent before. The seed was also received too late in the season, being sown just before the rains, a large number of the seeds probably rotten before they could germinate.

"In future no mahogany ought to be sown after August 1st. Although the plants received from Madras looked well, it is improbable that they will grow to any size, as most of them had been pot-bound before being put into the baskets and had long roots, which in some cases, I found have been doubled up on transplanting in Madras."

The Conservator is in hopes that the cultivation of mahogany on a large scale at Sríharikót will succeed.

5. The Collector of Cuddapah forwards a full detailed account of the progress of mahogany planting drawn up by Mr. C. L. Toussaint, Sub-Assistant Conservator of Forests, which is given as enclosure to this letter.

The Conservator lately visited the Pallegundalamadugu plantation and was pleased with the way it had been made. The plants grown by the department had done well, those received from the Agri-Horticultural Society, through the Director of Revenue Settlement and Agriculture, had been badly basketted and were eaten by white-ants, the experience thus coinciding with that recorded from Nellore.

6. The following report illustrated by a map (enclosed) has been received from the Collector of Nilgiris:—

"The mahogany plants reared from the two first consignment of seeds sent in August and October 1885 were 7,300, of which 6,000 were basketted between April and June last. After they had been well established in the baskets, they were put at an average distance of 22×23 feet apart, between June and November 1886, in compartments Nos. 5, 4, 3, 2 and part of one in block No. IV of Kullar reserve, with 1,200 unbasketted and big plants; 700 Berriya Ammonilla have also been planted here and there between the mahogany plants in compartments Nos. 5 and 4.

"The ranger could not plant all of them at once in consequence of the weather having been very unfavorable, and he had to wait for wet days for several months. There were only sixty-three casualties and the rest are in flourishing condition, especially those on the bed of the stream.

"The height of those planted on the bank of the stream is from 1½ to 4½ feet and of those on the higher ground is 12 to 18 inches in some places and in others of similar height as those on the wet ground.

"The accompanying plan, prepared by the Coonoor ranger, shows the area stocked with mahogany.

"The 10 lb. of the seeds with the Conservator's No. 1318 A. dated 3rd September 1886, were sown on the 30th of the same month in Kullar nursery beds. The number of seeds were 11,145, of which 4,098 germinated after the 6th day and the rest of the seeds did not sprout. The present height of the plants is from 5 to 6 inches, and they are healthy. The moist locality appears to suit the plants better than dry places. All these plants are being basketted and looked after carefully."

The Conservator has several times visited this plantation and been quite satisfied with the work done. He considers that so far we may consider the plantation a decided success. The area is about 100 acres. It will be further noticed in an Inspection Note now under preparation.

7. The experimental cultivation of mahogany had better perhaps in the future be confined to Sríharikót and the lower forests of the Nilgiris. It is of no use to make small plantations in a case like this; the only way to really prove that mahogany can be properly grown, and to produce some result commensurate with the expenditure, is to work on a sufficiently large area.

ENCLOSURE No. 1.

Report on the Mahogany Plantations, Kodur Range, Cuddapah District.

There are two plantations in this range under the management of the Forest Department, one on the Seshachellam hills and the other on low ground at the foot of the Velligondas. The former is called the Aremanibanda plantation and the latter is known by the name of Pallegundalamadugu.

2. *Aremanibanda plantation—Situation.*—The plantation lies in the Seshachellam reserved forest about four miles west of the village of Settigunta within the wall of the old Balapalle west reserve, and is approached from Settigunta by a rough bridle-path and from Balapalle by the Mogalipenta forest road, which runs within half-a-mile of the plantation. It is situated on a level bit of ground in an elevated valley between the outer and second ridges of the Seshachellam range at the head of a gorge, which runs south-east and opens out in the low country at Balapalle. The altitude is about 1,000 feet above the sea. There are two plots here containing mahogany, one on either side of a small stream.

3. The first plot is a clearing in a bamboo brake, about 3 acres in area. A few standards of *Terminalia belleriea* and *Bombax Malabaricum* have been left, but afford no cover. The soil is a dark, clayey loam, overlying a bed of rocks which crop up at the eastern edge of the plantation and form the bed of the stream above mentioned. The soil appears to be deep, and, judging from the appearance of the Bombax and from the fact that it is found here, it may be inferred is moist all the year round. It was planted with young mahogany partly in 1883-84 and partly in 1884-85, the plants being put out in baskets when about 3 inches and 4 inches high. There were altogether in this plot 139 plants in pits, which are in lines. The distance between the lines and plants in the lines is the same, viz., 30 feet. Eighty-six plants now survive. The undergrowth now consists of dense grass and

many herbs. The lines are kept clear. The plantation is sheltered on all sides except the east. It is open to the north-east monsoon, but somewhat sheltered from the south-west. The same remarks apply to insolation; it gets the morning sun full, but the forest shelters it during the hottest part of the day. The majority of those plants which survive are looking very healthy and on the whole growth has been rapid. The average height now is about 3½ feet, some plants are between 4 feet and 5 feet, while one is 6 feet and has a girth of about 6 inches. The crowns look healthy, and the leaves are of a good green. In most cases the plants have a bush of leading shoots instead of one healthy one, and in some instances the stem has forked from the ground. This is due to browsing by sambhur and jungle-sheep. The plants must have great recuperative power, judging from the quantity of new shoots. The plantation is fenced round with a bamboo fence except on the eastern edge, where, as before mentioned, the rocks crop up and it is impossible to drive in stakes.

4. The second plot lies about a furlong from the first on the other side of the stream. It is also a clearing in the bamboo brake, about 1¼ acres in extent, and protected on all sides. The plants here were planted in 1884-85. Out of seventy-one plants put down, some fifty survive. The soil is not so free as in the first plot. The average height of the plants is about 2½ feet. The stems in all are very thin, and they do not seem to be doing very well, and are not so healthy-looking as the trees in the other plot. This plot is also subject to the attacks of deer. In other respects what was said of the first plot also applies to this one.

5. *Cost.*—A special watchman is employed on R6 per mensem. His duty is to free the plants of weeds, keep the fence in order, hunt off wild animals, and in the hot weather to water the plants. There is water in the stream all the year round. The plants are hand-watered. The whole cost to the end of 1886 has been about R600.

6. *Pulligundalamadugu plantation.*—This plot is situated at the foot of the Velligonda hills in the Settigunta reserved forest, within and near the northern boundary of the old Balapalle east reserve. It covers an area of 30 acres and lies on fairly level ground with a gentle slope away from the hills. The soil is a clayey loam, dark and moist, and in some places nearly akin to humus. On the top of the slope it is not quite so good as in other places, for it is stiffer, lighter in color and there are more stones. No regular clearing has been made here as in Aremanibanda. The mahoganies are planted in suitable spots in a bamboo brake not pure, some of the companion trees being Terminalias, Anogeissus, Eugenias, Vitex, Pterospermum suberifolium, and species of Ficus. The undergrowth consists of Murraya Koenigii, Indigofera, and dense grass in places. In some spots there is no undergrowth at all, the soil being covered with a good layer of dead and decaying leaves. The plantation is open to the south-west monsoon and partly sheltered by the hills from the north-east monsoon. It does not suffer from excessive insolation at any time of the day, as the brake is pretty dense and there is a good deal of shade.

7. In this plantation 1,650 plants were put out in baskets in 2-cube pits; 500 of them came from the Agri-Horticultural Society's garden at Madras, the rest were raised and basketted in the neighbouring Balapalle nursery. They were planted in the beginning of July 1886, when the average height of the plants was about 9 inches. Their average height now is about 2 feet, some individuals being over 3 feet. There are a good many failures, due partly to bad basketting. White-ants abound, but their depredations seem to be confined to a small area. For the first two months or so the plantation got little or no rain, and probably a good many plants suffered in consequence. Those that survive are looking healthy, and a great many are putting forth new leaves. The crowns are full and the leaves of a rich green color. One or two plants have been dug up by beats. Mr. Toussaint noticed one plant that had been bitten clean off from the root collum, and the stem had marks on it of very sharp teeth, as though the animal wanted to get the epidermis off. The marks looked like those left by the teeth of rodents.

9. *Cost of upkeep—Maintenance operations.*—No special watchman is employed here. The plants are not watered. Maintenance operations are confined to clearing cover above the plants and thinning the brake generally, which is done by the watchmen of the adjoining forest. The cost up to the end of 1886 may be put down at R150.

10. *Means of communication.*—A bandy track runs from the village of Settigunta to the plantation and another from Balapalle nursery. By the latter track carts can bring plants to fill up blanks, which are to be filled up with more mahoganies, *Xylia dolabriformis*, red sanders, and *Acrocarpus fasimifolius*.

11. On the 20th and 21st September 5 lb. of mahogany seed were sown in the Balapalle nursery. By the middle of October nearly all had germinated, and are now about 4 inches or 5 inches high and are looking very well. The failures are not many, and probably about 1,000 or 1,500 plants will be reared.

(Signed) A. W. B. HIGGENS,
District Forest-officer.

Resolution—dated 20th May 1887.—The results of the experiment appear on the whole to be fairly satisfactory, though it seems likely that better results would have been obtained in the Cuddapah district and elsewhere if more attention had been paid to the protection of the young plants from the attacks of deer and insects. The Board support the Conservator's proposal in paragraph 7 of the foregoing letter, but consider that as the results in the Kistna district seem to promise well, the experiment should be continued there also. It is obvious, however, that much closer and more careful supervision of the young plantations than they seem to have received in the Northern Circle is essential if the plants are to be successfully reared.

THE BELIGEDI OR BAEL FRUIT.—According to a London market report in the *Chemist and Druggist*, this fruit was without demand. At auction 450 whole fruits, with soft pale pulp, were offered and bought in at 3d. each.

THE EURASIAN AND ANGLO-INDIAN SETTLEMENTS are thus referred to in the Madras Report of the Agricultural Dept. for 1885-86:—Mr. Glenny, when acting as Director, visited the settlements in the Mysore territory formed by the Eurasian and Anglo-Indian Association of South India and found them in a prosperous condition. The settlers are men of moderate means and have taken to cultivation the ordinary cereals of the country, fruit and vegetable growing, preserving, poultry-farming, pork and bacon curing, &c. Mr. Glenny obtained the permission of Government to lend, for the common use of the settlers, an Aden bull and a donkey stallion.

FIBRE MACHINES.—With reference to plantain stems the Madras Agricultural Report states:—It was found in these experiments that the cost of extracting the fibre ran up to about 3·6 as per lb.—a price quite prohibiting the extraction of the fibre commercially. As has been noted in previous reports, what is required is a simple machine to squeeze the stems and extract the fibre; such a one has, it is believed, been devised by Major Johnston of Mettupalaiyam, but has not been yet introduced to the public. Inquiries in Mauritius resulted during the year in a decision of Government that, looking at the dangerous character of the machines, it was not advisable to take any steps to introduce the "Cassietti and "Grattense" for the purpose of extracting fibre from the aloe and other plants. It appears also that the extraction of fibre from the aloe is still in its experimental stage in Mauritius.

THE SILO PRINCIPLE FOR CEYLON.

A correspondent asks how far in our opinion the use of silo pits (for preserving fodder in a green state) might be adopted in some of our island districts which are more especially liable to long-continued drought, such as has for more than half a year now dried up the tanks, diminished the rivers and streams, and destroyed the crops and pasturage in vast regions of the eastern, north-central and northern districts of the island. Our correspondent tells us how often it has come within his experience to see the sheep in such districts forced from want of growing grass to kneel down and scrape with one foot until the roots of the herbage were exposed sufficiently for them to tear them up and eat them: and he believes that if the use of silos became common the animals need not be driven to such an extremity. We have always ourselves understood, however, that during the season at which this practice is common, the sheep, when slaughtered, yield sweeter meat than at any other time. Still we know that an enormous number of the grazing stock die off from sheer want of food when the rainfall has been long suspended, as is at present the case, and we believe that this mortality might be avoided were judicious attention paid to the preservation of fodder during the time of the rains, when herbage springs up luxuriantly, or at any rate of artificial grasses grown by irrigation under tanks or by the sides of streams. In the districts of Australia which are particularly liable to long-continued drought, it is said that the use of the silo system has proved in many cases very efficacious. The chief difficulty experienced by the Australian sheep farmers is the employment of that system on a sufficiently large scale to provide for the wants of the enormous number of sheep which are fed upon the runs of the austral continent. No such difficulty need be anticipated with regard to the relatively small flocks of sheep or herds of cattle which are fed on the arid lands about Jaffna, Mannar, Anuradhapura, Hambantota, Batticaloa and other districts, which, for some eight consecutive months of the year, may be said to be almost entirely without rainfall. The farms in those districts are divided into small holdings, and we doubt much if there be a single owner possessed of more than a few hundred sheep, and perhaps a dozen or a score of cattle. Such men could, it may be believed, guard against the mortality we have referred to as being of constant recurrence by the judicious employment of the system which has proved so valuable an adjunct to pastoral pursuits in other countries?

As it is—owing to the fact that the preservation of grass by converting it into hay is almost entirely unknown in Ceylon—a very large proportion of the fodder which nature provides is annually lost to us. We are unaware how far the grasses grow in such districts as we have referred to are suitable for preservation in silos. So much advance has however been made in effectively dealing with a wide variety of grasses, that we should think that it would require but a short period of trial to overcome any difficulties which may at first present themselves in the use of the silo system with almost any variety of fodder plants legumes as well as grasses. We cannot ourselves answer the query of our correspondent as to how far experiment has proceeded in this direction in the districts to which he more especially refers. We only know that Mr. Twynam, Government Agent of the Northern Province, did not share the sanguine views of his Assistant, Mr. Boake, on this subject. European energy has been more applied towards this subject in Ceylon among the higher elevations of the island, wherein the rainfall is tolerably constant; and necessity has not therefore compelled any very wide attention being given to the subject. Still, we have understood that the system has been tried, and with a certain measure of success, upon estates which do not possess within their boundaries any considerable amount of pasture land. The late Dr. Thwaites of the Peradeniya Gardens drew attention to the fact that the poor patana grasses were greatly improved by being converted into hay, and we should think they would be still more sweetened by the silo process. Starting upon the basis of such experience as may have been acquired as the result of experiment in up-country localities, there could be no hindrance to extending its results to at all events some tentative trials in the drier districts of the island. The subject is one to which the attention of the agents of Government in localities so circumstanced might well be directed. Trials made at home have taken the procedure far beyond the crude stage, and every agricultural exhibition shows numerous forms of appliances designed for more efficiently applying it. In any endeavour to spread the use of silos among our agricultural population in the north and east of the island, it would, we hold, be desirable to start from the point nearest to perfection already attained in Europe in the application of mechanical knowledge to the efficient construction of silo pits. It is wellknown to those who have studied the application of the system that a gradual but constant pressure on the green fodder is desirable to be maintained. All sorts of devices are in use for the effecting of this purpose, and it seems to us that Government might wisely obtain from England (or perhaps from India, where the system has been largely tried), under the best advice obtainable, one or two sets of such appliances and place them in the hands of the Government Agents, say of our Northern, North-Central and Eastern Province. The experience of a single season with the aid of high class machines (both native and foreign grasses being grown by irrigation in seasons of drought,) would doubtless do much to decide the question as to whether it would be advisable to pursue the course of experiment further. Should a certain amount of success attend a first endeavour, there can be no doubt that it would be justifiable to incur some outlay—which is certain in such a case of some degree of ultimate recoupment—in the endeavour to persuade the wealthier farmers in certain parts of Ceylon to pursue the trials of the system on a wider scale. We do not advocate the trial being made on any rough and ready method. The efficient and economical working of a silo would be best attained, as we have said, by the use of the most approved methods known. Until these were adopted, failure was constantly the result of attempts to work the silo system in England. If trial is to be made let it therefore start from the point at which European practice has attained the largest measure of success.

Sheep are valuable for manuring purposes as well as feeding for the market, while good strong cattle are as necessary as a plentiful supply of water to the cultivation of grain crops. But neither sheep nor cattle can flourish unless plenty of good food for them is available. We should think, therefore, that while rice as the food of human beings is mainly grown on lands provid-

ed with means of irrigation, it would pay to devote a few fields in localities where flocks and herds are kept to the growth of fodder plants to be cut at the proper stage and preserved green against seasons of drought such as that which is now producing such lamentable effects in the tank regions in the eastern and northern portions of the island.

THE INTRODUCTION OF COFFEE INTO CEYLON AND INDIA.

We take so much for granted in this world, that t is scarcely wonderful if we followed an authority like Tennent in asserting that coffee had been introduced into Ceylon by the Arab voyagers. We have been asked to point to any reliable authority and at the same time reminded that even into Yemen (Arabia Felix) the plant was introduced from Abysinnia at a date so recent that the stream of Muhammadan voyaging to Ceylon and India had then ceased. On going thoroughly into the question we are reluctantly compelled to arrive at the conclusion that there is no evidence of the appearance of the coffee plant in Ceylon and India until early in the 18th century. So far as historical mention goes there is not only no proof that the plant was here in ante-European times, but no proof that Portuguese writers on Ceylon and India ever mentioned the plant. Knox, who was a captive in Ceylon in the Dutch period, was a very keen observer, but he says nothing of the existence of the plant in the Kandyan territories. Had it existed and had it been utilized only for the sake of its flowers to be laid on the Buddhist altars, it is scarcely conceivable that Knox should have missed noticing and describing it. Our chief English authorities on coffee in Ceylon are Austin, Bailey and though last not least Tennent. We quote what they wrote :—

Mr. Austin, in his paper "On the Commencement and Progress of Coffee Planting in Ceylon," in the appendix to Lee's translation of Ribeiro, wrote :—

The coffee tree was probably first introduced into Ceylon by the Arab traders, *as it was found when the Portuguese gained possession of the island* ; but it seems to have been reared by the Ceylonese rather on account of the flower than the fruit, and it is a question whether they knew the use of coffee as a beverage.

When the British took possession of the Kandian country, they found, at a place called Hanguranketty, a considerable tract of land planted with coffee, under forest trees ; this went by the name of the King's Garden, and the flowers alone were used for floral offerings in their temples.

The coffee tree was also found near all villages in the Kandian Province and trees of very great age may now be seen.

The British finally took possession of the Kandyan country only in 1815, and by that time a century had elapsed since the plant had been introduced by the Dutch, a period sufficient to allow of the culture spreading into the Kandyan country and for the production of large trees. Mr. John Bailey of the Civil Service, in a note to his elaborate paper on irrigation, wrote :—

Yemen, a province of Arabia, bordering on the Red Sea, whose principal seaport is Mokha. Arabia is generally supposed to have been the native region of the Coffee tree. There is, however, reason to believe, that it passed into that country from Persia, whose inhabitants had themselves received it from Ethiopia, where the people had made use of its fruits, from time immemorial."—(Vide Porter's Tropical Agriculturist, p. 51.) Coffee was only introduced into Java, in 1690, by VanHooen, the Governor of Batavia who sent a plant to Amsterdam, whence it reached the West Indies.—Stated on the authority of Boerhaave, p. 53. The Coffee tree appears to have been long known to the Kandyans, but not the use of the berry. The leaves were cut up and chewed as an anti-narcotic, and the flowers offered at temples. We have seen that Ceylon was in constant communication with the Persians, Ethiopians, and Arabians. Is it impossible that the tree was thus introduced, though the use of the berry was forgotten ? It is scarcely possible that had the tree been introduced into the Kandyan country by the Portuguese or Dutch, that the berry should have been unknown to the Kandyans, till comparatively a recent date.

It will be observed that Mr. Bailey dealt only with "probabilities" and "possibilities," which cannot settle the question. Coffee was introduced into Batavia about 1690, and it seems to be as certain as anything can be, that the Dutch did not grow it in Ceylon until twenty years subsequently. Austin wrote about 1849 and Bailey in 1856. Sir Emerson Tennent in his work on Ceylon published in 1859, (the papers by Austin and Bailey having been seen by him,) wrote still more positively, thus :—

Although the coffee plant, the *kawah* of the Arabs which is a native of Africa, was known in Yemen at an early period, it is doubtful whether there, or in any other country in the world, its use as a stimulant had been discovered before the beginning of the fifteenth century. The Arabs introduced it early into India, and before the arrival of the Portuguese or Dutch, the tree had been grown in Ceylon ; but the preparation of a beverage from its berries was totally unknown to the Sinhalese, who only employed its tender leaves for their curries, and its delicate jasmine-like flowers for ornamenting their temples and shrines.

The Dutch carried the coffee tree to Batavia in 1690, and about the same time they began its cultivation in Ceylon. But as their operations were confined to the low lands around Negombo and Galle, the locality proved unsuitable, both in temperature and soil. The natives, too, were unfavourably disposed to the innovation ; and although the quality of the coffee is said to have been excellent, it was found that it could not be raised to advantage in comparison with that of Java, where the experiment proved eminently successful. At length, in 1739, the effort was suspended ; but the systematic culture, although neglected by the Government, was not abandoned by the Singhalese ; for having learned the commercial value of the article, they continued to grow it in small quantities, and after the British obtained possession of Ceylon, the Moors, who collected it in the villages, brought it into Colombo and Galle, to be bartered for cutlery, cotton and trinkets.

On the occupation of Kandy, after its cession in 1815, the English found the coffee tree growing in the vicinity of the temples ; and gardens had been formed of it by the King on the banks of the Mahawelli-ganga, and close to his palace at Hanguran-ketti. * * *

As to coffee, although the plant had existed from time immemorial on the island (having probably been introduced from Mocha by the Arabs), the natives were ignorant of the value of its berries, and only used its leaves to flavour their curries, and its flowers to decorate their temples. It was not till nearly a century after the arrival of the Dutch that one of their Governors attempted to cultivate it as a commercial speculation.

If mere tradition could be trusted, we might trace the introduction of coffee into British India to so distant a date as the middle of the 15th century. The tradition is thus stated :—

A writer to a Madras paper on coffee in Mysore refers to a tradition carrying back the introduction of coffee into India to 1400 A. D., as follows :—"Coffee is largely grown on the slopes of the Baba Buden Hills which derive their name from a Mohammedan hermit

to whom, it is stated, the origin of coffee in South India is due. Baba Buden proceeded on a pilgrimage to Mecca about 480 years ago, and on his return brought a few coffee berries in his calabash, and settling down on these hills, planted the seeds around his cave! but local tradition associates the introduction of coffee with one Rid Jamal Alla Magarabi, who was one of the successors of Baba Buden. These trees are, I believe, yet in existence."

But here, as is true of the extracts from Austin, Bailey and Tennent, we are referred to no authentic authority.

The truth seems to be, judging by the statements in Valentijn, that the coffee plant was not introduced into India until the eighteenth century was some years old. Curiously enough he says nothing about coffee in Ceylon in his time, although his book was published in 1726. The statement that a trial was made in 1690 and the growth of the plant then prohibited is not authenticated. Valentijn, in his description of the Coromandel Coast (pp. 189-98), gives a description of the coffee tree and a history of the use of the drink. He says nothing of the cultivation of the tree in Ceylon, but he tells us:—

In 1707 I took 6 plants with me from Batavia to Amboina, of which I kept 2 and gave the rest to this and that friend. From these, and a few that in the previous year Governor van der Stel had brought, in a very short time all the gardens of Amboina were so stocked, that in the third year (for I had brought them when a year old) I obtained from these trees more berries than I and many others had need of, and had 60 coffee trees in my garden alone. I also found the fruit very palatable, and moreover not so watery as the Batavian, of which after this time many plantations were begun both there and in Amboina by the natives.

He also states that he kept most of the trees low by topping, as he found that when allowed to grow to their natural height the stems were spindly. The following statement regarding the attempted cultivation of coffee by the British at Madras is new to us:—

As the Hollanders made an experiment with planting these trees at Batavia, so also did the English at Madraspatam, but with as little and even less success, wherefore they also abandoned it. The French also made an experiment with it on the island of Mascarenhas, and reported in 1722 that it had succeeded well, and that they had brought 26 lb of it by the "Triton" for the Duke Regent. An experiment was made in Holland in the Medical Garden of Amsterdam whether this tree could be propagated there, and one was obtained which the Right Honorable the Magistrate deemed worthy to be presented to Louis XIV, King of France, 1714, as something uncommon in these countries, and more have since been raised in that garden.

With respect to coffee as a beverage he says:—

This drink, now so generally used in our land, that the servant girls and seamstresses must have their coffee of a morning, or the thread will not go through the eye of the needle, was, I remember very well, 40 years ago, in this town, as little known as the tea-drink (there being very few, except Indian men, who drank it, to wit, Messrs Van den Brouke and D. De Leonardis). Now however the tea and coffee trades are each a trade of great importance. I remember very well, that in 1681 for the first time in my life I drank tea at the house of an Indian clergyman, and could not understand how men of sense could have a taste for a drink that tasted no better than hay-water; and I wondered still more, when in 1681 I drank green tea at the house of a gentleman in Rotterdam, which had cost 80 guilders the pound; but I had not then seen or drunk coffee, which however also came here afterwards, and was used by the English.

Heydt, in his "Allerneuester Geographisch- und Topographischer Schau-Platz von Africa und Ost-Indien," 1744 (p. 155), in describing "a view of Hulfsdorff" (*sic*), in which is shown a garden containing various fruit trees, says that it included "a fine patch of coffee, from which we obtained every year a good supply of coffee beans." The "Beknopte Historie van de Voornaamste Gebeurtenissen op Ceilon," compiled in 1760 at the office of the Political Secretary in Colombo, in describing an outbreak among the Chaliyas in 1735, mentions that a large body of them "came over the river to Pass *Naklegam* and the village *Pellègore* [Peliyagoda], where after plundering this and that garden they forcibly attacked the coffee plantation *Het Hof altijdzomer* [the garden of eternal summer], broke down the hedge, treated the Company's servants there in a most impertinent fashion, drove off the cattle and killed two calves, brought out the liquors stored in the Company's distillery and emptied them out, broke the barrels into pieces, carried off the iron hooping thereof and finally took away with them the Lascarins who were on guard there." What became of the coffee trees is not stated; and this is the only reference to the product that we can find in this book. Baldæus, whose book was published in 1672, seems to have had a very different opinion of the respective merits of coffee and tea to that held by Vallentijn, for he denounces the former as bilious, while he extols the latter highly.

Col. Yule, with his marvellous erudition, would certainly have quoted in his Vocabulary some passages, had any existed, showing the *cultivation* of coffee in Ceylon and India before the beginning of the 18th century. He gives passages from Terry 1616, and Fryer 1673, showing that a beverage made from the coffee berries (received from Aden and Mocha, no doubt) was used in India early in the 17th century and onwards. But there is not a word as to the plant being grown in India or Ceylon. The negative evidence is, therefore, very strong against the theory of the existence of coffee eastward of Yemen as a cultivated plant before the Dutch and British introduced it early in the 17th century. But why talk of evidence, positive or negative, in the face of the assertion of the learned M. Paschius that the parched corn which Abigail presented to David was COFFEE! The learned man of Leipzig must have had a presentiment of the practice which has been common in modern days, that of passing off parched corn for coffee!

We quote from Yule as follows:—

Coffee, s. Arab. *Kahwa*, a word which appears to have been originally a term for wine.* It is probable, therefore, that a somewhat similar word was twisted into this form by the usual propensity to strive after meaning. Indeed, the derivation of the name has been plausibly traced to *Kaffa*, one of those districts of the S. Abyssinian highlands (Enarea and Kaffa) which appear to have been the original habitat of the coffee plant (*Coffea arabica*, L.); and if this is correct, then *Coffee* is nearer the original name than *Kahwa*. On the other hand, *Kahwa*, or some form thereof, is in the earliest mentions, appropriated to the drink, whilst some form of the word *Bunn* is that given to the plant, and *Bun* is the existing name of the plant in Shoa. This name is also that applied in Yemen to the coffee-berry. There is very fair evidence in Arabic literature that the use of coffee was introduced into Aden by a certain Sheikh Shahabuddin Dhabhani, who had made acquaintance with it on the African coast, and who died in the year H. 875, i.e. A.D. 1470, so that the introduction may be put about the middle of the 15th century, a time consistent with the other negative and positive data.† From Yemen it [illegible]

* It is curious that Ducange has a [illegible] *cahua*, 'vinum album et debile.'

† See the extract in De Sacy's [illegible] cited below. Playfair, in his history of Yemen, says coffee was first introduced from Abyssinia by Jamal-uddin Ibn Abdalla, Kadi of Aden, in the middle of the 15th century: the person differs, but the time coincides.

spread to Mecca (where there arose after some years, in 1511, a crusade against its use as unlawful), to Cairo, to Damascus and Aleppo, and to Constantinople where the first coffee-house was established in 1554. The first European mention of coffee seems to be by Rauwolff who knew it at Aleppo in 1573. It is singular that in the *Observations* of Pierre Belon, who was in Egypt, 1546-1549, full of intelligence and curious matter as they are, there is no indication of a knowledge of coffee.

1598. In a note on the use of tea in Japan, Dr. Paludanus says: "The Turkes holde almost the same maner of drinking of their *Chaona* (read Chaoua), which they make of a cetaine fruit, which is like unto the *Bakelaer*,* and by the Egyptians called *Bon* or *Ban*: they take of this fruite one pound and a halfe, and roast them a little in the fire, and then sieth them in twentie poundes of water, till the half be consumed away; this drinke they take everie morning fasting in their chambers, out of an earthen pot, being verie hote, as we doe here drinke *aqua composita* in the morning; and they say that it strengtheneth them and maketh them warme, breaketh wind, and openeth any stopping." In *Linschoten*, 46.

1616. "Many of the people there (in India), who are strict in their Religion, drink no Wine at all; but they use a Liquor more wholesome than pleasant, they call Coffee; made by a black Seed boyld in water, which turnes it almost into the same colour, but doth very little alter the taste of the water (!): notwithstanding it is very good to help Digestion, to quicken the Spirits, and to cleanse the Blood."—*Terry*, ed. of 1665, p. 365.

c. 1628. "They drink (in Persia) . . . above all the rest, Coho or Copha: by Turk and Arab called Caphe and Cahua: a drink imitating that in the Stigian lake, black, thick, and bitter: destrain'd from Bunchy, Bunnu, or Bay berries; wholesome they say, if hot, for it expels melancholy . . . but not so much regarded for those good properties, as from a Romance, that it was invented and brew'd by Gabriel . . . . to restore the decayed radical Moysture of kind hearted *Mahomet*."—*Sir T. Herbert, Travels*, ed. 1638, p. 241.

c. 1637. "There came in my time to the Coll: (Balliol) one Nathaniel Conopios out of Greece, from Cyrill the Patriarch of Constantinople . . . He was the first I ever saw drink coffee, which custom came not into England till 30 years after."—*Evelyn's Diary*.

1673. "Every one pays him their congratulations, and after a Dish of Coho or Tea, mounting, accompany him to the Palace."—*Fryer*, 225.

1726. "A certain gentleman, M. Paschius, maintains in his Latin work published at Leipzig in 1700, that the parched corn (1 Sam. xxv. 18) which Abigail presented with other things to David, to appease his wrath, was nought else but Coffi-beans."—*Valentijn*, v. 192.

* i. e. *Baccæ Lauri*; laurel berry.

TIPUOOK TEA COMPANY LIMITED.

Capital, £26,000; area, 830 acres. The nineteenth ordinary annual meeting of this company was held yesterday, when the following report was presented:—

Herewith is presented to the members the eighteenth annual report of the directors, together with balance-sheet of the company on Dec. 31st, 1886, and profit and loss account for the year 1886.

The company's out-turn of tea in 1886 amounted to 158,410 lb. only, or 64,794 lb. below the previous year's out-turn.

This large decrease was owing, in some measure to the system of plucking fine leaf, to the season itself commencing late, and more particularly, and above all other causes, to deficiency of rain-fall.

From the middle of April to middle of September the manager's complaints on this last head were continuous.

Although the quantity has thus proved below expectation, the quality has been very excellent, the average price of 1s 5·80d per lb. obtained for the whole crop, being exceptionally high as compared with 1s 1·78d per lb. obtained for the 1885 crop.

This high price on the reduced out-turn gives a net profit of £3,126 7s 7d, which is equivalent to £12 0s 5 d per cent, on the company's paid-up capital of £26,000, as follows:—

Proceeds of tea			£11,639	19 2
Proceeds of tea seed...			30	0 0
			£11,669	19 2
Less:				
General expenditure,	£6,253	4 4		
Charges on tea ...	1,270	12 0		
Insurance	152	8 5		
Manager's and assistants' commission	798	14 10		
Income tax... ...	68	12 0	8,543	11 7
			£3,126	7 7

At an extraordinary general meeting of the members, held on the 24th February last, it was resolved to pay an interim dividend of 5 per cent, which was accordingly done, and the directors now recommend the payment of a final dividend of 5 per cent., this making 10 per cent. for the year 1886, and the carrying over of the balance, viz., £526 7s. 7d., to the reserve fund of undivided profits.

This fund will then amount to £2,699 11s. 8d., equivalent to £10 7s. 7d. per cent. on the capital.

SEASON 1887.

For this season an out-turn of 2,500 maunds, or 200,000 lb. is looked for; continued attention being given to fine plucking, with the view of maintaining a high standard of quality.

The quantity plucked to middle of June is only 180 maunds, but it was not expected that leaf in any quantity would be gathered before this month, owing to the system of pruning carried out at the close of last year.

EXTENSIONS.

Following out the plan of gradually extending the garden, as noted in the directors' last annual report, the area under tea now reaches to 830 acres.

Of these, 740 acres are bearing and 90 non-b aring.

A dividend as proposed was unanimously agreed to.—*H. & C. Mail*, July 15th.

THE JAVA IMPORT TRADE.

The report of the directors and the statement of accounts of the Handelsvereeniging "Amsterdam," or Amsterdam Trading Company for last year show that the state of the Java import Trade continued unsatisfactory last year. Mainly in consequence of the large quantity of goods offered in the market, with a diminished buying power on the part of the population, the prices obtained were generally unremunerative, and the number of buyers who were unable to meet their engagements did not fall below the similar deficiencies of 1885. Taking these general experiences into account, however, the directors state that they have no reason to complain of the results of the year's operations, and though they have decided that prudence demands that they should not distribute any dividend, they intimate that the position at the end of the year was such as to cause a difference of opinion even on this point. After mature consideration, they have decided to retain the whole of the ascertained profits as a security against still possible losses. But they add that in so doing the company may consider that all losses of which there is any danger on the items included in the balance-sheets are fully provided for, and that unless some extraordinary and totally unforeseen circumstances should intervene, a regular distribution of profits may be henceforth expected. The directors make the encouraging statement that althongh the Java import trade must undergo some improvement all round before it can be spoken of as favourable, yet so far as the company's operations go this branch has continued, and still continues, to progress. Since the company began to restrict imports on its own account, it has received continually increasing consignments for sale on account not only of Dutch but of foreign manufacturers; and the directors hope for a further extension of this class of business. The com-

pany's operations in Java produce have been moderate, and, considering the advance of prices, some regret is expressed that more extensive engagements were not entered upon. The directors, however, make no contracts for the consignment of produce without stipulating that the produce shall be delivered in the same year in which the advances are made, and they reserve the right of cancelling any arrangement of this nature from year to year. Desiring to participate in the favourable results which are constantly being attained by the cultivation of tobacco in Sumatra, the directors have combined, with other mercantile establishments, in opening an establishment at Siak, by way of experiment, and on such terms that in case of total failure the company's loss cannot be serious, while, should the experiment be successful, the undertaking may prove a fruitful source of revenue. The reports concerning this attempt have so far been satisfactory; but everything depends on the quality of the produce, and it will be some months before there can be any certainty on this point. During the current year the unsubscribed balance of the original issue 1,500,000fl. (say £125,000) debenture stock, amounting to 474,000fl. (say £39,500), has been disposed of at a price equivalent to a trifle over 74 per cent of the par price. From the details it appears that the directors are chiefly anxious respecting an amount owing by one of the sugar factories in Java. If the prices of sugar do not permanently improve the company runs the risk of losing 300,000fl. (£25,000), and it is mainly on this account that the directors have not proposed any division of profits. Petroleum has lately yielded little profit, in consequence of severe competition and continually low prices. Last year, it is stated, the company only exceptionally discounted in Java, and the rate of exchange was on the whole not unfavourable for remitting to Europe. As regards goods sent out, prices have lately improved somewhat in Java; the stock has been very considerably lessened, and the prospect altogether is said to have become more encouraging. The news respecting the current year's transactions up to June 1 may be considered satisfactory.—*H. & C. Mail*, July 15th.

MALACCA.

Mr. R. V. Boswell, Acting Superintendent of Works and Surveys, some time ago succeeded in extracting spirit from tapioca refuse, and recently he has been making experiments with the Glam tree. He has been successful in making a perfume and a medicinal decoction, useful as a diarrhœa mixture, from the leaves and a lifebelt from the bark. The specimens have been forwarded to Singapore for the information of His Excellency the Governor, with a paper from which the following information has been taken.

The Gelam tree is of the *Myrtaceæ* family, and attains a height of about 45 feet and a girth of 5 to 6 feet at the base. It has a few upright and contorted branches, innumerable twigs with a liberal diffusion of dark green almond shaped leaves, the latter when bruised in the hand emit a strong aromatic odour not unlike cajeput oil. The tree is indigenous to Malacca and as far as can be ascertained it cannot be found in the other settlements, but a few hundred young plants were introduced into Singapore from Malacca last year for roadside planting, for which purpose they are very suitable. They make splendid avenues when planted alongside roads crossing freshwater swamps or paddy-fields. The water becomes discoloured by tannin from the fallen leaves. The natives make a decoction from the leaves which is very astringent and assumes the colour of strong tea. It is said to be a specific administered in cases of diarrhœa and dysentery. The bark is extremely light, buoyant, soft and pithlike, about 3 8th of an inch thick, overlying the wood in thin white and light brown layers of the thickness of tissue paper interlarded with woody fibre and white powder. Like the *Quercus Suber* or cork tree it regularly sheds its bark and acquires a fresh coat. The natives use it instead of oakum for caulking the seams of their boats. The wood is used as poles and putlogs for scaffolding, the construction of fishing stakes and for fuel. The tree thrives and abounds in Malacca in the inland marshes and outlying lands, and as fast as they are felled seedlings spring up to take their place.

We congratulate Mr. Boswell upon the result of his researches, and we hope further success may attend his efforts.—*Singapore Free Press*, July 26th.

[If we have not got this tree in Ceylon already, we should think Dr. Trimen will lose no time in supplying the deficiency.—ED.]

A LARGE TEA LEAF.—We have received a very fine tea leaf gathered on Kirkoswald estate, Bogawantalawa. It is exactly 11 inches long and rather more than 3¾ inches wide. The bush from which the leaf was taken is rising 3 years old, the elevation of the estate being 4,300 feet. The tea leaf is not supposed to be from indigenous seed.—It is the largest we have seen, except a leaf of indigenous, grown on Somerset estate, Dolosbage, which was exactly 1 foot in length. Good hybrid bushes, when young, yield leaves which can scarcely be distinguished from indigenous.

HOW MANY CUPS OF AVERAGE TEA CAN BE OBTAINED FROM A POUND OF THE LEAF?—The answer to this statement can be deduced from the figures given for the number of cups drunk at the great Exhibition and the number of pounds of leaf from which they were brewed. The figures are 730,780 cups from 12,183 pounds. It follows, therefore, that a pound of good Indian or Ceylon tea leaf will yield as closely as possible 60 cups of the beverage,—average-sized cups, of course. At this rate an ounce would yield 3¾ cups. How does this accord with results obtained in household use? Of the quantity of tea sold in packages at the Exhibition, the proportions for India (23,606 lb.) and Ceylon (23,086 lb.) were nearly equal, the figures for Natal being 547 lb. But in the quantities infused Ceylon took the lead with 6,055 lb. yielding 363,300 cups, Indian tea being given at 5,784 lb. and 347,040 cups; while 344 lb. of Natal tea yielded 20,640 cups. Tea was exhibited from a larger number of Ceylon than of Indian gardens,—167 Ceylon to 150 Indian, but the samples from India were somewhat in excess, 684 against 624 from Ceylon. As yet India and Ceylon are the only British possessions which produce appreciable quantities of tea. But others, not so favoured in regard to labour supplies, are following in our wake and it looks as if Natal and Fiji would come rather respectably to the front. The one would find a fair market in South Africa, while the other is near at hand to supply Australia and New Zealand. Now that Indian labour is allowed to be imported to the Straits, other portions of the Malay Peninsula besides Johore will grow tea. The labour difficulty will, we suspect, keep Jamaica back. When Upper Burma is pacified and commences the process of receiving population from Madras, such as has advanced lower Burmah so rapidly, we may have another very formidable competitor. The danger looming in the future is over-production and a low level of prices. Meantime, the additions to Indian and Ceylon tea at the Exhibition were Natal with 37 samples from 6 estates; Fiji 16 from 2; Johore 9 from 1, and Jamaica 4 from 1. In all 1,374 samples of tea from 327 gardens. The numbers who had a chance of seeing or tasting those teas was 5,550,745.

FELSPAR AS A POTASH MANURE.

Sir,—I observe in your issue of the 20th instant that Dr. Aitken has made some successful experiments on the manurial properties of ground felspar. Ordinary pink felspar, known mineralogically as *orthoclase*, forms one of the constituents of granite and consists chiefly of sillica alumina, and about 12 per cent. of potash. As felspar is generally regarded as an insoluble mineral, it may be of interest to draw attention to a series of experiments on the solubility of various minerals, described by Mr. A. Johnstone in the lately published *Transactions* of the Edinburgh Geological Society. At page 282, vol. 5, Mr. Johnstone states that he took three pieces of orthoclase, and after carefully weighing them put them into separate vessels containing distilled water saturated with carbonic acid gas, and allowed them to remain immersed for three months.

The first specimen was placed in a flask, which was then corked and put away on a shelf, where it remained motionless during that period. The second was suspended in a beaker, the water in which it was immersed being agitated for about ten minutes every day for the three months. The third was placed in a shallow dish and barely covered with the carbonic acidulated water so that the upper surface of the crystal was nearly in close contact with the air. The water was gently shaken for about ten minutes every day during the three months.

When the specimens were examined at the end of that period, the first had become slightly softer on the surface than before, but had scarcely decreased in weight and the liquid surrounding it, when evaporated down scarcely left any residue. The second specimen was decidedly softer, and the solution left a residue containing potash and carbonic acid, with traces of lime and soda. The upper surface of the specimen which had been in almost close contact with the air was found to have altered its appearance and to have changed its bright translucent aspect and become covered with an opaque dust-like crust of kaolin. The solution left a larger residue consisting of potash, soda and carbonic acid, with traces of lime and silica.

In these and other experiments on various felfpathic minerals, it was always found that decomposition takes place fastest when the water is in ready contact with air. The more air, in fact along with water, the more rapidly desintegration proceeds. These results are agriculturally of interest as they show the comparative ease and rapidity with which felspar can be decomposed and its alkaline ingredients dissolved out. The experiments were made on single crystals of felspar, with the smallest possible surface on which the atmospheric disintegrating elements could work. By grinding the mineral, and so enormously increasing the surface, the alkalies might be practically all extracted in a season, if the powder were used as a light manure.

The felspar used in Dr. Aitken's experiments was obtained from Norway; but there is no need of going so far a field as this mineral exists in abundance in the remote parts of our own Highlands, and in some of the very poorest districts where the crofters are most in need of employment. The western coasts of Sutherland and Ross, with the whole of the outer Hebrides, consist of barren tracts of gneiss, traversed by multitudes of veins of pegmatite,—a coarse variety of granite, chiefly made up of orthoclase felspar. Water power is often abundant in these poverty-stricken parts of Britain, and the mineral might there be quarried and ground, and shipped to the south at a cheap rate.—H. M. CADELL, in *North British Agriculturist*.

THE ROYAL BOTANIC GARDEN, CALCUTTA.

Annals of the Royal Botanic Garden, Calcutta. Vol. 1. The Species of Ficus of the Indo-Malayan and Chinese Countries; Part 1. Palæomorphe and Urostigma. By George King, M. B., F. L. S., &c., Superintendent of the Royal Botanic Garden, Calcutta. (London; Reeve and Co., 1887.)

Dr. King deserves well of botanists for his protracted, though evidently profitable, labours on so varied and difficult a genus as *Ficus*. From obvious causes a large proportion of the large arboreous tropical genera of plants are still very imperfectly known, and, prominent among them, *Ficus*; therefore Dr. King could hardly have extended his researches in a more useful direction. The present publication, which, from its general title, we may assume will not be limited to a monograph of the Asiatic species of *Ficus*; is a tall quarto of sufficient size to illustrate adequately almost all the species of the genus in question. Indeed, this monograph possesses a quite special value, inasmuch as every species is carefully figured in natural size, with enlarged analyses of the floral structure.

Most persons interested in such matters will be familiar with Fritz Müller and Solms Laubach's investigations of the sexual conditions in the flowers of various species of *Ficus*, and the singular phenomena attendant on the fertilization of the ovules. Nevertheless, it may be convenient to give here a brief account of the process.* The edible fig, which may be given as an example of the fruit of the genus generally, consists of a thick hollow receptacle, the inner surface of which is thickly studded with flowers; and, in the edible fig, exclusively with female flowers. Male flowers of this species of fig are borne on different plants, called the caprifig; and associated with these male flowers, in the same receptacles are numerous female flowers, occupying the greater part of the space. Invariably these female flowers are infested by gall-producing insects, hence they are termed gall-flowers, and very rarely indeed is a single ripe seed found in a receptacle of the caprifig. The insects hatched and nourished in the gall-flowers leave the receptacles of the caprifig at a period when the pollen of the male flowers is being shed, and in making their exit bear some of it with them to the receptacles of the edible fig, which they next visit; but they are unable to deposit their eggs in the perfect females, and only serve to convey pollen to them. On similar mutual adaptations the fertilization of all the species of *Ficus* seems to depend.

In an introduction to the descriptive part of his work, Dr. King details the results of his own examination of several hundred species, extending over some nine years: and he states that Solms-Laubach anticipated him only in his explanation of the true nature of the "gall-flowers," for he had found them in every species of the genus that had come under his notice. He also enters into some further particulars concerning the insects acting in the process of fertilization, though he adds nothing more conclusive. While admitting, and even assuming, that the pollen of the males must be conveyed by the insects developed in the gall-flowers "to the perfect female imprisoned in the neighbouring recepacles," he is still puzzled as to the way in which it is done. We are under the impression that Solms-Laubach indicates, if he does not actually state in so many words, that he had not frequently seen the winged female insect issuing from the receptacles of the caprifig, but that he had likewise occasionally observed them enter the repectacles of the cultivated fig, which is the female of the same species.

This, the first part of King's monograph, contains descriptions and figures of seventy-six species of *Ficus*, whereof ten belong to his section *Palæomorphe*, and the rest to *Urostigma*, which was originally proposed as an independent genus by Gasparrini, and provisionally retained as such by Miquel. King found five different kinds of flower, variously associated or removed, in the Asiatic species of fig; and upon characters derived from the differentiation and arrangement of the sexual organs he classifies the species in two primary groups and seven sections. The species of the relatively small group *Palæomorphe* are distinguishable from all the others by having spuriously bisexual flowers associated with gall-flowers, while the fertile females occupy separate receptacles. In the definitions of the sections, the pistil in the functionally male

* Further details will be found in *Nature*, vol. xxvii p. 584.

flowers is described as rudimentary, though perhaps sterile would be a better term to use, because, as figured, and designated in the explanations of the figures, it is a fully-developed gall-pistil. This condition is regarded as the nearest approach to assumed original complete hermaphroditism.

In all six sections of the larger group the sexes are strictly separated, as to the individual flowers; and in the section *Urostigma*, male, gall, and perfect female flowers are intermingled in the same receptacles. We have overlooked it if there is any explanation of the advantage derivable from the presence of gall-flowers where both sexes are also found in the same receptacle; but it may, perhaps, be found in the fact that the inflorescence is proterogynous or proterandrous, hence insect agency is as necessary as in those species where the sexes are in different receptacles.

In the remaining five sections the male and gall-flowers are invariably borne in one set of receptacles, and the fertile female flowers in another set; and the presence of neuter flowers in the female receptacles characterizes the section *Synœcia*. The neuter flowers contain rudiments of neither sex, which condition King explains by saying the neuter flowers are asexual.

Neuter flowers are wanting in the sections *Sycidium*, *Covellia*, *Eusyce*, and *Neomorphe*; but the arrangement of the flowers is otherwise the same as in *Synœcia*. The two first of these sections have monandrous male flowers, and the two last have diandrous or triandrous male flowers: while the receptacles of the first and third are mostly axillary, those of the second and fourth are usually borne in fascicles on the stem and branches. Thus it will be perceived that the distinctive characters of these four sections are somewhat artificial. However, it is only fair to say that the author himself points out this fact.

We have very little to say except in favour of this work, which is certainly one of the most important of recent contributions to systematic botany; but we should have liked to see a closer adherence to established usage in the application of certain botanical terms. To use the terms monœcious and dicœcious in relation to the individual receptacles as well as the whole tree is perplexing, and also unnecessary, because suitable terms for expressing these distinctions are current, and even employed by the author himself in some passages.—W. B. H.—*Nature*.

THE CULTIVATION OF A WOOD FOR TEA BOXES.

Dr. H. Meyer, Lecturer in Forest Botany at the University of Munich, has recently published the results of his inquiries as to Forest Cultivation, in a tour of some months which he made through the northern part of India. Being informed of the scarcity of indigenous wood suitable for Tea Boxes, he directed his particular attention to this subject, and he has come to the conclusion, taking soil, climate, and other contingent matters into full consideration, that the quickest, cheapest, surest means of providing for a future suitable supply of wood for Tea-boxes, in this country, would be to cultivate the *Cupressus* (Japanese *suji*), or, as Dr. Meyer calls it, *Sequoia Japonica*, for the Hills round Darjeeling, and the *Pandanus odoratissimus* or the Japanese *Aoki* for the plains, Terai, and lower hills of the N. W. P. and the Punjab. It may be argued that the proper persons to give attention to and advice on this subject are the Forest Department, and no doubt the matter will be taken up by them, but it is within the ability of any planter to create for himself timber reserves, and the doing so will be found by no means unprofitable.

In Japan the *Suji* (Japanese cedar) is largely cultivated all over the whole empire, and it is also found in a wild state. It forms a splendid mass of forest in many districts, and grows to the height of 150 feet, with a girth of 6 feet and more. The tree is said to be a native of China. At any rate trees of this country the first specimens [illegible] by Mr. Fortune. A few trees only were at the time planted, but the kindly way in which they have taken to the hill soil and climate shows the adaptability of the place to their cultivation, and it is to be hoped now that the value and suitability of the wood for tea boxes is established, it will induce a considerable extention of cultivation.

In Japan itself the wood is highly prized, and very extensively used. It grows in all situations and soils,—in damp villages as well as on high mountain slopes, and is one of the commonest and also one of the most useful of Japanese timber-trees. The sapwood is whitish yellow, from 2 to 3 inches broad, and is, when beams or boards are wanted, generally not removed from the dark-reddish sometimes blackbluish, striped heart-wood. The wood is very light and soft, and easily manipulated; and may be used for all kinds of carpentry besides tea-boxes. For propagation of the *Suji*, the terminal piece of every branch is used, 1½ to 2 feet long. The plantation in the ground must be made before or at the beginning of the rainy season, the cuttings being put 3 to 5 inches deep in the soil. This method is much perferred to sowing, the young seedling being tender, and easily killed by frost. Although, of course, the tree takes many years to arrive at maturity, its commercial value is none the less ascertainable at any stage, and a tea estate possessing a reserve of the timber, in almost any stage of growth, would possess a marketable commodity of ascertainable value.

In planting, scarcely 4 feet should be left apart, for only in a dense growth does the *Suji* soon lose its branches, and produce a clean, straight, and valuable bole.

There is another timber-yielding tree, the wood of which is suitable for tea boxes,—the *paulownai imperialis* (called *kiri* in Japanese), but it does not grow well in the wet climate of the Eastern Himalayas. The wood of *paulownai* is largely used in Japan, not only for tea boxes, but for boxes and furniture of every kind. One peculiarity in the cultivation of this tree is, that when the seedlings are two years old, they are cut off close to the ground, and the new shoots grow straight up to a height of 10 feet or more without a branch, in a single year.

When the tree attains a girth of from 3 to 4 feet, the timber is available for use for tea boxes. In Japan the tree is sawn off, every 8 or 10 years, very close to the ground, and the new shoots grow straight up to a height of 10 feet or more, without a branch, in a single year.

Dr. Meyer, who supplies us with all this information, offers to provide the Forest Department with seeds from Japan, and we trust that his offer will be availed of, and the seeds distributed to such as are willing to experiment with them.

It would be no small thing gained if we could grow in the Terai and hill districts of India a wood more suitable for tea boxes than that we now possess, and although, perhaps, it may seem a long time to look forward to for the realization of any personal advantage from such cultivation, yet the land thus planted with wood of an unaltering value, would always be by so much enhanced in saleable merit.

We commend the subject to the attention of owners of tea properties, who may find thus, in time, their timber land even more valuable than the land under the tea stself.—*Indian Tea Gazette*.

RUBBER.—The belt of land around the globe, 500 miles south of the equator, abounds in trees producing the gum of India rubber. They can be tapped for twenty successive seasons without injury, and the trees stand so close that one man can gather the sap of eighty in a day, each tree yielding on an average three table-spoonfuls a day. Forty-three thousand of these trees have been counted in a tract of country a mile long by eight wide. There are in America and Europe more than 150 manufactories of Indiarubber articles, employing some 500 operatives, and consuming more than 10,000,000 pounds of gum a year, and the business is considered to be still in its infancy.—*South of India Observer*.

Correspondence.

To the Editor of the "Ceylon Observer."

THE CINCHONA BARK MARKET AND CHEAP QUININE.

30th June 1887.

DEAR SIR,—The quantity of Ceylon cinchona bark sold in London in 1886 was 15,210,000 lb.

In December 1886 the price of bark was higher than since the beginning of the year. At a sale in December, 3 per cent bark of mine fetched 4d the unit, there was keen competition at the sale and prices would probably have continued to rise but for the enormous imports from Ceylon, which for the first 4 months of 1887 reached 6,200,000 lb. The price then fell to 2½d to 3d, being a fall of 31 per cent in 4 months.

The imports from Ceylon in 1885 were much larger than in 1884. People then said the imports for the next year would be smaller.

The imports from Ceylon in 1886 were much larger than in 1885. People again said the imports for the next year (1887) would be smaller.

For the first 4 months of 1887 the imports were 6,200,000 lb., thus promising a total for the year of more than for the year 1886.

In Ceylon there are, say, 50 millions of cinchona trees growing, the majority being succirubra. The average annual yield per tree from a large number of trees, some young, some old, some barked annually, some not, some coppiced, would be less than 4 ounces per tree of dry bark.

The average yield from a number of trees uprooted would be, say, 4 lb. of dry bark per tree, or 16 times as much as from trees barked as above.

Uprooting in Ceylon is going on largely and is likely to increase, so that for some years to come the shipments are likely to be increasingly larger.

The number of cinchona trees growing in India is about 25 millions, the majority being succirubra.

It is known that the number of cinchona trees growing in Java is large, that the trees are now young, and that in three or four years the shipments of bark from Java will be large.

The shipments of bark from cultivated cinchona in South America are increasing.

The bulk, however, of the bark now imported comes from Ceylon and India, is the produce of the cinchona succirubra and, therefore, of a poor kind.

Judging by prices realized, one-fourth of the imports from Ceylon is composed of bark yielding less than 1½ per cent.

It is generally allowed by the bark brokers in London who are the best judges, that could we relieve the European market of one-fourth of the quantity of bark at present imported prices would rise.

The value of the unit may go lower than it is at present, but taking it at 2½d to 3d, the low quality bark would be worth, say, per lb. 2½d.

Deduct curing, shipping, and sale charges 1 d.

Value to producer .. .. 1½d.

Comparison of results to planters supposing that none of the low quality (below 1½ per cent) came into the European market:

Proceeds from 20 tons of Bark.

Prices have risen 1½d per unit owing to low quality bark having been taken off the market.

	£
*15 tons at 4d per lb.	1100
Deduct curing, shipping and sale charges at 1d per lb.	135
	£965
	619
Gain to the planter	£346

* 5 tons out of the 20 tons not being even valued.

Proceeds from 20 tons of bark.

Prices as before owing to the large quantity on the European market.

	£
20 tons at 2½d per lb.	802
Deduct curing, shipping and sale charges at 1d per lb.	183
	£619

With such results is it worth the planter's while to swamp the market with his low quality stuff?

I have been a cinchona planter for the last 20 years, for the last 6 years of which period I have lived in England and sold my bark so that I have had some experience of the London market. I, for one, should be only too glad not to sell either in Europe or in the East (for if sold in the East it would ultimately reach Europe) any bark analysing less than 1½ per cent.

This is a vital question with all cinchona planters and is one which can be solved if they will work together.

I have my opinions with regard to a solution and intend to give them, meantime I hope Ceylon planters may be induced to take up the subject in earnest. They constitute the great majority of cinchona planters and it is chiefly their bark which is swamping the market.

May I suggest the following facts for consideration. The enormous scope for increased consumption of cinchona bark alkaloids

IN CHINA.—The population of China proper alone is 360,000,000, a great part of the country being more or less feverish. Colquhoun in "Across Chrysê" writes: "Quinine is the best present any traveller in Yunnan can carry." "For gifts quinine &c. may be recommended." "A crowd of people came beseeching us for medicines. We could only give them a few small doses of quinine." "The magistrate had sent to ask us for some medicine for destroying the passion for the black smoke, viz., opium."

The value of the opium consumed in China is 14 or 15 million pounds sterling. This shows that the Chinese are willing to pay for what they want. Might not the introduction of the cinchona alkaloid be made to supersede some of this opium?

BURMA is another large country, a large portion of which is feverish.

SOUTHERN INDIA.—Dr. Cornish, an officer who has lately held high appointments in South India, says the use of the cinchona alkaloids may be largely extended.

IN TROPICAL AFRICA AND SOUTHERN EUROPE fevers are prevalent. The existing generation of planters is hardly likely to see the consumption of the cinchona alkaloids much increased if it waits for the course of supply and demand in the countries (mostly uncivilized) I have named.

THE PRICE OF QUINETUM in London now is 1s 9d per ounce, of sulphate of quinine 2s 10d per ounce.

THE EXPENSES OF MAKING QUINETUM in Ceylon from low quality bark would probably be not more than 4d per ounce, including cost of bark at market value.

W. T. HODY COX.

GREEN BUG IN UVA.—Uva, 31st July.—We unfortunately have this last scourge of the coffee and I may say of the coffee planter, but I do not think my friends should take the very serious view of the question which some do. I have seen green bug literally kill coffee trees "in Uva" but it was invariably on places where coffee would hardly grow I have not in Uva seen green bug do "serious" damage to coffee where the trees were healthy and in good cultivation at 3,000 feet or over.

PLANTING IN CEYLON IN 1847-1860.

FROM A LECTURE BY A. M. FERGUSON, C.M.G.

In a previous lecture delivered in this place* a year ago, I gave a brief glance at events occurring and persons prominent in the annals of Ceylon during the score of years between 1837 and the end of 1846. The retrospect, indeed, extended to the close, in April 1847, of the administration of Lieut.-General Sir Colin Campbell, a peninsular veteran, the last of the regularly appointed rulers of Ceylon, in whose person civil functions and military command were combined. In the period of this Governor's rule, during the five years commencing with April 1841, the Coffee planting enterprize, assisted with British capital and conducted by British energy and enterprize, (supplies of Tamil labour from Southern India becoming gradually available, made steady progress); the revenue of the Island, as has ever been the case, rising in proportion to the capital spent in planting operations, whether those engaged in such operations profited or the reverse. Judged merely by the revenual test, so prosperous did the Colony seem, that the Colonial and Home authorities felt justified in adding considerably to the numbers and emoluments of the civil establishments; so leaving, as has repeatedly happened, a legacy of embarassment and enforced reduction to their successors. While all appeared prosperous, a terrible storm of financial trouble in Europe, with its reflex action on Ceylon, was impending, which burst between 1845 and 1847, and the depressing and discouraging effects of which continued to be felt all along the years extending to 1850. Small comparatively as was the export of Coffee from Ceylon (the figures for 1846 being only 174,000 cwt.), yet consumption of the fragrant berry was then so limited, that, added to the stoppage of supplies of capital from Europe, came the fall in prices in the consuming markets, which ever follows in the wake of overproduction at the sources of supply. To say that crops, even with returns of 5 to 10 cwt. and more per acre, did not pay the cost of cultivation, would be to give but a faint idea of the disastrous crisis of 1845 to 1849. Suffice it to state that parchment coffee, which we have seen readily selling in the local market at R12 per bushel, was then parted with at R3, while at Kandy a bushel of rice and a cwt. of coffee were selling for an equal sum of money. As if to put the finishing stroke to the fate of the once promising Ceylon coffee enterprize, the scale-insect or coccus, known popularly as black bug, which years previously, had spread to portions of the coffee plantations from the indigenous jungle, now became rapidly and virulently prevalent, the black fungus, which ever accompanies the really brown insect, giving a funereal aspect to the once glossy-green vegetation, and whole plantations, on which blossom and fruit were no longer able to show themselves, seemed to the depressed onlooker in mourning for a dead industry. The death of the enterprize was indeed confidently anticipated in 1847, from the combined attacks of black bug and black grub, and there can be no doubt that the mode in which the coffee plant then resisted the pestiferous influences of such formidable enemies, finally triumphing over them, emerging into a new life of vigour, umbrageousness, bright blossom and profitable fruit crops tended greatly to lull even the most experienced and sagacious planters into security, when a generation afterwards, with far less warning and with far more fatal effect, *hemileia vastatrix* escaped from the gloomy recesses of its jungle home to perplex scientists and spread ruin amongst thousands dependent on the enterprize so mysteriously and so destructively affected. With white grubs, the offspring of cockchafer beetles, at the roots of the trees which were simultaneously divested of their foliage by the fungus foe, it might well be said of the coffee plant from 1869 onwards, that its candle of life was being consumed at both ends: and yet it was while whole fields of coffee in Ceylon were tinted orange by the spores of the fatal fungus, that estates changed hands at fabulous prices, and that merchants, brokers and bankers competed with each other in pressing accomodation on planters, deemed lucky and to be envied as the possessors of coffee property and who pooh-poohed the new enemy as an evanescent evil, seeing that it had not yet materially lessened crops which were selling in London at prices up to 120s. per cwt. Scientists tell us, and we are probably bound to accept their dicta, that such visitations as bug and grub and fungus in coffee, with *helopeltis* and red spider on tea, are retributive and corrective in their nature, sent as warnings against disturbing a so-called "balance of nature," whereby many and varied species of vegetation grow over the same area, instead of vast expanses of a single product being presented, as is so frequently the case when the clearing and cultivating agency of man appears on the scene. The fate of coffee growers in the Eastern world, following on the misfortunes of the cultivators of vines, wheat and potatoes in Europe and other parts of the world, seems to establish the principle alluded to, although doubtless other more or less obscure laws of soil and atmosphere may have been unconsciously violated. Then again it may be amongst the beneficent designs of the Ruler of nature, and "natural laws" so-called, that the misfortunes of the few should conduce the greatest good of the greatest number, an end which certainly has been largely attained by the impetus which the failure of coffee in Ceylon gave to the cultivation of the plants which yield the most effective relief to suffering humanity, when afflicted by malarious fevers (the most common and most formidable diseases of the world, probably) or when depressed by debility, the consequence of other affections. Ceylon planters, who when their Old King became moribund and got into "the sere and yellow leaf" showed so much enterprize, energy and I may add, success, in the cultivation of the febrifuge-yielding cinchonas in a scene so far away from the Andean home of those interesting plants, may, in the absence, during late years, of appreciable profits from this source, derive what consolation they can from the reflection that the benefits they have conferred on the world, by cheapening and so rendering generally and easily accessible a medicine the most valuable in its properties and the most certain in its effects of all the substances included in the pharmacopœia, are co-extensive with humanity itself. As I have been led to anticipate so far, I may be permitted to advert to another new product which had not been seriously and decisively considered as a probable staple product of the island in the period I am reviewing, but which is as intimately connected with the decadence of coffee as effect is with cause. I refer, of course, to our new staple TEA, which as a medicine is only inferior to quinine. I have proof of this in the fact stated to me by a lady doctor from India, that, failing supplies of cheap quinine, she in her own practice substituted, and with perfect success, cheap tea as a remedy for the severe malarial fevers, which annually decimate the poor natives in the North-west of India. But tea has the grand advantage over quinine of being not merely a medicine, but a nutritious and innocently stimulative article of food, popular already with a considerable portion of the human race and likely, ultimately, very largely to supplant alcoholic stimulants and narcotics. Good tea has prophylactic as well as medicinal and nutritious virtues, and when the time comes, as come it probably will, when the vast majority of the human race will regularly use tea as an article of diet, the cases in which quinine and other febrifuges or tonics may be "indicated," will become few and far between. Without disparaging coffee or chocolate, it is certain that tea is one of the most easily prepared and one of the most grateful of the non alcoholic stimulants, and the most likely therefore ere long from its universality of use to deserve the epithet "sublime," which Byron applied to a narcotic weed the use of which would, in the opinion of some of us, be "more honored in the breach than the observance." Reflections such as these may help to reassure and cheer Ceylon tea planters, as the phantom of "over-

* Baptist Church, Cinnamon Gardens, Colombo.

production" rises up or is conjured to strike terror to their souls. Comfort, too, is to be derived from the fact of the superior quality of our insular product and its as yet wonderful immunity from enemies of the nature of those which between 1847 and 1886 have proved so destructive, so largely fatal indeed, to the once flourishing staple of our export commerce. May all that was prosperous and nothing of what was adverse in the history of OLD KING COFFEE, distinguish the rule, perpetual let us hope, of the NEW SOVEREIGN of the "new products" of Ceylon. Before passing from the subject of tea, I feel bound to observe that little doubt can be entertained of the fact that trials of this cosmopolitan plant on an extended scale by Ceylon planters in the period with which I am dealing, were hindered by the information conveyed to Sir Emerson Tennent by the Bros. Worms and by Tennent embodied in his great work on Ceylon, that the result of the Rothschild experiment of introducing first tea and then tea-makers from China, was that each pound of manufactured leaf cost them £5 sterling. In view of that statement we were all long in the habit of saying — "Tea can be grown in Ceylon but not to pay." Thus, apart from the fact that while coffee prospered its profits (and at certain periods and in certain cases these profits were very large) were so much in excess of what could possibly be expected from tea, there seemed to be no inducement to engage in the cultivation of the latter. Mr. Maurice Worms having spent some time in China, it was only natural that the seed with which he and his elder brother tried their experiment should have been imported from the country which had long been deemed the original home of the tea plant. So in most of the experiments the species or variety of tea available was China. To Mr. Llewellyn, a Calcutta gentleman, who owned land in Dolosbage, I believe, belongs the credit of having first introduced indigenous Assam tea, decendants of his bushes or rather trees, if not some of the originals being still in existence. Before their value as seed-bearers was appreciated, many of the big trees were cut down and converted into rafters for buildings. To Mr. Harrison, of Messrs. Keir, Dundas & Co., probably belongs the merit of the first introduction, on an appreciable scale, of seed of the Assam Hybrid, the value of which as both prolific and hardy had been so fully recognized, before tea planting was extensively taken up, in Ceylon that, fortunately, our planters had in this matter, as in others, the benefit of Indian experience, so that with the fewest exceptions possible, the Ceylon tea plantations possess the best jât of plants from Assam: either indigenous or high quality hybrid. Without disputing the proposition, that, in order fully to enjoy the delicate and delicious flavor of tea, the infusion ought to be drunk without sugar or milk, it must be affirmed that as an article of human diet the value of tea is immensely increased by the fact that by the majority of those who use it, it is employed as a medium to convey into the system such nutritious substances as milk and sugar. Of milk I need not speak, except to say that Ceylon milk is generally watery in an abnormal sense, so that the milk vendors of our capital city have least cause to complain of a delayed water supply. But sugar, especially in its refined form, is not only difficult to adulterate (apart from the absence of temptation owing to its now extreme cheapness), but those who have studied the subject of nutrition are agreed, that if a human being were condemned to the use of only a single article of food, life could be longer sustained on sugar than on ony other one substance, milk forming no exception. It is not for us, in Ceylon, therefore, to join our friends of the West Indian colonies, British Guiana and Mauritius, in denouncing the policy of certain European nations who by means of bounties out of their general taxation help their sugar growers and refiners to give British subjects, at home and in the colonies, cheap sugar, at a cost of many millions to such nations themselves. For, in the period of my review, experiments were tried in such widely separated portions of the island, as Dumbara, Negombo, Matara and Kalutara, on a scale large enough and for a sufficiently protracted number of years, to prove conclusively in the estimation of those concerned and intelligent lookers on, that while the sugarcane can be grown (and it grows luxuriantly in many localities in Ceylon) it cannot be grown for sugar-making on a large scale, so as to yield a commercial profit. As that is what we long and, as the event has proved, erroneously thought and said regarding tea, of course I feel that even in the face of all I know of capital and labour wasted and hearts broken in the attempts to grow the sweet cane and manufacture sugar from it in Ceylon, I would hesitate to say that the prospect of a successful experiment in the future, is hopeless. Circumstances may arise, which will justify the expenditure of capital on guano and other fertilizing substances, calculated to correct comparative poverty of soil and excess of moisture in our atmosphere, such as rendered success in the past impossible, in consequence of the canes yielding a maximum of water and a minimum of saccharine matter. But in view of the subsidized competition mentioned, I do not suppose any person, who has a regard to remunerative returns, will act on the belief that the time for a revival of experiments which forty years ago ended so disastrously has yet arrived. My first introduction to sugar manufacture was in Dumbara in May 1841 (45½ years ago), and I still vividly remember the anxious warning of my old and valued friend Mr. Robert Tytler (then a young and blooming lad, now, alas, gone from scenes of enterprize in which he took so active a part) not to touch the film of sugar which was forming over the top of a mass of boiling liquid. Half a dozen years subsequently, I saw the superintendent of an estate in the Negombo district watching a caldron of boiling and bubbling molasses, which he complained, he could by no means induce to crystallize. That seemed the great difficulty in Ceylon, although Mr. Macgregor, Lord Elphinstone's Superintendent on Paradua estate succeeded in producing white loaves, one of which he brought to the *Observer* Office, as a proof of what could be done; yet the enterprize paid Lord Elphinstone no better than others, and his lands which once grew sugar now grow tea. For the present, at least, we must consent to a division of labour, in supplying the ingredients of the cup which, with no intoxicating property, cheers and strengthens the wearied frame and replaces wasted tissue. We in Ceylon must be contented to supply the world with the best possible tea, leaving it to our friends of the canefields of other tropical lands to compete with the beet farmers of continental Europe, in providing the best and cheapest sugar. To show what mistakes the most careful and intelligent man can make, I may mention that my late friend Dr. Elliott with all his local knowledge and his great sagacity deliberately preferred a trial of sugar cultivation near Negombo to going into coffee even when he knew of the splendid returns yielded by such early estates as Hantane and Oodowella. Happily for him and his family, the estate on which he had spent, all his savings was purchased on behalf of Messrs. Arbuthnot & Co., of Madras, by an old west Indian sugar planter, Mr. Fraser, who also owned "Charlie's Hope" near Kalutara. All Mr. Fraser's experience and skill could not make sugar a success and the Negombo lands only became really valuable in the hands of Dr. Elliott and others when planted with coconut palms, the expansion of which form of cultivation, I may say, received an immense impetus in the period I am dealing with. So did cinnamon, which has now for many years suffered like so much else from overproduction. Unlike cinnamon, coconut cultivation must always have a steady and moderately profitable value from the enormous extent to which its chief product is used as a staple food of the fast increasing indigenous population. Cinnamon, apart from any value it may have as a drug, is mainly a luxury for the rich: while the fruits and other numerous and varied products of the coconut palms supply the necessities of the multitude who must be classed as poor or just above the reach of want. Before passing away from the subject of sugar cultivation in Ceylon, I ought to

have noticed the death during the period under review of the pioneer in the British rule of this enterprize and other enterprizes in Ceylon, Mr. George Winter. He and his descendants managed to make sugar cultivation pay on a small scale on the banks of the Gindura river, at Baddegama near Galle. So long as the great mail companies made the latter port their headquarters, there was always a steady and fairly profitable demand for raw sugar for the supply of the ships which brought coal for the steamers. In the course of a discussion a few years ago on the question of reviving sugar culture in Ceylon, on a large scale, Mr. Curtis, who, as the husband of a grand-daughter of Mr. Winter, is in charge of the Baddegama estate, confirmed the correctness of my estimate that against as much as 11 per cent saccharine matter which I had seen tested in Northern Queensland, Ceylon canes could not be expected to give more at the utmost than 8 per cent. Unlike Mr. Winter, another old friend, Mr. Robert Craig, lost his money and I may add his life, from embarking in sugar culture. He worked up a coffee estate in the Kadugannawa district in the early days of 10 cwt. an acre until he was able to sell out for £12,000. To him and to his family this was comparative wealth, but he was unfortunately induced to spend the price received for his coffee estate in opening a sugar plantation near Matara. The enterprize was a failure, poor Craig had lost his all and he died like so many others from heart disease, the result, doubtless, of anxiety and depression. In all worldly pursuits, there must be vicissitudes such as I have noticed, and the natural mistake we all make is to concentrate our attention too exclusively on our own success or the reverse as individuals, as if the universe revolved around us, to the exclusion of wider views of the gradual progress, after frequent temporary retrogression it may be, of the body politic of which we are merely component parts.—Of Ceylon we can still say what Galileo said of our globe: "It moves, nevertheless," and the movement is after all, and in the face of all retarding influences, onwards.

It may be well while thus noticing enterprizes in agricultural products on an extensive scale by Europeans in Ceylon, to state that cotton, in the period referred to, equally with sugar, received extensive trials and with equal want of success: in the Jaffna peninsula by the brothers Whitehouse and Messrs. Clarke and Hardy, and in the neighbourhood of Negombo, by the agents of Baron Delmar, to whom, by the way the once well-known planter, Mr. Crüwell, had acted as Private Secretary. One of the great difficulties about the culture of cotton in this island is that the boles or pods in which the wool which encircles the seed is contained, ripen and burst when our monsoon rains are heaviest. The produce is thus damaged if not destroyed.

CAOUTCHOUC-YIELDING PLANTS.

I should like to say a few words on Mr. Bruce Warren's letter on "Caoutchouc yielding plants," on page 760 of the *Journal* for June 17th,* because some of the statements contained therein require explanation. In the first place, Mr. Warren does not seem to be aware that for many years past a considerable amount of attention has been given to the cultivation and acclimatisation of useful plants in the botanical gardens of our Colonies and in India. The whole thing has been taken up so thoroughly, especially of late years, and fostered at Kew, with which all the botanic gardens are in communication, that it has been reduced to a system. These are facts so well known that I need not dwell upon them; indeed it is for the purpose of answering some of Mr. Bruce Warren's questions, and setting some of his statements in a clearer light, that I now write.

Mr. Warren asks if the *Mangifera indica* "is botanically allied to the Mangabeira (*Hancornia speciosa*), which yields Pernambuco and Ceara rubber." In answer to this, allow me to say that the *Mangifera indica* is the mango tree of India, chiefly valued for its fruit, and belonging to the natural order Anacardiaceæ, while the *Hancornia speciosa*, the common name of which is Mangabeira, is a native of Pernambuco, and though the fruits are edible, the chief value of the tree is for the rubber which it yields, known as Pernambuco, and not Ceara rubber, which is furnished by a totally different plant, namely, *Manihot glaziovii*, a euphorbiaceous tree. *Hancornia speciosa* belongs to the Apocynaceæ, an order well known for the elastic juice found in the stems of many of its species, which fact Mr. Warren seems to be aware of when he says that West African rubber is principally obtained from plants of this order. These plants are, however, natives of the East and West Coasts of Africa, as *Landolphia florida*, *L. Owariensis*, *L. Kirkii*, *L. Petersiana*, &c., and not of Madagascar, as stated by Mr. Warren.

In confirmation of Mr. Warren's statement that "there are instances of plants which are herbaceous, having arborescent representatives in warm climates," I need but mention the common castor-oil plant *(Ricinus communis)*, which is an annual 4 ft. to 5 ft. high in this country, while in Spain and Sicily it is a bush or small tree, and in tropical countries it becomes a tree 40 ft. high. This plant belongs to the Euphorbiaceæ, and shows the great variation we sometimes find in the same species, without the necessity of comparing two such totally distinct plants as the Para-rubber *(Hevea brasiliensis)*, which is naturally a large tree, and the "caper plant," or caper spurge (*Euphorbia Lathyris*). It is one of the characteristic properties of the Euphorbiaceæ to yield milk or elastic juices. Mr. Warren refers to the lactescent character of plants belonging to the tribe Cichoraceæ of the natural order Compositæ. This milky juice, which is found in the dandelion and allied plants, dries and becomes hard on exposure to the air, and is not elastic. In its closaelly, the lettuce, it is narcotic, and is known as lettuce opium

Regarding the Sapotaceæ, though they do not yield caoutchouc pure and simple, they yield an analogous substance, namely gutta percha, the principal source of this being a sapotaceous tree (*Dichopsis gutta*). Many of the species, principally belonging to the genus *Bassia*, as *B. latifolia*, *B. longifolia*, *B. butyracea*, all Indian trees, and *Bassia Parkii* of Western Africa, yield a quantity of fat from their seeds, generally known as vegetable butter. The character, therefore, of the Sapotaceæ is to give a solid fat from their seeds and an elastic juice or gutta from the stems.—JOHN R. JACKSON, Museum, Royal-gardens, Kew, June 21, 1887. —*Journal of the Society of Arts.*

VEGETABLES.

(BY A FAMILY DOCTOR.)

The *tomato* should be a greater favourite with us. It contains a cooling acid, a *volatile oil*, some mineral matter and salts, as well as fragrant resinous matter. It is used in soups, ketchups, sauces, and pickles. But inasmuch as the volatile oil—which words I purposely italicise in the last sentence—is dissipated by heat, the ripe tomato should, in my opinion, be consumed raw if it is considered palatable—*i. e.*, if it suits the individual taste. N. B.—No attempt should be made by anyone to acquire particular tastes, whether for tobacco, strange vegetables, olives, or caviare; to do so is simply to turn one's idiosyncrasy "tapsalteerie," to use a most expressive Scotch word. Let, therefore, whosoever is fond of any particular vegetable eat freely thereof; it is a food natural to him, a food that suits his system and cannot injure him; what he does not like he ought to avoid; there is no craving in the system for it, no want in his organism which it can supply. I have often observed that people of the nervous or nervo-sanguineous temperament are more partial to Solanaceous vegetables—potatoes, for instance—than those of the lymphatic are. As an article of diet, potatoes suit such people, for in addition to their nutrient qualities, they contain a certain amount of a property that is singularly soothing to the nerves. *Mustard* is a good stomachic; the ground seeds are used, or the tender leaves, in salads. Bearing

* See p. 106 *T. A.*—ED.

in mind how much mustard suffers at the hands of the unprincipled dealer, I think it is a pity mustard is not more often grown for table consumption in our kitchen gardens. The seeds of home-cultivated mustard, pounded in a mortar with cream and a little salt added, make a sauce fit for an epicure.

Cress, generally called American Cress, is a mild stomachic; it forms a valuable adjunct to a salad. *Water-Cress* is a still more important vegetable, possessing, as I believe it does, tonic properties. It is usually eaten with cheese, but ought to be used with beef and mutton.

Spinach, it should be remembered by those fond of it, is laxative in its properties and also highly diuretic. It makes an excellent breakfast vegetable for hot weather, although few people in this country think of cooking vegetables for morning consumption.

The *turnip*, one of the *Cruciferæ*, is far more valuable as an article of diet or adjunct to other food than most people think. It is also more nutrient than is generally supposed, and is valuable as a demulcent. Swedish turnips are usually ignored by the cook; this is a pity; they are better in every way than any other kind. Turnips ought to be well chosen, not too big nor too small; they ought to be gathered fresh, well boiled and well mashed. The green tops of the young turnips are also very healthful and in some degree tonic.

Parsnips and *carrots* belong to the *Umbelliferæ* family, and probably possess in some slight degree the medicinal properties of that family. In addition therefore to being highly nutritious, owing to the large quantity of starch they contain, they are, we may presume, alterative and resolvent. They make, at all events, an excellent change in our vegetable scale of diet.

Parsley is another of the umbelliferous vegetables used at table, chiefly for garnishing or stuffing. It is an excellent blood-purifying herb, and deserves to be used far more than it is. It ought to be put in soups and in sauces, eaten raw and eaten cooked. It is well known that parsley chewed sweetens the breath.

Beetroot—natural family *Chenopodiaceæ*—is one of the most nutrient vegetables we have. It is likewise cooling and slightly laxative; it should not, however, be partaken too freely of, even in summer, or it may produce painful flatulence and diarrhœa.

Beans of all kinds are nutritious; but people whose digestive organs are not strong should take care how they indulge in them. French beans require to be very tender indeed, and very well cooked, to be safe.

Celery is another vegetable which, though wholesome enough when cooked and mixed in soups, &c., should be partaken of with caution in the raw state, especially by delicate people or those who lead a sedentary life.

Rhubarb is most wholesome; it helps to purify and cool the blood, and to a great extent aids digestion, while at the same time it is healthfully laxative.

Garden-lettuces.—These vegetables are well-known to possess anodyne and narcotic properties. Hence they are best for supper. They should, however, be eaten sparingly, and the younger and fresher they are the better. The older leaves should be rejected as apt to irritate instead of cooling the system.

Asparagus belongs to the *Liliaceæ*, which gives the medicinal squill. It is a delicious and very wholesome vegetable, and contains cooling diuretic properties; indeed, it seems to soothe the mucous membranes of both lungs and kidneys, while it acts sedatively at the same time.

Onions, *shalots*, *chives*, and *leeks* are all members of the family *Liliaceæ*, and are not only highly nutritious when properly cooked, but are possessed in a greater or less degree of cooling and diuretic properties. They are also valuable stomachics and demulcents, but are apt to disagree, and should therefore be partaken of but sparingly. They have an effect for good on common colds and slight congestions of the air-passages.

From the natural family *Cucurbitaceæ* we get many valuable vegetables, some of which, as the *cucumber*, are eaten raw. This latter is, if eaten with pepper and vinegar, a stomachic stimulant, and it also purifies the blood by acting on the secreting organs. It should never be partaken of too freely, even by those whose digestive organs are strong, and by dyspeptics not at all.—*South of India Observer.*

BUG AND FUNGUS.

A merchant writes:—

"Herewith copy of extract from letter about green bug:—

"I do not fear the effects of green bug on this season's crop, and I am of opinion that if the land is manured and well forked, the bug will disappear, as I think that bug and such like pests originate from sourness of soil. I also notice a fungus is growing over the bug cells which I have examined under a microscope and find the young bugs contained inside the cells dead, this fungus is spreading on all coffee affected with bug. I send a few coffee leaves with the fungus on them by this post for your inspection."

Another merchant adds:—

"Touching the fungus growing over the bug, a superintendent writes to us:—'Green bug is beginning to "damp off" as is usual during the monsoon, but the weather has not been sufficiently wet to check it entirely. Early in July he informed us that 'a large part of the coffee is black with bug, but the pest does not seem to be spreading much during this wet weather.'"

Let us hope that bug, both black and green, will speedily disappear, while coffee, what remains of it, takes a new lease of life.

THE EFFECT OF MANURE ON CINCHONA OFFICINALIS

is thus described by the Madras Quinologist, in a paper supplied to us by Government:—

Plot XI., Dodabetta, was in April of last year divided, as near as possible, into five equal portions. Four portions were respectively treated with cattle, stable, lime and stable, and bone manures; the fifth portion in the centre was left in its natural state. In April of this year the entire plot was harvested by means of the stripping process, and the green bark from each portion was collected and dried separately, and its weight ascertained. The trees in each portion were counted, so that the average amount of bark from a number of trees could be calculated, and compared with the weight of others differently manured. The result of the harvest proved that the amount of bark per tree was highest in the portion containing cattle manure, and the next, that from prepared bones, but the quantities of bark from the stable, and lime and stable manured portions did not materially exceed the amount of natural bark from the unmanured trees. Turning now to the effect of manuring trees in order to increase the alkaloidal yield of the bark, the following analysis of the five samples will show how that object has been attained. It will be seen that all the manures have raised the value of the barks, but in different degrees; the analyses are therefore arranged according to the following order, the best being placed first:—

	Quinine.	Cinchonidine.	Quinidine.	Cinchonine.	Amorphous Alkaloids.	Total.
Bone manure	3·30	1·59	·10	·38	·43	5·80
Cattle do.	3·25	1·50	·13	·35	·41	5·64
Lime and stable manure	3·18	1·40	·08	·21	·48	5·35
Stable manure	3·05	1·41	·12	·32	·38	5·28
Unmanured manure*	2·88	1·45	·11	·24	·25	4·93

The increase in each instance is not very great; if the unmanured be compared with the highest in the table, the quinine will be found to have an addition of only 14·58 per cent., and the rest smaller in proportion. In last year's report, it was shown that a Succirubra and a Hybrid gave a much superior yield of quinine under the influence of cattle com-

* *Trees* meant, of course.—ED.

post than these did, and the manure applied to them had been down only six months before the samples were taken for analyses. It is well-known that Officinalis is one of the slowest growing of all the cinchonas; so that it is very probable that manure requires a long period to stimulate the yield of alkaloids in this, than it would in other species. The experiments at Dodabetta point to cattle manure and bones as the best agents of the series tried for manuring cinchonas; the one increased the bark per tree more than the rest, and the other increased the alkaloids in the bark, and, as both these objects are sought for by all scientific cultivators, it is very likely that the application of a mixture of the two would have still more favourable results than if they were used separately. Cattle manure is organic, and contains ammonia compounds; bones are phosphatic and consist principally of phosphate of lime, a combination of these typical manures is found in "Guano," the excrement of sea-fowl; it might in consequence be inferred that the use of this substance in cinchona plantations would be attended with an excellent outturn. The prepared bones were made by breaking up the bones to a coarse powder, and treating them with 10 per cent of the weight of sulphuric acid; this would cause the insoluble phospate to become soluble, and therefore more readily absorbed by the plants when put in the soil. In the absence of the more expensive artificial manures, it is satisfactory to find such good bark resulting from the use of cattle manure, one that is more available on these Hills than any other.

This is of course interesting, and much of our Ceylon cinchona must have profited by manures applied to the coffee amidst which so much of it was cultivated. At present prices of the bark, we suppose no one would think of going to the expense of bones or guano, unless in the case of superior *Ledgeriana*. But even the bark of that kind, yielding 10 per cent of quinine realized only 2s 2d per lb. recently. Some of the early Java specimens sold for 18s per lb.

IT is stated that M. Monvault, a French weaver, is manufacturing carpets from the moss known as *Hypnum vulgaris.—Indian Agriculturist.*

KOLA NUTS.—I notice in your last number that Mr. Morris, of Kew, says that Mr. Thomas Christy supplied me with the information in my paper about the kola nut. It is right that I should say Mr. Christy never saw my paper until it was published, and that I consulted him in no way about it. About six months ago I sent an order for twenty tons for him to Trinidad; the order could not be filled.—A. J. ADDERLEY, June 22, 1887.—*Journal of the Society of Arts.*

RUBBER AND COPAL IN CENTRAL AFRICA.—On the road between Dar es Salaam and the Nyassa country, rubber vines abound, and, apparently, are but little affected, except in the immediate neighbourhood of the villages, by the reckless mode of tapping employed. In many parts a native can still gather 3lbs. of rubber daily. Another great staple of the district is copal, which is found in many parts. It seems that this fossil resin exists, even in the richest diggings, only in patches, as though it had been produced by isolated trees. The natives appear nowhere to work the country systematically, but to sink test holes, and, on finding traces of the resin in any part, to work that thoroughly. The resin now found underground, usually in red, sandy soil is undoubtedly the produce of the same species of tree as still exists in these jungles, which now yields an inferior sort of resin; the difference between the two being the consequence of age, and a chemical or molecular change effected by time. The copal tree grows throughout the Uzamaro country, and is by no means confined to the sea coast, but is even more abundant inland, beyond the first coast ridge not however after the limestone formations appear.—*Journal of the Society of Arts.*

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

PARIS, JULY 9.

Of late there has been a good deal of indefinite conversation on the subject of dried blood or powdered meat as a supplemental or adjunct food for horses. It is difficult to obtain precise particulars of an innovation, which it is asserted has many supporters. M. de Lamothe, a breeder of Anglo-Arab horses in the department of the Corrèze, draws attention to the powdered dry meat of the Liebig Co. It contains 74 per cent of azotized and carbonaceous matters, of which 11 per cent represent nitrogen alone, and 17 per cent of fatty matters. Dried blood is almost similar in composition, only white meat powder costs 21 fr. per 224 lb. at Hamburg, the price of dried blood is 120 fr. or six times dearer. The blood desired is dried in a store, and 5 or 6 quarts of fresh make 2 lb. of dried blood. The latter contains all the fixed principles of fresh blood. When given to calves it is boiled in advance in order to avoid diarrhœa.

Two different bloods are contained in animals and the blood varies during its passage through the system. Arterial differs much from venous blood. When freshly extracted blood coagulates rapidly, and as the clot contracts it expels from its pores a liquid rich in albumen called serum. The odor of blood and its taste vary with each animal; the cause of the odor is not exactly known, but supposed to be connected with acetic and butyric acids. Its taste is strongly alkaline due to soda salts. The density of the blood with man, sheep and the ox is almost identical save in the case of young animals and females. Examined under the microscope, blood consists of a multitude of tiny globules, red and white floating in a colorless fluid; 1,000 grains of the blood of man and a horse contain 604 to 630 and 674 to 646 red globules respectively; the globules are not all of the same shape in animals; and the fatty matters in the blood are next to identical with those of the brain. The blood of birds is richest in globules, the pigeon ranking first, and next poultry. The diameter of the blood-globule—strictly speaking it is a concave sphere—is about 1-3500th of an inch in size and the thickness about 1-438th of an inch. Vierordt and Welcker assert there are five million globules in a cubic millimeters of healthy human blood. There is one white to every 335 red blood globules.

M. de Railly would only give blood to animals not younger than six months. The dose is 1 to 1½ oz. per day per 2 cwt. of the animals live weight. If well dried the blood will keep for a long time and especially if mixed with flour and meal. The same gentleman has also employed phosphate of lime in the rearing of not only calves but foals. Dried blood for the latter produced most beneficial results in point of growth the hams especially. Brood-mares have also derived marked benefit from the aliment. Another novelty that is being experimented with, is arseniate of strychnine: this is intended as a homeopathic stimulant to farm horses.

The plan is extending of utilising meadow forage according to ensilage principles. But the process is applied rather to artificial than to natural grass. Not that the latter is in any way difficult to conserve or inferior for consumption. The ensilage augments the assimilation of all substances by rendering the cellulose or woody-matter digestible. The ensilaged fodder can be prepared either with a mild or an acid taste. It will be acid if the trench or stack be made up rapidly and at once weight-covered; it will be mild if several days are devoted to the filling in or stacking up; after a layer has been deposited, it is left to heat till the temperature rises to 131 degrees Fahr., that which is sufficient according to Pasteur to destroy the fermentation bacteræ or animalcules. Next proceed with a second layer. It is not exactly settled whether the acid or the sweet preserve is the more nutritive practically, their value would seem to be the

same. The mild seems to be best suited for dairy stock. The acid fodder will require an addition of some fatty rations.

It cannot be too often reiterated that the secret of all ensilage lies in the pressing the mass. Those apostles of stacking the green soiling, Messrs. Houlès and Rouvière continue to receive proof of the extension of their views and confirmation of the success of their system in their own practices. The heaping of the mass should proceed regularly so as to bind the stack-rectangular shape preferred in one solid mass. The covering weight ought to be 16 to 28 cwt. per square yard. Eleven feet wide and thirteen high length as desired are good stack dimensions. The forage should be cut when it is in full flower. It will be seen that no outlay is required for stack ensilage, and the fodder will conserve for a year; it can be given alone, but it is better to mix it with other aliments. Some meadow farmers manage to sell off their fat stock in June and July; the aftermath is cut in September and ensilaged; no stock is purchased till January following when prices are low; the animals bought are fed on the silo food for a few months, and next supplied with green stuff when they are fattened rapidly and are fit for the butcher by June or July.

M. Nordlinger of Urach, Germany, has recorded a series of readings of the thermometer to test the comparative temperature between forest and plain. His experiments were made in a forest of fir trees 50 years old, and a plain half a mile distant. During the night the air of the forest is two degrees in summer and one degree at other epochs warmer than the air of the fields at the height of a man. The branches act as a screen against the radiation of heat. This will explain why the air over the summit of trees is during the morning in winter of a more elevated temperature than the surrounding plain. At two o'clock, the warmest part of the day, there is no perceptible temperature—difference between the air over the summit of trees and the plain. The interior of the woods is, as a rule, slightly warmer than the air of the open at the height of six feet.

It is a well-known fact that in spring potatoes suffer in their qualities alike for table as for seed. This depreciation tells equally when the tubers are required for distillation, or the preparation of fecula. The richness of fecula can descend from 89 to 51 per cent following the mode of preservation. A clear dry and cool place is the best for storing the tuber.

M. Tessier has informed the Academy of Sciences that diphtheria is transmissible from barn-door fowl to man and *vice versa*. It is through the disease—germs floating in the air—and the offspring of manure emanations &c. entering the respiratory organs that infectious maladies are contracted; pigeons, and next hens are the most active agents in the propagation of diphtheria.

Veterinary Professor Sauson has analysed and reported upon the cakes or biscuits having sawdust for base intended as food for cattle and horses in particular. It is an aliment not new to Germany. This prepared aliment has for chief ingredient very fine red sawdust acted upon by muriatic acid a powerful digesting agent. The cakes are thin, 8 to 10 inches in diameter and weight about one pound. In two samples the biscuit was mixed with bran and oats. No one of course expects that sawdust alone could be utilized as food; it is too poor in protein, but it can act by "ballasting" the digestive apparatus giving it the required volume for working.

As a stomach-ballast sawdust could then enter into competition with inferior straws. Chemically the biscuits were not nutritively richer than hay, while in point of digestibility they were inferior. In case of cavalry when campaigning, where economical rations are desirable, there would be required 41 lb. of the oat—sawdust cake—more if of bran to equal 10 lb. of hay and the same weight of oats. Now horses when on the war path must be laden with as few heavy weights as possible. The weight of the cakes could be reduced by dessiccation and volume by the introduction of some highly concentrated aliment. The biscuits should be estimated at the same value as that of medium hay. Sawdust can be eaten without danger by horses. The Omnibus Company, when they employed that substance for litter, never prevented the horses from eating it, that which did them no harm. In Sweden, very fine larch sawdust is employed with advantage instead of chopped straw, and mixed with sliced mangolds for bullocks and dairy stock.

That sheep are the "most profitable cattle" a farmer can have is an axiom as old as the hills. French agriculturists continue to be divided as to the maintenance of pure local or perhaps native races in preference to cross breeds. Does it always pay to rely on fleece alone? or to unite wool and precocity in flesh? The French farmer will in all probability stick to the breed suitable to his locality. He is a worshipper of the Merino; it comes more up as a general rule to his conditions of climate pasturage and selection—the latter not in the sense of crossing, but from the best specimens of the Merino type. It is mooted that a special show of Merinos should be organized where animals from Spain and Germany could be compared with those of Naz and Rambouillet along with fleeces from Australia and those from long-woolled sheep in general. Such an exhibition would be interesting, but in all probability would have little effect on the decision of French wool growers.

The Merino breed appears to have a fascination for them. Its fine wool preserves its characteristics, remains so constant that no deterioration—ordinary hygienic conditions being observed—is to be feared. And this explains why when crossings are undertaken with local breeds the Merino is chosen. If precosity cannot be achieved at least a paying fleece can be secured. The Merino has exercised a profound influence on sheep in every part of the world. Now it is this cosmopolitan faculty that the breed has inherited from the mode of life of the foundation-stock, which makes it so much a favorite because so often a necessity. And the type remains the same every where, while its aptitudes have been developed, following economic necessities. It was in Saxony that the Merino first made a sensation outside Spain; the Elector in 1765 imported over 100 choice rams and ewes and by maintaining the purity of the race upheld the fineness of the fleece. Only the French Merino—the race Naz could match the Saxon wool in fineness of staple, and this was the more singular as in Saxony parsimonious feeding was resorted to as an aid to the production of such a quality, while in France no such plan was ever adopted.

It is an error to suppose then that the introduction of the Merino in France dates only from 1786. Colbert had introduced Merino rams from Spain for breeding in the province of Roussillon. But it is to Daubenton reverts the honor of having seriously occupied himself with fine wool raising at Montbard in 1766. Louis XVI in 1786 executed a treaty with the King of Spain to introduce Merinos into France. The first flock, 42 rams and 342 ewes left Spain (Segovia) in the middle of June 1786 and arrived—less a few deaths—at Rambouillet in the environs of Paris in October following. Later another flock set out. By the treaty of Bâle in 1796, Spain bound herself to send 100 rams and 100 ewes annually during five years to France. It was by these divers importations, that the Merino spread over France. In time it assumed two distinct varieties distinguished by volume of body and fineness of wool. But the parent-type has remained unchanged.

Naz in the department of the Ain is the head centre of the Merino with large body, while retaining the conformation of the true Spanish type. In point of fleece it owes its amelioration to selection. The staple is homogenous fine, not in lumps and light. It approaches a good deal the Saxon Merino by the softness and fineness of its wool. But it has the small body, large belly, big head, and voluminous horns, besides being agile, hardy, and everywhere at home. The sheep receive only in winter a necessary

ration of turnips and hay; in summer they feed on the scanty pasturages of the mountains.

It is estimated that the annual cost of keeping a sheep in France is 8 fr., often the fleece does not realize this sum. The Rambouillet breed of sheep is the most numerous variety of Merino in France; its wool though long is not so fine as that from the Naz race; it is a more generous feeder, hence puts up more flesh. Indeed there are not a few who aim to give a Southdown form to the Rambouillet. Lambs of the latter have a mean live-weight, varying from 55 to 77 lb. An adult ram will weigh 209 lb. and the unwashed fleece 11 lb. The fleece of a Rambouillet—owing to greater weight—will fetch one-third more money than the Naz. Combing wool is the staple sought to be attained. The Rambouillets do not suffer more from fluke and foot rot than other breeds.

COFFEE.

By HENRY PASTEUR.

The total production of coffee in the world is roughly estimated at about 600,000 tons, to 650,000 tons, of which Brazil alone produces between 340,000 and 380,000 tons, and Java 60,000 tons to 90,000 tons, the proportion of British-grown coffee being only about 35,000 tons, of which India contributes 15,000 to 18,000 tons, Ceylon 10,000 to 12,000 tons, and Jamaica 4000 to 5000. Although numerically very small, the productions of our Colonies and of India occupy the front rank, owing to their excellence. Nowhere is finer coffee grown than in India and Jamaica, and its value, as well as that of Ceylon, is firmly established above that of all other kinds, even of Mocha, which at one time stood above all others.

A considerable amount of work and preparation has to be expended on coffee, from the moment it is picked from the trees until it is in a fit state to be sent to market. The berries, as may be seen from the numerous samples exhibited at South Kensington, are enveloped in an outer, coarse, thick, fleshy substance, the cherry, and an inner, loose envelope of thin, hard skin, called parchment, from its resemblance to that substance. When allowed to grow to complete maturity on the trees, as in the case of Mocha, the cherry withers and dries, and is then easily removed by crushing or pounding, the berry inside having by that time become of a pale greenish or yellowish colour. The usual course, however is to pick the cherry before complete maturity when it is of a deep red or cherry colour, the berry inside being then found to be of a fine dark-green or bluish-green, which it is the endeavour of the planter to preserve as carefully as possible, the value of his coffee depending chiefly on the depth and brightness of the colour. On gardens and plantations cultivated by Europeans, the cherry is removed as quickly as possible after being picked, being put through pulpers, and undergoing a very careful and delicate process of mashing and washing, until the berries are left with their parchment envelope perfectly clean. In many cases, however, there are neither appliances, nor time or labour, to put the fresh-gathered fruit through this process, and under a tropical sun the cherry dries quickly, and has then to be pounded, to the great detriment of the colour, as well as the quality of the bean; hence the difference between *unwashed* or ordinary pale, and *washed* or coloured or plantation coffee, the taste of the *washed* coffee being, as a rule, much more delicate, and free from the earthiness and common rough flavour of the *unwashed*. A large portion of the crops from Brazil, Java, St. Domingo, to a less extent Central America and Guatemala, in fact fully three-fourths of the world's production, are prepared as *unwashed* or pale coffee; whilst nearly the whole of the Ceylon crop, three-fourths of the Indian, and one-fourth to one-third of the Java, are prepared as *washed* or green coffee. The clean parchment has to be dried with the utmost care, and taken to the curing mills on or near the estate, or more generally at the port of shipment; it is then put through the peelers, which break the parchment, and remove as much as possible off the thin silver-skin adherent to the bean itself; then through sizers, which divide the berries into the various sizes, and after being hand-picked by a number of women and children, who remove the defective, broken, black, or light beans, the coffee is ready for packing in bags or casks for shipment. All those various operations require to be carried out with the utmost care and nicety, the slightest neglect or mistake in any one of them being liable to injure the quality to the extent of 5, 10, or even 20 per cent.

The above remarks, to some extent, explain the reasons for the superiority of British-grown coffee over that of most other countries, and also the great variety existing in the appearance, quality, and value of the samples exhibited by our various colonies and dependencies.

INDIA.—India now stands first and foremost amongst British possessions, both for the quantity and quality of its production. The samples prepared by the Indian Coffee Planters' Committee have been carefully selected in London from the earlier arrivals of the crop of 1885-6, and represent the produce of British plantations in the four chief districts of Mysore, Coorg, Neilgherry and Wynaad, as well as the less important one of Travancore. The exhibits from the three first-named districts are remarkable for their high average excellence, and for the presence of many of the points which, in the eyes of connoisseurs, constitute the nearest approach to perfection, viz., size, colour, smoothness, plumpness, and weight of the berries. These coffees have always been, and are likely to continue, in high favour with the buyers for home consumption. Next to them come the Wynaad exhibits, which, if they lack some of the weight and fine shape of the others, are nearly equal in size, colour, and smoothness, and find favour with home as well as export buyers. Travancore is a comparatively new district where plantations are generally at a lower elevation; it has suffered much of late years from repeated attacks of leaf-disease which has destroyed many estates and weakened the trees on most others, and the result is seen in a small crop, deficient in colour, size and quality. Leaf-disease has likewise been raging in the other districts of India, to the serious detriment of crops, both in extent and quality; fortunately, the severity of its attacks has greatly diminished during the past few years, and it has almost disappeared in many parts of the country. It has, however, in many places affected the vitality and shaken the strength of the trees, so that they have been less able to resist periods of drought or of heavy monsoon weather, and small and irregular crops have been the consequence. It would seem, however, as if plantations were gradually recovering their former strength, and with good cultivation and manuring and fair seasons India may hope to maintain its position as our largest and best field for the production of fine coffee. A hopeful sign for the future may be gathered from the superior average quality of the crop of 1885-6 over that of the two or three previous ones.

Among the samples of Wynaad coffee, those from the Eva Estate deserve special attention, one-half of that crop having been dispatched in parchment, to be peeled and sized in London. The experiment has proved quite successful, the coffee represented by the sizes 1st, 2nd and Peaberry, being fully equal in colour and appearance to the corresponding sizes prepared in India. The whole was sold at the same public auction, the London *cured* realising a rather better price than the other half. Similar and more recent experiments, made with some shipments from Costa Rica, Guatemala, and New Grenada, have shown startling results, the portion prepared in London having realised from 10s. to 14s. per cwt. more than that cured in Central America. These experiments would tend to show that the parchment preserves in a remarkable degree the colour and the quality of the cherry against the incidents or accidents of a land and sea transport. In the case of the Costa Rica and New Grenada shipments cured in London, the berries seemed fuller and of better shape and weight than the others, as it (which is by no means improbable) the parchment, left for

two or three months longer than usual around the berries, had acted as a kind of natural preserver, inside of which the berry had time, as it were, to mature more completely than when deprived of its outer and inner coating almost immediately after being picked. The curing requires machinery, motive power, drying grounds, delicate manipulation, and constant supervision; where any of these requisites fail, the coffee suffers in appearance, and consequently in value. Suitable machinery for treating parchment has been erected at two of the London wharves; and there is every reason to hope that this is only the beginning of a new and profitable home industry. Growers will not be slow to perceive that the small increase of freight which they have to pay on parchment, is more than compensated by the enhanced price which the improvement in the quality of their coffee will enable them to obtain.

In addition to the produce of British Plantations, India grows native coffee, chiefly in the districts of Coorg, Mysore, and Wynaad. Of late years the greater part has found its way to the French markets, where it is much appreciated, and latterly also to Trieste. It is a matter for regret that shippers from the Malabar coast have not sent any specimens of those kinds to the Exhibition; they are quite suitable for our home consumption, and form an important item of the Indian production.

Mysore is represented by 105 samples from twenty-seven estates; four samples—viz., *large size*, *bulk*, *small size*, and *Peaberry*—being in most cases shown from each estate. Rather less than one-half appears to be of the true, rounded, heavy silvered-skin Mysore berry, the remainder partaking more of the character of the large, flat, deep-coloured Coorg type. This is the result of the extensive planting of Coorg seed, the old chick or Mysore having become weak and unable to bear fruit or to be propagated as easily as formerly; the hardier Coorg plants grow more quickly and yield larger crops, although not of such fine quality as the real Mysore plant. It would seem, however, as if the produce of the Coorg trees, on getting better acclimatised, showed some tendency to assimilate to the old Mysore, the finest and most esteemed of the Indian types. Of Neilgherry there are twenty-four samples from seven estates; of Coorg, forty-five samples from thirteen estates; of Wynaad, nineteen samples from five estates; and from Travancore, eight samples from three estates; a total of 201 samples from fifty-five estates, besides twenty-eight samples in parchment or cherry.

Taking 90s. per cwt. as the average value of the bulk from the estates of true Mysore type, the Coorg, Mysore estates would be worth 80s., for bulk, the Neilgherry 83s., the Coorg 82s., Wynaad 78s., and Travancore 70s. per cwt.; while native Mysore of average quality would be worth 63s., and native Coorg or Wynaad 60s. per cwt. The finest qualities of Mysore range in value from 100s. to 135s. per cwt. The export of coffee from India in 1885 amounted to 328,317 cwt.

CEYLON.—When looking at the fine samples which were exhibited in the Ceylon Court in the neat barrels prepared under the direction of the Planters' Association, one could not avoid a feeling of sadness and regret at the thought that they represented only the fast vanishing remains of what was but nine years ago the most extensive and flourishing of the coffee crops raised on British soil by British enterprise and capital. The production which in 1873 amounted to nearly 1,000,000 cwt., declined to 665,000 cwt. in 1876, 312,000 cwt. in 1884, and 230,000 cwt. in 1885. The scourge of leaf-disease, a fungus (the *Hemileia vastatrix*) which first made its appearance in 1869, has gradually swept over the whole island, weakening the trees, undermining the crop capabilities, and leading to the gradual extinction of the plantations over many of the best districts. Coffee, however, has been able to maintain its ground in some parts, notably in Haputale, Badulla, &c., which are more favourably situated as regards soil and rainfall, and crops of from 150,000 to 200,000 cwt. may fairly be looked for for a few years to come, though it is not probable that cultivation can again extend in the island, as there is but little suitable forest land remaining unopened.

The variety known as Liberian coffee, which was planted extensively in the low country some years ago, under the belief that it would resist leaf-disease, has succumbed to it; besides which the quality is not appreciated in the home markets, on account of its coarseness, oily taste, and want of strength and aroma; and the prices realised for this sort are not likely to give a fair return to the growers.

Twenty-seven barrels exhibited by the Planters' Association of Ceylon, the produce of eight different estates, showed to what degree of excellence the preparation of coffee has attained in the curing establishments of Colombo. Three specimens from each mark—large size, bulk and Peaberry, were shown, the former ranging in value from 90s. to 105s., and the latter from 87 to 95s. The samples of bulk range from 75s. to 85s., averaging 80s., per cwt., according to the depth and brightness of the colour, smoothness and size, and weight and hardness of the berries; these latter characteristics vary according to the soil and height of the estates, high-grown coffee being the most esteemed in the English market. Four barrels were shown of low grown, the produce of native gardens, cured and prepared like estate coffee, a very good and useful quality, though inferior in appearance and value to the produce of European plantations. Five samples were shown of pale or native coffee, extremely well sized and picked, and of an average value of 58s. per cwt. There were, further, five samples from two European plantations, and one of Liberian sort, of very large bean, smooth and well picked, worth 60s. per cwt., or about 8s. to 10s. per cwt. more than the average Liberian quality.

STRAITS SETTLEMENTS.—Coffee does not appear to grow in the British Settlements of Singapore, Penang, and Malacca, except in gardens and on a very small scale; but in the three Native States of Perak, Sunjei-Ujong, and Selangor, taken under our protection in 1874, its cultivation has been introduced, and some interesting exhibits from Perak testify to the adaptability of the soil and climate for its production.

In Perak, where mountain ranges, reaching to 7000 feet, occupy a large portion of a well-watered country, a considerable acreage, above 1000 feet elevation, is reported to be suitable for coffee cultivation, whilst the Liberian sort thrives on the lower slopes and the plains. In Selangor, planting has only been introduced during the last few years, whilst in Sunjei-Ujong estates have been established on the slopes of the Berumbun range, which rises to a height of 3000 to 4000 feet, and the cultivation of Liberian has been introduced on the lowlands. Of the fourteen exhibits from Perak, five are from the experimental hill gardens opened by Government; the sample marked Hill garden is strong and full flavoured, and worth 90s.; those marked Waterloo and Hermitage have probably suffered somewhat in drying, being coarse and musty in the cup, and worth 70s. and 76s. Such kinds, if purposely prepared on the spot, or in London, should the necessary appliances not exist at the plantations, and if perfectly sweet and clean, would supply an extremely good quality, suitable for home consumption as well as export, the coffee being, for size, colour, and general appearance, on a par with good Ceylon plantation. The climate, soil, and rainfall are all that can be wished on the Perak hills, but the great drawback hitherto has been the cost of labour, which, however, has now been arranged satisfactorily, and the difficulty of transport. One sample of large pale berries, very smooth, but out of condition and mildewed, would be worth 60s. if sound; two of Liberian, viz., Lindum Estate, in Sungei-Ujong, and Waterloo were very large, and worth 53s. to 55s.; and three of ordinary Liberian quality, 48s. to 52s, per cwt.; the remainder consisted of parchment and cherry.

The growth of Liberian is not to be encouraged, for the reasons stated above under the head of Ceylon.

Samples of Bâli, Bonthyne, and Philippine coffee, exhibited in the division of Straits Settlements, were probably not British-grown, but the produce of some of the Dutch islands in the neighbourhood of the Straits

QUEENSLAND.—The climate and soil of this Colony appear to be well suited to the growth of coffee, which is found growing in various parts without any special care other than weeding. It is cultivated on some farms, but only as an adjunct to other crops, and the eight specimens shown in the Exhibition are such as should encourage its extension. A sample from Stanmore, Yatala, although not properly picked, showed a fair greenish quality, worth, as it is, 63s. per cwt., and which might probably be improved by cultivation and careful preparation. A sample from Buderim Mountain Mooloolah, was still better in quality.

FIJI.—A considerable portion of the interior of the islands of Viti Levu, Vanua Levu, and Taviuni appears to be well adapted for the cultivation of coffee. There is an abundance of rich soil, and favourable conditions of climate, moisture, &c.; the plant grows quickly and yields good crops. The pest of leaf-disease, which visited the islands four or five years ago, led to the destruction or abandonment of several estates, but now that it has disappeared,* growers anticipate a prosperous future and increasing production.

Of fourteen samples exhibited, one showed a good quality of washed or plantation coffee, well grown and of large bean, but deficient in colour, and worth about 68s. per cwt.; one Peaberry, worth 75s.; one sound though rather rough and discoloured, 63s. per cwt.; they were all three of strong, clean, good roasting quality. The remainder in parchment were somewhat similar, though mostly of a dark blackish colour, owing probably to insufficient drying.

NATAL.—Judging from the exhibits of Natal coffee, eleven in number, it would appear that the soil and climate of some portions of the Colony are eminently suited to its growth. The samples from Umzinto and Umzimkulu, to the south and extreme south of Durban, were of excellent quality, well prepared, heavy, round berries of good size and colour, and not unlike Coorg in appearance; such qualities would find a ready sale here for home consumption and export, and are worth from 73s. to 83s. per cwt. The samples from Tongaat and Riet Valley, in Victoria county, north of Durban, were also of useful quality, hard, greyish, roasting and tasting well, though not so well picked and prepared as the others, and rather deficient in colour; their value was from 60s. to 65s. per cwt.

The Natal plantations are mostly in the valleys, and on the hill slopes along the sea-coast. The cultivation began some thirty years ago, had assumed rather large proportions in 1870 (there were then upwards of 4000 acres planted, and the annual production amounted to 12,000 cwt.); but disease of the trees and failure of crops have since led to the gradual abandonment of the plantations, and the produce now is not estimated at much more than 2,000 cwt. annually.

In a country which can produce such fine coffee as that exhibited from Natal, there ought to be a promising field for future success open to the planter who devotes care and intelligence to the choice of the land, the quality of the seed, the growth and cultivation of his fields, and the preparation of his crop.

WEST AFRICA SETTLEMENTS—MAURITIUS.—The exhibits from Sierra Leone, the Gold Coast and Gambia were few in number and of poor quality, consisting chiefly of Liberian and of the small brown Casanga kind; the former worth 48s. to 50s., and the latter 42s. to 45s. per cwt. One sample from the Gold Coast raised at the Bâle Mission at Akropong, showed rather better quality of pale brownish native kind, worth 53s. per cwt. From the appearance of the samples, coffee seems to be cultivated in a very primitive way, and on a small scale only, and the varieties grown are those of lowest commercial value in the European markets.

From Mauritius, one sample of good yellow Liberian was shown, and from the Andaman Islands also one sample of Liberian of large size, both worth about 54s. per cwt.

WEST INDIES—JAMAICA.—Coffee is grown in almost every one of the West India Islands, but Jamaica is the only one where the cultivation is carried out on an extensive scale, the quantity exported in 1885 mounting to 80,600 cwt., and occupying the third rank in value of the products exported from this island. From 8000 to 10,000 cwt. are produced annually on plantations situated on the high lands of the Blue Mountains, which have long been known as one of the finest coffee-growing districts in the world, thanks to a fine rich soil and a favourable climate, combined with all the care and intelligence which the means of European planters can command. The coffee from those favoured localities is all consumed in this country, and realises almost the highest prices in the market—say from 90s. to 140s. per cwt. The remaining 60,000 to 70,000 cwt. are grown in various parts of the island; some in the Manchester district is of medium quality and well prepared, but the portion is cultivated in small patches or gardens by settlers and small proprietors who do not possess the knowledge or the means of preparing their crops properly, or in the low country, where an inferior quality is raised; hence the great difference in prices between fine mountain and the ordinary Jamaica. The want of proper curing establishments is much felt in many parts; it is probable, too, that the plants are not raised from good seed, and that better cultivation and manuring are needed. But even this will not suffice to ensure the good quality of the crop, unless due attention is paid to picking at the right moment, and to immediate pulping and thorough drying of the parchment. This should ensure the proper colour, but, in the absence of the necessary appliances, the planter would best consult his interest by sending his parchment to be peeled, &c., at the nearest works, or better still by shipping it to London for treatment. Ordinary Jamaica coffee is now selling here at 50s. to 53s. per cwt., and there is every reason to believe that with better care in picking and curing, and with quick dispatch of the parchment to London, the grower might obtain from 10s. to 12s. per cwt. more than he does at present. There does not seem to be any good reason why, in a country where the highest priced coffee is grown, the bulk of the production should rank on a par with common Brazil or the lowest known qualities.

The extensive planting of the Liberian variety, which appears to be going on in Jamaica and other places, will most probably lead to disappointment; the quality is so poor, so deficient in strength and aroma, and so little appreciated in the home markets, that any material increase in the supply must inevitably lead to a lower range of prices, which will fail to repay the outlay.

The Jamaica plantations appear to have been so far quite free from leaf disease, bug, or other enemies of the coffee-tree, and there is an abundance of forest lands of proper elevation in the St. Ann and Clarendon districts and the northern slopes of the Blue Mountains, suitable for extending the cultivation of the finer classes, which ought to give handsome returns for the capital so invested.

Of the sixty-nine samples exhibited in the Jamaica Court, sixteen were parchment and cherry, nine from the finest estates were worth from 110s. to 140s. per cwt. averaging 120s. to 125s.; eight averaged 90s. per cwt.; eight more 75s. per cwt.; eight were worth from 54s. to 65s.; and two about 47s. There were also twelve samples of Peaberry from 70s. for the lowest to 105s. for the best; and two samples of Liberian worth 56s. and 50s. per cwt.

In addition to the above, ten samples were shown in the Indian Court, mostly duplicates of some of the finest estates, and twenty-seven jars of average samples, also from the finer marks of extremely good quality, and of a value not less than 120s. per cwt.

Proceeding from Jamaica in a south-easterly direction towards the continent of South America, I found amongst the British West India Islands which have sent specimens of Coffee to the Exhibition:—

ST. KITTS AND NEVIS with two samples of nice polish-green, soft quality, worth 60s.

ANTIGUA.—Two samples of pale greyish, somewhat uneven, worth 54s.

MONTSERRAT.—One sample ordinary native kind, 50s., and one greenish, of good size, 58s.

* Which we exceedingly doubt.—ED.

DOMINICA.—Coffee was at the beginning of this century the leading article of export from this island, and it was then considered one of the best kinds produced in the West Indies. The trees, however, were attacked some forty years ago by an insect blight which spread devastation among the plantations, and destroyed the greater portion of them, so reducing the production that at the present time it is hardly equal to the consumption of the island. Cultivation is now reviving to some extent, and it appears that the blight, although still in existence, is comparatively harmless at high elevations. The Liberian variety has also been introduced. There is an abundance of fine forest land and rich soil on the slopes of the bold mountains which cover the country, with plenty of moisture, conditions which are eminently favourable to the growth of coffee.

Of the ten samples exhibited, two were of a very small, hard, heavy, greenish bean worth about 70s. per cwt., one pale native kind 50s., one Liberian 52s.; the remainder were of good size, greenish to rather good green colour, and if properly picked and prepared, would be worth from 63s. to 76s. per cwt. As it is, they were of a very indifferent quality in the cup, and not worth more than from 56s. to 68s.

ST. LUCIA.—One sample, small close brownish, native kind, 52s.

BARBADOS.—One sample, ordinary pale uneven native sort, 52s., and one small of very well prepared good bluish plantation, of even size, though a little rough, worth 80s. per cwt.

GRENADA.—One sample, large pale greenish, useful quality, 54s.

TOBAGO.—Two samples of dull greenish and brownish Creole coffee, not sized, but good of its kind, worth 56s. to 58s. per cwt.

TRINIDAD.—Ten samples were exhibited: two of them consisted of very common dull brown and red badly prepared coffee, worth 47s.; four were Creole or pale native kind, of a useful quality, ranging in value from 52s. to 54s.; the others were better, and with more care in their preparation might be turned into good coffee, worth probably 60s. or 70s.; but being imperfectly picked and of a brownish colour, their value was reduced to 58s. to 60s. per cwt.

There appears to be a good deal of land suitable for opening into coffee gardens or plantations, and planting has been carried on lately on a larger scale. It is to be hoped that the Botanic Gardens, which supply plants from their nurseries, will endeavour to provide none but those grown from the best seed of *Coffea arabica*, which can easily be procured from Jamaica or from New Grenada. In an island where the cultivation and preparation of cocoa has been brought to such a degree of perfection, there ought to be no lack of skilled labour to prepare coffee much better than is apparent from the samples exhibited. The shape and size of the berries show that the soil and climate are favourable, and that it is only labour, care, and skill which are required to give the coffee its proper value.

BRITISH GUIANA.—British Guiana situated on the north-east coast of South America, comprises the Colonies of Essequibo, Demerara, and Berbice, the two latter well known some forty or fifty years ago as producing coffee of esteemed quality. The cultivation, however, diminished steadily, until in recent years of Demerara or Berbice coffee the name alone remained. The decrease is ascribed more to cost and want of labour than to climate or soil, which are both favourable; and the few samples shown, from plantations which have again been started in the last few years, tend to prove that excellent coffee can be grown in the Colony. The cultivated part of the country is a flat alluvial plain of forty miles extent, between the sea and the rising ground, at and even below the sea-level, and traversed by large rivers; cultivation is restricted to the river banks and the coast.

Of the six samples exhibited, three of extremely useful pale bean, very well prepared, would be worth 58s. to 63s. per cwt., if perfectly clean and sweet and unaffected by sugar, which is not the case with the samples shown; one was Peaberry and two Liberian, of average sort, valued at about 45s. to 52s. per cwt.

BRITISH HONDURAS.—Coffee cultivation does not appear to have begun until within the last four or five years, when one or two plantations were established. Probably not more than a few hundred acres are planted; but coffee arabica grows wild in some parts. Two bags were exhibited of very good pale greenish native kind, strong and roasting well, worth 63s. per cwt., and one sample of parchment. The adjoining State of Guatemala is gradually becoming one of the leading coffee-growing countries, and British Honduras should be a very suitable place for a more extended cultivation.

In concluding this report it is difficult to avoid alluding to the extraordinary treatment to which coffee is subjected at the hands of the British Government. Had it had extended to it the same amount of fair play and protection against fraud as is accorded to Tea, it is probable that the greater portion of the 35,000 tons of British-grown coffee would be retained for home consumption, instead of a paltry 14,000 tons, or at the rate of about 15 oz. per head of the population per annum, against 2¾ lbs. per head in France, 5 lbs. in Germany, 7¾ lbs. in the United States, &c. It would almost seem as if the Treasury, which is directly responsible for the legislation on the subject, was bent upon discouraging by every means in its power the use of one of the most delicious and beneficent of the non-alcoholic drinks, by the sanction which it gives to its adulteration with any vegetable matter; it is impossible to recognise coffee in the wretched mixtures which are sold in every shop or store, or in the thick dark liquid which is served under that name in many of the coffee palaces and temperance houses throughout the kingdom. No wonder that consumption decreases year by year, not of coffee alone, but even of chicory and mixtures. The Local Government Board and the Board of H. M.'s Customs join in their annual reports in ascribing the diminishing revenue from coffee and chicory to adulteration, and in condemning the present state of legislation on the subject. Surely those who are engaged in the cultivation, importation, and trade in coffee, ought to make an effort to obtain redress for what is acknowledged almost on all hands to be a crying injustice.—*Planters' Gazette.*

COFFEE ADULTERATION.

The following letter, from Mr. Shirley Hibberd, appeared recently in *The Times* with reference to coffee adulteration:—

"SIR,—Coffee deserves the importance it has acquired as a subject of public discussion, and the more so because it is but little understood. At good tables poor coffee is too often seen, and it may be said that on the world's table (in these parts) it is never at all, but in its place appear various nauseous and injurious imitations.

"Valuing coffee as a great aid in hard work, I made a resolve to have the real thing on my table daily, or 'perish in the attempt.' Thereupon, I entered upon a series of experiments that were at least amusing if not particularly profitable. I bought every kind of coffee I could see or hear of, and tried every possible (and some impossible way of making it having the assistance therein of a diligent and clever cook. One striking result was the discovery that ready-ground coffees sold in canisters, packets, and other convenient parcels are bad, some very bad, a few infamously bad. After trying innumerable samples without noting one that was worth trying again, I concluded that canister coffee is an unmitigated cheat, consisting usually of a mere shadow of the real thing, with a great bulk of chicory, and more or less of what is termed 'colour,' this being simply burnt sugar to give a fictitious strength. What may be termed 'chandler's coffee' is so bad that I strongly recommend a trial of it to respectable people who love good living, for they ought to know by a taste of real agony how the poor are robbed, and poisoned, and have, as it appears, no protection from law, gospel, or the customs of society.

"It is not good policy to purchase coffee ready ground, but if it must be done the supplies should be small and frequent. Anyone may test the purity of ground coffee by shaking a little over a tumbler of

clear, bright, cold water, and leaving it for an hour or so. Pure coffee communicates its colour to cold water slowly, and when the colour has been imparted the infusion is still bright and clear, and the colour is never deep. But chicory and other adulterants quickly produce an opaque and dark infusion. The difference is so striking that for ordinary purposes a better test is not required.

"To place good coffee on the table daily is a simple and inexpensive business, but it cannot be done at a penny a cup, as some folks are in haste to aver. At from 1s. to 1s. 8d. per pound, a good coffee in berry is always obtainable, and 1s. 4d. may at the present time be considered a fair family price. It is best to roast and grind as wanted, but the grinding is the one important point, because ground coffee quickly parts with its aroma, and there is a great charm in having it made immediately from the mill. In some houses the trouble of grinding is thought much of, but as a matter of fact, it is almost nothing, and a mill costing only a few shillings will last a lifetime.

"Coffee should never be boiled; it should be made with soft boiling water at boiling heat, but if hard water must be used, it should not be made to boil until wanted, for boiling augments its hardness. A common tall coffee-pot will make as good coffee as any patented invention, but a cafetière is a convenient thing, as it produces bright coffee in a few minutes, and thus enables us to secure a maximum of the aroma and dispenses with the use of any rubbish called 'finings.' Everyone to his taste, we will say, but as careless people make the coffee too strong one day and too weak the next, the ground coffee and the boiling water should be both measured, and it will always take as much as four cups of water to make three cups of coffee. For the breakfast table the addition of about one-eighth of chicory is an improvement, but for the dinner table coffee should be made without chicory, because it dulls the piquant flavour of the genuine article.

"Two points in coffee-making deter people from using it—the trouble of grinding and the boiling of the milk. The grinding, however, must be done, and it is really nothing, but the boiling of the milk may be advantageously evaded by using Swiss milk, which harmonises perfectly, and by many well-trained palates is preferred to fresh milk heated.

"Good coffee is such a grand help to men who work hard, that I shall hope to be pardoned if I have said a word too many on the subject."

SUNFLOWER OIL.

Mr. Charles Halleck has furnished an exchange with some interesting information touching the results of a series of experiments conducted by him looking to the extraction of oil from sunflower seeds. Having to fill a contract for a certain line of canned goods into which cotton seed oil enters as an ingredient, and knowing of the success which had attended sunflower culture in Russia, India and China, Mr. Halleck was induced to enter upon his experimental investigations. The first difficulty he encountered was in procuring reliable information relative to the conduct of the industry in countries where sunflower seed oil has become a recognized article of commerce. The plant is cultivated here only by a few country housewives, either for fattening poultry or on account of its supposed value in warding off malaria. An application to the Commissioner of Agriculture elicited nothing of value; the inquirer was informed that the department had but little information and few seeds, and was referred to the private florists and seedmen. Inquiries among these tradesmen proved as fruitless as had those addressed to the Commissioner, and Mr. Halleck had recourse to Dr. W. F. De Niedman, a native of Russia, at present connected with the Botanical Gardens at Washington, D. C. From the latter gentleman he received some valuable information regarding sunflower culture in Russia, which is here with given.

The variety of the plant grown in Russia is the grandiflora. It grows in one slender stalk, five feet high, producing one monstrous head. A good, warm summer is required to bring the flower to perfection; the climate of Minnesota closely resembles that of south-western Russia, where the cultivation of the plant is extensively conducted. The sunflower is exceedingly exhaustive to the soil, and after two crops the land is allowed to rest. Time has been found to be the best manure. The seeds constitute, of course, the most valuable portion of the crop, whose yield is about fifty bushels to the acre, but every portion of the plant is utilized. The leaves are used for fodder, and when steeped in strong tobacco water so closely resemble in color, texture and smell those of the tobacco plant, that they have been known to be used to adulterate the tobacco of commerce. The stalks are prized as fuel, and their ashes are readily sold to soap makers on account of their richness in soda. On small plantations the heads of the plants when full ripe, are cut with knives, the stalks being left standing that they may become more thoroughly dried; but where the cultivation is carried on an extensive scale sickles are used, the stalks are cut close to the ground, and both stalk and flowers left on the ground for about a week, In the former case, the heads are in small piles and, according to the weather, dried either in the sun or in sheds. The seeds are thrashed out, usually by flails. After the separation of the seeds has been accomplished, and they are thoroughly dried, they are hulled. To accomplish this, specially constructed mills or grindstones are used; a fan is commonly attached, and the motive power is a pair of horses. That the manufacture in Russia is found to be a source of profit is shown by the fact that sunflower cultivation is constantly increasing. The amount of needed seed for planting is about the same in measure as of corn.

Cold pressure has been found to extract the first and best oil. The crude oil is refined, but seldom (if ever) boiled. Latterly, the process employed in this country in the refinement of cotton seed oil has been adopted to some extent. The product is largely used in Russia as a substitute for olive oil, both for culinary and other purposes, and is pronounced excellent, although its taste is peculiar. It is said that it has never been known to become rancid. Mr. Halleck expresses himself as well satisfied with the result of his own experiments. He is of the opinion that he would have obtained still better results had not some of the seed used by him been of the variety known as the ordinary American multiflora, which had been, without his knowledge, mixed with the Russian grandiflora seed which he had ordered. He says that the oil which he obtained was "bright, transparent, limpid, of a pale straw colour and pleasant to the taste." It showed no rancidity after an exposure for more than a year to an atmosphere varying from 50 to 150 deg. Fahrenheit. It is also worthy of note that oil of this description is said to equal linseed as a drying oil.—*Oil, Paint and Drug Reporter.*

[An experiment tried by Mr. C. H. de Soysa in Ceylon was very decisively unfavourable. Apart from the exhaustion of the soil, the seed did not realize a paying price.—ED.]

COTTON SEED OIL AND ITS USES.

Quite a stir has been made of late about the enormous consumption of cotton seed oil in the United States and the uses to which it is put, and the New York *Times*, which among other prominent dailies has taken the subject up, recently published a lengthy article on the adulteration of various articles of food with this product. The extent of its employment can only be surmised after the publication in the above paper of a statement said to emanate from one of the leading lard refiners on the continent, who acknowledged the use by his firm of millions of gallons annually in the manufacture of lard. That which is used in the making of lard is but the indication of that which goes into other food products. The cotton seed oil people themselves indorse the declaration of *The Times* that of the manufacturers of food use this oil, they should be willing to acknowledge it publicly. According to the oil makers there is only purity in their product. Being simply vegetable, it is free from the suspicion of disease and bad qualities that other adulterants might have. It has no tissue of putrid refuse in it, they say: it is wholly healthy

And upon this account they insist that it would be a good rather than a bad thing for them, as well as for the public, if the law require a specific labeling of the products into which it enters, and, going further, they aver that it would be even a wise and beneficial thing for manufacturers like Armour & Co. to be open in the matter in dealing with the public, inasmuch as the public would recognize on investigation that the use of the oil as an ingredient would be healthful while cheapening cost.

A ton of cotton seed yields from 35 to 40 gallons of oil. It has recently been stated by persons familiar with the business that 500,000 tons of seed were crushed in the mills last year. The oil product was therefore from 17,500,000 to 20,000,000 gallons. Mr. Armour admits that he used in his lard factory one-fifth of this, or from 3,500,000 to 4,000,000 gallons. Three or four years ago the president of the then existing Crushers' Association declared that one pound of cotton seed oil would "go as far as one and one-quarter pounds of lard."

It is very much cheaper than lard. In the calendar year 1886 there were exported from this country 6,574,000 gallons of this oil, valued at a little less than 40 cents a gallon. A large part of the oil exported is said to come back to us in the form of olive oil, so-called. It appears that exporters and Armour & Co. take about one-half of the entire product. A large quantity must be used by other manufacturers of lard who compete with Armour & Co.

There seems no longer to be the ardent desire that once was supposed to exist for keeping in utter secrecy the business corporation having the monopoly of this cotton seed oil production. A gentleman largely interested in the Cotton Seed Oil Trust, as the corporation is called, gave some interesting facts regarding that business recently. The 6,500,000 bales of cotton that makes the crop of the country, he says, turns out 3,250,000 tons of cotton seed, most of which falls to the ground and is unharvested. About 700,000 tons are used now, and that sends something like $7,000,000 into the South as an absolutely new income to planters there. The oil mills in the trust comprise 90 out of the 95 mills that have been established in the country, all of the large mills in fact. The trust also controls 27 refineries, and the refineries and mills alike are controlled by nine trustees, who have issued certificates to the various companies representing their value; this whole capitalization is somewhat less than $40,000,000. Such a monopoly of course has vast profits in it, it being estimated that at least $4.50 is net profit on each ton they use annually.

With what amounts to a centralization management of the 90 mills in the trust extensive economies of course are possible, and thus, even allowing for large profits, it is that it is found possible by such food producers as Armour & Co. to buy quantities of it at prices that enable them to put it into lard to cheapen that article. It is an open secret that much more than a half of the olive oil that is consumed in this country is in fact merely this same oil of the American cotton seed. It is sent also in large quantities to England and Germany, where it enters into lardine, butterine, and olive oil the same as on this side of the water. Holland imports great cargoes of it to make Dutch cheese. The oil refinery at Providence sold 4,000 barrels last year to preserve sardines in. Soap is made by the thousand boxes in Chicago with the same base. And along with all this is the assertion that the industry as yet is in its infancy. There is no telling into how many food products it will enter speedily, nor how largely.

It is stated that in addition to making $4.50 on each ton of seed used in making oil, the trust obtains 750 pounds of "cake" from the crushed seed, which is marketable at a good price for food for cattle in this country and in Europe.—*Australasian and South American.*

JARRAH WOOD.

Jarrah wood (*Eucalyptus marginata*) is a product of Western Australia, where it is found in considerable abundance. Mr. Thomas Laslett, Timber Inspector to the Admiralty, in his valuable work, "Timber and Timber Trees, Native and Foreign," says of it:—"It is of straight growth and very large dimensions, but, unfortunately, is liable to early decay in the centre. The sound trees, however yield solid and useful timber of from 20 feet to 40 feet in length by 11 inches to 24 inches square, while those with faulty centres furnish only indifferent squares of smaller sizes or pieces unequally sided, called flitches. The wood is red in color, hard, heavy, close in texture, slightly wavy in grain, and with occasionally enough figure to give it value for ornamental purposes; it works up quite smoothly, and takes a good polish. Cabinet makers may, therefore, readily employ it for furniture; but for architectural and other works, where great strength is needed, it should be used with caution, as the experiments prove it to be somewhat brittle in character. Some few years since a small supply of this wood was sent to the Woolwich Dockyard, with the view to test its quality and fitness for employment in shipbuilding; but the sample did not turn out well owing to the want of proper care in the selection of the wood in the colony."

The clerk of works at Freemantle, in reporting upon the opinions expressed by shipbuilders and others says: "The sound timber resists the attack of the *Teredo navalis* and white ant. On analysis by Professor Abel, it was found to contain a pungent acid that was destructive to life. The principle, however, was not found to be present in the unsound portions. Great care is therefore necessary in preparing the wood for use by flitching the log so as to cut all the defective portions of the heart out, and using only the perfectly sound timber."

Very much has been said about jarrah being subject to split when exported to England in logs. It must be borne in mind that its density renders seasoning very slow, and that the inner portions of the larger trees are often in a state of decay, even while the outer portions are in full vigor. A tree under these conditions, the inner portions comparatively dry, and the outer full of sap, shipped at once to such a variable climate as that of England, very naturally bursts from unequal shrinkage, being also exposed to very great changes of temperature. To obviate this peculiarity and apparent defect, let the jarrah be felled when the sap is at the lowest ebb, and carefully flitched, as previously suggested.

The methods adopted in seasoning jarrah are as follows:—The logs are thrown into the sea and left there for a few weeks: they are then drawn up through the sand, and after being covered with seaweed a few inches deep, are left to lie on the beach, care being taken to prevent the sun getting at their ends. The logs are then left many months to season. When taken up they are cut into boards seven inches wide, and stacked so as to admit of a free circulation of air round them for five or six months before using them.

In a communication forwarded to India by H. E. Victor, Esq., C. E., of Perth, in reply to inquiries made by some gentlemen engaged in the carrying out of several large contracts for public works in India, he says:—"Undoubted authority is unanimous in declaring that the timber of the jarrah, under certain conditions, is indestructible."

Professor Von Mueller, Government Botanical Director of Victoria, says:—"Its wood is indestructible; is attacked neither by chelura, teredo, nor termites, and is therefore much sought after for jetties and other structures exposed to sea-water. Vessels built with this timber have been enabled to do away with all copper-plating. It is very strong, of a close grain, slightly oily and resinous in its nature, works well, takes a fine finish, and is, by shipbuilders in Melbourne, considered superior to oak, teak, or any other wood for their purpose."

The committee of Lloyd's, after the representations of His Excellency Governor Weld, determined to rank this timber with those in line 3, Table A, of the Society's rules; thus ranking it with *Cuba sabicu*, pencil cedar, etc., for the construction and classific-

ation of ships. The purposes to which jarrah may be applied are innumerable; it fills the place where saul and teak could not be admitted, as well as where they are used; and as the material can be supplied at a price considerably less than the timbers named, in the log, and at half their price in scantling, it should be employed where hitherto timber has been considered undesirable—for instance, in sea-facing, dock-lining, landing-stages, break-waters and beacons; curbs, road-paving, block-flooring, weather-boarding, and wainscot partitions, wallings, ceilings and roof coverings.

A Western Australian almanac says:—"None of the neighbouring colonies possess timber of a similar character to the jarrah, or endowed with equally valuable properties. If cut at the proper season, when the sap has expended itself and the tree is at rest, it will be found the most enduring of all woods. On this condition it defies decay; time, weather, water, the white ant, and the sea worm have no effect upon it. Specimens have been exhibited of portions of wood which had been nearly thirty years partly under water and partly out. Others had been used as posts, and for the same period buried in sand, where the white ant destroys in a few weeks every other kind of wood. For this peculiar property the jarrah is now much sought after for railway sleepers and telegraph posts in India and the colonies. It is admirably adopted for dock gates, piles, and other purposes, and for keel pieces, keelsons, and other heavy timber in shipbuilding. Vessels of considerable burden are built entirely of this wood, the peculiar properties of which render copper-sheathing entirely unnecessary, although the sea worm is most abundant in these waters."

Though in the foregoing there are a diversity of opinions, yet the general tendency is to testify to the usefulness in an extraordinary degree, under stated conditions, of jarrah wood, and the practical mind will quickly see many opportunities for taking advantage of a wood possessing so many valuable qualities as this wood has been found to contain; and it is not saying too much to express a hope that the shipments now in the London docks will be but the prelude to many other, and more important, consignments to this country, where intrinsic merit is the only passport necessary to gain public favor and support when commercial interests are concerned. —*Quoted by the Nilgiri Express.*

TRADE NOTES FROM THE SEYCHELLES ISLANDS.

OPENINGS FOR BRITISH MERCHANTS.

Mahé, Seychelles, September 4.

There is every probability that before many months are over, little out-of-the-world and hardly-known Seychelles will suddenly obtain an unexpected importance. For some months back it has been rumoured that the Messageries Maritimes meant to radically alter their steamship service in these seas. At present their Marseilles-Australia line calls at Bourbon and Mauritius, where connection is made with a smaller line running between those ports to Tamatave and Mosambique. However, it has dawned upon the French company that unless they greatly shorten the journey to and from Australia they are likely soon to be ousted from their Australian traffic. Consequently it has been decided that their steamers should coal here at Seychelles, and then proceed directly to Adelaide and the other Australian ports. It is stated that this new arrangement will commence on January 1 next. Mahé will also be the connecting station for the Mauritius-Bourbon and Tamatave-Mozambique lines. Thus there is every probability that in a few years Seychelles will become a second St. Thomas in these seas. Of course this new arrangement will do a great deal of good to Seychelles—it could not be otherwise. Still it cannot be denied that it is sad to see piping hot the monopoly would fall be but in French hands, and particularly in the hands of a company that has always treated Seychelles in such a high handed manner. Before the alteration above alluded to was definitely announced, there was a good deal of talk amongst the planters about starting a small English steamer to trade between the islands and Mauritius, and to convey their produce to that port, where low freights can always be obtained for England. As matters now are, it is very probable that no move will be made in this direction until it is seen how the new service works. To give an instance of the freights at present charged by the Messageries Maritimes, I have only to quote one of our principal exports, namely, vanilla. Freight at the rate of 3*d.* per lb. on the gross weight is demanded. As it is customary to pack vanilla first in tin boxes, and then in stout wooden cases, this rate, high as it may appear at first sight, is, in reality, higher still. All this is bad enough, but the worst thing we have to put up with is the uncertainty as to whether the steamers will carry our goods or not. I wonder how many times during the last year or two our valuable goods have been shipped on board more or less rotten lighters, and taken outside to the mail steamer in the outer harbour only to be brought back and unloaded again (at our expense, of course), because, for some reason or other—or, perhaps, none at all—the captain thinks his ship would be better without them. Now that the Messageries are making all these alterations, I hope the authorities at St. Martin's-le-Grand will see their way to improving the letter service with this colony. To be brief. It now takes five weeks to obtain an answer to a letter from Paris, but nine for one from London. We have on very rare occasions received answers from England at the shorter period, but this has only happened twice during the last year. It is in this that French houses doing business with Seychelles have such an immense pull over their English competitors.

Our vanilla crops last year were fairly good. This year a larger area ought to come into bearing. From the number of "buttons" to be seen on the vines, there is every probability of a good crop. Several of the more enterprising planters have lately commenced to dry their vanilla by artificial means, so far with great success. As others are likely to follow suit a good demand for heating-stoves is likely to spring up. A small stove capable of burning wood is the thing required.

Vanilla is grown by a number of persons on a very small scale, and it is doubtful whether they will ever adopt the new method; it is thus likely that the old-fashioned sun-drying has still a long life before it. Vanilla to be dried properly in the sun must be covered by a blanket. These blankets are at present in great request, and, consequently, very dear. The creoles have an idea that the darker the blanket the better the vanilla is cured. This may be erroneous for all I know, but exporters at home should notice the fact. Blankets of the very commonest quality are the things required. I believe there is a quality at home known as the "charity blanket," which would, I think, just suit the requirements of this market. Nearly all the vanilla blankets at present in use are of French manufacture. I may add that a planter, a gentleman from Bradford, sent a sample back to his native town, but was informed that nothing so bad was manufactured in that district. Now that I am discussing blankets, I may add that I have noticed that all kinds of woollen goods are both dear and very hard to get in Mahé. In proof I may state that I recently obtained a large quantity of green baize for my house. I have since been deluged with offers, which, had I wished to sell, would have left me a very fair profit.

The principal industry of the place is the manufacture of coconut oil. A very large proportion of the oil quoted at home as "Mauritius" comes from Seychelles. Nearly all the mills in the colony are of the most primitive description—a hollowed tree-trunk, a spar, an ox, and a boy with a stick, and the apparatus is complete. There is a good opening for improved mills. It is true one or two such were introduced here some years ago, but they failed for two reasons—they easily got out of order, and "they did their work too well." In these parts

the poonac is nearly as valuable as the oil itself. If, however, all the oil is extracted, it becomes of hardly any value for feeding cattle, pigs, &c. And it was, I hear (for I never saw the mills) in this respect that our English machinery so utterly failed. That there is an opening for improved machinery cannot be denied, when there are without exaggeration several hundreds of the old-fashioned kind at present at work. Visitors at the Colonial Exhibition must certainly have noticed the fine specimens of *cocos de mer* exhibited in the Seychelles section of the Mauritius court. Seychelles is the only place where the double coconut is to be met with. In fact, even here, there is only one island, that of Peaslin, where it grows in profusion. The nut when cut in two and properly polished makes a first-rate and very ornamental bread-dish or flower-stand. I therefore recommend it to the notice of British *bric-à-brac* manufacturers. It is much to be regretted that samples of the straw, straw-plait and hats made from the leaves of the *coco de mer* were not also forwarded for exhibition. The straw hats are very similar in colour, &c., to those manufactured at home. I have never heard of any *coco de mer* straw having been exported, though there are tons and tons of leaves left rotting at Peaslin every year. Perhaps some use might be found for it at home. Luton manufacturers had therefore better try a sample. I, if applied to, would of course be only too pleased to assist in any way in my power.

A thing that militates much against the trade direct between this place and England is the entire absence of banks. Nothing of the kind is to be found in the colony. Merchants usually make their remittances in vanilla or other produce, which they purchase from the many small growers that abound here—persons who usually are unable to wait till their produce is sold in Europe, and who, consequently, are forced to accept any prices the merchants choose to fix. The rupee is now quoted at about 45 per cent. discount in Mauritius, but vanilla can be purchased in small quantities at figures so low that when remittances are made to Europe this heavy discount is hardly felt at all. The principal traders are usually Indians from Madras, they are very pushing, and have almost the whole trade of the place in their own hands.—*British Trade Journal.*

COUNT FICALHO'S HISTORY OF GARCIA DA ORTA AND HIS TIME.

By Professor Flückiger.

Among the publications of the "Sociedade de Geographia de Lisboa," there is to be noticed a very valuable catalogue of the useful plants of the Portuguese possessions in Africa, by the Professor of Botany in the Polytechnic School of Lisbon, Count de Ficalho: "*Plantas uteis da Africa Portugueza*," published in Lisbon, 1884, *i. e.*, the first part of the volume, 279 pages, in 8vo, which contains the Dicotyledons and the Gymnosperms. I am sorry the second part, which will be devoted to the Monocotyledons, has not yet made its appearance.

In the first part of the 'Plantas uteis,' the author gives a very careful history of the discovery and the exploration of the countries which he terms "Africa Portugueza." From this preface it is evident that Count Ficalho is not only throughly acquainted with the geographic literature of his own people, but also with that of England, France and Germany, and his catalogue is far from being a mere enumeration. He gives a very full and interesting account of every one of the plants he deals with, and here again I am pleased to see that the author furnishes in a very correct and exhaustive way all the botanical, practical and historical references which may be desirable in order to illustrate each of his "Useful Plants." I have read with particular interest, especially the chapters on *Xylopia æthiopica*, *Jateorhiza Calumba*, *Adansonia digitata*, *Cola acuminata*, *Arachis hypogæa*, Tamarindus, the several Copal plants, *Carica Papaya*, Coffea, Landolphia, Sesamum, *Manihot utilissima* and many others.

Count Ficalho with good reason restricted his work to the African settlements of Portugal, those in the Indian Peninsula being too insignificant. They were important in the sixteenth century; Goa was then a great centre of commercial activity, but is now entirely superseded by Bombay. In Goa there was living, apparently for about thirty years, an intelligent surgeon, Garcia da Orta, physician to the Portuguese Viceroy and to a hospital of Goa. This city was the place where most of the drugs occurring in the various regions of Asia were to be met with in the bazaars as they are now-a-days chiefly in Bombay. Garcia da Orta zealously availed himself of the exquisite opportunity of examining these drugs, at least the more interesting among them. He compiled his observations in the volume which bears the following title: "Coloquios dos Simples e drogas he cousas medicinais da India e assi de alguas frutas achadas nella onde se tratam alguas cousas tocantes amedician, pratica, e outras cousas boas, pera saber copostos pello Doutor garcia dorta; fisico del Rey nosso senhor. . . . Impresso em Goa, por Joannes de endem as x dias de Abril de 1563 annos."

A colloquy is not precisely the form which would answer to the taste of readers in our days, surely not in questions of materia medica. But Garcia's 'Coloquios' are nevertheless one of the most remarkable documents of the kind. The original edition is at the same time a book of utmost importance to biblophiles or bibliomanes, for it is thought to exist only in a few copies still, say a dozen; Count Ficalho states that he knows of one in India, three in Portugal, one in the Paris library, and one at Leiden. I have consulted that of the British Museum.* But the knowledge of Garcia's notes or Coloquios was very soon widely spread by the Latin translation by Clusius, first published in 1567.

Garcia da Orta being one of the most interesting Portuguese authors of his time, it is or was a pity that but very little was known as to his person. It was a good plan, therefore, proposed by the Royal Academy of Lisbon, to cause a new edition of Garcia's work to be elaborated, and to have it accompanied and elucidated by critical notes concerning of course also a biographic investigation. The Academy had the excellent fortune to possess among its own fellows the only man to whose care that task could be safely entrusted; Count Ficalho had largely proved by his 'Plantas uteis da Africa Portugueza' that he was the right man to appreciate and illustrate Garcia de Orta. †

I have been most obligingly presented, by the author, with the first part of his investigation, which appeared under the title: "*Garcia da Orta e o seu tempo pelo Conde de Ficalho, Lente de Botanica na escola polytechnica, Socio effective da Academia real das Sciencias de Lisboa.*" Lisboa, Imprensa nacional, 1886, 4to, 392 pp. 8vo. In the preface the author states that he felt obliged to seek first for information about Garcia's person before elaborating the new edition of the Coloquios. In doing so Count Ficalho considered at the same time the period of Garcia's stay in India from a general standpoint, and at last secured such an amount

* See 'Pharmacographia,' second edition, 1879, 760. —There is also a copy in the imperial library of Rio de Janeiro, according to Varnhagen.

† I may also quote his 'Investigations on the Botanical Influence of the Discoveries of the Portuguese,' 1878, which I have also before me.

of new and interesting information that he justly resolved to publish in the first line a book *about* Garcia, that under notice, being a very acceptable introduction to the Coloquios which are to follow.

Count Ficalho has not succeeded in discovering any information about the family of Garcia, nor of the date of his birth, but he shows that Garcia was a native of Elvas, in the upper (or eastern) part of the Portuguese province of Alemtejo (not far from the Spanish place of Badajoz), where he was born, in all probability, towards the end of the fifteenth century.

It is proved that Garcia devoted himself to the study of medicine in the Spanish universities of Salamanca and Alcalá de Henares, near Madrid. Particulars on Garcia's personal work in those high schools are wanting; the author, as he expressly states in the very title of his book: "Garcia da Orta *and his century*," or time, attempts, on the other hand, to afford an attractive picture of the way in which the Spanish "Estudante" of the sixteenth century satisfied his thirst of science. In Salamanca, where the number of students frequently exceeded 6,000 or even nearly reached 14,000, the study of medicine was based as well on the old Greek and Latin classical books as on their Arabic followers, some of which were translated in Salamanca. In the old Roman town of *Complutum*, now Alcala de Henares, Hippocrates would appear to have been prevailing; this university had been established in 1498, nearly two centuries later than that of Salamanca, in a period when the splendour of Arabic science and rule was on the decline. Garcia himself states in one of his Coloquios that in Salamanca he was acquainted with a Dominican friar, Domingo de Baltanas, and in Alcalo with Tordelaguna, originally a pharmacist, but subsequently a student of medicine. As this man is stated by Garcia to have possessed some knowledge of Arabic, as well as of botany, he may perhaps have encouraged Garcia in extending his studies in those directions too. That is absolutely all we know about the few years spent by Garcia in the two Spanish universities, no other trace of his stay there has been discovered, not even in the records of either Salamanca or Alcala.

In the second chapter: "Castello de Vide and Lisbon," the author is happy enough to introduce two documents of the 5th and 10th of April 1526, one of which had not been printed before. In these charters the lecenceado Gracia dorta or Guarcia dorta, then an inhabitant of the town of Castello de Vide, a small place south of the region where the Tejo enters into the Portuguese territory, is stated to have passed his examination, and acknowledged to be "soficiemte e ydonyo na teorica como na pratica" as a "fisyquo." King Johann III. consequently authorizes Garcia to cure throughout the realm of Portugal, and even to travel, for that purpose, on horse or mule's back. At Castello de Vide the young medico de provincia, Gaicia da Orta, spent six years. By what means he succeeded in making his name known to the scientific body of the metropolis cannot be traced, suffice it to say that Garcia was called, in 1532, to a professorship in the University of Lisbon. But strange enough, yet quite in accordance with the views of that time which ruled all the universities of the Peninsula, Garcia's lectures were devoted not to medicine, but to the "Summulæ logicales," an abstract of scholastic logics. Count Ficalho explains that the mediæval sentence: "Dialectica est ars artium, scientiæ cæterarum," was not yet overthrown by the evolution of those sciences which now are holding the prominent place in human exertion throughout the civilized world.

Garcia happily occupied his philosophical chair in Lisbon only from January, 1532, to February or March, 1534; nothing more is recorded as to his other occupations there, neither by himself nor by any contemporary writer. It was a brilliant period of Portuguese story, that of the admirable discovery of and success in India, when Garcia lived in Lisbon.

He appears to have been early acquainted with the great and noble family de Souza, who partly resided in Alemtejo, the native province of Garcia. Dom Martim Affonso de Souza, one of the distinguished navigators of Portugal, being appointed chief admiral, "capitão mór do mar," for India, chose Garcia his physician. He had, in all probability, been honoured for a long time already by Dom Martim Affonso's friendship, so at least Count Ficalho shows it to be probable. In the Coloquios, Garcia mentioned the admiral in high terms of real affection, and dedicated the book to Dom Martim.

When the admiral's squadron arrived in Goa, in the fall of the year 1534, the Portuguese possessions were governed by Nuno da Cunha, a worthy successor to the great men who had established in India the power of their nation. Great things remained still to be done in order to settle ultimately the Portuguese dominion, and the admiral, Dom Martim Affonso, had to perform several expeditions and surveys in the interest of his country. Doctor Garcia, who accompanied him, no doubt took great interest in these explorations along the coasts of India, and availed himself diligently of the excellent occasions for procuring exact information on several drugs; he also visited the famous temple of Elephanta; the chapter iv., "Baçaim e Diu" gives the interesting narrative of those campaigns to the north-western coasts.

In the year 1536, the governor or viceroy, Nuno da Cunha, ordered Dom Martim Affonso de Souza to the coast of Malabar, where a struggle was engaged between the Rajahs of Calicut and Cochim. This expedition, which Garcia accompanied as a military surgeon, also afforded him the invaluable opportunity of examining *in loco* the most important medicinal plants and drugs; he spent the end of the year 1537 in the port of Cochim, then a very great emporium of spices and drugs. In 1538, a similar expedition of the Portuguese fleet under command of Dom Martim Affonso being directed to Ceylon, Doctor Garcia da Orta probably paid a short visit to that island, but we are not sure of the fact. In his Coloquios he speaks of the productions of Ceylon so exactly as to suggest that he made a stay there; thus, for instance, Garcia displays a good knowledge of the precious stones for which the island has always been famous. Very likely he had acquired some mineralogic notions during his university studies in Spain.

In 1538, Dom Martim Affonso was called back to Portugal, but Garcia appears to have been settled at Goa quite satisfactorily, so that he continued there and was again rejoined by Martim Affonso, when this nobleman returned to Goa, and occupied, from 1542 to 1545, the high post of governor-general of the Portuguese possessions. Count Ficalho skilfully collected every kind of informati n relating to the way of living, to the commercial and intellectual resources of that Portuguese colony in which Garcia da Orta spent his life in useful work, both as a medical practitioner and an investigator of the natural productions of the East; the splendid metropolis of Goa no doubt was an excellent place to a man like Garcia. He was also appreciated in Portugal, for in one of the Coloquios, in speaking of another governor of

viceroy, evidently after the time of Martim Affonso, Garcia mentions that the king of Portugal, Joao III., had pointed out to the new governor (D. Pedro Mascarenhas), that, with regard to Garcia da Orta, it was not necessary to take with him a physician from Portugal to Goa. By perusing critically the Coloquios, Count Ficalho was led to the view that Garcia in all his doings and living was guided by very sound principles; he appears to have avoided the temptations of the opulent high life of the vice-regal court and its tricks, as well as the exaggerated exertions and ceremonies of an idolatrous church, although, on the other hand, Garcia evidently was honoured by the governors and the Portuguese colony, as well as by the indigenous princes and wealthy people, who were indebted to his medical services. Garcia also was always a devoted son of the church, and a friend of the Franciscan and Dominican orders settled in Goa. The famous poet, Luiz de Camoes, one of the illustrious of Portuguese literature, was on very good terms with Garcia, whose Coloquios the poet favoured with an ode in verses, which, however, appear to have been printed very incorrectly. Without knowing exactly the place of Garcia's residence at Goa, it may be inferred from incidental quotations in the Coloquios that his cottage and garden were in a commanding situation; here the physician and naturalist enjoyed, apparently as a bachelor, his leisure hours. He delighted in the cultivation of useful plants, and especially of the various edible fruits of India. Sometimes the doctor also sent exquisite fruits to the palace of the viceroy. Garcia's gardens were attended by numerous servants, as shown in the Coloquios, where mention is made of a native doctor who devoted his services to at least the female part of Garcia's slaves; the doctor of Salamanca or Alcala kindly, and, perhaps, prudently allowed the people to resort to his Indian medical colleague Malupa. Garcia also possessed an estate at Bombaim, now Bombay; Simão Toscano was the name of Garcia's farmer there. The doctor quotes a lot of books in his Coloquios; certainly he had them at hand in his own library, which, therefore, may be supposed to have been the richest in India, at least in books on materia medica or botany and medicine: it also is evident that Garcia had a collection of drugs and curious things of natural history in his rooms.

The vivid picture of Garcia's life at Goa would not be complete without expressly dwelling also on his affectionate friend the Prince Nizamaluco or Buhran, to whom Garcia paid several visits in that ruler's magnificent metropolis Ahmednaggar. Here the Portuguese doctor met with the learned Mussulman physicians (Hakims), to whom he was no doubt indebted for a good deal of his intimate knowledge of Indian materia medica. Ficalho gives at length the interesting story of Buhran Nizam Shah, an intelligent and learned prince, who was in constant good relations to the Portuguese Government of Goa.

Garcia da Orta was already mentioned to have had a farmer at Bombaim, or Bombaym, the island now occupied by the city of Bombay. The learned author of the book under notice is of the opinion that Doctor Garcia had taken in lease the whole of the said island, certainly a most interesting fact. We refrain from following here Count Ficalho's convincing arguments (p. 261), but they seem to be absolutely in favour of his suggestion. He treats that question skilfully in the best historical way, affording or quoting a full set of documents, both published and unpublished notes from the Portuguese archives. Certainly, a most unexpected and most curious result of Count Ficalho's excellent investigation, viz., Garcia da Orta's chief receiver or farmer ("rendeiro," p. 217) collected the rents of his employer probably on the very same grounds which are now occupied by one of the grand emporia of the British Empire in the east.

Two chapters of Ficalho's book are devoted to a short, but highly interesting review of the Coloquios, which are duly appreciated as well as their author, whom the Count (p. 350) shows clearly to have been "the right man in the right place." But Ficalho at the same time (p. 381) is fully aware that Garcia's work was very badly written, that there is no order in it, that its style is utterly wanting of anything like consequence, method or elegance, notwithstanding the unusually large amount of excellent observations it affords. Ficalho gives a list of about fifty books which Garcia quotes repeatedly in his Coloquios, and also points out some of the most remarkable plants or drugs met with in the Coloquios. They had, we may say, the good chance to be translated, as early as in 1567, by the most competent man of the time, viz., Charles Clusius, but we fully understand that the Latin translation, which was thoroughly modified by Clusius, is but moderately esteemed by the Portuguese. The new edition by F. A. Varnhagen, Visconde de Porto Seguro (Lisboa, 1872,) is but a reprint of the original work which had been carelessly printed at Goa, and Varnhagen seems to have even increased the number of mistakes. So it will be an honour due to the memory of that eminent Portuguese naturalist to prepare a good edition of the Coloquios and to illustrate it by critical notes. This will be a rather difficult task; the editor ought to be thoroughly acquainted with botany, geography, history, and should also be conversant with the leading idioms both of Europe and India; certainly an amount of knowledge not frequently to be found in one person. The book before us happily proves that Count Ficalho is the right man; to all those scientific qualifications he joins a good deal of noble and enlightened patriotism, desirous of illustrating Dr. Garcia da Orta as a distinguished "representante do espirito portuguez," one of the "robustos e originaes homens do XVI seculo." A thoroughly competent man, Joaquim Heliodoro da Cunha Rivera, who lived for some time at Goa, stated in a letter to the author, that he was not able to trace at Goa any reminiscence of Garcia. Rivera's investigations even proved not a single copy of the Coloquios to exist there, in the very place where they had originated. Even the date of Garcia's death is unknown, nor are we informed whether it occurred in Goa.

Count Ficalho's book gives an attracting sketch of the most interesting and important periods of Portuguese story, and on this animated and rich background some of the outlines, as exactly as they could be traced by the endeavourings of that well-informed and zealous investigator, become apparent of Garcia's remarkable life devoted to materia medica and medicine itself.

Two things only remain to be regretted. In the first line, the large stock of information embodied in the book 'Garcia da Orta e o seu tempo,' ought to have been made more completely accessible by a good alphabetical index. The "Summario" of the fourteen chapters of the book is very carefully elaborated indeed, yet not quite sufficient for easy reference. And secondly, it is highly desirable to have the excellent book, or at least the essential matter of its contents, translated into English; the short notice of Count Ficalho's book which is afforded by my lines giving only a very imperfect idea of the author's work. I hope some Portuguese scholar in England or the United States will be found who may be able and willing to undertake the translation. And I hope that Count

Ficalho also will be pleased to secure an English or French edition of the Coloquios,* when he is about to publish the new critical edition of them which we are expecting with great satisfaction.

PLANTING IN NETHERLANDS INDIA.

(Translated for the *Straits Times*.)

The steady rise in the price of coffee with every prospect of its continuance at a high figure for many a year to come, has brought about a revival of plantation enterprise in Java, so says the Sourabaya *Courant*. The Government has in consequence been overwhelmed, as it were, with applications for waste land. Coffee planting has now become the rage among people dazzled by the excessively high prices ruling of late for that article. Owners of extensive estates have applied to Government for large areas of land to be tacked on to their plantations. People who have hitherto fought shy of coffee, can now be easily persuaded to invest their money in growing the article. In the province of Kedirie, Europeans have been going about the villages and mountains in quest of land suitable for coffee cultivation.

Tea growing in Java stands far behind enterprise in the same direction in Ceylon. This branch of industry in Java is in private hands, and as such cannot be expected to find favour from Government Officials who set store by discouraging private enterprise in every way. For many years, tea growing in the Preanger Regencies was systematically counteracted, lest it should interfere with the compulsory Government coffee cultivation. Planters in Java far from being aided and backed by the State, find themselves hampered and interfered with by it at every turn. The pressure of taxation on them is heavy indeed. They have to pay assessment, quit rent, coolies' poll tax, license tax, horse tax, also high freight rates on Government railways and export duties. The fiscal screw is turned pretty tight in Netherlands India, and effectually checks the steady growth of planting enterprise. Had the Government favoured the development of the productive resources of Java and Sumatra in the past, these islands would have outstripped Ceylon in prosperity.

In Java, a planter has been experimenting with grafting Arabian coffee on the Liberian variety. At the outset, the experiments proved successful save in one respect. The gentleman in question hoped to secure plants proof against leaf disease, but found himself disappointed. The grafts grew very well on the Liberian stocks. But leaf disease did not spare them. Soon, they were as severely stricken as the ordinary coffee trees.

In many parts of Java, the population reaches the same density as in Belgium. Some districts are actually over-populated. No wonder that the people under such circumstances readily take to emigrating to Deli to work as coolies on the tobacco estates there. The Government does not favour this kind of emigration in the least, from apprehension lest the illusions of the immigrants should prove greater than the reality offers. Yet the poorer Javanese would be undoubtedly better off there, than in living in starvation in their homes. Many portions of the Archipelago now neglected would be materially advantaged by a regular supply of labour from Java.

The Java Government coffee crop this year is estimated at under half a million of piculs. The yield is expected to fall below four hundred thousand piculs. Private estates too show the same shortcoming. All over the island the coffee crop has proved short on private estates as well. On the west coast of Sumatra the amount of available coffee has turned out so miserably small that it is intended to make up for the deficiency by eking out the stock in hand with Preanger coffee, which has beans large enough to admit of passing muster for Sumatra coffee. These signs of the times betoken evidently that Government coffee cultivation has seen its best days in Java and Sumatra.

The Batavia *Nieuwsblad* has been inviting information for publication in its columns on the subject of coconut pearls. A correspondent in reply states that he had often seen these concretions in Banda and Amboyna. An officer at one of these places has a pearl of this kind of large size. The wife of a native headman at Amboyna wears one set in a ring. It is said that similar concretions are found in other kinds of fruit. They are often found in the maws of fishes. The natives at these places call the pearls by the name of Mastieka. They are reputed to bring their possessor luck in gambling.

In the district of Berabei in S. E. Borneo, a planter named Salomonsen has set about tobacco growing. His success seems assured. Large capital, that mighty factor, is at his command. Land in that district suits this kind of cultivation admirably; and long stretches of it are now lying waste. Abundance of labour on the spot is another advantage. Indigo and pepper cultivation is said to suit the local environment. But in Holland there is no inclination to turn these extensive tracts of fertile land to any profitable account, though the country only needs capital and industrial enterprise to become a second Deli.

In Java, strange to say, nothing is done in the cultivation and preparation of gambier. The custom house returns shew that the imports of this article there reach a considerable figure. For mixing with sirih leaves alone, the Javanese require large quantities of gambier.

The Deli *Courant* of the 30th July asserts that, of late, the price demanded on engaging coolies for that Settlement in the Straits, has been steadily rising. Seventy dollars and even more per head have to be paid. The brokers having gained the upper hand owing to division among the planters, carry all before them. Nothing more is heard of direct importation of labour from China. Every hope of anything of the kind being set on foot must now be given up. Direct shipments of coolies from China to Banka too does not answer. At least an agreement entered into by the Netherlands Indian Government with the firm of Pasedag and Co., for the enlistment of Hokien coolies for the behoof of the tin mines in Banka, have not led to any satisfactory results. The consequence is that a European Netherlands Indian Chinese interpreter now staying in China, on a special mission has been charged to enlist 600 Hokien Chinese for Banka. Several leading Deli planters, a year and a half ago, commissioned him to do likewise for them, but not a single Chinaman engaged by that official has yet arrived in Deli. In Banka, too, the coolie supply threatens to run short. It seems that the Straits brokers do wield greater influence than ever in Chinese ports, by a free distribution of money as a matter of course. So long as the planters cannot command a like influence there, direct coolie immigration from China will remain impracticable. The brokers evidently have the Deli planters completely in their power.

* An English translation has, we are glad to say, already been undertaken by a lady in London under the direction of Col. Yule, which is to be annotated by Prof. Ball. We reprint Flückiger's article, some of the idioms in which are peculiar, as affording a curious glimpse of life in Portuguese India, when Portugal was in its glory.—ED.

The subsidy granted by the German Government to the North German Lloyd Company, has enabled Deli planters to save two hundred thousand guilders in freight charges between that colony and Amsterdam. A German trade journal cannot see the expediency of subsidising German steamers to supply the Amsterdam market with cheap tobacco, that port being a rival of Bremen.

The importation of Sumatra tobacco into America has increased from 8,277 bales in 1881 to 23,932 in 1886.

In England an association has been started for carrying on plantation enterprise in the State of Asshan. It is styled the Qualla Asshan Company, and intends to grow tobacco. Mr Verwaaien will be manager and Messrs. Wilson and Meredith, commissioners.

CEYLON UPCOUNTRY PLANTING REPORT.

THE DROUGHT AND ITS EFFECTS ON CROPS—COOLIES OUT OF EMPLOY—PROSPECTS OF COFFEE.

15th August 1887.

You hear nothing but wails about this dry season, the worst for ever so long, is the general opinion. Will there be a wet N.-E. to make up for it? is an anxious question. We hear from India that the signs there are all pointing to drought: for the meteorologists watching the snow line on the Himalayas report the shrinkage which is ominous. The snow does not lie, they say, falling evidently as sleet, and disappearing immediately. Fortunately with us there is another factor in the calculation—the sea, which is pretty constant.

Meanwhile the cardamom crop his suffered much, and estimated returns from that source will be a long way behind.

As to the young tea plants, even in wet districts like Maskeliya they have had a rough time of it, while in drier places they have had a rougher. "Will you have much supplying to do in your new clearing?" asked one planter of another the other day, and got for a reply "Well no, it will be *replanting* 150 acres rather"! "I put out 20,000 plants when we had last rain, and there has been ten days' sun on the top of them, not a drop since," is another man's tale. He was not looking for much good from that effect. But all over it is pretty much the same.

Gangs of coolies are going about seeking employment: "no work," on the estates they say, and are being paid off in consequence, the precious "tundus" they produce revealing their all but hopeless indebtedness. The smaller the gang the bigger the debt is the rule which seems most generally to obtain. The bearer of this tale of pecuniary bondage is always very hopeful, he can easily increase his gang if the "master" wants, has a good connection at the Coast, but everything is in the future. Too often the amount of advances tells of "funk" at some time on the part of the superintendent fearing a short labour supply. In some of the recruiting districts of India, the want of rain there is turning the minds of the labourers Ceylonwards, and there is reasonable hope that the stream of immigrants, which is trickling now, will ere long swell to the proportion of our wants. Just at present it seems as if we had more than we needed.

Coffee in the lower districts is beginning to ripen a little. But there is so little of it, that although the trees are bearing well, where the bug has been slight, and better where they have been altogether free of the pest, still, when all will be told, it will be but a poor show. PEPPERCORN.

CINCHONA IN JAVA.

The following is a translation of Mr. Van Romunde's report on the Government cinchona enterprize in Java for the 3rd quarter 1887:—

The weather continued very rainy during the past quarter also, with the exception of the second half of July. The continuous damp weather was good for the nurseries and the young plants, but interfered greatly with the regular gathering of bark. The crop of 1887 amounts to about 270,000 half-kilograms, which was obtained almost without exception by the needful thinning out of dense ledgeriana and succirubra plantations. In 1886 the crop for a similar period amounted to about 120,000 pounds. The plantations on the Southern Mountains are specially those that are increasing largely in productiveness and productive power, so much so, that at the gardens on Goenoeng Malabar the crop of ledgeriana for the first half of 1887 already exceeds that of the whole year 1886. Of the harvested bark by the end of the second quarter 221,227 half-kilograms had been despatched to Britain. The whole crop of 1887 is estimated at about 700,000 half-kilograms, that is, if the weather does not interfere greatly with the operations connected with the gathering and drying of the bark. On 10th March and 21st April sales of Government cinchona bark of the crop of 1886 were held at Amsterdam. The average prices obtained at these sales were 57·42 and 66·72 cents per half-kilogram. Experiments with the grafting of *C. ledgeriana* on *C. succirubra* in the open were renewed, after a cessation of some years on account of the unfavourable results, and, as far as can be judged from the initial results, with very marked success. The propagation of ledgeriana and succirubra seedlings was, thanks to the continuous moist weather, carried on vigorously and incessantly, so that in the course of this year, more than ever before, the rooting out of inferior varieties of cinchona and the replanting of the uprooted ground with *C. ledgeriana* and *C. succirubra* can be carried out. At Tirtasats a commencement was made with the clearing of jungle for the formation of ledgeriana graft plantations. In consequence of the mild east monsoon of 1886 the harvest of ledgeriana and succirubra seed is so small, that hitherto it has been impossible to have any sales of cinchona seed.

MR. J. L. SHAND ON THE LIVERPOOL EXHIBITION.

Planters' Association of Ceylon,
Kandy, 19th August 1887.

To the Editor, *Ceylon Observer*.

SIR,—I beg to enclose copy of a letter received from Mr. J. L. Shand on the subject of the Liverpool Exhibition.—Yours faithfully,

A. PHILIP, Secretary.

(*Copy.*)

London, 28th July 1887.

The Secretary, Planters' Association of Ceylon, Kandy.

Dear Sir,—I duly received and thank you for your letter of 17th June. I note the wish of the Association that I should receive offers for the show cases and submit such offers to Ceylon, but as I mentioned before, nobody will make an offer worth entertaining upon these terms. I hope, however, Mr. Christie may be able to arrange for the cases being used next year at Glasgow. I have been in correspondence with him on the subject. The Glasgow exhibition will be decidedly *the* exhibition of next year and it will be important that Ceylon should be well represented there.

There is I think rather a growing feeling in Ceylon against exhibitions and the idea that we have had enough of them is not unnatural, because in spite of the money spent on exhibitions Ceylon tea has

fallen in price, but planters in Ceylon must remember that though Ceylon tea has fallen, Indian and China teas have fallen far more and any tea dealer or tea broker in London knows that the price now obtained for the lower grades of Ceylon tea in London is disproportionate to their value in comparison to Indian teas and is attributative to the taste which has been created by advertizing. Now as long as tea is not only shown in an exhibition but can be tasted, there cannot be a better advertizing medium provided the sale is honestly carried out.

In Liverpool, as at South Kensington, we use in cup the tea we retail at 2s 6d per lb., and though our sales have been so far small, the general demand is for a "packet of the same tea we have been drinking" so much so that we sell far more of that than of all other kinds put together.

I tried hard to get into the Manchester exhibition this year, but there is no use letting people look at tea; they must taste it and I could not make satisfactory arrangements for selling in cup or packet.

Through no fault of the exhibition itself because it is an interesting show in a splendid building, the Liverpool exhibition has so far failed to attract the number of visitors expected. Newcastle and Saltaire, but specially Manchester, are drawing people from it, and it is now plain that London is the only place that can run consecutive exhibitions.

We are selling three cups of Ceylon tea for every cup of Indian tea that is sold in the exhibition, and many people who had never heard of Ceylon tea before are loud in its praises. I received safely all the goods sent by the P. A. and its members all in order except a box of arecanuts and indiarubber which had got wet and the contents of which had to be thrown away, and I now send you a slight sketch of what the Court contains.

It is approached from the main avenue under two arches, to the main support of which is attached Mr. Ferguson's Summary of Ceylon Statistics prepared last year and under each archway are hung large models of canoes and catamarans.

The P. A. satinwood cases are the chief objects which attract attention on entering the Court, and they are filled with tea, cardamoms, cocoa, and spices as per annexed list.

The walls are covered with Miss Gordon Cumming's pictures, a large picture of Kandy, photographs of Mr. Skeen, a collection of masks, horns, mats, &c., and the sides of the Court are taken up chiefly with specimens of natural history, leopards, stuffed birds, snake skins, heads and horns, tusks, elephants' pads, flying-foxes, squirrels, &c., and with models of boats of many sorts, carts, elephant kraals, pearl diving, ploughing, oil mills, toddy drawing, arrack distilling, &c., &c.

A case in the centre of the Court shows mats, baskets, brass and pottery work and many other objects of interest exhibited by Sir Charles Layard. One case contains silk, cotton and fibres of many kinds and another resins, dyes and medicines, and a third coconuts and their produce, cinnamon, cigars, tobacco &c., and other cases show precious stones in the rough and set, and plumbago is also well shown; another case shows mats, baskets, porcupine quill work, ivory, tortoiseshell &c., and we have a small literary corner showing Sinhalese bibles and books sent by C. M. Society and several publications sent hy Messrs. Ferguson. It would not be becoming in me to say much about the arrangement of the Court, but this I can say that there is no agricultural or commercial enterprise of any moment in Ceylon which is not represented, and which any who desire to obtain information upon have not the means of doing so.

I have omitted to mention the collection of cabinet woods which are much noticed. Liverpool is the great centre of the mahogany and other cabinet woods trade, and I am constantly asked questions which I cannot answer: such as what I could put satinwood down at per ton in Liverpool.

Fibres, oils, tree cotton etc., etc., have all met with more practical attention here than they did at South Kensington, and there is a general feeling that freight being the same from Colombo to Liverpool, as to London, and wharf and warehousing charges being lower, shippers should consign direct to Liverpool. There is also a desire to regain the tea market, for Liverpool was not long ago the great centre of the tea trade and as it is a great centre of population charges are less, and railway transport from London to Liverpool 37s per ton would be saved. A good deal of the North England and Irish trade might be done in Liverpool.

A great drawback we had at first at Liverpool was having hardly anyone interested in Ceylon to support us and back us up and the rivalry of local dealers who supply Indian tea.

At South Kensington last year those who were connected with Ceylon often went far towards filling our tea room, but in Liverpool hardly anybody ever heard of Ceylon before, and we have no zealous contingent to rally round us. We have now got over this, and in great measure owing to our native servants, our tea room has become a very popular resort. I now send list which is I think very nearly correct of what I have received through the instrumentality of the P. A., and I take the opportunity of thanking those gentlemen who kindly sent me exhibits and enabled me to bring forward a collection, which, though the attendance at the exhibition has been to some extent disappointing, has already done much to draw attention to the industries of Ceylon and especially to its main *industry*—tea.

Samples of tea from Broadoak, Walaha, Uva, Scrubs, Castlereagh, Chapelton, Lethenty, Theberton, Peredeniya, Arslena, Balgownie, Barnagalla, Kohinoor, Tillyrie, Torwood, Waltrim, Mayfield, Elbedde, St. John Del Rey, Lindula, Ouvakelle, Ferndale, Loolecondura, Blackstone, Strathellie, Mahacoodagalla, Amunamulla, Great Valley, Darrawelle, Kandepolle, Great Western, St. Andrews, Pansalatenne, Diagama, Kanangama, Glenugie, Rookwood, Hatale, Dalhousie, Kintyre, Blair Athol, Glenalpine, New Peradeniya, Scarborough, Deanstone, Newton, Dewalakanda, Vellaioya, Frotoft, Dunedin.

These fill our show cases and in addition we have a special exhibit from Kintyre, Attabage, Riverside and Hattanwella and fancy teas from Kanangama, Sembawatte and Mariawatte and the unclaimed fancy teas from New Brunswick and Galbodde which I had at hand from S. Kensington, are also shown.

COFFEE.—The Ceylon Land and Produce Company helped me out of a difficulty, for I had but little to show until I received their exhibits of Liberian and Arabian in husk and cleaned from Alloowihari, New Peradeniya and North Matale and what is a very interesting exhibit bottles of Liberian and Arabian cherries.

CINCHONA.—We have some of the fine Glenlyon specimens of last year shown by Messrs. Patry & Pasteur and good and varied collections from Alloowihari, Rickarton, Blair Athol and Newton.

CARDAMOMS are well shown, Messrs. Mackwood & Co. size them commercially, and Castlereagh, St. Martins, Alloowihari, North Matale, Ferndale, Katooloya, Barnagalla, Dryburgh and Kobonella exhibit some splendid specimens.

In COCOA, North Matale, and Allowihari have come forward with several exhibits and I had some good specimens left over from last year and

PEPPER.—Very fine specimens are shown by Arduthie, Alloowihari and North Matale. These estates also send cinnamon sticks and coconuts, tobacco and cigars, castor oil and seed, croton seed and pod, tree cotton clean and in pod, anatto husked and clean, some vanilla orchids which arrived alive but suffering and I have handed to the botanic gardens for treatment, and a dried tea tree which is an object of great interest. Messrs. Mackwood & Co. also send fine samples of oils and plumbago. I think this completes the list of exhibits received through you. I feel sure the gentlemen who have been good enough to send exhibits of tea across the water will find a manifold return, and I trust the Association will look to next year's exhibition in Glasgow as an advertizing medium which may stand in good stead when the great struggle of over-production of tea which is already looming has to be entered upon.—Faithfully yours,

(Signed) J. L. SHAND

SINGAPORE AND THE FRENCH PLANTER, M. CHASSERIAU.

From the *Singapore Free Press* we take a lively and quite characteristic narrative by a Frenchman of his visit to the Straits, in which there is some information regarding the enterprising sugar, manioc and Liberian coffee-planter, M. Chasseriau. He added coconut planting to his other enterprises, but the palms did not flourish in the clayey soil of his estate, and when we visited his interesting plantation in 1881, he was cutting down his fourteen-year-old palms, because all these many years he had come seeking fruit and finding none. But, in reality, even in the most favourable circumstances of soil and climate in Ceylon, coconut trees yield very little up to the fourteenth year, although there are, of course, exceptional trees which commence to bear at half that age. We doubt, however, if a whole plantation is ever in *full* bearing before its twentieth year. How long the trees will live and bear, those which escape beetles in youth and lightning in mature years, is an unsettled point. Sixty years has been mentioned, but we know trees still vigorous and bearing well which must have attained the full century. It did not seem to us, however, that the soil of Singapore was favourable for the cultivation of the coconut palm. On the other hand, that delicious fruit, the Mangosteen, flourishes there in low, swampy ground. At the time of our visit, M. Chasseriau's manioc cultivation and his factory for the conversion of the tubers into tapioca were, without doubt, the most extensive in the world, and the system of manuring by means of the ashes and *débris* of turf, cut from the broad carriage tracks which intersected the estate and subjected to a smouldering process was in full force. Varieties of manioc from Brazil and many parts of the world were successfully cultivated and the finest possible tapioca was turned out by means of very ingenious appliances, which we were permitted to see only when our worthy host and guide was satisfied we were not a Dutchman: only a newspaper editor seeing what he could see. We have a grateful remembrance of his kindness in driving us about and showing and explaining everything. But, as we remarked recently, tapioca was overdone and had ceased to be profitable. Now, M. Chasseriau has turned his attention to Liberian coffee, and we trust he may be more successful with that once source of sanguine hopes, than we in Ceylon have been. The effects of *Hemileia vastatrix* (which was not imported from Brazil) are with us most serious, while Liberian coffee did not sell well in the London market. In the Straits, the experience may be different. The story about *slips* of the Liberian coffee plant seems as apocryphal as that of a boy of 16 who could not read, and yet was, in three months, an accountant. M. Chasseriau is, however, a very remarkable man, and we shall be sincerely glad to learn that in the evening of his days his fortunes have been retrieved.

THE STRAITS SETTLEMENTS.

(From *Deux Mois Autour du Monde*, by GEORGES LIEUSFOU.)

The town of Singapore is situated upon the south coast of the island of that name, about 1° 6′ north latitude and 103° 35′ longitude east from the meridian of Paris, at 120 kilometres from the equator. The island is 43 kilometres long and 22 broad. It is separated from the Malay peninsula (territory of the Sultan of Johore) by an arm of the sea about two or three kilometres wide. There is here a curious mixture of races and religions. Singapore, which has existed only for fifty years, has attained a considerable expansion because it forms a necessary stopping place on the great line to the Far East. There may be found the products of India as well as those of China and Japan. Trade is in the hands of the Chinese. Colonisation, favoured by rich soil and a fine climate, has itself reached a brilliant development. The island shares in two monsoons, one of which comes to it from the China Sea for six months, the other from the Indian ocean during the remaining six months. That explains why the temperature, in spite of the latitude, is relatively mild. Nevertheless one's body is always moist, with a mean temperature of 28° Cent. We have bad news. For Batavia there are only Chinese boats up to February 3rd, the date of the sailing of the Messageries steamer, which makes ten days delay. The exchange of money is very heavy. The American dollar current here is not used in Java. A letter of credit upon the Dutch Banks in that island is neceesary. The syce asks a dollar; this being the monetary unit is a very much worse affair than the rupee. The horse being a rare and costly animal here, makes carriage hire a very expensive matter. In addition the jinricksha (*pousse-pousse japonais*) propelled by Chinese is in constant use. There is not much of interest about the town. There are only Chinese there, and offices. The Europeans live in the suburbs, often a good distance out, which makes driving about an endless affair. Some splendid new buildings are occupied by the public offices. We notice the Town Hall before which, upon a pedestal, stands a big elephant, a present from the King of Siam. The esplanade is a pretty promenade on which a lawn-tennis club is installed. It runs along the margin of the sea for a considerable distance. People take the air also upon the pier from which you can get a comprehensive view of the harbour. The evenings are generally cool enough to permit one to walk about, a fact which we naturally appreciate.

Sunday, 25th January.—We arrive at the only promenade of Singapore, situated three miles from town, by fine avenues passing through the midst of European dwellings scattered about in verdant parks. Government House, which we leave on our right upon an eminence is a fine building surrounded with a park. The Botanic Garden is environed by charming villas, but scarcely merits its name save as a matter of etiquette. There is little shade there. An aviary contains some beautiful specimens of the birds of this region.

The garden is enlarged almost every year at the expense of the neighbouring forest, a forest which in several respects is yet still virgin. In one of the paths recently made in it, we watch with curiosity the gambols of a band of large monkeys which leap from branch to branch. After a long detour in the country we return to a pretty lake where swans are gliding about.

In the evening we visit the pretty residence of the Director of the Messageries charmingly situated upon an eminence from which one can see the bay. For a period of twenty years M. Brasier de Thuys has gathered an interesting collection of *objets d'art*.

Monday, 26th January.—The Chinese boat, which after several stoppages will arrive at Batavia as soon as it can, leaves Singapore this evening. It is not a comforting prospect. Before coming to a decision we take a sampan rowed by a single Chinaman, and go on board. The sea is a little lively, and

the sampan, a mere nut-shell, is knocked about a good deal. We find the steamer surrounded by trading craft. We have to achieve a gymnastic feat, perilous in proportion to the roughness of the waves in order to pass over these boats and reach the side-ladder. The filth and discomfort of the ship is unspeakable. The cabins are habitable. The meal served on deck for the English officers would have at once destroyed the most voracious appetite. This visit takes away from us all desire of departure, and causes us to find charms in a stay in Singapore, to which we hasten back, executing the same gymnastic feats as before, only in the opposite direction.

Tuesday, 27th January.—We leave at six o'clock, and the coachman conveys us to the Chasseriau estate in forty-five minutes. The journey is delightful through a beautiful green country. The property of M. Chasseriau, a Frenchman, is in process of transformation. The cultivation of manioc for tapioca, which from 6 piastres has fallen to *3.*50 per picul, not being any longer profitable, he is substituting for it the cultivation of coffee. The life of the proprietor is very interesting.

Having landed at Bourbon at the age of sixteen years, unable to read and write, in three months he becomes an accountant. He leaves for Mauritius, then for Penang where he enters a sugar plantation as an assistant. Soon afterwards he takes up on his own account in Province Wellesley an abandoned estate, infested by pirates, whose former proprietor had even been assassinated. There he made his fortune: but desirous of revisiting France, he purchased a vine-crop near Bordeaux and married there. The phylloxera destroyed his property: he returned to Penang where his partner had brought the estate to grief. He was ruined, but he obtained a concession at Singapore for ninety-nine years and to it added other adjacent portions of land, the whole containing about 3,108 acres. M. Chasseriau has lived in Singapore for eighteen years. He is sixty years of age and is yet very robust.

Tapioca.—Manioc is a small shrub propagated by slips, which are uprooted after the manner of potatoes. The elongated root is of a whitish substance and tastes exactly like chestnut. Its cultivation has become very expensive, on account of the manure, which has to be imported. The preparation of the root is proceeded with on the spot in the factory, like the manufacture of potato-starch. A washer is made use of to cleanse and remove the bark. A second machine, the rasp, forms the *fecula*.

This latter passes through two sieves from which it issues with water. This water is collected into large reservoirs where the pulp is deposited at the end of several hours. Thence it is removed in big hard and solid lumps which are laid out to bake upon hot plates after the style of tea, where it is kept in constant motion. There the tapioca is formed. It is permitted to cool on large copper dryers, and it is then sent away in large bags. Before being sent out for consumption tapioca undergoes a final process intended to reduce the residue into yet finer powder.

Coffee.—It is well-known that at this moment the cultivation of coffee is undergoing a crisis, almost everywhere, in Ceylon, in Java, in the Nilgheris. This crisis is due to the malady which has suddenly fallen upon the plantations somewhat like the phylloxera in France, without any one being able to put a stop to it. Imported from Brazil,* this pest, which bears the name of *Hemileia Vastatrix* and which attacks the variety of Arabian coffee universally cultivated, consists of a sort of mouldiness falling upon the leaves.

* Incorect: see our remarks.—ED.

A planter from the Republic of Liberia, in Africa, who came to establish himself in Singapore brought with him some seeds of Liberian coffee, which were unproductive. He had made a present to M. Chasseriau of some slips which on the contrary produced splendid results, even when planted in soil that was unprepared. The Liberian coffee shrub is a real tree which in a few years, in its original habitat, attains a height of from thirty to forty feet, and is enormously productive. This coffee has an excellent flavour.* From a careful study of this plant, M. Chasseriau has concluded that it presented several characteristics of a nature to render its cultivation more profitable than that of the Arabian variety.

(1). Whilst the Arabian kind is only worth anything at a height of at least three thousand feet, which limits coffee cultivation to mountains, the Liberian can live near the sea-side and up to a height of 1,800 feet.

(2). Becoming a tree rapidly, the Liberian is productive in truly marvellous proportions.

(3). These coffee plants undergo the malady without being any the worse.† The leaves that are attacked soon fall and are easily replaced. The only remedy employed is manure.

(4). The revenue from twenty or thirty acres planted under Liberian is more considerable than that from two or three hundred acres planted with Arabian.

M. Chasseriau, has made an exact calculation of the minimum expenditure and income per acre planted under Liberian. This calculation is based upon a period of six years beginning from the time of planting. It is the period of the smallest yield.

Mode of preparation.—M. Chasseriau realises an economy besides in the preparation of manure, in causing the turf to be raised, which is disposed in heaps of eight feet broad and three feet high. While the turf is slowly burning the grass which has sprung is lifted in its turn and arranged in smaller heaps, which are set on fire, care being taken to cover them with earth so that the smoke does not escape. At the end of six hours a black mould is thus obtained with which the holes made at the roots of the coffee shrubs are filled up. The labourer who does this is paid at the rate of 17 cents a day, and in one day he can arrange thirty plants. The seed-plots are sheltered by matting in special nurseries. M. Chasseriau possesses at present a hundred-thousand young plants. His workmen engaged in transplanting make use of a long and narrow hollow cylinder, which they plunge into the soil around the slip, after having moistened the earth, which thus adheres to the instrument. The cylinders containing the young plants are brought to the plantation. The slip is extracted after the cylinder has been pushed into the soil, and it is covered up with dry moss. The plantation occupies at this time from four to five hundred Chinese or Malay labourers under the supervision of two European overseers. The intelligent and continual activity of the proprietor has made this plantation one of the finest that can be seen. We observe there for the first time an experiment in cultivation upon level soil, which may, on account of the lack of drainage, bring about the inconvenience of the rotting of the roots. Upon the slopes the system of drainage is excellent. The rows of shrubs are disposed in successive terraces communicating by canalisations. The water is directed along the hollows. It is enough besides to water only once, after planting

* Unfortunately the public do not like it.—ED.

† So we hoped in Ceylon, but in reality the virulence of the disease was in proportion to the increased surface of the leaves.—ED.

unless a great drought requires the soil to be moistened before that operation. The neighbourhood of still uncleared forests is perceptibly injurious to the cultivation of coffee. The monkeys are excessively fond of the coffee berries; three hunters are specially told off to kill all those that trespass on the estate. These forests contain also numerous deer, tigers, and reptiles. A watchman this morning recognised the tracks of a tiger. In order to rid themselves of these unpleasant neighbours, the Chinese frequently set fire to the woods. A conflagration had recently occurred.

We take delicious coconuts whose milk is druuk, and whose kernel, of hazel-nut flavour, is eaten with relish. Besides the fruits of the country, among which are the pineapple and the banana, we find the pamplemousse.

The country is very undulating and the two promenades we take through the plantation, sometimes in our carriage, sometimes on foot, are very pleasant. The property contains twenty-seven miles of roads perfectly kept in order for the passage of wheeled vehicles. The mill for the manufacture of tapioca can without too much expenditure be converted into a factory for coffee.

BRITISH INDIA TEA COMPANY, LIMITED.

The annual general meeting of the above company was held on the 21st inst., under the presidency of Mr. Arthur Capel. The following report was adopted and a vote of thanks to the chairman passed:—

The directors beg to submit to the shareholders the annual statements of accounts, duly audited, as follows:—

1.—Revenue statment for the past season 1885-86.

2.—Statement showing the working of the gardens for past season 1885-86.

3.—General balance sheet to June 30th, 1887.

4.—Profit and loss account.

From the accounts it will be seen that the amount of £3,794 15s 1d. stands at the credit of the revenue statement, and after deducting from this £1,183 12s for debenture interest, £1,033 16s 6d for extension, and £119 19s 10d for income tax, &c., there remains a balance at profit and loss account of £1,101 18s 9d. As there is a very fair presumption that this poor result on last year's working is exceptional, and considering the prospects of the present season are more encouraging, the directors recommend adding to the above balance of profit and loss account the sum of £418 13s 9d, out of the £1,000 reserved last year for equalising dividends, to allow of the payment now of 2s 6d. per share, leaving £581 0s 3d still at reserve.

PRODUCE OF 1885-86.—The crop for this season was estimated at 588,000lb. of tea; the actual quantity made and shipped, however, was 632,234 lb., being an increase of 44,234 lb. on the estimate, and of 35,779 lb. on the actual of 1885. It was disposed of as follows:—

Shipped to London and sold there	617,172 lb.
Lost in transit—value recovered	4,670 „
Trade allowance for taring, &c.	10,392 „
Total crop	632,234 lb.

The sales show the following results:—

Chests.	Invoice weight. lb.	Account Sales weight. lb.	Nett proceeds. £ s. d.
6,997	632,234	621,842	20,041 12 2

Average per lb., gross 9·53d.; nett 7·73d.

In the half-yearly report issued last January, the directors referred to the very serious falling off in the yield at Urrunabund owing to the hailstorms which had taken place at that garden in April and May last year, the out-turn being 29,918 lb. less than was estimated; but for this unfortunate visitation there would have been about £1,000 more at the credit of profit and loss account.

This is the more to be regretted as the prices of Indian tea during the past year were the lowest on record, and showed an average fall of nearly 3d per lb., as compared with the previous year, the drop in the prices of this company's tea being exactly 2¾d per lb.

It will be seen from the accounts of nearly all the Cachar concerns, that the crop throughout that province was an exceptionally poor one, owing mainly to climatic causes, and unfortunately this company suffered with the rest in this respect.

The following abstract of the 1885-86 revenue statement, gives the results per lb. worked out on the account sales weight, viz., 621,842 lb.

	£	s.	per lb. d.	d.
Gross proceeds of tea sold &c.	24,965	4	4	=9·53
Less expenditure—				
Total Indian	21,233	3	0	=8·19
Less equation of exchange	5,579	0	6	=2·15
	15,654	2	6	=6·04
London charges	432	14	4	=0·16
Freight, dock dues, insurance agency, &c.	4,653	11	2	=1·80
Total..	£20,740	8	0	=8·00
Commission to garden managers	160	1	3	=0·06
Total expenditure under all heads	£20,900	9	3	=8·06
Profit...	£3,794	15	1	=1·47

By the above figures it will be seen that the cost of working, including all expenses, was 8d per lb., and the estimates for 1886-87 show that it is to be kept within that figure this year, but the special attention of all the managers has been called to the consideration of the best means of effecting still greater reductions in expenditure, and again to the very important question of improving the quality of the tea, in order that a possible further decline in market prices may be met by a saving on the total estimated cost.

The usual profit and loss statements of each garden are shown, giving the results of each for the past season as compared with those of 1884-85.

ESTIMATES.—The out-turn has been put at 7,950 maunds, or 636,000 lb. for a total Indian outlay of R222,854, which at an exchange of 1s 5d per rupee, would be £15,785, or 5·96d, f.o.b. Calcutta; to this has to be added £5,425 for stores, machinery, freight, dock dues, sale charges, and London expenses, making a total expenditure under all heads of £21,210, or 8d per lb.

The directors are glad to be able to state that no serious hailstorms have occurred this year, and that the out-turn received by telegram, showed an excess to July 9th of 62,900 lb. as compared with the figures to the same date last year. It therefore seems very probable that the estimated yield will be obtained, if not exceeded.

MARKET STATISTICS.—The following figures will be interesting to the shareholders:—

	lb.	lb.
Total imports from India in 1886-87	78,200,000	
Total imports from Ceylon in 1886-87	8,060,000	
		86,260,000
Total deliveries—India, in 1886-87	75,425,000	
Total deliveries—Ceylon in 1886-87	7,744,000	
		83,169,000
Estimated imports—India in 1887-88	86,000,000	
Estimated imports—Ceylon in 1887-88	16,000,000	
		102,000,000

The above heavy increase of 16,000,000 over last year's imports would point to a further drop in prices; but the consumption of Indian and Ceylon

teas has, so far, kept pace with the imports, and if this continues—which it is expected by many will be the case—prices may be maintained.

The directors who retire by rotation are Mr. Alfred Wilson, and Mr. Alex. Lawrie, both of whom, being eligible, offer themselves for re-election.—*H. & C. Mail.*

THE TEA TRADE OF CHINA IN 1886.

From the report of Consul General Hughes to the Marquis of Salisbury on the trade of Shanghai for 1886 we quote the following :—

In the total export of black tea for 1886, the returns show a considerable increase, amounting to 3,324,933 lb. more than the export of 1885. This is accounted for by the increase of the export to America and Russia. In the export to England there was a decrease of 938,400 lb. Tea had never been bought in China so cheaply as in 1886, and the low rates of exchange were in favour of buyers : but it was sold in London at lower prices still, and the result was disastrous to shippers. The ill reception which China tea now meets with is ascribed to various causes. For example, the leaf is said to be hastily prepared, and to be consequently wanting in keeping power ; the competition of Indian tea is also an important factor in the question, but, perhaps, the manner in which the London market is flooded with China tea is the chief cause of its depreciation in value. Defective preparation of the leaf is a matter which the Chinese can be induced to avoid if they find it their interest to do so ; and to make them feel that it is their interest is the business of the foreign buyer. Competition of Indian tea may, of course, be taken into calculation by the ordinary buyer. The overstocking of the London market would seem, at first sight, easily prevented ; but, owing to the conditions under which the trade is conducted, this is really a question of considerable difficulty, which has not yet received a satisfactory solution. The result is that in no business are losses of such frequent occurrence, if we may judge from the complaints which are heard every year. Profits are apparently rare ; and, indeed, under existing circumstances it is hard to see how they can be expected. Many millions of pounds of tea are hastily shipped and despatched by steamers to London. This apparent hurry is for various reasons unavoidable. On its arrival—and the vessels' arrival at intervals of a few days—the tea is often got rid of at auction sales without reserve, even faster than it was shipped in China. Comment on a system so well known and often discussed may seem unecessary ; but the subject is of so much importance that one may be excused for briefly alluding to it, in the hope that qualified persons may be able to suggest a remedy for a state of things which seems to those concerned in shipping tea from this country a perennial source of unavailing grief. It may be objected that these remarks are more applicable to the ports from which the bulk of the first crop of tea is shipped than to Shanghai. This is no doubt the case, but the subject is one in which the merchants of Shanghai are deeply interested. The hopeful sign in the black tea trade is its great power of expansion, and the prospect that in a few years the use of tea will become much more general than it is at present on the continent of Europe, as well as in America. There was, as usual, a considerable decline in the export of green tea to England, a decline which was not compensated by the proportionately small increase in the export to America ; so that, on the total export of green tea, there was a falling off amounting to more than 3,000,000 lb. on the export of the previous year. America is still the great consumer of green tea The losses in 1885 induced caution among foreign buyers, and several of the shipments were made on Chinese account. The results are said to have been satisfactory.—*L. & C. Express.*

MR. E. H. EDWARDS ON SEYCHELLES.

[We quote the following article for two reasons : Mahé is an important place of call for steamers, and the Mr. Edwards mentioned was formerly well known in Ceylon.—ED.]

We print in another column a copy of a letter that has been handed to us for the purpose by Mr. E. H. Edwards of Seychelles. As will be seen, it was addressed to Mr. E. Didier St. Amand, and it is highly instructive from beginning to end. The first item alluded to is the old cry for roads and bridges. It really seems as if Mahé was destined to remain without roads for ever. Mr. Franklyn gave the first push to road-making, and perhaps accomplished more in that direction, out of the same amount of revenue, than any man who has followed him. There does not appear to have been any great activity, in 1886, in pushing on new lines of communication. The sum put down in the estimates for that year is simply absurd ;—R1,500 for extensions and maintenance of roads and bridges, is a simple financial farce, and no more. It is presumed that some equally munificent amount would be provided under the head of construction and maintenance of public buildings. It is evident, however, that there could not be either any extension of roads nor erection of new buildings ; and the office of Superintendent of Public Works must in the circumstances have become a mere sinecure. A salary of R3,000 a year for superintending the expenditure of about an equal sum is manifestly absurd. The holder of the office is not to blame for this state of things. It is those upon whom the duty devolves of distributing the revenue amongst the objects for which it is raised. The local rate is levied for the express object of road-making. In fact, it used to be called the road-tax. What becomes of that money—about R15,000 a year? Surely there is a screw loose somewhere. What are the sapient Board of Civil Commissioners about, that they pass such estimates? But we had forgotten. The independent element was eliminated from the Board some years ago. As Mr. Edwards pertinently observes, the Board requires to be re-constructed.

Mr. Edwards has put his finger upon a sore place when he speaks of "The Moitié System" as being "one of the principal sources of vagabondism." But, whilst some persons may admit the existence of the evil complained of—that is, vagabondism—few people in Seychelles would care to assist in the suppression of the "moitié-system." The parents of the system are idleness and poverty, and vagabondism is the true representative of both. A man has a piece of land which he either cannot, or will not, sell. He, and his sons, are too proud to work it ; for who ever heard of a Seychelles landed proprietor tilling his own ground—that is, with his own hands? He has no money with which to pay for labourers. So he has recourse to the moitié-system. He induces people to squat on his ground, to each of whom he assigns a portion of it to be planted with something—manioc, pumpkins, maize, sweet-potatoes. If the squatter really means work and intends to stay he may raise a few bananas and plantains ; but he will never rise to the dignity of a cocoanut. When harvest time comes they—he and his landlord—divide the fruits of the earth between them. So far, the system has no radical defect. The arrangement

appears at first sight to have been mutually beneficial to both parties, and when both parties loyally fulfil their respective contracts there is no doubt that it is so. But that is seldom the case on either side. In the first place the squatter is not bound as to the quantity of produce he shall raise. He may be, and often is, an arrant vagabond who has no desire to be kept close at work at fixed wages. His primary object is to obtain a fixed domicile and an ostensible occupation. He is then out of reach of the police. He works by fits and starts, does a little in the way of petty larceny, and otherwise amuses himself. The consequence is that the produce of the soil that falls to the share of the landlord is not very much. He may rub on, however, if he can get a dozen of these gentry upon his property, especially if he has a few score coconut trees as a stand-by.

But it may be easily inferred that the evil is only yet in the bud. It will next blossom. Then follows the ripe fruit. They are now gathering the fruit at Seychelles, just as we are gathering the same product in Mauritius. The ripening process may not have been the same in both places, but the result is the same always. We have seen how the Seychelles squatter obtained his domicile. It is admitted that, occasionally, he may have been honest and industrious, but as a rule, he was neither one nor the other —at least, not in an eminent degree. Having land and a hut, he was free to "engage," as his labourers, other people to help him. The landlord would make no objection to "numbers," if the amount of "produce" was increased; so the one hut become two, three, or four, upon each "allotment." These "labourers" may, or may not, have been *bona fide* workers. As a rule, they were *bona fide* idlers by day, occasionally displaying a little more activity at night. And so the thing went on until the evil of vagabondism assumed its present ugly proportions. The "Moitié-Moitié-system," as it is termed, has called into existence numerous centres in which idleness revels unchecked, in which vagabondage and vagrancy find homes, and in which crime too often lies securely hidden.—*Commercial Gazette.*

BELIGEDI OR BAEL FRUIT.—In your paper of the 5th August the following para is quoted—"According to a London market report in the *Chemist and Druggist* this fruit was without demand. At auction 450 whole fruits, with soft pale pulp, were offered and bought in at 3d each." The equivalent of 3d English money in Ceylon currency, I believe, is 16 cents. According to my experience of the price fetched for a beli-fruit at the market is one cent, and it struck me forcibly that 16 cents for it was more than could be desired,—a price that no Sinhalese would in his wildest dream have expected. Is the bael-fruit imported to England from Ceylon, and is it also the fruit that is commonly called slime-apple? If it is so, it is largely used by the natives in cases of chronic diarrhœa and dysentery. The infusion of the fruit thinly sliced, or the whole fruit boiled, or roasted under hot ashes, is prescribed generally in such cases. Will you enlighten me on the subject?—*Cor.*

THE quantity of tea that arrived at Kobe from the various tea districts, during last month, was 3,694,825 lb.; of leaf sold to foreign firms, 3,789,450 lb., the quantity in stock being 841,148 lb. The average price was $29¼ per picul for superior quanity, $19 6-10ths for medium, and $12 8-10ths for inferior. —*Japan Weekly Mail*, July 16th.

A NEW INSECTICIDE.—The Horticultural and Agricultural Chemical Company, Tonbridge, Kent, of which Mr. G. Freeland is manager, were present with a new insecticide, which will be of interest to the owners of tea-plantations and to fruit-growers abroad generally. The preparation is described as essentially a complete and permanent emulsion, in which has been incorporated a large quantity of oily liquids (including certain kinds of paraffin oil) as destroy the insect pests of plants. Hitherto the rough methods in use for preparing such emulsions have failed to effect the perfect distribution of the oily matter in the wash, and in consequence oily drops of sensible size have spotted and injured the leaves and tender shoots of the plant. By a long series of experiments, however, the inventor of the new insecticide has discovered a method of incorporating these materials in the preparation under notice, which has received the patronage of many leading growers of fruit and flowers, and, among other authorities, of Professor A. H. Church. The preparation is sold in bottles of 8 and 20 oz. for gardeners use, and in casks and drums for use on a larger scale. A single gallon is sufficient to make from 150 to 200 gallons of efficient wash. The invention is of great importance in its application to the tea-plant, which suffers from blight in the dry season; and it has been pointed out by Professor Church that the paraffin in the insecticide would not affect the tea, as it has been used in greenhouse on scented plants; and, though the smell is perceptible for forty-eight hours, it was not permanent. The company introducing the new discovery should therefore before long find the preparation in demand among tea-growers, to say nothing of the numerous cultivators of fruit at the Antipodes.—*British Trades Journal.*

HYDROCHLORATE OF COCAINE IN VETERINARY PRACTICE.—The Inspector of Cattle Diseases, Madras Presidency, writes in his report for 1885-86:—Having heard a great deal regarding the advantages of the use of Hydrochlorate of Cocaine in operations on the human eye, I decided, on the first opportunity, to give it a trial. Fortunately, a case of "worm in the eye" (Filaria oculi) was admitted into the Veterinary Hospital on the 2nd of June 1885. The patient was a large waler mare, extremely troublesome and nervous; in fact, it was with the utmost difficulty that anything like a good view of the eye could be obtained. I therefore cast her, when the parasite was clearly seen wriggling about in the aqueous humour. There was slight inflammation, with partial opacity in the lower portion of the cornea, involving nearly one-half of its surface, which was undoubtedly brought about by the case having been allowed to go too far before surgical aid was sought for, as the worm had been noticed in the eye fifteen days before the mare was brought to me. I procured a solution containing one grain of cocaine in twenty-five minims of water, of a strength of 4 per cent.; the Membrana Nictitans was held back and the solution painted over the surface of the cornea, conjunctiva and eyelids with a camel's hair-brush. In about ten minutes complete anæsthesia had taken place, with considerable dilatation of the pupil. I then made a small puncture with the point of a Macnamara cataract knife, well guarded with lint at the upper portion of the cornea, through which the Filaria escaped. In a little less than twenty minutes sensation returned to the eye. No inflammation followed the operation, and the case did well from the first. The opacity gradually disappeared and the patient was discharged cured in fourteen days. This new local anæsthetic cannot but prove of the utmost value in veterinary practice, more especially in operations on the eye. It has only one drawback, and that is its high price. Previously, in operations of this kind, I always used to administer chloroform with the best results, but, of course, although I have never had any accidents with chloroform on the horse, still the danger attending its use, compared with the use of cocaine, is great indeed. Therefore, the latter must, for the future, act as a valuable and safe substitute for chloroform, for the production of local anæthesia.

THE TRADE IN DOUBLE MANURE SALT.

The manufacture of "double manure salt" has become an important industry within the past few years, the centre of production being at Stassfurt, in Germany. The import of the article into this country, where, as its name implies, it enters into the production of chemical fertilizers, has been on a steadily increasing scale since its first introduction, about ten years ago. At first the quantity made was not of enough consequence to entitle it to a prominent place among merchantable commodities, but of late years the Stassfurt manufacturers have paid more attention to its production, and it is now brought over here and is consumed extensively by the manufacturers of phosphates. Double manure salt is a sulphate of potash and sulphate of magnesia, being a concentrated form of kainit and kieserite. The manufacturers, finding it a good substitute for the pure sulphate of potash, have gradually given it preference over the latter, until it has practically superceded the sulphate. With the manure salt the manufacturers are able to use the moist ammoniates in the production of superphosphate, as according to their testimony the sulphate of magnesia, which constitutes forty to forty-five per cent. of the salt, absorbs the moisture and produces a "drillable" fertilizer. For most purposes, however, the pure sulphate of potash would no doubt be given the preference, but for the great difference in cost. Sulphate of potash pays a duty of 20 per cent.,* while manure salt is admitted free; hence while the former is quoted in this market at two and a quarter to two and a half cents per hundred pounds for 95 to 98 per cent. sulphate of potash, the latter is obtainable at 1·05 cents per hundred pounds for 48 to 50 per cent. sulphate. Other competing products have been affected adversely by the introduction of manure salt, principal among which is muriate of potash, which, although imported on a larger scale than before the manure salt was introduced, does not enter as extensively into the composition of superphosphates as formerly. The growth of the chemical fertilizer industry in this country has been very great during the past few years and a comparison of the imports of double manure salt with those of competing chemicals would therefore be valueless as showing to what extent the former has supplanted the latter in the estimation of superphosphate manufacturers. The receipts of kainit and kieserite as would naturally be inferred, show a falling off in consequence of this competition, the superphosphate manufacturers preferring the double manure salt which although composed of kieserite and kainit contains a much smaller percentage of chlorine, and element injurious to plant life. On the other hand the receipts of muriate of potash have increased which is to be accounted for by the fact that agriculturists in many cases prefer to use this chemical by itself as a fertilizer.—*Oil, Paint and Drug Reporter.*

* In the United States.—ED.

A BURDEN UPON AGRICULTURE.

The following article from a publication sent to us from the United States Department of Agriculture, shows that mortgages are not lighter in America than in Ceylon:—

A mortgage is a blessing when it enables a poor but industrious young man to secure a home and a profitable business and to pay for it in sure and easy installments; it is a withering curse when it makes production dear and difficult, consumes a crop before it is made, and renders indebtedness hopeless. The system of advances by merchants or brokers upon growing crops is especially dangerous and disastrous. It is not usually a prevalent practice, except in districts where a single crop dominates rural industry and brings ready money at any time, rendering borrowing easy and encouraging the habit of spending before earning. It has been prevalent from time immemorial—at least for forty years, from personal knowledge of the writer—in the cotton States. No product of agriculture is more surely a money crop in any part of the world than cotton, and none more promptly traverses the ways of commerce. It has therefore become, with perhaps one principal associate—maize—almost the sole product of large districts of country, rendering necessary the purchase abroad of supplies of all kinds, agricultural and industrial, and their original cost, long-distance transportation and wholesale and retail profits, render them exceedingly expensive. It is selling the cheapest cotton in the world and buying all supplies at enormous prices—a practice with which only fertile lands, abundant crops, and persistent industry can save from bankruptcy. In the Northwest, where wheat is a specialty and the predominant crop, the mortgage appears to be one of the essential equipments of the farm. The extent of indebtedness there deserves future investigation. Our correspondents have so frequently referred to this burden upon agriculture, advances secured upon the growing crops and permanent indebtedness resulting mainly from this practice, that the State agents of the cotton States have been asked to state the facts and make some estimates of the extent of the evil. As a result the following answers are given: [Then follow replies thus summed up]

This record makes a burden of interest that is unendurable. The estimate of North Carolina is 25 per cent., including the advanced prices of supplies furnished; of South Carolina, 15 per cent.; of Georgia, 50 per cent. in the prices of advances, and 10 per cent. interest on pastive indebtedness; of Florida, 16 per cent.; of Alabama, 50 per cent. increase in price of goods and 20 per cent. on mortgages; of Mississippi, 15 per cent. on advances, without reference to increase of prices, and 10 per cent. on general indebtedness; of Louisiana, 15 per cent., besides higher prices of goods and more for advances by country merchants; of Texas, 12 per cent. nominal interest for supplies charged at excess of 25 to 50 per cent.; of Arkansas, 10 per cent. by contract, on supplies charged an extra profit of 40 per cent. These are the averages assumed by our State agents as the cost of interest on advances secured by crop liens. It appears that a large proportion of cotton planters are in debt for current supplies, and that the loss resulting amounts to five million dollars per annum in some States, and absorbs nearly or quite all the profits of production, while the soil is wearing away, with the lives of the cultivators, for the benefit of the commercial class.

ROYAL GARDENS, KEW.

(*From the Bulletin of Miscellaneous Information.*)

ANNATTO.

(*Bixa Orellana, L.*)

From the seeds of *Bixa Orellana* is obtained a colouring sustance which is known under various names. It is called Annatto, Arnatto, or Annotto in Jamaica; in the French islands it is known as Roucou, Urucu, Rocour; while on the Spanish Main the Indians call it Achiotl. This colouring substance has long been known and used for various purposes. It is, however, liable to so many fluctuations, and the prices generally are so low, that it has never received serious attention in British Colonies, and hence few, if any, plantations have been exclusively devoted in such colonies to the Annatto plant. The Annatto of commerce is practically, therefore, a forest product obtained from wild or semi-wild plants, and the supply has only kept pace with the demand. Of late years a slight revival has taken place in the use of Annatto, especially in America, and inquiries have in consequence been made for information as regards cultivation, preparation, which it is proposed to supply as briefly as possible in the following notes.

The Annatto plant is a native of tropical America, but is now widely distributed throughout most tropical countries, where it is often found in a naturalized state, and growing freely in waste places and around native villages. It seldom attains a greater height than 8 to 12 feet, but is of stout bushy habit, well furnished with bright attractive foliage. These are about 4 inches long and 2½ broad with a long petiole, and dotted. The showy flowers are produced in loose panicles at the ends of the branches,

with five petals of a rosy and sometimes of a white colour. The stamens are very numerous, yellow, tipped with purple. The fruit consists of a dry ovate or mitre-shaped capsule covered with soft spinules, brown or green when ripe, splitting into two valves, on the inside of which are attached numerous (30 to 40) seeds. These seeds are about the size and shape of grape seeds, and covered with a waxy substance (the testa), which readily stains the fingers a red colour. This waxy substance covering the seeds yields the Annotto of commerce, and gives the plant its chief industrial value.

Annotto plants are readily raised from seed, and are of a hardy character. They prefer cool, moist situations, such as the banks of streams, and luxuriate in shaded places in and around dwellings. They are, however, readily established on comparatively poor soils, and although the growth under such circumstances is necessarily less robust, the yield in seeds is fairly large. If a plantation of Annatto is proposed to be established, plants may first be raised in seed beds in nurseries, and transplanted during the rainy season when about 6 or 8 inches high. The distance apart of permanent plants may vary from 10 to 15 or 20 feet, according to the character of the soil and the nature of any subsidiary cultivation that may be carried on. In many cases seeds may be sown at once in the places where the permanent plants are desired, and of the seedlings grown, the strongest only is ultimately retained. As cattle, horses, and goats do not eat the leaves of Annatto, planters in the West Indies often u ilize hil y pasture lands by planting Annatto upon them. In this way very little expense is incurred for maintenance; and should the price of the produce prove of an unremunerative character, no steps are taken to gather the crop.

The range of cultivation for Annatto is a wide one. In the West Indies it grows readily from sea-level up to an altitude of 2,000 feet. In Ceylon it is known to grow up to 3,000 feet, but it is particularly flourishing in the lowlands. It appears to be well adapted for moist warm situations, with a mean annual temperature of 75° to 80° Fahr. It requires an abundant rainfall, and hence is not suitable for arid situations, or those subject to prolonged droughts. Under favourable circumstances Annatto plants begin to yield seed in about two years, and remain fruitful for a long period.

The plant is supposed to be wild at Jamaica and St Lucia, in the British West India Islands, and in the former island it has been extended by partial cultivation. The export of Annatto seeds from Jamaica in 1886 consisted of 369,284 pounds, of the value of 7,693*l*. At Guadaloupe, one of the principal French islands, Roucou, as it is there called, forms an important article of export, and the returns show the existence of 48 Roucou plantations, employing 1,044 labourers. The export in 1883 consisted of 700,500 kilos of prepared Roucou. [Flag Annatto.]

As regards British Guiana, the Superintendent of the Botanic Garden, writing in 1881, remarks as follows:—"Though the Annatto plant is a nat-"ive of British Guiana, and abounds on the banks "of some of the rivers, it does not appear to "be cultivated at all, nor is the fruit of the "wild plant turned to any commercial account. All "the Annatto that is exported from British Guiana "is first imported, and the source from which it comes, "so far as I have been able to gather, is French "Guiana. A portion may occasionally come from "Surinam." As may naturally be expected, a plant of so hardy a character, and the seed of which is so easily carried from place to place, has long been established throughout the Tropics. At Ceylon the plant is supposed to have been introduced by the Dutch, and long ago as 1829 it was used as a dye plant by basket makers at Kalutara.

In the Report of the Director of the Botanic Gardens, Ceylon, for 1881, it is mentioned: "Several "gentlemen have made inquiries as to the mode in "which Annatto is prepared for the market; and, as "I could find no very definite published account, "I applied to the authorities at the Royal Gardens, "Kew, for information, and have received several "communications from them, the most important "being from Mr. Vilmorin's report on 'Produits "Agricoles non Alimentaires' (Paris Exhibition, "'Rapports du Jury International'). The following "is a summary:—*Bixa Orellana* is native to Tropical "America, but fairly naturalized in other hot coutries, "as in India and Ceylon. Annatto (Roucou is the "French name), however, is prepared almost wholly "in the French colonies, chiefly Cayenne (French "Guiana) and Guadaloupe (which each produce about "400-500,000 kilos), but lately taken up also in "Réunion and the Indian Possessions of France. The "Guadaloupe samples were the best at the Paris "Exhibition."

In India the two forms of the species, one with pink flowers and brown capsule and the other with white flowers and greenish capsule are well represented. Dr. Buchanan, writing in 1833, mentions the Annatto plant as follows:—"The *Bixa*, an American plant, "is now rapidly spreading over Bengal, the inhabitants "having found it a useful yellow dye, which they "employ to give their cloths a temporary colour in "*Dolyatra*, or festival of Krishna. With this also they "colour the water, which, on the same occasion, they "throw at each other with squirts. For these purposes "it is well qualified, as the colour easily washes out, "and the infusion has a pleasant smell. By them "it is called *Lotkan*, and they say that before it grew "commonly in the country, the dry fruit was brought "from Patna. Probably some other fruit was then "brought, and its use has been superseded by that "of the *Bixa*, to which the natives have given the "old name, as there can be no doubt of its being an "American plant, and its fruit could scarcely have been "brought here from the West Indies. In many parts "it is called European Turmeric."

As regards the preparation of Annatto, it would appear that various methods are used, with the result that an article is produced with a wide range of merit and a corresponding variation in market value. At the request of this establishment, inquiry was made respecting the method adopted in French Guiana, and the Superintendent of the Botanic Gardens at British Guiana obtained the following from the French Consul at the place. The manufacture of Roucou is as follows:

"Pick the small red seeds from the husk, put them "in fresh and clear water to soak for not less than "two days, then pass them through a mill or crusher. "When crushed let them remain 24 hours in fresh "water; after this pass them through a sieve; the "residue is again passed through the mill until nothing "remains of the seeds.

"The produce of the seeds so prepared is put in "water until it has precipitated; the surface water is "then made to run out. After the surface water has "become perfectly clear, the paste is boiled during "four or five hours time. After this process has been "gone through, the paste is placed in cases with "curing holes, with a weight placed on it, and a cloth "at the bottom to prevent the finely crushed powder "from passing through. When the above process has "been gone through, the paste should be in a fit "state for shipment. It is then packed in layers "with plantain leaves between each layer to retain the "necessary amount of moisture and to check acidity."

A method for preparing Annatto, at one time prevalent in the West India Islands, is well described by Dr. Macfadyen in the *Flora of Jamaica*, p. 42, in the following words:—

"It is from the pulp which covers the seeds of this "tree that the substance known by the names of "*Arnotta* or *Annotta* in England, and *Roucou* in France, "is procured. It is collected by pouring boiling water "on the seeds in any convenient vessel; after stirring "the whole, the water, with the farina suspended in "it, is poured off; and this is repeated till the naked "seeds are left. The water, after allowing it to stand "for some time, is then to be poured off clear leaving "the *Arnotta* which has settled at the bottom. The "addition of an acid is said to hasten the process. "The sediment is afterwards to be placed in shallow "vessels and dried by evaporation in the shade. When

"it has acquired a proper consistence, it is to be made "into cakes or balls; after which it is so to be thoroughly "dried till hard, when it is in a fit state to be sent "to market."

To this Dr. Macfadyen adds some general remarks as regards Annatto and its local uses in the West Indies, which, as they occur in a book now comparatively scarce, may be usefully included in these notes:—

"*Annatto* is of a resinous nature, and dissolves "more completely in alcohol than in water. When "prepared for market it is moderately hard, of a "brown colour externally, and dull red within. It is "occasionally imported in cakes of two or three pounds "weight, of the consistence of paste, wrapped up in "large flag [banana] leaves, and packed in casks. "The roll *Annatto* is much harder, and of a very "superior quality, containing a larger proportion of "the colouring matter. It was formerly employed in "dyeing silk, to produce the colour called *Aurora*. "As the addition of an alkali increases its solubility, "it is the practice, when used in dyeing, to mix it "with at least its own weight of potash. It is now, "however, but seldom employed as a dye in Great "Britain. The Indians mix it with oil, or with lime-"juice and a gum, to make the crimson paint with "which they anoint their bodies, not so much for "the purpose of ornament as to protect them from "the attacks of insects. It is said to be esteemed "by painters as a colour. In Gloucestershire it is "employed under the name of *cheese colouring*, to "give a yellowish-orange tint to cheese, and in Holland "to butter. It has never had any great character "as a medicine. It is a gentle purgative, and a light "stomachic; it has been employed in dysentery, and "as an antidote for the bitter Cassada. The Spaniards "use it in their chocolate and soups to heighten the "flavour and to give a rich agreeable colour. In "Jamaica, a liquid preparation is usually kept for "culinary purposes, made by boiling the pulp, diffused "in water, with sugar and salt to the consistence of "cream, which, if put into well-corked bottles, will "keep for several years."

A method recommended by the Director of the Botanic Gardens at Ceylon for preparing Annatto, and which, no doubt, has been followed in the manufacture of some fine samples of Annatto lately exported from that island, is as follows:—"The best method "of preparation appears to be (there are some "discrepancies in different accounts) the following:— "The seeds, with their pulpy envelopes, are pounded "in a wooden mortar, and, after adding hot water, "the mixture is left in the mortar for several days, "after which it is passed through a sieve. The liquid "is then left to ferment for eight days, when the "water is decanted off, and the deposited pulp left "to become concentrated by evaporation in the shade. "When it has acquired the consistency of firm putty, "it is made up into cakes of 1½-2 kilos weight. "These are packed with plantain leaves, and have a "lively orange-yellow colour; the value is about 4 fr. "the kilo. In Cayenne it would appear that the "pulp is sometimes boiled for four or five hours, "and afterwards put under weights to squeeze out "the water. It is also sometimes made into rolls "instead of cakes, in which state it appears to fetch "an inferior price."

* * * * *

"The trade in Annatto is a limited one. It is used "as a dye occasionally, but its principal employment "is for colouring cheese and butter."

POULTRY NOTES.

Now is the time to apply plenty of whitewash, as the warm weather is here and the chances for being overrun with vermin are increased.

There is nothing connected with poultry raising, either for exhibition or for market, which an average woman cannot do better than the average man.

The droppings of the hens should be occasionally removed; they should not be allowed to accumulate. The floors should be covered with loam or sand.

Poultry require salt as well as other animals. A few pinches of salt in the soft food will make the food more relished, as well as assisting digestion, and keeping the hens in condition.

In the case of eggs while waiting for the hatching, a place is preferred that is neither hot nor cold, damp, nor dry. If the eggs are to be kept but a little while, turning them every day will answer, a box or basket being sufficient.

The hen-house and other outbuildings, if unpainted, will be all the better for a coat of whitewash. A very little glue dissolved in hot water before the lime is put in will make the lime adhere. This whitewash combined with glue should never be used on fruit trees. It is often so applied, but does more harm than good.

Small chickens should never be kept or fed with old ones. They are apt to be injured. Have two or three yards, and separate them according to size and strength.

When a hen becomes broody and you do not want her to sit, the sooner she is broken up the better, as the longer she sits the longer it will take her to recuperate and commence laying again. To do this, shut her up twenty-four hours without food, then let her hunt her own feed. If she takes to the nest, try it again; the third time seldom fails with the most persistent old hens.—*Rural Californian.*

CEMENTS FOR SPECIAL PURPOSES.

The value of a cement is, first, that it should become a strongly cohering medium between the substances joined; and, second, that it should withstand the action of heat, or any solvent action of water or acids. Cement often fails in regard to the last consideration. For waterproof uses several mixtures are recommended, and the following may be mentioned:—

One is, to mix white lead, red lead, and boiled oil, together with good size, to the consistency of putty. Another is, powdered resin, 1 oz., dissolved in 10 oz. of strong ammonia; gelatine, 5 parts; solution of acid chromate of lime, 1 part. Exposing the article to sunlight is useful for some purposes. A waterproof paste cement is said to be made by adding to hot starch paste half its weight of turpentine and a small piece of alum. As a cement lining for cisterns, powdered brick 2, quicklime 2, wood ashes 2, made into a paste, with boiled oil, is recommended.

The following are cements for steam and water joints:—Ground litharge, 10 pounds; plaster of Paris, 4 pounds; yellow ochre, one-half pound; red lead, 2 pounds; hemp, cut into one-half inch lengths, one-half ounce; mixed with boiled linseed oil to the consistency of putty. White lead, 10 parts; black oxide of manganese, 3; litharge, 1; mixed with boiled linseed oil.

A cement for joints to resist great heat is made thus:—Asbestos powder, made into a thick paste, with liquid silicate of soda.

For coating acid troughs, a mixture of 1 part pitch 1 part resin, and 1 part plaster of Paris is melted and is said to be a good cement coating.

Correspondents frequently ask for a good cement for fixing iron bars into stone in lieu of lead, and nothing better is known than a compound of equal parts of sulphur and pitch. A good cement for stoves and ranges is made of fireclay with a solution of silicate of soda. A glue to resist damp can be prepared with boiled linseed oil and ordinary glue or by melting 1 pound of glue in 2 quarts of skimmed milk; shellac, 4 ounces; borax, 1 ounce, boiled in a little water and concentrated by heat to paste. A cement to resist white heat may be usefully mentioned here: Pulverised clay, 4 parts; plumbago, 2; iron filings, free from oxide, 2; peroxide of manganese, 1; borax, one-half; sea salt, one-half; mix with water to thick paste, use immediately, and heat gradually to a nearly white heat.

Many of the cements used which are exposed to great heat fail from the expansion of one or more ingredients in them, and an equal stress is produced; or the two substances united have unequal rates of expansibility or contractility; the chemical or galvanic action is important. The whole subject of cements has not received the attention it deserves from

practical men. Only Portland cement has received anything like scientific notice, and a few experiments upon waterproof, heat-resisting, and other cements would show which cements are the best to use under certain circumstances.—*Van Nostrands' Magazine.*

ARTIFICIAL QUININE.

The startling announcement that a medical man had succeeded in producing quinine artificially has naturally given rise to much uneasiness in the drug market. Such a discovery would several years ago have been hailed with enthusiasm, but just at present the merchants are desirous that chemists who work at the synthesis of quinine should take a very long holiday. At the London docks there lies an overwhelming stock of cinchona bark; in our colonies immense sums of money have been invested in cinchona plantations, and quinine is fast becoming a byword in Mincing Lane for whatsoever is uncertain and unprofitable. We have cried long for cheap quinine; now we have it, and many wish it to be dearer, and watch week after week for the smallest sign of an advance, as though the present low prices were a calamity. We take it that no one who has watched the great advance in our knowledge of the composition of some alkaloids, and of bodies closely allied to alkaloids generally, will dispute for a moment that artificial quinine will yet be produced. The manufacture of salicylic acid from carbolic acid by Kolbe is a most noteworthy achievement of science: and the synthetical preparation of indigo is of itself a proof that chemists are competent to bridge the gap between inorganic and organic bodies. It is little more than four years ago since M. Maumené, a French chemist, announced that by the discovery of H_2N, or amidogen, he had succeeded in building up quinine, and actually deposited a packet of the supposed alkaloid with the president of the Institute of France, while he had the physiological effects investigated. But nothing came of that, although the discoverer had determined the physical and chemical characters of the synthetic body to be the same as those of the natural one. Occasionally there have been scares similar to that of this week. When chinoline was introduced a few years ago as an antipyretic, and the attention of pharmacists was thus forcibly drawn to the relation between chinoline and quinine, it was for a short time considered that we were on the eve of the important discovery. Closely following chinoline were several new bodies, such as kairine, which have served to keep alive the feeling that the days of natural quinine are numbered. But these circumstances, from a chemical point of view, are trivial in comparison to the great advance which has been made in our knowledge of the decomposition products of alkaloids. It is in this direction that it is hoped to arrive at workable synthetical methods. Although it is perfectly well known that alkaloids are derivatives of ammonia, there is no known law which will enable us to represent such a complex formula as that of quinine ($C_{20}H_{24}N_2O_2$) in typical and constitutional order. Possibly in the molecule containing so many atoms of carbon, hydrogen, and the rest, these are associated in groups along with a nucleus, and the tendency of recent research is to show that it is so. That research has also shown that all alkaloids, with a few exceptions, are associated with one of two groups of organic bodies—viz., the pyridine and chinoline bases, which are now conveniently ranked amongst alkaloids. These bases can be synthetically prepared; many of them are found in coal tar, and they can be made cheaply on a manufacturing scale. It is assumed by chemists that they represent the rational starting-points for the artificial manufacture of alkaloids. It is here that the value of decomposition experiments becomes apparent. Obviously, if the products of decomposition be known, the putting together of these products in proper proportion will result in the original body. For example, Ladenberg succeeded in making atropine artificially by combining tropine and tropic acid, the two decomposition products of atropine; and since then tropic acid has been synthetically prepared The object of the investigator is to start with the lowest or the intermediate derivatives of the alkaloid which he desires to prepare, and already we have several bodies which have been formed on this basis. The formation of codeine from morphine referred to in our last issue is a good example of a very simple process. The formation of caffeine from guanine is more complex. Guanine is obtained from guano, and has the formula $C_5H_5N_5O$; by treating it with nitrous acid xanthine ($C_5H_4N_4O_2$) is obtained, and this again, by proper treatment, yields theobromine ($J_7H_8N_4O_2$). Caffeine is methyl-theobromine (just as codeine is methyl-morphine), and by acting upon theobromine with methyl iodide, the methyl radicle takes the place of a hydrogen atom, and caffeine, $C_7H_7(CH_3)N_4O_2$ is formed. In this case a naturally formed body is started with, so that even this excellent example of synthesis is not perfect synthesis; but we have the desired illustration in Ladenburg's process for the preparation of piperidine, in which trimethylenecyanide is started with. This body can be built up from its elements, and is readily converted into pentamethylene diamine, the hydrochloride of which splits up into ammonia and piperidine hydrochloride on heating. By the union of piperidine and piperic acid piperine, the active principle of *Piper nigrum*, is formed. The last stage of this synthesis is synonymous with the formation of atropine from tropine and tropic acid, for piperidine and piperic acid are the products which are formed by decomposing piperine with alcoholic potash. It will be noticed that in the case of atropine it is the acidulous product which has been formed artificially, whereas with piperine it is the basic product. Coniine and some other alkaloids have also been synthetically prepared, but as yet only on the experimental scale, and not from the ultimate organic bases, pyridine and chinoline, or their homologues. Since Perkins's endeavours to prepare artificial quinine by the oxidation of allyltoluidine, many chemists have followed in his track; as yet they have been baffled, but success seems more possible now than it was ten years ago. The suggestion has been put forth that amorphous quinine may be converted into the crystalline variety. If this were done, the effect upon the price of quinine would not be serious, for any unusual demand for the large stocks of this by-product which manufacturers hold would naturally make them suspicious, and they would find it to their interest not to sell.—*Chemist and Druggist.*

THE CULTIVATION OF THE CITRON:

HOW TO MAKE CANDIED LEMONS.

The cultivation of citron as an article of commerce forms an important industry, which is extensively carried on in Southern Europe, and it may be interesting to many of our readers to know something about the growth of this useful produce, and the process by which citrus fruits are preserved by the natives for export to the various countries of the world. Under favourable conditions great profit is made in the culture of the citron, and some hints, therefore, as to the planting and rearing of citron-trees, and the best methods of preserving the fruit, may prove useful to those already engaged in the industry, and suggest a channel for profitable investment to traders who are on the look-out for an opportunity of employing capital in the development of any industry which promises a fair return for their money.

The citron was the first of the citrus family introduced into Europe. It is closely allied to the orange and the lemon, but in its bearing and general appearance it is the most strongly characterised of the genus. The citron tree, or shrub, as might naturally be expected, will grow wherever lemon or orange trees grow. It flourishes, however, only in a sandy soil, and in the immediate neighbourhood of the sea. It is most successful in sheltered situations on the shores of bays. As might naturally be expected, it is largely grown on the Ligurian coast, which is sheltered by mountains from the north wind, and also in the Southern Mediterranean provinces of Italy and in Sicily. The French island of Corsica is probably the most prolifi

citron-producing district of the Mediterranean basin. The cultivation of the citron plant, however, requires the greatest care, it being much more tender and delicate than either the lemon or the orange. It begins with the sowing of the seed of the bitter orange, being the same seed from the fruit of which marmalade is made. After four or five years, when the seed has produced plants or small trees, they are transplanted at the time of blossoming in regular rows, at a distance which depends much upon the location and nature of the soil. It varies from 3 to 4 yards in different localities. When the locality is warm, and the soil is naturally rich, mellow, and of easy culture, the distance between the trees must be greater than when the soil is hard and the climate colder, because the trees will grow more luxuriantly and form larger tops. But the judgment of the horticulturist must determine this matter. When the plants have a diameter of about 2 or 3 inches they are grafted with small citron branches. The grafting is indispensable to give long life to the trees and hasten the production of the fruit. Three years after the grafting the trees are again transplanted to the orchard into a ditch about 40 inches wide and about the same depth, at a distance of between 4 and 5 yards from one another.

In planting the trees in the ditch particular care should be taken not to injure any part of the roots. The leaves are taken from the trees, and the branches cut back to the length of 8 inches. The ditch is filled with earth to a depth not exceeding 10 inches, and left sufficiently loose to allow the roots to spread with ease and prevent smothering the plants. If the plants do not sprout at once the earth round the roots is loosened and moistened. For fertilizing old manure should be applied. No fresh manure ought to be used, because it would be injurious, and have a tendency to kill the plants. Manure should be used only in the winter (that is, in Southern Europe, between October and March), and be placed at a distance of from 4 to 6 inches from the roots. Around the tree a deepening in the shape of a basin should be formed, and, unless the ground be moist or damp the plants require frequent applications of water during the summer. As a general guide, it may be taken that the rest of the cultivation is the same as for the orange and lemon. The tree requires great protection against severe cold or very warm winds, as well as against hail-storms. The amount and kind of artificial protection needed must, of course, be determined by the climate; but in Naples, were the citron is largely cultivated, in order to give it as much protection as possible, hedges are planted, and coverings of straw matting or something similar provided, having regard, of course, to the situation of the tree and the means within reach of the cultivators.

The tree blossoms in Southern Europe between March and May, and up to the months of September and October, at which time the fruit is ripe. In about two or three years' time the grafts will begin to bear fruit. The average crop per acre of citron can hardly be ascertained, as the size of a crop depends upon so many conditions, such as the climate and soil. If we assume that each shrub or tree is planted three yards from every other which by many growers is regarded as the best arrangement, there would be about 450 shrubs to the acre. If the average product of each shrub be assumed to be 14 citrons, we should have a total product of 6,300 citrons to the acre. In some parts, however, the citron-tree bears a much larger quantity of fruit than this estimate. In Messina, for instance, a citron-tree bears from 35 to 50 citrons. Much depends upon the climate and method of cultivation. To propagate by cuttings, young healthy shoots that are straight are selected. They should be about 1 foot in length, and must be planted on the ground to the depth of 4 or 5 inches in a soil similar to that used for seed. Care should be taken to plant the cutting upright, as it grows upon the tree. When the cutting becomes well rooted, and has had a healthy growth of a year or two, it may be removed for final planting to the orchard.

As to the cost of production, it varies so greatly in different localities and at different times that no trustworthy and generally useful answer to the question of cost can be given. The greatest part of the expense in the cultivation is caused by covering the tree to protect it against the winds; but in mild climates this expense is not incurred, and the only outlay is for manuring and hoeing. These expenses vary according to the price of labour in the different localities. We may, however, say, as a general indication, that the cost for manure and cultivation in the best orchards per hectare (about 2½ acres), as estimated by a practical grower at Catania, is on the average, 26*l*. The exact amount of profit cannot be given, as it varies according to the price obtained for the fruit, which is subject to great fluctuations. In Corsica, for instance, where the citron is cultivated to a very large extent, when the crops were large the fruit sold for 12*s*. a quintal (229 lbs.); while at other times, when the crop was small, 4*l*. a quintal was paid. Great care is taken in preparing the fruit for the market. In Sicily and other places, where the citron is exported in its natural state, each individual fruit is carefully cleaned of all the insects or injurious matter with a sponge and cold water, and is wiped perfectly dry before boxing. The boxes for the fruit are so constructed that they will hold from 250 to 360 of the fruit.

The citrons which are subsequently converted into the candied citron of commerce are grown chiefly in Greece, Calabria, and the islands of Sicily and Corsica. The citron is chiefly prepared for the market at Leghorn which is the most important citron port in the Mediterranean. The fruit is shipped to the factories for candying sometimes in sacks, but usually in large hogsheads filled with brine. On being unpacked they are placed in tubs containing fresh brine, and left for about a month. The brine is then renewed, and the fruit may remain in it until required for use, even for a period of four or five months. When the citrons are to be candied they are taken out of these tubs and boiled in fresh water until sufficiently soft, which is ascertained by testing them with a fork. This usually takes about one hour and a quarter. They are then cut into pieces, and, after the seeds have been carefully removed, they are immersed in cold water and left for twenty-four hours, during which they become a green colour. After this they are placed in large earthen jars with hot syrup, which should entirely cover them. There they remain about three weeks. During this time the proportion of sugar in the syrup is gradually increased. They are then put into boilers, with crystallised sugar dissolved in a little water, and cooked; then allowed to cool for twenty-four hours, and boiled again until they can absorb no more sugar. Then they are taken out of the boilers and placed on a wire netting to dry. They are now ready for picking, and are placed in small wooden boxes, containing about 25 lbs. each. These, in their turn, are packed in cases which contain usually ten of them.

The proportion of sugar used in candying is about 80 lbs. of sugar to 100 lbs. of citron, and the kind used at Leghorn is generally Egyptian crystallised sugar. The citrons, both fresh and in brine, are exported in immense quantities from Messina, Palermo, and other places to foreign countries, but chiefly to the English markets.—*British Trade Journal.*

VITALITY OF SEEDS.

A change of residence from Jamaica to Trinidad has prevented my seeing until to-day Mr. Watson's comments on my note relating to "Transmission of Seeds from the Tropics." On referring to my note, however, I can find nothing to justify Mr. Watson in making the assertion that I condemned paper bags for the transmission of seeds to the Tropics. I did not do so; what I intended to convey, and, now reiterate as an incontrovertible fact, is, that the quality of European seeds is depreciated by being kept in canvas or paper bags "after they arrive in the Tropics." In hermetically sealed tin cases, provided the seeds are put up when the humidity of the atmosphere is in a proper condition, it will be found that the seeds retain vitality for a much longer period; but the cases should be small, one for each variety, and should only be opened when required. I may say here that I am writing with

special reference to supplies of vegetable seeds required by European residents in the Tropics. Seeds of Kidney Beans in Jamaica I have found useless on numerous occasions after being kept for a period equal to that mentioned in Mr. Watson's note in italics; and Peas especially are well-known, by all who have grown them in the Tropics, to be of very uncertain growth after a few months only. These facts are no mere theory, but have been ascertained by personal observation during a series of years. Even the negro cultivator hesitates to purchase from a seed-store until he knows that some friend has purchased, and that the seed was fresh from actual trial. To make certain of seeds growing, residents in the Tropics should make it a practice to order at intervals, and always keep a fresh supply on hand for use, but they can order at longer intervals if the seeds are in sealed cases, and only opened as required.

The cause of the failure of so many seeds is undoubtedly the humidity and high temperature which we experience. If we could find in the tropics such a convenient drawer as Mr. Watson describes, it would not have been necessary to write upon the subject, but when we have a state of humidity represented by 77, taking saturation at 100, and a mean annual temperature of over 77° Fahr., the conditions are somewhat difficult to estimate and understand by residents in a temperate clime. To enable Mr. Watson to estimate the value of such conditions, I would recommend him to place a series of seeds in a tropical-house at Kew, where a relative humidity and temperature to that mentioned could be conveniently maintained, and correctly registered by the hygrometer. I think the result would enable him to discuss the subject on rather different lines, and with much greater force.

When writing my note supporting Mr. Thierry's assertion, that seeds "lose their vitality much sooner in the Tropics than in Europe," I was not in any way depreciating the easy and generally successful method adopted at Kew, and many other places for the transmission of seeds, but was pointing out how Nature showed us the way to preserve the vitality of seeds by giving to some such a hardened exterior coat that they have been known to survive immersion in sea-water for months, perform a long voyage, and then germinate. Perhaps we could not seal as effectually as Nature does, but we cannot dispute the fact that the sealing preserves the seeds, for after cutting one of a similar character through its exterior it will germinate immediately, but as long as it remains intact and undecayed the vital germ is kept in a state of preservation.—J. H. HART, Superintendent of Botanic Gardens, Trinidad.—*Gardeners' Chronicle.*

ORANGE AND OLIVE GROWING IN NEW ZEALAND.—In the province of Auckland the cultivation of the Orange is making rapid headway, and it is believed that in the course of a few years the industry will be one of some importance. For a number of years Orange trees, chiefly seedlings, have been grown here and there, and in not a few instances have yielded excellent crops; but only very recently has the regular planting of Orange groves been carried on. In one particular district, where both soil and situation are favourable to their growth, there are already some thousands of Orange trees set out, the greater portion of which have been grafted or budded, as worked trees bear so much earlier than seedlings. It is calculated that in this district during the present season there will be crops of fruit, on comparatively young trees, amounting to 30,000 Oranges. There are quite a number of trees, not yet six years old, that been 100 to 200 Oranges each. During the next decade, no doubt, the planting of the Orange will go on vigorously, so that there should be plentiful supply of fruit, if not for export, at all events for the people living in the colony, the supplies hitherto having come from Fiji and other islands, and some from Australia. Some orchardists are of opinion that the culture of Oranges will be more profitable than that of Apples or Pears. It may be mentioned that Lemons of good marketable quality have been raised for a number of years. Limes, too, have been grown, which on being analysed, would compare favourably with those grown in other countries, and showing that these fruits might be profitably cultivated for the manufacture of citric acid. In regard to Olive growing, for a number of years experiments have been carried on just outside Auckland city by Dr. Campbell, on a portion of his valuable estate, suitable, for the culture of the Olive. The experiment is a somewhat extensive one, inasmuch as upwards of 20 acres have been planted with trees, according to the quincunx system, 20 feet apart every way. As a start for this Olive plantation 5,000 seedling trees were obtained from Adelaide some years ago. These were afterwards grafted at different times, though the grafts did not all succeed. Transplanting took place in due course, and there are now some 2,500 trees thriving vigorously, and this season bearing abundance of fruit. Arrangements have been made with the Auckland oil and Candle Co., for treating the Olives when perfectly ripe, Dr. Campbell having decided that the oil shall be placed on the market in a form and with a quality equal to the imported article. So far as climate is concerned, the experiment may be said to have settled the point whether the Olive would do in New Zealand.—WILLIAM MORGAN, Purekohe, East Auckland.—*Gardeners' Chronicle.*

THE "YELLOW-EYED BEETLE" is still doing good work in the way of devouring scale-bugs. The lady-bugs are also very plentiful, and it is hoped are doing good work. It may be well to protect, as much as possible, these enemies to the scale-bugs.—*Orange Tribune.*

SOILS are formed by the disintegration of rock and the decomposition of vegetable matter. The rock furnishes the mineral part and the vegetable the organic part. Hence the character of the soil will vary with the kind of rock from which it was produced, the extent of the decomposition it has undergone, and the kind and amount of organic matter that is mixed with the decomposed rock.—*Rural Californian.*

RICE GROWING.—Before our civil war, rice culture was an important industry in several of the Southern States. Cheap slave labor enables Southern planters to compete with the coolie labor of India, and the rice from this country, being of better quality than that furnished elsewhere, had the monopoly of our own market and was to some extent exported. It is one of the signs that labor has about got down to bed rock, that the rice-growing industry in this country is picking up. Last year one hundred and fifty million pounds were grown, and about one hundred millions more imported. This year our production is estimated at one hundred and seventy-five millon pounds and perhaps more. Rice is being substituted for sugar on plantations in Louisiana, where the latter has been found unprofitable. It is also grown to some extent in Minnesota, though this is mainly wild rice, and the chief expense of the crop is in harvesting and cleaning it. To grow rice under the best conditions, the land must be alternately flooded and drained. The crop requires promptitude in harvesting as when fully ripe it soon shells and wastes. An average crop is thirty bushels of rice, besides some waste, broken rice and meal that is used for feeding stock. The wholesale price now is 4¾ to five cents per pound, and a bushel weighs about twenty-eight pounds. In many retail groceries, broken rice is mixed with the whole grain, and as this can be bought for one cent per pound, the mixed product can be sold low and yet realize a good profit. There are many risks in rice growing and the price often fluctuates largely. In those countries where rice is a staple food famines are more frequent than in those where dependence is hard on a greater variety of grain. It is hardly probable that at present price rice growing will prove profitable in the Northern States. If tried it should be either on some lakes or ponds on the borders of which rice formerly grew, or the upland rice should be sown, which may be cultivated and harvested the same as other grain.—*American Cultivator.*

Correspondence.

To the Editor of the "Ceylon Observer."

COMPARATIVE COST OF OPENING TEA ESTATES.

DEAR MR. EDITOR,—I am one, and, no doubt, there are others who wish to invest in a block of land in the lowcountry, but are in the same dilemma as myself regarding cheap districts. Udagama, I have often observed in print, is considered one of the cheapest for opening up an estate, so that should this meet the eyes of Messrs. Dobree, Kershaw, or any other gentlemen, then a reply to my few questions I should take as a favour.

Cost of felling and clearing per acre of ordinary jungle not being virgin forest.

Holing per hundred holes 9″ + 15″.

Planting per acre and shading if necessary with fern.

Drains per chain 15″ × 12″.

Roads 3 feet on solid with 9″ side drain.—Yours truly, IGNORAMUS.

THE CINCHONA MARKET.

65 Cornhill, London, 27th July 1887.

DEAR SIR,—I beg to thank you for some cuttings from *Ceylon Observer* received this morning. I go to London tomorrow and will circulate them among those interested in cinchona.

In my letter of the beginning of July I sent you some figures under the head of results to planters which must have been quite unintelligible. I now give these figures in an intelligible form:—

Result to planters supposing that none of the low quality (below 1½ per cent) bark came into the European market.

Increase in price owing to low quality bark (¼ of the whole) not coming into the European market.

	£
15 tons (average 2 per cent) at 4d per unit = 8d per lb.	1,100
Less curing, shipping and sale charges at 1d per lb.	135
	£965
	£619
Gain to planter	£346

All bark being sent to Europe for sale as at present.

	£
15 tons (average 2 per cent) at 2½d per unit = 5d per lb.	688
5 tons (1 per cent) at 2½d per unit = 2½d per lb.	114
	£802
Less curing, shipping and sale charges at 1d ...	£183
	£619

I said I would write again on the subject of utilizing abroad the low quality bark analyzing under 1½ per cent quinine of which one-fourth of the shipments from Ceylon is composed, and so keeping it off the European market.

My proposal is that all those interested in the cultivation of cinchona should form an Association or Company to manufacture in the East, say at Colombo, the low quality bark in the form of "quinetum."

2. That members take shares of say £1 each as follows:—10 shares for every 100,000 cinchona trees or under. This is a very small proportion, but the object is to get as many as possible to join the Association. Any members wishing to take a larger number of shares can do so.

3. That members agree to sell all their branch bark to the Association after it has commenced work and can take the bark.

4. That the bark be paid for by the Association at the rate of 1½d per lb., the price to be lowered if the value of the unit should go lower than it is at present.

5. That the manufactured quinetum be packed in small bottles containing ¼ ounce marked with the trade mark of the Association and distributed at first *gratis* with the object of creating a demand.

In India through the Government and its officers.
" China " the missionaries and "medicine men."
" Africa " " "

I have merely sketched the outlines of a scheme which I believe to be perfectly practicable if the planters will only exert themselves to carry it out.

I am already working in England in the matter among those interested, but men here, naturally, say it is useless for them to consider such a scheme unless it is organized by the planters in Ceylon and India who are the persons chiefly interested and who have it in their power to make it a success or the reverse.

Judging by the prices which parcels of bark realize at every sale, 1d, 2d, 3d per lb., many planters must have already realized that they are actually losers by shipping.

The preparation of quinetum is a most simple and inexpensive process. The manufacture might be commenced at once and carried on for some time at least in a hired building.

CONSUMPTION.—In answer to the proposal that the great London drug houses should make known the present cheapness and the virtues of the febrifuges, I can state that the London manufacturers charge 1s 9d per ounce for quinetum. That quinetum can be prepared in India or Ceylon at less than 6d per ounce including cost of bark.

When a demand for quinetum arises, it might be sold at an absurdly low price, yet at a price which would pay the Association handsomely.

I believe that it is in the power of the producers of bark to increase the consumption of the alkaloids enormously.—Yours faithfully,

W. T. HODY COX.

EXPORTS OF CINCHONA FROM CEYLON.—In the face of the wretched—and we should think in many cases unremunerative—prices obtained, and although many large growers of cinchona have either ceased to harvest, or have merely stored their bark to wait for better times, the export of bark from Ceylon for 1886-87 is likely to closely approach the highest figures yet attained. Up to date the quantity sent forward approaches 13¼ millions of pounds, so that there can be little doubt that by 30th Sept. the round 15 millions will either be made up or closely approached. No signs of exhaustion yet, and European cinchona planters seem as perversely determined to swamp the market with twig bark as the Burgher and native growers of cinnamon have been in regard to chips.

EXPORTS OF COFFEE, CACAO AND CARDAMOMS.—Having devoted special paragraphs to tea and cinchona, we must not forget poor old coffee, although he is "in the sear and yellow leaf of decadence." The figures to date are below 170,000 cwt., so that we suspect the total to 30th September will not much exceed, if even it reaches, 200,000 cwt. Ah what a falling off is here! compared with more than a million cwts. in 1869, the year in which the fatal fungus suddenly and mysteriously appeared. But even now we are asked to wait for "next year." Cacao, like tea and cinchona, however, has advanced, and the total for the season is likely to reach 18,000 cwt., while cardamoms already exceed 300,000 lb. so that the total will probably reach or exceed 320,000 pounds.

SPECULATION IN COFFEE IN BRAZIL, *Gazeta de Noticias*, June 15th.

The Rio de Janeiro market is under the pressure of yet another disaster caused by coffee speculations; and the consequences of which may bring about losses as great as, or greater than those caused by the celebrated syndicate.

The fabulous results obtained from recent operations in coffee, and the upward tendency shown in American markets carried away various persons, who made, through two commercial houses in our city, heavy purchases in New York. These purchases reached 60,000 bags, at 22*c* per lb.

Saturday, in the morning, coffee fell to 19*c* and further margins were asked for from the United States to meet this decline. This demand was met the day-before-yesterday in the morning, but when the margins reached New York, at the morning Board, coffee had dropped to 17*c*.

The representatives of the Rio houses were "cornered," and as it was not possible to put up further margins in the space of two hours, 60,000 bags of coffee were announced for sale, for want of this payment at auction. To increase the depreciation of the article, the American speculators offered at auction 40,000 bags in addition. This abundant supply of coffee caused a decline to 14.90*c*, at which price only the 60,000 bags belonging to Brazilian merchants were sold.

After the liquidation of this operation the same speculators advanced prices to 17*c*, on the afternoon of the day-before-yesterday, and yesterday morning were selling at 17.80—17.95*c*. This trap (*guet-apens*) will cause a real crisis in our market.

Journal de Commercio, June 16th.

. . . . It was thoroughly known that many persons of this city, interested or not in the coffee business, have sent or were sending daily, through houses established here, orders to purchase lots of coffee in New York, principally counting upon reselling them with a considerable profit, or even in some cases upon making the differences only.

It was a serious error, considered as a commercial operation; as a speculation, or rather as gambling [for we do not absolutely condemn commercial speculation] it was most risky. Better informed than we are, perhaps even as to our own business, the New York speculators, more intrepid, possessing more ready capital and at lower rates, watched for the opportunity, and availed of it to bring about successive declines, and demanded from the gamblers (*jogadores*) here, or their representatives there, constant margins in proportion to the decline made.

The agents who disposed of resources and had discretionary orders met in time these demands and frustrated in part the plans (of the speculators?); others less strong, or less authorized, ask for remittances, and we hear that about 2,000,000$ was drawn in favor of the New York market during the past days.

Notwithstanding this assistance, which arrived too late or was considered to have done so, the speculative coffee not duly "margined" was sold at low prices with great loss to the holders. —*Rio News.*

THE TROUBLES of the Florida orange growers are now being increased by a drought of nearly two months' duration, from the effects of which the trees are suffering badly. Our irrigating ditches are very handy in dry weather.—*Rural Californian.*

ORANGES.—We frequently print reports in these columns of large profits made by orange growers and Muscat vineyardists, sometimes ranging as high as $400 to $500 an acre, but our Eastern friends coming here to make homes must not expect that *all* our orchards do so well. That would be beyond a reasonable profit. A good average for an orchard or vineyard is $125 an acre above all expense of handling the fruit and cultivating the lands. Such profits are very common and are large enough to satisfy any man of moderate ambition.—*Rural Californian.*

GETTING RID OF STUMPS.—I see in *Dispatch* of 27th inst. (June) page 548, "Getting Rid of Stumps," taken from the *Scientific American.* I tried it on 15 stumps, let them stand six months after putting in saltpetre, water and plug; then put in kerosine and tried to fire them but they would not burn. I found it impossible to burn kerosine or keep it burning in a hole with no draught. It is no good.—R. E. MCMAHAN.—*Florida Dispatch.*

SOCOTRINE ALOE LEAVES have been suggested for burns: One of the thick aloe leaves is split in half, and the fresh inside portion is applied to the burn. The pain disappears instantly. The green juice of the plant turns violet, and all traces of the burn often disappear by the next day, except a violet tinge, which may remain for ten or twelve days —*Chemist and Druggist.*

TO GROW PLANTS FROM CUTTINGS.—The old way of rooting cuttings in a small glass bottle filled with water is a good method when a hot-bed cannot be used; but the bottle should not be put so close to the window as to become hot, and thus scald the rootlets. A little cotton or wool within the rim of the bottle will prevent evaporation. In two or three weeks the roots will be plentiful, and then the cuttings may be transferred to thumb-posts, or, if the season suits, into beds. As each cutting is taken from the bottle, dip the roots into a little warm sand until each fibre is coated; this will keep them apart and prevent wilting. If pots are used, nearly fill them with a rich sandy compost, and press it to the sides, so as to leave room in the centre. Put the roots in gently, and give the plant a little twist to spread the roots, or separate them with a hairpin. Then put in more soil, and press it about roots. Tight pressing is one of the secrets of success in raising plants from cuttings. Water the young plants well, and shade them at first from the sun. Cuttings can also be started in pots of sandy compost, with a glass tumbler over them to confine the moisture, and keep them from the sun two or three days; then place the pots in the warmest window, exposed to the southeast. Wet sand is also good for growing cuttings, and they will start quicker than in compost. A shallow pan is preferable; fill it up with sand (not sea sand) sopping wet, then press in the cuttings tightly, and keep them wet. When new leaves show themselves, in two or three days, transplant into pots filled with light sandy loam. After standing a day or two, they may have ample sunshine and sufficient water to keep them moist.—*Southern Planter.*

SUNFLOWERS AS FUEL.—In some of the treeless districts of the West the difficulty of obtaining fuel is very great, and many substitutes for wood and coal have been used during the long and severe winters. A correspondent of a Wyoming paper gives his experience with sunflowers for this purpose as follows: "I grow one acre of them every year, and have plenty of fuel for one stove the whole year round, and use some in the other stove besides. I plant them in hills the same as corn (only three seeds to the hill) and cultivate the same as corn. I cut them when the leader or top flower is ripe, letting them lie on the ground two or three days. In that time I cut off all the seed heads, which are put into an open shed with a floor in it, the same as a corn crib. The stalks are then hauled home and packed in a common shed with a good roof on it. When cut in the right time the stalks, when dry, are hard as oak, and make a good, hot fire, while the seed heads with the seed in, make a better fire, than the best hard coal. The seed being very rich in oil, will burn better and longer, bushel for bushel, than hard coal. The sunflower is very hard on land. The piece of ground selected to plant on should be highly enriched with manures. In the greater steppes (prairie) region in the interior of Russia and in Tartary, where the winters are more severe than in Dakota the sunflowers are, and have been for centuries past, the only kind of fuel used.—*Oil, Paint and Drug Reporter.*

EXPORTS AND ESTIMATES OF TEA.

A leading member of the planting community writes :—

"My last London news *re* produce is:—*Plantation* is selling readily at 96s to 98s for middling to good middling. All kinds of tea of distinctive character, whether China, India or Ceylon, are in good demand at firm to higher prices, but the ordinary colourless Ceylon are slow of sale and irregular.

"Don't you think Rutherford's estimate in Forbes & Walker's report of 1887-88 crop (tea) too high? It will not be much more than 12,000,000 lb. in 1886-87. From 12,000,000 to 22,550,000 is rather a jump, especially as men will try to make *better tea*, which means finer plucking."

Our correspondent's question represents the feeling with which we read the estimate referred to. Mr. Rutherford has so carefully examined the statistics of tea and is generally so cautious, that we feel diffident in questioning his figures, but certainly the jump from 12 millions of pounds in 1886-87 to very nearly double that quantity in 1887-88 does seem somewhat to approach the "prodigious." The estimated increase partakes more of geometrical progression than of ordinary arithmetical advance. The figures may, nevertheless, be reached, if there is now a reaction to weather favourable to flushing from the very unseasonable meteorological conditions which tea planters have had to contend with for months past. Notwithstanding such adverse influences, we have exported to date about 10½ millions of pounds, so that by 30th September it seems probable the round figure of 12 millions will be quite made up. Then will come in October to January, what are reckoned the best flushing months, over a large number of the districts in which mature tea is largely grown, and unless we are visited by a third visitation of drought and cold, the tea harvest ought to be good. On the whole, looking at the fact that the reality this season will be about one million of pounds below the estimate, we should think 20 millions a safer figure for the year which will commence on 1st Oct. than 22½ millions. But there are too many elements of doubt in the question to render prophesying safe until after the event. A general resort to finer plucking, which has been pressed on the planters would doubtless restrict the quantity manufactued, but having stated these possibly qualifying conditions we must leave our readers to form their own judgment.

IMPORTANT CHEMICAL DISCOVERY:

CONCRETE AS AFFECTED BY SEA-WATER.

Some time ago the *Scotsman* drew attention to an interesting discovery that had been made in connection with the Aberdeen harbour sea-works, and the experiments that have since been carried on will have a very important bearing in the building of similar structures throughout the country, and, indeed, in every part of the world. Engineers and architects have hitherto regarded Portland cement concrete, which has been almost exclusively employed in the construction of harbour, dock, and other works, as almost infallible. After the lapse of a certain period, however, from the completion of their work, engineers are now being frequently discouraged to find that their best efforts to secure good material and workmanship have been seriously operated against by indications of failure where this valuable cementing material is depended upon to perform one of the chief functions in the execution of extensive and costly undertakings of the kind alluded to. Although its effect was suspected, the nature of the chemical action of sea water on cement has never been thoroughly investigated, and this is therefore the first experiment that has really resulted in what promises to be a successful explanation of the deleterious substances that have up till the present moment baffled the skill of the analyst. The destruction of enormous concrete blocks and concrete walls ac Aberdeen has usually been ascribed to the force of th" sea and other mechanical influences. The "decayed concrete, however, is first swept away, and chemical action did not become so noticeable at the pier as it was in the graving dock in still water. Where the quay-walls have stood in still water without pressure, this process has been comparatively slow and insignificant. It is the action of the sea-water under pressure, in still water, that has rendered the nature of the damage in the present instance so conspicuous. Similar effects have recently been observed at the entrance to other graving docks—for instance, at Maryport, the Walter Scott Dock, Newcastle-on-Tyne, and elsewhere. The decay of the concrete of sea-works may now, however, be accounted for, in view of the light thrown upon the subject by Professor Brazier, of Aberdeen University, in conjunction with Mr. William Smith, the harbour engineer.

Since its construction some fifteen years ago, one of the destructive influences bearing on the south breakwater has evidently been the disintegration of the surface of the concrete by the chemical action of the salt water on the Portland cement. A similar effect, but on a larger scale, has also been manifesting itself on the graving dock, which was completed two years ago. The entrance walls are built of Portland cement concrete, composed of one measure of cement, two measures of sand, and three measures of stones, with large rubble stones incorporated in the walls. The surface of the walls, from the foundation up to a level of three feet of low water, is plastered with Portland cement mortar, made up of one measure of Portland cement and one measure of sand. The upper part of the wall is faced with granite ashlar stones, surmounted by a massive granite cope. Portland cement plaster was supposed to be sufficiently watertight to a form a sound, hard skin on the concrete walls. It appears, however, that the process of emptying the water from the graving dock, when it is occupied by ships, places a hydraulic pressure, varying with the tides, of from 5 lb to 11 lb. on the square inch on this concrete skin. The sea water, forcing its way freely through the small pores in the skin, has saturated the quay wall. The presence of sea water has occasioned a swelling due to the chemical change produced by the water, which in its turn opened up the skin in a series of larger cracks, allowing access to a greater volume, so that the chemical action proceeded more quickly the longer it lasted. The pressure of water being relieved from the surface of the entrance wall, which is within the caisson gate, flows through the pores of the upper part and out into the dock through the cracks in the skin of the inner part, the whole of the entrance walls in the neighbourhood of the caisson having expanded about 2¾ inches on the height of the walls. The chemical change is hastened the longer the exposure continues; it is increased by the perpetual passage of the current of sea water through the body of the concrete. To this must be ascribed the rapidity of the chemical action in this case beyond what is generally observed in concrete works under sea water. The injury to the dock-gate entrance walls was first observed from the opening of the joints of the ashlar facing at the south-east corner. It was found that the surface of the concrete at this point immediately beneath the ashlar had loosened, allowing the ashlar to drop slightly. The concrete behind the ashlar under high-water mark had also loosened thus breaking the bond of the stones with the concrete. The damage so far to the walls is found to be superficial in extent, and it is believed that a new facing of granite built in Portland cement mortar will be effectual in preventing the extension of the chemical action. On the discovery of the softening of the Portland cement concrete, the engineer consulted Professor Brazier as to the composition of the decayed concretes. Test briquettes were submitted for analysis. Some of the briquettes were broken during the course of the work, and found to be fully up to the mechanical standard. The chemical analysis was made with the view of discovering the proportion of magnesia these contained, the presence of magnesia being supposed to

be the cause of the damage. It was found that the Portland cement had not contained more than one-half per cent of magnesia, but the analysis of the decayed concretes showed an increase in the quantity of hydrate of magnesia of 13½, 15, 22, and in one case as much as 40 per cent. There is no other possible source from which the hydrate of magnesia could be derived than the sea water. Another deleterious substance was discovered by Professor Brazier in the course of the investigation—namely, carbonate of lime. Whereas in the Portland cement there were only traces of carbonic acid found, in the decayed concretes the proportion of carbonate of lime in the various specimens amounted to 6·6, 15·8, 45·7, 37·4, and 38·4. It should be observed that all the concrete which has decayed was made with the best Portland cement, the tests of which were fully up to, if not indeed above, the standard, the chemical analysis also proving it to be of the best quality. The sand and stones were perfectly clean and sea washed, and the concrete was mixed by the contractor in the Messent's patent mixers. The latter were also used continuously at the south breakwater and north pier. The whole of the work was executed under careful inspection, and the walls, which are perfectly hard, stood for fully six months within the temporary dam before being immersed in sea water. Since the discovery of the chemical change of the Portland cement at the graving dock, Professor Brazier has analysed a sample of the decayed concrete from the south breakwater, which is found to have undergone a similar process to that already described. The outer quay walls surrounding the side of the graving dock were built of what is called plastic concrete—that is, Portland cement concrete, mixed in the usual way with a measured quantity of water, and allowed to set from two to four hours is then broken up and deposited within frames under water in skips with opening bottoms, which are lowered and then drawn up, leaving the concrete in the frame. The concrete deposited in this manner under water is fluxed by the water, and consolidates in a dense non-porous mass, practically impervious to water. In this way the immersed concrete of Provost Jamieson's quay and the graving dock walls was deposited, and these walls do not show the same indications of chemi al action or decay. The south-east corner of the dock, which is the most decayed, is at present under repair. The stones and decayed concrete have been removed, the walls having been rebuilt with Roman cement concrete under water, and ashlar stones built in Roman cement above water. So far as has yet been observed, the Roman cement has not been acted upon by the sea water. The only practical preventative for the chemical action appears to be the complete protection of the Portland cement concrete from the sea water by lining it with stones or other facing and making it non-porous.

Two years ago the Institution of Civil Engineers discussed the subject of concrete work under water, and Mr. Harrison Hayter, the vice-president, indicated that failures had been met with in the last year or two in the use of Portland cement concrete. The cement in every case had stood the ordinary mechanical tests, the sand and shingle had been good, and the concrete had set as hard as usual. But after a time expansion set in. In one case a vertical wall about 35 feet high had lifted about 2½ inches, and in another case a mass of concrete 16 feet thick lifted from ½ inch to 1¼ inch. In a wall the first appearance of expansion is indicated by cracking followed by pieces flaking off the face. In every case a white substance of the consistency of cream is seen in the concrete. M. Lechartier alludes to many failures in works of all kinds in which Portland cement had been used, and in which every care seemed to have been taken. Mr. Hayter had an analysis made of this "cream-like substance," and it was found to contain 80 per cent of magnesian hydrate, consisting of about two-thirds magnesian oxide (magnesia) and about one-third water. He also had concrete analysed that had failed, and in every case magnesia was present. Indeed, in one specimen of concrete there was so much of this substance that the chemist thought the cement had been made from dolomite, not from chalk as an ingredient; but this was not the case. It is evident that both M. Lechartier and Mr. Hayter took for granted that magnesia existed in the Portland cement, their theory being that the magnesia had an affinity for water; every 2 lb of magnesia in becoming hydrated took up and solidified 1 lb or 27·7 cubic inches of water, and in bulk every ton of magnesia would have to find room for about 18 cubic feet of water. It was in finding room for this water that the concrete became disintegrated. The action went on whether the concrete was in air or in water, but as might be expected, more rapidly in water; in the former case it became hydrated by the slow absorption of moisture from the atmosphere. Another substance in Portland cement which Mr. Hayter considers injurious but in a less degree than magnesia, is carbonate of lime. In adding water to the cement a crystallised double silicate of lime and aluminia was formed. But if there was too much lime in the cement it was not taken up by the silica. It did not prevent the setting, but after a while the free lime absorbed carbonic acid from the atmosphere, and was converted into the carbonate of lime, which remained inert in the cement and weakened it. The engineering authority just quoted understood that the carbonate acid was taken up from the atmosphere, and that the magnesia existed in the Portland cement, which in consequence was defective to that extent. Professor Brazier's discovery, however, proves that all Portland cements are liable to decomposition in sea water, the magnesia and carbonate of lime being derived from the sea water.

Professor Brazier holds the opinion that the magnesia in these white deposits, or "decomposed cements," comes from the sea water, and is the result of the action of sea water upon the cement. He has digested some of the cement blocks, after being powdered with some of the sea water, and finds that very soon there occurs a decomposition; evidently some of the lime of the cement becomes dissolved, but as instantly causes a precipitation of magnesia, as contained in the sea water. The lime, further, becomes more or less carbonated, and hence the formation of the white deposit in the dock so frequently noticed as a "creamy-like substance." It might be objected that the process he has been using for testing the action of sea water upon the cement is a severe one—namely, by accelerating it both by powdering the cement and raising the temperature of the sea water; on the other hand, the analyst imagines the slower or natural process, where the salt water acts upon the solid block, and cement must be of a similar character, but of far longer duration. The results obtained by digesting some of the Portland cement in sea water may be mentioned here. 200 grains of a sample were digested in an imperial pint of sea water for four (days 96) hours continously, and during this time heat was applied at intervals for about fourteen hours in all. The amount of lime and magnesia contained in the sea water in its original state was found to be, per imperial pint—lime 3·04, magnesia 12·98. The pint of sea water in which the cement had been digested, after being separated from the cement was found to contain—lime 31·70, magnesia 0·46, There is therefore a gain of 28·16 grains of lime and a loss of 12·52 grains of magnesia amounting to nearly all the magnesia contained in the original sea water. By watching the experiment it was easily seen that magnesia was forming a deposit, and by mixing with the cement was producing a material very similar in appearance to the samples of the decomposed cement and concrete. On making a qualitative examination of the insoluble matter, after being washed and dried, abundance of magnesia was easily found. Portions of the same sample of cement were exposed to the action of plain water, when evidently free hydrate of lime was dissolved. There was not sufficient time at the analyst's disposal for making any estimation of the proportion of lime dissolved in this case, nor was it so absolutely necessary when it is known that a pint of water under the most favourable circumstances can only dissolve

about 12½ grains of lime, whereas this quantity is more than doubled when sea water takes the place of plain water. The analyst is of opinion that the action of plain water, should it be a hard water, and when the hardness is due to the presence of chalk (carbonate of lime) held in solution by excess of carbonic acid, would be gradually lessened. In this case the free lime of the cement would seize upon the carbonic acid holding the chalk in solution, and a crust of carbonate of lime would be produced, acting more or less as a protecting surface to the interior portion of the cement. With regard to the character of Portland cement, Professor Brazier considers that it has not sufficient power to resist the action of sea water. It is usually understood that the chemical process concerned in the solidification of hydraulic lime is due to the presence and mutual action of the silica and caustic lime contained in it; and the more silica, therefore, that can be introduced into the composition of the material within certain limits, the better it must be for the purpose. The whole question of the damage to the concrete is meantime under the consideration of a committee of the Harbour Board.—*Scotsman.*

COFFEE IN VENEZUELA.—From the *St. James's Budget* of August 6th we learn, that in the *American Magazine*, Dr. W. F. Hutchinson recounts his experiences of Venezuela, where "everybody raises coffee, deals in coffee, or owns coffee," but nobody can make a cup fit to drink—as Americans like it. Large quantities of "Java" and "Mocha" are imported into the United States, and haply other States, from Venezuela.

A HUGE COFFEE TREE IN BRAZIL is thus described in the *Rio News*:—

A recent offer to the Club of Engineers is the trunk of a coffee tree from the neighbourhood of Campinas, S. Paulo, measuring 8.20 metres in length, and 48 years old at which ripe age 6¼ *alqueires* of cherries were gathered from it. The party offering this proof of Brazilian fecundity desires that it be presented to the National Museum, where, possibly, Sr. Sant'Anna Nery may be enabled to triumphantly vindicate his theory that in Brazil it is necessary to climb the trees to gather the coffee crop.

COFFEE PRODUCTION IN BRAZIL.—While the production of coffee has largely increased in the comparatively new field in the Province of Santos, there has been a corresponding diminution in the old scenes of culture in Rio de Janeiro. The deficiency in 1886-87 as compared with 1880-81 is represented by no less than a million bags of 60 kilos each, the figures being for 1880-81, 4,519,874 bags; for 1886-87, 3,500,059 bags. The figures for seven years are as follows:—

1880-81	..	4,519,874	bags.
1881-82	..	3,839,053	,,
1882-83	..	4,736,678	,,
1883-84	..	3,188,426	,,
1884-85	..	4,114,903	,,
1885-86	..	3,888,378	,,
1886-87	..	3,500,059	,,

CEYLON *vs.* CHINA TEAS.—Messrs. I. A. Rucker & Bencraft, in their weekly tea circular of August 4th make the following remarks:—We suppose pretty nearly every individual on this side who has the smallest interest in Ceylon, has at some time or other impressed upon his correspondents the absolute necessity of keeping up quality and thus limiting quantity. The importance of this to the Colony cannot be over stated. In our last Circular we pointed out that China Teas under 8d are far cheaper and better than low Ceylons, and it will not be long before the trade finds that out. We have had to tackle over 6,000 packages of Ceylon Tea in the auction room this week, and by this time our urgent warnings must be coming home to shippers. Those who have stuck to fine Tea have done remarkably well, but those who have laid themselves out for quantity, and get account sales of large parcels down to 8½d average, will understand us when we say there is no security the average will not touch 6d for inferior Tea.

IS IT CHEMICAL ACTION SOLELY OR IS THE FAULT IN THE CEMENT?—Such is the pertinent question propounded by a correspondent of an Aberdeen paper regarding the case of the Portland cement concrete which has recently engaged so much attention and the details of which are so fully given in an article quoted on page 185 from the *Scotsman*. The paragraph is as follows:—"What about this new story of the 'chemical action' of sea water on the Aberdeen Graving Dock?" asks a correspondent. "The whole thing looks to me very queer. How happens it that the action in question, and what the Harbour Engineer learnedly styles 'the unbalanced pressure' upon a certain part of the works, was neither discovered nor foreseen till now? Is the simple explanation of it all—bad concrete? I am aware that, when the Aberdeen South Breakwater was built, the proportions of cement, &c., were radically wrong, and that consequently the concrete was bad, as is well seen by the holes that have been and still are continuously breaking out in the structure. But in other localities the composition of concrete for sea works has got to be fully understood, and, as a consequence, nothing is heard of 'chemical action' playing such unexpected tricks. My own opinion is that if the Harbour Trustees don't insist upon having a thorough inquiry by some competent person with practical experience, and that person instructed to report the whole truth and nothing but the truth, they will commit a very grave mistake."—*Aberdeen Herald.*

MR. MCCOMBIE MURRAY ON GREEN TEA FOR THE UNITED STATES.—Mr. McCombie Murray writes:—

Philadelphia, 22nd July 1887.

Has green tea been manufactured in Ceylon? I am asked at times if there is such a thing as green tea in Ceylon, and I am not at all sure, but that it might be well for Ceylon that such an article should be manufactured. A *pure* green tea would go down well here. It is hard to get a green tea drinker to change to a black, but I do believe that a green tea guaranteed free from *all colouring* matter would meet a ready demand in this country. If any enterprizing proprietor will fix up a case of 100 lb. or so of pure Ceylon green tea, I will take pleasure in disposing of it for him without charge and will return the proceeds in full after deducting the expenses incurred. Mr. Gow's opinion on the matter would be valuable, and, if he has not already expressed any opinion on the subject, I doubt not but he would interest himself in the matter. There is a decided 'cry out' for a *pure article* in America. The bakers are getting it hot at present for using chrome yellow in their buns, a custom which has been carried too far in one conspicuous case and has caused the death of several people. Green tea is powdered thickly over to give it 'the colour' wanted. It is now the colour *not* wanted, or fast becoming so. I believe a blend of Ceylon green and black tea would take well here, and am anxious to try it if anyone on your side will risk a little on the experiment. Weather very hot. Over 100 degrees in the shade for several days in succession. Mr. Pineo is in Nova Scotia at present. I don't know what he has decided on doing. Business dull, and everyone who has a dollar to spend goes out of town to spend it. The Japan Oolong tea, which is so great a favourite in the United States, is a highly roasted tea with a good deal of the flavour of green tea.

PLANTING IN NETHLRLANDS INDIA.

(*Translated for the Straits Times.*)

In Palembang the tracing of absconding coolies is greatly facilitated by setting a price on their head. Recently, the police there met with so many difficulties in catching sundry Chinese coolies who had deserted from a tobacco estate there, that a reward of five guilders was promised for the delivery of each absconder to the estate manager or to the controller. This offer of reward worked so well that out of 21 coolies who had absconded on a certain night, no less than 8 were delivered to the authorities within 3 days by the country people. The Batavia *Nieuwsblad* hopes that the system of offering rewards in such cases will be continued, and that the rewards themselves will be increased as the only way to prevent Chinese robber bands from infesting the jungles of Palembang. Runaway coolies are for the most part conspirators, bandits, and murderers who had fled from China, and will readily take to crime when driven to the uttermost by want and misery.

The Java Government looks with disfavour upon Javanese emigrating to Deli. Headmen in Java have been instructed to tell intending emigrants to demand at least ten guilders a month as minimum rate of pay on arrival in Sumatra. The steady enhancement of wages as has been the case with Chinese coolies there, will prove detrimental to plantation enterprise in that quarter. Villagers from the overpeopled portions of Java should be encouraged by the authorities to seek their fortune in Deli, where they have every prospect of earning 40 guilder cents a day as minimum wage, with free house, and good treatment, without anything to fear from land tax collectors and exactions from headmen. Now that the Government has set its face against emigration to Deli, the local authorities will assuredly do their best to discourage the movement.

The sugar crop in Java, now that the dry season has set in, promises to be abundant.

The Sultan of Sambas in West Borneo has become desirous of Europeans settling in his dominions. He is willing to grant waste land there to intending settlers on 75 years leases at a quit rent of one guilder per bouw of 1¾ acre.

The new variety of sugar cane from Borneo now under cultivation in Java, where it yields some 140 piculs of sugar per acre, bears among the natives the name of *tebu keong*. So far as it has been tried the cane has yielded splendid results. The hard times now befalling sugar growers have spurred them on to seek new and better canes, to replace the degenerate ones now cultivated in Java. The newly introduced cane surpasses all others for the present. Should it take kindly to new surroundings and be proof against degeneration, this kind of cane has a glorious future before it, and will save sugar cultivation in Java from otherwise certain ruin. As might beexpected a heavy demand has set in for it. The firm of Fraser Eaton & Co. of Surabaya, so says the local *Courant* is so deeply interested in the sugar trade that it can run great risks in experiments and trial ventures. The encouraging results attending the cultivation of the novel cane, has led it to despatch an agricultural expert in its service to Borneo, to trace out the native land of that productive plant, and bring down a large supply of specimens should circumstances allow. Should this mission prove successful of which there is no doubt, Java, within a year will become possessed of a kind of cane highly superior to all other varieties. The question however rises whether his cane drawing so much sugar out of the soil, will flourish on more than a few select spots, and will not lose its good qualities by transplantation.

Advices from Hamburg recently received at Surabaya, show that the price of coffee has every prospect of rising higher still in consequence of the labour crisis in Brazil. There, the emancipation of the slaves, which is said to be going on apace, has exercised a very detrimental effect on the coffee crop. In this respect, matters will go from bad to worse in the near future. The present crop suffers terribly from lack of labour. The emancipated slaves leave the plantations as soon as they can. There are thousands of hands short for picking and preparing the berries for market. Endeavours to prevail upon the slaves to stay five years longer for wages on the estates, have proved fruitless. The Brazilian Government seldom interferes with the matter. These tidings had the effect of making the coffee market firmer.

WYNAAD PLANTERS' ASSOCIATION.

August 3rd, 1887.

PRESENT:—Messrs. Abbott, Achard, Atzenwiler, Gooding, Lamb, D. Mackenzie, Mackinlay, Malcolm, Puenzieux, Trollope, Walker, Winterbotham, Van Reesma and Hockin, Hon. Secy.

CINCHONA.—The Honorary Secretary laid on the table G. O. Revenue No. 634 dated 4th July 1887 on manuring Cinchonas forwarded by Messrs. Arbuthnot & Co. and correspondence about the same, and was instructed to write and thank that firm for their exertions to obtain an early issue of reports on experiments carried out on Government Plantations and to assure them of the hearty support of the Association in their endeavours.

CINCHONA.—The Honorary Secretary stated he had received from the Secretary the report of the Ceylon Planters' Association for the year ending February 1887 containing the following interesting figures on the cultivation of cinchona in Java compiled by the Planters' Association of Sakabami and the British Consul at Batavia.

a The following are the only kinds recommended for cultivation.

1.—C. LEDGERIANA.—Of extremely slow growth ripe barks giving 6 to 12 per cent quinine and cultivated at 3,500 to 4,000 Rhynland feet above sea level.

2.—C. SUCCIRUBRA.—Stripping is said to be injurious and bark is left till 15 or 20 years of age to be sold as Chemist's bark by the look.

3.—HYBRID OF C. LEDGERIANA AND C. SUCCIRUBRA.—Some give 10 per cent of quinine with a growth nearly equal to Succirubra.

b The cultivation is not likely to be extended but existing plantations will be cultivated to the utmost and by high culture may double their present yield.

Government Plantations covered in 1883, 1778 Acres and will yield 544,000 lb. for 1887.

They contained in Sept. 1886.
- Plants in Nursery.— 1,249,000 Ledger.
- 560,000 Succirubra
- 755,700 Ledger.
- 234,000 Officinalis.
- Plants in the field.— 74,000 Calisaya & Haskarliana. 8,000 Lancifolia, 556,000 Succirubra & Calapta.

Private Plantations in 1886 covered 21,000 Acres and contained Succirubra 14,000,000 trees.
Other (Ledger.?) 16,000,000 „

30,000,000

The Crop for 1887 is estimated at 1,433,520 lb.

C. MODE OF CULTIVATION.—Stripping is condemned and all plantations are worked as plantations of fir in Europe by planting closely (4×4 Rhynland feet) and thinning and lopping yearly to promote robust growth. The yield is 180 lb. per Acre for Ledger for the 3rd year increasing yearly till it reaches 600 lb. per Acre in the 10th year or 3,000 lb. in all in the 8 years. After the 10th year none but fully developed trees will be left when uprooting must be

resorted to and 2,400 lb. per acre may be expected. The loppings of the 3rd year contain only ½ per cent of quinine increasing ½ per cent each year till after 10 years 5 per cent is expected. The collection of ½ and 1 per cent barks in the 3rd and 4th year will depend entirely on the market. 1 per cent is now considered just sufficient to cover the expenses of collection.

The Succirubra loppings give 180 lb. in the 5th year (those of the 3rd and 4th not being saleable now) increasing yearly to 480 lb. in the 10th and yield 2,000 lb per acre in the six years after which none but robust trees will remain. To obtain fine quill bark the plantations must be left to 15 to 20 years of age when 3,000 lb per acre may be expected.

The exports from Uva Ceylon are likely to increase.

C. Robusta is recommended by Dr. Paul for Ceylon, and both he and Messrs. Howard say prices cannot rise till Ceylon shipments fall off but would do so if they would cease to export twig and inferior barks.

The Honorary Secretary was requested to thank the Secretary of the Ceylon Association for this very interesting report and to ask if Ceylon cannot give Cinchona statistics in return for those from Java and Wynnad.

IV. CATTLE TRESSPASS.—Read letters from Messrs. Hinde & Co. and the Collector of Malabar.

Resolved that as the matter is receiving the attention of Government, the Association will await their decision before agitating further, but the Honorary Secretary was requested to find out what measures Government found necessary for the protection of Forest Reserves that similar measures might be asked for in aid of Plantations.

The Honorary Secretary was further instructed to ask the Collector of Malabar to erect a pound at Meppadi.

V. ROADS.—It was stated that the Battery road is n a very bad state; that in consequence the price of grain in Vythery has been raised; that the Coffee crop is expected to be very early this year especially on the Battery side, and that the present allowance of 5 coolies a mile is totally inadequate to prevent the road becoming impassable much less to improve it.

The Honorary Secretary was requested to write the President District Board and point out that though ample funds were voted, none seem to be applied with any effect, and that the road connecting Wynaad with Mysore, the chief source of grain; and the best cropping district of Wynaad with the coast, is consequently the worst in the Taluq.

VI. JUBILEE HALL.—Resolved that Messrs. Winterbotham, Jowitt, and Hockin be requested to form a Committee to select a site for the proposed Hall.

The site to be as near Chundale as possible.

VII. PAPERS ON TABLE.—G. O. Revenue No. 613, 614, 24th June 1887, on cultivation of Ipecacuanha, stating there is a possibility of the supplies from S. America ceasing, and Government hope private enterprise will take up the cultivation. It grows best at Nilambur.

G. O. Revenue No. 634 on manuring Cinchonas.

Report of the Ceylon Planters' Association for year ending February 1887.

Report on Coffee and Cocoa written by order of the Royal Commissioners for the Colonial and Indian Exhibition 1886 by Mr. Pasteur. The Honorary Secretary was requested to write and thank the author.

Report of the N. Mysore Planters' Association.

Proceedings of Wynaad Taluk Board.

VIII. PLACE OF MEETING.—The next meeting will be held at the Volunteer Reading Room, Vayitri, by kind permission of Capt. Walker.

(Signed) J. R. MALCOLM, *Chairman.*
" J. WILLIAMS HOCKIN, *Hony. Secy.*

HYDROCHLORATE OF COCAINE IN VETERINARY PRACTICE.—The Inspector of Cattle Diseases, Madras Presidency, writes in his report for 1885-86:—Having heard a great deal regarding the advantages of the use of Hydrochlorate of Cocaine in operations on the human eye, I decided, on the first opportunity, to give it a trial. Fortunately, a case of "worm in the eye" (Filaria oculi) was admitted into the Veterinary Hospital on the 2nd of June 1885. The patient was a large waler mare, extremely troublesome and nervous in fact, it was with the utmost difficulty that anything like a good view of the eye could be obtained. I therefore cast her, when the parasite was clearly seen wriggling about in the aqueous humour. There was slight inflammation, with partial opacity in the lower portion of the cornea, involving nearly one-half of its surface, which was undoubtedly brought about by the case having been allowed to go too far before surgical aid was sought for, as the worm had been noticed in the eye fifteen days before the mare was brought to me. I procured a solution containing one grain of cocaine in twenty-five minims of water, of a strength of 4 per cent.; the Membrana Nictitans was held back and the solution painted over the surface of the cornea, conjunctiva and eyelids with a camel's hair-brush. In about ten minutes complete anæsthesia had taken place, with considerable dilatation of the pupil. I then made a small puncture with the point of a Macnamara cataract knife, well guarded with lint at the upper portion of the cornea, through which the Filaria escaped. In a little less than twenty minutes sensation returned to the eye. No inflammation followed the operation, and the case did well from the first. The opacity gradually disappeared and the patient was discharged cured in fourteen days. This new local anæsthetic cannot but prove of the utmost value in veterinary practice, more especially in operations on the eye. It has only one drawback, and that is its high price. Previously, in operations of this kind, I always used to administer chloroform with the best results, but, of course, although I have never had any accidents with chloroform on the horse, still the danger attending its use, compared with the use of cocaine, is great indeed. Therefore, the latter must, for the future, act as a valuable and safe substitute for chloroform, for the production of local anæthesia.

THE ALTITUDE IN WHICH COFFEE IS GROWN IN BRAZIL.

In our note to the query of our correspondent who wrote about trying coffee at 500 feet elevation in India, and whose letter signed "S." appears on page 197, we omitted to answer his query about the altitude of coffee lands in Brazil. We refer him and all others interested to Van Delden Laërne's great work, an English translation of which has been published by Messrs. W. H. Allen & Co. It is a mine of the most varied and valuable information. Premising that the coffee region of Brazil is in the latitude of Australia, (between 10° and 40° south) Mr. Laërne deals with altitude for coffee in the passage we quote, and with reference to which we need merely remind our readers that a meter is very nearly equivalent to 3′ 3⅜″:—

The actual coffee-producing district, however; that is to say, the great Parahyba valley,—is enclosed between the Serra da Mantiquiera and the Serra do Mar, or sea-board mountains, which following the coast from Santos near the small sea-port town of Angra dos Reis, curve farther landwards until at length after having split the province of Rio de Janeiro from south-west to north-east into two almost equal parts, they lose themselves in the hilly districts of Espirito Santo.

These two above-mentioned chains of mountains which change their names very often, are frequently connected with each other various points by their at numerous branches, ridges, and spurs, so that the intervening country, such as the Parahyba plateau, has a good right to its name of Serra Acima, in contradistinction to the coast lands to the east of the Serra do Mar, which form the Sera Abaixo, or low mountain lands.

That this Serra Acima or mountain plain consists of a series of different valleys, requires, after what I have said above, no further demonstration. It is however, just those valleys that give such a peculiar character to the coffee-producing districts in this zone.

In order to conceive of them as they really are, one must picture to oneself a number of sloping valleys, studded with a chain, more or less perfect, of upheaded, hills or morros from 50 to 80 meters high, and shaped like a half orange. Then one may obtain a distinct notion of the coffee-grounds of the Rio Zone, the favourite terras de meia laranjas. And when one then pictures those chains of hills planted with coffee-trees, or, to speak more correctly, with coffee-shrubs without trees yielding shade, it will be obvious that the aspect presented by those coffee-producing districts is very peculiar and bare indeed.

The Serra Acima, the actual plateau of the Parahyba is usually subdivided into three strips or zones.

a. Terra abaixo or low lands, from 100 to 200 meters high, which are comparatively little sought after.

b. Terra medio, or lands between 200 and 550 meters above sea level.

c. Terra frio, or cold, lands situated more than 550 meters above the level of the sea.

Of course one cannot always adhere strictly to this division, seeing that the slope of the valleys and their situation in regard to the sun, exercise a great influence on the success of coffee-growing on lands higher or lower than the terra medio. For there are valleys, for instance those of the Rio Negro and the Rio Granda in the district of Cantagallo, where coffee is successfully cultivated at a height of 130 or 150 meters thus in the terra abaixo itself; while cafesaes there at a height of more than 450 meters yield little fruit, although they look more flourishing than the lower-lying ones.

On the whole, however, we may say that in the Rio zone the terra frio, or lands situated more than 550 meters above the level of the sea, are unsuitable for coffee-planting; seeing that the trees there, although they thrive very well, yield little fruit, while many of the beans are empty shells or chôchôs. Moreover these high-lying cafesaes ripen their fruit very late, while the season of full blossom generally falls in the end of January and beginning of February. But the crop of these cafesaes does not mature till the beginning of the rainy season; that is to say, in November and December, frequently even in January.

It is this coffee which, peculiarly oblong in shape, and often imperfectly formed (rosca), is known in commerce as Café das aguas or rain-coffee. But it is very little thought of.

This is why the coffee-grounds in the mountainous Rio zone are designated according to their exposure to the sun, soalheiro and norwega lands.

By soalheiros are meant the lands longest exposed to the sun — that is to say from about eleven in the forenoon till sunset. These are thus situated to the north, north-west, west and south-west of the morros or hills; while the norwega lands, which only get the morning sun till eleven o'clock, form the opposite slopes of the morros.

In several districts, especially in the Cantagallo, one may ride for hours through coffee plantations, where the one side consists exclusively of soalheiros, the other of norwegas.

As to which of those exposures is preferable, that of course depends on the altitude as well as the general slope of the valley. In the province of Rio, for instance, at an average height of from 450 to 500 meters, the warm soalheiro lands are preferred, while at from 150 to 300 meters more profit is often expected from the clearing and tilling of the shaded norwegas.

It will thus be seen that generally the best zone of altitude in Brazil is from 600 feet to 1,800. In the San Paulo district, however, conditions of climate render coffee cultivation profitable at considerably higher elevations. But what our correspondent wanted to know was how low he could go at 17° north in India. In Brazil the favourite elevation is above 600 feet, although in some cases coffee grows well at 450 feet, and in Jamaica, which is in 17° south, the best coffee grown is the "Blue Mountains" product. What we feel is that provided leaf-disease is absent, our correspondent might reckon on half-a-dozen large crops and then on collapse.

NATIVE AND FOREIGN PLOUGHS AND RETURNS OF RICE CULTURE.

"Some thirty-fold, some sixty-fold, some a hundred-fold," constituted the illustrations of one of the matchless parables of Him "who spake as never man spake," and one hundred-fold was evidently used to indicate the highest increase which could be expected under the most favourable circumstances from a grain far more prolific than rice,—viz. wheat. No wonder, therefore, if our breath was taken away when we read Mr. Green's statement made at the anniversary meeting of the Prince of Wales's College, that, as the result of improved culture here in Ceylon by the use of an improved plough, the yield of rice had been raised from the wretched figure of 8-fold, not to 18-fold, not to 28-fold, or even 80-fold, but 108-fold at one jump! Professor Wallace of the Agricultural Chair in Edinburgh University came to our office immediately after we had seen this statement, and on our mentioning it to him, he at once said:—"That is the way harm is done and reform arrested: by exaggerated statements founded on isolated and extreme cases." But our readers will observe that Mr. Green now deliberately repeats the statement in an official letter, contenting himself with the calm remark that such a result as the gathering of a one-hundred-and-eight-fold crop is "fairly good." In our opinion it is so much more than fairly good, that we should like to have full details of all the circumstances, of seed grain, soil, depth turned up, subsequent treatment of soil, quantity of water used, mode of germinating, system of planting out, &c. Above all, was manure applied? f so of what nature and in what quantity? We have heard of seventy-fold, under favourable circumstances, in Ceylon, but we should like to be assured that the statement was made on ascertained and undoubted data. Sure we are that 18-fold is a very fair average in our island, while too frequently the yield does not get beyond the 8-fold of Mr. Green's experiment. Mr. Elliott, who takes a sanguine view of the possibilities of rice culture in Ceylon, thus wrote in his paper on the subject contributed to the Journal of the Ceylon Asiatic Society:—

I will now pass to consider *the quantity of paddy that can be grown on an acre* of land. But I must first point out that the yield in Ceylon is generally spoken of by "fold," and, ordinarily, without reference to the amount of seed sown, or the mode of sowing adopted. In India the seed is, I believe, invariably sown in small beds, and the plants transferred when about a month old to the prepared land in which they are to be matured. Under this system 50 to 60 pounds weight of paddy, or about an English bushel by measurement suffices to sow an acre of land.

In Ceylon (except, perhaps in Jaffna on a small scale) this system is not followed. The seed is sown broadcast, and in the Batticaloa District for the munmari without being previously germinated, as usual in the Sinhalese districts. This leads, I believe, to great waste, as much as 3¾ bushels to the acre being, it is alleged, sown in some lands in Batticaloa, and nowhere less than two; while in the Sinhalese districts it takes six bushels to sow an amunam's extent, or about 2½ bushels to the acre. A return, therefore, which might be termed one of 30-fold in India, would be equivalent to one of 12 in most parts of Ceylon, and in some parts to only 7½-fold. In examining the figures for Ceylon, therefore, it will be well for purposes of comparison to reduce the returns secured to the number of bushels of paddy per acre.

In Mannar, Baldæus speaks of a return of a 100-fold, and Mr. De Hoedt, late Head Clerk of the District Kachcheri, and a landowner and practical cultivator, assures me that in a favourable season (in the absence of proper irrigation) he has ordinarily

obtained a return of 30-fold on a sowing of 3½ bushels, or over 100 bushels an acre ; and that 25-fold or 87 bushels is the usual return cultivating in the ordinary native way.

In Matara, before irrigation was introduced, in favourable localties a return of 30-fold or 75 bushels an acre was admittedly obtained ; and Mr. Dawson, in his reports as Grain Commissioner, speaks of a similar return being secured in two villages near Hikkaduwa. These returns are exceptional, it is admitted, under existing circumstances ; but they are mentioned to show what can be, and is being, secured in Ceylon without the stimulus of improved cultivation or regular irrigation.

A result equal to 25 or 30 fold is recognized as exceptionally good in Ceylon rice culture, so that it is of much importance we should be informed of *all* the circumstances leading to a return of 108-fold, in order that we may be able to judge if similar results can be obtained on a large scale and over widely separated areas of rice land in Ceylon. Mr. Elliott deems a full supply of irrigating water of great importance. But we have long held that the great fault of rice culture in Ceylon is the waste of water which converts the soil into soft mud and the cereal into a purely aquatic plant. If only good cattle were available, we believe an enormous improvement might be effected by substituting dry ploughing and harrowing for the present wretched system of merely stirring the saturated mud. But while we thus advocate dry ploughing and even pretty deep ploughing where there is a certainty that a fertile soil rests on a sweet subsoil, yet we vividly recognize the danger and damage which might result from recklessly turning up to the surface a sour subsoil earth. There is a logical connection between the weakly animals and men, the soil converted into mud and the implements by which the mud is stirred, and we fear we cannot hope for improved ploughs and ploughing amongst the natives and yields in proportion, at least to any great extent, until the careful cultivation of good native or introduced grasses and a better knowledge of cattle breeding and treatment, render superior draft animals available. In our columns today, will be found a letter from a correspondent who has paid a good deal of attention to the subject of native ploughs, and he quotes the opinion of Professor Wallace that as matters stand at present, the breed of cattle being so inferior, more is to be expected from improvements of the simple native plough than from its supercession by iron ploughs after European patterns. But neither Professor Wallace, correspondent nor editor professes to be infallible, and by this time Mr. Green must have obtained experience which ought to give his matured opinions great value. We are simply startled and led to stand in doubt by the bare, unexplained (certainly imperfectly explained) results of an experiment which raised the yield of rice from 8-fold to 108-fold and we and our readers should like to have fuller details and explanations of processes which, if they can be continued with the same results, will revolutionize rice culture in Ceylon.

COFFEE GROWN BY MEANS OF IRRIGATION.

The following interesting communication has reached us from Southern India :—

Ootacamund, 17th Aug.

SIR, I have just read your *T. A.* for June, and find on page 836 a para with reference to coffee grown at "Seegoor and Musnagoody." I don't know who is responsible for the information given to the *Nilgiri Express* that we had lost 20 per cent of our blossom, but I can assure you this is not the fact. There are only four estates down here (3,000 feet) two of which I am in charge of, and we all have good crops especially the ones I am managing and which are under heavy "irrigation" and have been for the last 20 years!!

You say you "doubt the success of coffee when it has to be irrigated;" well, sir, all I can say is that those two estates have given an average crop of 10 cwt per acre for 17 years. And the crops of 1884-85-86-87 reached 17 cwt per acre!!

For the last 5 years the crop has been 12 cwt per acre, so this does not look as if coffee would *not* do under irrigation. This system of cultivation requires heavy manuring or otherwise it would be "fatal." I, like my brother planters, get my share of "leaf disease" (this year rather bad) but the trees seem to shake it off and go on bearing in a wonderful way. "Leaf" affects my young coffee most, but I doubt not that when this gets its "manure" it will go ahead at

10 CWT PER ACRE.

We are not, of course, responsible for the statement which appeared in the *Nilgiri Express*. Our scepticism as to coffee flourishing in a climate where it required artificial irrigation was, founded on, we admit, limited experience in Ceylon. Here the only important experiment of the kind was made in the hot, dry valley of Dumbara, by the late Mr. R. B. Tytler. In the palmy days of coffee the difference in value of crop to him and his partner, Mr. Elliott, was calculated at £10,000. Mr. Tytler, therefore, felt himself justified in spending £20,000 in excavating a long canal from the Mahaweliganga, to work a turbine and raise the surplus water by means of a very powerful set of pumps, to the top of a knoll over 400 feet above the level of the water works. The water sent up to this elevation was to be distributed by a system of pipes. But wash took place from the tremendous pressure, the irrigation water was found to be but a poor substitute for rain showers, and in short the expensive experiment was largely a failure. We suppose that the estates managed by our correspondents are situated on comparatively flat, or gently sloping country, "under a tank" or a series of tanks, as is the case with irrigated rice fields ? The experiment has been so successful, manure added to irrigation water enabling the coffee bushes to combat leaf-disease and yield exceptionally large crops, that we should be very glad and our readers would be much interested, were full details furnished of the history of those estates. The climate must, of course, be dry for at least a large portion of the year. But we should like to know about "the lay of the land" and the sources of the irrigation water? Is it taken from a river, direct to the land, by means of an anicut, a larger canal and a series of smaller distributing channels ? Or is there a natural lake? or an artificial tank supplied from captured or diverted streams? Can the whole surface of the estates receive a supply of water at once, or are fields irrigated in succession ? Is the irrigating water supplied exclusively to the roots of the trees, or is attempt made to produce a spray in imitation of rain, so as to wet the leaves? We are led to suppose that the estates are well situated for supplies of cattle manure ? But we assume the use also of artificial fertilizers, bones, broken or ground or in the form of super-phosphate, castor poonac, &c. ?

Here in Ceylon, leaf-disease has been so virulent, often so absolutely fatal, that after a time the struggle to fight leaf-disease with manure was abandoned. But in some of the drier parts of such districts as Matale and Uva, a combination of irrigation water and manure might at least be tried and might lead to important results. But before we can recommend any experiment in Ceylon,

we desiderate full details of the history and conditions of the wonderfully successful experiment made on the sub-ranges of the Nilgiris, and we hope our correspondent will gratify by a more lengthened communication the curiosity which his short but interesting note has excited.

IMPROVED PLOUGHS AND REFORM IN RICE CULTIVATION.

We take over from the "Examiner" a letter in which Mr. Green, the Director of Public Instruction, explains his position in regard to ploughs and ploughing. It will be seen that Mr. Green does not recommend iron ploughs for operating on mud, but only for turning over dry soil.

We have no further information of an official character respecting the Toppur experiment, but the brother of the Agricultural Instructor who had charge of the experiment has handed us a number of letters in which the Instructor mentions the progress of his work and the manifold hindrances experienced from drought, from wild pigs and worms, from the unwillingness of schoolboys to work, and from sceptical villagers. In the case where 108-fold was obtained, the process of improved cultivation and the planting out of the rice seedlings instead of the usual broadcast sowing are described, but we find no mention of manure, which the gentleman who handed us the letter said *he thought* was used. This is the one important point on which full information is desiderated; and we trust it will be forthcoming. With the liberal use of good fertilizing substances, added to careful culture, the result of 108-fold may not be so astonishing as it now seems. We are struck as we read with the evident good faith of the Agricultural Instructor, whose system was favourably reported on by the Mudaliyar and others. But the attitude of the villagers, as described by the Mudaliyar, is very characteristic:—

"I questioned the villagers about this. They say that it is a good system. When I asked them whether they will adopt it for their next cultivation, they began to pull a long yarn and say we cannot afford to pay for such ploughs and pay coolies for transplanting.

"I then pointed out the small quantity of seed required for the plantation and the larger produce they may expect to get which alone was enough to pay for the expenses and have a good saving. The reply was 'Yes, sir,' but I observed that the 'yes, sir,' was not a sincere one. However, perseverance of this system may ultimately open their eyes when they see repeated good results."

From a letter dated 3rd August we quote full details of the result of the experiment, as stated by the Agricultural Instructor, Mr. B. W. Chinivasagam:—

We were busily engaged in thrashing our paddy up to the present date. The whole amount of our paddy is nearly 8 avunams, *i.e.*, 112 bushels. I expected to have some more paddy, but unfortunately pigs damaged a great deal. It is not a custom here to thrash immediately after reaping. So I was unable to send you the number of bushels. After thrashing, I got it measured separately in the presence of the schoolmaster, the police headman and the Watte-vidana as requested by the Director of P. I. and distributed as follows:—

		Avunams.
1	Rent of the land	2
2	Government share	0½
3	Seed paddy borrowed, returned with interest	1¼
4	Cooly hire for reaping, heaping and thrashing	1¼
5	Miscellaneous, *i.e.*, cart hire, paupers, &c.	0½
6	Remainder	1½
7	Seed paddy for next year ...	1
	Total ...	8

Out of the whole, my share is about six bushels. Anyhow our yield is much better than the villagers'. I put in nursery bed only five measures for transplanting which yielded 18 bushels, that is to say 108-fold. We ploughed and sowed five bushels which yielded 78 bushels, that is to say 15 3-5th-fold. We sowed two bushels in the native way and their yield was 16 bushels, that is to say 8-fold. Some of the heaps of the adjoining fields are not yet thrashed, but those that are thrashed is only seven and eight. The yield we have to compare is also 8-fold. Seed-paddy is in charge of the police headman and the Government share is in my charge. I distributed the remainder to the ten boys according to their work. All the boys received their shares excepting one boy, who is willing to cut away from the school. Many of the other fellows are also not willing to come to the garden work. This is because our Vanniah asked the boys to put up a fence around the garden land. It is very difficult to manage with these small boys. As they were unable to watch properly, pigs damaged so much. If the Government try to check the pigs coming into the plain, we can have better crops with advantage. Another disadvantage we had this year is [a scarcity of] water.

One feels that as far as the Agricultural Instructor is concerned there is no attempt to exaggerate. The crop was obtained and divided. The only defect in the information afforded is that nothing is said about manure, that is, if any fertilizing substance was really used. We should like to know if manure was used by the natives and in all the experiments of the Agricultural Instructor? and specially if manure in more than ordinary quantity or of better than ordinary quality was used on the field which returned 108-fold?

Since writing the above we have received the following most interesting and important letter from Mr. Green, showing the wonderful results which improved cultivation of rice has given, not merely 108-fold but 360-fold! The head of rice which accompanied the letter is very fine, reminding us of the short sheaves with robust grain we saw ready for feeding horses at every stopping place in Java, rather than anything we have seen in Ceylon. Mr. Green writes:—

27th August 1887.

Dear Sir,—Referring to the desire expressed in your editorial of last night for more information regarding the Toppur yield of 108-fold from paddy planted out on land previously ploughed with Howard's Cingalee plough, I have to state that nothing (except the ploughing) was altered from the ordinary native methods of germinating the seed paddy and sowing it in seed bed, and then planting it out.

I am telegraphing to the Asst. Agent, Trincomalee, to confirm me in my understanding that no manure was used. But I am sure that no manure was used. If it had been, the result would have been much larger, witness the inclosed ear of paddy with more than 300 grains from one seed where manure was used. In the present case five seers of paddy thus planted out over rather less than two roods of the three acres cut gave eighteen bushels—strictly speaking *over* 108-fold, indeed 115-fold.

But I have had 360-fold from planting out *when manure was used.*

The share of the plough is simply to increase by usually from 1-6th to over ½ (in different and numerous experiments made) the yield which an ordinary native gets. But it is the planting out which gives the enormous yield.

Take the Toppur case. In the land sown broadcast our plough just about doubled the yield—similarly in the planted out land; an ordinary native would expect 40 or 50 or 60-fold, because each seed planted out

throws up 5, 6, or 7 shoots, with 5, 6 or 7 ears of corn—all our plough did was to make the ears of corn nearly twice as big, thus turning a 50 or 60-fold crop into 108 or 115-fold.

The great thing to remember is the enormosu multiplication of shoots thrown up *by one grain or seed* when it is planted out, whereas when it is sown broadcast, one seed produces usually one, and at most two shoots and ears.

Every native knows this—but they say "we can' plant out large tracts of land because of the labour," too many of them, however, neglect planting out their little plots for the same reason.

Take the case of the ordinary cottager with his ¼ acre lot, or ½ acre lot from which he gets a few bushels only because he sows it broadcast, and thus lives in semi-starvation. With a little bit of trouble, without any "new fangled apparatus," and without any manure, he could get from this plot of land at least five or six times what he now gets, while if he would use his house sweepings etc. as manure, and cultivate on improved principles, I can hardly say where the yield would stop.

The more I see of planting out paddy the more I am astonished at the possibilities of yield. As I said before, I have had it up to 360-fold. But with broadcast sowing I call 25-fold good, even when my ploughs are properly used.—I am, sir, yours very faithfully,

H. W. GREEN.

FAREWELL TO COFFEE.

THE DEMON DISEASE KILLING IT.

AN OLD AND EXPERIENCED COFFEE PLANTER FROM CEYLON TELLS THE REASON FOR THE HIGH PRICE AND SCARCITY OF YOUR BREAKFAST DRINK.

Seldom has the price of a product in use for general consumption advanced with greater rapidity than has that of coffee within the last twelve months, and the bean is now selling about 135 per cent higher than it did this time last year. It is the general opinion among the uninitiated that this is owing to a "corner" in the coffee market and that the high price is only temporary, to fall again when those who are running the corner have made all they can out of the deal. But this is far from being the real state of the case. True, there may be a corner, but at the same time it is very unlikely that the price of coffee will ever again be as low as it has been.

The real facts are that the high price now ruling are not due to a corner, but to the fact that the supply of coffee throughout the coffee-growing countries has been getting shorter and shorter every year, and the present outlook is that it will continue to decrease until coffee becomes a luxury only within the reach of the wealthy. The cause of the shortness of the crop is not, as stated in an article the other day, the effects of rust and flies on the plantations, but it is owing to the ravages of the hemileia-vastatrix, or coffee-leaf disease, a disease that is now absolutely rampant over every coffee-producing country in the world.

Dealers and speculators in Europe and America appear to be only now waking up to the fact that this disease is universal,* and that it has come to stay. The "boom" in coffee some years ago was so great that numbers of new plantations were opened and the additional supply obtained from this source, when they began to yield, nominally kept up the crops, but they soon died out, and nearly all the old plantations have for years not yielded one-fifth, and in some cases not one-tenth, of their original average. Then dealers hugged themselves with the belief that the hemileia would depart and the coffee tree recover from the disease in the same way as it had done when attacked with "black-bug" and "rust," but this is a very different matter and shows not the slightest signs of abatement.

The writer was a practical coffee planter in Ceylon when this dread disease first made its appearance no one knew from where. At that time coffee was "booming," and would net $25 per 100 pounds in London, sometimes more. A fair average crop on a second-rate plantation would run about 500 pounds to an acre, the estates or plantations varying from 150 acres up to 800 and 1,000 acres. Sometimes as much as 1,000 pounds per acre would be obtained from an estate. This, too, without the aid of fertilizers; in fact, the soil in Ceylon was so rich that until this disease appeared, no fertilizers were required.* But one day a planter noticed on the leaves of his coffee trees a small black spot surrounded with a yellowish fungus that came off like dust. On some leaves it was unnoticeable until they were held up against the sun, and then the black spot was distinctly visible. He at first took no notice of it until he found that all his trees were similarly affected and that the leaves were beginning to turn yellow and drop off. The coolies, when they went into the coffee, would come out with their black, naked bodies stained as if with yellow ochre. The attention of his brother planters was called to this phenomenon, and it was then found that nearly every plantation in the island was similarly affected.

At Peradenyia, near Kandy, the Government has a botanical garden, perhaps the finest and most complete in the world, and the superintendent, the late Dr. Thwaites, a botanist of world-wide renown, gave his whole attention to this new disease, bestowing on it the name of hemileia-vastatrix. In his opinion the disease would die out in the same way as previous plagues had,† but as month after month passed and the trees began to look sicklier and sicklier the planters were alarmed. Crops began to drop from 500 pounds an acre to 200, and then to as low even as 100, and in some estates to nothing at all. Once flourishing estates were completely snuffed out and abandoned. This, too, in spite of the greatest care and a high expenditure in artificial manures. Some planters would spend as high as $75 an acre in fertilizers and get a crop that did not bring them a return of $25 an acre.

At this time, also, Brazil was comparatively untouched by the disease and was pouring coffee by the ton into the European markets. The Ceylon planters tried everything, but matters got worse every day. Every known agricultural chemist in Europe was communicated with and experts brought from Europe at an expense of thousands of dollars, but the money might just as well have been thrown in the ditch.

There was not a fertilizer in the market, no matter how high-priced it might be, but was tried, and the only one that had any effect, and that was but slight, was sulphur blown upon the leaves. The disease was a peculiar one. Wood would grow plentifully upon the tree and it would be covered with leaves that to all appearance were perfectly healthy. Then the blossom would come and "set" beautifully, the branches being well laden with berries sufficient to yield a crop of from five to six hundred pounds. But a change would soon come over the spirit of the planter's dream of wealth. Before the berries were half-formed the fatal spot on the leaves would appear, then the leaves and the half-formed berries would drop off, and what had been a splendidly wooded estate became in a month or two a lot of bare sticks, with scarcely sufficient crop on them to pay the superintendent's salary.

The drop in values of estates was enormous. As an instance, the writer was interested in an estate for which, just after the leaf disease appeared and before it began to frighten people, $250,000 cash was paid. The estate rose in value, and about six months after the purchase was mortgaged to a Scotch land company for $150,000. Eighteen months afterward the estate was valued at $100,000, or $50,000 less than it was mortgaged for. It would have taken the purse of Fortunatus to stand such losses as that and at the same time keep up the heavy working expenses of the plantation, so the consequence was that every planter with anything to lose lost it. An attempt was made to stem

* We have no distinct evidence that *hemileia vastatrix* has reached the Western Hemisphere.—ED.

* Most incorrect. Manure was very largely used.—ED.

† Incorrect. Thwaites took at once the gravest view, and he was pooh-poohed by the most experienced planters.—ED.

the flood by introducing new varieties of coffee, and what was known as L b rian coffee was planted. The Liberian variety has a much larger bean than the Arabica, but it has a bitter taste. The experiment was a failure, as the Liberian trees showed the disease just as badly as the Arabica.

When the disease was at its height in Ceylon the Java people and the Brazilians denied that they were afflicted at all, and they induced the dealers in Europe and this country to believe them. They either did not know the symptoms of the disease they had, or they had some ulterior motive in denying it. They have continued to strenuously deny the existence of the disease on their plantations up to a very recent date, and they have been supported by many of the dealers; but their game, for whatever purpose they played it, is played out, and it is now a universally acknowledged fact that the disease is everywhere, and that it shows no signs whatever of abating its virulence, and that, moreover, it is as bad in Brazil and Java as it is and has been for years in Ceylon.

A few years ago a syndicate was formed among some New York men, prominent among whom were Jay Gould and ex-Senator Dorsey, for the purpose of acquiring a large tract of land in New Mexico and opening it up with coffee, which will no doubt grow there. The writer was consulted as a practical planter as to the feasibility of the project, and he gave it as his opinion, and he is of the same opinion still, that as a speculation it would never grow to pay. In the first place, as long as the hemileia lasts, and it will probably last for ever, you could never obtain healthy plants, and in the next place to grow coffee profitably you must have an abundant supply of cheap labour. This was what favoured Ceylon, as she had an inexhaustible supply of cheap labour to draw from the neighbouring continent of India, and planters could hire all the men they required at an average of 15 cents per man per diem and 12 cents for women.

In New Mexico all the labour would have to be imported at great cost. Then there is not sufficient work to keep all hands employed during the entire year. It is only in crop time that you can work a full force. The coffee berry may ripen up in a single night and acres become "blood red." If it is not at once picked it becomes "dead-ripe" and drops to the ground, where it is lost. What will be the end of all this is hard to tell. The writer's opinion, and, as has been said, he has had experience of the disease from the outset, is that in course of time it will eventually kill coffee entirely.—*Chicago Morning News*, June 7th.

[Coffee diseases are numerous and virulent in Brazil, but we have no evidence that *hemileia vastatrix* has as yet reached the Western Continent.—ED.]

HEMILEIA VASTATRIX.

Dr. A. G. Bourne, Professor of Biology in the Pre idency College, sends us the following interesting communication on the subject of *Hemileia vastatrix*:—

Sir,—"Novice," in your issues of the 26th ultimo, and 9th instant, has dealt with a subject which is not only of immeasurable importance to the coffee planter, but is one which possesses great interest for the biologist. It is a subject upon which it is as important to have the opinion—based upon a series of careful experiments of a trained biologist—as it is to have that of a chemist upon the operations carried on by bleachers or dyers. The Ceylon Government recognised this, and Mr. Morris, and subsequently Mr. Marshall Ward, were appointed to investigate the matter. This they did and after a prolonged and very careful enquiry communicated certain results, which are all embodied in Mr. Marshall Ward's final report to the Ceylon Government [Colombo, Sessional Paper XVII., 1881]. I think it is hardly possible that your correspondent has not seen this report but his letters shew a startling disregard of its contents

I would not for a moment lose sight of the fact that it is one thing to try certain experiments in a laboratory and quite another to repeat the same on a plantation. But Mr. Ward did more than record his laboratory experiments, he pointed out the possible application of the facts he had ascertained, and until all the planters of any one district have united together and given his suggestions a fair trial, I maintain that they have not used the advantages offered to them. Your correspondent does not distinguish between the disease and the organism which causes it. The organism is a fungus. *Hemileia vastatrix*, the spores of this fungus, fall upon the leaf and the filaments growing from them pass through the stomata on the under surface and ramify in the substance of the leaf, and until this occurs there is no "disorganised appearance," there is, in short no disease. A healthy leaf on a healthy plant is just as liable to be attacked as any other. The leaf, after being badly attacked falls off, and when many leaves are thus lost the plant, with its limited leaf area, cannot meet the demand of the fruit or seed. A bush which has been attacked cannot therefore bear as much fruit as a healthy plant, and so long as there are not enough leaves no amount of manure, as your correspondent says, will do any good unless it is assimilated, but it will help to form new leaves, and so enable the bush to assimilate more of it. If the leaves are attacked by the fungus they will fall off whether the bush grows in the shade or in the sun. It may be advantageous to grow coffee under shade for other reasons, but there is nothing to shew that shade, by virtue of its retarding the metabolic functions of the leaf, has any effect upon the parasitic fungus. What is wanted is to prevent the spores of the *Hemileia vastatrix* from getting at the leaf at all. The spores are blown on to the leaves by the wind either from other infected estates or from some other plant (at present we are in the dark as to what plant this is) which serves as a host for the fungus in a wild state. All shelter belts from wind then are likely to prevent the disease spreading. Cinchona grown among the coffee is probably useful in this respect. Further, where the disease is actually prevalent the diseased leaves (on which new spores are being rapidly formed) must be gathered as soon as they fall and carried in carefully closed (so that the wind may not scatter the spores) vessels to some place where they can be buried, together with the weeds growing among the infected coffee and the prunings, caustic lime being thrown over them and all left undisturbed for several months, until the spores shall have perished. Manure is no cure when the bushes are attacked, the fungus uses the manure, and thrives upon it just as much as the plant; it does, however, enable the tree to put forth new leaves and so to better afford the sacrifice of the attacked leaves. The fungus seems most easily to penetrate the young leaves, and Mr. Ward has made suggestions which might prove valuable as to the possibility of manuring and pruning so as to arrange that large masses of young foliage are not present when either monsoon bursts, as it is then that the spores seem to be specially carried long. distances. If "Another Novice," whose letter appeared in your issue of the 9th instant, has not read Mr. Ward's report I would strongly advise him to do so.—*Madras Mail.*

[Dr. Bourne's article is a favourable contrast to the pedantic array of learned verbiage in the letters he notices. But the Professor errs in supposing that the planters in Ceylon did not, individually and in combination, do all that men could do. But all was in vain and apparently all will be in vain, until the fungus and coffee disappear together.—ED.]

THE BRAZIL COFFEE CROP

for the year ended June 1887 is thus noticed by the *Rio News*:—

The coffee-crop year just finished must have been extremely favourable to the planter, and the speculative movement, so largely participated in by parties here, must have left a handsome sum to the credit of Rio, even after deducting the considerable losses made in June. July opened with prices of Ordinary 1st at 5$750 per arroba and exchange 20 15s 16d

A fair amount of business was done during the month (the reported sales reaching 317,000 bags) and prices at the end were 5$950 per arroba with exchange unchanged. Early in July the estimates of the 1886-87 crop were somewhat reduced and the probable outturn fixed at 3,500,000 to 3,750,000 bags. The month of August opened with Ordinary 1st quoted at 5$900 and exchange 21d. During the latter half of this month European buyers showed great animation, and the sales for the month were 445,600 bags, the price of Ordinary 1st advancing to 6$200 per arroba while exchange was quoted at 21½d. September opened with the quality we are quoting at 6$400 per arroba, and the market seemed rather quieter. In the middle of the month prices were suddenly sharply advanced, under a large business kept private at the time, which advance was followed by a slight reaction. The sales for the month were 330,800 bags and on the 30th the quotation was 7$150 per arroba for Ordinary 1st with exchange quoted at 22 1/16d. October opened with quotations reduced about 300 rs. per arroba and the market seemed quiet, but holders became very firm about the middle of the month and prices which had declined to 6$550, were advanced to 7$050, exchange also advancing to 22 3/16. Towards the end of October it became evident that a great "bull" operation was commenced and since then the course of our market has been steadily towards higher prices with only an occasional slight reaction. The reported sales in October were 318,300 bags, and prices had advanced to 7$550, while exchange was quoted at 22. The early part of November was rather quiet, but the "bull" movement in consuming markets, or, we should say, on foreign coffee exchanges, became more developed towards the end of the month, and the sales reported for the month were 438,500 bags, with Ordinary 1st advanced to 7$800 and exchange quoted at 22 3/16. During the first half of December great animation was shown; receipts fell off, advices from abroad were stimulating and our market advanced rapidly, although exchange was steadily advancing. Towards the end of the month the market was quieter, but rains in the interior kept receipts very moderate, and holders were firm. The proposed "bull" movement had further developed. In December the sales reported were 347,600 bags, prices of Ordinary 1st had advanced to 8$500 per arroba and exchange was quoted at 22½. Early in January we called attention to the disparity between the reported sales and the shipments. This was later on corrected by the brokers, who have also adopted the very sensible plan of following shipments by sales, where purchasers are not in the trade. This action will possibly prevent such differences as we have thought it our duty to call attention to. Early in January there were torrential rains in both the coffee zones of Rio and Santos; receipts were much reduced, prices advanced and the "bulls" were jubilant. About this time estimates for the 1887-88 crop appeared and the figures given for Rio were from 2,000,000 to 2,750,000 bags. Ordinary 1st reached 9$300 per arroba, but there was a slight reaction on the 21st, and the market closed at 9$100, with exchange quoted at 22 3/16. The reported sales in January were 187,300 bags. Prices declined again slightly at the commencement of February, and towards the end of the month the smartly increased receipts and less favourable advices from abroad produced great quietness in the market. For the month only 140,000 bags were reported sold, and brokers had reduced quotations to 8$600, while exchange was quoted at 22¾. Holders showed little inclination to sell at the decline, and the quotations were considered somewhat nominal. Up to the middle of March very little was doing and the quotations for both coffee and exchange showed no variations. Towards the end of the month, however, great activity was shown and buyers seemed crowding each other in their eagerness. The reported sales in March were 373,500 bags and the closing quotations were 9$100 per arroba for Ordinary 1st and 21 11/16d for commercial bills on London. During the early part of April the market was excited; prices rapidly advanced and the "bull" attack again became enthusiastic. In April the sales reported were 279,900 bags —although a much larger quantity was known to have changed hands—and quotations had been advanced to 10$700, with exchange quoted at 21 15/16. May opened very firm; there was not so much doing during the early part of the month, but quotations steadily advanced and all sorts of prophecies were made as to where prices were to go. A large speculative interest was created in Rio and market was "booming." During the latter part of the month the market seemed to have gone wild; quotations were almost daily advanced and the speculative purchases abroad increased; the more experienced operators are said, however, to have quietly relieved themselves of their purchases, and those speculators not directly interested in the trade had to support the burden of the subsequent losses. The sales, reported in May were 355,800 bags, Ordinary 1st was quoted at 13$000 per arroba and exchange at 22⅛. Between the 1st and 3rd June prices were advanced 1$000 per arroba, and as the reported sales to exporters had somewhat exceeded receipts, our brokers declared that 50,000 bags reported sold had been resold to dealers, and added this quantity to stock. Early in the month the first mutterings of the coming storm were heard, and this broke in all its fury about the middle of the month; foreign exchanges gave way, increased margins were called for, and when not met the purchases were sold out, and prices abroad were quoted at ruinous figures. Rio has kept firm, however, and June closes with nothing doing and prices nominal. Our usual tables furnish details of the year.

PUMICE.

Sir,—In reply to your correspondent, J. K. Gossain, I beg to say—(1) That Pumice is found in any quantity and of various qualities in Upper Burmah, the Central Provinces, and Aden.

(2) That it is largely used in the preparation of cement for fortifications, harbour defences, and reclamation works. Also by shoemakers and builders.

(3) Because, in consequence of its peculiar hydraulic qualities, and containing gypsum or natural sulphate of lime.

(4) The essential constituents of every good hydraulic mortar are caustic lime and silica.

HEM CHUNDRA DUTTA.

Calcutta, July 19th, 1887.

—*Indian Agriculturist.*

[The fragments which floated to Colombo from Krakatao were gathered and sold to carriage builders, we understood for polishing purposes, in lieu of the cuttle fish bones, which are generally employed for the purpose. Recent experiments have shown that "volcanic glass" when burnt, resolves itself into pumice.—ED.]

DIRECT IMPORTATION OF INDIAN TEA.

Some nine months ago a movement was set on foot for bringing Indian and Ceylon tea direct to Glasgow, and the measure of success which has been achieved in the tentative efforts already made has induced its promoters to believe that it has in it all the elements of success. Today the first consignment of the new season's tea arrives in Glasgow by the "City of Bombay," and the occasion is therefore appropriate for calling public attention to the subject.

The primary idea of the movement is to bring trade to the Clyde, between which river and the Ganges three first-class lines of steamers regularly ply, and in the matters of transit, warehousing, and so on, the facilities of Glasgow are unrivalled. On the other hand, the charges for such accommodation in London have hitherto been excessive, and the economies which might thus be effected would, it is contended, be a sufficient inducement to planters to market their tea here. The following table shows the difference between the London and Glasgow charges at a recent date on a chest weighing from 160 to 190 lb.:—

LONDON CHARGES.

	Private. s. d.		Public. s. d.
Landing housing	2 3	or	2 9
Taring	1 6	„	1 6
Bulkling	1 6	„	1 6
Rent per week	0 1	„	0 1
	5 4		5 10

GLASGOW CHARGES.

	s. d.
Clyde dues	0 2½
Cartage to warehouse	0 2½
Receiving	0 1
Taring	0 3
Bulking	0 3
Rent per week	0 0½
	1 0½

The London charges have now been reduced by 40 per cent. Before the reduction took place, the dues on tea imported into London were not infrequently equal to the freight paid for bringing this commodity all the way from Calcutta. Such a surprising state of matters was no doubt partly due to the low rate of freights which have recently been ruling, but in any case it seems absurd that the warehouse dues should be at least two-thirds of a reasonable freight from India.

The reduction already mentioned large though it is, but slightly affects the relative proportion of the Glasgow and London dues. We do not propose to enter too curiously into the probable cause of this reduction. Competition among the various docks in London may have something to do with the modification, but it is not unlikely that the fear of Scottish competition has had some influence in bringing about this result. If the competition from Scotland should become severe, doubtless the London charges will be further reduced, but in point of cheapness it is impossible for London to compete with Glasgow.

The saving effected will naturally go to the planters, and a gain of, say, two shillings per chest would amount to something very considerable on the total produce of a tea garden, and might make all the difference between failure and moderate success. This feature will naturally commend Glasgow as a market to the tea-planters of India and Ceylon.

Even those who deride, the idea of attempting to establish a tea market in Glasgow admit that warehouse dues would be much more moderate in that city, but they contend that there is some special fitness in London as a tea-distributing centre, not only for the United Kingdom, but for other parts of the world. Anyone may see from the Board of Trade returns that London does a large tea trade with Germany, and a considerable trade with Russia, British North America, and other countries not enumerated. In the matter of teas different countries have doubtless different tastes, and all have in the meantime a chance of suiting themselves, in the London market. This, however is no reason why teas suitable for the district of country which can be most conveniently supplied from Glasgow should not be brought direct to the Clyde. Indian teas are already regarded with great favour in Scotland. In proof of this, we may mention that the *Indian Planters Gazette* of the 14th June, commenting on the quietness of the London tea market, assigned the occurrence of a bank holiday in Scotland as the reason for the "quiet week so far as Darjeeling and the flavoury kinds of tea were concerned." In London there are trained tea-tasters, who give independent reports, and purchasers who are doubtful of their own judgment can make their selections in accordance with skilled neutral opinions. This is urged as a reason for retaining the headquarters of the tea trade in London, but the same thing could easily be done in Glasgow, if necessary, when the trade develops. The strong point in the London argument is that there only is the mystery of blending correctly understood. The promoters of the Glasgow scheme admit this. Their contention, however, is that teas from India and Ceylon require no blending, and in this they have the support of skilled opinion in India, as shown in a letter recently sent to Messrs. Hastings & Co., of Bothwell Street, Glasgow, by Messrs. Moran & Co., of Calcutta. The public must be the ultimate judge of this, and they will have suitable opportunities for making up their mind, as part of the tea brought to Glasgow will be sold from the garden-packed chests.

Glasgow in itself affords a market in which a large quantity of strong Indian and Ceylon teas might easily be placed, and there is no reason why it should not be sent direct. That city has also great facilities as a distributing centre for other parts of Scotland, and for the North of England and the North of Ireland. Mr. A. Erskine Muirhead, who is the organiser of the import scheme, is sparing no efforts to make it a success. We have no doubt that, from the advantages which it seems to promise both to the Indian and Ceylon tea-planters and to the Scottish public, it will have a fair trial; and in the commercial interests of Scotland it is to be hoped that it will achieve a large measure of success.—*Scotsman*, July 25th.

GERMAN SUGAR COMPANIES.—We give the results of the working of sixteen German Companies for the year 1886-87, which we have tabulated from the particulars published in the *Deutsche Zuckerindustrie*. About one half show losses, in three others the profits have gone to reduce or wipe off the losses of previous years. Only two declare dividends, although a third Company (Gandersheim) shows a net profit equal to 25 per cent upon the *returns*, which is certainly a remarkable showing when we consider the low price of sugar during this period.—*Sugar Cane*.

THE CALCUTTA SYNDICATE AND INDIAN TEA.—The success which appears to have attended the efforts of the Calcutta syndicate formed four or five years ago to promote a trade in Indian tea in Australia has induced the Calcutta merchants to turn their attention now to the United States and Canada, markets which have hitherto been mainly supplied with tea from Japan. A scheme has lately been proposed for stimulating the sale of Indian tea on the other side of the Atlantic by enabling consumers to buy direct from the producers, and it is said that there is already a prospect of practical results. Meanwhile it has been pointed out that as India imports for its own consumption about 4,000,000lb of tea per annum from China, something might well be done to promote the consumption of Indian tea in India itself. It is admitted that the natives of India enjoy tea as a beverage, and it is urged that it might easily be made the national drink. A correspondent of a Calcutta paper suggests that an association should be formed, with a capital to begin with of say R300,000 and that all tea shareholders, proprietors, companies, agents, managers, and garden assistants should be invited to take shares. These would be made as small as R10 each, and should be allotted among as many persons interested in the trade as possible, so that the earning of a large dividend would become an object of secondary importance to the fostering of the Indian tea industry itself. It is then proposed that the commercial association thus formed should buy up common and broken teas at the weekly auctions in Calcutta, and should make them up in 1oz, 2oz, and 4 oz. lead packets, with the weight and prices printed on neat labels on each side of the packet in English, Urdu, and the different vernaculars, so that purchasers could read for themselves what they were buying. Agents for the sale of these packets would then be appointed in every town and bazaar of importance throughout the country. These various movements and the remarkable success of the tea industry in Ceylon give good promise that tea will before long be one of the most extensive branches of Indian trade. —*Manchester Courier*.

Correspondence.

QUERIES ABOUT THE PREPARATION OF TEA.

Matale, 20th August 1887.

DEAR SIR,—Can one of your numerous correspondents answer the following questions?—

(1.) Up to what percentage is it best to wither, highest and lowest?

(2.) How ought leaf to be covered to ferment? I find that when withering from 60 to 63 per cent the roll blackens and the outturn is dull.

Some cover up their leaf to ferment in the jute hessian, some with cloth, and some in the blanket. Some, again, damp the cloth that covers the roll, others do not. There is another question I wish to have answered. Leaf, after it has been rolled is sifted for dhoolie, while some put the large leaf again into the roller, others allow it to ferment, and then roll hard. What is it better to do, roll at once after sifting "dhoolie" or allow it to ferment and then roll. In some notes that I have taken from the *Indian Tea Planters' Gazette* the following occurs:—"Leaf opens out during colouring and requires re-rolling. *Heavy re-rolling* before firing softens the tea, a light pressure to excite a little moisture gives the twist and polish required." Again, with regard to flavour, I have notes that contradict each other. One says: Care given to withering ensures a good colour, care given to roll ensures strength, but care will not ensure flavour. The other says: Flavour could be obtained from very even plucking, light rolling, etc. E. B.

ENGLISH *VS.* NATIVE PLOUGHS.

21st August 1887.

DEAR SIR,—In your impression of the 16th inst. I notice a very extraordinary letter signed "W. A. D. S." It professes to contradict certain statements of mine, concerning the relative merits of ploughs, and to correct "misrepresentations" made by me. A charge of misrepresentation is a very grave charge to make against anyone, and should never be made unless it can be proved. "W. A. D. S." does not attempt to do so. It is very difficult for me to meet this writer and to controvert his reckless and vague assertions, as his letter is not "understandable" to ordinary intellects, due, I believe, to the fact that a high educational test is not required for entrance to our Agricultural School. It will be well for this writer, before he attempts to criticize anything, to be sure that he has carefully read and understood what he criticizes. His opening sentence affords conclusive proof that he has not done this, or is a misrepresentation. I have nowhere said that natives do not require improved implements. His laboured attempts in involved sentences to prove the contrary is a beautiful example of industriously raising up a man in buckram for the pleasure it affords to knock him down.

It is kind of this writer to point out to the natives how they may acquire an improved plough—"they can club together and buy one." In his experience have they done so? "When richer land-owners buy it, others poorer will very readily hire it for a reasonable sum." Is this too within his experience? I will give you mine. I have an iron plough and I know that its owner will very readily give it gratis for use amongst the villagers if only to overcome their prejudices and to popularize it. Not only is no application for it made, but once when I wanted buffaloes to work it, and offered to hire them, I was told that if it was to work the iron plough no buffaloes were available, but if for the native plough I could have buffaloes without any payment. Though I have had the plough in use for about 3 years it has never yet been worked with village cattle.

Your correspondent "W. A. D. S." must excuse me, though he writes with the high sanction of an Agricultural Instructor, if I refuse to surrender my opinion to his, that Mr. Green did *not* take sufficient account of the difference in the conditions of agriculture when he introduced ploughs worked with horses in European Agriculture, for the cultivation of our rice fields. Their unsuitability lies not in the work they do, which is eminently satisfactory, but in their weight and consequen unsuitability for our small breed of cattle, and for our muddy fields. Given a not too muddy field and a couple pair of good buffaloes, I would much rather use an iron plough than two native ploughs, both for economy and efficiency of work. My opinion, which is the result of observation and experience, as to the unsuitability of the heavy iron plough for wet cultivation, is endorsed by so high an authority on agriculture as Professor Wallace of the Edinburgh University, who is now in our midst and with whom I had the privilege of discussing ploughs and their work. He agrees with me that the native plough does the work expected of it, and that the only objection to it is its narrow furrow. Widen it and natives want no expensive, heavy iron ploughs. The ploughs at present in use necessitate or at least cause the waste of an immense amount of human and animal power. Widen them and the only objection to them vanishes.

I remember Mr. Walker's Report mentioning that the yield of the field the Agricultural students worked would have been higher but for the floods. Was not the field the natives worked, so that the yield of both may be compared, subject to the same amount of damage from floods? If it was not, no comparison could be drawn between the two for the conditions vary.

I am much obliged to "W. A. D. S." for recommending me to read so advanced a book on Agriculture as Green's Primer. I leave such literature to Agricultural Instructors and their ignorant village pupils. Sorry to disappoint "W. A. D. S." But his letter has failed to "enlighten" me. It has sorely puzzled me as to what he meant to say, Let him not attempt the task again. I will not reply.—Truly yours, B.

A BIG TEA LEAF FROM A HIGH ALTITUDE.

Agra Patanas, August 23rd, 1887.

DEAR SIR,—Enclosed tea leaf does not quite come up to Dolosbage but it 's not a bad specimen I think grown at over 5,000 ft. elevation—from seed put into nurseries in April and planted out September or October 1885.

When pulled this morning, it measured 10½ in. by 4 in.—FULL both ways.—Yours faithfully, G.

[A beautiful leaf, the proportion of breadth to length showing high jât.—ED.]

COFFEE PLANTING AT LOW ELEVATIONS.

SIR,—Can you or any of your readers kindly give me any information regarding the cultivation of coffee in valleys at the foot of mountain ranges? So far as my knowledge goes, coffee is in Ceylon and India successfully cultivated by Europeans only at certain elevations above the plains—and I believe hat the same circumstances are found requisite in all regions in the eastern hemisphere. I should be glad to hear what the obstacles are to cultivation in valleys at the foot of hills in India. What is the elevation of the plantations in Brazil? Is it necessary to grow coffee on the slopes of hills in that country?

I am thinking of experimenting with coffee in a valley in the Eastern Ghauts of India, facing the east with a backbone of mountains on the west—the soil deep loamy stuff, the lie of the ground the ordinary rolling slopes found in such localities; elevation above the sea, 500 feet.

Rains commence with showers in April and May, followed by monsoon weather in June, July, August and September, with a further monsoon in November and part of December. I wish to know whether there is anything in the elevation or lie of land that puts success out of the question. I would add

that an experimental garden at 1,000 to 1,500 and above again at 2,500 feet promise well—the soil is so much more promising looking at the 500 feet that crops ought to be far heavier, but as all the plantations I have ever seen are situated at higher elevations than this, I am in doubt whether there may not be some wellknown objection against low-country planting that I am unacquainted with and which may wreck the enterprise.

The latitude of the proposed site of experiment is about 17° North Latitude. S.

[Here in Ceylon, native coffee, unpruned, well-manured bushes around native huts grow and yield, pretty well at a little over sea level. But regular plantations have seldom given good results under 2,000 feet, the favourite zone being 2,500 to 4,500 feet. The locality in which our correspondent wishes to try his experiment is nearly ten degrees further north than Ceylon, which must make a considerable difference, and the soil is described as exceptionally rich. We should therefore feel inclined to recommend a tentative experiment were it not for the fearful fungus pest, of which nothing is said.—ED.]

BUG ON TEA LEAVES.

August 25th.

MY DEAR SIR,—I don't know if "bug" has been noticed on tea leaves before, but I send you two leaves plucked from plants growing under coffee. The orange, mango, lime and guava leaves were equally affected.—Yours, L.

[The leaves are black with the fungus which ever accompanies the brown coccus. Yes: bug in a bad form has often been seen on tea grown under coffee, and the fact has been urged as an argument for the immediate removal of coffee under which tea has been planted. When this has been done bug has disappeared from the tea, and in no case that we are aware of has bug done special harm to tea.—ED.]

IMPROVED PLOUGHING AND CULTIVATION AND THE RESULTS.

No. 557. Office of the Director P. I.,
Colombo, 25th August 1887.

SIR,—I have the honor to annex for your information copy of a letter No. 289 of the 13th instant addressed by me to the Hon. the Colonial Secretary concerning work done at one of the new branch Agricultural Schools.

As the subject is interesting to many I should be glad if it could find a place in your columns.—I am, sir, your obedient servant.

H. W. GREEN, Director.

No. 289. *Copy of letter referred to.*

From the Director of Public Instruction to the Hon. the Colonial Secretary, Colombo. 13th August 1887.

SIR,—I have the honour to report that the Agricultural Instructor at Toppur in the Trincomalee district has reaped his first crop of paddy cultivated by the boys of the Toppur vernacular school under his directions.

2. Ordinary paddy land in the middle of a tract of fields cultivated by natives was selected and the results were:—

(*a.*) For land cultivated in the ordinary native style, 8 fold, the neighbours also getting 8 fold and 7 fold.

(*b.*) For land cultivated with the imported ploughs, but otherwise exactly in the native style, and without manure, 15 3-5ths fold, or as nearly as possible double that obtained by his neighbours with the native plough.

(*c.*) For land where the paddy was planted out instead of sown broadcast, as well as being ploughed with the imported ploughs, 108 fold.

3. These results are I think fairly satisfactory, and they are guaranteed by the Vatte Vidana and Police Headman who checked the measuring.

4. The results would have been better but for severe drought and a plague of insects. But of course this equally affected the neighbours, so the comparison of the work under the improved methods is not affected.

5. The extent of ground cultivated for these experiments was approximately 3 acres.—I am, sir, your obedient servant, (Signed) H. W. GREEN, *Director.*

MR. GREEN AND PROFESSOR WALLACE.

Colombo, 25th August 1887.

To the Editor of the Examiner.

Dear Sir,—May I ask you to reprint the following passage from your Veyangoda correspondent's letter in last night's issue, together with my remarks upon it? The passage runs thus:—

"Professor Wallace of the Edinburgh University, who came to Ceylon after a prolonged tour through India, visited Franklands Estate in this district last Friday. I had the advantage or meeting him, and conferring with him on agricultural subjects. His condemnation of iron ploughs, as unsuitable for our wet rice cultivation, is unqualified. I do not go as far as the learned Professor in condemning them, for I have one in use for some time and have every reason to be pleased with its work. All I say against them is that they are too heavy for our paddy fields, and that Mr. Green when introducing them did not take sufficient account of the difference between agriculture in the West and East, and forgot that ploughs that are considered light on dry ground and for horses, will be beyond the powers of our small breed of cattle in muddy land, to walk on which alone is a severe task."

I would remark,

1. That I have never advised an iron plough for wet rice cultivation. There is, therefore, no contradiction between the opinion attributed to Professor Wallace and my own theory and practice.

2. As regards your correspondent's statement that the iron ploughs are too heavy for "muddy land, to walk on which alone is a severe task," may I reiterate that ploughing in mud with an iron plough is useless.

Let me repeat the directions so often given—(a) Plough with the iron plough about 2 months or 6 weeks before the rain comes (or before you turn on the water from your irrigation system if you have have one), (b) when the rain has come or when you have turned on your water, cross plough with the native plough in the mud, and follow the natives' custom of cultivation prevailing in your district, which has generally been selected for some good reason.

The one sole use of the iron plough is when used in dry land before the mud work begins. It is an addition to the work done by the native cultivator, not an alteration of his work.

As regards weight, I fancy your correspondent must have one of the Swedish Ploughs which require buffaloes. The "Cingalee" Plough which Messrs. Howard Brothers of Bedford have made for us, weighs only 39½ pounds, and can be carried about anywhere on the shoulder.

3. To return to Professor Wallace. I had three interviews with him, and he was unsparing of his fault finding of the Indian iron ploughs, except one which he had seen at Cawnpore. This he said would do until he had devised a plough which he thought could easily be made, and the principle of which he was good enough to explain to me. I asked him for the name of this Cawnpore plough. He could not for the moment remember it, but on seeing a photograph of our "Cingalee" plough he exclaimed, "That is almost the same; it will do just as well."

4. In the space of this letter it is not necessary for me to deal in detail with Professor Wallace's Indian objections, beyond saying that (granted the use of the "Cingalee" plough) they do not apply to the Sinhalese Provinces of Ceylon, being mainly climatic.—I am, yours faithfully, H. W. GREEN, D.P.I.

INDIAN EXPERIENCES:

THE COFFEE LEAF DISEASE.

As stated in my last paper, I returned in 1871 to the Wynaad from the Neilgherries, after an absence of some five years, to find matters relative to coffee planting greatly altered. As a crowning blow to the hopes and prospects of the planter, leaf disease had taken firm hold of the plantations that had struggled through all the other ills that the Coffee plant is heir to, and was making such rapid and destructive progress as seemed to have paralysed the planter and well nigh caused him to give up in despair. The disease appeared first in Ceylon a year or two previous to the above date, then amongst the Coffee estate of Travancore, the most southern limit of Coffee cultivation in India. From Travancore the malady gradually travelled northwards till it reached Wynaad, Coorg, Mysore, and the most northern limits of the industry. With regard to Ceylon, I believe that at the earlier stages of the leaf disease Dr. Thwaites unhesitatingly recorded his opinion, after close and careful examination of the subject, that the disease would only finish its march of destruction with the death of the last Coffee tree in the island; and although he subsequently modified this opinion, I, for one, am inclined to believe that Dr. Thwaites' first impression was a correct one. It is at least quite certain that no more formidable enemy, or one more difficult to attack and subdue, has ever appeared on the earth to test the powers of scientists and the patience of any community of cultivators. To accurately describe the ravages of this mysterious fungoid growth on the leaves of the Coffee trees, and the consternation it caused throughout the Coffee districts of Southern India, is no easy task. I had seen the Potato blight in its worst form, as well as other kinds of plant diseases and injury by insects in England, and of course I had come face to face with the wide-spread injury caused to Coffee plantations by bug, borer, drought, &c., but such an affliction as this leaf disease, at once so rapid, devastating, and ruinous in its nature, I had never before seen, nor even dreamt of. It took a stout heart on the part of any planter to boldly face the difficulty, and after the first shock had passed over to begin courageously to battle with the disease and endeavour to eradicate it by a higher system of cultivation than he had previously resorted to. This was done in numerous instances, and large sums of money were again spent in artificial and other manures in order to sustain the vigour of the plant and, as it was supposed, to render it less liable to the attacks of the fungus; but up to the time I left the country in 1877, all this expenditure of energy and money had resulted only in a partial and limited degree of success.

The fungus could be seen more or less on the leaves of the Coffee bushes throughout the whole year, but the time of its greatest appearance was between the ending of the south-west rains—about the middle of September—and the end of crop-gathering—the end of December. At the latter date it was no unusual sight to see plantations denuded of leaves and with quantities of fruit of a greenish yellow colour, which refused to ripen, and which had to be gathered in that state, dried in the cherry, and afterwards pounded out in mortars, yielding Coffee of a very inferior quality. The fungus, or rust as it was sometimes called, first appeared on the leaves in the form of spots of a bright orange-red colour, which gradually merged into each other till the whole of the back of the leaf became covered with a thick coating of the fungus, resembling a red powder, staining the fingers freely when touched. On the first appearance of the fungus in the form of spots alluded to above, each spot contained a small worm about 3-16th of an inch in length, which could be easily seen by the naked eye; but whether this little worm or maggot was the outcome of the growth of the fungus on which it fed or whether it was the attack of the insect on the leaf which caused the growth of the fungus, no one seemed to be able to say, but the presence of the insect was an undoubted as well as a curious and interesting fact. As the fungoid growth spread on the under side of the leaf, the upper surface gradually became yellow, owing no doubt to the tissues of the leaf being destroyed and ending in the leaf falling. The disease was not confined to Coffee under any particular condition as regards culture, but appeared everywhere, on highly cultivated estates, on estates receiving cultivation only in name, on the trees remaining on abandoned plantations, and on trees that had sprung up from stray seeds in the jungle, so that it would appear that the disease was propagated by the spores floating in the atmosphere, detecting a congenial lodging place on the leaves of the Coffee plant, wherever or in whatever condition found.

An idea sprung up in the minds of a number of planters—after it was found that the highest cultivation it was possible to adopt had but a limited effect in checking the disease—that such a deterioration had taken place in the constitution of the ordinary Coffee grown in Southern India from some cause unknown, that it was absolutely necessary to procure "fresh blood" in the form of a distinct species of Coffee, possessing, if possible, a more robust constitution. Just at that time the Liberian Coffee was much spoken of, and an English firm of nurserymen was raising plants from seed procured direct from the West Coast of Africa for export to India or elsewhere to any one wishing to try the experiment. I was induced amongst others to order a Wardian case of plants to be sent out, which was done very promptly by the firm alluded to. The case contained seventy plants in thumb pots, and so admirably were they packed that every plant reached me in perfect health after a voyage and journey covering some forty days. The case reached me in December. I opened it at once and shifted the plants, which were then only about 3 inches high, into larger pots; they at once started into growth, and by planting-out time had grown into strong, healthy plants of an average height of 1 foot. These I planted out very carefully on a piece of good land on a new plantation I was then engaged in forming. The plants did not make much progress in the open ground during the continuance of the heavy monsoon rains; but as soon as these began to moderate, the plants began to grow rapidly, and by the time the dry weather had fairly set in had produced shoots of a very satisfactory growth, and leaves of an enormous size in comparison with the ordinary Coffee of the district. As time went on I found traces of the leaf disease on the young Coffee trees of the ordinary type, of which I had planted some 150,000 at the same time as the Liberian species; but no appearance of disease of any kind on the plants from England.

Matters grew gradually worse with the common species of Coffee on the estate till at last they were utterly divested of every leaf and left to weather the ensuing hot season under bare poles as best they could. The Liberian plants resisted the disease for such a length of time that I thought they were going to be proof against it; but in this I was mistaken, they caught the contagion at last and perished more rapidly than the plants of the old species of the same age. This was a very disappointing and disheartening experiment to me. It cost the respectable sum of 500r., or £50, which was, of course, thrown to the winds. I may also add that this particular plantation, although formed under the most favourable circumstances with regard to richness of soil, abundance of water, favourable aspect, &c., had to be abandoned long before the period at which it ought, under ordinary circumstances, to have yielded its first crop, and this solely in consequence of the leaf disease. It would appear from the above experiment that the disease was propagated by atmospheric influences alone, and was not the result of any inherent weakness in the ordinary Coffee of the district produced by raising plants from the same seed for a number

of years, as was supposed at one time by many planters.

Estates at high elevations escaped the scourge of leaf disease for a considerable time after it had wrought such havoc on estates at an average elevation of 3000 feet, but eventually it reached them, but hardly with such disastrous results, the colder nature of the climate at these higher elevations helping the plants through their season of privation. When an estate suffered to such an extent (I mean on the lower elevations) as to leave it without a single healthy leaf by the end of December—which was often the case—it was usual to prune the trees back severely, the primary shoots coming under this operation, which, under more favourable circumstances, were never touched. Manure was then given to the roots to the greatest extent possible, and with the first rain the trees at once started into growth, and were quickly reclothed in verdure, but of course no hope could be entertained of a crop for the next season, the tree only producing fruit on the one-year-old wood. All would go well up to the bursting of the monsoon, and throughout all the rainy months. When the rains ceased the trees presented generally a very beautiful appearance, covered with long freshly made shoots and glossy leaves, but only, alas! to succumb to the attacks of the fatal fungus as soon as the dry weather again set in, and thus the battle went on till the year I left India; in some instances the planter continuing the unequal contest season after season, while others, not believing that any ultimate good would result from such an expenditure of money, abandoned their properties to the indigenous growths of the country, which quickly obliterated every trace of the coffee shrub and former cultivation. Many planters are, I am given to understand, even up to the present date, continuing the fight, but with what result I am unable to say; but I know, that notwithstanding all the efforts to counteract this disease, they have not succeeded in driving it from the land.

With one exception I never found the fungus attack any other plant, even in the near neighbourhood of plantations suffering from the disease. This exception was in the case of a large timber tree—Lagerstrœmia microcarpa. The leaves of this solitary tree were to all appearance affected by the same kind of fungus, but it did not seem to spread to other trees, and the disease may be said to belong essentially to the Coffee plant, but its origin and gradual dispersion over Ceylon and the Coffee districts of Southern India is enshrouded in mystery.

To make matters still worse for the Coffee planter of the Wynaad, if that could possibly be, the great Madras famine took place during the last two years of my sojourn in India—viz. 1876-77. This dire calamity resulting by some computations in the death of nearly six millions of human beings in the Madras Presidency, affected the Coffee planter in several ways. Labourers came in from the Mysore to the estates in such a wretched condition from a long-continued scarcity of food, that they were wholly unfitted for work, and in hundreds of instances only arrived on the plantations to die, and their bodies in too many cases to go without burial. Hundreds perished by the waysides, their unburied bodies becoming the prey to wild animals of various kinds, the planters and even the representatives of Government itself in this wild district being quite unable to meet the emergency. The sights seen all over the district were appalling and revolting to the last degree, and can never be effaced from my memory. Every effort was made on the part of the planters to mitigate the distress, but under the circumstances they could do but little. Each and every hut on the estates was transformed into an hospital, full of men, women, and children, perishing from hunger and disease, and receiving no response to their piteous cries for help. In the district of Wynaad itself there was no actual failure of crops, as the total failure of the south-west monsoon in that region was never known, but in the Mysore country it was different, and as sufficient grain could not be produced in the Wynaad for the consumption of the imported coolies, and as the famine extended all over the Mysore territory, it followed that when the bands of labourers arrived on the Coffee estates, if in some cases able to work, could find little or no grain to purchase with the wages received. Grain was imported at the instance of proprietors of estates from Bombay, and even Burmah, but only in insufficient quantity to supply the working portion of the estate coolies, and as the district was far from the centres of Government relief arrangements, little could be done for those who were unable to work, and great mortality followed in consequence. It was very remarkable the quiet behaviour of the labourers under these fearful circumstances. No attempt was ever made to loot the small stores of grain on the different estates although any step in that direction could not have been successfully met by the planters. Seemingly, the natives preferred quietly to suffer starvation and death rather than break the law, and this was characteristic of their conduct, not alone in the Wynaad, but all over the Madras Presidency, during those two dreadful years. Previous to this famine it was the general belief that the ryots of Mysore had enough Raggy and other grain stored in the underground granaries to last out the longest period of any famine, but the fallacy of this belief was soon revealed after the first six months of 1876 had passed. The English nation responded nobly to the urgent call for help, and if I rightly remember, something like £600,000 was sent out for the relief of the perishing thousands. This sum together with that voted by the Indian Government doubtless saved innumberable lives, but relief could only reach certain centres, such as the town of Madras and other large towns along the lines of railways; the districts and towns remote from these means of communication suffering beyond the belief of all except those resident in the particular districts at the time. Could the terrible evils and consequences of an Indian famine be fully realised by all those engaged in the legislation of the Empire, they would, I imagine, throw fewer obstacles in the way of any scheme of irrigation or other work having for its object the prevention of any such disaster as over-took a large portion of Southern India during 1876-77, resulting in the death of some six millions of the native population.

This closes my remarks on the district of Wynaad. The little I have to add in my concluding papers will be devoted to subjects in connection with the Neilgherry Hills.—PLANTER.—*Journal of Horticulture.*

VEGETABLE PRODUCTS OF THE CANARY ISLANDS.—According to a recent report from Teneriffe the Cochineal cultivation still continues to decline, notwithstanding which it remains the staple article of export from the islands, the total quantity exported amounting to 1,449,698 lb., valued at £78,525. The average price during the year was calculated at about 1*s*. 1*d*. per lb., being 3*d*. lower in the pound than in 1885. Oranges and Bananas were shipped in great quantities for London and Liverpool. The exportation of the latter had considerably increased over the year before, and would doubtless have been still greater had it not been for quarantine impediments on arrivals from the River Plate; nevertheless, some 50,000 clusters of this fruit were exported at the average price of 3*s*. per cluster, equal in value to about £4,400. Tobacco as an article of export is becoming of great importance in Teneriffe and Grand Canary, where several factories have been established, which turn out considerable quantities of good cigars, much approved of in Germany, Spain, and South America. Large consignments were made last year to Spain under contract with the Government.—*Gardeners' Chronicle.*

PEPPER GROWING.

The cultivation of pepper though simple is an interesting one and affords ample scope for the application on intelligence of a higher order than we are generally ready to accord to the coolies employed in the work. The lines are laid out seven feet apart and the holes dug two feet square by over one foot deep, the centre of the holes being seven feet apart in line. At one corner of the hole a split post six or eight inches square is put in having about ten feet out of ground. The post should be of such wood as will not be readily eaten by white ants and tarred to prevent decay, for this post performs a very important part in the cultivation. It is usual to put three cuttings eighteen inches long into each hole in the opposite corner to the post, burying the cutting about six inches deep and for over a foot in length; it then throws out lateral roots from all the joints that are under ground which gives it ample strength to procure nourishment from the soil it is placed in. The cuttings are taken from the tops of the vine and are usually put in the ground to root before being planted out. The vines come into bearing in 2½ to 3 years and average half a catty to the vine for the first crop, increasing to three catties in the fifth year. A vine is in full bearing when 6 to 7 years old, but continues to increase year by year if manured and not allowed to over-run or overbear itself in any one year. A fair average crop I am told is 20 piculs to the acre and a good crop 28 piculs to the acre. Of this product there are two crops a year. Black pepper is simply the berries dried. The white come from the ripest berries which are let lie in a heap for some days to ferment, when the skins are removed by the coolies trampling amongst them; they are then washed and dried upon an improvised drying apparatus on which they are spread with a slow fire beneath. In order to make the vine throw out laterals and spread, it is topped when about two feet high. Such briefly is a sketch of the pepper culture, barring manuring, weeding, and cost of laying out a garden, which I believe all included for the first three years does not exceed $100 per acre. The gambier is grown simultaneously with the pepper in order that the refuse may be used as manure for the latter. Like the areca palm and coconut of Muar, pepper and gambier are the staple products of this part of Johore, but are not confined to this part of the territory, being grown I believe at Sedilli on the East and Batu Pahat on the west. But as showing the large quantity now raised I find that nearly two-thirds of the exports of these articles from Singapore are produced in Johore.—*Straits Times.*

NEW VARIETIES OF VANILLA.

A small trial shipment of vanilla pods of a kind not hitherto seen on our market, arrived in London a few days ago, and was placed in the showroom of a firm of Mincing Lane drug-brokers for inspection. The pods are from four to eight inches in length and from one to two inches in width, deep brown in colour and of a rather disagreeable rancid odour, possibly caused by the oil in which they have been steeped. The vanilla does not belong to the *planifolia* species, which is the sort generally met with on this market, but may be the fruit of the *Vanilla palmarum* or *V. aromatica* varieties which are known to flourish in Brazil, from which country the shipment in question is said to have been imported. The pods are entirely devoid of "frost," and it is very unlikely that, in the condition in which they are offered at present, they will at all secure a favourable reception. But it is by no means impossible that the growers may improve their product by paying greater attention to its cultivation and preparation for the European market, and in that case the ungainly-looking sample now offered to our buyers may prove to be the predecessor of regular and marketable supplies. The pods somewhat resemble a specimen described some years ago by Mr. Charbonnier, in the *Répertoire de Pharmacie* as the product of Guadeloupe, in which island it had been cultivated for several years, and whence consignments varying from 150 to 2,000 kilos. per annum have been shipped to French ports, where it sold at about one-half the price of Bourbon vanilla. Shipments of Brazilian vanilla have also been received in France from time to time, but the quality gave no satisfaction, and the supplies have also been of a spasmodic character. Most of the so-called vanillon sold on the French markets is also said to be a Brazilian product. Its use is almost confined to perfumery purposes.

It would certainly seem that there is room for an extension of the sources of supply of vanilla, provided the cultivation of the plant be conducted with care, and the fruit prepared in a manner suitable to the taste of the European market. The planters of Réunion and Mauritius have contrived to do this, with the result that a thriving vanilla industry has been created in these islands, the former of which now produces perhaps 100,000 lbs. vanilla per annum, and the latter more than half that quantity. Mexican vanilla, the best variety known, is mostly consumed in the United States, which country imports nearly 100,000 lbs. of vanilla yearly. In Java, Ceylon, and several of the Polynesian Islands, vanilla is to some extent successfully cultivated; but it will probably be a long time before the yield of these islands becomes an appreciable factor in the trade. The eastern coast of Madagascar appears to possess a soil eminently suitable for vanilla cultivation, but capital and skilled labour are required to develop the industry. As yet no particular effort has been made to create a trade in the product, but it is said that in some parts of the island the cultivation of the plant is increasing rapidly.

The extension of vanilla cultivation in various foreign countries should be beneficial to the London market. Hitherto trial shipments of new vanillas have generally been directed to Bordeaux, but the French Government, in the protective mood which at present distinguishes them, have just laid before the Chamber of Deputies a Bill imposing an additional duty of 416f. per 100 kilos. (about 1*s.* 6*d.* per lb.) on all foreign vanillas, irrespective of the duty of 416f. per 100 kilos. which is already levied upon all vanillas alike. Of course the doubling of the import duty on the foreign article is intended to secure to the vanilla-growers in Réunion (or Bourbon), which is a French colony, the monopoly of the market in the mother country. The result of the new impost will probably be to direct to London such consignments of Mauritius and, perhaps, Mexican vanilla as have hitherto found their way to Bordeaux. And if the vanilla cultivation in Madagascar should increase the produce from that island, which has not as yet been incorporated in the territories of the French Republic, it will probably also be shipped to London, and to this port also shipments from Brazil and the Australasian islands will eventually find their way. So far as we are concerned there is, therefore, no cause for grumbling. It should be added that the French Government, to do the thing thoroughly, propose to place a duty of 104f. per kilo. (about 36*s.* per lb.) on vanillin or artificial vanilla made in France, and 208f. per kilo. on foreign vanillin. The present market value of vanillin, which is mostly imported from Germany, is about 900f. per kilo. (10*s.* per oz.).—*Chemist and Druggist.*

ABOUT MAHOGANY AND OTHER PLANTS

we find the following information in the proceedings of the Madras Agri-Horticultural Society:—

Read the following letter from D. Morris, Esq., Assistant Director, Royal Gardens, Kew, dated 5th May, 1887:—

"Mr. Thiselton Dyer has received your letter of the 9th ultimo, and has carefully noted its contents. As he is now very busy with general administration work consequent upon the beginning of the new official year, he has asked me to acknowledge your kindness and to say that we are very pleased to hear good accounts of the mahogany seed last sent. It would be, as you say, a very desirable arrangement to get

the seed over so as to sow it in the hot weather, but unfortunately the pods only ripen in the West Indies about March to May, and hence the seed cannot possibly reach you much before August or September. I secured the last lot while I was travelling through the islands, and we shall get a small lot this year, not nearly so much as previously. It is strange that at Barbados, where the mahogany has been introduced within the last hundred years or so, it has established itself freely everywhere and forms thickets of self-sown saplings. The large trees seed most abundantly in this island, and it is much easier and more convenient to get mahogany seed from Barbados than either Jamaica or British Honduras: although in the latter places the tree is indigenous and the timber exported as an article of commerce. The difference is that the Barbados trees grow in the open and with a smooth surface underneath them, when the seed can be readily gathered. In the forests of British Honduras, the mahogany trees are of such large size and their surroundings so dense and over-grown that it is almost impossible to gather seed or get at the pods before they burst.

"We shall be sending you some more seeds shortly from a supply now on its way from Barbados.

"I am glad to find that the tree Tomato is becoming established in Southern India; the chief points about it are, if it is to be eaten raw, it should be dead ripe, if to be cooked all the seeds should be carefully removed.

"Dr. Shortt sent here some preserve made from fruits raised by him, and it was very good. I dare say for curries and chutneys it might be very useful."

"You appear to be rather badly off in India for good fruits, and there was little or nothing shown in this way at the Colonial and Indian Exhibition. Dr. Bonavia has prepared a paper on Indian fruits which will probably be read before the Society of Arts. This is a useful summary of the subject which will do good.

"Our Bulletin is becoming more widely known, and we look forward to a useful career for it. I enclose a circular respecting it, which will show that it can be ordered through any booksellers in case members of your Society wish to see it.

"There is a variety of *Moringa pterygosperma* known as *M. concanensis*. Do you think this is your plant? We should be glad of specimens. We have no seed of M. *aptera*, but we may be able to spare you a plant later.

"As Gamble is likely to be home soon, we shall discuss the *Memecylon* with him. It quite possible specimens may have been selected by him already. We have a single plant of *Rhamnus Purshiana* and we shall try and establish a few cuttings from it."

Read also the following letter from Mr. Morris, dated 9th May, 1887:—

"Since writting to you on the.....I find that we have one or two plants of *Moringa aptera* that are now in the resting stage, and we are happy to forward them in a small tin box, by post, in the hope that they will reach you safely. You will notice that the young plants have a very distinct bulb, which no doubt enables them to survive the prolonged drought of the Sinai desert. Dr. Schweinfurth, when at Kew last summer, mentioned that the Bedouins use the bulbs of this plant regularly as an article of food; and, indeed, on trying them here they were very similar to a succulent turnip or radish and if once the plant were naturalized in Southern India you would have a very agreeable salad, well adapted to the driest parts of India, while, at the same time, you would have an oil plant of great value."

Recorded with many thanks.

VII.—Read the following letter from the Rev. G. Richter, dated Mercara, 17th June, 1887:—

"By to-day's post, I send you a specimen of the *Eragrostis abyssinica*, the seed of which I got from you at the end of February, and which I put down on the 1st March in two beds of different soil, the one being dryer and less rich than the other. The seed germinated very freely on the third day and soon presented the appearance of a rich verdant cornfield, the moister bed excelling in luxuriance. In the beginning of May the plants, then 18 inches to 2 feet high flowered, and towards the end of the month turned yellow, and, as the monsoon set in on the 3rd June, I cut the crop, which, however, proved useless for grain, but was most eagerly eaten as dainty food by my cattle. I kept a little seed to make another trial after the monsoon, so as to give it the full benefit of the dry weather at harvest time.

"At the end of May I had the pleasure of watching the development of the extraordinary and curious flower of an *Amorphophallus* sp. (?) in my garden, whither I had transplanted the root with its four feet high snake like marked stem, with culminating, large, palmate leaves, three years ago from a jungle in South-Coorg. The herbaceous stem having died down after the rains for two successive seasons, this year no stem appeared, but the flower unfolded direct from the root, the purply top of the spadix appearing first and then the leathery spathe surrounding it. The spadix with its peculiar conical top, reached a height of 15 inches, and the diameter of the spathe expanding like an inverted hat, 11 inches. When the unisexual flowers arranged in two distinct belts around the fleshy spike, the female flowers being below, were fully matured, the plant emitted for one whole day a most fœtid smell, like rotten meat, and on examining the flower, I found a number of blue-bottle flies attracted to it and crawling over the spike, no doubt assisting in the process of fertilization. The offensive smell completely ceased the following day, but then also the whole flower rapidly decayed. The development of the flower from its first appearance above ground till its maturity took just four weeks, and with the setting in of the rains the flower rotted away."

THE CULTIVATION OF DRUGS IN ASSAM.

Mr. Oswin Weynton, a gentleman who has been a resident in Assam for about twenty years, recently delivered a lecture on the commercial products of that province to the members of the East India Association, and pointed out that the country is capable of almost unlimited development. Mr. Weynton considers that an intelligent, energetic young man of sound physique, and possessed of a minimum capital of 4,000*l.* (a condition which, we fear, will considerably reduce the number of eligible emigrants), could not look for a more certain competence than by starting as a planter in Assam. That country, which covers an extensive area in the north-eastern corner of British India, and is at present mainly known in Europe as a tea-producing district, might, if cultivated on scientific and modern principles, become a source of supply of a large number of articles which are at present derived from other parts of the British dominions or from foreign countries.

The obstacles to the development of Assam are in the first place, want of capital; secondly, the absence of railway communication with the outer world; and thirdly, the scarcity of labour, and consequent high rates of wages. The latter difficulty might be obviated by the immigration of labourers from Bengal or Burmah, or of Chinese; and the subject of railway construction throughout Assam is receiving the "serious attention of Government," whatever that may be worth. Among the products of the country in which Mr. Weynton thinks that profitable business might be created are many of pharmaceutical interest, besides tea, indiarubber (for which the soil seems especially suitable in many parts), silk, and tobacco.

The cultivation of arrowroot, tapioca, sago, and sugar is not considered likely to become profitable at present, but indigo planting would doubtless prove a satisfactory source of revenue. The drainable swamps possess a soil admirably adapted for the growth of the plant, while the heavy dew falling up to the end of February would bring it to maturity by the middle of May; and the manufacture, by the aid of artificial irrigation, might be finished before the regular rains set in in mid-June.

Lac products might yield another source of revenue though the depreciation of shellac renders it doubtful, we think, whether it would pay Englishmen to invest money in this industry at the present time

The lac insect (*Coccus lacca*) abounds in the jungle, being of the best quality in the neighbourhood of the Khassia Hills. It is also found on the north side of the Assam Valley proper, encrusting the branches of a variety of shrubs about four feet from the ground, and in the densest underwood, so that, for successful propagation, dampness and shade are requisite. The insects with which to stock a plantation should be collected in November in their lac-cells, about 40 lbs. of the latter per acre being required. This lac is affixed to the trees of the plantation, and the insects left to propagate. The increase of cell-formation soon becomes apparent. At first a streak of crimson draws out from the pieces of lac, which, if inspected with a magnifying-glass will be found to be a column of insects; then the colour deepens and the size increases each insect forms a separate cell and begins to exude the tough substance, until by the end of the rains it becomes necessary, in many cases, to support the branches weighed down by the incrustation. A year after the introduction of the insect, each tree yields an average of 8 lbs. of lac, or 6 lbs. of clean seed lac, the present price of which, in the London market, at 40s. per cwt., gives a gross return of 144*l.* per acre. The lac is pounded small, washed in water with a little unslaked lime, dried under shade, packed in chests of 56 or 112 lbs., and sent direct to London; and as there is a growing preference among dealers and manufacturers for seed lac in lieu of shellac, the expense of converting the former into the latter need not be attempted.

Ginger and turmeric, if well cultivated and prepared for the market with care, can be grown in Assam at a considerable profit. At present they are reared in a desultory manner in almost every village, but so little care is bestowed upon the culture and drying that only a very low price is obtained in the local bazaars. Generally the roots receive a superficial washing, are then smeared with fresh cow-dung, and hung in baskets or spread on trays among the rafters of the native huts, the ascending smoke doing the rest. The dried root consequently is dirty, shrivelled, and, despite the constant smoke invariably riddled with the bamboo-borer insect. It was proved, however, by experiments on one of the Sylhet plantations about twenty years ago, that if properly cured Assam ginger will command a price nearly equalling that paid for the best Jamaica ginger, and Mr. Weynton says it might be worth, perhaps, to extract the essential oil on the spot and only ship the latter.

Anise and star anise are found in abundance in Assam, the one under the name of Mahori, the latter under that of Badian. Among the low hills round Gowhatti, and in the forests of the Khassia and Naga Hills, sufficient seedlings of anise for stocking can be easily procured, but considerable care is required in transporting them, and this should be done during the cold weather, the plants lifted with as much earth round the roots as can conveniently be carried. As the object with anise is to obtain as luxuriant a foliage as possible, high cultivation and copious manuring should be restored to; the plant may be put in 4 feet by 4 feet—the same distance as tea, but if the district in which the plantation is situated is more than ordinarily subject to visitations of blight and red spider, it will be prudent to plant somewhat wider—say 5 feet by 5 feet; for the quality of the oil will be adversely affected by the presence of deceased leaves. Anise leaves should be gathered like tea, and pluckings take place in dry weather only. The leaves may be subjected to a light rolling, so as to break the cells, and the oil pressed out or extracted by distillation. The oil may be shipped in small casks or bottles, the latter being always easily procurable in the growing districts.

For the cultivation of star anise or badian, a manure containing a high percentage of phosphates, such as limestone, bones, or animal offal, answers best. The seed, or rather fruit, is of course the principal product, but the bark of the badian is almost equally rich in aromatic constituents. Both seed and bark may be lightly crushed and infused in alcohol or distilled in the usual manner. The flavour of anise preparations is so pungent that the house set apart for their manipulation should be kept distinct from all buildings devoted to other manufactures, and the people employed in the anise business should be retained for that special purpose. Natives are proverbially careless, so that strict vigilance to prevent interchange of the tea and aniseed baskets must be specially guarded against. Scented tea is all very well in its way, but impregnated with the powerful odour of anise it would find scant favour either with dealers or the general consumer.

Andropogon Schœnanthus, or Ghundho bina, as the Bengalis term it, is a small stunted-looking shrub that is found under the hills on the south side of the two valleys now forming Assam. It is well-known in Ceylon and Southern India, and from its fresh-gathered leaves is distilled the lemon-grass oil of commerce; in its native state Ghundho is rather barren, but well manured and cultivated it responds to generous treatment, and repays those who raise it. The pruning is much the same as that demanded for other leaf-producing crops; even the coarse, older leaves are impregnated with the essence, but care must be exercised to avoid over-plucking. The plant should be allowed to attain six feet in height before plucking, and as soon as signs of exhaustion, such as drooping of the lower leaves, become apparent, an interval of rest should be accorded. It should not be touched from October to April, and only on bright, warm days. If fire is used the heat must be low, but a brighter and clearer oil is obtained if a glass retort is employed, so arranged as to revolve slowly in the full beams of the sun, otherwise the product is streaked with films of dark muddy lines that will detract considerably from its market value. The plant may be propagated from layers, cuttings, or separation of the roots, but is sufficiently abundant to provide independent saplings for stock without recourse being had to the above somewhat tedious methods of multiplication. Either bottles or half-maund tins may be used for the first exportations. The refuse, after all oil has been extracted, is liable to ferment and become offensive, and should therefore be burnt without delay.

Cajuput (*Melaleuca cajaputi Roxb.*), a small tree somewhat resembling the weeping willow, is found mostly at the entrance of ravines, but it might be procured from the Tipperah Hills, or from any other locality in which ruined temples are found, for in such places it was formerly carefully propagated by the priests, who had a knowledge of its medicinal virtues, though they seldom extracted the oil, but applied the hot, bruised leaves for sprains, bruises, and rheumatism. The tree reaches maturity in its fourth year, but the young shoots may be constantly cropped, and in this manner returns may be had eighteen months after planting. The leaves should be collected in fine hot weather, from April to September, lightly rolled, chopped, macerated in water for twelve hours, strained, and placed in a glass or enamelled still. The product is a light green or bluish tinged, limpid oil, which, as it is apt to discolour if exposed to light, should be packed as soon as possible. There is a large local demand for cajuput oil, not only in Assam, but also in the neighbouring state of Munnipoor and in Burmah, and probably the whole production could be sold to supply local wants. The cost of cultivating the plants is very small, the preparation inexpensive, and the returns handsome. The plant may be grown on almost any soil above swamp mark, scattered about in unused plots, and should be placed in groups large enough to afford leaves for one day's systematic plucking.

Another plant which might be profitably cultivated is the *Gynocardia odorata*, or Ta-fung-yu of China, which yields the so-called Chaulmoogra oil of commerce. The oil was previously expressed by the inmates of the gaols in the Sylhet district, but trees are found wherever there is an intact primeval forest

Chaulmoogra oil, under the name of Ta-fung-yu, is a very large article of trade with China, where for ages it has been regarded as a specific in syphilitic diseases, and all over the East, where cutaneous maladies are so prevalent, unbounded faith in its virtues exists, and so esteemed is in Persia and the countries adjacent, that at Shiraz and Bushire one rupee per oz. is readily paid for it. Ringworm, from which new-commerce from Europe to Assam almost universally suffer, rapidly yields to the mixture of chaulmoogra and cinnabar. The *Gynocardia odorata* blossoms in April and May, and the fruit, which takes the form of an oblong nut—not much dissimilar in shape to a Brazil nut—ripens towards the end of the rains, is smooth, and of a greyish colour, yielding, on cold pressure, 10 per cent of rather thick resinous oil. Although it bears in the fifth or sixth year the tree attains the size of a full-grown mango, so that wide planting is necessary, but beneath its shade other plants may be raised. The residual cake is unfit for cattle feeding because of its nauseating qualities; although pigs readily consume it without any apparent deleterious effect.

The *Dipterocarpus* trees, which yield the oily gurjun resin have now become very scarce in the accessible parts of Assam, but are still extant in the outlying jungles, which will have to be explored by intending settlers. It will be well to resort to the raising of the trees from seed, although they are slow of growth, and those which are fit for tapping are presumedly some forty to fifty years old. Of late years the gatherers have not only tapped the trees to death, but in many cases actually felled them, but even now gurjun is still found in the deep valleys of the Looshai Hills, and reported by the inhabitants to abound far in the interior, the crude resin finding its way to the markets on the Chittagong side of those hills. A considerable number of untouched trees may also be noticed in the valley of the Kopoli and also in the forest about the Brahmakhoond. The seeds ripen in October, and should be sown as fresh as they can be procured, for they rapidly lose their germinating power. From mature trees the resin may be abstracted any time from November to May in the following manner:—One or more oblong perpendicular holes are made at a convenient distance from the ground—2 feet long by 6 inches broad—cutting well into the body of the tree through the bark; at the lower end a cup-like cavity must be scooped out of sufficient capacity to hold a fluid quart; fire is then introduced and kept up with charcoal for from two to three hours until the cavity is thoroughly well charred; on cooling the gurjun commences to trickle out needing baling night and morning. The yield per annum from a fully matured tree—maturity being approximately indicated by a height of 70 feet, and girth 4 feet from the base, of 18 feet—was 346 lbs. Gurjun oil is the best varnish for all woods known throughout the East, and mixed with ground sulphate or copper and boiled to the consistency of a syrup, is an excellent preservative against dampness and insects. It is also used as a cosmetic, and mixed with neem-tree leaves as a poultice. Castor-oil may be easily obtained as a by-product in silk culture being yielded by the seeds of the plants on which the silkworms feed. So-called "cold drawn" castor-oil which fetches the highest price is now largely used in soap-making and even in confectionery, and these employments, added to its use in medicine, will in all probability keep up the demand. The residual cake, dried in the sun, finds a market in Calcutta.

Croton Tiglium, the "Jummul ghuti" of the natives, is very plentiful in Assam, abounding in the drier districts to such an extent as to require frequent weeding out. Linseed and mustard also abound, but their cultivation, except in a few instances should be left to natives. The same may be said as regards the cultivation of cotton, which, under existing circumstances, offers but little inducement to Europeans, but as immigration rendered feasible by rail communication, sets eastward, matters may, and no doubt will alter. Careful calculation based on experiments conducted over three years in the Jaintia Hills show that the fibre may be expected to return a profit of 1*d.* per lb. on that purchased from the hillmen, but an additional profit might be looked for from the oil and cake. If the seed can be obtained fresh, about 8 per cent of oil may be pressed from it, and the returns will be found highly profitable, especially as the demand for cotton-seed oil is rapidly growing. The residual cake also finds a good demand in the country and for export.

As the development of Assam proceeds many drugs will no doubt be discovered in the country which may form profitable articles of export to Europe. It is well-known now, for instance, that *Cinchona crispa* grows wild on the summit of the forest-clad cliffs overlooking the plains of Sylhet and Cachar at an elevation of some 1,500 feet, while ipecacuanha is found in abundance in the Larnai Valley, within a dozen miles of Shillong, though neither of the latter plants are likely to be successfully cultivated below the elevations indicated as their true *habitat*.

The terrestrial orchid that yields the aromatic pods of vanilla, though better grown at 1,000 feet or 2,000 feet above sea-level, may, with care and attention to keeping the young roots clear of ants and other insects, be successfully raised in the Assam plains and trained on the stems of the areca. *Bael* fruit may be introduced from native gardens, but as the best is grown about Dacca, seed should be imported thence. Bael will yield in the seventh year, and the pulp, contained in a hard calabash, which, beaten up with sugar and strained through coarse muslin, has a regulating effect upon the bowels is specially valuable in choleraic complaints. Anglo-Indian chemists manufacture a dried preparation of this fruit called dietetic bael; but much of the virtue of the pulp is lost during the process, and for export the form of preserve should invariably be adhered to.

Nuxvomica, under the name of Koochela, is found growing wild in many parts of Assam, especially in Cachar, and as the natives all know the tree, the fruit may be obtained in any quantity without trouble. The seeds need simply be dried in the sun and packed in tea-chests for export.

Cassia lignea is also indigenous on the Assam hills, and the true cinnamon was introduced successfully, though only for experimental purposes about 1867. The products of the neem tree, which are in high repute among native medical practitioners, may also possibly in future find a sale in Europe. One of the most promising branches to which a European settler in Assam could devote his attention is apiculture, the remunerative character of which has been fully demostrated in all semi-tropical countries where it has been carried out intelligently. Systematic apiculture is at present confined to one Assamese village only, the insects being so numerous throughout the country that native collectors have hitherto been content to simply search the jungles for combs. If properly constructed hives were established in the shade of the *Ficus elastica*, the cultivation of that tree could be carried on side by side with apiculture. Orange groves are also excellent plantations in which to keep bees. The hives must be double the size employed in England, as swarms measuring five feet in length are by no means uncommon. At the end of the year little difficulty will be experienced in any part of the province in finding a swarm, but the removal to the hive must be undertaken by Europeans conversant with the process, as both nerve and patience are needed.—*Chemist and Druggist*.

AGRICULTURE ON THE CONTINENT OF EUROPE.

(*Special Letter.*)

PARIS, August 6.

The population of France is close on 38 millions; of this total 21 millions are engaged in agriculture, a profession in which 100 milliards of francs are invested. France is a country of small cultures, the general size of farms is a mean average; large hold-

ings are rare. What measures are taken to instruct these millions in their calling and how do such work? It was only about 1790 that legislators gave a serious thought to agriculture. It was then proposed to nominate a special minister to take charge of that important branch of national wealth. Later, other projects were mooted, as the founding of farmers' societies, prize meetings and practical instructors to make known the advantages of sowing wheat in autumn.

Prussia was earlier in the field, as Frederick II. between 1763 and 1788, expended 160 million francs on agricultural schools and yet Prussia both in climate, soil and resources was much inferior to France. Indeed, after the battle of Iena in 1806, Prussia although defeated and numbering but 7 millions of population, immediately founded the famous agricultural school at Moeglin with Thaër for director. Tallyrand presented to the Constituent Assembly a project for agricultural education, and Lavoisier applied his chemical discoveries on his Vendomois estate. But it is to F. de Neufchateau, which reverts the honor of suggesting the Agronomical Institute or university in 1800 and which was realized half a century later.

The Revolution and the Napoleonic wars left France no time for the arts of peace. The restored Bourbons did nothing for agricultural education. The only effort in that sense during their reign was by Mathieu de Dombsale, whose name is a household word with French farmers. In 1818, he established at Roville near Nancy, a kind of experimental and model farm of 260 acres and with difficulty obtained by subscription a sum of 45,000 fr. to work his plans. He translated the works of Thaër and Sir John Sinclair. The institution disappeared in 1842, but Dombsale had left his mark; he succeeded in popularizing the three-course rotation and of substituting a root crop for the idle fallow. He implanted also numerous other good points of husbandry, and above all, he formed pupils to propagate his ideas, the most eminent of whom was M. Reiffel, the founder of the Regional School of Agriculture at Grand Jouan in the department of the Loire-Inférieure, and, which is at present flourishing.

In 1792, it was suggested that the elements of agriculture be taught once a week in the primary or national schools. Both the teachers and the populations petitioned for that advantage, but nothing came from this excellent intention. And strange, in 1833 when Guigot propounded his vast scheme of national education, he completely overlooked the paramount claims of agriculture. It was only in 1838 the idea was boldly taken in hand, when Parliament was asked to attach chairs of agriculture to the normal or training schools for teachers. It was but logical to demand that to teach agriculture the teacher should himself be taught. This plan was sanctioned by a decree in 1839 and a few Departmental Training Schools had their professor of agriculture and school-farm. At best it was only an experiment.

Five days after the successful revolution of 1848, a decree was published to enforce that of 1839 relative to agricultural professorships being attached to the normal colleges; it was also urged to teach the principles of rural economy in the national schools. The authorities were still handicapped by the political situation of the country. Louis Philippe's government had granted subsidies to three agricultural colleges created by private enterprize—Grignon, Grand Jouan and La Saulsaic, helped school-farms and nominated inspectors of agriculture. But it was M. Tourret, Minister of Agriculture, who, in 1848, brought forward a vast scheme for agronomical education. It was to embrace three degrees like the general instruction of the country—primary, secondary and superior. In other words model-farm schools, regional or departmental colleges and a Central University or Agronomical Institute. The base of this plan exists.

The farm-schools were to bring home, and on the spot practical improvements to the cultivators; they were directed by competent teachers and managed at their own risks and perils; conducted in accordance with and subject to official programmes and inspection; pupils were to remain three or four years; were admitted by local jury who granted them certificates on leaving, the State's aid was limited to an annual donation of 250 fr. per pupil.

Above the farm-school was the regional or departments' Agricultural College, of which that at Grand Jouan founded in 1840 was the type. These colleges were to represent a well-defined and ameliorated type of culture, harmonizing with a group of deportments or a region; science was to march here hand in hand with practice; the state worked them at its own expense; conducted experiments, and the pupil boarders paid 750 fr. a year; there were a few sizarships reserved for the prize pupils of the farm-schools, all pupils had to give a certain time to the labors of the farm.

The third degree or superior was the Agricultural University or Agronomical—the more generic and milder term—Institute. It was to effect for agriculture what the other high schools did for the army, engineers and manufcturers. The graduates were somewhat like architects, who are not compelled to be masons or carpenters; or as the engineer, not required to work at the anvil. The institute was to turn out men capable of grasping the whole range of theoretic and scientfic farming economy and the best professors in the land were to be engaged. Students were to remain two years at the institute; on the expiration of which, diplomas were accorded by a jury of examiners, and three of the most successful were employed by the Government to report on the farming of a foreign country or on a home mission. In December 1848, the Government allocated crown lands at Versailles for this institute, and named 9 professors it had in 1851 upwards of 51 pupils and 150 free auditors. It was suppressed in 1852, being not only considered expensive, but its range of studies too high and not suited for the small properties of France. On this point Boussingault pertinently observed progress is propagated from high to low—even to the utmost limits, but it never remounts.

In 1850, only two regional colleges were in existence, Grignon near Paris founded by Auguste Bella and a joint stock company in 1830, and that of Grand Jouan in Britany also a private speculation. The college of Saint-Angean in the centre of France, in a mountainous and pastoral region closed, and that of Saulsaic was transferred and recast into the present institution of Montpellier. For a time the farm schools were very popular, but they became enveloped in the net-work of abuses which prevailed during the sinking days of the second Empire. In July 1875, the first reform of agricultural education after an inquiry took place in 1875: the aim was the suppression of the farm-schools—at one time they numbered 59—now only 19—and the organisation of "Practica Schools of Agriculture" as now existing. These are tol be established by three or four departements clubbing together and to be worked at the risks and perils of the director. The State only pays the educational staff; if very poor, however, it will aid a little in the material organization. The minister of agriculture selects the farm, fixes the price of boarding; programmes and type of culture to be followed. A local council superintends the working, and certificates of competency are granted to the pupils, and which, as in the case of after colleges, accord the conscript to serve one instead of five years under the flag. There are 16 of these practical schools, and the average number of professors to each varies from 6 to 12—Chemistry, Zotechny, Botany, Physics, Book-keeping, Horticulture &c. are some of the branches taught.

In 1876, the legislature revived the Agronomical Institute, but fixed it in Paris instead of Versailles. It has an experimental farm at Vincennes close to the Alfort Veterinary College of 250 acres—not destined, however to turn out either agricultural laborers or even working farmers, but rather Master Agriculturists. The professors in each of their walks are the most eminent, and the educational staff numbers 51 individuals. It must not be forgotten that the elements of agriculture are now taught in every primary school and as obligatory, as reading, writing and arithmetic.

Working in with all this is the system of departmental professors, one for each of the 89 departments and established in 1880. The professors are selected by public competition; they are a kind of ambulatory organizing teachers or practical instructors; they reside near the departmental Training Schools for the national teachers and there deliver lectures; they hold two conferences for the benefit of farmers at fixed places in their districts; visit holdings, look up the agricultural lessons given in the national school, keep themselves in a word in touch with their agricultural community; but above all to remain well-pasted up in all scientific and practical operations in the farming industries special to their locality. The departement pays the professor's travelling expenses and the State his salary.

There now remains the Regional Colleges still imperfectly organized, or rather insufficiently represented considering the several different zones of culture special to France. The Grignon College started in 1830 with a capital of 300,000 fr. aimed at high farming or *intensive* culture. It has an educational staff of 32 persons; it studies cereals, industrial plants, forrages, the improvement in the breeds of animals and all that relates to the agriculture of northern France. Grand-Jouan College has for speciality the reclamation of land, mixed culture of pasture and tillage, the *metayage* system of owner and farmer sharing profits, and field fruit raising. Montpellier College is situated in the region of the Mediterranean and takes cognizance of sheep grazing or runs; the replanting of forests or treeing of districts, the reclamation of waste lands, and all that relates to the culture of the vine, the orange, olive and mulberry.

There is no type-college of this class for the vast district of the south-west of France and its claret vineyards; it will be necessary also to resuscitate the Regional College of Saint-Angean in the interests of pasturages and dairy industries.

In addition to all this agricultural educational machinery proper, France has a school for shepherds and sheep management at Rambouillet; one for dairy stock at Corbon. I say nothing of the studs for stallions and mares nor the Horticultural School of Veisailles and its staff of 17 professors, nor of the local chambers of agriculture to keep the Government couched on all administrative or legislative needs of the farmer, nor of the 39 agronomic stations, nor of the local farming societies, nor the regional agricultural shows organized by the Government.

The Minister of Agriculture's Budget is 24 million francs; all the data is the latest that for 1886. The details are not clearly set forth, but roughly speaking about 2½ millions of the total sum are devoted to agricultural education proper. There are four inspectors for the scholastic supervision.

In this survey of French agricultural education, some facts very prominently crop out. First, the sowing of the seed for a taste for the profession of agriculture, by making instruction in its elements compulsory in the ordinary national schools; second, in the case of the practical schools, leaving the actual farming expenses at the risks of the director, and so placing him *ex æquo* in the matter of profit and loss with the surrounding farmers he invites to model after him; third, coping the two degrees of study by the highest system of education in scientific specialities and theoretic experiments; fourth, keeping up by the regional colleges efficient type-centres of practical progress; fifth, binding these efforts by departemental professors; and sixth, the Government while leaving the management to local self-government keeps in its hands all the threads for imparting unity of effort, community of ideas, and singleness of aim to the collective organization.

The most important of current topics is the general harvest. The season has been exceptionally dry and has naturally told on vegetation. The hay of course has been well-saved, but the yield is very light. Root crops are a souvenir, and the aim now is to sow everything in the way of a help to early winter and spring feeding. Wheat will be of good quality and the yield somewhat superior to last year. Oats and barley leave much to be desired and the latter wants color. Rye has not filled well; indeed in the case of all cereals the ears in this respect have but too much in common. The vintage will be excellent and the quality being irreproachable, higher prices will be obtained. However, the dominant thought of the moment is how to provide for stock during the coming winter. Straw cut up and mixed with everything digestible, cake, seeds, meals, &c. and the mess steamed or macerated is the only solution.

PLANTING IN DELI.

(Translated for the "Straits Times.")

According to the Deli *Courant* of the 3rd August, the pepper crop in Acheen promises to be heavier than ever. One consequence is that the Rajah of Edi, who deals considerably in pepper and can afford to spend money freely, now that a bumper yield of that article is in prospect, has laid out no less than sixty thousand dollars at Penang to the great joy of purveyors and contractors there.

The Deli *Courant* of the 13th August asserts on good authority that the tobacco crop in that colony this year will not be a large one by any means. There is every prospect of the yield proving very moderate in quantity. It appears that this untoward result is ascribed to the months of June and July being too dry for the young tobacco plants. From want of Chinese coolies on many estates, planting operations could not be set about until late in the season, so that the young tobacco suffered greatly from drought. Matters are not much better on upcountry estates. Generally speaking an outturn of 6 or 7 piculs per unit of area will be looked upon as satisfactory this year. Nothing definite can yet be stated as to quality. In the coast districts the situation is as bad as in the upland ones. There, too, the planters had to cope with a severe drought. Rumour says that many of them find ruin imminent.

The Deli *Courant* holds that the reason why ill success has alway attended the endeavours made to bring about coolie emigration from India to that colony lies in the ignorance of how matters really stand there in Government circles at Calcutta. That journal urges the despatch of a commission of experts to India. The Planters' Associa tionrecommended this course to the Governor-General as far back as 1884. His Excellency promised to do everything in his power to carry out their wishes. The Governor-General who happened to be then in Deli soon left for Java. Three years have since passed away, but nothing whatever has been done to further Tamil emigration from India to Deli. The Netherlands India Government seem now inclined to take the matter up once more. But success can only be secured by fully enlightening the Indian Government how matters stand economically in Deli, and as to the securities for the due adm nistration of justice to its subjects there. In that respect the situation has vastly improved since 1884. When once the crass ignorance as to Deli affairs has been removed, it needs only tact and sound judgment to negociate a coolie convention.

At the prompting of the Government in Holland, the Netherlands India authorities have once more taken up the subject of cooly emigration from British India to the East Coast of Sumatra, a matter of the highest importance to Deli. It has been repeatedly brought under the notice of the Dutch Government by the planters concerned. The question has been under discussion for the last ten years. But, in spite of petitions, conferences, and correspondence, it is no nearer a solution than

heretofore, owing to the subject being taken up at the wrong end. It appears that the negociations carried on by the Netherlands Indian Government with the British Indian one have never been deemed to be of any great significance in the official world in Madras. From time to time, a despatch bearing upon the matter, came *via* Calcutta, or another came from the Straits inquiring into the likelihood of concluding a coolie convention, but under the administration of Sir Grant Duff, the affair got no further. That official was, from principle, against emigration of this kind on the ground that the Government instead of entering upon such agreements, would answer requirements better by doing everything in its power to keep natives in the country by developing the resources of the latter for their benefit. The Straits Settlements had to struggle against this fixed idea, and could only secure the free emigration of coolies for the benefit of Penang and Province Wellesley under burdensome conditions. A sickly philanthropy was then dominant in India. Emigration was looked upon as a sign of impoverishment and retrogression alienating the native from the land of his birth. Last but not least, information gained from the Straits regarding Deli was far from favourable. It may be that trade jealousy coloured the information forwarded. At all events, the administration of justice in Deli was reported against. On the Dutch side little or nothing was done to remove these unfavourable impressions, and represent matters in their true light.

INDIAN, AS COMPARED WITH ENGLISH COTTON FACTORIES.

By Lord Brassey.

Bombay is the Manchester of India. Its factories give employment to sixty thousand operatives. A large proportion of the capital invested has been provided from native sources. I had the privilege of accompanying Lady Reay on the occasion of her visit to a mill, established by a Parsi association organised by Mr. Petit, a leading member of the Parsi community. As an indication of the scale of the factory, I may mention that the steam engine is of the latest construction, and indicates no less than 4,000 horse-power. Four thousand operatives are employed. In the other mills belonging to the same association the aggregate number of operatives is twelve thousand. It is satisfactory to know that an industry on this vast scale has been established by the enterprise of a native association, without any assistance from capital in England.

In connection with this subject, some observations may be appropriately introduced, bearing on the efficiency of the native labour in India as compared with that of the workers in the factories in Lancashire. This object has recently been investigated by a Commission appointed by the Government of Bombay to consider the working of factories in that presidency. As a general result, it was shown that a mill in India employs about three times the number of hands that a similar mill in England would require, for the same out-put and quality of work. The cost of labour, whether at the comparatively liberal scale of wages obtained in England, or at the low rates of India, shows a remarkable identity of result. It is another illustration of the practical working of that great law of compensation, under which, with widest difference of nominal amount, the cost of work is approximately the same over the world.

The superiority in point of efficiency of English labour is most conspicuous in the case of the young hands. It was stated by an English manager examined by the Commission, that, while in Bombay a boy attends from 120 to 140 spindles, in England a girl of eighteen, who had been employed by the witness, had attended 512 spindles.

Turning to elements in the cost of production other than labour. Coal here is about the same as at home as regards efficiency, but the price averages 17 rupees—£1 5s 6d—per ton, delivered at the mill, as against 7s 6d to 11s in England. Cotton, owing to shipping charges, freight, commission, &c., costs 3d per lb. less to the Bombay mills than to English spinners, but as a rule the Bombay manufacturer uses a slightly better cotton than the European to produce the same result.

Although the general conditions under which the cotton industry of India is conducted show no material advantage in favour of the Indian producer, the development in Bombay and elsewhere presents a steady, indeed, a considerable growth.

On the whole, this careful enquiry points to the conclusion that, while the introduction of the manufacture of cotton into India must to a certain extent affect importation, it is not probable that we shall lose ground. We are superior in quality. We are well informed as to the demands of our Indian customers. In the cost of labour we have nothing to fear.

Turning to the comparative condition of the workers. In England the operatives work 260 days a year of ten hours each, and 52 days of six hours. In India they work 339 days of twelve and a half hours each. In the Indian Factory Act no maximum limits are prescribed within which regulated labour is to be taken. Women can be worked as long as men. The Indian factories are run from sunrise to sunset throughout the year. This gives 11½ hours a day of work in the cold weather, and 14 hours a day in the hot weather. If the hours of labour are longer in India, attendance is irregular—operatives often absent themselves for several days—and the employment of women is much less considerable than with us. In Lancashire of 433,000 workers employed in the cotton factories 253,000 are females. In Bombay, of 49,928 operatives in textile factories 10,794 are females. The earnings of the women in the mills are higher than they could obtain elsewhere, and the work demands less physical strength. In going over the mills, under the guidance of Mr. Petit, we were struck by the lavish display of gold ornaments among the female operatives.

While it is said that employment in the factories is eagerly sought for, witnesses, appearing for the workmen, informed the Commission that the mill hands in Bombay complain of the long hours of labour, of the want of periodical days of rest, and of the delay in the settlement of wages. One witness stated that he and his fellow workmen received their pay for September at the end of October.

The Commission recommended that women and children should not be allowed to work before 6 a.m. or after 6 p.m., and that in that period they should have an hour's interval for food and rest. The readiness with which the workers have accepted the longer hours hitherto in force, points the more clearly to the necessity for some intervention, on the part of the Government, to give protection to people who, without its fostering care, seem helpless to resist the pressure caused by competition for employment in an overcrowded labour market.—*Planter's Gazette*. A bi-metallist has published a statement to the effect that the Indian mills are able to compete with those of Manchester, even in regard to coarse fabrics, only because of the condition of exchange due to a silver standard in the East.—Ed.]

THE WHEAT CROP OF THE WORLD.

The Department of Agriculture at Washington has gathered from all available sources statistics of the wheat crop of the world for 1886. China and Japan are not included, but their wheat crop is insignificant. The total crop is placed at 2,031,322,285 bushels, or in round numbers rather over two hundred thousand millions. The United States heads the list of wheat producing countries:—

	Bushels.
United States	457,000,000
France	299,000,000
India	214,000,000
Russia	214,000,000
Austria-Hungary	143,000,000
Spain	132,000,000
Italy	130,000,000
Germany	82,000,000
Great Britain	65,000,000
Turkey	41,000,000
Canada	37,000,000
Algiers	33,000,000
Argentine Republic and Chili	29,000,000
Roumania	23,000,000
Australia	22,000,000
Belgium	19,000,000
Egypt	16,600,000
Sweden and Norway	2,500,000
Switzerland	1,600,000

India, Russia and Germany, unlike France and the United States, do not grow wheat as their staple. Great Britain is the largest wheat buying country in the world. All the surplus wheat of Australia and India, and a goodly share of that of the United States, is sold in British markets, and we probably consume more wheat per head than any other country in the world except France, where wheat is the common food of the entire people. Although the United States leads the way in the gross yield, the amount per acre is about 12 bushels, while in Great Britain it was about 27. —*Planter and Farmer.*

THE INDIAN TEA COMPANIES.

Although there has been some deterioration in the quality produced, in common with nearly all tea-growing countries this year, the rapid increase in the outturn of the crop of Assam and other Indian teas, is confirmed by later accounts, and it is expected that the crop for 1887-88, will be unprecedentedly heavy; but what are claiming a deal of attention at the moment are the magnificent results of the past year's working as disclosed by the publication of the "averages" obtained by several of the tea companies, whose dividends have ranged from 5 per cent up to as high as 18 per cent, as the annexed statement clearly shows:-

	Yield per acre. lb.	Average Price. per lb.	Gross Profit. £	Dividend. per cent
Assam Company	304	11¾d	17,300	10
Bramapootra do.	422	11¾d	17,300	15
Darjeeling do.	297	1s 3½d	10,000	7½
Dooars do.	464	9¾d	8,000	6
Doom Dooma do.	746	8⅝d	7,400	6½
Jhanzie Association	306	1s 7¼d	13,000	10
Jokai Company	411	1s	9,500	10
Jorehaut do.	309	1s 3¾d	26,500	18
Lebong do.	344	1s 1½d	7,000	8
Luckimpore do.	370	1s 2¾d	8,500	6
Panitola do.	635	1s	8,000	10
Scottish Assam do.	300	1s 4½d	5,000	5

From the liberal dividends declared by the larger companies, it may be inferred there is a good margin for profit in the growth and cultivation of the tea plant in British India, which may be classed amongst the most flourishing industries of that country. According to these calculations, importers can well afford to lose 2d per lb. on their teas, as they sometimes do, when hastily disposing of them in Mincing Lane, and this is as often due to the undesirable nature of the supply itself as to the unpreventable flatness of the market when the wholesale dealers are overstocked. All the tea companies do not produce equally fine tea, and those who do can easily add in extra 3 to 5 per cent to their net profits. This may be taken a further proof of the general superiority of India teas, and the great preference that is shown for them by consumers who make it a *sine quâ non* that the tea they drink must be strong and flavoury. While the Indian tea-planters work up to a high standard of excellence, the competition of other growers will not injure them, but rather act as a healthy stimulus to still higher attainments and more favourable results; for it must not be forgotten that the value of the different tea companies' shares, from one cause and another, is not always at a satisfactory level for investors, and during the past twelve months or so the quotations of a few of the leading shares on the London Stock Exchange early in the month have been as under:—

	Assam.	Darjeeling.	Jorehaut.	Luckimpore.	Lebong.	Scottish Assam.
July 1886 ...	46⅝	24½	45½	4⅜	13⅛	5¾
January, 1887 ...	47¼	24⅜	41¾	...	13 3-16	5⅛
July, 1887 ...	40	24¼	47	6⅞	13¼	6⅝

— *Grocer.*

TEA ESTATES AND PRODUCTION IN ASSAM AND CACHAR are thus noticed in the *Pioneer* of Aug. 22nd:—Some Tea Items.—There were 838 tea-gardens in Assam at the close of last year. The number had been reduced by about sixty, owing to the amalgamation of small gardens with the estates to which they were attached. Most of the gardens are in the four districts of Kachar, Sylhet, Sibsagar, and Lakimpur. The total area under cultivation has increased, and amounts to 203,993 acres. But that is only about a fourth of the land held by planters. In the Kachar district there is a tendency to extend the planting of tea on lowlying lands which formerly grew rice, and to abandon hilly lands, on which tea is found to be less profitable. The yield of tea last year is given by the District Officers as 61,719,678 lb., but the Committee of the Indian Tea Association makes the outturn about two and-a-third millions less. Either figure is considerably above the amount of 1885, which was a good average year.

THE PRODUCTION OF CAMPHOR IN TAIWAU.—In a report from Taiwau, China, it is stated that there was formerly a fair trade done in camphor at that place; but of late years the export has almost entirely ceased, in consequence of the risky nature of the trade. The camphor is so badly prepared, and is adulterated to such an extent, that the loss in weight is excessive, and unless the cost price is extremely low, there is little temptation to engage in the business. The possible supply is practically unlimited, but the inferior quality as compared with Japan camphor prevents any great demand for it in Hong-Kong, the only market at present for Formosa camphor. In 1885, a foreign firm at Taiwau made an attempt to revive the trade. Contracts were entered into at a price that, in view of the then state of the Hong-Kong market, promised to show a handsome profit. In May 1886, however, a proclamation was issued by the Governor of the island announcing that the Government monopoly in camphor, which was abolished in 1868, had been revived, in order to defray the expenses consequent on the attempts made to subdue and civilise the aborigines. The camphor already produced and stored in the interior, awaiting a favourable opportunity for sending it down to the port for shipment, was seized by the Chinese authorities, notwithstanding its being covered by a transit pass, and since the date of the issue of the proclamation not a single tub of camphor has found its way to the port. In the meantime the monopoly has not proved so profitable to the Government as was anticipated. The fixed rate offered is much below that which foreign merchants are prepared to pay, and the result of the Governor's action has, so far, been simply to nip the reviving trade in the bud, without improving his revenues in the slightest degree.—*Gardeners' Chronicle.*

IMPROVED RICE CULTURE IN CEYLON.

The Director of Public Instruction has received a telegram from the Assistant Government Agent of Trincomalee, indicating that no manure was used in the Toppur experiment, so that the excellent result is to be traced mainly to the system adopted of planting out seedlings in the prepared soil instead of sowing the seed broadcast. This system is not new. It has long been applied and with great success to the culture of wheat in Europe, maize in America and even to rice in Java and elsewhere, and always with the result of improving the yield in quantity and quality. Experiments in Ceylon so far seem to show that the result of the supersession of the slovenly native mode of cultivation by a system of improved tillage and culture is that (with a great saving of seed grain) the yield is increased from 8-fold to 115-fold, without the stimulus of manure. With fertilizing materials (will Mr. Green kindly particularize?) added to improved tillage and scientific culture, returns have been raised in quantity to over 300-fold, with an immense improvement in the quality of the grain. It would be well if in respect to both sets of experiments the effects on straw were stated, as this product has an important bearing on what is at the very root of improved culture, the rearing of a breed of healthy and strong draft cattle. After all is said, what Mr. Green has communicated, although highly interesting and so far satisfactory, amounts, as Mr. Green will readily admit, but to the results of special and isolated experiments. To judge fully of what may reasonably be hoped for from operations on a large scale, we must imitate Oliver Twist and ask for "more." Was the site of the experiment at Toppur virgin soil? or was it previously aswedumized and cultivated land? In the latter case, of course, the effects of previous manuring might more or less enter into the result. If, as we presume, a piece of virgin soil was chosen, then experiments ought to be continued, the land being cultivated once or twice a year, so that data may be available to show how soon, under the improved method of cultivation and exceptionally heavy cropping, the soil will become exhausted, so as to necessitate a resort to fallowing or manuring. It seems to stand to reason that the soil would be more speedily exhausted under a system which compels it to yield over 100-fold, than under the native custom of thick-sowing broadcast whereby a return of only 8-fold is harvested. Then we must, to aid sound conclusions, have full details of the comparative cost (as far as it can be possibly ascertained) of the two modes of culture. We quoted as characteristic of the poor "fusionless" natives what they said to the Mudaliyar. They could not, forsooth, afford to pay for the necessary cooly labour to carry out the system of planting seedlings, with the other operations of improved culture. These people require to be taught the very alphabet of political economy. They must be told that capital in money is but the accumulation of the wages or earnings of labour,—told so in the simplest vernacular of course. The owners of small holdings of land, with no money savings (the condition, we suppose, of nine-tenths of the rice cultivators of Ceylon), must, instead of absurd talk about employing cooly labour (for which they ought to get at least a good shaking), apply their own labour and that of members of their families to improved culture which yielding them not only rice enough for their wants but a surplus for sale, will in time convert them from labourers into capitalists and enable them to hire coolies to supplement or supersede their own toil. But the idea of employing coolies, except in the case of owners of large tracts of land, seems absurd. Surely the co-operative principle, already, we believe, not unknown in ploughing and reaping, and on which the very existence of irrigation works depends, could be extended to the operations of improved tillage and culture. If the results of improved tillage and culture should be the more rapid exhaustion of soil, then the question will arise, which is the better process to pursue: to give the land rest as fallow or to enable it to go on yielding crops by supplying it with manure? The subsidiary questions connected with manure are the kinds of fertilizers to be used and their respective costs and results. Of course cattle manure, in more or less quantity and of varying quality, must be always available where cattle are employed to plough the rice lands. Many of the rice growers, also, use the slightly phosphatic and highly ammoniacal deposits in bat and swallow caves, while in some cases a good deal of bone dust is used. The Director of Public Instruction will be able to supply information as to which of these, or what other substances he employed when he obtained the enormous return of 306-fold from manured land. The quantity and cost per acre and the increased quantity and improved quality directly traceable to the use of manure (or different manures) are points on which information would be interesting and valuable. In the arid regions of Ceylon rice cannot be grown at all without means of artificial irrigation. But having at great cost provided the people with water, they must be taught that to use the fluid in excess is not only slothful on their part, but positively adverse to the best returns of crop in quantity and quality. The lesson which has to be learnt in most cases is that half the quantity of water generally used would give better results, if the land were ploughed and pulverized when dry and broadcast sowing superseded by the planting out of seedlings. A little coercion by civil servants and the higher native headmen might well be applied to the cultivators for their good. That, however, is not in Mr. Green's line, although the success of the experiments now being carried out by his department depends largely on the aid rendered by Civilians, Mudaliyars, Arachchies and influential inhabitants. One argument ought to have great weight with the people who grumble about heavy commutation. They have but to adopt improved culture to secure crops which will render the assessment of their fields a mere bagatelle, viewed as a percentage. If men like Messrs. De Soysa, De Alwis and Fonseka would teach their humbler fellow natives lessons in the direction we have indicated, they would effect much more good than by giving voice to protests (very often unreasoning protests) against rates of taxation which are only heavy because of short crops, the result generally of lazy and unscientific culture. The Agricultural Instructors, backed by the other servants of Government, are teaching lessons which may yet effect wonderful changes in the condition of Ceylon, which at present does not grow more than two-thirds of the grain she consumes, being dependent on other countries mainly on continental India, for not only grain but live stock, dry fish and other staple articles of food to a degree which, making all allowances, is most unsatisfactory. The day may come when the surplus grain of the now desolate tank regions of Ceylon may justify the extension of the railway to the ancient capital of the island. But meantime much remains to be done in order largely to increase returns of cereal crops in centres of population and established scenes of a culture which appears to be susceptible of enormous improvement, by the adop-

tion of a few simple scientific methods and of steady well-directed labour.

Since writing the above, we have re-perused Mr. Elliott's paper on rice culture contributed to the transactions of the local Asiatic Society, in which he shows that where, in districts well supplied with irrigation water, like Matara and Batticaloa, men apply their own labour and capital (without borrowing, as so many do, at the extortionate rate of 50 per cent) rice cultivation, even with very moderate comparative yields is thoroughly remunerative. He mentions the co-operative principle as in force in Matara, while there and in Batticaloa those who assist in culture and reaping are paid by shares of crop. Of course, without a good supply of water rice cannot be profitably grown, but the experiments reported by Mr. Green show that Mr. Elliott erred in undervaluing improved implements and modes of culture, just as we under-estimated their effects. We quote what is said of Matara, a district with which Mr. Elliott is specially familiar, having helped to an important degree in supplying it with irrigation water:—

In *Matara*, one or more cultivators jointly undertake the tillage of a field. One at least of these men has generally a proprietary interest in the land. There is no hiring of coolies or money payments for any additional requirements. The work is done on the co-operative or bee system, neighbours mutually assisting each other without any special remuneration beyond a good meal provided by the individual whose land is being tilled.

The cultivation of paddy has been so extended in the Matara District, and the available land is so incessantly under crop (two harvests being almost invariably taken from the same land in the irrigated villages), that there is little or no grazing ground left for cattle, and the buffaloes especially have to be driven long distances*—some beyond Tangalla, 15 miles away—for pasturage.

In consequence of this difficulty and the abundant supply of manual labour, cattle are very little used, and the fields are almost entirely tilled with the mamotie. The soil is dug up and turned three times and then sown, and this occupies a man about 40 days for an area of an amunam, or 2½ acres.

As the cattle are folded or driven away, there is no fancing to be done, and watching too has been nearly given up, as all the people live in gardens bordering the fields, and there are no wild animals, such as pigs or elephants, to be guarded against.

Reaping an amunam's extent occupies a man 16 days and threshing and winnowing about 30 days for an average good crop. Allowing a margin for contingencies, the cultivation and harvesting of an amunam of land in the irrigated villages of the Matara District require 90 days of a man's labour, or 36 days† per acre, besides an outlay of about four bushels of paddy for seed and tools.

I may here mention that Mr. Weeracoddy, in the report of his experiment in Kegalla, gives 34 days per acre as his outlay in labour, inclusive of certain permanent improvements he had to undertake.

Similar but more lengthy details are given regarding *the* rice district of Ceylon, Batticaloa, which sends a surplus for sale to Jaffna, and the summing up is as follows:—

The only point which is really open to discussion is the rate of yield. This I have purposely kept low, I believe below the truth, and I appeal to the gentlemen who have experience in such matters if I have not been most moderate in basing my calculations upon a yield in irrigated lands which would, in the Sinhalese districts, be spoken of as varying from 10 to 15-fold, and of 7 to 10-fold in the localities where 3¾ bushels to the acre are sown.

I have selected for the investigation of this question two districts in which the construction of irrigation works has introduced a considerable element of certainty in the cultivation of paddy, and it is practicable to judge results by pecuniary tests in accordance with European ideas. When a reliable water-supply is absent, and paddy-growing depends on the rainfall, it is probably liable to more vicissitudes than any other branch of agriculture in the island, perhaps in the world. It would be a waste of time to consider its pecuniary capabilities under such conditions.

But, fortunately, the rainfall in some parts of the island, and in the more populous districts, is well distributed, and paddy cultivation is carried on with results only second to those ensured by irrigation. Where such favourable circumstances are wanting, there is really only one remedy, and that may be summed up in the single word "irrigation."

I know no other of equal efficacy. Improved modes of cultivation, new implements, and fresh seed, are all of secondary importance. Where necessary, make the water-supply tolerably secure, and we may and can rival India, if we do not do so already, in the economical production of paddy, though it may be a long day before we can entirely overtake the local demand. Still, the fact remains that while paddy cannot apparently be imported into Ceylon for much under R1·50 per bushel, we can produce it in the island for one-third this sum at the very outside.

The rate of yield, it is evident, is capable of increase by means of improved implements and culture to a degree of which even this sanguine writer never dreamed.

PRODUCTION OF PADDY AND MR. GREEN'S RESULTS.

A correspondent who has paid some attention to the question writes:—

The information given by Mr. Green of his experiments is, no doubt, most useful and encouraging and confirmatory of the views I hold of paddy cultivation. But I now would beg him to abstain from using the term *fold*, which is most misleading. What we want to know is what is the crop that can be got out of *an acre* of land by improved modes of cultivation. This is not clearly set out in the published accounts; indeed these notes don't supply data for a full comparison. For instance, it is not stated over what acreage the two bushels sown in the native way was scattered. Probably in about ⅔rds of an acre, as they sow 3 bushels to the acre in that part of the country, I am credibly informed, so the yield was at the rate stated (8-fold) equal to 24 *bushels an acre*.

Coming to the *transplanting*, 5 seers were planted out in about half-an-acre of land and the yield was 18 bushels, or 36 *bushels an acre*.

The difference in return between the native crop and the transplanting system was accordingly equal to 12 bushels of paddy per acre. *Per contra* will Mr. Green state what was the difference in the *cost of cultivation* between the two modes; is it sufficient to cover the additional outlay on labour for transplanting? I was lately told it cost R10 an acre to transplant by one who practically tried it in a district where labour is cheaper than at Trincomalee. In the Eastern Province, labour is scarce and land is plenty, and there is undoubtedly what is generally termed slovenly, but what is rather rough and ready cultivation, and paddy is grown at a very moderate rate probably as low as 4½d currency a bushel. There is a good deal of communication with the coast, and the people are perfectly well aware of the

* In Matara District in 1882 the number of buffaloes was only 10,162, and in the chief irrigated Pattu, the Gangaboda, only 1,800, or one to every 8 acres. In Batticaloa the number was 6,630 in 1882, or about 1 to every 2 acres cultivated with paddy.

† I find Ludovici in his "Rice Cultivation" estimates the labour for cultivating an acre at very nearly the same number of days.

modes of transplanting and manuring followed there, as well as in the Jaffna Peninsula, where the conditions of land and labour are reversed. But the argument used is that in the Eastern Province the additional outlay (labour being worth about four times what it is in Southern India) required for the more careful cultivation *does not pay*. In fact the matter goes back to the question on which the opinion of agriculturists at home is, I believe, divided: *does high farming pay?*

So far, it seems to me, the only point established by these experiments is that far too much seed paddy is sown, as a rule, in accordance with English views; but, on the other hand, it must be remembered that for each field almost it is fixed by experience, and that it varies from one bushel an acre to nearly four in places. This is to provide for all contingencies and it is known it will not all germinate.

All honour to Mr. Green for his efforts to improve cultivation, and I trust he will accept this criticism in the spirit it is offered, viz., to keep clearly before us the real results obtained, so that in pressing any particular improvement on practical native agriculturists we are not relying on theoretical results, which may end in disappointment when put to the test on a large scale.

As mentioned in the paragraph extracted by you in Friday's issue, over 80 bushels per acre is not an unusual crop in Mannar district without any transplanting or deep ploughing; and over a large portion of the irrigated lands in the Eastern Province, I have heard it asserted by competent authority, the average crop per acre is quite equal to Mr. Green's "108-fold crop" *of* 18 bushels from the half acre.

The above reflects to a good extent what we wrote yesterday. As we understand the matter,—given land of equal quality and equal in genera circumstances of liability to pests, &c.; given also seed of equal quality, the ordinary native will till in the old fashion and use four bushels of seed grain getting an 8-fold return. Under the scientific system, three bushels of seed paddy are saved to begin with, while from one bushel of seed properly planted out in thoroughly tilled land a return of over 100-fold is obtained. Deducting the value of the three bushels of paddy saved, let the expenditure be compared to see if the increased yield has been obtained at a paying outlay. Of course, the liability of the soil to exhaustion if greater under the new system, ought to be taken into account.

CEYLON UPCOUNTRY PLANTING REPORT.

THE CAUSE OF CEYLON TEA AVERAGE PRICES BEING SO MUCH ALIKE ALL ROUND—CEYLON PLANTERS AND THEIR INDIAN BRETHREN—A COMPLIMENT TO THE "T.A."—CROTON—COCA—MANURING NUTMEGS—COFFEE IN DUMBARA—A CREAMY TEA—THE WEATHER AND TEA FLUSHING.

29th August 1887.

The free exchange of views which is so characteristic of Ceylon planters, is doubtless one of the reasons, if not the chief reason, why in the race of tea prices there is so close a heat. When you look down a London Tea Circular the range of values is not very wide. The great majority of estates keep pretty close together, even from the first start, when all allowances are made for fine or course plucking and the various natural elements which favour one over the other. It is to get away from the ruck where the difficulty comes in, and those who do this are, as a rule, willing enough to put you in the way of following, if you have a mind to. If from the first we all had had to find our own way, and there had been that same exclusiveness here, which characterises the tea planters of India, where to enter a neighbour's factory, without his permission, is a serious breach of planting etiquette, and information is often refused without the sanction of the Calcutta agents, the place of Ceylon teas in the markets of the world would not be so proud a one as it is today. This "shoulder to shoulder', policy has stood us all in good stead in the past' and will doubtless continue to do so in time to come. I heard the other day rather a high compliment paid to the worth of your *Tropical Agriculturist*, in that it was thought that you did Ceylon some injustice in giving to the planters of the tropics, through the columns of your monthly, so much valuable information, and thus placing them abreast of the times here. If there be secrets in connection with any of our agricultural pursuits, they are not close ones. That frank readiness to assist with counsel and advice, which so distinguishes the planter of Ceylon, and to which he owes so much, is but reflected in the wealth of accurate information which gives the *Tropical Agriculturist* a high place among journals of its kind. To condemn such a policy, is to condemn ourselves, for the only secret which is known amongst us is the open secret.

Croton is in the shade at present. Last year the pest of caterpillars which reduced the bush to bare poles was regarded with dread, but this season, so far as I know, the caterpillar is not. But if the croton tree is vigorous, and the crop more than usually plentiful, the price has declined, as I learned from a man who sold last season at R27 a cwt. and has parted with what he now has at R8! This, however, is cheerful to one who shipped some months ago, and was called upon for a cheque to make good the loss the shipment involved. The proceeds did not cover the freight and charges!

The cultivation of coca goes on in a quiet way. Some people seem to believe in it, and there is a demand more or less for plants and seeds, which are to be had at the Royal Botanic Gardens, Peradeniya. If half the things you read of in connection with coca are true, it is a treasure. It is valued by the occulist and the vet, it assuages hunger, and arrests waste, and lately it has been discovered that even man can get drunk on it—note it is a superior kind of intoxication they say. If with all it produces, if such a thing can be, this adaptability to meet the wants and weaknesses of beast and man, coca does not turn up trump in the near future, it will be because those who have its interests in hand don't know how to push and advertise them, and not because Ceylon men have forgotten to plant it.

In the culture of nutmegs there is little else to be done than keeping the trees free from parasites, a pest to which they are very liable. To manure nutmegs has been considered as the next thing to killing them. "That is how they died out in the Straits," has for many years been the closer to all further enquiry in the matter. A final word on the subject. We live however and learn; and I have to record a successful experiment in nutmeg manuring, with the result of a very much increased yield. The Chinese who killed the trees in the Straits had for a system of manuring digging a trench round the tree, just outside the furthest reach of the branches, and although not many roots were destroyed, still such damage was done as to lead to the disastrous results we have all heard of. The new style, which I am assured is a success, means a surface manuring underneath the boughs, and close up to the tree. The ground is slightly pricked all over not to disturb or injure the close network of roots, and the manure is scattered over it, and allowed to find it way in through the action of the rains, and other natural means.

The gathering of the coffee crop in Dumbara has begun and goes on in fine style. Spite of the dry season we have just come through, the percentage of light is nothing like what might have been expected, and although the bean is small it is a full one. To hear that on one well-known property there, as much as 5,000 bushels of parchment is confidently looked for, and that on a single morning 300 bushels have been washed, is like a gleam of a happy past. So encouraging has the revival of coffee culture in Dumbara become, that extensions have been made of considerable size. The seed is imported from Coorg, and the trees are said to be in fine health, with little or no leaf-disease and just a suspicion of bug.

A friend of mine is anxious to know how to make a creamy tea. Sometimes he has done it and often not, and he is quite at sea as to why this should be. If the tea were very young it could be better understood, but at three and a half years, it is somewhat of a puzzle.

During this month tea has been flushing well, and many of the estates above Kandy have nearly doubled what was plucked in July. The weather is all in our favour still, although most of us would prefer to see just a little more rain.

PEPPERCORN.

COFFEE.

(From the *Straits Times*, Aug. 13th.)

Coffee quoted at $19·50 last January now stands at $28·50 for the Bali kind, after reaching fluctuating quotations in the interval. These high prices, however they may increase the quantity brought to market, have brought on deterioration in quality. In Bali, by last advices, the heavy rise in price has so stimulated the greed of the natives, that in picking they gather ripe and immature berries alike, confident as they were of finding customers no matter how inferior the quality may prove. The crop there has turned out short. In Java, the high quotations now ruling have revived plantation enterprise in the fragrant berry long depressed under low prices and leaf disease. Prospecting parties have gone out there far and wide in quest of land suitable for coffee. Applications for extensive stretches of waste land for the purpose keep pouring in upon Government. It will take years before estates started under the stimulus of improved prices can yield sufficiently to materially affect the market. The total production of coffee throughout the world is esimated at 650,000 tons, of which Brazil alone contributes 380,000, and Java 90,000. Coffee grown in British Colonies totals 35,000 of which India yields 18,000 Ceylon, 12,000, and Jamaica 5,000. Coffee growers in this part of the world have every reason to look forward to the future with confidence. The action of Brazil, the main determining factor in the coffee market, tends inevitably to keep prices higher than ever. The emancipation of the slaves in that vast empire, expected to be carried through within twelve years or before 1899 cannot fail to work unfavourably on coffee cultivation there. Experienced persons assert that the emancipated slaves will fight shy of plantation work, and take to easier ways of earning a livelihood. How coffee growing can be carried on there under these circumstances is a problem, not easy of solution. The Brazilian Government try to meet the difficulty by offering inducements to European immigrants settling down as estate labourers, but hitherto without success. The class of labour sought to be attracted gives Brazil a wide berth, owing to the disadvantages of settlement there proving a powerful deterrent. Hence there is every likelihood of the cultivation of coffee in the South American Empire decreasing greatly within the next few years. Coffee growers in the East will hail this result with satisfaction. It will make the cultivation of the berry in the East Indies as remunerative as it was in bye-gone years. The Residential reports on the different Malay Protected States show that planters there have not been slow to take advantage of such a favourable concatenation of circumstances by starting coffee estates. It is to be hoped that before investing heavily in this form of plantation enterprise, hope of gain will not lead them to overlook climatic considerations. Arabian coffee is a plant requiring a climate with regular wet and dry seasons to ensure success. It will only flourish under certain conditions always to be taken into account, such as a warm and moist atmosphere from 64 to 85 deg. in countries with heavy but not excessive rainfall periodically, and a soil continually moist. Plantations yield the heaviest where a moist atmosphere and warm temperature go together. In Johore, climatic peculiarities arising from the irregularity of the seasons proved fatal to Arabian coffee growing. In these Settlements, Liberian coffee seems most suitable with proper methods of cultivation. In Java it has been found to withstand leaf-disease far better than the Arabian kind. It takes so kindly to low elevations that its cultivation here will assuredly make rapid progress, should the local environment and careful tillage be systematically attended to.

HEMILEIA VASTATRIX.

SIR,—The letters in the *Madras Mail* regarding leaf disease lead me to ask for a little, space in your paper. Here (Travancore) the disease appeared in 1872, and has in the south swept away many once flourishing estates. In Peermaud the destruction has not been so severe, but except under shade it appears likely to be only a matter of time before the district is either converted into tea or abandoned to the sambur. That shade is a great protection is, as "Novice" remarks, a recognised fact, and I have seen leaf disease stop abruptly at a piece of shaded coffee while all the fields around were wrecked by the disease. I have seen coffee in pieces of original forest and under jack and, other shade trees, and in every instance the coffee has escaped and yielded fairly good crops. The best shade I have seen tried is the *Grevillia Robusta* which for rapid growth beats everything else at this elevation (3,500 feet). In three years it grows into a good, shady tree, and besides forming a good protection soon begins to enrich the soil with its leaves, which form good mould. "Novice" appears to think that carefully selected seed may secure healthy plants, but in connection with this I will mention the following fact. A few years ago, I had some well-selected seed from coffee under shade that had never shown any taint of the disease. One-half was treated to a soaking of weak carbolic acid and water; and the other half put into the nursery in the usual way. The latter showed signs of the disease soon after germination, but the medicated seed germinated well and continued healthy till planted out (in freshly opened forest) but soon afterwards became as diseased as any old coffee. In my opinion carefully selected seed if treated to a solution of carbolic acid and planted in partly shaded land, may be made to bear fairly remunerative crops, and even coffee not too far injured by leaf disease may be pulled round by being planted up with fast growing shade trees either in belts or at distances through the estate.

Peermaud, 17th Aug. M.

II.

SIR,—We planters are indebted to Dr. Bourne for sending such a concise and clear epitome of Mr. Ward's report on leaf disease. In the first volume of the Tropical Agriculturalist there are recorded three or four reports by Mr. Ward as well as interesting correspondence on *Hemileia Vastatrix*. Perhaps Dr. Bourne will permit me to take up the matter from a planter's point of view. Mr. Ward made the same mistake which Dr. Bourne follows. The life history of the fungus; the necessary conditions favourable for development of the spores; the damage to the plant in devastating the food cells by the spores entering the stomata; the terrible drain on the plant by such a severe call on it for fresh leaves to enable it to resist the fungus—all these were clearly shown but who has found a remedy? Shade does undoubted good in the case of all pests, but it is not necessarily

in itself a cure for *Hemileia Vastatrix*. Where Indian planters score over their Ceylon brethren is in the climate. Hear Marshall Ward. "But another series of events suggested an equally important connection with atmospheric moisture. Of two series of plants in the same exposed verandah, I found that those placed on the edges of the verandah and kept wetter on the whole (from drip, driving rain, &c.,) appear to become worse "diseased" than more sheltered ones (what about shade Dr. Bourne?). "Experiments then proved that plants strewn with spores and placed in wardian cases became diseased in a fortnight to three weeks, if the interior of the cases was kept wet and the atmosphere surcharged with moisture; whereas *in very dry cases no such infection took place*." I am responsible for the italics. In India we have long unbroken droughts. These check the progress of the pest. To return:—"These and other experiments now before you led to the establishment of the connection between rain, dew, &c., and the outbreak of disease, and is in agreement with the known facts *Hemileia* flourishes especially in damp steamy districts and breaks out suddenly and badly in close hot weather after rain." So with black rot, so with a mushroom bed. But we planters asked for a cure and we got a life-history. The life-history may be interesting to science but to a planter's pocket it has hitherto brought anything but profit. Another idea which Indian planters have been shrewd enough in largely, nay universally, availing themselves of is *fresh seed*. The more vigorous coffee from the south, the Coorg variety, has nearly altogther displaced the old Mysore tree. Then Indian men score enormously over Ceylon in having a good soil which responds to cultivation. Since leaving Ceylon for five years I cannot say I have seen leaf disease in Mysore. The fungus is here at times, but with lots of manure and liberal treatment a planter, with the new variety of coffee, should average five hundredweight an acre, which, with present prices, should make him happy. To conclude, I repeat that the long droughts are the salvation of Indian estates.

Mysore, 18th August. W. A. TYTLER.

[Mr. Tytler ought to have added that "a perfect cure" was found in lime and sulphur. The resulting sulphurous gas was fatal to all the spores it reached. But, as all the spores in the island could not be reached, the remedy proved ineffectual.—ED.]

LIQUID FUEL.

Mr. Isaac M. Sowers, ex-Mayor of Oil City, is at home for a few days from a cruise in the West. Mr. Sowers is one of the Standard Oil Company's petroleum fuel brigade and a gentleman whose long experience has made him thoroughly conversant with the oil business in all its branches. He has for several months been working in the interest of fuel oil, with headquarters at Chicago. The subject of utilizing Lima crude for fuel is one that is receiving a great deal of attention from business men and manufacturers. It is a subject of special interest to the producers of Ohio, who have 2,500,000 barrels of crude above ground and no market for it. A representative of the *Derrick* called upon Mr. Sowers and was given some points in regard to the progress that is being made in introducing Lima oil as fuel. "Like every innovation," said Mr. Sowers, "the public take to it slowly; but we are working on solid ground and are making our way gradually and satisfactorily. All our recent experiments have been successful, and I hear of good results being met with by other gentlemen in the field. I have been much encouraged by the results obtained in Chicago. Our tests obtained at the Calumet Iron and Steel Works have been very gratifying."

In reply to a question if the proprietors of the Calumet works were satisfied with the result of their tests, Mr. Sowers said they were entirely satisfied, as they are now supplanting their coal with Lima crude. 'Our tests there were made in a Siemen's open hearth furnace for melting steel in which we did all the work they had been doing with coal, at 50 per cent less cost and eliminated over 50 per cent of the sulphur and phosphorus. These results could not but be gratifying to the iron manufacturers as well as to ourselves. These extraordinary tests mean, in my judgment, that coal will have to go, except in such places as it can be laid down for consumption at a mere nominal cost. Ordinarily coal cannot compete in price with liquid fuel, to say nothing of the superior product that may be turned out from the oil. On Monday we go into the Union Steel Works, Chicago, where they have 63 large boilers. If we succeed in demonstrating that we can fire their boilers successfully—and I have no doubt on this point—the owner will be ready to contract for liquid fuel, not only for his boilers, but for his heating furnaces as well. On Monday we also begin operations in St. Paul and Minneapolis, in the Brush and Edison electric light establishments there. They want an economical power for driving their large dynamos, and I am sure we can give it to them. I have been negotiating with the managers of the Minneapolis Industrial exposition to fire their battery of boilers during the coming exposition. They are also figuring with coal men, but I have reason to believe the latter will not be able to compete successfully with us. This is oil furnished in Chicago at 63 cents per barrel.

Mr. Sowers stated that his tests so far indicated that for the purposes of making steam or manufacturing iron, from three to three and one-fourth barrels of oil were equivalent to a ton of good coal.

"Do you believe oil fuel will ever be generally used for domestic purposes?"

"Yes, I think it will be. It is now being used in residences in Aurora and other towns in Illinois for cooking purposes, and I am told with the best possible results. It is furnished there at 4 cents a gallon, which is cheaper than coal, and then it is much cleaner, more convenient, and absolutely safe. The device used for burning it is cheap and simple, so that it becomes a matter of practical utility for any household."—*Derrick*.

THE DATE PALM AT LAL BAGH.

In the last Report on the Lal Bagh, we find the following notice of this valuable palm. The Report is written by Mr. Cameron, the Superintendent of the Gardens:—Acting on the suggestion of Dr. Bonavia, Civil Surgeon at Etawah, who is an authority on the subject, I applied to Government and obtained sanction for the expenditure of Rs. 200 on introducing the Arabian date palm (*Phœnix dactytifera*) direct from the Persian Gulf. This work has been promptly and so far successfully carried out, thanks to Mr. Girdlestone, the Acting British Resident, who kindly gave me a letter of introduction to Colonel Ross, the British Resident at the Persian Gulf. In October we received 116 offsets of the finest varieties of date, and excepting 6 which I believe are dead, the offsets are doing fairly well. Being unrooted, the present dry season is much against them, but when the rains set in, I hope to see a decided improvement in their condition. Last January we received from the Persian Gulf 41 lbs. of seed in pulp, and these have been distributed. The offsets and seeds arrived in capital order, and I am indebted to Mr. A. R. Hakim Khan Bahadur, Assistant to the Political Resident, for much valuable information which accompanied them. But prior to receiving the above consignments, I had obtained some seeds from Mr. Ridley, Superintendent of the Horticultural Gardens, Lucknow, where the date palm is already domesticated through the efforts of Dr. Bonavia and Mr. Ridley. This seed produced 63 healthy seedlings, which are now growing vigorously. An attempt was made to introduce the date palm in 1872-73, which resulted in failure; but Dr. Bonavia is sanguine of success, and I shall do everything in my power to support such a worthy object. Writing to me a few days ago, the doctor urges the importance of sowing and planting periodically in the following words:—"I am very glad to hear you have made so good a start with the date palm. If you go on sowing and planting every year, when they begin to fruit you will have the satisfaction of knowing that every year

more and *more* will fruit. But if you plant one lot and then stop to watch the result you will be sorry when you see the result, that you did not make an *annual sowing*." I quite concur in the above opinion. To make the experiment felt, we must obtain and sow large quantities of seeds at various centres every year. The importation of seeds is not an expensive measure, and judging from the courtesy already experienced, I believe we have only to make our requirement known to be well served by the authorities at the Persian Gulf.—B. S.—*Madras Mail.*

EUROPEAN CONSUMPTION OF COFFEE.—The consumption of coffee seems to be steadily increasing in Europe. The *Economiste Français* has some interesting statistics on this subject. Holland seems to show the greatest consumption per capita. The amount used is 9·18 kilogrammes (about twenty pounds.) The smallest consumption is in Russia, where only ·09 of a kilogramme is consumed per annum. In the United Kingdom only ·41 of a kilogramme is used per head. Singularly enough the consumption in the last-mentioned countries shows decreases when compared with previous years. All others mentioned show increases. Belgium ranks next to Holland in coffee consumption, with an average per head of 4·48 kilogrammes. Germany consumes 2·31 kilogrammes per head of population. France 1·73 kilogrammes.—*Bradstreet's.*

[In the United Kingdom and Russia tea is increasing more in proportion than coffee is decreasing in consumption. When Ceylon was a great coffee country we used to mourn the neglect of coffee in favour of tea in the United Kingdom. In the past decade there has been quite a revolution of feeling following on essentially changed conditions.—ED.]

INDIAN AND AMERICAN WHEAT.—Mr. Smeaton, Director of Agriculture for the North-West Provinces of India, has issued an interesting note on the competition between Indian and American wheat. The conclusion to which he comes is that it is not in prime cost that India is at a disadvantage. For the same outlay she can raise nearly 20 per cent. more grain than America, and of not much inferior quality; while she has resources enough in area and labour to raise sufficient wheat to supply the entire demand of the British market. India, Mr. Smeaton thinks, possesses means to compel America to withdraw her hostile tariffs and to open her markets to the products of British industry, but she is burdened in the struggle with America by, first, a primary railway freight about 25 per cent. higher; secondly, an extra railway freight of 5 per cent. on ballast; thirdly, a further extra freight on bags; fourthly, excessive handling; and fifthly, she brings into the English market an article inferior in appearance, though on the whole not much inferior in quality, to the rival one. He urges the London merchants to take the matter up and use their influence with the Indian railway companies and merchants.

CINCHONAS IN JAVA.—Consul McNeill, reporting on the trade and commerce of the island of Java, says that the area of land planted with Cinchona on private account is estimated at 21,000 acres, and the number of trees at 30,000,000, of which about, 14,000,000 are of C. succirubra. The crop for the present year was estimated at the time of writing at 1,433,250 lb. The average proportion of sulphate extracted from the bark is estimated at about 3 per cent. In 1883, the last year for which returns are available of this area of land planted by the Government, it was 1778 acres. At the end of 1886 the statistics of the Government estates were al follows:—

	Number.
Plants in the nurseries:—	
Ledgerianna	1,443,000
Succirubra	675,000
Plants in the open ground:—	
Ledgeriana	826,700
Calisaya and Hasskarliana	56,000
Succirubra and caloptera	573,000
Officinalis	225,000
Lancifolia	8,000

—*Gardeners' Chronicle.*

TESTS WITH VARIOUS INSECTICIDES.—Professor Riley, Entomologist of the United States Department of Agriculture, has been experimenting upon the relative values of insecticides. His results show that ice water is not reliable as a remedy against the cabbage worm, while salt and water and saltpetre and water also failed. One part carbolic acid to 100 parts of water injured the leaves and did not kill the worms under the leaves, Pyrethrum, 1 part; and flour, 3 parts, dusted on the plants killed three-fourths of worms. Kerosene emulsion destroyed 80 per cent. of all worms exposed to it, but buckwheat flour, ammonia, powdered alum, copperas water, carbolised lime, black pepper, tar water, and tomato water were failures. Copperas, 4 oz, to a quart of water, killed all the worms. Tar water and Wolf's soap drove the margined blister beetles from beets, but they returned. One part carbolic acid and 64 parts water drove ants away permanently. Kerosene emulsion destroyed yellow-necked caterpillars. Two applications of a saturated solution of salt killed lice on lettuce. The woolly aphis on apple trees was destroyed by kerosene emulsion, which, as the results show, is about the best insecticide, but has the drawbacks of imparting its odour to cabbage leaves.—*Chemist and Druggist.*

SCIENTIFIC RICE CULTIVATION.—The "Examiner" thus concludes an article on the recent experiments:—

It is a mistake to suppose that transplanting is practically unknown in Ceylon. It is appreciated and largely practised in the Kandyan country, and may be seen very generally adopted on the low lying fields bordering the Railway line between Gampola and Peradeniya which are, probably, as fertile low lands as any in the country. The Trincomalie experiment, without manure, proves what splendid results could be obtained by transplanting; and, where labour is available, we think it should invariably be adopted, unless careful calculations show the cost to be prohibitory. This objection should not, of course, stand in the way of the *goiya*, whose labour is his own, and who, when he does not work in his field, generally idles, or is engaged in some harmful pursuit proverbially attractive to idle hands. Results such as have been recorded at Toppur, if widely published, and obtained in other parts of the country over a wider area, will lead to more willing converts to transplanting, which costs no money, than to the iron plough which does. The experiment at Toppur, though valuable in itself, and as exhibiting one benefit of the Agricultural School in teaching its pupils not only to be observant, but accurately to note results, an accomplishment very far from common, affords no information as to cost, and from its nature could not be expected to. We should be glad if any of our friends who pay for labour, and do not practise transplanting, would try an experiment noting the cost, and also the enhanced yield, as compared with the average out-turn of the field on which the experiment is carried out. If headmen generally adopt transplanting, and obtain results approaching that recorded from Toppur, the *goiya* will not long retain his objections to the uncomfortablep osition in which transplantation has to be performed; but whether the *goiya* turn convert or not to iron ploughs and transplanting, we are very clear as to the duty of more intelligent agriculturists.

As regards the controversy on ploughs and ploughing, no doubt the difficulty is to replace the native implement by anything approaching it in lightness and cheapness. If it be really true, as stated by the Veyangoda correspondent of the "Examiner," that the rice plant feeds only down to two inches (!), the necessity for any deeper ploughing than at present is not apparent. But we should think four inches nearer the mark and the limit for upturning soil six to eight inches. The number of ploughs in India is calculated at 20 millions. We suppose the number in Ceylon is under 200,000?

CONSULS' REPORTS.

MADAGASCAR.

Copal.—The copal produced in the northern shores of Madagascar is of a quality inferior by over 10 per cent to that of Zanzibar; as Zanzibar copal is found both in its fossil, and also in its recent gum state, and Madagascar copal only in its recent gum state. There is, however, a considerable trade in this article.

Orchilla.—Orchilla is largely collected on the west coast of the island, for yielding the well-known valuable dye. St. Augustine's Bay is the chief emporium of this trade.

Indiarubber.—There is abundance of indiarubber vines in all the forests; but owing to the rude method of collecting the sap, many are destroyed. The vines could be cultivated with success, and it is much to be regretted that the Malagasy Government have not only protected this valuable plant, but have also not organised a system of re-planting in the forest. The indiarubber is of good quality, and trade in this article is capabale of much further development.

Spices.—Cloves and cinnamon can also be cultivated with success, but as they are of very slow growth, their cultivation is discouraging to foreign planters, and the natives have not the means to plant extensively.—*Chemist and Druggist.*

CARBOLIC SOAP AS AN INSECTICIDE.

No doubt there are many of your readers who are pestered with earwigs, caterpillars, blight, &c., on their plants and trees, and to all of whom an efficacious remedy would be a boon; permit me, therefore, to state my experience with substances that seem to me to be a sovereign remedy against all such destructive garden pests. The plants are singularly free from blight and insects in my garden, excepting earwigs and caterpillars, both of which abound, but a friend of mine has had his wall fruit trees annually attacked by the American blight, and his Currant bushes with the aphides that cause the leaves to curl and cockle up. as a remedy for the blight I tried last year petroleum in water, but it was tedious work, and moreover, this year some of the trees attacked have completely decayed; therefore this year I determined to try the effect of carbolic soap, knowing full well that that body is a powerful antiseptic and destroyer of all germs and insect life. I therefore dissolved a quarter of a pound of carbolic soap in a gallon of water, and then with a common paint brush washed all the stems, branches, and exils wherever the American blight appeared. It was very thick I rubbed the brush on a piece of the soap held in my other hand. I was surprised to see with what readiness the blight was brushed off the trees. All the white woolly portion and the gummy red bodies were washed off completely. I next tried the effect of the soap solution on the Currant bushes, brushing the liquid into the axils and under the leaves wherever they were curled up with the insects. The fluid acted marvellously, and since I washed them, a week ago, the shoots have started fresh growth, whereas before the growth was checked by the presence of these aphides.

I next tried the effect of the soap in my own garden, for the earwigs and caterpillars have made a wretched appearance of the Sunflowers and Dahlias I have in bloom. I first tried the effect of painting several inches of the flower stems with the soapy water, but I found that had no effect, for both earwigs and caterpillars crawled over it. This was not encouraging, but finding that the fluid did destroy them I placed a few caterpillars and insects in a saucer with a little of the soap solution, and in ten seconds the caterpillars were dead, and in twenty seconds the earwigs were dead. I tried the effect of dropping some of the liquid into the flowers round the base of the petals where the earwigs seem to secrete themselves most. The effects of this was to preserve the flowers, for neither yesterday nor to-day do the flowers show any signs of heaving been gnawed, and moreover, today I picked out a few dead earwigs from the base of the petals, plainly showing that the soap solution I had placed there had killed them. From these facts I shall try the effect of the soapy liquid on more delicate flower buds, using a toy squirt to deposit the fluid in the flower buds. The flowers themselves seem apparently not affected by the liquid. Perhaps some of your numerous readers will try this carbolic fluid —of course a solution of carbolic crystals would be stronger than one made from the soap—and report their experience. From the few facts I have gathered it seems to me to be a most effectual eradicator of garden pests.—H. O. STANDAGE.—*Journal of Horticulture.*

A GREAT EXPORT OF EGGS FROM INDIA TO BURMA is thus noticed by the *Pioneer*:—The partiality of Burmans and the Burma Chinese for eggs has of recent years developed a large and increasing export trade from Chittagong to Rangoon. Most of the eggs exported from Chittagong to Burma are ducks' eggs, large numbers of ducks as well as fowls being kept by natives in the neighbourhood of Chittagong. The eggs are packed in large jars, each containing about 1,500 eggs, and are thus shipped by the weekly British India steamers proceeding from Chittagong along the Arakan coast to Rangoon. It occasionaly happens that one of these steamers, with a number of these jars on board, encounters bad weather, and then the smash up of the eggs therein involves considerable loss to the exporters; whilst the mixture of broken eggs and lime soon develope an odour which could hold its own with that of the dreaded "dorian" fruit, equally appreciated by Burmans. A proportion of about 50 per cent, perhaps out of the 75,000 to 100,000 eggs cent from Chittagong to Rangoon weekly, reach the palates of their consumers fresh; but a large number of the remainder degenerate into what grocers at home sell as "pudding" eggs. Burmans prefer fresh eggs, but Chinamen are not particular in this respect, and, if anything, have aliking for a full flavoured article. Chinamen, however, as is tolerably well known, are specially gifted by nature in the matter of palates and digestions. Besides Chittagong, Vizagapatam (known by many natives as Moorghi-patam) and Bimlipatam on the north Coromadel coast export hundreds of fowls' eggs to Burma annually.

CEYLON UPCOUNTRY PLANTING REPORT.

REASONS FOR GOING IN FOR TEA CULTIVATION—COFFEE STEALING—BUG ON COFFEE—CARDAMOM PRUNING—THE S.-W. MONSOON—CACAO PROSPECTS—JALAP.

12th Sept. 1887.

If all the tea planters in Ceylon were to give the reasons why they have gone in for that cultivation, I fancy some of them would be amusing enough. It would however take a very funny one to beat the following, which I quote from the letter of a Burgher youth:—"Mr. —— of —— intends taking me into his factory about the 15th of this month, and I am very anxious of doing this work because my father died in such occupation"!

Coffee stealing has begun, now that the crop is ripening, and green strippings, are worth the risk. This style of open plunder is not the worst type we have to deal with, a good lookout and active watchmen can keep that sort of thing within bounds; but the rogue who is hardest to combat is the man who sells toddy, and who encourages your own coolies to bring a little coffee now and a little again, in exchange for his beverage. When 75 cents can be got for a measure of coffee, the temptation to take a handful from time to time is very great, and if a taste has been acquired for either toddy or arrack it strengthens that temptation very considerably. Although on heavy bearing trees there has been a good deal of blackening of the tips of the branches, yet the coffee got therefrom is not so empty as that of former years. I heard one place which sold what was first gathered—generally worthless stuff—and R4 a cut Government bushel was the price paid. Old trees that are bearing well are rather bare of leaves, but the rain we have been having for more than a week now will do a lot of good, and help very considerably to carry the crop through. I fancy by the end of October most of the coffee on the Kandy side will be gathered; as it is, half-bushel pickings and more are common.

Bug is still about, and its presence quite paralyzes all kind of enterprise in regard to high cultivation. You fear to spend money on anything except picking, for then you can tell at once whether it will pay or not, but to prune or manure and then run the risks of several months, is in these days, spite of the high prices, a flight too long sustained for any but the venturesome. If we could insure ourselves against attacks of bug, leaf disease in its present mitigated form could, I think, be successfully combated by a return to high cultivation.

Cardamom pruning, in the sense of cutting them all down where they have ceased to bear and allowing new shoots to come up again, is, I am told, a success, and brings about a renewal of fruitfulness. I heard of two men who had fields of cardamoms to clear out. They met and compared notes:—"What did the work cost you," asked the one of the other, "did n't you find it shockingly dear?" "Well no," was the reply, "about R3 an acre." "Three rupees! You mean thirty?" "Not a bit of it." Then he explained how he did it: cut off the tops, and made the weeders break off every shoot that appeared, and ere long the bulbs rotted. The R30-an-acre man had dug them up and carried them away.

The S.-W. monsoon is bent on making up its lost time and redeeming its character for boisterousness. For some days the wind has been very high, with more or less rain, and the thermometer has fallen considerably. As to tea flushing it has ceased and what leaf was in, it was impossible to wither well or get a good fermentation. Planting and supplying go on where they have yet to be done, and for these more favourable weather could hardly be, except perhaps in regard to the wind.

Cacao is full of blossom, and the prospects of a spring crop are good. The good results of shade are manifest everywhere, and cacao property should rise in value, and be a much more easily saleable article than it has ever been before. It is becoming very clear that with shade regular crops may be expected, and the various enemies which threatened at one time to all but extinguish cacao culture in Ceylon may be successfully kept at bay. Cacao under shade will not however bear so well as in the open, but then the risks are reduced to a minimum. The hardier varieties, which the Royal Botanic Gardens imported, seem to do perhaps better without shade at all, and those that have attained to six or eight years are noble specimens of trees.

Jalap (*Exogonium purga*) I hear is being tried in some places and is growing well. Whether this cultivation will result in having a commercial value remains to be seen. Some years ago it was cultivated in Ootacamund, with much success, indeed too much, for the tubers were so big, and so unlike the article known in the home market, that buyers fought shy of the Indian variety, and it failed to obtain a place.

In the Mexican Andes it grows from an elevation of 5,000 to 8,000 feet above sea-level. In Jamaica it was grown among the cinchona, but this had to be given up, as it exhausted the soil very quickly. It is said to want shade and a deep rich soil. An article of this kind would be very easily overdone, as the average imports into Great Britain are only 180,000 lb.

PEPPERCORN.

THE CEYLON TEA PLANTING ENTERPRISE.

In offering to our readers the following reliable *précis* and figures connected with embarking upon the tea-planting enterprise in Ceylon, it will be as well to say, at the outset, that it is done with no object of foisting an estate upon them. We are in no way connected or interested directly or indirectly, with any property in that island. Knowing how many of the investing public have not only a few thousand pounds, but also a pair of willing hands lying idle, it may be as well to put before them the draft of a plan by which they may not only find a remunerative use for their modest capital, but also a healthy life and pleasant work. Many tired-out city men would give a great deal to be able to change their present unhealthy or unsuitable mode of life for one at once hard, outdoor and bracing. England is not always the best climate in which to live, especially for dyspeptics, or those suffering from chronic pulmonary complaints. Ceylon has been brought to a very low financial ebb, as the failure after failure of good firms attests, culminating perhaps, in the suspension of payment by the Old Oriental Bank Corporation, in May, 1884. Foreclosure after foreclosure of mortgages—at one time deemed as safe as colonial loans—followed, or rather in many cases was found useless, in that an estate which had borrowed £10,000 could not readily find a buyer at £2,000. Tea at this time was rapidly establishing itself as the staple product of the island, and the banks were regaining sufficient confidence to make advances to promising young tea gardens. Still, the acreage in coffee, ten years ago, was immense, and all or nearly all that acreage will grow tea if the land be suitably treated. More than this, an immense tract of land in the low country, never before made use of by Europeans has of late years been found to give profitable tea crops and has been in demand. The valuable estates in the Kalutara district can speak for themselves as to the low elevation at which fine leaf crops can be gathered. The forest and "chena" land around Awisawella is rapidly becoming a fine

tea producing district, and one likely to command good prices in the Lane. Rapid as the progress of the tea enterprise has been, there are in England, and especially in Scotland, too many people smarting from their coffee losses to feel anything but shy at again putting capital in Ceylon. In a year or two more, when this shyness will be overcome by facts and figures, the price of tea estates and available land will increase greatly, and another cycle of prosperity visit the planting community. The railway will then be extended to Haputale, and the yearly festivities which have been so much upon the wane of late may again assume prosperous proportions. Then will be the time to sell; to sell while the demand is brisk and buyers eager. Tea may not last for ever, but if it enjoys a reign of forty years as coffee has done, it should satisfy the present generation. The pubic may be interested to know that the following estimate is given in its entirety, although of course, numerous small corrections of actual expenditure up to date could have been made. It has not been deemed worth while to alter any item, so little have they differed from the money estimated for their cost. What difference there has been, has been a saving effected under various heads. Exchange, having fallen so much during these past two years, makes a difference which is more apparent than real in that it affects both expenditure and crop sold alike. We will not commit ourselves by recommending any particular district or elevation for choosing a property. It will be obvious that should an abandoned coffee estate be selected with the usual stores and buildings upon it, a substantial reduction in the following estimate can be made under the head of buildings, bungalow, and so on. Many of the finest tea properties now realising yearly profits, were, in the years 1880 to 1884, abandoned as useless coffee estates.

Estimate for opening 100 acres in 1884, and 200 acres in 1885. The block containing 470 acres, and costing 5,500rs. New land in the low country.

EXPENDITURE.

	R	R
First year, 1884:		
Cost of land	5,500	
Salary and allowances ..	2,070	
Survey fees	200	
Felling and clearing	1,200	
Lining, holing, &c.	2,100	
Cost of seed and nurseries ..	4,000	
Planting and supplying ..	600	
Weeding	1,000	
Roads	360	
Drains	1,000	
Bungalow	700	
Cooly lines	1,000	
Tools	680	
Contingencies	300	
Outlet road..	800	
		21,510
Second year, 1885 (200 acres):		
Felling and clearing	2,200	
Survey fees	400	
Nursery, and cost of 80 maunds of seeds	6,300	
Roads	700	
Drains	2,000	
Lining, holing and planting ..	5,600	
Weeding	2,400	
Tools and contingences ..	1,200	
		20,800
Salaries	4,500	
		4,500
1885 or 1886:		
Buildings, lines	300	
Permanent factory	3,000	
Roller	1,000	
Dryer	1,500	
Engine	1,500	
Erecting and transport ..	500	
		7,800
Upkeep of 1884 clearing:		
Weeding	1,200	
Supplying	150	
Seed and nurseries	475	
Upkeep roads and drains ..	275	
		2,100
Total expenditure to end of 1885		56,710
1886—Upkeep, 200 acres, of 1885:		
Weeding	2,400	
Seed supplying, &c.	1,050	
Roads and drains	200	
Contingencies	150	
Salary	2,000	
		5,800
100 acres clearing of 1884: Weeding, pruning, supervision, &c., included in cost of manufacture, at 45 cents per lb., also London charges. Yield of tea 1½ to 2½ years old from 100 acres, at 200 lb. per acre		9,000
		71,510
Less value of 20,000 lb. tea, at 75 cents per lb.		15,000
Total outlay		56,510
1887.—300 acres tea open, viz., No. 1 field, 2½ to 3½ years old:		
100 acres, at 350 lb. per acre 35,000 lb.		
200 acres, at 200 lb. per acre 40,000 „		
75,000 „		
75,000 lb. tea to cost 45 cents per lb., including 10 cents. for London charges	33,750	
Making an outlet road into cart road	2,500	
		36,250
		92,760
Less 75,000 lb. tea at 75 cents. per lb.		56,250
Outlay		36,510
		36,510
1888.—No. 1 field, 3½ to 4½ years old, at 550 lb. per acre ... 5,000 lb.		
No. 2, at 350 lb. ... .. 7,000 „		
125,000 „		
125,000 lb. at 45 cents.	56,250	
Additions to tea factory, Barbacue, and machinery	4,000	
Outlet road	1,000	
Permanent bungalow	3,000	
		64,250
		100,760
Less 125,000 lb. tea at 75 cents. ...		93,750
Outstanding outlay		7,010
1889.—No. 1 field, 4½ to 5½ years old, at 600 lb. per acre .. 60,000 lb.		
No. 2 field, at 550 lb. ... 110,000 „		
170,000 „		
170,000 lb. at 45 cents.		76,5
		83,500
Sale of 170,000 lb. tea at 75 cents per lb		127,500
Profit		4,500
1890.—300 acres of tea, yielding 600 per acre, at 75 cents.	135,000	
Cost of 180,000 lb. tea at 40 cents..	72,000	
		63,000
Total profit		107,000

Contingencies.....	·03¼
	·40 cts per lb. of tea.

Remarks.—The maximum yield of tea is taken at 600 lbs. per acre; but the estate from the books of which the items are taken gave an average of 730 lb. per acre at six years old. Weeding and supervision are set down at the highest rates; 3½ cents are allowed for contingencies—an exorbitant rate; 75 cents is taken as London price of the tea—a much higher rate was obtained by many estates last year. Yield on Galbodde, from tea planted in 1878: From 1st July, 1880, to 30th June, 1881 (bushes being two to three years old), yield 4¾ maunds=380 lb. per acre. [Authenticated by J. Roydon Hughes in Ceylon, September, 1881, and by Herbert H. Corfe, visiting agent to Messrs. Sabonadière and Co., of Colombo.]

Estimates of yield have been avoided, but reference can be made to the published returns from Mariawatte Estate, near Gampola, the property of Mr. David Reid, which has yielded over 1,100 lb.of tea per acre !* Anyone having an idea of residing in the tropics, and at the same time engaging in pleasant, although somewhat hard, outdoor work, may find it worth while to gather facts concerning the tea planting enterprise, as one likely to give him a steady and handsome return for his capital and work. It must always be borne in mind that tea, unlike coffee, is not merely an annual crop, dependent upon a favourable blossoming season, but is steadily plucked all the year round at intervals of about three weeks, except just after the pruning season. With coffee, as with English wall-fruit, one heavy thunder-shower may cause the same failure of crop as a May frost. Thousands of bushes of blossom can be knocked off in a single night before it has set, and, when a bushel of coffee may be roughly estimated at 10 rupees, the serious loss and risk can be easily appreciated. Many coffee estates in Ceylon have given one year £5,000 profit, and the next £4,000 loss. The expenditure upon a fine coffee estate yielding 15,000 bushels of parchment would be about £7,000, allowing for manuring. The next year's yield might be 2,000 bushels, and the expenditure would be hardly under £6,000. Hundreds of fine estates in Dimbula and Dikoya—and probably a dozen other districts—oscillated between handsome profits and grievous losses in the above proportion. And when, added to this, the fluctuation of price obtained for coffee in Mincing-lane is taken into consideration the risk of a planter's financial position becomes painfully apparent. Now in Ceylon *nous avons changé tout cela.* The yield of tea may one year be far better than another, according to the rainfall or other climatic influences, and also, of course, may vary with the amount of cultivation and manure expended on the estate, but this is all. Coffee cultivation is, in many instances, a lottery, whose prize is often at the caprice of the weather during a critical week or so. Crop estimates of coffee have frequently varied by four or five thousand bushels, and have then turned out utterly misleading. The yield of tea leaf, from a given estate, can be very fairly estimated, and a corresponding amount of expenditure allowed. The price of tea will fall is almost certain to, but still a good margin remains for the producers, who with a relative or partially relative reduction of necessary expenses, may manage to secure a return of twelve to fifteen per cent upon capital invested.—*The Citizen.*

Tea in Korea.—Owing to drought this year in Korea the tea plants have almost withered, and a small yield of poor quality is the result. Silk-worms are dying daily on account of the lateness of the mulberry leaf, mainly owing to drought.—*Japan Weekly Mail.*

The quantity of tea that arrived at Kobe from the opening of the season up to the 10th instant was 8,390,485 lb., of which 7,602,400 lb. were sold to foreign firms up to that date, showing a decrease of 617,674 lb., and 285,020 lb., respectively as compared with the same date last year.—*Japan Weekly Mail.*

The Red Sea Mother of Pearl Fisheries.—The Vienna commercial journal *Das Handels Museum* says that mother-of-pearl fishing is carried on all over the Red Sea, from the north down to the Gulf of Aden, but the best fishing-grounds are in the neighbourhood of Suakin, Massowah, and the Farsan Islands. The fishing fleet consists of about 300 boats, mostly belonging to the Zobeid Bedouins, a tribe inhabiting the coast between Jeddah and Yambo. About 50 belong to Jeddah, and others to other localities. They are open boats, of from eight to 20 tons burden, with one lateen sail. The crew varies from eight to 12 men. There are two different fishing seasons, one of four and the other of eight months, and during these the boats remain almost constantly at sea, except for a few weeks. The crew, consisting in great part of black slaves, receives two-thirds of the catch, deductions being made for their food; the owners of the boat keep the other third. Accidents are seldom heard of, and the divers are remarkable for their physical vigour and robust health. They range in age between 10 and 40, and the work seems to do them no harm. The fishing-grounds are in the neighbourhood of coral reefs, where the boats are anchored; the divers then go out in small canoes, specially imported from the Malabar coast for the purpose, and begin their work all round. It is necessary that the sea should be calm, otherwise the shells cannot be seen. For some years past the negroes have been in the habit of using old tin canisters, with glass in the bottom, to enable them to see better. In the course of the past ten years the catch has fallen 10 to 20 per cent., but by reason of the increased price good and bad shells have met with a ready sale. The annual production varies from $120,000 to $170,000. During the last season of four months it reached only $25,000, against $40,000 to $50,000 in the corresponding periods of other years. Jeddah was formerly the sole market, but on account of the corruption of the Customs officials there the port only receives about a quarter of the catch now, the rest going to Suakin and Massowah. Pearls to the value of $4.000 or $5,000 are found annually; but this estimate is uncertain, as the larger and more valuable ones are sold secretly. The mother-of-pearl shells are sold at public action in Jeddah in lots of about fifty pounds. Ten years ago all that came on the market at Jeddah was shipped off in Arab vessels to Suez, whence, it was sent to Cairo, where it was sold. At present the greater part is sent to Trieste, the rest going to Havre and London. The largest and most perfect and beautiful shells are purchased by traders from Bethlehem, who take them home, and cut and sell them to pilgrims. Jeddah shells are less valued in Europe than those of Suakin and Massowah because of their yellow tinge. In an ordinary lot of shells, as sold in the market, 9 per sent, will be large, 20 per cent. medium-sized, 25 per cent. small medium, 10 per cent. small, 22 per cent. dead or cracked, and 6 per cent. will consist of impurities and coralloid marble. Some years since a German attempted pearl-fishing with a fleet manned by Greeks but as the experiment was never renewed, it is to be presumed that it was a failure.—*The Times.*

* Well manured.—Ed.

LANTANA FIBRE.

A correspondent of the *Madras Times* says:—"I have often wondered why an enterprising company has never been raised to do something lucrative with Lantana. It stretches away by the mile over some districts. The stems are of a tough fibrous consistency, and would, I should imagine, be well adapted for many purposes. At present it is merely regarded as the grave of by-gone glories and the renovator of worn-out lands."

Whatever value the Lantana fibre may have, could easily be ascertained as we have now a fibre-cleaning machine here in working order. But the last sentence of the above suggests a few remarks bearing upon this country, where the Lantana has for some years past been regarded as a curse. Granting that the country would probably be better off without this plant, it receives more blame than it deserves. It is certainly a handsome shrub, makes fine hedges and gives food for chickens, pigeons, doves, and many other birds necessary for our comfort and wellbeing.

Now as regards the overrunning valuable lands, the Lantana is certainly not as obnoxious as many other weeds (if it must be called such). Let anyone gather some seeds and sow them, and it will be seen that it is not so very easy to make them germinate and become plants. Young Lantana are easily pulled out of the ground the same as weeds, but old ones are hard to kill.

The question hinges simply upon this, if the lands overrun with Lantana had been receiving the care their value demands, there would be none now and the lands not deserving such care cannot be harmed by the Lantana, because it must add to certain climatical influences like any other plant, and thereby benefit the adjoining lands. After all, the Lantana may not be as black as it is painted, and if its fibre could be made use of, the much abused Lantana might prove to be a blessing in disguise.—*Honolulu Planters' Monthly.*

BLIGHT, SMUT, BUNT, APHIS, SCALE BUG, AND OTHER PARASITIC OR FUNGOID DISEASES OF PLANTS.

The information which has hitherto been gained in connection with this subject is yet far from perfect, but private individuals could do much towards this cause by recording and making known the results of their experiments.

In many cases the spore or germ of these pests is already attached to the seed before being sown, and the young plant is simply the means of propagating it, unless precautions are taken to cleanse the seed beforehand.

By dipping suspected seeds in a solution of 2 oz. of blue vitriol sulphate of copper, powdered, and dissolved in a pint of water, this difficulty may be overcome.

There are many kinds of parasites, the attacks of which become more or less active according to the resisting power of the object attacked, and that power is increased or diminished in proportion to its healthy or unhealthy condition.

"Healthy trees, as a rule, will take care of themselves," but it is well known that immature fruit trees especially, roses and other plants, growing in soil properly prepared, manured, irrigated and everything done to insure thrift, will still get the blight.

Large mature trees are not easily infested, but should they be, a good manuring about the roots is perhaps the only remedy. Younger trees and smaller plants are greatly benefitted by having their branches and leaves cleaned from these pests. Various insecticides and washes known, and in general use, are answering the purpose to a certain degree, but are all somewhat laborious to apply.

The question to solve is, what remedy is the most effective, cheapest, and requiring the least amount of labor.

The following mixture is the best remedy against plant parasites among the many which have been tried, and until something better is found, we strongly recommend its use. Sprinkle or wash the leaves and branches of the infected trees, as it will kill the pests without injuring the plants.

Dissolve 2 oz. soft soap in half-pint rain water, make an infusion of 1½ oz. tobacco in half-pint water, mix together; add 2½ oz. fusel-oil and half-pint of methylated spirit, and make up the mixture to a quart.

The druggists of Honolulu keep the article on hand ready prepared for use. It is suggested not to apply the mixture from the bottle direct, but rather pour into a small container, the quantity needed for immediate purposes. A common nail-brush is the simplest tool to use.

An athemizer may be useful where large numbers of plants require cleaning.

Our readers should remember that the simple application of the wash to branch, twig or leaf is sufficient—no rubbing is necessary, if the troublesome insects don't disappear at once you will find them drop off in a day or two.—*Honolulu Planters' Monthly.*

SILK COTTON.

Kapok or silk cotton, a tree which grows readily here and yields a product of high economic value, has of late come into greater prominence than ever. In Java, where it is met with abundantly, kapok has attracted considerable attention from the promising prospects of carrying on a lucrative trade in it. Within the last two years, this article has vigorously pushed its way to the fore. Until recently, Java exporters had to rely almost exclusively on Holland as market for the product. But now circumstances have wholly changed. The demand for the article is growing in other countries also, as its good qualities become better known. So far as appearances go, there is every prospect, before long, that the supply, however much it may increase in Java, will hardly meet present requirements, and will certainly fall short of the future demand. At present, in that island, the cleaning and preparation of kapok have been carried on in an extremely primitive manner. These operations were performed exclusively by manual labour. The results were often disappointing as regards the cleanness of the kapok turned out, and the mode of packing it. Experiments have been made lately in executing, cleaning, and packing operations by machinery. The product secured proved to be of first rate quality, with a considerable reduction of working expenses. The reports from foreign consumers of kapok so prepared for the market, are all of them favourable to the substitution of machinery for hand labour, as carried on by natives and Chinese. The seeds which are separated from the kapok during cleaning operations yield on pressure a very pure and clear oil. Trials made with it in sugar mills in Java have proved that it answers admirably for lubricating purposes. As machine oil, it promises to find ready sale at remunerative rates. In the neighbouring Dutch Colony as we have seen, kapok has come into notice as an article that will certainly yield high profits in the near future. In Europe it is coming into greater demand for manufacturing purposes, machinery to suit it having been brought into play. People who take to kapok cultivation will find that in quickness and rapidity of growth, it has a decided advantage. Ordinary soil suits it. On hills it grows luxuriantly at any altitude up to 5000 feet above sea level in this part of the world. It begins to yield fibre in the third year of its growth. With ordinary care the outturn is abundant. Notwithstanding its suitability to the soil and climate of the Straits Settlements, it does not take a prominent place among the export articles of the Colony. It was first imported into Europe in 1851, but, as above mentioned, its value was appreciated in Holland alone. A few years ago an increasing demand sprung up for it in the Australian Colonies, from its proven suitability for bedding and upholstery purposes. Hitherto Java stands at the head of kapok-exporting countries, British India standing next. The Indian kapok lies under the disadvantage of bad quality from intermixture with inferior fibre, and adulteration with sand and other heavy articles to increase the weight.

With Java kapok it is quite the contrary. Kapok evidently has a brilliant future before it. Plantation enterprise directed to its cultivation has every chance of proving remunerative.—*Straits Times.*

THE EAST INDIA ASSOCIATION: THE COMMERCIAL PRODUCTS OF SIAM.

BY O. WEYNTON.

In a paper on "The Commercial Products of Siam," read before the East India Association on the 7th of April, the following information was given respecting articles of more or less interest to pharmacists:—

To most people the province of Assam is an utter *terra incognita*. Those tolerably well up in Indian geography may possibly be able to point out its position on the map, describing it, generally, as the north-eastern frontier district of India, separated from our most recent acquisition of Upper Burmah by the semi-independent state of Manipûr and the wild hill-tracts lying north and south of that country. Of course the general public have heard of Assam tea, but beyond that commodity, few have the faintest idea of the vast and varied indigenous wealth lying undeveloped within Assam's political boundaries.

India-rubber (*Ficus elastica*).—For this plant such portions of an estate should be selected where the soil or nature of the ground indicates to be unfitted for bringing under cultivation with prospect of immediate return, cutting small paths thirty feet apart, intersecting one another at right angles; the lower such portion lies without partaking of a swampy character the better, and dense shade is desirable though not actually necessary; the nature of the soil is a small matter. The portion should be carefully mapped, the paths cut quite straight, and where they intersect one another, slips of this vine (*Ficus elastica*) should be planted. The vine is abundant in the ravines, and although the main stems will be found to have been *blazed* most unmercifully, the new shoots are always vigorous, strong, and strike easily; each should be some three to four feet long, placed upright, if possible against a jungle-tree, and about one foot inserted in the ground; a notch cut some four inches from the inserted end will facilitate striking, and although the slips may be planted at any time during the year, the most suitable season is March, just after the usual hail-storms have moistened the ground. The slips may be left to nature, but as time goes on, pretty constant supervision will be requisite during the cold weather, especially if the land is near the hills or in the vicinity of the villages in the plains, for in either case poaching may be expected, and the jungle-roaming nomads, both Aryan and non-Aryan, will most certainly tap the shoots if they get the chance; but as the gum exudes only in the cold weather, and cannot be removed under twelve hours after incision, it is not an arduous undertaking to capture pilferers. In five or six years the vine will have attained sufficient size to be independent of shade other than that afforded by its own foliage, and the surrounding forest may be utilized, if need be, for other plants or purposes. In twenty-five years it may be tapped in moderation not by mercilessly *blazing* the branches, but by scooping the earth from beneath the stoutest lateral roots—the parts subjected to incision being washed entirely free from soil, and a common earthen *gurrah* placed beneath to receive the gum, care being taken that sufficient space is left between the incision and mouth of the receptacle to admit of the free circulation of air, but at the same time, so as to prevent the admixture of sand, twigs and leaves. These details may seem over elaborate, but the purer the gum the higher the price. Vines of the age mentioned may easily be tapped to the amount of one maund the first year; that is 82 pounds avoirdupois of clear gum during the three months of December, January and February. Each successive year an additional ten pounds may be taken, but they will require watching, and should signs of exhaustion become apparent, such as sluggish exudation and drooping leaves, the incision should be closed and the roots earthed up; but those matters must be left to the judgment of the cultivator, and unless incising the trunk and branches is resorted to, there need be little fear of having to stop collecting during the season. The yield given is only approximate. I once took eight maunds from a vine that had escaped the attentions of the Meekers, in a remote ravine near the Kopoli river, which I estimated as near as I could to be about sixty years old, and as a plantation of *Ficus* would enjoy all the advantages that this plant had, being allowed to attain full vigour and maturity, there is no reason to doubt that similar results, in proportion to age would be obtained. Roughly estimated, an acre would contain forty-seven trees; hence, if the reader cares to work out the calculation, at the present price per pound 2*s.*, he will find, allowing a wide enough margin for freight, collecting, etc., that an acre, only thus partially occupied, would return something over £300 per annum in the twenty-fifth year. A quarter of a century seems a long time to look forward to, but presuming that a hundred acres had been put under *Ficus* when the rush to Assam for tea investment took place, just twenty-five years back, many private proprietors would be in a vastly different position from that they now occupy. The Italians have a proverb that "He who would grow rich should plant an olive." The Assam settler may substitute for the olive—*Ficus* slips.

The Lac Insect; *Coccus Lacca.*—The curious little insect that produces the lac and lac dye of commerce abounds in all the terai jungle, being more abundant and of the best quality in the neighbourhood of the Khassia Hills, and that mountain chain. It is also found on the north side of the Assam Valley proper, as likewise under the Tipperah Hill south of Sylhet and Cachar, but from the last-named locality is inferior in size, being also in other respects less desirable. In its native state it is found encrusting the branches of a variety of shrubs about four feet from the ground, and in the densest underwood, so that, for successful propagation dampness and shade are requisite; these conditions may easily be had, and the profits of the cultivation, if such a term is permissible, are so handsome as fully to warrant sufficient outlay to attain them. I shall confine myself to one acre in dealing with each item, but of course the operator can suit himself as to area, though it is as well to caution enthusiasts as to the proverb of "putting all the eggs into one basket." Though the insect seems to have no predilection for any particular bush, the Meekers, who have, so to speak, domesticated it, have ascertained that the urhur dhâl shrub rears it in the best manner, and though experiments may hereafter demonstrate that other trees are as suitable, we may take the urhur as our propagating means. It is quite unnecessary to enter upon a description of this shrub as it is known, and the pulse it produces eaten all over India. In fact the plant will grow almost anywhere, and could the lac insect accommodate itself to every clime in which the dhâl thrives the enormous amount produced would soon overstock the market, but it cannot exist in dry arid parts, hence the advantage Assam, and similar humid countries, has and is likely to maintain. Seedlings of the urhur, though abundant, are difficult to collect, each *vustee* or homestead raising just sufficient for its own necessities, so it must be raised in your vegetable garden for the purpose, and as to attain the biggest tree in the shortest possible time is your object, high cultivation must be resorted to. If sown and well watered in November the young plants will be fit to plant out at the close of the following rains—the end of October, and should then be good stout saplings, averaging four feet in height. When planted in rows four feet by eight apart, about 1,360 will go to the acre, and if well cultivated will be found quite ready to receive the insect exactly two years from the date of first sowing. To cover an acre of ground with wire netting may seem a costly proceeding, so those who do not care to incur that expense may substitute bamboo trellis-work, but I recommend starting with wire at the outset. Birds, especially the *bulbul*, are particularly destructive, so some protection is absolutely necessary. There is another enemy to be guarded against, the ant, the big red and black ones, as also the smaller species; hence the stem of each tree a little way from the ground should be furnished

with a grummet of jute, which it will be necessary to keep moist with petroleum. November is the time to get your stock lac, but arrangements should have been made earlier in the season; say August. The lac must be soft and pliable, otherwise the insect will be dried up in the cells and useless. About half a maund, or fourty pounds, will be found sufficient for one acre, and though the cost for fresh material may amount to a rupee a seer (2 lb.), it is well worth the expense, for once stocked you are independent. The best method of conveying the lac to the factory is in baskets well lined with fresh plantain leaves, and as very little motion causes the insect to leave the cells, the packing should be torn in strips and wound in and about the branches of the dhâl, while if any appear on the baskets the latter should be broken up and secured to the limbs of the tree, into the forks of which lumps of *lac* must be stuck until a a uniform distribution over the whole plantation has been accomplished. Almost daily the increase of the cell formation can be noted; first a streak of crimson draws out from the pieces of lac, which, if inspected with a magnifying glass, will be found to be a column of insects; they gradually deepen in colour and increase in size, each forms a cell and rapidly begins to exude the tough horny substance, until by the end of the rains it becomes necessary in many cases to support the branches weighed down by the incrustation. If the insect has been left undisturbed and the shade properly attended to, three years from the commencement of operations and one from the introduction of the insect, each tree will yield an average of eight pounds of lac, which when freed from extraneous matters, such as twigs and leaves, and the dye washed out, will give six pounds per bush of clean seed lac, the present price of which in the London market at 40*s.* per cwt. gives £144 per acre, less charges such as initial cost upkeep, freight, etc.; but if care is taken to leave sufficient nucleous on the branches this sum may be looked for annually without the expense of re-stocking. In preparing lac for the market it is pounded up small and then washed in plastered wooden tanks, about the size of two tea-chests thrown into one; while rubbing and mascerating the lac a few pinches of unslacked lime thrown into the water will greatly help the precipitation of the dye. After it has been washed thoroughly clean, it should be dried under shade, packed in chests of 56 or 112 pounds and sent direct to London; and as there is a growing preference among dealers and manufacturers for seed lac in lieu of shell lac, the expense of converting the former into the latter need not be attempted. Unfortunately lac dye is now a drug in the home market, having been ousted by the cheap aniline preparations, but in these whirligig days of constant commercial revolution, as there is no telling but what a demand for it may again spring up, I mention the method of preparation:—When the seed lac has been removed from the tank all scum should be carefully taken off and the dye allowed to settle for twenty-four hours; the water may then be drawn off and the sediment put into trays of about two inches deep, two feet long and eighteen inches in breadth, the sides and ends having slots cut down to the bottom every three inches. As the dye dries it must be lightly pressed down and divided by strings drawn through the slots, thus portioning the dye into cakes of three inches square by one deep. Under no account must metal come in contact with lac during the process of manufacture. Under present circumstances the dye may be sent to Calcutta and put up without reserve, as native dyers still make use of it; also a trade may be opened in it with Munnipoor and the hills, and eventually Burmah, but these details must be left to the consideration of the investor.

Indigo.—The neglect of this plant by Assam planters can only be accounted for the blind devotion to the one object with which they came to the province, the higher bheel land and drainable swamps between the teelahs possessing, as they do, a soil admirably adapted for the growth of the plant, while the heavy dew that falls up to the end of February would bring it to maturity by the middle of May. The abundant water supply avilable from the numerous springs and streams, moreover, would supply artificial irrigation—should such be deemed advisable—so that the plant might be cut and manufacture finished ere the regular rains set in about mid-June.

Arrowroot, Topioca and Sago.—Although these three are indigenous, their commercial value is so small that, though a patch of the two former may be kept for household consumption, and seedlings of the latter may be scattered about the unused portions of the grant, unless they can be placed in a manufactured state, free on board, at about a penny per pound, it would not pay to devote any further attention to their preparation. Under present circumstances they can be had cheaper as importations from London, and undertaking the preparation of them to supply any local demand, inexpensive as such preparation is, must be determined by close calculation as to whether "the game is worth the candle." For exportation they must be turned out by the ton, small quantities will not pay, any more than would match-making by the box.

Ginger and Turmeric.—Both of these tubers, if well cultivated, highly manured and treated with care in the preparation for market, can be grown at considerable profit. Each is reared in a desultory manner in almost every village, but so little care is bestowed upon the culture and drying that the minimum price is obtained in the local bazaars, and wholesale dealers would hardly take notice of them. Generally speaking, the roots when taken up receive but a superficial washing, are then smeared with fresh cowdung and hung in baskets or spread on trays among the rafters of the native huts, the ever-ascending smoke doing the rest. The result is that the out-turn presents a most uninviting aspect, dirty, shrivelled, and, despite the almost constant smoke, the dried tubers are invariably riddled with the bamboo-borer insect. If on being dug out the tubers of ginger are thoroughly well scrubbed in water with a hard brush until every earthy particle is removed and then steeped for a night in a pretty strong solution of lime water (one ounce of unslacked lime to the gallon), then well rinsed in clean water and dried slowly in a brick oven at a temperature of 140° to 160°, it will command a price closely approximating the best Jamaica ginger; this was ascertained some twenty years ago in the case of some samples so treated on one of the Sylhet plantations. Though ginger may be had, as stock, from almost any village, the best is procurable from the bazaars frequented by the hill tribes under the foot of the hills. As ginger is a bulky article it might be worth while to consider the advisability of extracting the essence and confining dealings in it to that.

Turmeric may be treated in the same manner, omitting the bleaching by lime water, and sent to the best market ruling prices indicate. There is another tuber that might be cultivated with great advantage and profit, but having regard to the climate in which it is found I doubt very much whether it could be raised in the plains of Assam. I allude to the *Salep misree* brought round by the Afghan fruit pedlars every cold weather. Dried to an almost adamantine consistency in its journey from Balk, that retailed by the traders may be presumed to have lost its vitality and the extreme difficulty of procuring anything direct from Afghanistan precludes all hope of getting it thence; but, under the name of "little men's bread," it is known to the Badaghurs of the Neilgherries and may be procured either from the Botanical Gardens at Ootacamund or from planters on that plateau. It is best germinated in damp flannel until the eyes begin to protrude, when it may be planted in well earthed ridges, kept moderately moist, and shaded until the leaves appear; it is fit for lifting in a twelvemonth. Though unknown in Europe and almost entirely so to any of the medical profession who have not served in the East, it possesses most wonderful vivifying properties, and has been famous throughout Persia for ages as a stimulative

in cases of extreme prostration. Once introduced, its value would become apparent and a highly remunerative price commanded. It reproduces about eight tubers from one, maturity being indicated, as with arrowroot, by the drying up of the leaves. Should it not be found suitable to the plains it would, I am convinced, succeed at Shillong or any other station at an elevation of our 2000 feet outside the rain-belt; my own observations in the Neilgherries leading to the conclusion that any rainfall in excess of 100 inches would induce rot.

Though many economic plants will doubtless suggest themselves to the intending establisher of what may be called an *omnium* plantation, and nothing need be said to deter one from introducing them, it would be better to defer their planting until the place is well stocked with indigenous ones of ascertained commercial value ere experimentalizing with exotics, the successful rearing of which must be at least speculative.

Aniseed and anise star are both to be found in abundance in Assam, the one under the name of Mahori, the latter under that of Badian. Among the low hills round about Gowhatti, on the old road to Cherraponjee, and in the terai forest of both sides of the Khassia and Naga hills, sufficient seedlings of aniseed for stocking an acre can be easily procured, but considerable care is required in transporting them, and this should be done during the cold weather, the plants lifted with as much earth round the roots as can conveniently be carried. As the object with the former plant is to obtain as luxuriant a foliage as possible, high cultivation and copious manuring should be resorted to; the plant may be put in 4 feet by 4—the same distance as tea is planted; but if that part of the district in which the grant is situated is more than ordinarily subject to visitations of blight and red spider, it will be prudent to plant somewhat wider—say 5 by 5; for though tea leaves afflicted with the two pests mentioned make but little perceptible difference in the turn-out (not out-turn), the quality of the oil of aniseed will be very sensibly affected by the presence of unhealthy leaves, hence the aniseed plantation must be kept clean and in good order. To get the largest yield from the plant, pruning with that view may be carried out as experience dictates, and the best treatment followed with tea will probably be found to answer. The plant readily responds to the use of the knife, and will yield, weight for weight, about 50 per cent above tea, so that the usual task for plucking may be increased in proportion. The leaves should be gathered precisely as with tea, but removed from the plucking baskets *more often*, for no heating must be permitted, and plucking should only take place in dry weather. The leaf may be subjected with advantage to a light rolling in the mass just sufficient to break the cells and the oil then pressed out, or may be extracted by distillation; but whichever method is pursued, both press and still should be enamelled or of polished iron and kept scrupulously clean, as on the clearness of the oil and freshness of the leaves depends its price. It may then be sent to market either in small casks or bottles, and as numbers of the latter can be always purchased for an almost nominal value in the districts, for the first consignment or two their use would, perhaps, be preferable; but of course all these matters need careful calculation as to cost.

Anise star or Badian, the object with which is to procure the largest amount of fruit (or seed)—which latter is not quite the correct term—will require that class of manure that contains the greatest amount of phosphates. Hence pulverized limestones, bones, and animal or fish offal will be best for it, and as all these can be had at small cost, large crops may be secured; although the chief dependence should be placed on the fruit, the bark of Badian is almost equally rich in properties peculiar to the shrub. Both seeds and bark may be lightly crushed and then infused in spirits of wine or distilled in the usual manner. The large demand all over Europe and America for anisette for flavouring purposes would tend to make this particular industry a considerably remunerative one. Packing, for export, must depend upon circumstances; but, as this is a choice article, well corked and sealed bottles are to be recommended. It is as well to mention that the flavour of the preparations from both these plants is so pungent and penetrating, that the house set apart for their manipulation should be kept distinct from all buildings devoted to other manufactures, and that the few people it will be necessary to employ in the aniseed business should be retained for that special purpose. Natives are proverbially careless in these matters, so that strict vigilance to prevent interchange of the tea and aniseed baskets must be specially guarded against. Scented tea is all very well in its way, but, impregnated with the powerful odour of anisette, would find scant favour either with dealers or the general consumers.

Andropogon Schœnanthus, or *Ghundho bina*, as the Bengalis term it, is a small stunted-looking shrub that is found under the hills on the south side of the two valleys that now form Assam. It is well-known in Ceylon and Southern India, and from its fresh-gathered leaves is distilled the lemon-grass oil of commerce. In its native state the Ghundho appears an unpromising plant from which to expect any large yield of leaf, but when well manured and cultivated it responds to generous treatment, and will well repay those who care to raise it. The pruning is much the same as that demanded for other leaf-producing crops, and, though even the coarse, tough, older leaves are impregnated with the essence and yield largely, care must be exercised to avoid over-plucking, as the plant needs considerable lung power, and if unmercifully taxed will soon die out and have to be replaced. It is better allowed to attain 6 feet in height ere plucking, when it will be sufficiently robust to withstand close cropping, but as soon as signs of exhaustion, such as drooping of the lower leaves, become apparent an interval of rest should be accorded. It should not be touched from October to April, and only on bright warm days. If fire is used the heat must be low, but a brighter and clearer oil is obtained if a glass retort is made use of, so arranged as to revolve slowly in the full beams of the sun that the mass of leaf may be kept constantly turning over, otherwise a disposition to "cake" is induced, and the outturn is streaked with unsightly films of dark muddy line that will detract considerably from its market value. The plant may be propagated from layers, cuttings, or separation of the roots, but is sufficiently abundant to provide independent saplings for stock without recourse being had to the above somewhat tedious methods of multiplication. As this is an essential oil, and the produce of your experimental acre will not amount to any large quantity, either bottles or half-maund tins may be used for the first exportations. The refuse, after all oil has been extracted, being liable to ferment and become offensive, should be burnt and consigned to the general ash-pit, the sifted lye from which will be found the best thing to use for cleaning all oil presses, retorts, etc.—*Pharmaceutical Journal*.

IN MAURITIUS there is a cactus, closely resembling the ordinary prickly pear, except that it has not a single thorn or hair on it. It is used on that island as a forage plant. We should like further information from one of our Mauritius confrères, for it would be of considerable benefit to some parts of these Islands, which at present are useless during dry seasons, for cattle feeding. The plant has been introduced at the Cape of Good Hope with excellent results. [On this paragraph, from the [illegible], we would remark that we shall believe in a perfectly thornless cactus when we see it. But the thorns of the ordinary prickly pear can be got rid of by means of fire, after which the branches can be crushed for forage. ED.]

DISEASE IN CALADIUMS.—A fungus closely allied to the one that causes so much trouble to the potato, has attacked the Caladium. It is very bad on the C. esculentum which is much used for food in the West Indies and elsewhere.—*Journal of Horticulture.*

MOSQUITOES.—It is said that nitre paper burned in a room will drive out mosquitoes. We have not tried this, but a mixture of equal parts of essential oils of eucalyptus and lavender applied freely to the skin will repel their attacks. And we can assert from experience that essential oil of lavender applied to a bite without delay will at once relieve all irritation and prevent swelling.—*Chemist and Druggist.*

RICE BLANC MANGE.—One cupful raw rice (washed), three pints water (cold), one cupful sugar, one lemon (grated rind only), a little salt, a little cinnamon, half a cupful cream, half a cupful preserve-juice or jelly (may be omitted). Boil the rice in the water till every grain is dissolved and the water displaced by a thick paste of rice. Stir into it the sugar and lemon rind, salt and cinnamon. Beat the cream to a stiff froth and stir into the rice. Then mix in the preserve-juice or jelly, which should be of a bright color. Pack the blanc mange in wet moulds. When stiff, turn out and serve with custard or cream.—*How to Cook Well.*

SUGAR SALE EXTRAORDINARY.—We have had sent to us the particulars of an Account Sales of a shipment of sugar from the West Indies to this country, which we should hope is without a parallel. The shipment was made in the autumn of 1883, when the price of fair to good refining was 20s., it was held in the hope of obtaining a better price, and after keeping it a year and quarter it was sold, in December last, at 10s., or rather this was the figure at which the sale was reported. The expenses were just over £6 the ton, that is for commission, discount, loss in weight, freight and sundries; leaving for the unfortunate planter not quite £4 per ton. The charge made for freight was 2s. 6d. per cwt. —*Sugar Cane.*

WATERING FINE SEEDS.—Mr. J. T. Saltau, Little Efford, Plymouth, has forwarded us an ingenious, inexpensive, and useful contrivance which he employs for lessening the stream of water flowing from a watering-pot, as is often necessary when watering small plants, cuttings, &c. The usual way of securing the end in view is by partly blocking the orifice by the finger. Mr. Saltau procures a cork, and burns a hole through its centre by means of a hot iron, and then inserts a portion of a goose-quill which is slightly longer than the cork itself. The cork tapers, so that it will suit almost any can. We think our readers may find the contrivance of use, and one that anybody can easily manufacture for himself.—*Gardeners' Chronicle.*

KILLING BY MULCHING.—Where there is a small patch of thistles they may be destroyed most effectually by mulching. Do not cut off the tops, but bury them under the straw, pressing it down so that they cannot rise up. If new sprouts rise through the mulch, bend them down under the straw or add more. This mulching process should not be tried under trees that it is desired to save. It will destroy them as well as the weeds. Wherever dirt from excavations is piled around trees in Summer while in full leaf it is pretty sure to kill them. The leaves turn yellow because the extra covering over the roots excludes the air. In Fall or Winter there is less liability to injury, as the soil is loosened by freezing and the tree will start new roots higher up if not covered too deeply. If a straw stack is built around a large tree it is almost sure to kill it. —*American Cultivator.*

THE FALLING-OFF in the consumption of coffee in this country is attracting some attention. In 1860 the consumption, with a population of 29,000,000 was 35,674,381 lb., or 1·23 lb. per head. In 1884, with a population of 36,000,000, the consumption was only 33,016,256 lb., or 0·91 lb. per head, or a diminution of 25 per cent. On the other hand, the consumption of cocoa during the same period has increased from 0·12 lb. per head to 0·38 lb. per head. The increase in the consumption of tea shows an important increase. In 1860, 2·66 lb. per head were consumed, in 1884 it was 4·82 lb. per head. This decrease in the consumption of coffee is the more remarkable, since during the past few years a very large number of coffee houses have been established throughout Great Britain and Ireland. In some papers we see that the figures given are 69,000 tons in 1861, against 41,000 in 1884, a diminution of 28,000 tons since 1861, which is evidently an error.—*Sugar Cane.*

CORNERS IN FOOD.—High prices invariably bring out hidden supplies. Speculators, or those who engineer corners in food, are unmindful of this fact, and they also forget that extreme figures for any commodity places a premium upon the use of substitutes. The Chicago wheat clique underestimated the quantity of wheat in farmers' hands, and failed because of the enormous lots of cash wheat which came pouring into market from all directions to get the advantage of the clique's artificial prices. Several years ago a speculation in sugar failed, because high prices drew supplies from countries that previously had neglected the United States as a market. The coffee speculation which culminated in 1880 failed, because the high prices maintained by the clique for years so stimulated production that finally supplies swamped the leading operators. During the recently-exploded coffee speculation there was a difference of nearly 1¼ @ 1½ cents per pound between spot coffee and that sold for delivery in November and later months, speculators being shy of the real bean. It is for the reasons named above that most all attempts to corner supplies of food have failed, and probably will always fail.—*American Grocer.*

KOORCHI OR KOORCHEE.—Manufacturing pharmacists whose trade extends to India often meet with unusual names for drugs in the orders received, a tincture, extract, or other preparation being required. Amongst the number the above is occasionally quoted, and hence reference to books has to be made. Our English authors of works on materia medica do not indulge too freely, if at all, in vernacular names of foreign drugs, so that it is of little use to seek for this kind of information from them. The Indian Pharmacopœia does not allude to this drug-name under the account of this particular remedy which is contained therein. The omission, perhaps, can be explained if we conclude that koorchi is a new name, because the Indian Pharmacopœia is now somewhat antiquated. The bark of wrightia or holarrhena anti-dysenterica (*Nerium anti-dysentericum*) is known as koorchi, koorchee, or indrajab. The plant yielding it is a small shrub belonging to the natural order Apocynaceæ (Dogbane order), and grows wild in the hilly districts of the Concan, Ghauts, and other parts of India. This bark, which is the Conessi or Telicherry bark of materia medica, is also called codaga pala, or corte de pala, and is of a spongy texture, a dull rusty-brown colour, and possesses a bitter taste and has astringent properties. It is much used in India as a febrifuge and tonic bitter, and in case of dysentery and other troubles of the bowels, whether chronic or acute, it is much prized by the native doctors; hence also the specific name of the plant. Dr. Stenhouse examined the seeds of this plant, and found that they contained a bitter alkaloid which received the name of *nereine* or *wrightine*, and more recently *conessine*. Its formula is stated to be $C_{11}H_{18}N$. The reputation of koorchee has on several occasions suffered because of the use of an allied bark, viz., that of *Wrightia tinctoria*, which if it is not absolutely inert, certainly does not yield the good results expected from the administration of the preparations of the genuine bark.—F. H. ALCOCK. —*Chemist and Druggist.*

TEA IN JAPAN.

From the British Consular Report for 1886 we quote as follows:—

The export of tea from Japan during the last seven years has been.—

	Lb.
In 1880	40,436,877
1881	38 483,854
1882	37 734,845
1883	37,146,914
1884	35,766,600
1885	41,244,718
1886	47,595,651

These figures show that the export for 1886 exceeded that of any previous year in the current decade by over 6,000,000 lb. and the average export during the period of 1880-85 by over 9,000,000 lb. The only market for Japanese teas is found in the United States and Canada, and practically the whole export of 1886 was to those two countries. In the United States, the rate of consumption of tea is calculated to be about 1¼ lb. per head of the population. Taking the same low rate for Canada, the total annual consumption by the two countries amounts to nearly 70,00,000 lb., two-thirds of which may be said to consist of green teas, and large, therefore, as was the export from Japan during 1886, there is no reason why it should not be maintained or even extended in the future, if the Japanese producers are careful to consult the American taste for quality and flavour, not, as has been done in the past, ruthlessly sacrificing both in the expectation of profitably rushing excessive quantities upon the markets. At present the tea trade of Japan directly interests Great Britain only in so far as it affords employment for British capital and British shipping. An extension of the trade will bring about a proportionate increase in both these cases, and, in another point, it may afford an opening for British trade in supplying machinery that might profitably be used in the operations that are now done by hand. The export of rice in 1886 showed an increase of 63,732 tons in quantity, and of £416,142 in value over that of 1885; and, with the exception of 1878, it was the largest export that has ever hitherto taken place in any one year from Japan. Silk, tea, and rice are the most valuable and extensive productions of Japan, but an increase has taken place in the export of coal, copper, dried fish, and sea-weed. For copper there is a large demand in China, and a practically limitless one for the two latter staples. In these, it may be hoped that the demand will, to a considerable extent, be met from Japan, as the Hokkaido, the principal seat of the fisheries, has lately been freed from the crushing burden of taxation formerly imposed upon it, to which reference was made in the report on the trade of 1881.—*L. & C. Express*, Aug. 12th

PLANTING IN NORTH BORNEO.

(*British North Borneo Herald*, Aug. 21st.)

The British Borneo Trading and Planting Co.'s manager Mr. A. Walker burnt off a clearing of 60 acress on the 22nd July at Boccara in Sandakan Bay. This clearing is the proposed commencement of a fibre plantation and arrangements have been made for the delivery of over 100,000 pine-apple plants. One of Death's fibre cleaning machines has been erected and some pine-apple leaves put through with very favourable results.

Mr. Walker's pepper clearing on the Segaliud is ready for planting and vines from Singapore are expected in a few days.

Mr. A. Walker finds that he can get all the labour he requires at $8 per month.

Mr. José Hayman one of Baron Stein's representatives in British North Borneo left Sandakan on the 21st July in the S. S. "Pakman" with 22 coolies from Labuan for Lahad Dato, where Mr. Voorwyk the manager is pushing on his preparationsfor next year's crop. The S. S. "Royalist" which left Sandakan on the 18th July took down 33 Javanese coolies and an assistant manager Mr. Brown for the same estate. We are glad to think that Mr. Voorwyk's preparations are made in such good time as may enable him to plant his tobacco fields in May or perhaps before. Hitherto although the quality of the tobacco grown in British North Borneo has been generally praised the quantity has not been satisfactory and this has been due to late planting, for it is in our knowledge that a good deal of the tobacco planting in the last two years has been done in July and August. If three crops are to be expected the planting must not be later than May.

A correspondent who has lately visited Marudu Bay writes very hopefully of the prospects of planting in that neighbourhood. At the German Borneo Co.'s Estate, Banguey, 500,000 tobacco plants were already in the ground, growing as regularly as a regiment of soldiers; and 500,000 more were to be planted out in a week or two, making in all 100 fields, from which Mr. Lind hopes to obtain at least 600 piculs prepared tobacco by the end of the year,

The estate belonging to the Borneo Tabac Maatschappy is situated about an hours pull up the small river Ranow at the southern end of Marudu Bay. The land on either side of the bay is composed chiefly of low rolling hills, but there is a considerable amount of flat land in the bottom of the bay just between high water mark between the nipah and where the hills commence, which rise range after range culminating in Mount Tamboyukong 9,000 feet high. This land is considered by experts to be admirably adapted for tobacco growing. We hear 34,000 acres have already been selected for that purpose, and we must congratulate Count Geloes on his foresight in securing such a valuable concession as 26,000 acres in such a favourable situation.

At Ranow the manager Mr. Persyn is doing his work economically and well, a good road 30 feet wide with four feet ditches on either side has been constructed from the landing place to the estate, about one mile distant. Mr. Persyn has had the usual pioneer difficulties to contend with which has thrown his work back somewhat but he is pushing on, and hopes to have 65 fields planted out in a few weeks.

Messrs. Persyn and Lind have had considerable experience in tobacco the latter three years in Banguey and therefore it is satisfactory to hear that both these gentlemen are convinced that Borneo must become a tobacco producing country.

Mr. Christian's Liberian Coffee estate which is situated about two miles from Kudat, was also visited and was found to be looking very promising. The young plants on a 36 acre block appeared dark, glossy, and healthy. In view of the late rise in the price of coffee, and of the possible abolition of slavery in Brazil in the near future Mr. Christian is sanguine of success, and we believe after the satisfactory results from Silam coffee estate this year, that Liberian coffee can now be added to the list of products which will pay to plant in British North Borneo.† Mr. Christian is a strong advocate for Indian Immigration and we hope the Government will secure this as it will be of immense advantage both to planters and the country.

FORESTRY.

In May of the present year a Select Committee of the House of Commons was appointed to consider whether, by the establishment of a Forest School or otherwise, our woodlands could be rendered more remunerative. Eighteen members were appointed of the Committee, with the usual powers, and at the first meeting, on June 8th, Sir E. Lechmere was called to the chair. In all eight meetings were held, the last on August 3rd; and twelve persons, representing various professions, occupations, and interests connected with woodlands and forest management in England, Scotland and Ireland were examined as witnesses.

The report, which was agreed to unanimously, was published yesterday, and is, with very slight amendments, the draft report of the chairman. It should be mentioned that the Committee was

originally appointed in 1885, and was reappointed in 1886, when, in consequence of the general election, it had not time to consider the report.

The Committee directed its attention to the following points:—(1) How far there is need of some means of giving instruction to those engaged in the cultivation and management of woodlands; (2) how far the establishment of schools of forestry would meet that need; (3) whether a board of persons representing various interests and associations connected with agriculture, arboriculture and silviculture should be formed with the assistance of Parliament for the purpose of examination, granting certificates, and generally promoting the improvement of our woodlands: (4) whether by either or both of such means the cultivation could be made more remunerative.

In the course of the report it is pointed out that the woodlands in private hands amount to 1,466,000 acres in England, 163,000 in Wales, 829,000 in Scotland, and 330,000 in Ireland; and there is no doubt that the management of these 2,788,000 acres might be materially improved. Attention is particularly called to the New Forest, where over 40,000 acres of waste land are lying idle and worthless. It is also stated that there would be considerable advantage in an extensive system of planting in many parts of the kingdom, especially in the West of Ireland and in the Highlands of Scotland. It is to be noted that nearly every other civilized State possesses one or more forest schools, while in this country no organized system of forestry instruction is in existence excepting in connexion with the Indian service. The general conclusions to which the Committee came may be gathered from the words of the report:—

Your Committee recommend the establishment of a forest board. They are also satisfied by the evidence that the establishment of forest schools, or at any rate, of a course of instruction and examination in forestry, would be desirable, and they think that the consideration of the best mode of carrying this into effect might be one of the functions intrusted to such a forest board.

As regards the Board of Forestry, the Committee submit the following suggestions:—

1. That the Board should be presided over by a responsible official (an expert by preference) appointed by the Government, and reporting annually to some department of the Government.

2. That the Board should be so constituted as to comprise the principal agencies interested in the promotion of a sounder knowledge of forestry, especially the various teaching and examining bodies, as well as the professional societies.

3. That the following bodies should be invited to send delegates to the Board:—

The Royal Agricultural Society of England, the Highland and Agricultural Society of Scotland, the Royal Dublin Society, the Office of Woods and Forests, the Linnæan Society, the Surveyors' Institution, the English Arboricultural Society, the Scottish Arboricultural Society, and that the director of Kew Gardens should be a member *ex officio*.

That the Board should also comprise three members of each House of Parliament, and a certain number of owners or managers of large woodlands, a preference in the latter case being given to those who are in a position to afford facilities for study in their woods.

4. That the functions of the Board should be:—(*a*) To organize forest schools, or, at any rate, a course of instruction in forestry; (*b*) to make provision for examinations; (*c*) to prepare an official syllabus and text-book.

5. That the examiners should be required to examine in the following subjects—namely:—(*a*) Practical forestry; (*b*) botany; (*c*) vegetable physiology and entomology, especially in connexion with diseases and insects affecting the growth of trees; (*d*) geology, with special reference to soils; (*e*) subjects connected with land agency, such as land drainage, surveying, timber measuring, &c.

The expense of secretarial staff and examiners need not, in the opinion of the Committee, exceed £500 a year, and the cost might be considerably reduced by fees for diplomas.

The fact that the Indian Government already incurred some expense in promoting the education of forestry students for the Indian Service suggests the adoption of the Royal Indian Engineering College at Cooper's-hill as a nucleus for the proposed forestry instruction.

Inducements might be offered to the agricultural colleges and the Surveyors' Institution to send their students for examination, by a system of exemption from examination in certain preliminary subjects, in respect of which the candidates could produce a certificate of proficiency.—*London Times.*

THE WEIGHING AND SAMPLING OF INDIAN TEA.

At the annual meeting of the London Wholesale Tea Dealers' Association, held on Thursday week, Mr. Francis Peek (Peek, Winch & Co.) presiding, some proposals for reforming the present system of weighing, docking, and sampling Indian tea were discussed, and the secretary read the report in which the following reference to these subjects was made:—

Your committee, in accordance with their usual custom, have now the pleasure of submitting their annual report and statement of accounts. Amongst the various subjects which have occupied the attention of your committee, the following are of special interest to the members, viz.:—The opinion was invited of the trade last year upon the weighing of Indian teas upon the average net principle, and some cases of irregularity in weights were reported, when notice was given to the Customs' authorities and the Indian tea importers that the trade would cease to buy upon average net weights unless greater care was exercised in correctly packing the tea. Your committee would now be glad to receive a further expression of opinion as to the desirability of continuing the average net weight system or otherwise. Your committee hoped last year to obtain a further reduction in the warehouse charges for sampling teas, and they are glad to report that, after much opposition, the proprietors agreed to reduce the rates to 3d a chest, 2d a half-chest, and 2d a box from June 1st last. This, the members will notice, is a reduction of 50 per cent on chests and half-chests upon the charges made two years ago. The subject of a change in the mode of sampling teas is now being favourably considered by the leading dock companies, and your committee venture to think a reasonable scheme will be proposed, and, if sanctioned by her Majesty's Customs, your committee hope will work satisfactorily to the benefit of the trade and purchasers of tea generally. It is with great satisfaction that your committee mention the fact that, after many interviews and lengthy correspondence, the London and St. Katharine's Dock Company have met the reasonable wishes of buyers in covering them against loss by fire for all teas lying in their warehouses, and there is reason to believe the East and West India Docks will follow their example. The proprietors of Chamberlain's and Butler's Wharves have agreed to make an allowance to dealers to compensate them for the cost of insurance, whilst the proprietors of the City Warehouse and Oliver's Wharf have arranged to cover and insure the teas in their keeping. The subject now rests with the trade to consider the saving effected by purchasing teas lying where these allowances are made, and the following resolution will be submitted to the meeting, to which your particular attention is requested, viz.:—"That, as the London and St. Katharine's Dock Company, Butler's Wharf, Chamberlain's Wharf, Oliver's Wharf and the proprietors of the City Warehouse, either, cover and insure the buyers of tea, or make an allowance in respect thereof, it is obviously to the interests of the trade to give a preference to teas stored in these warehouses, and that notice be given to all importers and brokers that this meeting pledges itself to give such a preference in purchasing teas, and to

exhibit notices to this effect in their sale rooms." The condition of sale by which brokers are allowed seven days to furnish weigh-notes has frequently been taken advantage of to the full extent, so that partial deliveries in some instances cannot be obtained under the full limit of time; this your committee feel is straining the original intention of the condition of sale, and they consider a fair portion of the tea should be ready for delivery at the time of sale, and the balance of the weight-notes ready before or not later than seven days. A little firmness on the part of buyers would, it is confidently thought, remove the inconvenience and annoyance of any unreasonable delay.

The chairman after speaking of other matters said: As to the weighing of Indian teas there had been great loss sustained by the old system, and many complaints had been received from customers. He believed there had not been so many complaints lately. Whether that was owing to the more complete adoption of the net weight system he could not say. There were advantages in both systems, and the committee left it to the members of the meeting to express their opinions in the matter. The question of sampling was one of the greatest importance—the present system was radically bad. He believed there was no trade in the country in which buyers were allowed to draw samples and return inferior qualities to replace them. But this was what generally occurred in the tea trade.* This, therefore, needed to be remedied, and though the loss fell principally upon their customers, yet it was a most important matter for them to take up. The next question referred to in the report was one of great importance to the wholesale trade, and which required to be dealt with immediately; it was the question of insurance, He did not know whether they all appreciated fully the extent to which this question affected them, and therefore, he would venture to put it somewhat fully. There were certain warehouses where the insurance could be effected at comparatively low rates. For example, at the St. Katharine's Docks, they could insure teas at 3s 6d. per cent. But if they went outside the docks to some of the inconvenient outlying warehouses it costs them 7s. per cent. But as teas in these warehouses were often being moved about, in order to have any security for them it was necessary to take out floating policies, which cost them 15s. per cent., or ½ per cent. more than on teas lying in the docks. He felt they ought not to bear that ½ per cent. because merchants or importers chose to store their teas in outside warehouses where some small extra advantages were offered them. Their committee, therefore urged upon the warehouse proprietors that allowances in the rent should be made to cover the cost of such policies, and to this Butler's and Chamberlain's wharves had agreed; Oliver's had arranged to cover it by insurance on the teas themselves, as had also St. Katharine's Docks. As an illustration of the importance of this matter to every dealer, he pointed out that if any one of them bought £100 worth of tea lying in the St. Katharine's Docks warehouse, they would save fifteen shillings per cent as against teas in outside warehouses where the allowances he had mentioned were not made, and this amount represented a very appreciable difference in these hard times. The committee therefore, wished to pass the resolution mentioned in the report so that they might strengthen the hands of these warehouse proprietors who had promised to make the allowances the committee had urged. And he hoped that they would not only pass that resolution but that the trade would be united in their action in the matter, because if the trade took no notice of the resolution and bought teas lying in warehouses where the allowance was not granted it was very certain that the docks would soon cease to insure.

Mr. Lowcock seconded this, and, there being no question raised, the resolution was put and carried unanimously.

Mr. Absolom next moved the following resolution:—"That, as the London and St. Katharine's Dock Company, Butler's Wharf, Chamberlain's Wharf, Oliver's Wharf, and the proprietors of the City Warehouse, either cover and insure the buyers of tea, or make an allowance in respect thereof, it is obviously to the interests of the trade to give a preference to teas stored in these warehouses, and that notice be given to all importers and brokers, that this meeting pledges itself to give such a preference in purchasing teas, and to exhibit notices to this effect in their sale rooms."

Mr. Game seconded this resolution, which was carried *nem. con.*

Mr. Holborn moved that—"That this meeting deems the subject of improvement as to the mode of sampling tea, referred to in the fifth paragraph of the report, to be worthy of the continued consideration of the committee, and will hail with satisfaction any arrangements sanctioned by her Majesty's Customs by which the grievance complained of may be relieved without unreasonable loss to the wholesale dealers."

This was seconded by Mr. Burbidge.

Mr. Salmon pointed out that in considering the resolution there were some difficult points, such as ullage packages and the samples taken for public sale purposes, and he wished to remind them that though the trade suffered by having inferior tea as returns, and by the undue disturbance of the tea in sampling, yet they had a set off in the pound draft which they got, and which had only been obtained after a strong fight.

There being no further discussion, the resolution as above was put and carried.

Mr. Mennell referring to the weighing of Indian teas asked whether the lessening of the number of complaints on this matter was not due to the fact that the system of net weights, had been more completely carried out than previously. The one great ground of complaint was the sending in of irregular net weights. As far as he knew the trade was against the system of net weights. Had the system of sending in irregular net weights been discontinued?

The Hon. Secretary explained that though there had been no written agreement on the subject, he had seen Mr. Tye, the secretary of the Indian Tea Growers' Association, who had given him to understand that no further parcels with irregular net weights would be sent in. The Committee had given the growers notice that they were not keeping their part of the agreement which had been made between them and the importers, and he thought the notice which had been sent out to India had had an influence upon planters since.

* Here is a nice revelation!—Ed.

HORTICULTURE ON THE SHEVAROY HILLS.

The following occurs in the proceedings of the Madras Agri-Horticultural Society:—

Read the following interesting Report for 1886, from Deputy Surgeon-General John Shortt, Yercaud, Shevaroy Hills, received on the 7th July, 1887:—

"I have the pleasure to send you the following notes of these hills, and regret exceedingly the unavoidable delay that has occurred in submitting them.

"The rainfall at Yercaud during the year on the whole was favourable for conducting Agricultural operations, being 71 inches 4½ cents, registered in 10 months, distributed over 114 days of the year, showing an excess of 1 inch and 13½ cents over that of 1885. We had no rain in the months of February and April, 26 cents fell in January, and the maximum being 18 inches and 23½ cents in August. The greatest fall on any day of the year occurred on the 3rd of August, when 3 inches and 70 cents were registered in the 24 hours. Coffee has again proved disappointing. A few of the estates on the Western side of these hills produced what may be called fair crops, whilst on others there were no crops at all owing to the failure of rain at the proper time, but the rise in the price of Coffee in the English market has compensated a few Planters to some small extent.

"Of the seeds received from the Society of 'Cupressus sempervirens' and 'Torulosa,' only 2 plants of each variety, germinated. The 'Thuia orientalis' and the 'Berberis' species germinated, but died off, after attaining about 2 inches in height, ex-

cept the 'Berberis nepalensis,' which is thriving. and which is now nearly a foot in height. Of the 'Pinus longifolia' and 'excelsa' also, the first supply germinated, but died off leaving 2 plants of the former, and one of the latter now thriving. The second supply of 'Pinus longifolia' seeds, received from the Society has succeeded well, and I have now some 15 or 20 thriving plants. Neither the 'Cedrus deodara,' nor the 'Araucaria excelsa' seeds have germinated, nor have my own seeds of the latter, the produce of these hills, as yet. Colonel Beddome kindly sent me out some seeds of tuberous Begonias and 'Begonia Frœbelii' and 'Streptocarpus prolifera, but none of them germinated. I purchased a pound each of Walnuts, Barcelona, Brazilian and Cobnuts, from one of the shops in Madras and put them down. only 8 Walnut and 4 Barcelona nuts have germinated and are thriving. The Society sent me 6 Chesnuts and 6 Walnuts, 4 out of the 6 Walnuts germinated, and are thriving, whereas the Chesnuts failed. The 'Araucaria excelsa' ripened its seed, and I had the pleasure of distributing seeds to Bangalore, Mercara and Madras. I have also put down some seeds here, but they have not germinated as yet. The Olive seeds I distributed largely have succeeded everywhere,* but the Spanish Chesnuts were a complete failure. Owing to its hard shell the Olive takes from 3 to 6 months to germinate. I have 9 plants of 'Erythroxylon coca,' they are thriving, but slowly. I have been trying the Persian Date up here for some years and have a few plants, they do not grow but remain stationary. I have succeeded in growing the seeds from the Date fruits procurable in Madras Bazaars, as well as those procurable on the Western coast. This is a good way of securing good plants, as the fruits can be selected and the pulp eaten to make certain of their quality, and the seeds planted ; or the entire fruit may be planted at once, the pulp furnishing manure to the future seedling. I hoped the Date would succeed well here from the examples seen of the 'Phœnix pedunculata,' which grows wild and fruits freely. Though there is little pulp on the seed, the coolies eat not only the ripe fruits, but the green also, which they use as a substitute for the arecanut. The next time I raise a crop of Date plants from Bazaar fruits, I mean to try and graft them on to the 'Phœnix pedunculata' and watch the result.

"Cactaceæ:—Of the six Cactus cuttings I received from the Director of Revenue Settlement and Agriculture, 2 rotted away, and the other 4 are thriving and are about three feet in height and breadth. Of the Maltese Cactus received through the Society, several are alive, and have only thrown out one or two small shoots each as yet; they seem to grow very slowly. Of my own Cactus plants, one plant produced a small crop of fruits, but these much to my disappointment were destroyed by rats just as they were ripening, not a single fruit escaping their ravages.

"Of low country trees, the 'Cicca disticha,' or country Star Gooseberry, and the 'Averrhoa carambola' fruited for the first time on these hills.

"The tree Tomato has been doing well and I have been distributing seeds and plants to all who cared to have them. Unfortunately they are very liable to attacks from white ants, which concealed under ground, destroy the base of the root stem and kill the plants. To guard against these attacks it is necessary that the soil around the roots be frequently loosened, and the parts examined carefully to prevent destruction.

"Aurantiaceæ":—The Orange family grows freely here, producing a large number of varieties. Of these, we have the 'Burra' 'Cheen,' called in the Northern District 'Batavia,' and in Madras, 'Chernie,' it is also popularly known as the 'Saut-ghur Orange taking its name from a village at the foot of the ghauts, some 40 miles from Vellore, where it used to be grown in large numbers and imported into Madras and elsewhere. We have also the sweet and bitter Seville Oranges, the seeds of which were originally imported from abroad. The country Orange termed 'Kolinge' and 'Dihlee' in Tamil and 'Koda' in Hindustanee is also found here, but is not much appreciated. The juice of this fruit abounds in mucilage, and the Native Confectioners prefer the half ripe fruits to candy or preserve entire in sugar. We have some 3 varieties of the Pumelo, distinguished chiefly by the size of the fruit and colouring of the flesh into pink and white; but as a whole owing either to the soil or elevated climate, the fruits produced on these hills are worthless as a fruit.

"Of the loose skin varieties, popularly termed 'Kumla,' in two sizes, amongst which are some of the finest Orange fruits; these chiefly come from the Hill Districts of the Northern Division, Wynaad and Coorg, and are much appreciated as fruits.

"We have also the 'Citrus japonica or Kumquat' of China, the fruit of which is small, acid and oval. The chief difference between the Orange varieties and the Lemon, Citron, &c., consists in the adherence of the rind to the fruit which is not separable like that of the Orange itself. I regret to observe that most of the old Orange trees planted some 60 years ago, soon after these hills were opened out and occupied, are now dying out fast from natural decay. The citron also does well here, and fruits freely, a good fruit often weighing 5lb. We have only one variety of the citron here.

"We have also several varieties of Lime, of which, the chief are the sweet and sour Lemon, and the common round Lime known in Hindustanee as Nemboo, and 'Elemitchum pullum' in Tamil; besides we have two varieties, one nearly as large as a medium sized Pumelo, and the other that of a large Orange and the fruit umbilicated."

* Those tried in these gardens unfortunately failed. —J. S.

A WONDERFUL BEAN.

From the proceedings of the Madras Agri-Horticultural Society we quote as follows, but with much scepticism as to the alleged power of cedron bean to cure snake bite :—

Read letter from Rev. G. Ritcher, dated Mercara, 22nd July, 1887, thanking for the Onion and 'Eragrostis' seed and ferns sent, and adding:—

"I read lately in a German Publication "Das Neue Universum" (The new universe) a very interesting article on the Cedron bean, 'Simaruba ferruginea or Simaba cedron,' which deserves your notice, and Mr. Stephenson may perhaps be able to obtain the bean for an experiment in India.

"'During my journey in Panama,' writes Mr. John Penn Curvy, 'I observed in front of my tent a rattle-snake about 15 paces distant. It bit a bird, sitting upon a branch about 3 feet from the ground, and before I could kill the snake, it bit the bird again. I counted 14 rattles on the tail of the snake. The bird a kind of Bustard, recovered so far that it flew a distance of about 25 paces, where it pecked at a shrub which resembled the American quince, and then rose into high air as if nothing had happened. I drew the attention of one of my native servants to the occurrence, but looking at me with astonishment, he laughed at my ignorance of this well-known remedy against the bite from poisonous snakes and insects. 'We care as little for the bite of a rattle, Moccasin, Copper-snake, or Tarantula, as we do for that of a mosquito,' he said; 'the Cedron-bean kills the poison in 5 minutes.' We all doubted his assertion, but on the following night he caught a large rattle-snake, and next morning in front of the whole camp he allowed himself to be bitten several times on the left hand and then killed the snake. The punctures of the bite were as large as a pin's head and soon assumed a purple inflammation which spread over the whole hand. We offered the wounded man our help, but he declined and pulled from his pocket a Cedron-bean of the size of a chesnut, gnawed at it, and spread the saliva over the wound. He then prepared with the scrapings of the bean and hot water, a decoction which he swallowed, and after half an hour all the external symptoms of the inflammation had disappeared. "Tony" only felt a little nausea, but after two hours he was quite well again, Other experiments

confirmed this experience. I took some beans with me ot San Francisco, where Prof. Langwert, at my request, made several experiments with the best success.'

"In the "Alta California" and "London Lancet" reports have been published on the medical virtues of the Cedron-bean. A Cedron-tincture of a quarter bean and two ounces of alcohol in doses of 15 to 20 drops twice a day is very effective in cases of obstinate gout.

"The natives of Central America also affirm that in no case of hydrophobia a fatal termination occurs, the remedy being an infusion of the Cedron-bean. Even dogs have been observed gnawing occasionally at the bean. The matter deserves serious investigation. 'Zeitschrift des deutschen Apotheker-Vereins.'"

Read also note on "Simaba Cedron," published at p. 52 of Christy's New Commercial Plants and Drugs, No. 9.

IS COFFEE CONSUMPTION DECREASING?

RACINE, O., June 6th, 1886.

Editor, American Grocer.

In these days, when the boom in coffee is rapidly enriching every importer and speculator, and when almost every wholesale grocer has become a bull in the coffee market, it is high time the retailer was looking well to the future of coffee.

According to the statement of B. G. Arnold, the consumption of coffee had, owing to low prices, advanced from 4¾ lb. to 9½ lb. per capita in this country, and this, together with a shortage of one-fourth in the crop, has caused the unprecedented advance in greens from 8 to 22c for Fair cargoes.

Now, if cheap coffee caused an increase in the consumption of 100 per cent, does it not stand to reason that very dear coffee will cause a corresponding decrease in consumption?

Does not every retailer notice a marked falling off in his sales of coffee?

Our experience is that we are not selling more that one-half as much coffee as three months ago, but the ales of tea have largely increased.

It is therefore our belief that we, as retailers should buy coffee from hand to mouth, but should keep well stocked in teas.

We should like to ask, through your columns, whether the experience of other retail dealers throughout the country, regarding the decrease in the sales of coffee, correspond with ours.

It seems to us that a clear view of the effect on consumption of the present high prices of coffees can be best and most quickly obtained by an exchange of retail dealers' views on this subject, and we know full well that if the consumption of coffee falls off 40 or 50 per cent the present price of coffee cannot be maintained.—Yours truly, W. A. ELLIS & Co.

Undoubtedly periods of low prices have stimulated the consumption of coffee. Other causes operate, as when the civil war reduced consumption 200,000 lb. causing the per capita consumption in this country to drop to 2.2 lb in 1863, in 1864 to 3.7 lb and in 1865 to 2.4 lb. In 1866 and 1867 it rose to 5 lb, then the next three years to a little over 6 lb; in 1871 to 7.9 lb., averaging a little over 7 lb for the next nine years—a period of high prices—after which, under the stimulus of lower prices, it rose to 8.8 lb. in 1880 and remained between 8 and 9 lb. until 1884, when it advanced to a fraction over 9 lb. reaching 9½ lb. in 1885, when Fair to prime cargoes of Brazil coffee averaged 9 cents for the year, the lowest price made since 1852. In 1869 the average yearly price of Fair to prime coffee was from 9¼ to 11¼ cents. In 1873 and 1871 prices were 19.40 to 21.02 cents. and 19.71 and 21.98 cents respectively.

On general principles cheap coffee tends to increase consumption, while high-priced coffee reduces the demand, as it causes the poorer classes to give up coffee and use tea, and because it put a premium on the pushing by the retailer of the sale of coffee mixtures, which afford a much better profit. There has been, thus far in 1887, an average monthly decline of nearly 3,000 tons in the consumption, the details of which were given in the last issue of the *American Grocer*, Undoubtedly the policy which you suggest of buying for actual requirements only is the safest for all dealers. We have in course of preparation an artcle showing the position of coffee throughout the world for several years past. Undoubtedly a point has been reached where consumption is in excess of last year's production, the deficiency being met in the accumulations of former years. We believe that for the next few years a higher range of prices will prevail than from 1882 to 1886, inclusive. Present extreme figures are wholly the result of speculative manipulation, and in our opinion are unwarranted by the facts. We must recognize, however that speculators are rarely governed in their operations by the actual situation. It is largely a question of manipulation and who has the longest purse.

We will be very glad if our readers will act upon your suggestion and give us their experiences as to the effect of high prices upon consumption, and also whether they have advanced retail prices as fast and to the same extent as they have risen in the wholesale market.

Postscript—Since the above was written the bulls have been routed, and coffee forced down several cents per pound.

THE CEYLON COURT AT LIVERPOOL EXHIBITION.

Despite the statement of an enthusiastic writer on Ceylon, that "there is no island in the world, Great Britain itself not excepted, that has attracted the attention of authors in so many distant ages and so many different countries as Ceylon," we are afraid that the general public of this home-country, which owns it as a colony, have but little idea of what a magnificent possession it is. They may connect it in their minds with extensive jungles in which the colossal elephant reigns monarch of all it surveys, and, possibly, they may have read that in its encircling seas "pearls lie deep;" but much further their information has not reached.

To those, therefore, who desire to extend knowledge of an island of singular fascination, and of great commercial interest at the present moment, we would recommend a visit to the Ceylon Court of the Liverpool Exhibition, where there is to be seen a representative collection of the most notable products of the island, together with many exhibits illustrative of its manners and customs.

Tea—that article of universal necessity and enjoyment with us—is the main exhibit, and the story of its introduction into and cultivation in Ceylon is one of the romances of resourceful perseverance. Up to about a dozen years ago, coffee was the main article of export from the island; but, then, an ineradicable fungus attacked the plant, and eventually rendered it all but fruitless. At first the blight mainly presented itself in alternate years, but rapidly bad crops became the rule to such an extent that an export of 1,000,000 hundredweights in 1876-7 fell off to one-fifth a few years later, and the colonists had to face the fact that if they were not utterly to succumb to dire calamity, they must find a substitute for the article of agricultural production which had for long years been their staple dependence. They set about this with commendable energy, perseverance, and determination. The West Indies was visited, the American cinchona forests were explored, the tea districts of India were laid under contribution for knowledge, and the result was a variety of experiments which proved more or less successful. The main things relied on were cardamums, cinchona, and tea.

First, with regard to cocoa. It was grown with great success in certain districts of Ceylon, but the fact that it requires perfect shelter and good soil, conditions which do not always go together in the island, limited the possible area of its production; and, therefore, it must remain a secondary article of cultivation. The fact, however, that 15,000 cwt. will be shipped this year is indicative that it must be no mean help towards recuperation of the island's partially-lost prosperity. That in the various forms of manufacture of the article the Ceylonese have attained great perfection is made evident by the exhibits in the court.

Cinchona has found the island so congenial to its growth that the Ceylonese producer has been able to supply the markets of the world, and thus a great benefaction has undoubtedly been conferred on humanity; but the result has been so to reduce the price so that cultivation scarcely pays. Cardamums, which, it may be necessary to explain, is a spice used both in medicine and confectionery for flavouring purposes has also proved so successful in cultivation that its prime cost has been reduced from 6s. to 2s. a pound.

Now we come to tea, and in relation to it a few statistics will prove interesting. In 1880 the export of tea was 114,000 lb. in round figures; 1881, 311,000; 1882 621,000; 1883 1,599,000; 1884, 2,285,000; 1885, 4,352,000; 1886, 7,790,000; 1887, 15,000,000; and it is anticipated that in 1890 Ceylon will be able to export the enormous quantity of 40,000,000 lb. The Ceylonese tea-grower does not wish to enter into unfriendly competition with the Indian grower, but with genuine, unsophisticated teas he seeks to oust the spurious teas of China, which can be purchased, less duty, in London for fourpence to sixpence a pound. Ceylon teas are somewhat higher in price, but they can be relied on for purity; and in use a given quantity goes further than a similar quantity of the teas of China. For flavour they are incomparable. Cleanliness, too, which we prize so highly as a virtue in this country, is strictly regarded in the manufacture of tea in Ceylon. Whereas in China all operations are carried out by hand, hand labour on a Ceylonese tea estate ceases almost entirely with the plucking of the leaves. Every after operation is carried out automatically, and thus security from all possible taint is secured. Under these circumstances the hope of the Ceylonese that the full tea production of their island will be taken by the tea-drinkers of Great Britain and the United States ought to be realised. The only check which they fear for their production is the want of markets, but they have already proved that they can place tea in the markets of the world cheaper than India can, whilst the wholesale price in Mincing-lane during the past three years has been higher than that of India. It is worth remembering in connection with the possibilities of this trade that, during the past six months, over £200,000 worth of machinery has gone out of this country to Ceylon. This introduces the element of reciprocity, which we are so desirous of cultivating with our colonies, and which in relation to our iron manufactures we stand so much in need of.

Among miscellaneous exhibits, all of which are of interest, are specimens of tree-cotton of a short fibre, for which, however, it is hoped that a market will be found for some purposes; and of aloe fibre, which is of great length and strength and apparent usefulness. Plumbago, more familiarly known as black lead, is an important production of the island, and it is shown in huge natural blocks and also in various manufactured states. Many other features of the exhibits of this court are sure to interest the visitor, but need not be enumerated here. —*The Porcupine*,

NOTES ON JALAP TUBERS GROWN AT MUSSOORIE, N. W. P., INDIA.

BY C. J. H. WARDEN,
Chemical Examiner to Government.

The jalap tubers referred to in this note were received from Mr. Duthie, Superintendent of the Government Botanical Gardens, Saharanpur, N. W. P. and were grown at the Mussoorie branch garden at an elevation of 5,000 feet. Mr. Gillan, the head gardener, kindly furnished the following particulars regarding the cultivation of the *Ipomœa purga*. He states:—

"We began in 1884 with 300 small tubers weighing 16 pounds, obtained from the Ootacamund gardens. In 1885, when the crop was lifted, the tubers numbered 2150 and weighed 100 pounds. I am somewhat doubtful, though, if the weight given was correct. They were weighed by the native overseer, who was there in charge of the gardens, and I think he purposely exaggerated the weight of produce. In 1886 the tubers were again lifted and weighed in my presence. The crop was a much larger one and equally as healthy as in the previous year, but I only found an increase of 74 pounds in weight on the crop of 1885. I did not count the tubers last year, so cannot compare numbers produced in 1886 with those of 1885. This year the plot has not been disturbed. I noticed when digging up the tubers last year that the roots were in active growth and many small tubers were destroyed. The vines had died down some time previously, and naturally one would not have expected active growth in the roots. As jalap will always have to be dug up at the same season, viz., during the month of February, a certain proportion of young tubers will always be destroyed during the process of lifting; but this will not matter so much after our stock is increased, for one or two plots can be lifted one year whilst others would be left undisturbed until the following year, and so on. The method of cultivation is as follows:—The ground is prepared by digging trenches two feet wide, and of the same depth, at intervals of six feet. The trenches are refilled with open surface soil finely intermixed with decayed cowdung. After all the required trenches have been prepared in this way a single row of tubers is planted in each trench at one foot apart, and the tubers inserted about six inchea deep in the ground. When the vines begin to shoot the rows are staked out with branches in the same manner as for garden peas. The vines climb on these, and no further care is necessary beyond watering during dry weather, and frequent weeding during the rains. The season for lifting or transplanting the tubers is in the month of February. Porcupines are fond of the fresh tubers, and where these animals exist the fields must be protected by efficient fencing."—*Pharmaceutical Journal.*

AUSTRALIAN VEGETATION.

Mr. Joseph Bosisto delivered a lecture on the "Indigenous Vegetation of Australia" in the Conference Hall of the Exhibition. The Eucalyptus, exists and reigns almost supreme over the greater portion of Australia and Tasmania, although entirely absent in the other islands of the South, with the exception of a few species in New Guinea. There can scarcely be a doubt but that at some period of the world's history, Tasmania and New Guinea formed a part of Australia; hence the eucalyptus may be considered as a vegetation purely Australian. Strong evidences exist proving that the eucalyptus is an ancient Australian vegetation. River beds of great antiquity have been met with, at depths varying from 100 to 200 feet, and even deeper, in various alluvial gold-mining districts of Victoria, revealing occasionally massive timber trees without any sign of decay, belonging to the family of the Eucalyptus, chiefly those of the red gum (*Rostrata*) and the iron bark (*Leucoxylon*) species. Some species growing at the present day on the alluvial flats, mountainous ranges, and in the valleys, attain a prodigious size, both as to girth and height, bespeaking their longevity

possibly contemporaneous with the cedars of Lebanon. The word "eucalyptus"—from *eu*, "well," and *kalypto*, "to cover"—is aptly chosen to distinguish this splendid family of plants from all others. This characteristic is observable in the limb of the calyx, completely covering the flower before expansion; and during its gradual development, the operculum, or lid, is uplifted in shape like an extinguisher, which falls off immediately the flower becomes matured. The chief characters of all eucalypts are in the firmness of the calyx, the absence of petals, the numerous rows of stamens inserted close to the edge of the calyx tube, the stamens being nearly always fertile, and also the many form-variations of the anthers in the different species. It is upon these variations of form that the division of the genus is arranged. This systematic arrangement was made by the late venerable Bentham, and acquiesced in by our Government botanist, Baron von Mueller, as being the wisest to adopt. The eucalyptus is an evergreen; it casts its bark annually, but this does not take place, like the falling leaf of England, at one given period of the year, hence there is always a rough and ragged appearance on the trunk of the tree. In the vegetable kingdom the Eucalypti belong to the myrtle family, so placed on account of its bearing certain botanical outlines to that of the garden myrtle of England; but the physical characters, as well as some peculiar botanical features of the eucalypts, place them as a distinct genus in the myrtle family of plants. Considering the vast area of the Australian continent—consisting of something over three millions of square miles, and measuring 2,500 miles from west to east, and 2,000 miles from north to south—it is surprising to find one tribe of trees forming at the present day four-fifths of the whole of the indigenous vegetation. An Australian traveller frequently feels the monotony of the scenery, but this is greatly dispelled by noticing the interesting variations in the leaf formation, in the colour both of leaf and flower, in the appearances of the tree-bark, and in shape and varied stature of the trees. Of the 150 kinds or species found existing over Australia, it can easily be understood that the variations must be very great indeed. On the mountains and in the valleys, and on the alluvial flats where the woodman's axe is but seldom heard, stand gigantic eucalyptus timber trees, in girth varying from 16 feet to 80 feet, and in height from 200 to 420 feet, and that often without a branch, the top being capped with radiating branches (like the ribs of an umbrella) full of foliage. In the scant rain tracts of Australia there are many millions of acres on which grow a scrub of dwarf eucalypti, averaging in height not more than eight feet; this scrub is so dense that it almost shuts out the sight of sun and sky. Although the leading forest timbers of Australia consist of the eucalyptus,* yet there are a variety of other kinds. In the eucalyptus the wood varies in character quite as much as do other kinds obtainable from other timber trees; for instance, the well-known blue gum (*E. Globulus*) is a hard light-coloured timber of great strength and tenacity, as well as durability extensively used for beams and joists in buildings and for railway sleepers, also piers and bridges—for which purposes a test has been made between some blue gum, English oak, and Indian teak. The blue gum carried 14 lb. weight more than the oak, and 17¼ lb. more than the teak per square inch. The red gum tree (*E. rostrata*) is a very hard compact wood, possessing a handsome curled but short grain, red in colour, well adapted for many purposes in ship-building, such as heavy framing, beams, and knees; it is also used in the construction of culverts, bridges, and wharfs, and by wheel-wrights for the felloes of heavy wheels, and is employed in Australia for railway sleepers and engine buffers; and owing to an acid it contains, termed "Eucalyptic acid," it resists the attack of the *Teredo navalis*, or sea-worm. The iron bark gum-tree is one of the hardest and heaviest of our native woods. The stringy bark tree (*E. obliqua*) is an easy-splitting wood, and is usually employed for palings, shingles, and posts; in like manner do all the varieties change. Many varieties of tree acacias are met with in all the forests of Australia, such as the myall and the wattles, also pines, banksias, casurinas, pittosporums, eugenias, melaleucas, and others too numerous to mention.

There is a factor at work throughout Australia which makes the climate so acceptable to human life, and that is the eucalyptus vegetation, belonging, as I have before intimated, to the myrtle family of plants. It is full of aromatising odours; the sense of smell when in our forests, or even travelling in the country, bears ample testimony to the presence of its volatile bodies in the air, for there is no mistaking the odour, as it is different from all others. There is not a single species but what possesses in its leaves a volatile essence. Each kind varies in percentage of yield, but still of the vast number they can be reduced for practical illustration under eight types, or species, namely:—The *viminalis*, or manna-yielding eucalyptus; the *odorata*, or sweet smelling; the *rostrata*, or red gum tree; the *obliqua*, or stringy bark; the *leucoxylon*, or iron bark; the *Globulus*, or blue gum; the *dumosa*, or mallee; the *amygdalina*, or peppermint-scented eucalyptus. The eight kinds I have mentioned supply the minimum to the maximum, the minimum yielding 7 fluid oz. of the volatile essence, and the maximum 500 fluid oz., or 25 imperial pints from every 1,000 lbs. weight of fresh leaves. No vegetation occupying so vast a country contains so much volatile bodies in its leaf portion as the eucalyptus; assessing alone the whole colony of Victoria (being that part of Australia in which most of my experiments were made, and I may tell you that I have practical experience extending over thirty years) at the low average of supply of 20 oz., or 1 pint to the acre, we have 9,730,500 gallons of an essential and volatile substance held at one and the same time in the eucalyptus vegetation. So far as I have been able to proceed in this investigation over the continent of Australia, similar conditions exist; so that it may be safely asserted that in the whole of the leaf surface of the eucalypts in Australia there is continually 96,877,440,000 gallons of this volatile material. If, therefore, the whole of the odorous principles were retained in the leaves until set free by the art of man, in that case its effect on climate would fail; but if they are given up freely by the natural forces of the tree under the aid of light, heat, or electricity as existing around, or by some or all of these forces in combination, then we have good reason to value the eucalyptus vegetation beyond all others in being capable of influencing the climate of a country for purposes of health. Leaves of trees necessarily are in close connection with the roots; together they keep up a continuous action of exhalation and replenishment; evergreen trees, especially the eucalyptus, unlike deciduous trees, which sleep during many months of the year, work constantly, but at times less energetically. Deciduous leaves generally perform their functions on one side only, that is, they change the sap juices of the plant on the side turned upward to the sun; but in the case of the eucalyptus it is quite different—these have a double action. There is no difference in the anatomy of the two sides of the leaf, breathing pores abound on each side, and the cells containing the volatile oil run through the leaf. These oil-cells in most cases are visible to the naked eye, and can be counted in hundreds.

* Most of the furniture in Australia is made of eucalypt timber, and it is found to be admirably suited for all kinds, from exquisite and artistic drawing-room furniture to the rough kinds used in the kitchen. The lecturer exhibited specimens of the timber and pointed out its remarkable density. The wood takes many years to mature, but when it does mature it is almost imperishable. A railway sleeper of *E. rostrata* wood was also shown which had been 22 years under the ground, yet it was almost unaffected by this long exposure. He had seen piles taken up in Sydney which, after 60 years, were in such good condition that, after a fine shaving was removed, it was found that the wood was as fresh as the day it was put down.

Light and warmth operate alike on both sides of the leaf; each being suspended in a line with the axis of the tree, giving facility for the remarkable and interesting movement of the petiole or leaf stalk, which is continuous in its action under the warm currents of the air, or the direct rays of the sun keeping one side or the other of the leaf's surface to face the sun or the warm air current, and so establishing perpetual leaf operation. Now it is by the natural forces of the tree and the leaf action acting in unison that the watery and odorous bodies are continually set free in the air, and in such minute and diffusive atoms that they may be expressed as the fragrant breath of the tree, requiring as it does thousands of its compound particles to form a single drop. Under such circumstances, these odorous bodies speedily change their molecular condition, and supply to the atmosphere an extra amount of active oxygen; it is this unceasing health factor throughout Australia which makes it on the whole the finest climate in the world. At the conclusion of the lecture, Mr. Bosisto intimated that there would be a magic-lantern entertainment, during which Victorian views would be thrown upon the screen.

The Hon. W. Wilson said Mr. Bosisto's modesty had prevented him referring to eucalyptus oil. He therefore took the liberty of telling the audience that to Mr. Bosisto was due the credit of having introduced the most valuable of oils. Eucalyptus oil, he said, was an oil which seemed to cure everything, and was universally used in Victoria. Mr. Bosisto in reply, showed the importance of the eucalyptuts oil industry, and stated that his firm operate upon sixty tons of leaves per week, and he considered its introduction into the Pharmacopœia as the greatest compliment that had been paid to him for his work on the subject.—*Chemist and Druggist.*

THE VINE IN JAPAN.

According to accounts furnished by Mr. Fukuwa Yaito, Director of the Vineyards at Harima, and from official Reports of the Minister of Agriculture and Commerce, translated from the Japanese by Mr. J. Dautremer, Interpreter to the French Legation in Japan, the vine is found nearly everywhere in Japan, but it is cultivated more especially in the province, or rather district, of Kôfu in the centre of the country. There is a tradition that 700 years ago, in the reign of the Emperor Gotoba, A.D. 1185, it was noticed by two peasants on the mountains of Kôfu, near the village of Kami-iwasaki. The peasants whose names are preserved, transported this wild vine to their garden at Zio-sei-zi, and after carefully tending it and endeavouring to propagate it, they succeeded so far that in 1193 they became possessed of thirteen plants. They proceeded to develope the culture, and in a few years were able to lay out plantations, the fruits of which became celebrated, and the reputation of the Kôfu grape still stands high, the fruit being greatly esteemed.

There are two species of vine; the *vitis vinifera* and the *vitis labraska*; but the former only is cultivated. Its fruit is much esteemed. The latter, superior to that found in America, is inferior, however, to the *vitis vinifera*. It is found in the mountains, where it shoots out like grass. It abounds in the province of Echiu, Kaga, Noto, Hida, Mutsu, Uzen, Ugo and in Hokkaido. In Echiu and Kaga, as well as in Hokkaido, several varieties of the wild vine are found—as many as twelve; some with stems indicating a growth of a dozen years. On the mountains of Kaga the author of this paper met with a vine the stem of which measured 1m. 80cm. in circumference, and covering a hectare of land, having produced, morever, 1,200 kilogrammes of fruit.

Such dimensions are not rare; many examples are found in the province of Idzu. Specimens of this size are not found in Europe; but at Oran and at Kasba in Algeria, vines with a diameter 0.24cm. and area 120m. and fruit 1,000 kilogrammes occur. This is looked upon as prodigious. Unfortunately, the Japanese have overlooked the value of this plant, and have left it to run wild, without special care being bestowed upon it. It is only in quite recent times that they have begun to engage themselves on its cultivation and to take an interest in the fruits.

The *V. vinifera* in Japan produces three sorts of grapes; the *red*, like the *Chablis*; the *black* like the *Frankenthal*, and the *white*, like the *Riesling*. They are all found in Kôfu. The black grape grown near Kyôto is the best in Japan.

Formerly the grape was only cultivated for eating. The plant in its wild state shows great vitality, and the yield is considerable; but latterly the Japanese have grafted and transplanted it and have found that it is capable of furnishing a good quality of wine-grape. In the cultivation of the vine two methods are in vogue, as in Europe, viz: (1) By slips inserted into the ground; (2) by allowing the vine to propagate itself by its branches taking root. This latter is the way in which the vine-dressers of France renew their plantations. The Japanese prefer for the vine sloping lands—stony or sandy. After digging a ditch 1m. 20cm. deep and about 2 metres wide, and having made the channels so that the water may flow freely, they fill the ditch with manure and earth and proceed to plant. This is usually done in autumn, but in Hokkaido, where the climate is cold, the spring is preferred. For manure they use bonedust, rice-husks, the refuse of brewers, the residuum of oil manufacture, and finally closet-manure. But these manures have each their specific properties. The bone-dust, the rice-husks, and the *saké* refuse give to the grape a certain sweetness, and increase its size; the other manures give force to the plants and make the bunches more compact and complete. It is therefore necessary to employ a mixture to obtain good results. The pruning is done in the autumn; the stem is left 1m. 80cm. high, so that below the section two or three branches or shoots may be left for the coming spring.

First attempt at wine-making, the first idea of the Japanese was to cultivate the vine in order to eat the fruit; yet we are told that the people of Kôfu used the grape to make a liqueur, probably a sort of wine; for what purpose we do not know, for they certainly did not drink it. It was not until 1875 that an inhabitant of Kôfu resolved to make wine of the grape. But he neither knew the ancient nor the modern processes; the grapes which he used were not sufficiently ripe, and he did not succeed. In 1876, a certain person named Oto Matsugoro, having returned from California, where he had studied wine making, again made an attempt in Kôfu, and succeeded in producing a wine superior to that of his predecessor. Now the same vineyard produces 200 hect. of white wine, and as much alcohol. I have tasted several kinds of Kôfu wine, and I declare that it was detestable. At the present time in Hokkaido and in the provinces of Harima and Owari, some thousands of hectolitres of wine have been made, and yet the plants are only 5 or 6 years old and the bunches are naturally not large. In two or three years no doubt twenty to thirty thousand hectolitres will be produced, but it is doubtful whether the wine will be drinkable here for a long time. The produce is mixed by Japanese merchants with European wines and sometimes this mixture is sold to the Japanese as pure Bordeaux.

EUROPEAN AND AMERICAN VINES IMPORTED INTO JAPAN.—The first European vine transplanted into Japan was given to the *Shogun* by the Emperor Napoleon III. in 1868; afterwards came the Isabella and the Concord from America. They then imported the Frankenthal from Austria, as well as other vines from France; at last California furnished a considerable number of plants. We may say that there are altogether some 200 sorts in Japan. The attempts to cultivate them had generally been made in Tôkyo, at the Botanic Garden at Mita; but none have succeeded. For the European vine the soil of Tôkyo is too damp; although the vine grows well there it produces no fruit; the American vine only succeeds in Tôkyo; but the bunches although superb, are not of the first quality; they are certainly much inferior to Japanese grapes. Thus at present it is found that the proper way is to introduce vine-stocks from Europe, and those only which produce well.

The chief plantations are to be found in Harima and also in Kiushiu. In this latter island the *Muscat Pinot* and the *Chasselas* succeed marvellously; thanks to the geological nature of the soil. The *Chasselas* succeeds very well in the district of Harima, producing large and full bunches.

The Grape of Palestine has only been planted two years and has already given very fine results. Last year Mr. Fukuwa Yaito, Director of the Gardens at Harima, gave a bunch of these to Mr. Sarazin, adviser to the Minister for Foreign Affairs, and he in turn presented it to the French Minister. It weighed 3 kilogs.

VITICULTURE IN JAPAN.—The Government encourages the culture of the vine by the establishment of schools of viticulture, and by bringing from Europe a considerable number of young plants, and there is little doubt, but, that in a short time Japan will become a vine-growing country. They have introduced into the Harima establishment the *Gamay de Bordeaux and pinot Noirien*, and they hope soon to produce wine from them. The Harima grounds are 30 hactares; those of Owari 50 hectares and those of Hokkaido 40 hectares. The vines which succeed best in these places are: The *Gamay de Bordeaux*, *Bordeaux Blanc*, *Baltet Noir*, *Meslier Blanc*, *Meslier Noir*, *Frankenthal*, *Folle Blanche*, *Charbouneau*, *Muscat de Frontignan*, *Zinfindal*, *Riesling*, *Malvoisie*, *&c.*

DISEASES OF THE VINE.—The chief are the *oïdium* and the *brouissure*. These began in 1867 and since then the stems of the vines have suffered more or less. The ordinary remedy for the *oïdium* is sulphur; but no means has been found to get rid of the *brouissure*. As the stems of the vines in Japan are larger than those in Europe, the diseases are more difficult to cure. Insects are the great enemies to the vine, but they are comparatively easy to destroy if care is taken, and especially if the *phylloxera vastatrix* be not present. This insect had not yet appeared here until last year, 1885, It has been necessary to scorch the soil occupied by the affected vines. This is a perfect remedy. The Japanese belive that this insect was brought to Japan from America with the vines imported in 1881.

YIELD.—Before the appearance of the *oïdium*, 17,000 to 20,000 kilogrammes per hectare were harvested in the provinces of Koshiu (Kofu), Kawachi and Yamashiro; but after 1867 the yield fell off suddenly 3,000 to 3,500 kilogrammes. It is, however, expected that with care the disease will disappear and the yield be increased. The most productive vines are the *Zinfindal* and the *Folle Blanche*; the average yield being 18,000 kilogrammes per hectare after five or six years' culture. These plants are superior to the Japanese, and their proneness to take disease is much less. The year 1885 was less favourable and the yield was low; it was only in Koshiu and Hokkaido that the vine succeeded. The heavy rains which fell at the time of blossoming in Kawachi Harima and Owari, and the inundations which followed, destroyed nearly all the blossoms, and the vines suffered very much.—*Japan Weekly Mail.*

MANURES AND MANURING.

BY PROFESSOR JOHN SCOTT.

The nitrogenous manures now in the market are those previously enumerated. The principal of these are nitrate of soda and sulphate of ammonia. Nitrate of soda is obtained from the crude salt deposit in Peru, after being purified by crystallisation. Good samples contain 95 per cent of pure nitrate of soda, or 19 per cent of ammonia, equal to about 15·6 per cent of nitrogen. The present market price of nitrate of soda is £9 5s. per ton, which is equivalent to 9s. 8¾d. per unit of ammonia. Sulphate of ammonia is prepared from the ammoniacal products of gas works. It contains about 24 per cent of ammonia worth at the present price of £10 10s. per ton for the sulphate, 8s 9d. per unit. At current rates, the sulphate of ammonia is therefore the cheaper article of the two.

Peruvian Ichaboe and Frey-Bentos guanos are chiefly valuable for the nitrogen they contain; Bolivian, Saldanha Bay, Kooriamooria, &c., guanos owe their value to their phosphates. Their chief defect is in potash, of which Peruvian guano contains more than the others. The best Peruvian guanos now imported only contain about 5 per cent of ammonia, with from 30 to 50 per cent of phosphates, and 2 to 3 per cent of potash. The phosphatic guanos contain from 50 to 75 per cent of phosphates, and from a mere trace to 1 per cent of ammonia, with little or no potash. All preparations of Peruvian guano add to the cost of the manure, without increasing the yield of the crop, or if they do, the latter have other defects. "This should be borne in mind in connection with the use of strong chemicals to make guano more soluble, which not only destroys its admirable mechanical texture, but breaks up the very numerous and peculiar compounds upon which the progressive action of Peruvian guano depends." At present raw guano is selling at about £7 10s. per ton, while dissolved guano is charged at £10 10s. per ton. The farmer will find it safest to use less of the guano in its raw state, and if more solvent manures are needed, supplement with nitrate of soda and superphosphate. "Prepared" guano is merely raw Peruvian guano to which ammonia salts, phosphates, &c, have been added to bring the sample up to guaranteed analysis. In the cargoes of guano now imported there is very little soluble nitrogenous matter, and therefore no expense should be incurred in fixing ammonia where there is none to fix.

The only cheap source of potash for agricultural purposes is the crude German salt known as kainit. Pure crystallized kainit has the formula $MgSO_4 + KCl + 3H_2O$; which represents 1 molecule of magnesic sulphate, 1 of potassic chloride, and 3 of water. 100 lb. of pure kainit contains, therefore, 18·9 lb. of potash, or 21·1 lb. per cwt. Commercial kainit, however, never contains more than 14 per cent of potash, or 15·68 lb. per cwt., and many samples not more than 12 per cent, or 13·44 lb. per cwt. The present price of kainit is £2 5s. to £2 7s. 6d. per ton.

Kainit acts directly by supplying potash to soils in which it is deficient, and indirectly by assisting the decomposition of the mineral matter of the soil and assisting in nitrification. In this way it is easy to explain how a first application of the kainit may be followed by results which do not attend a second or third application: for, as soon as the compounds difficult of decomposition existing in the soil have been broken up by the action of the potash salts, and rendered available for vegetation, there is nothing left for a renewed dose to work upon, and its indirect action for the time being at any rate, is at an end. The crops which benefit most by it directly are potatoes, beans, clover, and turnips, in the order named.

"Bone-dust" is not really what the name implies, but bones ground a little coarser than *bone meal* and a little finer than the *crushed bones* of commerce. "Bone ash" is the residue of burnt bones, "Superphosphate" is the name given to phosphates made more soluble by treatment with sulphuric acid; the superphosphate, however, always containing more or less undissolved phosphate. "ground phosphate" mineral phosphate or coprolite ground to a fine powder.

Phosphate of lime—this is, the tricalcic phosphate ($3CaO,P_2O_5$)—is only slightly soluble in water. But, from this tricalcic phosphate, either one or two parts of the lime can be taken away, and replaced by water, changing the tricalcic into dicalcic or monocalcic phosphate respectively. This is done by treating the phosphate of lime (tricalcic) with sulphuric acid. Two parts of the latter mixed with one of the former takes two eqivalents of lime from the phosphate and gives to it water instead; forming $CaH_4P_2O_8$ (monocalcic phosphate) and $2(CaO,SO_3)$ sulphate of lime). The monocalcic phosphate is most soluble in water, and is, therefore, known as "soluble phosphate." Monocalcic phosphate multiplied by 1·365, or dicalcic phosphate multiplied by 1·566, gives the corresponding amount of tricalcic phosphate.—*Scottish Agricultural Gazette.*

THE HOME OF THE MUSHROOM.

A VISITOR TO MR. BARTER'S RIDGES, BY LANCEFIELD-STREET.

On a vacant plot of building land in the immediate neighbourhood of the Harrow-road and within four miles of Charing-cross, is produced annually what is probably the most valuable crop grown in the open air, and without the aid of glass on any one acre of English soil. The space occupied is, indeed, rather more than an acre, the rent being just £12 a year, but the space devoted to mushrooms and manure is under an acre, and the uninitiated will be astonished to learn that from this small plot has been gathered in the last twelve months about 12,000 pounds weight of mushrooms, all of which have been sold at Covent Garden at a price varying according to the season, but averaging ten pence a pound for the whole year. Now the value of 12,000 lb. at ten pence per pound is just £500 sterling. We have, therefore, the amazing circumstance that an acre of our metropolitan area has produced a richer garden crop than the cosiest corner of Kent or the most favoured nook on Lord Sudeley's jam-farm in Gloucestershire, for instance, a crop of 30 cwt. per acre of hops is so great as to be of rare occurrence. The average price obtained for hops is now about £3 per cwt. It is obvious, therefore, that the sum obtained for the produce of our London acre of mushrooms is more than five times as great as what would be obtained in a particularly good year for a first-rate crop of hops. The following are exceptional prices that, as we are assured on competent authority, have been realised per statute acre for other fruits and vegetables in recent years:—

	£
Very early potatoes	100
Onions	192
Early cos lettuces	100
Plums	100
Gooseberries	100
Strawberries	150
Black currants	168
Filberts	200

It will be observed that onions and filberts head the list, but the produce of an acre of mushrooms is worth more than double that of either onions or filberts. What is still more extraordinary is that the wizard who has performed this miracle makes no secret of his method, and has not only been the means of encouraging many others to follow his example by showing them what he has done, and how he does it, but has published through the *Journal of Horticulture*, and subsequently in the form of a treatise written by Mr. John Wright, the Assistant Editor of that valuable journal, a full account of his method and its results. Of this volume a new edition will shortly be out, and it ought to be in the hands of all who wish to master the mystery of mushroom-growing. How then is it done? As you enter the ground from the Canterbury-road you at once see the source of so much fertility in various large heaps or stacks of stable manure. Of this commodity Mr. Barter's consumption is about twelve loads a week, costing on the spot 3*s.* 6*d.* a load. The larger portion of the ground is occupied by ridges three feet across at the base and three feet high, and covered carefully over with straw. This covering straw is the cleaner portion (about one-third) of the stable manure which is kept apart from the richer portion of what Mr. Hawthorn, at Brook Farm, used delicately to call the "gold mine," and is used for protecting the solid ridge beneath. Mr. Barter calculates that it needs two loads of manure, to build up three yards of ridge. Into the surface of this ridge and over all its extent are stuck, like almonds in a cake, fragments of the earth, bricks that contain the spawn of the mushroom. The entire ridge is then coated over with good fresh soil, a couple of inches thick, and the whole is wrapped up warm in a coat or layer of the above-mentioned cleaner straw, which may be thicker or thinner according to the season. It is now at the end of May, 8 or 10 inches thick. The spawn vegetating on the surface of the inner core of rich manure appears in the form of mushrooms on the surface of the thinner envelope of soil, and from the time of the first gathering—say, five to seven weeks after planting—the ridge continues to bear more or less freely for a period varying from six weeks to three months. When a ridge is exhausted and will bear no more mushrooms, the refuse manure is saleable to the gardeners at about half the price it originally cost, when it came from the stable. Such is, in brief, the economy of one of Mr. Barter's mushroom ridges. Three times a week, soon after dawn, his men may be seen, as I saw them this morning (May 24), passing down one of the ridges, knife in hand and a couple of baskets not far off. They uncover a few feet, the less the better, of the ridge, remove the mushrooms from its surface to the baskets, and covering all up again as rapidly as they can, continue till the whole ridge is cleared, only the tiniest white specks being left, which will be ready when this ridge is next visited four days hence. Several cwt. are soon ready to be stowed away in small chip baskets and sent off to market, to be retailed by the green grocer ultimately at about eighteen pence a pound, according to his conscience and the amount of competition. Since Mr. Barter's experience was made public, the competition has greatly increased. Twenty years ago, when he was a carpenter in Kentish-town, 5,000 bushels of spawn would have sufficed for all the mushroom-growers in England. Now he estimates the consumption at 25,000 bushels, of which one-fourth is produced in his own little laboratory at Lancefield-street. In the last six years the price of mushrooms has fallen about 20 per cent. This is partly owing to increased competition at home, but partly also to importation from France. In some parts of France the existence of caves gives the mushroom-grower an advantage. Through the equability of the cave temperature, these French beds can be cropped all the year round. In the open air here, there are three months, from July to October, during which cropping ceases. Mr. Barter, however, has his compensation. When cropping is over, at the end of next month, all hands turn their attention to the production of spawn. This is a process requiring much skill and experience. Into the little house where operations are conducted, Mr. Barter does not invite visitors to enter. He has given them much information about the growth of the crop. They owe him a debt on that score. If they wish to pay it they can do so by buying from him their supplies of spawn, which he sells to all comers at five shillings per bushel of sixteen bricks.

A strange variety of taste has prevailed in various countries in regard to mushrooms. In Russia I am assured that the peasants are never without them. They are hung up to dry in the roofs of the cottages like oak-cake in Lancashire, and from a greatly esteemed relish to all sorts of dishes. In some parts of Germany also they are largely preserved in brine for cooking purposes. In England, however, it is only lately that they have come at all into general use. When the potato had not yet come into vogue, when Jerusalem artichokes, the potato of Canada, as they were called, were equally unknown to the public, and the vegetable diet of England was restricted to very few dishes, it might have been supposed that mushrooms would have been highly esteemed. Not so, however; the old herbalists have little or nothing to say in their favour. Here is what John Gerarde says, writing in Queen Elizabeth's time from his garden in Holborne: "Some mushrumes grow forth on the earth; other upon the bodies of old trees, which differ altogether in kindes. Many wantons that dwell neere the sea, and have fish at will, are very desirous of change of diet to feed upon the birds of the mountains; and such as dwell upon the hills of champion grounds do long after sea fish. Many that have plenty of both do hunger after the earthy excrescences called Mushrumes; whereof some are very venomous and full of poyson, others not so noisome; and neither of them very wholesome meate." And again, "Few of them are good to be eaten, and most of them do suffocate and strangle the eater. Therefore I give my advice to those that love such strange and new fangled meates to beware of licking honey among thorns, least the sweetness of the

one do not countervaile the sharpnesse and pricking of the other." Now, Gerarde was the most enlightened gardener of Queen Elizabeth's time, and his hostile opinion is echoed by the still more famous John Parkinson, who followed him. And yet field mushrooms must have been as good and wholesome a dish then as they are now.—*Pall Mall Budget.*

LOWCOUNTRY PLANTING REPORT.

Hapitigam Korale, 1st Sept. 1887.

Since May our rainfall has been rather scanty till within the past week, during which there has been a daily increasing fall, and for the last two days it has been almost continuous. From the first week in July to the second week in August was rainless, then we had a few days of light partial showers, followed by ten dry days, and the present spell, which, if the fall has maintained the usual proportion in Kadugannawa and Dolosbage, must bring the river down in flood very soon.

One of the effects of the long drought in the early part of the season now appears not only in the smallness of the nuts lately gathered but in the thinness of the kernels, which tells sadly on the outturn of copra, in taking from 200 to 300 more nuts to the candy than usual, and as this happens when the price of copra is low, it must tell seriously on the income of proprietors. Prices are always at the lowest about this time of the year, on account of the large supply; the June and July gathering being about one-third of the whole crop of the year. It is a pity that coconuts cannot be safely kept in the husk for more than from three to four months, and though copra, if properly dried and carefully stored, will keep for any length of time required, it continues to lose weight, and buyers have not the habit of discriminating quality and paying accordingly, so that it is generally better to sell, while eight or ten per cent of the weight is eliminatable moisture, than to hold on for a rise.

Since the break-up of the drought in April, the trees have been putting on fair average crops for next year, but the recent month of dry weather has caused the fall of showers of germs from the June and July flowers. The present rains will, however, fit those that remain and secure a fair proportion of nuts on the August flowers, so that, with the coming N.-E. monsoon rains, the trees will probably have as large a crop by the end of the year, as they can safely carry through the dry season, which let us hope will be shorter, or more frequently broken, than the last.

There is a growing disposition in this district to spend a larger proportion than formerly, but the disposition to spend is far more apparent than the knowledge of how to do it to most advantage. I have not failed to tell some of my neighbours where they were going wrong, but they all know better than I do, what to do and how to do it. Were I to describe the various operations I see carried on around me, I would thereby point out individuals and get into rows, as nobody that I know likes to have his doings ridiculed. I will therefore for the tenth time explain my own system as succinctly as possible. I reserve for a future occasion the first few years after planting, and take it up at the end of the fifth year, or later if the trees are not then sufficiently advanced.

I require the trees I propose to deal with to have at least two feet of clear stem, and a head of not less than twenty green leaves. On such a field I sow broadcast 4 cwt. of bonedust over the whole surface of an an acre, and turn it into the soil mamoty deep. If the land is dirty, I keep it in fallow for twelve months, weeding it once in one or two months, according to the necessity. If it is already pretty clean, I allow pasture grasses to grow at once. The bonedust costs R13, the digging in from R5 to R8, and extra weeding R6, so that the outside expense is R27 per acre. At the end of three years I repeat the operation, at a cost in no case exceeding R20 per acre.

Bonedust is not a suitable manure for young plants, or weak or dwarfed trees of any age. A tree should be a strong well-grown plant, with a good head of leaf, in which case the phosphate will rapidly bring it into heavy bearing. If the tree has to be made up to the mark, and if the natural soil is not equal to the task in a reasonable time, the use of nitrogenous manure will help them forward to the point, when the phosphate can be used with advantage.

Whatever manure may be applied to coconuts, it should in no case be put within four feet of the stem, in no case be buried in holes or trenches. It should be spread equally over the whole surface, and turned in, none of it deeper than six or seven inches. Though the roots run deep into the earth, it is essentially a surface-feeder, and any food presented to it should be placed where it is most easily available.—W. B. L.

CEYLON COFFEE AND TEA CROPS.—We have had the advantage of a conversation with one of the best informed planters in Uva. He describes the season as perfect and the prospects of the coffee crop excellent. Last season crop came only in patches; this year it will be general. Weighing against this condition of things in Uva the large uprooting processes on the Kandy side of the mountain zone our friend at first inclined to a belief in a quarter of a million of cwt. for season 1887-88, but came down finally to 220,000 cwt. On the other hand, he has seen so many dry years (good for coffee but not for tea) follow each other, that he is not inclined to look for a tea crop beyond Mr. Rutherford's estimate of 22½ million lb.

ARAKENE is the volatile alkaloid of the betel leaf. Is is the residue after evaporation of an ethereal solution colorless and of the odour of weak meat-broth possessing a strongly alkaline reaction. It forms varnish-like salts with tartaric, citric, hydriodic and salicylic acids, the salicylate having a tobacco-like smell. The hydroclorate gives with plantinic chloride a yellow, with gold chloride a light yellow, with mercuric chloride a white, and with tannin a whitish precipitate. The taste of the alkaloid and the salts is slightly acrid, and increases the secretion of saliva, slackens the pulse, and has a purgative action.—*Indian Agriculturist.*

THE new tea route of the Canadian Pacific Railway Company, remarks the Montreal *Trade Bulletin*, has been productive of conditions in the market which were rather unexpected at the commencement of the season, owing to shipments of the new crop of Japan teas overlapping each other so quickly. One cargo has scarcely sufficient time to be worked off before another batch of consignments and purchases will be at hand, with advices of others on the way. The result of this has been to deprive those who ordered on their early teas of their usual profits, as the imports this season have come to hand with such rapidity that stocks have accumulated, and thus occasioned a desperately weak market. Quite a number of sales of new season Japans have been reported, one lot of 500 packages of good common being placed at 14c c.i.f. Montreal and several lots of medium to good medium at 15½c to 18c. An invoice of fine Japan was also reported at an average of 22½c. Choice lines are quoted at 27c to 30c. It is stated that in all probability importers will not go in so heavily for early teas next year.—*Home and Colonial Mail.*

PLANTING IN NETHERLANDS INDIA.

The *Locomotief* affirms that the tobacco planted in British North Borneo on land leased to Count de Geloes and Mr. Persyn, brought at Amsterdam, one guilder and eighty cents a picul. A price like this ensures, so to speak, the success of their enterprise. The fact that this estate is worked with 120,000 guilders raised at Batavia, nd that at the present moment, half-a-million more is being brought together in Holland for that purpose, shows there is still some enterprising spirit among Netherlanders.

A petition has been presented to the Second Chamber of the Netherlands States General signed by no less than 736 land owners, estate managers,traders, and private individuals in Netherlands India, respectfully and urgently praying the Chamber to bring pressure to bear upon the Minister for the Colonies, for the institution of an inquiry into the condition of the Colony and the reforms which are necessary to improve the same, the inquiry, to be made by a commission consisting half of unofficials.

The Netherlands Trading Company has issued a report for the last financial year. It shows that throughout Java, in 1885, the sugar crop proved highly unsatisfactory in most estates owing to the very low prices realised by the article. By way of remedy, an effort was made to economise and cut down expenses in order to produce sugar at a cheaper rate commensurate with the ruling quotations. Several estates succeeded in gaining this end last year, and have gone on working at a slight profit. This result lends some encouragement to a hopeful forecast of the future. But it must be borne in mind that the cost of production on most estates is still too high, the consequent losses being heavy indeed. Other sugar growers put their trust in the Tebu Keong, a newly discovered cane in East Borneo which yields a heavy outturn of sugar per acre. It appears that this desirable result has been attained at a few spots only in Java. Trials with it in other localities have not answered expectations.

MR. GLADSTONE ON HORTICULTURE.

Mr. Gladstone was yesterday afternoon present, with Mrs. Gladstone, at the distribution of prizes to the successful exhibitors at the annual show of the Hawarden and Buckley Horticultural Societies, and after stating that he was suffering from cold and cough, and congratulating them on the progress made since last year, he said that notwithstanding stagnation in trade, notwithstanding distress here and there, the people of the country are acquiring upon the whole an increased command over the necessaries and the necessary comforts, or at all events, the primary comforts of life. Whenever that is the case, it is a matter of moral certainty that a considerable portion of any available increase of means will, and must, go in the direction of food for the masses of mankind. What is called a small culture forms in France a very large share of the means of subsistence and of relative opulence for the small proprietors of that country, who are very important and numerous body; and as the means for this kind of cultivation—the cultivation of vegetables and fruits—are enlarged in this country, partly by awaking public attention partly by the multiplication of gardens and allotments (applause)—which is a matter of the utmost consequence—and by the increasing disposition of farmers here and there to include these important objects in their view, and to add to the variety of their resources by trying something in this direction, we shall have a large increase on the one hand of the means of wealth to producers, and on the other hand of the advantages enjoyed by the consumers of food both in that reasonable satisfaction which the Almighty never intended to be severed from the use of food, and likewise in that most important view in reference o the sanitary condition of the country—to the health of the people.—*Globe.*

SPRING VALLEY COFFEE COMPANY, LIMITED.

DIRECTORS:—John Brown, Esq., Managing Director; Edward Conder, Esq.; Leon Famin, Esq.; Henry Hart Potts, Esq.

Report to be presented to the Twenty-second Ordinary General Meeting of the Company, on Thursday, the 4th day of August, 1887, at 12 o'clock noon.

The usual Annual Accounts are now presented to the Shareholders, viz., Profit and Loss Account for Season 1885-86, balance Sheet made up to the 31st May, 1887.

The crop of coffee secured for season 1885-86 amounted to 1,069 cwt. 1 qr. 27 lb. against an estimate of 1,200 cwt. given in last year's report, while the harvest of Cinchona Bark exceeded the estimate, 80,139 lb. being sold.

It will be seen that the average prices realised for these products were 82s 3d per cwt. for Coffee and 6d per lb. for Bark, the total value of produce sold amounting to £6,481 19s 3d, and this deducted from the total expenditure for the year of £8,889 4s 2d shows a loss of £2,407 4s 11d.

A sum of £3,307 15s 4d was brought forward from last year, and, allowing for the above debit of £2,407 4s 11d, there still remains to the credit of Profit and Loss a balance of £900 10s 5d.

Your Directors now propose that a Dividend of 1 per cent for the year be paid, for which £800 will be required, leaving £100 10s 5d to be carried forward to next Account.

Much valuable work was accomplished during Season 1885-86 for the future advantages of the Company's Estates, the cultivation, weeding, &c., of 414 acres of Tea planted in 1884-85 was efficiently carried on, the Tea being too young to yield any crop, and, in addition to this, 237 acres of Tea were planted; the cost of these works amounted to R27,859 or £2,000; this sum includes all the expenditure on Oolanakanda Estate.

The whole of this £2,000 has been debited to this year's expenditure, and, as the Coffee Crop was practically a failure, only 1,069 cwt. being secured from the reduced Coffee area of 990 acres, the result under the circumstances is considered by the Board to be very satisfactory.

The following figures show the area now under Tea on the Company's properties, all of which is thriving vigorously:—

TEA.

Planted Nov./Dec.,	1884...	271 acres,	now 2½ years old.
,, May,	1885...	143 ,,	,, 2 ,,
,, Nov./Dec,,	1885...	230 ,,	,, 1½ ,,
,, May,	1886...	7 ,,	,, 1 year old.

Total area under tea 651 acres.

Leaf is now being plucked from the 2½ and 2 years old tea, and the yield will rapidly increase as the bushes grow older. To date 1,093 lb. of tea have been sold at 1s 0½d per lb.

CROP, 1886-87.

Owing to a favourable Season and the apparent decadence of leaf disease, your Directors are pleased to be able to report that the crop of coffee for season 1886-87 will be about 3,600 cwts., and, as better prices are ruling, that year will show a very satisfactory profit.

CROP, 1887-88.

Reports as to prospects for Crop 1887-88 are also favourable; leaf disease is still on the decline, and hope is entertained that it is gradually passing away. Your Directors, however, see some cause for anxiety in the presence of green bug on the Company's Estates; they trust, however, that the healthy condition in which the Coffee trees on Spring Valley are maintained by liberal cultivation will enable them to resist its attacks, and the spread of the pest is being guarded against in every possible way.

Mr. Brown returned from Ceylon in May, having visited the Company's Estates, and he would take this opportunity to express his satisfaction with the management and condition of the Company's pro-

perties, and he considers that much credit is due to the Manager and his Staff for their exertions in putting so large an area into Tea in so short a time.

Mr. H. H. Potts, a Member of the Board, retires on this occasion, and, being eligible, offers himself for re-election.

Messrs. Deloitte, Dever, Griffiths & Co., the Aditors, also offer themselves for re-election.

By order, J. ALEC ROBERTS, Sec y.

26th July 1887.

OUVAH COFFEE COMPANY, LIMITED.

Capital £100,000, in 10,000 shares of £10 each.

Directors :—John Brown, Esq., (Managing Director.) H. H. Potts, Esq., L. Famin, Esq., Edward Conder, Esq.

Report to be presented to the twenty-fourth Ordinary General Meeting of the Company, to be held at No. 5, Dowgate Hill, London, on Thursday, the 4th day of August, 1887, at 1 o'clock p.m.

The following accounts are now presented to shareholders :—Profit and loss account for crop 1885-86. Balance sheet made up to 31st May 1887.

In last year's report the crop of coffee for season 1885-86 was estimated at 1,500 cwt. and the actual weight secured was 1,424 cwt. 2 qr. 11 lb. The harvest of cinchona bark amounted to 122,239 lb.

It will be seen that the average gross prices obtained for produce were as follows :—Coffee, 80s 3d per cwt.; Bark, 6½d per lb.; and 9 cwts. of Cocoa sold for 70s 3d per cwt.; the total sum realised from sales of produce amounting to £9,359 11s 1d.

The total outgoings for the year amounted to £11,312 7s 11d, the result being a loss of £1,952 13s 10d, and this deducted from the sum of £2,193 1s 0d, brought forward from last year, leaves a balance of £240 7s 2d to the credit of the Profit and Loss Account.

Compared with the Crop of any former year, the above Crop of 1,424 cwt., which was secured from the reduced area of 1,270 acres of Coffee, can only be regarded as quite magnificent, and, in the loss of it, your Directors were anxious as to the outlay they had felt it their duty to incur for the future benefit of the Company.

The actual result, however, is better than could have been anticipated, and your Directors cannot but congratulate the Shareholders on the position in which the Company today stands, the prospects of the Company being greatly improved by the important works carried out during Seasons 1884-85 and 1885-86.

During Season 1885-86 356 acres of Tea were cultivated and weeded, the whole of which was too young to produce any Crop, and, in addition to this, no less than 447 acres of Tea were planted, and the cost of these works, R29,714, or £2,200, has been included in the year's expenditure. Had it not been for this large extra expenditure it will be seen that even the small Crop of 1885-86 would have shewn a profit.

The area of Tea on the Company's properties is as follows :—

TEA.

Planted Nov.-Dec. 1883	... 9 acres, now	3½	years old
,, ,, 1884	...347 ,, ,,	2½	,,
,, ,, 1885	...447 ,, ,,	1½	,,
,, ,, 1886	... 27 ,, ,,	6 months	old

Total area under Tea 830 acres.

All the tea is growing well, and the 3½ and 2½ years old tea is now being plucked, the yield steadily increasing as the tea gains age. To date, 9,778 lb. of tea have been sold at an average price of 1s per lb.

CROP 1886-87.

The Directors have much pleasure in reporting that owing to a favourable season and comparative immunity from leaf disease, about 4,000 cwt. of coffee will be secured for Season 1886-87, and as the market is favourable, a very good profit will be shewn.

CROP 1887-88.

Owing to the continued abatement of leaf disease, Crop prospects for 1887-88 are also good, but your Directors are caused no little anxiety by the appearance of Green Bug on the properties. Your Directors are however, hopeful that, owining to liberal cultivation the coffee on the Company's properties will be healthy enough to withstand the attacks of this pest, and every means is being taken to check its progress.

Mr. Brown returned from Ceylon in May, having visited the Company's properties. While there a large amount of his time was spent in seeing to the equipment of the necessary machinery and appliances for the manufacture of tea at the least possible outlay, and the Glen Alpin Factory is now in full working order. He here desires to express his thanks the Manager and his Staff for their exertions during a time when personal energy was so essential to the successful planting and bringing forward of so large an area of tea.

Mr. E. Conder, a member of the Board, retires on this occasion, and being eligible offers himself for re-election.

Messrs. Deloitte, Dever, Griffiths & Co., the Auditors, also offer themselves for re-election.

By Order,

J. ALEC ROBERTS,

26th July, 1887. *Secretary.*

CINCHONA CULTURE IN VICTORIA.—Many years ago plants of several species of Cinchona were reared and distributed for test culture in the colony of Victoria by Baron von Mueller. Among these, some were entrusted to Mr. G. W. Robinson, of the Western Port District, who cultivated them, with many other industrial plants, at his estate near Berwick, which is more forestral, and has a milder climate than the immediate vicinity of Melbourne. Some years since Mr. Robinson's plants not only produced flowers, but ripened seeds also, from which seedlings were raised. We learn now, with interest, that an analysis of the bark of these Berwick trees by Mr. W. E. Matthews gave the percentage of alkaloids as 6½. This fact is significant, as it is thereby demonstrated for the first time that Cinchonas grown in lowlands will also produce a fair quantity of alkaloids, so that the culture of these valuable plants has also for commercial purposes a far wider scope than was generally anticipated. The village of Berwick belongs quite to the coast region, it being only about 100 feet above the sea-level, while its distance from Melbourne is less than thirty miles —*Gardeners' Chronicle.*

THE WALNUT TREE grows most luxuriantly and fruits freely on the Nilgiris. Some fine specimens are to be found on the Llangollen farm where the trees are about fifteen years old. The late Mr. Frend was most assiduous in his efforts to cultivate this and other useful trees, and succeeded most completely. To the best of our recollection he was the only person who grew the walnut to maturity and sold the fresh nuts in Ootacamund. The following remarks on the walnut taken from the *Gardener's Chronicle* will be read with interest:—

"If it were generally known that the walnut succeeds far better when sown where it is intended to grow into a timber tree than when planted at however young an age, many persons would be tempted to cultivate the tree who are now debarred from doing so by the cost of young trees. The ground intended to be sown with the nuts must be trenched and manured the winter before sowing, or if it be intended to plant at wide intervals as is sometimes done in orchards and fields, then stations of two yards square only need be so manipulated. In sunnier climes than our own—for instance, in France and Southern Germany—the trees are grown in two lines, say 40 feet apart, and then a space of 30 yards to the next double line and so on over the whole area of the field. Early maturing crops of grain, as oats and barley, potatoes and cabbages are then sown and planted in the open spaces. Sown walnuts have two advantages over planted ones besides that of cheapness, namely, great power to withstand wind by reason of the retention of the great tap-roots (which are generally lost in transplanted trees) and which go deep into the soil, and by the absence of all check to growth experienced by transplanted trees, which lose one to two year's growth by the operation. The high price (5s. per cubic foot) the wood of the walnut now fetches in the market, owing to its increasing scarcity, should induce landowners to pay attention to its cultivation. Upland sites are preferable for growing the tree, as it is spring tender both here and on the Continent when grown in low-lying localities, the young shoots often getting cut with frost when they have reached 9 inches in length. In warm sheltered sites, and in the south of the country, the tree may be planted on lower lands without disadvantage, although the finest market timber, either pollarded or not, will be found in the colder positions, as these favour a somewhat slow rate of growth. For Military gunstock purposes the straighter grained wood, grown unpollarded and quickly, is, we believe, most liked."

TANNING IN CHINA.—Consul Shepard, of Hankow, says that the method of tanning pursued in his consular district is not dissimilar in its earlier stages from that pursued in the United States. A vat is prepared—generally sunk in the ground—capable of holding about thirty hides. These are covered and left to soak in a solution of lime, called by the natives, "milk of lime." They are kept in this bath sixteen days and upwards, according to the season, cold weather requiring more lime than warm. The hair is then loosened, and the hides are taken singly, spread upon a bench, and thoroughly put through a scraping process to remove the hair and offal from the flesh. The tool used for this purpose is of peculiar construction. It is shaped like the capital letter H, one side being a steel or iron blade, and the other the handle, the cross-bar merely connecting them. The blade is about a foot in length, and the handle two or three inches less. The workman places the handle against his breast for greater ease and power, and with this forcible application of the tool to the hide the hair is speedily removed. The hide is then turned with the flesh side up, and by a similar manipulation all offal is removed, and the hide is reduced to a uniform thickness. A thorough washing follows, and the skin is cleansed of all remains of the lime. The refuse hair is saved for agricultural purposes, and the scrapings of the flesh side are boiled down for glue. After the cleansing, the hides are subjected to a vigorous rubbing with a heavy sandstone, or similar article, until both sides are thoroughly smooth. When this process is completed, a strong decoction of nutgall is sprinkled over the green leather, and then the tanning is commenced. The nutgalls are boiled in water over a slow fire until they become liquefied, and the strained liquor furnishes all the tannin used. Nutgalls are abundant in the districts furnishing exports to Hankow, and considerable quantities are sent to the United States. The next process to which the skins are subjected is as follows. A kind of furnace is built underground with an opening in circular form, from which a dense smoke issues when the fuel is fired. The fuel required is either wheat straw or a species of grass gathered from the mountain side; it is believed that nothing else will answer the required purpose. For the space of seven days the hides are passed backwards and forwards through the smoke issuing from the furnace, and unless it is to be blacked, the tanning of the leather is thus completed. If it is to be blacked, a liquor of vinegar in which iron has been left to corrode, or a solution of nutgalls and copperas, is ordinarily used, but at times simple lamp-black is employed. The yellow-brown colour given to the leather by the smoking process is considered to be of remarkable beauty, and is therefore greatly preferred by manufacturers and wearers. The leather is made soft by sprinkling it with saltpetre during the smoking, accompanied by repeated and violent kneading of it, drying it in the air, instead of by exposure to the sun. The strength of the solution of saltpetre as applied is said to be kept secret, no apprentice being initiated to the knowledge of it until he has served for three years.—*Journal of the Society of Arts.*

CHINA AND JAPAN TEA EXPORTS: 1887-88.

Judging from the improving tone of the latest London tea telegrams, we think it is evident that the large decrease in the exports from China is at length slightly attracting the attention of those interested in the trade.

Naturally in the early days of the season, the decrease was attributed to differences which frequently occur at the opening of the season, between buyers and sellers, and it was generally thought that the deficiency would soon be made up by increased shipments.

When the bulk of the first crop was cleared off the Chinese dealers declared that owing to the unfavourable weather during cropping time, there would be comparatively very little second and third crop teas for export; and the quantity would be therefore very short.

As the season progresses, and there is no prospect of the decrease being largely reduced, owing to the fact of there being no such increase in the stocks in the shipping ports, from which so large a deficiency could be made good, some credence is being placed in the correctness of the Chinese prognostications.

By the China advices to the 24th ult. we learn that the export to Great Britain, which was 29½ million pounds short, was on that day 32¾ millions deficient. This additional decrease is, however, more apparent than real, because the stocks at Hankow were about 1½ million pounds in excess, and at Shanghai about five million pounds. There was no increase at Foochow. At Amoy there was an increase in the stocks of Formosa tea of 3½ millon of pounds, but as this tea is shipped to America, it does not affect the export to England.

Deducting the increase of stocks from the decrease of export, there would still be a deficient supply for the season of 25 millions of pounds: but it will probably be considerably more as the season progress, because the arrivals at Hankow and Foochow are, we gather, not likely to be equal to those of last season—owing to the decrease in the second and third crop teas.

At Hankow the arrivals of the former are only 85,000 half-chests against 220,000 half-chests and of third crop 1,000 half-chests against 16,000. It is said the Chinese are keeping back their crop. They may well do this at the prices being offered for them. The Chinese, however, deny the fact, and are apparently acting upon their belief, as they are large shippers on their own account.

There is no doubt as to the fact of there being a present deficient supply of China tea to England of 32½ millions. This cannot be ignored indefinitely we should think.

As everything connected with the tea trade of our chief competitor must be of great interest to Ceylon planters, especially at the present juncture, we have taken some trouble to enquire into the circumstances which surround it.

We, like may others, have always been under the impression that if prices in England were to advance considerably unlimited supplies could be obtained from China in a very short time. We now find that this opinion is entirely erroneous. We were surprized to discover that the export of tea from China is not regulated by the fluctuations in the English market, and that if the prices of China teas were now to advance three pence per pound, no more tea could be supplied this season, than will be if no advance takes place.

It appears that the consumption of tea in the Chinese Empire is so large, and increasing and is so nearly equal to the production, that there is only left a surplus of about 10 per cent available for export, and this quantity is liable to be diminished by unfavourable seasons as is now being demonstrated.

It is roughly estimated that the production of tea in China is 2,000 millions of pounds. We see that for several years past the export has not exceeded 10 per cent of this quantity.

Great Britain receives on an average one year with another 150 millions of pounds, the Continent of Europe about 10 millions, the Australian Colonies about 20 millions, and America 20 millions in addition to what she takes from Japan.

In support of our statement that the export is not regulated by English prices, we give the following returns of the export to Great Britain during the past five years:—

Season of	1882-3	..	150,435,668 lb.
	1883-4	..	151,140,186 ,,
	1884-5	..	144,759,120 ,,
	1885-6	..	152,649,902 ,,
	1886-7	..	150,160,271 ,,

The increase during 1885-6 was caused by two million pounds of the new tea from Canton and Macao being included in that year's export. The season opens much earlier in these ports than at the Northern.

During these five years prices in England have fluctuated largely, and they had declined to a point last year which would certainly have curtailed the export of low classed teas, if the export was effected by low prices, but we see the extraordinary uniformity of the supply year after year and this season, happily for us, is likely to be an exceptional one.

It appears to us probable if the present prices of low-classed tea remain unaltered, the Chinese will consume them themselves and will sell us an equal quantity of the finer descriptions which can better bear the cost of transport, manufacture, packing, octroi and export duties and middlemen's profits.

We have often wondered why the Chinese did not spread their supplies over a longer period and thus place themselves less at the mercy of buyers, but we now see that owing to the shortness of the shipping season, it is, with the exception of Canton and Macao, a case of Hobson's choice.

We have compiled the subjoined returns of the monthly shipments of tea from each of the shipping ports during the last three years, and it will be seen that the shipping season which begins about the 1st June is practically over by the end of December, but in point of fact so large a portion of the season's export has been shipped by the 31st October, that it is quite possible to estimate within three or four million pounds what the season's export will be, and we think by the middle of next month, by comparing this year's stocks in the ports with those of preceding years, we shall be able to form a correct opinion as to the possibility or otherwise of the present deficiency being overtaken by the end of the year.

When we consider the enormous production of tea in China, we can understand how insignificant the export trade is to the native grower. We doubt, if the average value of China tea is 7½d per lb. in London, whether he gets 2d per pound out of it—this is equal to ½d per pound for his green leaf—we who are accustomed to 2d per pound for green leaf can understand how the Chinese prefer the home trade. The people who benefit mostly the China tea trade are first the Government, then the manufacturers and packers, the middlemen, and lastly the foreign merchants, not the speculators who invest on shipments, because they get the lot on the spot, but the commission merchants who make a very decent thing out of the six

million pounds sterling which is about the value of the trade.

We have much more to say on this subject, but we must not be greedy and consume our reserves at one meal.

CINCHONA-GROWING IN RÉUNION.

Some time ago we reported that efforts were being made to propagate the cinchona tree in some of the French colonies, and that it was confidently assumed that these experiments would be so successful as to render French buyers independent of the London market in a few years' time.

Mr. C. L. St. John, British Consul in the French colony of Réunion, gives some interesting details of the cultivation of cinchona in that island. He states that for some years past, the planting of cinchona has absorbed much attention in Réunion; and, although the plantations have hitherto assumed no very extensive development, the results obtained are sufficiently satisfactory.

At Réunion the plantations are made in forests, at a height of about 4,000 feet. At this altitude, where there exist no high trees, but merely brushwood, parallel alleys from five to six feet wide are made, as far as practicable in spots sheltered from the winds. These alleys are separated by a range of brushwood 10 feet thick on each side, which serve to protect the young cinchona plants against the violent winds so common in Réunion. Holes are then dug at a distance of 15 feet apart, 20 inches in diameter, and the same in depth. They are then filled with the earth that has been dug up, and to which some mould is added. This mixture forms, at the surface of the soil, a convexity, into the middle of which the young cinchona plant is placed; and the alley, after a few showers of rain, is soon brought to a level.

In a soil thus prepared the young plant experiences no difficulty in its growth; but when it has attained a height of 1 foot 6 inches, care must be taken to cut the roots of the adjoining brushwood which may have found their way into the space reserved for the cinchona, in order that the plant may meet with no impediment in the course of its development.

At the end of seven or eight years, the plants have a diameter of 3½ inches, and are ready to be worked.

The following is the manner in which the bark is prepared:—Towards the month of October—that is to say, when the sap resumes its ascensive movement, and the bark is more easily detached—the plants are cut at about 2 inches from the ground. The bark is then taken off and put in the sun to dry. From the stump that remains there soon spring a great number of young shoots, which, when they have in their turn attained a certain size, should be lopped off, only leaving the number of sprigs which the stump is able to feed conveniently. These sprigs have a rapid growth, and, at the end of another period of six or eight years, a new crop is ready.

In this way the cultivation of this produce, once planted, can be continued almost indefinitely, and at little expense. The consul thinks that it is evident that the means employed in Réunion for the cultivation of the cinchona are very practical, and far more economical than those in vogue in Java.

Although the Réunion plantations are as yet only on a limited scale, the results are such as to induce their extension. Hitherto, experiments have only been made by the local Government on the Crown lands, and by a few wealthy planters. Lately, the Government sold a certain quantity, which fetched a little more than 2 francs per lb. in the market.

The manager of the Crédit Foncier Company has also expressed great satisfaction at the results he has obtained, and he will shortly sell over 200 lb. of cinchona planted in 1879. This year he expects to have a new crop from trees planted in 1880; and so on.

It may be stated that the stumps of the plants that were cut in October last are already covered with young shoots.—*Chemist and Druggist.*

Coca-Growing in Assam.—Mr. J. Buckingham, of Amgooria, Assam, who is making experiments in coca-growing on his plantations, states that the plants are healthy and have borne berries; he has gathered a small quantity of leaves which he prepared in the same manner as tea. In Darjeeling, where Mr. Flamsteed, of Seeyok, and other planters have tried to raise coca plants, the experiments have resulted in failure, the climate being found too cold.—*Chemist and Druggist.*

Sugar in Ceylon is thus noticed in a paper on sugars shown at the late Exhibition:—

Approximate annual production: 350 tons.

Ceylon sent but a poor show. A few samples of small-grained dirtyish white sugar, apparently produced by considerable washing, a very extravagant method of improving quality; also a few cakes of concrete. These had been put into small matted baskets, holding about ¼ lb. They must therefore either have been specially made for a sample or for some local demand, as in this form they would not be suitable as an article of commerce. They had the appearance of having been made for sale as sweetmeats.

The qualities of the sugars from Ceylon are thus indicated:—

1. White crystals; 2. White, small-grained; 3. Molasses and syrups; 4. Concrete, brown.—*Sugar Cane.*

Large Cacao Leaves.—Mr. Ross Wright, of "Labugama" estate, writes:—

"Noticing in your issue of 5th Sept. 1887 the enclosed slip 'A Large Cacao Leaf' &c., I send you 4 leaves from 'Labugama.' Now compare them with Dolosbage, and what do you think of them? 2 of the leaves measure 19 in. by 7 in."

As the dimensions of the leaf from Dolosbage were 18 inches by 6½, of course it has to yield precedence to the two which are each 19 inches by 7. As all the big leaves lie on our table we are reminded of the school visitor in *Punch* who asked:—"Now can any of you boys spell *tre-men-ji-ous?*"—"Tre-men-ji-ous" indeed! Where is the leaf competition going to stop? We had only just handed the above paragraph to the printer when a truly gigantic vegetable leaf arrived, accompanied by a leaf of paper thus inscribed:—

"Rakwana.—What do you think of this cacao leaf 21 inches by 7¼? The Cooroondoowatte leaf is nowhere. I've beaten it by 3 inches in length and ¾ of an inch in breadth. You ought to see some of my cacao pods. I have picked many 11 inches long."

As we have had a tea leaf 1 foot long, we suppose the end will be a cacao leaf of twice that length. Only 3 inches more wanted to make up the 2 feet!

PLANTING IN MYSORE.

A Review.*

By "Aberdonensis."

The second volume deals more with Agriculture. We will quote:—

"It is sufficient for your Anglo-Indian, as he toils along some dusty road, to glance at the Hindoo peasant with his plough on his shoulder, to see the faint furrow that is traced on the hard and uncongenial soil, to observe those greyhound bullocks of puny build and to conclude that, these being unlike English cart horses, plough and steam-engines, further examination is therefore needless; and that as the Hindoo will slumber on as he has done for the last two thousand years it is hopeless to try and improve him. Some, however, being bolder and more energetic, are determined to arouse these slumbering peasants, and the rage for creating a new state of things forthwith commences. No longer is the humble ryot to trace these faint furrows, nor to tread out the corn with his cattle, nor to burn his manure for fuel, nor to pound and grind his corn. The sanguine improver looks forward, and fondly hopes to see the day when the found of the threshing machine will be heard in the land, when ploughing shall result in a furrow broad and deep, when manure shall be carefully stored and utilized instead of being burnt for fuel, and when the hum of the water-mill shall succeed to the drudgery of pounding and grinding that corn which must now be converted into flour by the maidens and women of Hindustan. But the ardent mind rushes on to triumphs far transcending these, till reaping machines and steam-ploughs are talked of as things that those now alive may live to see in daily use."

Our author proves the fallacy of these theories by sneering at English farming in the first place. I do not see that that is good argument, still I agree with him that expensive theories break the bruised reed and quench the smoking flax. If Mysore planters were to attempt to go in for Ceylon expenditure, lavish as it still is, we would "drown the miller" altogether. This applies to native agriculture. A great deal of their operations forms part of their daily life. Then as regards ploughing. The native plough is a capital business. The native plough costs a few annas when new. It suits the bullocks, and the land. Anything English would put everything out of order. Why if you ploughed the paddy fields deeply you would come on a black stratum of what? Ask experts. The yearly and half yearly grubbing about in the liquid mud sends down saline and mineral particles to the depth the annual disturbance of mud reaches. Cut a section of paddy field and there is the black line. To turn this up is to poison your rice plants. Ragie and dry paddy fields have a sour subsoil that should not be disturbed. Remember these are cereals not trees like coffee and tea.

The whole drift of the discussion is "Let well alone." Don't force theories on the native. His surroundings are the same as in the time of Elijah the prophet, let his ways also remain the same. Educate the young and they will think for themselves and see the light, their eyes having been opened.

I must say the native manuring is amusingly crude. In my daily walks I have to cross and recross paddy fields in country say like Balangoda, and I see little scatterings of ashes, straw, cattle dung, either bleaching in the noontide sun or floating freely on the flooded fields (alliteration)! That is really very ludicrous. But they do their best and every little helps.

Now for planting at last! I must not allude to the hints as to making a nursery, or putting out plants to the readers of your journal, who bear the palm of being the finest agriculturists in the tropics. But softly. Have I not often remarked that this skill, this knowledge is sadly warped and twisted by the unreasonable conditions of things, such as V. A.'s, Colombo Agents, rigid estimates, &c., &c.? But still the training is grand and the work good.

It is easy to see our author is not a very practical planter. Beyond very trivial details he does not go, but flies off on the smallest provocation to general and broad views. But in these sometimes he is interesting. He comes to *shade*, to clearing forest, and now I begin to sniff sulphur, and snort for the battle! I will quote:—

"The next point that claims our attention is the clearing of the forest; and here it is not too much to say that the experience and example of Ceylon planters have more than half ruined planting in many parts of India, and a great deal more than half ruined it in Mysore and Coorg. In Ceylon the climate is oceanic; in many districts rain falls more or less during eight months out of the twelve; and in some, I believe, there is seldom a month that is certain to be without a shower. But in India we have a climate exactly the reverse of all this. We have, it is true, a rainfall which is in the aggregate, I believe, equal to, or even exceeding, that of Ceylon; but then we have the rain in certain consecutive wet months, which are followed by many months of cloudless skies and parching winds. The south-west monsoon breaks along the western shores of India with terrific force towards the end of May, and from then up to the end of September we have almost continuous rain. In October the weather is showery, but towards the end of the month all signs of rain disappear, and it is quite a matter of chance whether a single drop of rain may fall, within the next four months and-a-half, and in one season we had nearly six months without a single shower. But this is not all. The winds from November till early in March are mostly from the north-east; and a glance at the map of India will show the reader that the breeze must sweep over many hundreds of miles before it reaches the Western Ghauts, and I need not waste words in explaining that a landwind which has swept over so many miles of scorching plain must necessarily be of the most arid and withering nature. And yet, in spite of these obvious objections to planting without shade and shelter, planters of the greatest Ceylon experience have been employed by Indian proprietors, and in many instances they have themselves adopted an experience derived from a totally different climate, and an experience which they have obstinately refused to modify until taught, by the bitterest lessons, that a method of cultivation suited to one climate may be entirely unsuited to another. But it frequently happens that errors once committed in the formation of coffee plantations cannot be easily remedied. It is easy to cut down shade and shelter, but it requires years to build it up again; and it is melancholy to behold the uphill efforts of men to replace what, a few years before, they had irretrievably destroyed. Ceylon planters flocked into Coorg, and a sufficient number found their way into Mysore to cause enormous loss to those who were fool enough to adopt the experience that was current in Ceylon, the greatest of coffee-planting countries. The fruits of that experience we know too well. Taught by what was an ample and sufficient experience in a moist and oceanic climate, these

* The Experience of a Planter in the Jungle of Mysore. By Robert H. Elliot. 2 vols. Chapman & Hall, 1871.

who had shade to preserve their coffee in the long dry months, cut it down as fast as possible, and numerous plantations were formed where not a tree was left standing, and where shade was scouted as a thing of the past, and as a relic of barbarous times. The planters cut down the forest and planted their coffee; and then came dry seasons and sickly plants, and an insect called the borer, which aided (ended ?) in killing the trees from one end of the plantation almost, and, in many instances, quite, to the other. When I last visited Coorg in 1865 I recollect telling the superintendent of the district that I was then going to England, and that on my return to India I certainly expected that many of those plantations, which were then so promising would probably be used for firewood, and that many an acre in my own district would share the same fate. But though confidently predicting the inevitable result, I confess that when I returned to India in the spring of 1867 the result had far exceeded my expectations. The season of 1865 was dry and hot, and the season of 1866 had been worse; and during the last two months of 1865 and the first four months of 1866 there was not, on our side of the country, I think, a single shower to revive the drooping plants. It was then seen, but in many instances seen too late, that a wall is no stronger than its weakest point; that the weak point in our climate is bound occasionally to appear sooner or later; and that, when it does, it is sure to be accompanied by that enormous increase of insect life which invariably accompanies long droughts and dry seasons in any quarter of the globe. And here it will naturally be asked why it was that shade and shelter had been so universally neglected. One of the reasons I have already given; and the fact that experienced Ceylon planters were looked up to in India as the safest guides, was, of course, one of the principal reasons. But there was another, which had probably as much to do with the matter, for it had been already found on the Neilgherry Hills (on Mr. Ouchterloney's plantations, I think), that the coffee planted in the belts of forest-trees left for shelter was a total failure. The plants grew slowly, the branches were poor and lanky, and the yield was trifling, and there seemed to be some fatal objection to growing coffee in the shade at all. And the same thing was found elsewhere; and many instances of the same sort may be pointed to in other districts. It was therefore held that coffee under shade would not do, because, in many instances, it would not do under the shade of the old forest-trees. But no one seems to have asked whether it would not do under shade of another description; and the idea of cutting down the whole forest, allowing a secondary growth of forest trees to spring up and supplementing that by planting trees which were most suitable for coffee shade, seems to have been an experiment that no one thought of trying in Southern India until it was adopted by myself and a few other planters in Mysore. But the droughts and the borer together have at last opened the eyes of even the most prefudiced planters, and it is now pretty generally admitted that a light shade is no loss in any season; and that in the driest ones it is absolutely necessary, to preserve the plantation from the attacks of insects."

This was published in 1871; since then leaf-disease has come and troubled the planter, and shade has along with climate modified its ravages in Mysore. But there is another stage reached. Leaf-disease played such havoc that planters looked elsewhere and discovered a stronger caste of coffee in Coorg. Strange to say many trees that suited the old chick coffee are prejudicial to the New Coorg. Yet still the planter toils on and studies what is best. Ceylon men without shade, and in a climate favourable to blights, succumbed and have now taken to tea. This is a much more suitable plant in their climate, than the Arabian coffee tree.

But strange to tell—the cacao planters in Ceylon found themselves exactly in the same plight as that just now described by Mr. Elliot. To continue our author's test:—"When I entered Mysore in 1855 there was no such thing thought of as planting coffee without shade. * * * The general result was, that the plantation could not, at a little distance, be distinguished from virgin forest." This is much the description of an estate at the present time in Mysore. So planters have gone back to the old way. A V. A. on my last visit to Ceylon asked me how many *chains* apart did we have shade trees. "You mean how many feet or yards, I presume?" was my reply. *

Mr. Elliot now goes into "aspect as regards sun and heat," but you are all well enough instructed on that point whether with shade or without. I will, however, remark that whereas *northern* aspects are best for a shade plantation of coffee here, yet in *cardamoms* it is the very reverse. First, because the Ghauts forests, where the cardamoms spring up, want all the sun they can get from the south; and second, because the cardamom is very susceptible to the cold wind from the north and east.

The reason why the northern is better than the southern aspect is because the latter is twice as hot as the former. This is for coffee because heat dries up coffee.

The reason why the southern is better than the northern for cardamoms is because cardamoms love warmth. Mr. Elliot now enumerates the shade trees. This would not interest you except his remark:—"Of all the trees suitable to coffee, I am inclined to place jak at the head. From coffee planters I admit that I have heard very contradictory accounts of this tree; some asserting it to be indifferent and even injurious, while I have been informed by others that some very fine estates in Ceylon have numerous jak-trees scattered about amongst the coffee." †

Cacao planters in Ceylon have found the Erythrina, or Madre de Cacao, and Rubber (Ceará) to be good shade for cacao. As these trees shed their leaves in the *hot* weather it is evident that cacao, unlike coffee, wants a good roast, and shelter afterwards. The sycamore‡ sheds its leaves in the wet weather and thus gives light and shade exactly when required. Cacao evidently differs here from coffee. I must quote again our author's final remarks on shade:—"I find it impossible to quit this subject of shade without saying a few words as to the numerous advantages that plantations of coffee have, that can be grown under the shelter of the original forest. In the first place, from the greater part of the land being only cleared at first of the underwood, and from the fact of that being burnt in separate heaps, a large proportion of the soil is entirely uninjured by fire, and the valuable sur-

* Feet, or yards only, apart is close for mere forest; so that to support both the shade trees and the coffee, the soil must be exceptionally rich. The aridity of the climate, too, must greatly modify the density of leafage on the shade trees ?—ED.

† On tea estates we have seen groves of flourishing jaks which were, close on the timber-yielding stage ruthlessly cut down. The jak draws heavily on the soil and its foliage is specially dense.—ED.

‡ The "sycamore"? We suppose a species of Indian fig is meant?—ED.

face mould entirely preserved. In the next place, from the *preservation* of such a portion of this *vegetable matter*, and from the land being *annually recruited* by the *fallen leaves*, the rain water, instead *of running off, washing the land and so depriving it of a great deal of its most valuable constituents, soaks gradually* into and *lodges in the soil*, without the loss of a single drop. [The italics are mine.—*Aberdonensis.*] Thirdly, the forest trees afford shelter to innumerable birds, which are not only pleasant to see, and many of them to hear, but which are of *incalculable service* as *insect-eaters*. [My italics.] Then the planter with his shade, if he does not altogether laugh at dry seasons, in a great measure neutralizes their influence by preventing the sun and wind from drying up the soil and parching the plant. And, finally, both the planter and his people can work away all day, and seldom feel the fierce rays of the tropical sun, and this consideration alone is of immense money value to an estate." (Hear, hear!—*Aberdonensis.*) I notice Mr. Elliot confuses suckers with gormandizers. A gormandizer is a hybrid between a sucker and a branch as all planters know. It arises from cutting the heavy wood too drastically. Our author has an original idea to prevent the branches or primaries having too much of a curved set, thus bearing on their fellows below. He nips off the primary points. What would a V. A. say to this sacrilege? These holy primaries—sacred to the Sinna Durai! Nipped as to their points! just think.

There is too much knifing young coffee in Mysore. A little "judicious neglect" would help many fields of young coffee, you must have lots of leaves. Some men keep picking away as if they were busy at tea flushes. Control, but do not maim the energies of your tree. Mysore men lay great stress on not leaving more than a certain number of secondaries and tertiaries, and never allowing pairs of shoots. They have to be far more careful in selection than in Ceylon. In many districts in Ceylon the pruners have to tear away indiscriminately before they begin serious work so redundant is the wood. Some men like to prune early, others are in no hurry. Some men use men only—others prefer women. Tastes differ. Mr. Elliot rightly is of the idea that as there is a great deal of wood grown to be cast away after selection, that as a large growth and rush of wood is essential to the well-being of the coffee-plant, therefore nitrogenous manures are best. I would go farther. In the tropics heavy weeds are the result of nitrogen in the soil. A heavy growth of weeds promotes nitrification, so that a *clean* weeded estate has its nitrogen washed out of it like a sieve. Thus Hemileia fungus results from an un-nitrogenous area.*

Mr. Elliot objects to Tytler's *Sombreorum* as containing such a percentage of potash. That, being a result of combustion in the plant, should not necessarily be a food. The carbonic acid gas we breathe is a result of combustion but is deadly if breathed again. *Sombreorum* contains 40 per cent potash. It is a strange but true fact that this manure succeeded only in the immediate neighbourhood of Mr. Tytler's estates. Mr. Hughes recommended it, did he not?

As regards cattle manure, I must be dumb before you, as I remember the very splendid fodder, the palatial sheds, the vast heaps of steaming, reeking muck, applied one basket to a tree in days gone by in Ceylon. It was not all climate, but *tremendous manuring* that shut up your coffee stores. Such manuring the world has never seen, I truly believe. You had a rotten soil but "lashings" of muck. The Mysore men do not realize what two men to seven head of cattle means. Maana grass and Guinea grass, overflowing poonac tubs or troughs, reepered floor and pigs below revelling in the litter thrown down, the fresh guinea grass, the boiled jak fruit and the bubbling troughs of rich poonac. Alas! alas. All that fine organization, and beautiful results are gone. I saw the empty sheds in Matale not long ago.

In Ceylon they used generally to apply white castor, cake biscuits and steamed bones: the latter brown, the former white. In Mysore they use crushed bones and rich poonac half crushed by native machinery and full of oil: bones white, poonac brown. Castor cake is almost black and is liked by many—but "Hongay" is the favourite, I believe. I agree with Mr. Elliot that farm-yard manure is the king. I don't mean *cattle* manure but everything—cattle shed, stables (and here more horses are kept as horse-keep is so cheap), bungalow and garden sweepings, ashes, &c. &c., but I do not agree with him in thinking that bones and poonac should be mixed with this. The plan on the estate I am now in charge of is good. Estate divided into three parts *A*, *B* and *C*. First year field *A* gets farm-yard compost, previously carted out to depots near the field. *B* gets bones and poonac (one part to two), *C* gets nothing. Second year *B* gets compost (bulk), *C* artificial, *A* nothing. Third year *C* gets compost (bulk), *A* artificial, *B* nothing.

MANNER OF APPLICATION.—We will say before the first year renovation pits between the lines of coffee missing alternate squares have been closed, and in the missed alternate squares new pits have been dug. Well, in putting bulk to field *A*—the first cut pits which are now closed are partially reopened. The next set of pits which are now open are filled with leaves, litter and weeds. Half a basket of bulk is put on the top of the leaves, &c., and half a basket is put on the partially reopened old pits. Then men come and cut new pits *in the lines* in alternate spaces. The next pits will be cut in the remaining spaces in the lines. Do you follow this account, or have I muddled it? Mr. Elliot thinks that £5,000 will start a man here. If you like, I will send you particulars as to acquiring land and cost of opening.

Now come some remarks on enemies of coffee:—"Towards the end of 1866, and throughout the three years following, large numbers of coffee trees in Southern India, and in many instances whole plantations, perished clean off the face of the earth. On cutting open the dead trees, large numbers of an insect called by the planters the coffee-borer were found, and as these insects were almost invariably found in the dead trees, it was concluded that the borer, and the borer alone, was the cause and origin of decay and death. Thereupon there was a tremendous fuss made about this interesting insect. Not even after a man-eating tiger was there ever such a hunt. Pages were written on the insect. The Government was loudly called upon to exert itself, if it did not want all revenue from coffee suddenly to cease. Nor was the Government [illegible] in responding to the call. [illegible] Dr. Gibbs was [illegible] As for the unfortunate insect it was burnt and [illegible] of 1867 even sent to London to have the [illegible] inquired into. It arrived there by the [illegible] route, safely embedded in two [illegible]

* A very confident opinion, with no scientific basis to support it. The scientists who reported on the fungus were specially strong in recommending the removal of weeds and all growths likely to form a nidus for the spores.—ED.

which was 'cautiously sawed through' by Mr. John Keast Lord. By this gentleman it was declared to be a beetle of the second family of the *Coleoptera Cerambycidæ*, and to be closely allied to a somewhat common species known as the wasp-beetle (*Clytus avietus*), which usually undergoes its changes in old dry palings? Aided by the head of the Entomological Department of the British Museum, a specimen of the insect was at last found in the collection made by M. Chevrolat somewhere in Southern India. Appended to this specimen was the name of *Xylotrechus quadrupes*. On a further examination of the tree, Mr. Lord very soon came to the conclusion that the insect did not necessarily cause the death of tree at all, as it lived on the dead matter of the inner or heart wood of the stem, and only interfered with the circulation and sap-vessels of the tree when it worked up to the surface of the bark. And he finally was of opinion that 'the female beetle, guided by her instincts, selected trees, on, or in, or underneath of which she deposits her eggs, such trees being at the time, from some cause or other, not explicable, sickly and predisposed to early death.'"

The conditions were that starch was turned to sugar by the unfavourable surroundings, and like the Helopeltis, like the child with his barley-sugar the borer preferred the sugar. "W." told us it was so with the fungus. Was he right? We must keep our trees juicy; to obtain juiciness we must have lots of leaves and wood; and in this climate *shade*.

No word of "Hemileia Vastatrix." Significant in 1871! A little talk of black bug. What about this latest of Ceylon plague "Green Bug"? Our author steps innocently ignorant of these two last plagues and begins to treat of "Cinchona."

"Cinchona."—Saviour of Ceylon! Thy buoyant quills floated Ceylon just clear of shipwreck and nothing more. The good ship ground the rocks and damaged her keel, but, thanks to cinchona, she has floated free in the golden waters of Tea. We pass the subject by as we would the body of the warrior who has just saved his country. He is gone, he has won. Let us drop a passing tear.

Cinchona will never do in Mysore as a profitable speculation. Its growth is feeble and the market is dead.

"Cardamoms."—I will first describe what it was my fortune to see on my arrival in Mysore. I stepped right into a cardamom plantation or forest and worked there 2½ years. There are about three thousand to four thousand acres of grand virgin forest. Large areas of chena show where the ghastly borer swept away grand sheets of coffee. There the tiger prowls, there the sambur barks to the moon, or answers the far away howl of the jackal on the patana ridge above. The land is positively magnificent—"if it were in Ceylon." But those Ghaut forests like Morawak Korale, though bearing mighty trees do not possess great richness of soil. But still the land is fine. Three or four vast valleys all roaded;—and in that easy lie of land the roading is easy. The swamps have been all planted with cardamoms, the flats partly planted and partly sprung up; the ridges draped and festooned with pepper as well as fairly covered with cardamoms. But you must not imagine even in the richest places that the cardamoms are like your Rangala groves. When I arrived there the old gentleman who was to be my boss took me and another new arrival round. This old gentleman was the monarch of all he surveyed. He took me, the Ceylon chap, round his best fields and then spoke of breakfast much to the delight of the griffin—the new comer, who had still his European stomach with all its cravings. The Ceylon chap (that's me!) was not satisfied. He made a terrible mistake. He had seen grand cardamoms in Rangala, Medamahanuwara, &c. He had come to the *home* of cardamoms. He wanted something that would beat those Rangala fellows. He asked the old boy if he could be permitted to see the estate—was it near—would they be passing by. The old one looked at the young one, and his eagle, tiger-slaying eye glittered, his cheeks flushed red against his snow-white whiskers. "This Ceylon fellow is trying his jokes so soon. We will have to sit on the Ceylon fellow." In withering sarcasm which missed its mark he told the Ceylon fellow he had seen the best to be seen, though he was sorry he could not come up to Ceylon standard apparently. I (the Ceylon fellow) was puzzled. Where were the expected columnar stools of noble rhizomes bending their graceful fronds lovingly over their scattered fruit-laden racemes? Why we had come through jungle with occasional small young plants. I spoke: "But these are all young, are they not?" "A little younger than usual through damage from the heavy monsoon, but if you can find finer in Mysore, you will be clever." I walked behind my boss, and felt I had put my foot in it. The young lad from home was longing to put his knife and fork into something. The forest was naturally divided into three great valleys. The centre one was the chief division. There was the boss's bungalow and the assistant's. The western one was deeper in the Ghauts, and though it had, like that other valley, a bungalow, clerihew, and waterwheel, yet it was not at that time occupied. The superintendents had to provide themselves with horses and got R15 a month allowance to keep them. R6 for horsekeeper, R2 for shoeing, R6 say for horse food. On coffee estates where grass is more scanty and wages higher, one gives R8 for horsekeeper, R4 for female grass-cutter, R2 for shoeing (sometimes R1-8) and say R5 for food. A great deal of riding was done. The boss insisted that his men should have their horses always at hand. Crop time lasted from August to February, and a weary work it was to a man who had been 10 years at coffee. To leave a country where were all one's friends, to take an S. D.'s billet, to learn a new language, to learn new methods, to put up with being classed with 7 youngsters newly out from home—nay put under one with 3 months' experienced, to be at the level once again of favourite maistries spying to one's superior, and feel other influences at work as in days that one considered gone for ever;—besides this to be advised by one newly out that it is wrong to give anything to a native with one's left hand or to salaam with one's left hand, to be tied to a gang of wandering coolies; throughout the live-long day in dark dismal jungles following these hordes of coolies where never was a line marked out, where never was an ounce of manure, where all was chaos. Where was there any brain-work, where any room for showing one's worth? Sunk to the level of a "ganger," at the mercy of fortuitous circumstances, it only wanted the clank of the chain and the rattle of the bars to complete the idea of a prison. Monotonously stooping at occasional straggling clumps of cardamoms and pulling each particular capsule to see if any would come off. If one did, what abuse, what a torrent of hard words! The gangs moved on through the dark forest, then came the "jooleemen" or searchers to see if any fruit was missed, then the maistries, then the sad Ceylon durai sickly thinking of Dimbula or Namunakulakanda. His unkempt horse (for how could the horsekeeper be out all day, cut grass, groom, boil food for horse and himself?) kicking off the leeches and

munching the coarse grass of the forest. Then he would mount and ride home through monotonous melancholy forest. Though shikar was abundant I cared not to go. I hated cardamom planting, or rather picking and weeding. There was n't much *planting*. The weeding I managed to improve. That is instead of once a year sickling the grasses and undergrowth, the stuff was pulled up. When cardamoms were at R5 per pound the extravagant plan of setting the coolies to roam abreast and complete the round every twelve days was all right, but the hope of the old gentleman that he could last out these confounded Ceylon fellows I found to be futile in my last visit to Ceylon. It cost on this big place in Mysore in a big crop something over the rupee f.o.b. per pound. It cost Ceylon men something under 8 annas per pound f.o.b., and then the Ceylon style is cheap for other reasons. The fields are supplementary to the other chief work. The cardamoms fruit all the year round, a 40-acre field in the care of a maistry and a few select coolies will give as much as all those weary dark and dismal expanses of forest. The deliverance came at last, and I left with happy heart. I had one little joke the whole time. It was the way I pulled the Ceylon fellows' legs about the thousand acres of cardamoms and the tons of fruit. It was a dismal joke, and W. F. L. and G. P. were angry for a while. Also about the clipping. It was a clipping joke! Ceylon men, as you will see from Mr. Elliot's remarks, are not altogether favourites, but they are appreciated. A Mysore man insists that his brother from Ceylon shall keep the name of that island out of the conversation. A gentleman who used to be near Kelebokka, now in the north of Mysore, is finding this out. "Dry up about Ceylon now." Even at the meet I described to you in a former letter they had a piece recited which had for a refrain at the end of each verse, "That's the way we do in Ceylon." But they laugh on the wrong sides of their faces. I will stick up for Ceylon and wish all there prosperity and success. ABERDONENSIS.

TEA CULTURE IN ASSAM IN 1886.

The annual report on tea cultivation in Assam for 1886, is a most interesting document. It shows the great advance this important industry has made, and the changes that have been introduced during the past year.

We find that there were altogether 883 gardens at the close of the year, against 941 in 1885. This large decrease is more apparent than real, and is accounted for by amalgamations of small gardens with the estates to which they are attached. There were actually ten new gardens opened and sixteen old ones closed. The remainder of the decrease in numbers was due to amalgations. As a matter of fact, there was an increase of 18,288 acres in the area of tea grants, as compared with the previous year. In Sylhet alone, 9,417 acres were added, while in Sibsaugor and Darrang 7,607 and 3,970 acres, respectively, are shown as having been added during the year. It is, however, explained that this increase is partly owing to a revision in figures in the case of Sylhet and Sibsaugor, and to affiliation of existing waste-land grants, (not previously returned) to tea grants. Cachar has the largest area under tea,* viz., 258,022 acres; next comes Sibsaugor with 202,525; Sylhet with 152,106, Lakhimpore with 155,440, and Darrang with 109,346 acres, the remaining four districts having 87,395 acres between them, making a total of 934,134 acres under tea grants, against 915,846 acres in 1885.

A pleasing feature of the report is that, of the 883 gardens in the province, the managers or agents of no less than 770 have complied with the request of the Chief Commissioner to supply him with statistics of tea culture. In the majority of cases the information was promptly supplied, but in a few it was delayed. The past was the first year in which the definition of a 'mature' plant, as one four years old and upwards was adopted. From a table showing the land actually under tea cultivation for the last six years, we gather that the area under mature plants increased from 133,293 acres in 1881 to 170,138 acres in 1886; while that under immature plants rose from 25,134 in 1881 to 37,634 acres in 1885, but which fell to 33,855 acres in 1886. Thus by taking the figures under mature and immature plants together, a true comparison will be obtained of the area under cultivation in the last two years. The increase under mature will then be balanced by the decrease under immature plants.

A noticeable feature of the past year's record is that in the Cachar district the total area held by planters decreased, while the area under cultivation increased. The tendency in this district is to extend the planting of tea upon low-lying lands formerly grown with rice, and to abandon hilly lands on which tea is found to be less profitable. This is rather an important point, as it has been generally held that tea could not be grown upon rice lands. With regard to the generally accepted policy among managers, viz., to increase the area as much as possible without increasing the labour force, the opinion of a Mr. Milne of Cachar is quoted. This is to the effect that, in order to produce the crops as cheaply as possible, old worn out parts are being gradually abandoned, and the best soils available are being planted out with the class of seedlings which may reasonably be expected to yield better result. with the same expenditure of money and labour. "This," says Mr. Milne, "explains the curious fact that, in spite of low prices, constant large additions are being made to the area." The total area returned as under cultivation is 203,993 acres, against 197,510 acres at the close of 1885. The largest increase occurred in the districts of Cachar, Sibsaugor and Lakhimpore. In these three districts the expansion is steady.

The outturn of leaf, as reported by district officers, amounted to 61,719,678 lb., or an increase of over 8 million lb., when compared with the returns of 1885. These figures do not agree with those published by the committee of the Indian Tea Association, which states the outturn to have been 59,320,512 lb. The year 1884 was generally recognised as a bad one for tea: In 1885 the industry barely recovered itself, but last year the reaction was very evident. The rate of outturn of leaf per acre shows it to have been an average of 317 lb. in 1886, against 249 lb. in the previous year. Most Deputy Commissioners concur in stating that the increase in the yield per acre is due to the extensions of former years coming into full bearing. The largest yield per acre, viz., 508 lb, occurred in Lakhimpore; Goalpara comes next, with 403 lb; then come Sylhet, Sibsaugor and Darrang. With these figures before us, we are somewhat surprised to find the Deputy Commissioner of Goalpara taking a despairing view of the prospects of tea in that district but the Commissioner of the Assam Valleys districts remarks: "Tea is so successful in the Western Dooars, that I am surprised no one has tried the Eastern Dooars; they are beautifully drained." Here is a hint that might be taken advantage of by intending tea planters.

The quantity of tea exported during the financial year, ending 31st March 1887, according to the figures furnished by the steamer companies in whose vessels it is carrried down to Calcutta, amounted to 53,240,091 lb., against 49,763,816 lb. for the previous year. Hardly any tea is made before April, and some that is made during the last months of the working season is carried down during the first quarter of the next year.

Turning now to the cost of cultivation and manufacture, it may be stated at once, that anything like reliable figures are out of the question. The following averages of the cost per lb. in the Calcutta sale-room,

* No: not under tea, but total land held.—ED.

for a fair number of gardens in each of the districts named, are quoted:—

	A.	P.
Cachar	6	10
Nowgong	6	11
Lakhimpore	6	0

The following figures have been furnished by Messrs. Barry & Co. for 18 gardens in the Assam Valley and 23 gardens in the Surma Valley, showing the average cost per lb., including sale charges:—

		A.	P.
Brahmapootra Valley	1885	8	7
	1886	8	1
Surma Valley	1885	7	7
	1886	6	10

We are further told that all the Deputy Commissioners, and those managers who have expressed any opinion on the subject, are unanimous in attributing the bad prices of 1886 to the supply being in excess of the demand. The Deputy Commissioners of Sylhet and Cachar add that coarse plucking in some cases, contributed to the fall in prices.

On the subject of brick tea, the Deputy Commissioner of Kamroop, in his report on his annual visit to Divangiri, writes: "A few packages of brick tea are brought by Thibetan traders, who dispose of them in small quantities to Bhootias. From enquiries which I made I am quite satisfied that there is no opening whatever for Indian teas in Bhootan or Thibet, even if made in brick form. In the first place, the method of manufacture is different, and our teas do not suit the Bhootia taste. Secondly, the sale in Thibet is apparently a monopoly; and Indian teas, even if low-priced, would meet with no encouragement. Thirdly, carriage is so difficult and the routes are so steep that no trade in the article of any importance could be established. The carriage of four or five hundred pounds worth of brick tea would absorb all the available carriage of the country."

After such a decided expression of opinion, the attempt to manufacture brick-tea in India, and open up a market for it in Thibet, would appear to be well nigh hopeless.—*Indian Agriculturist.*

NOTES ON PRODUCE.

"The supply of Indian tea that has been put on the market since the first of this month has afforded an opportunity of forming a tolerable opinion of the quality of the present crop," says the *Grocer's Chronicle*. "During July, in any year the arrivals are never of sufficiently large quantity to base an opinion upon, as experience has always shown a considerable improvement subsequently. But since the arrival of the S. S. 'Vega,' a very fair selection of useful and desirable tea has been brought to market with satisfactory results to importers and growers. Buyers talk as though they were having to pay an advance on previous values, but the quality has improved so much over early arrivals that it is incorrect to say prices have advanced when the quality has also improved to an equal extent. Up to the present time the palm has undoubtedly been carried off by the teas from the Terai district. Some good teas have also been brought forward from the Dooars, but the bulk of the arrivals from Assam, Cachar, and Sylhet are still of only middling quality. Sylhet is decidedly inferior to last year, Cachar barely up to last year, whilst Assam varies somewhat, the produce of one or two gardens showing a marked improvement, whilst that of others is disappointing. No doubt this is due to the climatic conditions under which each lot was picked and prepared, and there is little doubt but the average quality of the present crop will be quite equal to that of any recent year. The firmness of the market is no doubt, partly due to the diminished export of China tea. According to the latest telegrams the total exports from all the Chinese ports amounts to 56 millions, against 85 millions in 1886, and 84 millions in 1885. Evidently the low rates at which China tea has been selling in this market for some time past are now sufficiently remunerative to induce operations on the same extended scale as formerly. But there need be no apprehension of a tea famine whilst India and Ceylon are likely to furnish over 100,000,000 this season. In view of the short supply of China tea, the position of Indian tea seems a strong one, and as the crop gives every indication of being quite up to the average as regards quality, its continued advancement is assured."

In a Foreign Office report, issued during the month, on the trade of Foochow for 1886, by the British Acting Consul, it is remarked, as bearing on the adulteration of Foochow teas, that at the beginning of the season a large quantity of what is known as "lie tea" was offered for sale. The fraud was clumsily carried out, and soon discovered in consequence, and a considerable portion of the spurious leaf was seized by the authorities, and afterwards burned. Proclamations were also issued by the Likin authorities, warning the people of the consequence of continuing to make counterfeit tea, and to place it on the market. Attention has again to be drawn to the great development in the manufacture of brick tea from dust and broken leaf by the Russian merchants. In 1886 brick tea has to be credited with more than four-fifths of the total increase in the export of tea of all kinds during the year, and almost the whole of it goes to Siberia. The export of 1886 is valued by the Russian exporters at close on 900,000 dols. One of the Russian firms has employed steam machinery in the manufacture for some time, and now another of them is introducing it, also intending to make bricks smaller in size and more attractive. It is expected that the export will again show an increase at the end of 1887.

The possibilities as regards the extension of coffee culture in the Brazils with free labour are indicated by the following story of what has been done by a single planter in the province of Sao Paulo. It is quoted from a Sao Paulo paper:—"In 1879 Dr. Martinho Prado purchased land in the then almost unknown district of Ribeirao Preto for a coffee plantation. The land had a few coffee trees, but it was twenty leagues from the railway, and its resources were untried. He at once began clearing the land and procuring free labour for the service. Now, eight years only have lapsed, and with the following results—a railway has reached that locality; the plantation possesses about 500,000 bearing trees and a large number of new trees; and the present coffee crop is estimated at from 60,000 to 70,000 arrobas. This same plantation, called 'Albertina,' has a capacity for about 600,000 trees more, and the same proprietor is now opening up another great plantation on the Mogyguassu, near the station of Martinho Prado, on which it is expected that 2,000,000 trees will be planted in the next two years."—*H. and C. Mail.*

RUBBER IN ASSAM.—An Assam correspondent writes to us:—

Rubber has been my business for many years back. I shall be glad to give you any information in my power about the Assam rubber. The most erroneous ideas prevail about it; for instance, the Forest Department in Assam have made plantations on the ground, whereas the plants should have been put on very high trees—the higher up the better—or on steep hillsides; if they were perpendicular for 100 feet or more the better. Another erroneous idea is that this rubber takes 34 years before it can be tapped. It can be tapped in 12 years. I have known a tree yield five maunds which was sold at 80s. per maund, but that was a very large tree; three maunds is often got from a tree that has never been cut before. I should like to publish a letter at home showing how the rubber is adulterated and spoilt in Assam. Could you give me the address of any paper at home that would put in a letter of this sort?

Our correspondent should write to the *Indiarubber and Guttapercha and Electrical Trades Journal*, published in London.

Correspondence.

To the Editor of the "Ceylon Observer."

KURAKKAN AND THE RIPENING PROCESSES IN CEREALS: THE MERITS OF DHOLL.

Mullaittivu, 23rd August 1887.

DEAR SIR,—While reading your editorial about the "Ceylon Medical Journal" in the *Weekly Observer* of the 12th instant, I came across the following extract from Dr. Kynsey's leading article of this new periodical:—"Like the maize in Italy there may be something in the mode of cultivation, gathering, storing or preparation of this grain (kurakkan) for food which may render it unwholesome and disease-producing; but in drawing attention to this I believe that Parangi is present among people of the island who never eat kurakkan. However the food they use may be rendered unwholesome by the same treatment that kurakkan is subjected to." I hope the following passage which I quote from Professor Tanner's "Elementary Lessons in the Science of Agricultural Practice," page 262 and 263, may throw some light upon what makes kurakkan so unwholesome a food in the form it is commonly used by natives:—"It is very commonly supposed that the ripening of corn has been completed when it is carried to the stack in good condition; but farmers and their ploughmen know better than this. New oats are looked upon with suspicion, and their use delayed, as long as old oats are within command on the farm. When the corn has been in stack for four or five months and especially when frost has passed through the stack by the cold, piercing wind penetrating it, the farmer knows that he may then use the oats with safety. The change which takes place during this time has yet to be determined by analysts. It is, however, more than probable that much of the nitrogenous (flesh-forming) matter existing in the oat when harvested remains in an imperfectly matured condition. What the farmer understands by this *ripening in the stack*, is probably the change of this nitrogenous matter into the more perfect form of gluten or some corresponding albuminoid. Some may be disposed to enquire, how it is that farmers and their ploughmen can know anything about such a point *of character*. The old saying applies here as in another case. 'The proof of the pudding is in the eating,' and here also the use of the oat as food gives the necessary proof. The ploughman finds the use of new oats causes an irritation on the skin of the horse, which soon leads to mischief and disease. The horse, instead of deriving that nourishment from the new oat which shall enable him to do his work, finds the food give more inconvenience than support, and he rapidly loses condition in struggling to accomplish his daily task. In the meantime, the imperfectly ripened nutriment has to be separated and removed from the blood, so that it is not merely in a large degree useless, but it is distinctly injurious. The more usual mode of ripening the oat is by the influence of cold, and the farmer then recognizes the oat as being in good condition; but this could not take place in very large stacks of corn. The thickness of these stacks effectually prevents the air penetrating to any great depth: but even here the oat ripens, but from a different cause. That which cold accomplished, warmth also effects. The larger size of these stacks causes a moderate warmth to be produced, which spreads through the stack, gently and slowly, accomplishing the necessary changes. We find a somewhat corresponding ripening taking place in other kinds of vegetation. The details of these changes have yet to be determined by chemical analyses: but the farmer knows when these changes have taken place, and that they are necessary, and the light of science will in due course give us the fuller information we need."

Again while speaking about wheat Professor Tanner remarks (page 264) "The complete ripening of wheat is an important and necessary sequel, to the early stage of ripening which precedes the placing in stack. What are the chemical changes which take place in this final stage of ripening, has not been fully determined. Farmers and millers are both aware of the necessity which demands it; and although some small portion of our wheats are ground before this ripening is completed, yet the injurious effects have to be checked by grinding in with them some old wheat."

Now from these passages, I think it may be fairly inferred that parangi may be in a great measure due to the use of kurakkan while new, *i. e.*, before it sufficiently ripens in the stack. The poor villager being, perhaps, pressed by scarcity of food and consequent hunger, cannot afford to wait till this subsequent ripening of the grain takes place. As is implied in Dr. Kynsey's remarks other native cereals, too, may prove unwholesome when not subjected to the necessary process of ripening in the stack. For instance, food prepared from new paddy is looked upon as heating, and people too often complain of dysentery, diarrhœa or boils after using such food. But, of course, the degree of unwholesomeness would differ in various kinds of new grain; and kurakkan in this imperfectly developed condition, seems to be about the most unwholesome of the ordinary native cereals; and its almost exclusive use predisposes the eater to the attack of the dreaded parangi disease.

But as Dr. Kynsey says there are other predisposing causes, too, such as the use of salted fish with little or no milk, eggs or fresh meat, impure water and air, &c. The consumption of buffalo milk and curd to excess is also said to have something to do with parangi. If this is true the dirty habits of buffaloes, especially their drinking filthy water, may account for the fact.

It is, however, with the greatest diffidence that I express my opinion on such a subject and should only be too glad if I could derive any further information from your columns about this dire disease to which we see several miserable victims in the Wanni. But I may safely say in conclusion that kurakkan whether new or old is in general a comparatively heating food and should not form the sole or even the chief article of food. Natives would do well to take to cultivating dholl for food rather than kurakkan in dry lands. Dholl is in great repute in India as a very wholesome and nutritious article of diet and may do much good to the poor suffering humanity in the feverish and parangi-stricken villages in Ceylon. It is now being extensively cultivated in village agricultural school gardens and the seed is also largely distributed among the villagers at the special order of our Director of Public Instruction. It is being rapidly introduced into the Mullaittivu district and there is scarcely a compound in the Mullaittivu town without at least a few dholl plants growing in it. They are grown with little or no trouble and do not exhaust the soil, as their hardy roots go deep down and absorb nutriment from the subsoil. It will be clearly seen from these facts that the dholl recommends itself from an agricultural as well as from a sanitary point of view and bids fair to supersede the much suspected kurakkan in the chenas and other dry lands of the villager and to form a favourite article of his food.

Hoping you will be pleased to give insertion to this letter in your valuable journal, excusing me for the rather long quotation, yours respectfully,

E. T. HOOLE.

[One of the alleged merits of dholl, in common with the whole of the pea and bean tribe, is, that the bulk of the nitrogen required by such plants is derived from the atmosphere.—ED.]

WHITE-ANTS AND YOUNG COCONUT PLANTS

Pate Rajah Estate, Ambalangoda, 5th Sept.

DEAR SIR,—Could any of your readers tell me of a *certain* protective against white-ants destroying coconut plants? I have tried salt, sea-sand, kerosine oil, habaroo, &c., with no satisfactory results.—Yours faithfully,

A. T. B.

[Our publication, "All about the Coconut Palm" (a copy of which "A. T. B." and all coconut planters ought to have) states that arsenic is the only cure.—ED.]

SUGGESTIONS AS TO HOOPING TEA PACKAGES FOR LOCAL SALE.

Colombo, 5th Sept. 1887.

DEAR SIR,—The lids of packages should be in two or more pieces, one piece being *un*hooped, allowing such portion to be removed for sampling without cutting the hoop iron. If this was attended to, it would save the sampler considerable time and trouble and the packages would appear much neater after nailing up.

I notice some planters hoop the top and bottom corners of their chests only. Packages, unless the side planks are of one piece of wood, require strengthening at the *sides*, so as to prevent the bottom half of the package coming away from the top. If your planting readers want an illustration of this, I would recommend them to go on board ship and see their packages being stowed away in the hold.—Yours faithfully, FRANCIS F. STREET.

TEA WITHERING.

Matale, Sept. 5th, 1887.

DEAR SIR,—I forgot to mention why I wrote for information about withering. If I am not mistaken the "Planting Molesworth" says "4 lb. green leaf=3 lb. withered," *i. e*, a 75 per cent wither. Rutherford's Note-book 100 lb. leaf withers down to 67 lb. and I have been told it is safe to wither down to 57 per cent. That means that leaf can safely be withered from 75 per cent to 57 per cent, a difference of 18 per cent. Now I wish to ask practical planters and I hope they will answer me, if withering down to 75 per cent will not break the leaf in rolling?—and if 57 per cent the leaf will not be overwithered?

One of the best tea makers, I might say the best in the island, says overwither rather than underwither. While a correspondent to the *Indigo Planter's Gazette*, from which you copy in *T. A.* page 133, August 1887, writes:—Be careful not to overwither, better to be a little under done. In the latter case you lose a few tips, and get some broken tea, but you save the liquor, while in the former case all the strength has gone, and you get a hard, dry brassy liquor."

If these questions are answered I should wish to ask a few more, because a beginner reading books on tea manufacture reads portions that seem to contradict each other. E. B.

COFFEE "GREEN BUG" IN COONOOR.

SIR,—Now that this new "pest" has shown itself on some of the estates in the Coonoor district, may I ask those planters, through your valuable paper, to let no false delicacy prevent them from giving publicity to their efforts in trying to stay this new calamity for such it is sure to be. If an effort is not made to stop it in its early stage it will be a bad look out. There must be a cure, so let all those affected try and find it, and then tell others what they did, so that we may be ready with a remedy when our turn comes. All the talking in the world won't stop it, nor will it disappear by saying "I have it, but do not think it will spread." What I say is, if you have it, try to get rid of it.

Coonoor, 24th Aug. N. HAY.

—*M. Mail*, Aug. 27th.

THE SIZE OF BREAKS OF INDIAN TEA.

To the Editor of *The Home and Colonial Mail*.

Sir,—As September 1st draws near, when every one fully expects the new regulations as to the size of sampling breaks to come into operation, there are rumours afloat to the effect that some importers are unwilling to consent to the proposed alteration. I venture, therefore, to ask for space in your columns to make an appeal to them not to put any difficulties in the way. I think the proposed limit of twelve chests, twenty half-chests, and forty boxes, will really be the minimum that it will be possible to entertain, if business is to be carried on in daylight, during the next six months.

I extremely deprecate such a thing as a conflict between buyers and sellers. Mutual forbearance and good will ought to rule. The large buyers have shown wonderful forbearance for years past, whilst little lots of eight or ten half-chests have been sold the net weight of which perhaps would barely equal four chests. Even on the proposed scale twenty half-chests will frequently contain but 800lb.; and as almost any buyer can now deal with thirty or forty chests it seems to be time the planters should aim at bigger things than they did thirty years ago.—I am, &c.,

D. F. SHILLINGTON.

THE FUEL OF THE FUTURE.—This question, which is down for notice at the Dimbula planters' meeting, is becoming a very serious one in regard to tea. Coal is twice the cost of wood, and it seems doubtful if kerosene oil can be obtained for less than twice the cost of coal. Our hope largely centres in oil residuum, *deodorized*, if that is possible, and perhaps mixed with charcoal or coke. There is, of course, the greater danger of the inflammability of oil, but from a long and interesting article in the *American Oil Review*, which we shall quote, its superiority otherwise over coal seems very great. Fewer men are required, there are no cinders or ashes, and the heating power is said to be considerably more than twice that of coal. For use in tea factories the odour is the great objection, but science can no doubt overcome that objection. The question will then be one of price.

THE DECREASE IN PALMYRA PLANTATIONS.—A correspondent justly complains of the decrease in palmyra plantations in the North. We have indeed, more than once, remarked with anxiety the lamentable fact now brought to our notice. As our correspondent says, people go on cutting down trees by hundreds, and never, it seems, at present, dream of supplying the voids so made by fresh plantations. Besides the trees felled for home use, great numbers are yearly exported to India, yet "vadalies," or young palmyra plantations, hardly ever meet the traveller's eye. Formerly, it was a custom among the country landowners, at the birth of a child, to plant a field with palmyras, which would begin to produce when the child came of age. Why has such a profitable custom fallen into disuse? We believe the reason is that the new generation find that palmyras take too long growing. Men are not satisfied now with what was ample for their forefathers. They must have a quick and large return. They do not mind which will be most profitable in the long run, they want to see the result at once. If you plant coconuts, before ten years they begin to produce, and they bear largely. Palmyras will not bear before 20 years, and their produce is not easily convertible into money; therefore, men conclude, palmyras are not worth planting. This is very pernicious reasoning. Coconut planting is very good indeed, but palmyra planting presents advantages not a few. Palmyras are slow growing, but they last much longer, at least three times as long as coconuts; palmyra fruit does not sell as coconuts do, but one coconut tree occupies as much ground as at least twenty palmyras; a drought or a storm will destroy a number of coconut trees, though perhaps not a single palmyra will suffer. Besides, and above all, when the coconut tree is too old to bear, it is all over with it, it cannot be turned to any practical account, whilst palmyras by their timber will bring in a large income. Such being the case, we cannot too strongly urge the people of the North to revert to the good old custom of planting palmyras."—"Jaffna C. Guardian."

PLANTING IN NETHERLANDS INDIA.

(Translated for the *Straits Times.*)

In the matter of adulteration, the Chinese are never at a loss for inventiveness. They are fully up to every trick of trade. Take for instance ground coffee. Since, that article has risen in price at Surabaya the Chinese dealers have mixed it with burnt maize so artfully that the falsification is only detected on using the mixture.

At Batavia on the 26th August, the date of the last advices, there was hardly anything doing in the produce market, though sugar and coffee showed tendency to a rise. As to sugar, it has been so often confidently asserted that prices must go up before long, that growers who waited for it had got impatient. They saw nothing of the kind coming. When it at last drew near, the change for the better proved to be too late for the many who had found the contest too much for them. At the outset of the crisis, there was no lack of dark pictures setting forth the evil consequences inevitably following the ruin of the sugar growing interest. Pity was especially expressed for the natives who would be deprived of opportunities to earn wages on sugar estates as coolies, thereby diminishing their power of purchasing imported goods. Yet, after several sugar plantations have been closed with the result of lessening the circulation of money among them, the import trade has been brisk notwithstanding. The Javanese for all this do suffer a great deal from Government compulsory labour and burdensome taxation.

A Netherlands merchant who has spent many years in the Indian Archipelago is, by last advices, doing his best to start a cultivation company in Holland for planting enterprise in East Borneo. His efforts to arouse interest in that country in Holland, have met with sore discouragment. The country itself is almost unknown in the mother country. Yet it abounds with coal and possesses a soil of high fertility. The land is, however, underpopulated. Doubtless the labour difficulty blocks the way.

The coffee crop in Bali this year, has fallen far below the average. A heavy decrease is noticeable in the quantities brought to market.

Tamil coolies have been tried and found wanting in West Sumatra. They had to be discharged owing to their turbulent character. This is however only the first trial with them there. Subsequent experimenting may turn out more successfully. Perseverance may result in the selection of better material. Failure at the outset is to be expected until the right way is hit upon at length. In Deli for instance, pioneering was no easy work at the start.

A correspondent of the *Java Bode* who has paid a visit to Deli, says that life there is not at all pleasant in comparison with Java. Yet capital and labour flow abundantly into the whole coast from the Acheen frontier to the southern boundary of Palembang. So great is the number of Europeans flocking thither from Java where planting prospects are gloomy indeed, that appearances point to their being rats leaving the sinking ship. In Deli itself almost all the available land has been taken up. The pioneers of civilisation have hence betaken themselves to more southerly districts. There the jungle on the seacoast has been cleared away to make room for tobacco fields. In Siak alone, more than thirty leases have been issued to planters. The local sultans and chiefs welcome monied pioneers with open arms as a matter of course. Quit-rent and land assessment bring them in a large revenue. They draw handsome fees from sealing, signing, and delivering the leases. Many of these estates are heavily backed by British or German capital. Some planters have a solid firm to draw upon, but those who try to get on trusting to themselves only find it hard work indeed to keep above water. Desertion and death among their labourers resulting in heavy losses by advances to them and in half cleared fields remaining uncultivated, a strict coolie ordinance, worms and locusts among their growing crops, inferior subsoil, and vicissitudes of the weather soon bring on the ruin of a young estate. Even when everything has been squared with the native authorities, the planter encounters difficulties with the European officials on the score of demarcation marks which are not easy to find or rightly fix amid jungle and bush. The settlement of boundary questions leads to lengthy correspondence and grievous trouble before a settlement is arrived at. This circumlocution policy comes with ill grace from a Government which has enriched itself with an overflowing revenue from districts opened out by the planters, in the shape of customs duties, registration fees, and sundry forms of taxation. Very little of all this money is spent for the benefit of the country, the balance going to swell the Java revenue. So disregarded are the requirements of the planters, that applications from them for the importation of firearms for the defence of their estates sometimes lie pigeonholed for a year, before the officials concerned come to a decision. Custom houses are set up at every river mouth for the levy of duties on almost every necessary of life. The planters are harassed by revenue demands, and by the need for filling up lengthy and burdensome official forms regarding their estates. The rattan forbidden to the planters, is freely used by the Government in the prisons. The inmates of the latter are said to be so grossly neglected that the estate coolies are far better off as regards medical attendance and rate of mortality. Remonstrance and protest against such an objectionable policy have alike proved unavailing.

On some of the estates on the East coast of Sumatra, the managers evidently require a tight hand over them on the part of the authorities. In Serdang the Controller has been obliged to take prompt action against the manager of the Timbang Deli estate, owing to his harbouring absconding coolies from other estates. The consequence was that the estate became the resort of all kinds of bad characters. Several Europeans who had gone thither to recover runaway coolies, were received in such a hostile manner that they had to beat a hasty retreat. The Controller thereupon set out for the spot himself, accompanied by policemen and several Europeans to recognise the coolies. On arriving, they found that the manager had made himself scarce. Of 200 coolies known to be on the estate, only 40 put in an appearance. The balance found it to their advantage to hide themselves in the neighbouring jungle. On the estate itself confusion and disorder reigned supreme. By degrees about 70 more coolies turned up who almost all of them proved to be absconders. They were, one and all, duly sent back to the estates to which they belonged. Some 60 remained in hiding in the bushes. The estate itself presented such a scene of bad and neglectful management, that the Europeans present asserted with one accord that it was scarcely possible such a state of things could exist now in Deli. The head tindal who, apparently had played a leading part in employing the absconders has been taken in custody. The owners of the estate will now endeavour to make the best of it with a new manager. This incident affords another instance of the need for prudence in selecting managers, to avoid loss of money and good name.

With the steady growth of planting enterprise on the East Coast of Sumatra and the continual increase in the number of estates, new brands have made their appearance in the tobacco market. Good and bad tobacco from the same estate is forwarded under different brands—the superior kind naturally under the same brand, but the inferior under fancy ones giving no clue to their place of origin. This practice has only come into vogue since last year. Buyers who have paid dearly for tobacco fancying that it was the whole crop of an estate will naturally feel aggrieved on finding out that, under novel brands, tobacco from the same estate has passed into other hands. A continuance of this practice cannot but harm the Deli planting interest.

Planters in Deli not only suffer from lack of Chinese coolies on the estates, but also from turbulence among those whom they have had the luck to secure. The other day, about fifty coolies from the Rimbun estate made their appearance before the Government

Controller in the neighbourhood, and lodged a complaint regarding the valuation of the tobacco delivered by them to their employer. They however did not care to inform him that they had committed deeds of violence on the estate, had threatened to illtreat a European overseer, and had refused to depute three men to see the Controller instead of going to him all in a body. These shortcomings were brought under their notice. They however refused to return to the estate, upon which they were all marched off to prison.

The Battaks, too, have taken to harassing the planters. Those of the Rayah tribe have fallen out with the Sultan of Deli's people, and have proved so defiant that the Controller and a force of armed natives have proceeded to the seat of disturbance. The Rayahs are expected to get the worst of it. These troubles have every prospect to prejudicially influencing the work on estates in the neighbourhood. Other Battaks seek to injure the planters by fire raising. On one estate they laid a bangsal stored with tobacco in ashes, and fired two others which only escaped a like fate by the prompt rendering of assistance. To admit of the fire gaining headier hold, petroleum had been freely used. The incendiaries left behind them several threatening letters, intimating that the action they took had for object to avenge the murder of a tribesman years ago on the estate by other Battaks. The manager of the estate had nothing at all to do with the murder.

THE PRESENT POSITION AND PROSPECTS OF THE COFFEE MARKET.

LONDON, August 25th, 1887.

A year ago we drew the attention of our friends to the strong position of coffee, and the probability that an advance would take place before long. On the 1st September, 1886, the European stocks of coffee had decreased to about 145,000 tons, against an average of 217,000 tons in the previous three years. The rise which we foresaw did take place, and was carried, during the first five months of 1887, to a point which few people anticipated a year ago. Prices are high now, and it is worth while examining whether present rates are justified by circumstances, and by the prospects of the article for the future.

We stand now much as we did in 1886. The stocks in Europe and America on August 1st were estimated at:—

	1887	1886	1885
	Tons	Tons	Tons
Europe	154,000	155,000	220,000
United States	41,000	33,000	30,000
Total	195,000	188,000	250,000
	1884	1883	1882
	Tons	Tons	Tons
Europe	226,000	217,000	185,000
United States	31,000	23,000	21,000
Total	257,000	240,000	206,000

With the exception of the stocks remaining at Rio and Santos on 1st July (estimated at 29,000 tons against 25,000 tons in 1886) and what remained of the old crop in the interior, (probably less than in previous seasons), the 1886-7 Brazil crop may be said to have been all received in Europe and the United States and to be included in the general stocks, whilst scarcely anything has been shipped as yet of the new crop. The exports from Brazil to Europe and the United States for twelve months ending 30th June, amounted to:—

1886-7	1885-6	1884-5	1883-4	1882-3	1881-2
Tons	Tons	Tons	Tons	Tons	Tons
348,000	335,000	390,000	313,000	391,000	328,000

on an average of 350,000 tons in the last six years.

During the same time the crop in Java have been:—

1886-7	1885-6	1884-5	1883-4	1882-3	1881-2
Tons	Tons	Tons	Tons	Tons	Tons
68,000	43000	82,000	87,000	80,000	76,000

or an averag, of 72,000 tons in the last six years.

We have now entered, however, upon a season which is likely to witness an extraordinary falling off in our supplies from the two leading producing countries. Owing to protracted wet and cold at the critical time of blossoming, and subsequent unfavourable weather, the Brazilian crops are turning out extremely small. The Rio and Santos firms have been unanimous in announcing for months past a great reduction in the outturn, which is estimated, as a maximum, at 1,000,000 bags or 240,000 tons for both crops, whilst several firms estimate the yield at not more than 3 to 3½ million bags.

The receipts of new crop, which began on July 1st, and amount up to date to 314,000 bags for Rio and Santos (against 737,000 bags in 1886 and 877,000 bags in 1885) are, so far, a striking confirmation of the Brazilian estimates. The prices of 80s to 85s obtainable in Europe would, in ordinary circumstances, induce the most strenuous efforts on the part of planters to hurry their crops to market, yet Brazilians hold their coffee with the greatest tenacity at prices which are from 5s to 10s per cwt. above those ruling in the consuming markets.

In Java, where leaf disease has been committing great havoc, the weather has also been unfavourable, and the result is the smallest crop known for may years. The Government crop will propably not exceed 300,000 bags, to which may be added 200,000 bags from private plantations, say, 500,000 bags together, or 31,000 tons, against 68,000 in 1886, and an average of 72,000 tons in the last six years.

Brazil and Java are not likely to contribute more than 275,000 tons for the twelve months ending 30th June 1888, against 415,000 tons in the previous season, and an average of 422,000 tons in the last six seasons. From no other quarter are there any indications of an increase in the production, which might to some extent counterbalance the Brazil and Java deficiency of some 140,000 tons. As at the rate of consumption in 1884 and 1885 (about 620,000 tons, exceeding 400,000 in Europe and 200,000 in the States) the production of coffee was just equal to the requirements, whilst the diminished supplies of 1886 led to a reduction of 70,000 tons in the stocks at the end of that year, it follows that the short supplies expected for the present season will be totally inadequate to the world's requirements, and that a considerable shrinkage of consumption must necessarily take place, otherwise the stocks now held, together with the supplies for the next twelve months, would be entirely absorbed, which is inadmissable. This can only be brought about by high prices, under the influence of which the trade have already been restricting their purchases during the last few months, leading to a considerable decrease in the deliveries; but there are strong indications that invisible stocks in consumers' hands are getting everywhere exhausted, and that a more active trade demand will soon set in, and we cannot help thinking that we shall then see prices carried to a higher level than we have seen them yet, as we greatly question whether the real consumption of coffee has been affected much, so far, by the enhanced price of the article.

We have left out of calculation any effect on prices from the movements which may arise in the several markets where large bull and bear speculations are carried on. The apparent supply of coffee may at times appear to be largely increased, whilst at other times the demand for real coffee to cover bear sales may add a powerful stimulus to the trade demand, and thus lead to excessive fluctuations.

Patry & Pasteur.

THE "TEA COMPANY OF CEYLON," UDUGAMA DISTRICT.

We recently made reference to this projected tea Company, and have just received some further particulars, which may be of interest to our readers. The land is described to us as being, without exception, heavy forest on an undulating lay of land. The lake, which we described as being situated in the centre of the land, is quite as large as we stated, and is found on examination to be very deep, having two or three very large streams flowing into it. The bund has a height of some 30 feet to 40 feet, a large stream of water overflowing the spill. At the foot of the bund, and some little distance from it, is the old sugar factory, still standing, with the vats, the crushing machinery, and the water-wheel, all complete. The whilom proprietor of the land has been utilizing the water-wheel, supplied as it is by an enormous stream of water, for the purpose of sawing timber, with which the land is very heavily stocked. There cannot be the slightest doubt that the present proprietors of the land—Messrs. J. F. Baker, Shelton Agar, and Hall—have a very valuable venture to offer to the public, as we believe they will very shortly do. Surveyors are at present at work cutting out the boundaries of this block of land, said to contain 2,178 acres, of which 500 acres in the centre (including 60 acres of lake) are now being felled, and nurseries are shortly to be laid down for future plantings. From the description which we have received of the lay of the land, we should imagine that no finer investment than that shortly to be offered in this Tea Company exists in Ceylon. One great point in favor of the Company will be its extreme accessibility, and the great facility of transport afforded, for we find that it has transport by river both to Galle (by the Gindura-ganga) and to Bentota (by the Bentota river), whichever is deemed preferable, as both streams pass in juxtaposition to the land.

TEA AND COFFEE AS SANITARY BEVERAGES.

(From the *English Mechanic*, Aug. 12th.)

Nearly every article of human consumption, *taken in excess*, has a deleterious effect on the system, more or less, according to the climate and constitution of the consumer—notably the above two vegetable products in daily domestic use.

Analytical investigation has long ago discovered two active principles, *theine* and *caffeine*, both of which proved fatal to cats in some laboratory experiments. The fresh leaves of the tea-plant are powerfully emetic, a property only removed by the bruising, squeezing, and rubbing they undergo on coarse bamboo mats in the first stage of manufacture. When the rolling tables are annually cleaned, this poisonous juice is found inspissated, or in dry masses. Some specimens were forwarded to Europe for examination; but I have never heard the result.

The infusion of high-class properly roasted leaf generally diluted with milk, on the moderate scale of a cup or two with a hearty meal, is highly beneficial to the digestive organs, being a very mild stimulant of a soothing character. Its value was recognised during a great epidemic of Asiatic cholera in France, for use of convalescents, who had a particular longing for this liquid food. It is also much prized in that country as a pleasant drink for sufferers from cold, and coughs. Only chemists keep tea in stock there, and no tea-dealers or grocer vendors (or were not at the time I mention), for our Gallic neighbours call it a *medicine*. In my own case of "Insomnia," produced by overstudy, very strong green tea, prescribed by an amateur homœopathist, on the usual *similia similibus* formulary, proved very effective. I was reading hard at three Oriental languages (often till midnight) and was brain racked by hard-worded phantasms—this, too, in spite of daily rides and many outdoor recreations. The counter excitant proved the stronger to the nervous system, and I soon slept well and naturally. Of course, there must be no milk in the infusion, and I have eschewed that animal fluid from boyhood, having a dislike to it—like the Chinese with whom I have occasionally enjoyed a cup of pure, aromatic Bohea, tasting only of itself.

Newly manufactured teas are stored in bulk for a year or more, with the object of ridding them of the acrid volatile principle adherent to the fresh leaf, besides adding aroma to the same. The Celestial opium-eater long ago discovered this "pick-me-up" preparation, without which aid he would have succumbed to sleep and sloth; still, he is short-lived.

No doubt the all day long tea-drinking habit of a few individuals in this country induces premature decay by impairing the functions of the stomach, and then the nervous system. I know a town practitioner who has been preaching widely to domestic servants on this addiction to "too much of a good thing;" but how much worse and more general is the abuse of alcohol, the gluttony in fat-producing aliments, and many other self-indulgences of modern life! For many years after I arrived in tropical climates I could not swallow the usual early morn cup of tea without the attendant emetic effect of ipecacuanha; hence I took a disgust to the beverage, and substituted iced water, or the coldest I could obtain, with much benefit to my stomach—a natural tonic of invigorating character, if the element be chemically pure.

The preparation and consumption of tea-leaves doubtless originated in China; hence the traveller in N. E. India comes across what is locally termed "Indigenous tea," scattered in occasional belts and patches over the great wilderness of Upper Assam, and in the forests of the Shan frontiers, where man without written language hunts the abundant fauna. He is fond of the native leaf; having collected a supply of the young shoots and buds, he pounds them between stones, kneads them, and mixes with salt. When dry, he gets a hollow joint of the large bamboo and rams this queer mess into the cavity. He slings this crude tea-caddy by a fibrous string over his shoulders, and when in want of the cheering cup he picks out some of the ugly, dirty compound with the point of his trade knife. I never saw his teapot or kettle, but having used a joint of bamboo as cooking-pot for rice myself in Savageland, I suppose the wild man can boil his tea equally well. In Kashmir and Central Asia "brick tea" is in popular use. This is merely any good sort of tea reduced to dust and kneaded with sheep's blood into small oblong slabs (for the sake of portability, I imagine). A large iron pot is placed on the fire; when the water boils, a large piece of the brick is thrown into it; then soda, bitter aromatic drugs, salt, sugar, butter, &c.—a most awful brew, which for politeness sake I have accepted, and secretly emptied on the ground, while I used to mutter, "Deliver me from *such* an afternoon tea." The colour of said decoction resembles that of a mountain torrent in first flood, ruddy and turbid! There are many agreeable substitutes to my thinking: fresh mint leaves with a slice of

lemon and a bit of sugar candy, or balm leaves, similarly used, as an infusion; or of lemon grass slightly acidulated with citric acid. All these are sudorifics, if taken hot, and great quenchers of thirst, too; they are of immense value in the febrile disorders of hot climates, where they act as "diuretics." I recommend them all as dog-day drinks in Great Britain; their cost, too, is within the reach of a beggar! As a milk hater, they are doubly valuable to me. ECS.

[The writer of the above is a pragmatical person who believes himself capable of teaching his grandmother. Tea is bad because extracts of theine and caffeine proved fatal to cats! Then a country doctor warned domestic servants against the evil effects of too much tea. Those who indulge in such excess are like those who are loved by the gods,—they die young,—witness Dr. Johnson. But even the writer benefited by the use of green tea when he had overset his brain by studying three languages at once!—excess with a vengeance. Tea is *not* prepared as he describes, and the best authorities are now agreed that tea is indigenous in India and was introduced thence to China. Curious that tea, which to the writer is so objectionable, should be recognized as an excellent medicine (which it is) in France. The article is a mass of contradictions and will not deter any sensible person from using tea.—ED.]

ON OIL AS A FUEL.

[The following is the article we alluded to recently as worthy of the attention of Ceylon tea planters in discussing the question of "the fuel of the future."—ED.]

C. W. Owston, Cleveland, has issued the following upon the subject of oil as fuel, in the form of a circular:

Inasmuch as the use of oil as a fuel is now engaging the serious attention of many of our principal engineers and manufacturers, we beg leave to submit for your consideration the following advantages which are claimed for oil as against coke, coal or wood as a fuel.

1st. A petroleum fire can be held in perfect control by one man of ordinary intelligence by the mere turning of a valve. He can increase or decrease the fire at will, and can maintain steam or heat at any desired point. When the fire is properly regulated to produce the heat required, it can be kept at that point with but slight attention, so slight, indeed, that one man can fire and care for a battery of from eight to ten 100 horse-power boilers without difficulty. By turning a valve you can instantly extinguish the fire, if occasion does not require its continuous use, and it can be again started with almost the same rapidity with a few shavings or sticks of wood. There is no waste, as with coal, when the work is done.

2nd. The heat generated with petroleum fire is much more uniform than that produced with coal or wood. The fire is not as sensitive to the fluctuation of the weather as other fires. A great advantage is gained in running machinery where regularity of speed is desirable. A constant supply of steam may be furnished, and there is no reduction of steam pressure in consequence of the replenishing of fires.

3rd. Economy of Boiling Capacity.—It has been demonstrated that one pound of oil will evaporate the water of more than two pounds of coal. The heat units of crude petroleum have been erroneously stated to be 27,531. The fact is that the correct figure, 29,240 heat units, has been repeatedly arrived at of late, after many tests with the best instruments to be obtained for that purpose. In comparing the calorific properties of petroleum it must be borne in mind that with coal there is an enormous waste of matter, such as sulphur, slate and earthy substances which are practically incombustible, and which do not add in the generation of heat. While coal theoretically contains about 14,300 heat units, that figure is by reason of these impurities reduced to about 8,000. Pure carbon—charcoal, for instance—contains 14,500 heat units. Considering, therefore, the imperceptible waste in the burning of oil, and the excessive waste in the burning of coal, the conclusion is reached that while theoretically the relative proportion of heat evolved in the combustion of oil compared with coal is as 20·2 is to 14·3, the proportion practically considered, is in favour of oil as 19 is to 8, or 8·5 at the furthest. We may quite safely assume, then, that the heating capacity of oil is considerably more than twice that of coal as far as now shown. With a clean boiler, properly attended, and with the best of coal fuel, well stoked, night and day—with every care to insure combustion and to avoid waste, the evaporation obtained in some isolated cases specially recorded has been as high as 9½ pounds. In our every-day experience, however, we find that eighty out of a hundred boilers will not vaporise more than from 7 to 7½ pounds of water per pound of fuel. On the other hand, oil tests which, while sufficiently conclusive for the present have not by any means been carried to the furthest limit, show the vaporization of from 18·24 to 19·5 pounds of water per pound of oil consumed, estimating feed water at from 212 deg. Fahrenheit.

4th. Economy in labour, cleanliness and safety are secured, as in burning oil complete combustion may be obtained. There is no shoveling of ashes, and consequently there is a great saving in labour. The absence of sparks and cinders and the ability to extinguish the fire instantly in case of danger makes it very desirable when considered with a view to safety.

5th. There being no necessity for opening doors for the introduction of fuel, there is no fluctuation of heat, and no sudden chilling of the flues and boiler. The absence of sulphur in the fuel makes its action on the metal of the boiler and the flues much less destructive than coal, and the flues remain cleaner and in better condition to absorb the heat.

6th. Oil or residuum, is without doubt the coming fuel on locomotive and ocean steamers, and by its use a great annoyance to passengers in the emission of cinders and smoke will not only be entirely avoided but less than one-half the room formerly used for coal will be required to store the oil for fuel, and only one-third the weight will be carried, thus saving a great deal of room in storage, which will enable shipowners to carry an additional quantity of freight, or to increase speed to the same amount of power. Besides this, where 70 stokers are now required to unload coal on ocean steamers, at least 60 could be dispensed with and the work be done without the labor of shoveling coal, and the great discomfort from heat and dust.

7th. Regarding the proper construction of furnaces for the consumption of oil it may be said that there is no occasion for having the combustion chamber as large as when burning coal. The latter article, being solid matter, requires more time for decomposition and the elimination of the products and supporters of combustion. Coal fuel requires a large firechamber and the means for the introduction of air beneath the grate-bars to aid combustion. Compared with oil the combustion of coal is tardy and requires some aid by way of a strong draft. Oil having no ash or refuse, when properly burned, requires much less space for combustion for the reason that, being a liquid and the compound of gases that are highly inflammable when united in proper proportions, it gives off heat with the utmost rapidity, and at the point of ignition is all ready for consumption. The changes required to burn oil in a coal furnace may be made at a nominal cost, so that even in this respect no additional expense is necessary for a change for the better.

8th. Three barrels of oil, each of 42 gallons, equal and slightly exceed the heating capacity of one ton of coal. The oil weighs 913·5 pounds and may be purchased and delivered in tank cars at any point in the United States at a very low figure. It should be remembered that oil need not be shoveled from the cars to the furnace, it needs no stoking nor poking, it leaves neither cinders nor ashes to be carted away and it makes no smoke. With an oil furnace one man may attend to a dozen boilers without any further assistance.

9th. The fact of being able to produce with oil a perfectly clear white fire, free from ashes, smoke, dust

and soot, which can be kept under control and regulated to any degree of heat required, makes its use invaluable in the manufacture of glass, steel, crockery, stoneware, sewer pipe, brick, and in fact almost any business where such a fire is required. This is shown by its having been adopted as fuel by the following manufactories, where it can be seen in operation, and to which we refer.

[A large number mentioned.]

In the glass works at Chicago and Canton and the steel works at Detroit and Cincinnati, a much better quality of glass and steel have been manufactured since the adoption of oil as a fuel than when coal was used. In the paper mills at Lima and Niles from 20 to 25 per cent have been added to their product by its use, and in the burning of lime and in the manufacture of illuminating gas, the very best results have been secured.

The use of oil as a fuel and heat producer is no longer an experiment. Improved forms of burners and methods of applying are being rapidly introduced, and events in the past few months have demonstrated its entire practicability and economy over the ordinary methods. The cost of adapting it to any furnace or boiler is very small, and, owing to its extreme simplicity, it can be applied without serious delay or important alterations, and can be changed from burning coal to oil, or from oil to coal with very little delay or expense. In addition to the manufactures named above the Calumet Iron and Steel Works of Chicago, the Cleveland Rolling Mill Co., the Britton Iron and Steel Works, and many other Cleveland work are using oil as a fuel successfully and a great number of the largest works of various kinds throughout the country are arranging to introduce it as rapidly as possible.—*Oil, Paint & Drug Reporter.*

[The one great difficulty is the cost of freight for a material so bulky and dangerous. Our hopes lie in bricks of the crude material mixed with pounded coke or charcoal, or some like substance. —ED.]

COCONUT raising is a growing industry in Southern Florida. Pineapple and coconuts pay very well. Ten thousand pineapples can be raised it is said to an acre, and the same amount of space will support coconut trees. The latter require very little cultivation. They begin to bear at from nine to twelve years of age and produce from 80 to 150 nuts to the tree. They bring about five cents apiece to the grower. Many groves have been planted within a few years. One new Jersey gentleman has 330,000 trees.—*Indian Agriculturist.* Of course the number of coconuts per tree is grossly exaggerated. —ED.

A LARGE number of planters in Brazil have just been very neatly hoist with their own petard. Two years ago a law was passed providing for the gradual emancipation of the slaves, of whom the empire still contains a large number. One of the provisions of this law was that every slaveholder should register the number and individual value of his slaves, and the period allowed for this registration expired at the end of March last. On the registers being overhauled it appeared that only a relatively small proportion of the slaves in the country had been "declared." The bulk of them had been omitted in order that their owners might escape the small registration fee to be paid on each slave.* As many of the planters own large numbers of slaves, the saving to them was considerable. Every slave not registered, however, [illegible] to claim their freedom: but the Brazilian Sambo has many friends. It appears, however, that most of the slaves who have so far become entitled to their liberty are voluntarily remaining with their old masters as hired labourers.—*St. James's Budget.*

* [illegible] Ceylon in regard to predial slavery.—ED.

INDIAN TEA.—In the Returns of Trade at the Treaty Ports in China, published under the Imperial Maritime Customs, there is more than one allusion to the successful competition of the Indian teas with the Chinese leaf. Mr. R. E. Bredon, Commissioner of Customs at Hankow, report that "all the tea buyers say that Indian tea is the tea of the future for people who can afford to pay for a good article"; and that there is now no reliable market for choice China tea except in Russia. He says that cheap kinds of tea can be produced in China and sold to the foreign buyer "to suit any pocket"; and that they can be made quite drinkable "by the addition of a few pennyworths of good full-flavoured Indian." Mr. C. Hannen, the Commissioner at Foochow, makes similar remarks on the neglect in the London market of teas "over a shilling a pound"; and says that last year the native dealers, by injudicious purchases from the growers, suffered severely from the falling prices. On the other hand, the overland tea trade with Russia enormously increased in 1886. This growth the Commissioner of Customs at Tientsin attributes to "the unusual luxuriance" of the Mongolian pastures which supply food to the dromedaries on whose backs the tea is transported. The Russians, however, recognising the fact that the experience of last year was in this respect exceptional, are busy with alternative railway schemes, one of which, involving the construction of a railway from Stretensk to Veringukunsk on the Amoor, seems to offer great advantages.—*Overland Mail.*

CAPABILITIES OF SOCOTRA.—A correspondent writes to the *China Mail*, suggesting several means by which our recent acquisition—the island of Socotra —may be rendered more useful. He says:—The British have just taken over Socotra and hoisted their flag there. There add, however, many things that must be done in order to make the place useful to us. First of all, it wants a light on its N. E. end, which might be seen 20 to 25 miles. If such a light had existed the "Oder" would not have come to grief. But what I think deserves most attention is the admirable manner in which the island is adapted for forming a garden from which we could provision Aden. I remember seeing, some seven years ago, the botanists that went over it. They were delighted with the island and said it would grow anything, tea, sugar, coffee, cotton &c. The best aloes in the world grow there, and dragon's blood trees may be found growing wild all over the island. There is plenty of water, and a warm temperature. It is 70 miles long, by 22 miles broad; there are hills in the centre 4,000 feet high; and it is only about 500 miles from Aden and the entrance of the Red Sea. We have got a grand island if we could only realise it and make good use of it. Now that Aden is to be made a great place and have about 4,000 troops, Socotra would seem as if placed there by Nature to become a store-house for it. And in order to develop the place best, I think China is the place to draw the labour from. The condition of things is exactly suited to the Chinese patient, steady hand labour. If some 300 men [illegible] pigs, poultry, &c., along with carpenters, road-[illegible] would [illegible] market for their produce at Aden.—*Singapore Free Press.*

ROYAL GARDENS, KEW.

(From the Bulletin of Miscellaneous Information.)

[*Introduction of certain West Indian Food-plants to the East Indies.* In the following notes information is given respecting certain food-plants from the West Indies recently introduced to the East Indies, and which are now established in the latter. These are the Tree Tomato *(Cyphomandra betacea)*, the Chocho (*Sechium edule*), the Arracacha (*Arracacia esculenta*), and the Cherimoyer (*Anona Cherimolia*).

The introduction of the Arracacha was first attempted, at the instance of the Government of India, in 1879, but, after many failures, was only successfully accomplished in 1883. The Chocho was introduced Ceylon by means of a single plant, which survived the journey direct from Jamaica to Ceylon, in January 1885. The Tree Tomato and Cherimoyer were introduced by seeds, which travel well and are more convenient for distribution than plants. In a few years, no doubt, all these plants will be widely distributed throughout the East, and they will be found useful additions to the vegetable diet of both Europeans and natives. Already the Chocho introduced to Ceylon as recently as 1885 is to be found in the local markets; and the Tree Tomato is mentioned "as a most valuable acquisition to Southern India."

All the four plants here mentioned are likely to thrive at Hill Stations in India and in all districts suitable for coffee and cinchona cultivation. They are sub-tropical rather than tropical in their requirements, and hence no doubt they will be found of service in South Africa, in certain parts of Australia, Northern New Zealand, and in hilly districts generally throughout our tropical possessions. The information here summarized will indicate their usefulness as food-plants and the sources both in the Old and New World from which future supplies of seeds and plants may conveniently be obtained.]

TREE TOMATO.

(*Cyphomandra batacea*, De Candolle.)

Although called a tomato, this plant, which is a native of the Andean regions of Tropical America, is a large free-growing shrub or small tree often attaining a height of 8 to 12 feet. The fruit in form is more like that of the egg-plant or brinjal, but in colour and flavour it more nearly approaches the tomato. Like these two, however, it belongs to the natural order *Solanaceae*.

* * *

On the mainland of Central America it is known as the Tomato de la Paz, in Jamaica as the "Tree Tomato," and sometimes, on account of its supposed beneficial action on the liver, "Vegetable Mercury." Plants are easily raised from seed, and come into bearing in about two years. They are very prolific bearers, and the fruit is available during the winter months, November to March, when ordinary tomatoes are not so easily obtained.

If the fruit is allowed to fully ripen on the trees it may be eaten raw, and it has somewhat the flavour of gooseberry. If the skin is removed and the fruit (without the seeds) stewed with sugar, it resembles apricot, but with a slight sub-acid flavour, which is very refreshing.

Mr. Miers (Hook. Journ. Botany, 1845, p. 358) describes this plant under the name of *Pionandra batacea*, and mentions that "this is doubtless the same fruit that I saw in the markets of Lima, where it is commonly used for cooking in lieu of the ordinary tomato the flavour of which it resembles."

The Tree Tomato was introduced to Jamaica many years ago, and it is sparingly met with on old coffee plantations in the hills of St. Andrew and Manchester. It does not flourish in the plains. Its range of elevation in Jamaica is from 2,000 feet to 5,000 feet, with a range of temperature from 72° to 63° Fahr. It is found at Madeira and the Azores, and cultivated in the South of Europe. According to Dr. Masters, the fruit is occasionally seen in Covent Garden Market under the erroneous name of "Grenadilla." Plants are grown at Kew in the Temperate House and also in the cool Economic House. They generally bear late in the autumn, and hence the fruit seldom ripens properly and is not in good order. Through the agency of the Botanical Department at Jamaica, seed of this plant and information respecting it, have been widely distributed throughout British Colonies, and it may now be considered fairly established in most of the regions of a sub-tropical character suited to its growth.

In the Report of the Director of the Botanical Gardens, Ceylon, for the year 1884 it is stated that the *Cyphomandra batacea* "is a close ally of the ordinary Tomato, and a native of Peru and neighbouring countries, but cultivated on the hills in many parts of South America and the West Indies. Its fruit, which is red, and the size of a pigeon's egg may be employed in all ways like the tomato, and resembles it in flavour. Seeds have been received from Jamaica, and there are now many young plants at Hakgala."

In the Report for the year 1885, Dr. Trimen mentions that at Hakgala at 6,000 feet, some of the tree Tomato plants "are now 11 feet high, and the fruits produced are very fine. They are egg-shaped, about 3 inches long and 2 inches in diameter, and when fully ripe are of a bright yellowish-red colour. They make excellent tarts, are very good stewed, and are much relished by most people when quite ripe, and eaten raw like gooseberries. The plant is very robust and easy to grow here, and I believe it will thrive and be very profitable from an elevation of 2,000 to 6,000 feet. Under favourable conditions the plant remains in bearing for many (10 or more) years."

In the last Report to hand, that for the year 1886, it is stated that "the Tree Tomato has spread rapidly through the hill country. This fruit keeps well after being gathered, and as it has a tough skin and travels well, it might be largely cultivated in the villages for sale in the towns."

CHOCHO.

(*Sechium edule*, Sw.)

This is a cucurbitaceous plant well known in Tropical Amercia, where its wholesome fruit is commonly used by all classes as an article of food. In Brazil it is called *Chuchu*, in Jamaica *Chocho*, in the French islands *Christophine*, in the English colonies *Vegetable pear*, at Madeira *Pipinella*, *Chayota*, or *Chahiota*,

The plant is a climber with three to five-cleft tendrils, and a smooth somewhat stout stem rising from a very large fleshy perennial root having the appearance of a yam. The leaves are heart-shaped, rough to the touch, and five angled. The flowers are green or yellow, with separate male and female flowers on the same plant. The fruit is pear-shaped, about three to five inches long, covered with soft prickles, and either green or cream coloured. The one seed or kernel is like a large thin almond. There are two well-marked varieties, *(a)* with flower and fruit of a pale green colour, and *(b)* with flower and fruit rather larger, cream coloured or white.

As a West Indian plant reference is made to the Chocho by Hans Sloane and Patrick Browne, but it was first described and named by Swartz, Fl. Ind. Occ., Vol. II., p. 1150. It was mentioned and figured by Jacquin as *Chayota edulis* (Amer. ed. pict. II. tab. 245). Descourtilz places it under *Cucumis acutangulus* (Fl. des Antilles, v. 94, tab. 328) as common in the Island of St. Christopher, and gives a fairly good drawing of the fruit, which, however, has nothing to do with *C. acutangulus*, Linn., now known as the common Luffa. The plant was recently figured and described by Cogniaux in Flora Brasiliensis. Vol. II., pt. 4, p. III, tab. xxxv. In this the fruit is evidently drawn from dried specimens and is not good. A better illustration of the fruit from a spiecimen received from Madeira, with a description by the Rev. M. J. Berkeley, is given in *Gardeners' Chronicle*, 1865, p. 51.

De Candolle states that "the plant is probably a native of the South of Mexico and of Central America, and was transported into the West India Islands and to Brazil in the eighteenth century."

At present, it is widely distributed in all parts of Tropical America, and it has also been introduced to Madeira and the Atlantic Islands, from whence the fruit is sometimes sent to the English market under the name of Chayote.

The introduction of this useful plant to some of our possessions in the East Indies was effected during the last two or three years, and already very gratifying accounts have been received of it.

In the West Indies the Chocho is cultivated in the hills, and it flourishes at temperatures ranging from 63° Fahr. to 75° Fahr. It apparently fails in the lowlands, and may therefore be looked upon as requiring sub-tropical rather than tropical conditions. It is easily propagated by planting the whole fruit, which after germination of the seed gives rise to a persistent amorphous rhizome of a woody or a fibrous-fleshy character. The stem can easily be trained to grow over fences or arbours; but failing these, it spreads along the ground, and has then much of the habit and appearance of the common vegetable marrow.

The Rev. R. T. Lowe, who met with this fruit at Madeira mentions (Flora of Madeira, p. 292) that boiled it is a favourite vegetable and highly esteemed. It resembles a young pumpkin rather than a cucumber, but when ripe is somewhat firmer, drier, or more mealy in consistence, with a peculiar nutty flavour. "The larger cream-coloured or white-fruited variety is better looking, but it is not considered so good as the green variety."

Macfadyen on the other hand states (Flora of Jamaica, Vol. II., p. 141) that the white variety "is by far the more delicate." He adds, with the addition of lime-juice and sugar, it supplies an ingredient for tarts; the root when dressed is very wholesome and palatable, and can scarcely be distinguished from the yam."

Lunan, in 1814 (Hort. Jamaicensis, Vol. I., p. 182), states that "the fruit is an agreeable, wholesome vegetable, but is much improved by lime juice, by salt or spicy ingredients. Mixed with lime juice and sugar it is a good substitute for apple sauce. The vine bears all the year round and makes very good arbours. The root of the old vine on being boiled or roasted is farinaceous and wholesome. The seeds (of which each fruit contains only one) are very good if taken out after the fruit is boiled and fried with butter.

The introduction of the Chocho to Ceylon was effected by means of the Botanical Gardens in that island. In the Report of the Director for the year 1884, p. 13, it is stated that a case of plants received from Kew in October were all dead on arrival, but that out of a box of germinating seeds sent direct from Jamaica in the following January one survived, from which afterwards three rooted cuttings were obtained.

In the Report for 1885, p. 11, it is stated that the "Chocho" has been successfully established at Hakgala from the single surviving seed of those sent from Jamaica in January.

Mr. Nock, Superintendent of the Hakgala Gardens, reports:—

"After being nursed up in the propagating house for a few weeks, the plant was put out at the end of February into the nursery. It commenced to bear in May and has continued to do so ever since, affording an excellent crop. The vegetable (fruit) it produces is pear-shaped, and the average weight is 3½ lb. The plant being perennial adds greatly to its value.

"As it is the first that has been grown in this country, it may be useful if I state the best way of cultivating it. It thrives best in a rich deep well-drained soil, but may be made to grow anywhere by preparing the site in the following manner:—Make a hole 4 or 5 feet in diameter and 18 inches to 3 feet deep according to the subsoil. If the subsoil is good and free, you may go to the depth of 3 feet, but if it is clayey or likely to hold water 18 inches will be quite deep enough. Place a layer of rough stones at of bottom of the hole to a depth of 6 to 9 inches for drainage, and over this a few inches deep of small twigs or half rotted leaves to prevent the fine soil from getting between the stones and choking the drainage. The hole may be filled up with the following compost: one-third ordinary garden soil, one-third half-rotted cattle or stable manure (cattle manure preferred for hot sandy soils, and stable manure for cold clayey soil), and the remaining third may be formed of leaf-mould, sand, wood ashes, lime, and the sweepings of the poultry yard, in about equal portions. When the hole has only been taken out about 18 inches deep, it will be necessary to raise the soil 18 inches above the ground; indeed in every case except in very dry districts it is best to raise it. The whole fruit, which is sent out in a germinated state, must be planted about 3 inches deep in the centre of the hole. It begins to grow at once, and in a week or 10 days, it will have made a good start. It is a creeper, and each plant will require a space of about 20 feet square."

"The Chocho also does very well at Peradeniya, but the fruit does not there attain quite so large a size. I think it will be less suitable for the lower elevations. I consider it to be a very valuable introduction, and a real addition to the vegetables of Ceylon. It most resembles the vegetable marrow, but is, in my opinion, superior in flavour to the best varieties of that vegetable."

In the Report for 1886 Dr. Trimen mentions that:—

"The Chocho of the West Indies (*Sechium edule*) has been widely distributed and has rapidly become common in the country. It is liked both by Europeans and by natives, and its easy culture is especially appreciated by the latter, by whom it is much esteemed for curries. I have noticed it for sale in the Kandy market at 1c. to 2c. the fruit."

In a letter addressed to Kew, dated 23rd October 1886, Mr. Nock mentions that:—

"The Tree Tomato and Chocho from Jamaica are a great success here. They are well established in different parts of the island and are much appreciated both by Europeans and natives. I should be much obliged if you will be good enough to use your influence in getting for us from Jamaica the *white* variety of the Chocho (what we have is the green one), and I am under the impression that the white variety will grow down almost to sea-level, and the green one here begins to feel uncomfortable below 2,000 feet."

ARRACACHA.

(*Arracacia esculenta*, De Candolle.)

The Arracacha is a valuable esculent common in the high lands of Venezuela, where it is regularly used as an article of food. The plant belongs to the natural order Umbelliferæ, and in appearance and habit of growth resembles the common parsnip. It is called in Spanish *Apio*, from its resemblance to the celery, as a substitute for which the blanched shoots can be used. The root is a fleshy tuber of large size, bearing numerous knots or tubers on the outside.

Of these the shoots on the upper surface inclining upwards give off leafy growths, marked about the base with horizontal rings bearing membranous sheaths, which afterwards wither away. These shoots when ripe can be broken away from the parent tuber and form new sets for planting. The other shoots, which are given off below the ground, are generally eight to ten in number; the largest measure about 6 inches long by 1½ to 2 inches in diameter. They are nearly of the same circumference throughout, tapering off suddenly and sending out a few fibres at the extremity. Their surface is nearly smooth, covered with a thin skin, marked across with transverse scars, like the roots of carrots. These underground shoots are called *hijos* (sons), and are the edible portions of the root, being more tender and more delicate in flavour than the main root or *madre* (mother).

The stem is 2 to 4 feet high, often streaked with purple. The leaves, rising directly from the root with long petioles, are deeply and irregularly pinnatifid. They are dark, green and shining above, paler beneath. The flowers borne in umbels are of two kinds; those in the centre are imperfect or bear stamens only, and have a flat disk in the centre.

The origin of this plant is uncertain. It is generally cultivated in Venezuela, New Granada, and Ecuador as a nutritious food plant. De Candolle staes that "the species is probably indigenous in the region where it is cultivated, but I do not find in any author a positive assertion of the fact. The existing descriptions are drawn from cultivated specimens."

"The best information about the cultivation of this plant was given by Dr. Bancroft to Sir William Hooker, and may be found in the *Botanical Magazine*, tab. 3,092. A. P. de Candolle published in *La 5° Notice sur les Plantes Rares des Jardin Bot. de Genève* an illustration showing the principal bulb."

From notes supplied to Kew in October 1882 by Mr. D. Morris, who had cultivated the Arracacha at Jamaica, we find that it is propagated either from seed or from "sets," the latter being off shoots from the main stem, which are freely produced, and grow with great facility. The valuable part of the plant is the root. During growth this gives rise to a number of small tubers or "fingers," eight or ten in number. The largest are from 8 to 9 inches in length, and about 2 inches in diameter. They are yellow or white in colour, with a smooth surface, and marked, like the carrot, with transverse scars. At Bogota, the main root is styled the *madre*, while the young edible tubercles or fingers are called *hijos* (or sons). The younger fingers are considered the best, the older ones being fibrous and strongly flavored.

The plant grows in almost any soil; it prefers, however, rich cool hollows, and in such situations is most prolific. It will even grow in stiff clay soils, as well as in those of a light sandy character, but under such circumstances the yield is not so great. At the Government Cinchona Plantation, Jamaica, it is planted in ridges, like potatoes, about a foot or 18 inches apart.

The first crop takes from eight to ten months to mature; but being perennial, fresh shoots are continually thrown out, which give a succession of crops for several years. It would, however, be better to plant fresh "sets" at the beginning of every rainy season, and so secure a constant supply of young fingers.

To prepare Arracacha for the table, the roots are first scraped and then boiled; a little salt should be added; and if the roots are not quite young it is customary to change the water once or twice. After being boiled, they may be grated and employed as an ingredient for thickening soup; or better still, mashed, mixed with pepper, salt, and a little butter, they form a most palatable dish.

Dr. Bancroft describes the following method of cultivating this plant at Bogota:—After separating the upper tubers, or knobs from the root, detach from these the offsets, singly, each with its portion of the substance of the tuber, which is then to be pared smoothly all round at the bottom, the outer leaves being stripped or cut off, so as to leave a sprout from half to two or three inches at the most. If any germs or eyes be seen at the base of the offsets, these must be carefully cut out. Thus prepared, the shoots are planted in loose mould, in a slanting directions at distances of 15 or 18 inches from each other, whether the ground be level or sloping. Afterwards, at intervals of about two months, the soil ought to be weeded; and when the plants have attained the height of 10 or 12 inches, or whenever they show a disposition to blossom, the budding tips should be taken off, as the process of flowering would hinder the root from coming to its greatest size, care being taken not to remove more than the budding extremities, lest the growth of the root should thereby also suffer; with the same view, any luxuriance in the shoots ought to be prevented since it must be at the expense of the root. From time to time, and particularly after weeding the ground, fresh mould should be laid round the foot of each plant, to aid likewise in the enlargement of the root.

From a letter addressed to the British Consul-General at Bogota by Mr. Henry Burchall in 1878, it is gathered that Arracacha requires from 10 to 12 months to reach maturity, but the tubers may be gathered two months earlier if much wanted. In this case the produce is of course smaller, but it is said to be equally wholesome and agreeable to the taste. Mr. Burchall mentions that old or central portions of the root are never planted a second time, as they produce the *macho*, or a flowering stalk, and not edible roots. If seed is used instead of "sets" it would take two or three seasons before the plants attain their full growth. With ripe "sets," as mentioned above, the mature crop is reaped in 10 to 12 months.

A full account of the Arracacha is given by Diaz in *El Agricultor Venezolano*, from which we take the following notes:—

"The Arracacha is indigenous to Venezuela and New Granada, and belongs to the family of Umbelliferæ. "Botanists have distinguished it by the name of *Arracacha esculenta*, preserving thus its primitive Indian denomination, and it was the first Spanish Colonist who called it Apio, generalising this name in such a fashion that many Venezuelans do not now know what the Arracacha is.

"It is raised generally from division of the crown or root-stock, provided with buds or shoots, and also from the seed, though less advantageously from the latter.

"If it be requisite to raise from seed, a seed-plot must be prepared and care taken that there is no lack of watering; the young plants must also be thinned out where very crowded. When it is time for transplanting the seedlings, no more plants should be taken up than can be planted within the time, and they should be put meanwhile into water so that the roots are kept wet and thus unite better with the soil. The proper temperature is that of the cool zone at a height of 2,000 varas (yards), and the soil requires to be light, containing plenty of leaf-mould (humus) and well worked, as is necessary for all tuberous plants grown for their roots. It can be cultivated down to 500 varas (yards) but to little advantage, results improving gradually with the ascent from that level.

"The proper season in natural non-irrigated lands is in the two springs of May and October, but in irrigated and highly cultivated ones sowing or planting can be done at any time, the plant being kept well weeded, watered, and earthed up like garden plants. If three months after planting they are tied up like endive, the shoots become blanched, and can be employed as salad or be stewed.

"The ordinary use which we make of the Arracacha, which we call also apio, is to boil it r use it for forced meats or fritters. This root yields a large quantity of starch, and is preferred to "sulu" for the sustenance of invalids. It is in season at the fourth month.

"The Arracacha requires a black soil, light and deep, which favours the development of the roots. To propagate it it is cut in pieces, each with an eye or bud, and these are planted separately. After three or four months growth the roots are sufficiently developed for use in the kitchen; if left in the ground for a longer period, they acquire greater volume without depreciation of flavour.

"The colour is white yellow or purple, but these variations do not affect the quality. The Arracacha which is most esteemed is produced in Lipacon, a small town situated two leagues north of Santa Fé de Bogota.

"The Arracachas, like potatoes, do not thrive in very warm localities, in such places they form much leafage, but the roots are poor and insipid; in the temperate reigions the produce is regular, but increases considerably in the cooler parts of Columbia, in which the medium temperature is 58° to 60° Fahr., equal to 12° Réaumur and 15° Centigrade. It is there that the root develops best and acquires the most delicious taste.

"The flavour is agreeable and slightly sweet; the odour is peculiar, to some people very pleasant but very repugnant to others. Amongst animals this repugnance to the smell is not remarked; on the contrary, it appears to be exceedingly agreeable to them and to excite their appetite, since immediately they smell it they show a lively desire to eat, and all devour it with avidity and eagerly seek it. I have observed that animals can consume large quantities of the Arracacha in their daily ration of food without, in a single case, the least repugnance being remarked.

"In connection with the importation of foreign cattle, the Arracacha is of all plants the most valuable, since in the transits from Honda to Bogota it is the forage which they accept with the greatest avidity, and that which enables them the soonest to recover from the poor condition in which they arrive. During the first months, whilst they are becoming acclimatized, the Arracacha is almost the only food which will satisfy them, and they prefer it to green grass, hay, or any other forage.

"When the crop is collected, the roots with buds are separated and preserved for some days in order to form with them a new plantation; but before planting them in the ground for development it is necessary to shorten the stem attached to the bud to about an inch, because it is said that if this precaution be not taken, the plants will not yield Arracachas nor acquire the same development as they do when subjected to this mutilation. Furthermore the leaves are suppressed which have already been formed; at the time of planting they are cut off at about two to three inches from the collar.

"Among the cultivated Arracachas we have distinguished three chief varieties; the yellow, to which probably is due its name of xanthorrhiza, which is not applicable to the others; the white, so called because the root is perfectly white, like some radishes and turnips; and the violet or mulberry-coloured (morada), which is also white but has a violet or mulberry-coloured ring around the insertion of the crown, or similarly coloured spots upon the widest parts.

"The yellow is the most common and almost the only sort cultivated in many localities; it yields the largest crops, whether in numbers of roots or in their individual bulk. Of all the varieties the yellow is the most robust and resists best the inclemencies of the weather, but unfortunately it is also the tardiest grower.

"The white is much in demand amongst connoisseurs as it possesses a more agreeable flavour, softer texture, and other culinary advantages; amongst the cultivators it is esteemed for its precocity, although it suffers more than the yellow when the meteorological conditions are not favourable, and its yield is always less as regards weight.

"The violet or mulberry-coloured (morada) appears to possess the same qualities as the white, and to resemble that variety very closely both with respect to its merit as an esculent and as regards its cultivation."

"From Ceylon Dr. Trimen has recently reported that he has raised the *Arracacha* from seed obtained direct from Jamaica. He appears to have obtained the tubers without difficulty and in abundance. As a matter of taste, he has a less favourable opinion of them than Mr. Morris. But the point to which I wish to draw your attention is that the introduction of the esculent into India is accomplished, and that its further diffusion need present no difficulty."

In the Report of the Director of the Botanical Gardens, Ceylon, for 1884, the Arracacha is mentioned as "an umbelliferous plant, native probably of the Andes of South America, where it is cultivated up to 6,000 feet, was introduced into Jamaica in 1822, and produces large edible starchy roots, with the flavour somewhat of parsnip. Two or three attempts to import the roots in a living state into Ceylon have proved completely unsuccessful; but Mr. Nock has now succeeded in raising some young plants from seeds sent from Jamaica, which it is hoped will in time develop the edible portion."

In the Report for the year 1886 it is stated that—

"The Arracacha is not generally liked by Europeans (though some like it), but much enjoyed by all the natives who taste it. Mr. Nock reports a good stock at Hakgala, and I am prepared to distribute through the Government Agents small quantities to the headmen of villages at 2,000 feet or more elevation, in the hope of its culture being taken up by the villagers. Much interest has been excited in India by the successful introduction of this vegetable in Ceylon, and in answers to applications we have sent boxes of the roots to the Botanic Garden at Saharunpur, the Agri Horticultural Society of Calcutta, and the Chief Commissioner of British Burmah."

CHERIMOYER.

(*Anona Cherimolia*, Mill.)

This is a sub-tropical member of the genus Anona, a native of the Andes of Ecuador and Peru. Like the species which yield the sweet-sop, sour-sop, and custard-apple, the Cherimoyer is a tree of about 15 feet to 20 feet high, with loose spreading branches and velvety leaves. In botanical character it appears to hold a place between the sweet-sop (*A. squamosa*) and the custard-apple (*A. reticulata*); the leaves partake of some of the character of both, and the fruit is somewhat scaly like that of the former, and reticulated like that of the latter.

As in most plants which have been a long time under cultivation, there are numerous varieties more or less differing as regards the size and character of the fruit, but it is generally agreed that the Cherimoyer is the most delicious of its kind, the flesh being firm, of a flaky character, and possessing a slightly agreeable acidity mingled with a luscious sweetness. The flowers are pendant and velvety; they are generally closed in the day and open at night, giving out a delicate odour resembling that of *Magnolia fuscata*. On this account they are said to be put into snuff as a substitute for the Tonquin bean. The fruit is usually the size and form of the sour-sop, of a light green colour, with a snowy-white pulp and black seeds.

De Candolle, discussing the origin of this species, states that "the Cherimoyer is mentioned by Lamarck and Dunal as growing in Peru; but Feuillée, who was first to speak of it, says that it is cultivated. Humboldt and Bonpland saw it cultivated in Venezuela and New Granada; Martius in Brazil, where the seeds had been introduced from Peru. The species is cultivated in the Cape Verde Islands and on the coast of Guinea. Its American origin is evident. Claude Gay says that the species have been cultivated in Chili from time immemorial. In conclusion, I consider it most probable that the species is indigenous in Ecuador, and perhaps in the neighbouring part of Peru."

A rough drawing of the fruit is given by Feuillée, Joun. des Obs., Vol. II., p. 24, tab. 17; the leaves and flowers are figured in Bot. Mag., tab. 2011, under the name of *Anona tripetala*, Ait. The only recent figure intended to be given is by Rodigas in *L'Illustration Horticole*, N.S., pl. 563, but in colour and the absence of reticulations and of the subsquamate character inseparable from the Cherimoyer, this figure more nearly resembles that of the custard-apple (*A. reticulata*).

The Cherimoyer is very common in the mountains in Jamaica and it must have been introduced there many years ago. It requires such sub-tropical conditions as are connected with a mean annual temperature, 78° to 63° Fahr., an annual rainfall of about 80 to 100 inches, and a fairly rich soil.

It is fairly abundant at Madeira, whence the fruit arrives in the autumn to the English market. It is also found at St. Helena and on the coast of Guinea, and its introduction to the mountainous districts of Ceylon and India has now been assured.

There is a tall plant under cultivation in the warm Economic House at Kew, but it has not flowered or fruited here. Specimens of Cherimoyer fruits are represented in the Kew Museums from Lima, presented by Sir Spencer St. John; from Botanical Department, Jamaica, Colonial and Indian Exhibition, 1886; and a fruit grown at Wallington, Newcastle, presented by Sir W. Trevelyan.

Seed of the Cherimoyer in large quantities were sent from Jamaica to Ceylon, and in the report of the Director of the Botanical Gardens for the year 1884 it is mentioned—

"There is a good supply of seeding Cherimoyer trees available at Hakgala. The fruit of this tree is considered to be far superior to the other species of the genus Anona (the custard-apple, sweet-sops, &c.), but the tree is adapted only to the hill climate in Ceylon."

Diaz, in *El Agricultor Venezolano*, mentions that the fruit of the Cherimoyer is very much appreciated, and its taste very pleasant, specially in cool districts

in the hills where the temperature suits it best. It is used for dessert, like the medlar, peach, &c., &c. The external portion of the husk is said to contain an active acid. The pulp is employed as a medicine for the alleviation of inflamed ulcers and for the maturing of abscesses. The seeds of all the species of this genus when reduced to powder are used for destroying insects. D. M.

INDIAN EXPERIENCES.

Before entering upon my remarks on the Neilgherry Hills proper, I may be permitted to say a few words on a famous valley, which if not forming part of the plateau of the Neilgherry range, is situated at the foot of its north-western slopes and within its jurisdiction. The Coffee tree has been cultivated in this valley since the year 1842, and has always had a wide-spread reputation of being by far the finest Coffee-producing district of southern India. This tract is called the "Ouchterlony" Valley, from the fact that in 1842 the late Mr. James Ouchterlony, then a member of the Madras Civil Service, obtained from the Rajah of Nellumboor (who was at that time in possession of a vast extent of country lying at the base of the west and north-western slopes of the Neilgherries) some forty square miles of this valley, portions of which he subsequently resold for the purpose of Coffee planting, the remainder being cultivated by himself. The history of Coffee planting in this wonderful and delightful valley of South India, from the year 1842 to the present time is, I venture to think, a deeply interesting one, as illustrating the sad fact of how tracts of magnificent and fertile virgin land may be permanently ruined from the combined influences of mismanagement, want of knowledge of the first principles of agriculture, and the thirst for immediate gain.

As stated above, the valley lies at the foot of the north-western slopes of the Neligherry Mountains, and is surrounded on two sides by precipitous hornblendic gneiss rocks, the detrition of which in the course of ages has formed in the valley below a soil of wonderful depth and richness. The elevation above the sea of this valley ranges from about 3,500 feet to 4,250 feet. The climate is therefore much more cool and agreeable than that of the neighbouring district of Wynaad. The rainfall, too, is very moderate, not exceeding perhaps an average of 75 inches per annum. With all these advantages therefore it is not surprising to find that the yield of Coffee for some years after the purchase of the tract by Mr. Ouchterlony frequently reached the enormous figure of 20 cwts. per acre, and this without manuring or any cultivation save the keeping of the plantations as clear of weeds as possible, and pruning in a variety of ways according to the caprice of the various superintendents. Some 4000 acres of the valley are at the present time under cultivation of Coffee in the hands of the Ouchterlony family, while other large areas are cultivated by others who had the good fortune to obtain land from the original purchaser. For twenty-five years at least this valley yielded excellent crops of Coffee on an average, notwithstanding the unscientific and wasteful system that was adopted throughout the whole of that period, so deep and fertile was the soil worked upon and so favourable the climate. But a time came at last when the Coffee tree began to show signs of loss of vigour and the want of something more in the way of support than merely the natural food to be found in the soil of the valley. The taking of larger crops of Coffee than the trees could well support the absence of systematic cultivation, and the varied and haphazard style of pruning adopted told their tale at last, and aroused the proprietors of the several properties to a sense of the absolute necessity of employing men trained in the art and practice of horticulture, and the adoption of measures having for their object a more rational system of cultivation, with a view to retrieving their fast-decaying fortunes. But all this was found to be too late; the evil had taken too deep a hold to be eradicated, with the consequence that, notwithstanding the expenditure of vast amounts of money and well-directed energy, the Coffee properties in the once-famous valley have for a number of years been gradually decreasing in yield of berry and value, till at the present time considerable tracts of land, once covered with a mantle of magnificent Coffee bushes, have been planted with Tea and Cinchona.

It would be difficult to exaggerate the financial benefits that might have accrued to the proprietors of this particular portion of the Coffee districts of South India, if, from the first opening of the plantations, they had procured the services of well trained gardeners from England, say men of a certain age and experience, as superintendents, and younger men to work under them. This common-sense view of the matter, however, does not appear to have occurred to them, and men were engaged to perform the work of planting, and subsequent so-called cultivation, utterly ignorant of the first principles of agriculture or horticulture.* My first visit to the Valley was about the year 1864, on my way to Ootacamund. I stayed a few days in the neighbourhood with a friend, and had a good opportunity afforded me of visiting the different estates, and of seeing the various modes of pruning and cultivation being carried out at that time. I found that the late Mr. Ouchterlony had then, as general manager of his properties, an ex-captain of a Peninsular and Oriental Steam Company's ship, with his fifth officer as an assistant, whilst the resident superintendents of the different plantations included not a single gardener or person in the slightest degree trained to, or in the possession in the faintest degree, of any kind of knowledge relating to the cultivation of the land. These last individuals were made up of clerks, sailors, carpenters, ex-army officers and sergeants, doctors, and others of various professions. These men seemed to adopt styles of pruning and cultivation according to their various fancies, and not from any general rule set down by the manager. It was no surprise, therefore, to find one plantation so pruned as to appear, from a little distance, very much like a brown grass hill, so ruthlessly were the unfortunate Coffee trees deprived of their branches, whilst on an adjoining estate the wood left on the trees produced a tangled mass to the entire exclusion of light and air. Some had the ground dug between the rows of trees to a depth of 6 or 8 inches during the height of the dry season, destroying innumerable fibrous roots in the process of turning over the huge clods, whilst others disturbed not the soil from one year's end to another. Some buried the weeds in pits dug between the lines of the Coffee plants several times a year as they were hoed up, whilst others never buried them at all, but left them on the surface of the ground to die. Some disbudded, or handled as it was called, heavily during the rains, whilst others handled not at all, but performed the one yearly act of pruning with the knife during the dry season. Some there were who placed bone and other artificial manures at the rate of a half coconut shellful to each plant close around its stem, whilst others placed it further out, or where the feeders of the Coffee tree would be more likely to find it, and thus the work went on with the frequent change of superintendents introducing new systems, if they deserved the name, till, as I have already said the trees began to tire of such treatment, grow sickly, and eventually give up bearing to a considerable extent. In a letter from a friend dated January of this year, I am informed that the crop of Coffee just picked from the 4000 acres in the hands of the Ouchterlony family only amounted to 350 tons, or 1¾ cwt. per acre; so that allowing the moderate sum of 30,000rs. or £3000 on account of working expenses for the year, and 21,000rs., or £2100, for value of crop, this leaves a deficit of 9000rs., or £900 on the year's labour, and there seems to be no probability of the planter in this valley ever being able to reverse this state of things in the future, no matter how high and liberal the cultivation may be that is adopted, seeing that the Hemileia vastatrix, or leaf disease, is now added to the long list of evils to which the unfortunate Coffee shrub has been subjected.—PLANTER.—*Journal of Horticulture.*

* The animus of all this is evident. Men with fair education soon acquire all the practical knowledge required.—ED.

HINTS ON ANNATTO CULTURE.

The export of dried annatto seeds from Ceylon and the West Indies, principally Jamaica, has lately assumed such proportions that the value has fallen to a level which can scarcely render the gathering of the seed remunerative. But concurrently with the low value and superabundant supply of seed there exists a steady if not a large demand for Brazilian, or so-called Pará roll annatto, which is worth, if good, about 1*s.* 8*d.* per lb. in first hand. The supply of the latter variety, as of many articles for which we depend upon the natives of the American tropics, is subject to frequent interruptions, and it sometimes occurs that no Brazilian annatto is obtainable for considerable periods.

Excluding Brazilian annatto there are two important sources from which the article is drawn, viz., the French West Indian settlements and the British East and West Indies. French Indian annatto is usually shipped to Bordeaux and Hâvre, and distributed thence over Europe, while the British Colonies mostly ship their produce to England and to the United States.
